22.100 The standard heats of formation of $\mathrm{H}_{2} \mathrm{O}(g), \mathrm{H}_{2} \mathrm{~S}(g), \mathrm{H}_{2} \mathrm{Se}(g)$, and $\mathrm{H}_{2} \mathrm{Te}(g)$ are $-241.8,-20.17,+29.7$, and $+99.6 \mathrm{~kJ} /$ mol, respectively. The enthalpies necessary to convert the elements in their standard states to one mole of gaseous atoms are $248,277,227$, and $197 \mathrm{~kJ} / \mathrm{mol}$ of atoms for $\mathrm{O}, \mathrm{S}$, Se , and Te , respectively. The enthalpy for dissociation of $\mathrm{H}_{2}$ is $436 \mathrm{~kJ} / \mathrm{mol}$. Calculate the average $\mathrm{H}-\mathrm{O}, \mathrm{H}-\mathrm{S}, \mathrm{H}-\mathrm{Se}$, and $\mathrm{H}-\mathrm{Te}$ bond enthalpies, and comment on their trend.
22.101 Manganese silicide has the empirical formula MnSi and melts at $1280^{\circ} \mathrm{C}$. It is insoluble in water but does dissolve in aqueous HF. (a) What type of compound do you expect MnSi to be: metallic, molecular, covalent-network, or ionic? (b) Write a likely balanced chemical equation for the reaction of MnSi with concentrated aqueous HF .
22.102 Nitric acid is a powerful oxidizing agent. Using standard reduction potentials, predict whether the following metals can be oxidized to +2 ions by nitric acid: (a) iron, (b) copper, (c) rhodium, (d) zinc, (e) lead, (f) tin.
22.103 Both dimethylhydrazine, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NNH}_{2}$, and methylhydrazine, $\mathrm{CH}_{3} \mathrm{NHNH}_{2}$, have been used as rocket fuels. When dinitrogen tetroxide $\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)$ is used as the oxidizer, the products are $\mathrm{H}_{2} \mathrm{O}, \mathrm{CO}_{2}$, and $\mathrm{N}_{2}$. If the thrust of the rocket depends on the volume of the products produced, which of the substituted hydrazines produces a greater thrust per gram total mass of oxidizer plus fuel? (Assume that both fuels generate the same temperature and that $\mathrm{H}_{2} \mathrm{O}(g)$ is formed.)
22.104 Borazine, $(\mathrm{BH})_{3}(\mathrm{NH})_{3}$, is an analog of $\mathrm{C}_{6} \mathrm{H}_{6}$, benzene. It can be prepared from the reaction of diborane with ammonia, with hydrogen as another product; or from lithium borohydride and ammonium chloride, with lithium chloride and hydrogen as the other products. (a) Write balanced chemical equations for the production of borazine using both synthetic methods. (b) Draw the Lewis dot structure of borazine. (c) How many grams of borazine can be prepared from 2.00 L of ammonia at STP, assuming diborane is in excess?

## Designing an Experiment

You are given samples of five substances. At room temperature, three are colorless gases, one is a colorless liquid, and one is a white solid. You are told that the substances are $\mathrm{NF}_{3}, \mathrm{PF}_{3}, \mathrm{PCl}_{3}, \mathrm{PF}_{5}$, and $\mathrm{PCl}_{5}$. Let's design experiments to determine which substance is which, using concepts from this and earlier chapters.
(a) Assuming that you don't have access to either the Internet or to a handbook of chemistry (as is the case during your exams!), design
experiments that would allow you to identify the substances. (b) How might you proceed differently if you had access to data from the Internet? (c) Which of the substances could undergo reaction to add more atoms around the central atom? What types of reactions might you choose to test this hypothesis? (d) Based on what you know about intermolecular forces, which of the substances is likely the solid?

# TRANSITION METALS AND COORDINATION CHEMISTRY 

> Humans, like all vertebrates, have red blood. The red color is due to an ironcontaining protein called hemoglobin found in red blood cells. Hemoglobin is responsible for binding oxygen in the lungs and transporting it to cells throughout the body.

However, not all animals have red blood. Some marine animals, including octopuses, squids, and lobsters, have blue blood because they rely on a copper-containing protein called hemocyanine for transporting oxygen. In the deoxygenated state, hemocyanine contains two $\mathrm{Cu}^{+}$ions separated from each other by over 400 pm , a distance too long to form a bond. When an oxygen molecule encounters this site in the protein, an electron transfer reaction takes place in which the $\mathrm{O}_{2}$ molecule is reduced to the peroxide ion, $\mathrm{O}_{2}{ }^{2-}$, while both copper ions are oxidized to $\mathrm{Cu}^{2+}$, as shown in Figure 23.1. The presence of $\mathrm{Cu}^{2+}$ ions in oxygenated hemocyanine is responsible for the blue color of the blood.

Among the blue bloods of the animal kingdom, the blood of the horseshoe crab is the most valuable. That's because the primitive immune system of the horseshoe crab contains a substance called limulus amoebocyte lysate (LAL), which protects the crabs from infection by binding to potentially harmful viruses and bacterial endotoxins. It was discovered in the early 1960s that LAL could be used to detect trace amounts of toxic substances in drugs and medical devices. The U.S. Food and Drug Administration now requires that all drugs intended for human consumption be tested with LAL.

To obtain sufficient quantities of LAL for the pharmaceutical industry, people harvest horseshoe crabs, attach them to machines that drain off roughly $30 \%$ of their blood, and then return them to the ocean. The LAL that is extracted from the blood can sell for up to $\$ 15,000$ per quart. Most animals survive the ordeal, the mortality rate is estimated

## WHAT'S AHEAD

The Transition Metals Examine the physical properties, electron configurations, oxidation states, and magnetic properties of the transition metals.
23.2 Transition-Metal Complexes Introduce the concepts of metal complexes and ligands and provide a brief history of the development of coordination chemistry.
23.3 Common Ligands in

Coordination Chemistry Explore some common geometries found in coordination complexes and how the geometries relate to coordination numbers.

Nomenclature and Isomerism
in Coordination Chemistry Learn the nomenclature used for naming metal complexes and become familiar with the concept of isomerism, where two compounds have the same composition but different structures.

Color and Magnetism in Coordination Chemistry Discover the underlying causes of color in coordination compounds, emphasizing the visible portion of the electromagnetic spectrum and the notion of complementary colors. We then see that many transitionmetal complexes are paramagnetic because they contain unpaired electrons.

Crystal-Field Theory Apply the concept of crystal-field theory to explain some of the interesting spectral and magnetic properties of coordination compounds.

[^62]

$\Delta$ Figure 23.1 Hemocyanine binds oxygen. The $\mathrm{Cu}^{+}$ions are each bound by three nitrogen atoms from the hemocyanine protein in the deoxygenated state (left). As the $\mathrm{O}_{2}$ molecule binds between the $\mathrm{Cu}^{+}$ ions, it is reduced to $\mathrm{O}_{2}{ }^{2-}$ while the $\mathrm{Cu}^{+}$ions are oxidized to $\mathrm{Cu}^{2+}$ ions.

Figure 23.2 The position of the transition metals in the periodic table. They are groups $3-12$ in periods 4,5 , and 6 . The short-lived, radioactive transition metals from period 7 are not shown.
to be between 5 and $30 \%$, although questions have been raised regarding the effects of this invasive process on the overall health of the wild population of horseshoe crabs.

The importance of transition metals such as iron and copper, is not limited to biology and medicine. Transition metals and their alloys are used as structural materials to make coins and jewelry, and as electronic conductors in wires and electronic devices. The presence of partially filled $d$-orbitals allows transition metal compounds to act as catalysts, magnets, and pigments. In this chapter, we take a closer look at this fascinating group of elements.

In earlier chapters, we saw that metal ions can function as Lewis acids, forming covalent bonds with molecules and ions that act as Lewis bases. 000 (Section 16.11) We have encountered many ions and compounds that result from such interactions, such as $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$in 000 Section 17.5 and hemoglobin in 000 Section 13.6. In this chapter, we focus on the rich and important chemistry associated with such complex assemblies of metal ions surrounded by molecules and ions. Metal compounds of this kind are called coordination compounds, and the branch of chemistry that focuses on them is called coordination chemistry.

### 23.1 The Transition Metals

The part of the periodic table in which the $d$ orbitals are being filled as we move left to right across a row is the home of the transition metals (Figure 23.2). 000 (Section 6.8)

With some exceptions (e.g., platinum, gold), metallic elements are found in nature as solid inorganic compounds called minerals. Notice from Table 23.1 that minerals are identified by common names rather than chemical names.

TABLE 23.1 Principal Mineral Sources of Some Transition Metals

| Metal | Mineral | Mineral Composition |
| :--- | :--- | :--- |
| Chromium | Chromite | $\mathrm{FeCr}_{2} \mathrm{O}_{4}$ |
| Cobalt | Cobaltite | $\mathrm{CoAsS}^{\text {Copper }}$ |
|  | Chalcocite | $\mathrm{Cu}_{2} \mathrm{~S}$ |
|  | Chalcopyrite | $\mathrm{CuFeS}_{2}$ |
|  | Malachite | $\mathrm{Cu}_{2} \mathrm{CO}_{3}(\mathrm{OH})_{2}$ |
| Iron | Hematite | $\mathrm{Fe}_{2} \mathrm{O}_{3}$ |
|  | Magnetite | $\mathrm{Fe}_{3} \mathrm{O}_{4}$ |
| Manganese | Pyrolusite | $\mathrm{MnO}_{2}$ |
| Mercury | Cinnabar | $\mathrm{HgS}^{\text {Molybdenum }}$ |
| Molybdenite | $\mathrm{MoS}_{2}$ |  |
| Titanium | Rutile | $\mathrm{TiO}_{2}$ |
| Zinc | Ilmenite | FeTiO |

**Manganese has a more complex crystal structure.
Most transition metals in minerals have oxidation states ranging from +1 to +4 . To obtain a pure metal from its mineral, various chemical processes must be performed to reduce the metal to its elemental form. Metallurgy is the science and technology of extracting metals from their natural sources and preparing them for practical use. It usually involves several steps: (1) mining, that is, removing the relevant ore (a mixture of minerals) from the ground, (2) concentrating the ore or otherwise preparing it for further treatment, (3) reducing the ore to obtain the free metal, (4) purifying the metal, and (5) mixing it with other elements to modify its properties. This last process produces an alloy, a metallic material composed of two or more elements. 000 (Section 12.3)

## Physical Properties

Some physical properties of the period 4 (also known as "first-row") transition metals are listed in Table 23.2. The properties of the heavier transition metals vary similarly across periods 5 and 6.

Figure 23.3 shows the atomic radius observed in closepacked metallic structures as a function of group number.* The trends seen in the graph are a result of two competing forces. On the one hand, increasing effective nuclear charge favors a decrease in radius as we move left to right across each period. $\infty \quad$ (Section 7.2) On the other hand, the metallic bonding strength increases until we reach the middle of each period and then decreases as we fill antibonding orbitals. $\infty 00$ (Section 12.4) As a general rule, a bond shortens as it becomes stronger. 000 (Section 8.8) For groups 3 through 6, these two effects work cooperatively and the result is a marked decrease in radius. In elements to the right of group 6, the two effects counteract each other, reducing the decrease and eventually leading to an increase in radius.

## Give It Some Thought

Which element has the largest bonding atomic radius: Ti , Cr , or Zn ?

In general, atomic radii increase as we move down in a given group in the periodic table because of the increasing principal quantum number of the outer-shell electrons. 000 (Section 7.3) However, Figure 23.2 shows that once we move beyond the group 3 elements, the period 5 and period 6 transition elements in a given group have virtually the same radii. In group 5, for example,
*Note that the radii defined in this way, often referred to as metallic radii, differ somewhat from the bonding atomic radii defined in Section 7.3.

## Go Figure

Does the variation in radius of the transition metals follow the same trend as the effective nuclear charge on moving from left to right across the periodic table?

A Figure 23.3 Radii of transition metals as a function of group number.
tantalum in period 6 has virtually the same radius as niobium in period 5. This interesting and important effect has its origin in the lanthanide series, elements 57 through 70. The filling of 4 forbitals through the lanthanide elements 000 (Figure 6.31) causes a steady increase in the effective nuclear charge, producing a size decrease, called the lanthanide contraction, that just offsets the increase we expect as we go from period 5 transition metals to period 6. Thus, the period 5 and period 6 transition metals in each group have very similar radii and chemical properties. For example, the group 4 metals zirconium (period 5) and hafnium (period 6) always occur together in nature and are very difficult to separate.

## Electron Configurations and Oxidation States

Transition metals owe their location in the periodic table to the filling of the $d$ subshells, as you saw in Figure 6.31. Many of the chemical and physical properties of transition metals result from the unique characteristics of the $d$ orbitals. For a given transition-metal atom, the valence ( $n-1$ )d orbitals are smaller than the corresponding valence $n s$ and $n p$ orbitals. In quantum mechanical terms, the $(n-1)$ d orbital wave functions drop off more rapidly as we move away from the nucleus than do the $n s$ and $n p$ orbital wave functions. This characteristic feature of the $d$ orbitals limits their interaction with orbitals on neighboring atoms, but not so much that they are insensitive to surrounding atoms. As a result, electrons in these orbitals behave sometimes like valence electrons and sometimes like core electrons. The details depend on location in the periodic table and the atom's environment.

When transition metals are oxidized, they lose their outer s electrons before they lose electrons from the d subshell. $0 \infty$ (Section 7.4) The electron configuration of Fe is $[\mathrm{Ar}] 3 d^{6} 4 s^{2}$, for example, whereas that of $\mathrm{Fe}^{2+}$ is $[\mathrm{Ar}] 3 d^{6}$. Formation of $\mathrm{Fe}^{3+}$ requires loss of one $3 d$ electron, giving $[\mathrm{Ar}] 3 d^{5}$. Most transition-metal ions contain partially occupied $d$ subshells, which are responsible in large part for three characteristics:

1. Transition metals often have more than one stable oxidation state.
2. Many transition-metal compounds are colored, as shown in Figure 23.4.
3. Transition metals and their compounds often exhibit magnetic properties.

## Go Figure

In which transition-metal ion of this group are the 3d orbitals completely filled?

Figure 23.4 Aqueous solutions of transition metal ions. Left to right: $\mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Cu}^{2+}$, and $\mathrm{Zn}^{2+}$. The counterion is nitrate in all cases.

Figure 23.5 shows the common nonzero oxidation states for the period 4 transition metals. The +2 oxidation state, which is common for most transition metals, is due to the loss of the two outer $4 s$ electrons. This oxidation state is found for all these elements except Sc, where the $3+$ ion with an [Ar] configuration is particularly stable.

Oxidation states above +2 are due to successive losses of $3 d$ electrons. From Sc through Mn the maximum oxidation state increases from +3 to +7 , equaling in each case the total number of $4 s$ plus $3 d$ electrons in the atom. Thus, manganese has a maximum oxidation state of $2+5=+7$. As we move to the right beyond Mn in Figure 23.5, the maximum oxidation state decreases. This decrease is due to the attraction of $d$ orbital electrons to the nucleus, which increases faster than the attraction of the $s$ orbital electrons to the nucleus as we move left to right across the periodic table. In other words, in each period the $d$ electrons become more corelike as the atomic number increases. By the time we get to zinc, it is not possible to remove electrons from the $3 d$ orbitals through chemical oxidation.

In the transition metals of periods 5 and 6, the increased size of the $4 d$ and $5 d$ orbitals makes it possible to attain maximum oxidation states as high as +8 , which is achieved in $\mathrm{RuO}_{4}$ and $\mathrm{OsO}_{4}$. In general, the maximum oxidation states are found only when the metals are combined with the most electronegative elements, especially $\mathrm{O}, \mathrm{F}$, and in some cases Cl .

## Give It Some Thought

Why does $\mathrm{Ti}^{5+}$ not exist?

## Magnetism

The spin that an electron possesses gives the electron a magnetic moment, a property that causes the electron to behave like a tiny magnet. In a diamagnetic solid, defined as one in which all the electrons in the solid are paired, the spin-up and spin-down electrons cancel one another. $\infty$ (Section 9.8) Diamagnetic substances are generally described as being nonmagnetic, but when a diamagnetic substance is placed in a magnetic field, the motions of the electrons cause the substance to be very weakly repelled by the magnet. In other words, these supposedly nonmagnetic substances do show some very faint magnetic character in the presence of a magnetic field.

A substance in which the atoms or ions have one or more unpaired electrons is paramagnetic. 000 (Section 9.8) In a paramagnetic solid, the electrons on one atom or ion do not influence the unpaired electrons on neighboring atoms or ions. As a result, the magnetic moments on the atoms or ions are randomly oriented and constantly changing direction, as shown in Figure 23.6(a). When a paramagnetic substance is placed in a magnetic field, however, the magnetic moments tend to align parallel to one another, producing a net attractive interaction with the magnet. Thus, unlike a diamagnetic substance, which is weakly repulsed by a magnetic field, a paramagnetic substance is attracted to a magnetic field.

When you think of a magnet, you probably picture a simple iron magnet. Iron exhibits ferromagnetism, a form of magnetism much stronger than paramagnetism. Ferromagnetism arises when the unpaired electrons of the atoms or ions in a solid are influenced by the orientations of the electrons in neighboring

## $\checkmark$ Go Figure

## Go Figure

Describe how the representation shown for the paramagnetic material would change if the material were placed in a magnetic field.

A Figure 23.6 The relative orientation of electron spins in various types of magnetic substances.

A Figure 23.7 A permanent magnet. Permanent magnets are made from ferromagnetic and ferrimagnetic materials.
atoms or ions. The most stable (lowest-energy) arrangement is when the spins of electrons on adjacent atoms or ions are aligned in the same direction, as in Figure 23.6(b). When a ferromagnetic solid is placed in a magnetic field, the electrons tend to align strongly in a direction parallel to the magnetic field. The attraction to the magnetic field that results may be as much as a million times stronger than that for a paramagnetic substance.

When a ferromagnet is removed from an external magnetic field, the interactions between the electrons cause the ferromagnetic substance to maintain a magnetic moment. We then refer to it as a permanent magnet (Figure 23.7).

The only ferromagnetic transition metals are $\mathrm{Fe}, \mathrm{Co}$, and Ni , but many alloys also exhibit ferromagnetism, which is in some cases stronger than the ferromagnetism of the pure metals. Particularly powerful ferromagnetism is found in compounds containing both transition metals and lanthanide metals. Two of the most important examples are $\mathrm{SmCo}_{5}$ and $\mathrm{Nd}_{2} \mathrm{Fe}_{14} \mathrm{~B}$.

Two additional types of magnetism involving ordered arrangements of unpaired electrons are depicted in Figure 23.6. In materials that exhibit antiferromagnetism [Figure 23.6(c)], the unpaired electrons on a given atom or ion align so that their spins are oriented in the direction opposite the spin direction on neighboring atoms. This means that the spin-up and spin-down electrons cancel each other. Examples of antiferromagnetic substances are chromium metal, FeMn alloys, and such transition-metal oxides as $\mathrm{Fe}_{2} \mathrm{O}_{3}$, $\mathrm{LaFeO}_{3}$, and MnO .

A substance that exhibits ferrimagnetism [Figure 23.6(d)] has both ferromagnetic and antiferromagnetic characteristics. Like an antiferromagnet, the unpaired electrons align so that the spins in adjacent atoms or ions point in opposite directions. However, unlike an antiferromagnet, the net magnetic moments of the spin-up electrons are not fully canceled by the spin-down electrons. This can happen because the magnetic centers have different numbers of unpaired electrons $\left(\mathrm{NiMnO}_{3}\right)$, because the number of magnetic sites aligned in one direction is larger than the number aligned in the other direction $\left(\mathrm{Y}_{3} \mathrm{Fe}_{5} \mathrm{O}_{12}\right)$, or because both of these conditions apply $\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right)$. Because the magnetic moments do not cancel, the properties of ferrimagnetic materials are similar to the properties of ferromagnetic materials.

## Give It Some Thought

How do you think spin-spin interactions of unpaired electrons on adjacent atoms in a substance are affected by the interatomic distance?

Ferromagnets, ferrimagnets, and antiferromagnets all become paramagnetic when heated above a critical temperature. This happens when the thermal energy is sufficient to overcome the forces determining the spin directions of the electrons. This temperature is called the Curie temperature, $T_{C}$, for ferromagnets and ferrimagnets and the Néel temperature, $T_{N}$, for antiferromagnets.

### 23.2 Transition-Metal Complexes

The transition metals occur in many interesting and important molecular forms. Species that are assemblies of a central transition-metal ion bonded to a group of surrounding molecules or ions, such as $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$and $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$, are called metal complexes, or merely complexes. ${ }^{*}$ If the complex carries a net charge, it is generally called a complex ion. ©oo (Section 17.5) Compounds that contain complexes are known as coordination compounds.
*Most of the coordination compounds we examine in this chapter contain transition-metal ions, although ions of other metals can also form complexes.

The molecules or ions that bond to the metal ion in a complex are known as ligands (from the Latin word ligare, "to bind"). There are two $\mathrm{NH}_{3}$ ligands bonded to $\mathrm{Ag}^{+}$in the complex ion $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$, for instance, and six $\mathrm{H}_{2} \mathrm{O}$ ligands bonded to $\mathrm{Fe}^{3+}$ in $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$. Each ligand functions as a Lewis base and so donates a pair of electrons to form the ligand-metal bond. $\infty$ (Section 16.11) Thus, every ligand has at least one unshared pair of valence electrons. Four of the most frequently encountered ligands,

illustrate that most ligands are either polar molecules or anions. In forming a complex, the ligands are said to coordinate to the metal.

## Give It Some Thought

Is the interaction between an ammonia ligand and a metal cation a Lewis acid-base interaction? If so, which species acts as the Lewis acid?

## The Development of Coordination Chemistry: Werner's Theory

Because compounds of the transition metals are beautifully colored, the chemistry of these elements fascinated chemists even before the periodic table was introduced. During the late 1700 s through the 1800 s, the many coordination compounds that were isolated and studied had properties that were puzzling in light of the bonding theories prevailing at the time. Table 23.3, for example, lists a series of $\mathrm{CoCl}_{3}-\mathrm{NH}_{3}$ compounds that have strikingly different colors. Note that the third and fourth species have different colors, even though the originally assigned formula was the same for both, $\mathrm{CoCl}_{3} \cdot 4 \mathrm{NH}_{3}$.

The modern formulations of the compounds in Table 23.3 are based on various lines of experimental evidence. For example, all four compounds are strong electrolytes ooo (Section 4.1) but yield different numbers of ions when dissolved in water. Dissolving $\mathrm{CoCl}_{3} \cdot 6 \mathrm{NH}_{3}$ in water yields four ions per formula unit $\left(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}\right.$ plus three $\mathrm{Cl}^{-}$ ions), whereas $\mathrm{CoCl}_{3} \cdot 5 \mathrm{NH}_{3}$ yields only three ions per formula unit $\left(\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}\right.$ and two $\mathrm{Cl}^{-}$ions). Furthermore, the reaction of the compounds with excess aqueous silver nitrate leads to the precipitation of different amounts of $\mathrm{AgCl}(s)$. When $\mathrm{CoCl}_{3} \cdot 6 \mathrm{NH}_{3}$ is treated with excess $\mathrm{AgNO}_{3}(a q), 3 \mathrm{~mol}$ of $\mathrm{AgCl}(s)$ precipitate per mole of complex, which means all three $\mathrm{Cl}^{-}$ions in the complex can react to form $\mathrm{AgCl}(s)$. By contrast, when $\mathrm{CoCl}_{3} \cdot 5 \mathrm{NH}_{3}$ is treated with excess $\mathrm{AgNO}_{3}(a q)$, only 2 mol of $\mathrm{AgCl}(s)$ precipitate per mole of complex, telling us that one of the $\mathrm{Cl}^{-}$ions in the complex does not react. These results are summarized in Table 23.3.

In 1893 , the Swiss chemist Alfred Werner (1866-1919) proposed a theory that successfully explained the observations in Table 23.3. In a theory that became the basis for understanding coordination chemistry, Werner proposed that any metal ion exhibits both a primary valence and a secondary valence. The primary valence is the oxidation

TABLE 23.3 Properties of Some Ammonia Complexes of Cobalt(III)

| Original <br> Formulation | Color | Ions per <br> Formula Unit | "Free" Cl- Ions <br> per Formula Unit | Modern Formulation |
| :--- | :--- | :---: | :---: | :--- |
| $\mathrm{CoCl}_{3} \cdot 6 \mathrm{NH}_{3}$ | Orange | 4 | 3 | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ |
| $\mathrm{CoCl}_{3} \cdot 5 \mathrm{NH}_{3}$ | Purple | 3 | 2 | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$ |
| $\mathrm{CoCl}_{3} \cdot 4 \mathrm{NH}_{3}$ | Green | 2 | 1 | trans- $\left.-\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$ |
| $\mathrm{CoCl}_{3} \cdot 4 \mathrm{NH}_{3}$ | Violet | 2 | 1 | cis- $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$ |

state of the metal, which is +3 for the complexes in Table 23.3. The secondary valence is the number of atoms bonded to the metal ion, which is also called the coordination number. For these cobalt complexes, Werner deduced a coordination number of 6 with the ligands in an octahedral arrangement around the $\mathrm{Co}^{3+}$ ion.

Werner's theory provided a beautiful explanation for the results in Table 23.3. The $\mathrm{NH}_{3}$ molecules are ligands bonded to the $\mathrm{Co}^{3+}$ ion (through the nitrogen atom as we will see later); if there are fewer than six $\mathrm{NH}_{3}$ molecules, the remaining ligands are $\mathrm{Cl}^{-}$ions. The central metal and the ligands bound to it constitute the coordination sphere of the complex.

In writing the chemical formula for a coordination compound, Werner suggested using square brackets to signify the makeup of the coordination sphere in any given compound. He therefore proposed that $\mathrm{CoCl}_{3} \cdot 6 \mathrm{NH}_{3}$ and $\mathrm{CoCl}_{3} \cdot 5 \mathrm{NH}_{3}$ are better written as $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ and $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$, respectively. He further proposed that the chloride ions that are part of the coordination sphere are bound so tightly that they do not dissociate when the complex is dissolved in water. Thus, dissolving $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$ in water produces a $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$ ion and two $\mathrm{Cl}^{-}$ions.

Werner's ideas also explained why there are two forms of $\mathrm{CoCl}_{3} \cdot 4 \mathrm{NH}_{3}$. Using Werner's postulates, we write the formula as $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$. As shown in Figure 23.8, there are two ways to arrange the ligands in the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$complex, called the cis and trans forms. In the cis form, the two chloride ligands occupy adjacent vertices of the octahedral arrangement. In trans- $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$the two chlorides are opposite each other. It is this difference in positions of the Cl ligands that leads to two compounds, one violet and one green.

The insight Werner provided into the bonding in coordination compounds is even more remarkable when we realize that his theory predated Lewis's ideas of covalent bonding by more than 20 years! Because of his tremendous contributions to coordination chemistry, Werner was awarded the 1913 Nobel Prize in Chemistry.

$\Delta$ Figure 23.8 Isomers of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$. The cis isomer is violet, and the trans isomer is green.

## Sample Exercise 23.1

Identifying the Coordination Sphere of a Complex
Palladium(II) tends to form complexes with coordination number 4. A compound has the composition $\mathrm{PdCl}_{2} \cdot 3 \mathrm{NH}_{3}$. (a) Write the formula for this compound that best shows the coordination structure. (b) When an aqueous solution of the compound is treated with excess $\mathrm{AgNO}_{3}(a q)$, how many moles of $\mathrm{AgCl}(s)$ are formed per mole of $\mathrm{PdCl}_{2} \cdot 3 \mathrm{NH}_{3}$ ?

## SOLUTION

Analyze We are given the coordination number of $\mathrm{Pd}(\mathrm{II})$ and a chemical formula indicating that the complex contains $\mathrm{NH}_{3}$ and $\mathrm{Cl}^{-}$. We are asked to determine (a) which ligands are attached to $\mathrm{Pd}(\mathrm{II})$ in the compound and (b) how the compound behaves toward $\mathrm{AgNO}_{3}$ in aqueous solution.
Plan (a) Because of their charge, the $\mathrm{Cl}^{-}$ions can be either in the coordination sphere, where they are bonded directly to the metal, or outside the coordination sphere, where they are bonded ionically to the complex. The electrically neutral $\mathrm{NH}_{3}$ ligands must be in the coordination sphere, and we will assume that four ligands are bonded to the Pd(II) ion. (b) Any chlorides in the coordination sphere do not precipitate as AgCl .
Solve
(a) By analogy to the ammonia complexes of cobalt(III) shown in Figure 23.7, we predict that the three $\mathrm{NH}_{3}$ are ligands attached to the $\mathrm{Pd}(\mathrm{II})$ ion. The fourth ligand around $\mathrm{Pd}(\mathrm{II})$ is one chloride ion. The second chloride ion is not a ligand; it serves only as a counterion (a noncoordinating ion that balances charge) in the compound. We conclude that the formula showing the structure best is $\left[\mathrm{Pd}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}\right] \mathrm{Cl}$.
(b) Because only the non-ligand $\mathrm{Cl}^{-}$can react, we expect to produce 1 mol of $\mathrm{AgCl}(s)$ per mole of complex. The balanced equation is

$$
\begin{aligned}
& {\left[\mathrm{Pd}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}\right] \mathrm{Cl}(a q)+\mathrm{AgNO}_{3}(a q) \longrightarrow } \\
& {[ }\left.\mathrm{Pd}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}\right] \mathrm{NO}_{3}(a q)+\mathrm{AgCl}(s)
\end{aligned}
$$

This is a metathesis reaction coo (Section 4.2) in which one of the cations is the $\left[\mathrm{Pd}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}\right]^{+}$complex ion.

## Practice Exercise 1

When the compound $\mathrm{RhCl}_{3} \cdot 4 \mathrm{NH}_{3}$ is dissolved in water and treated with excess $\mathrm{AgNO}_{3}(a q)$ one mole of $\mathrm{AgCl}(s)$ is formed for every mole of $\mathrm{RhCl}_{3} \cdot 4 \mathrm{NH}_{3}$. What is the correct way to write the formula of this compound?
(a) $\left[\mathrm{Rh}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{3}\right]$
(b) $\left[\mathrm{Rh}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}(\mathbf{c})\left[\mathrm{Rh}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}\right] \mathrm{Cl}_{2}$
(d) $\left[\mathrm{Rh}_{\left.\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}_{3}\left(\text { e) }\left[\mathrm{RhCl}_{3}\right]\left(\mathrm{NH}_{3}\right)_{4}\right.}\right.$

- Practice Exercise 2

Predict the number of ions produced per formula unit when the compound $\mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ dissolves in water to form an aqueous solution.

## The Metal-Ligand Bond

The bond between a ligand and a metal ion forms as a result of a Lewis acid-base interaction. 000 (Section 16.11) Because the ligands have available pairs of electrons, they can function as Lewis bases (electron-pair donors). Metal ions (particularly transition-metal ions) have empty valence orbitals, so they can act as Lewis acids (electron-pair acceptors). We can picture the bond between the metal ion and ligand as the result of their sharing a pair of electrons initially on the ligand:

The formation of metal-ligand bonds can markedly alter the properties we observe for the metal ion. A metal complex is a distinct chemical species that has physical and chemical properties different from those of the metal ion and ligands from which it is formed. As one example, Figure 23.9 shows the color change that occurs when aqueous solutions of $\mathrm{NCS}^{-}$(colorless) and $\mathrm{Fe}^{3+}$ (yellow) are mixed, forming $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{NCS}\right]^{2+}$.

Complex formation can also significantly change other properties of metal ions, such as their ease of oxidation or reduction. Silver ion, for example, is readily reduced in water,

$$
\begin{equation*}
\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s) \quad E^{\circ}=+0.799 \mathrm{~V} \tag{23.2}
\end{equation*}
$$

but the $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$ion is not so easily reduced because complexation by $\mathrm{CN}^{-}$ions stabilizes silver in the +1 oxidation state:

$$
\begin{equation*}
\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s)+2 \mathrm{CN}^{-}(a q) \quad E^{\circ}=-0.31 \mathrm{~V} \tag{23.3}
\end{equation*}
$$

## Go Figure

Does the coordination number of iron change during this reaction? Does the oxidation number of iron change?

$\mathrm{NH}_{4} \mathrm{NCS}(a q)$ solution
$-\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}(a q)$ solution
$\operatorname{Red}\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{NCS}\right]^{2+}$ forms

Figure 23.9 The reaction between $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}(a q)$ and $\mathrm{NCS}^{-}(a q)$.

Hydrated metal ions are complexes in which the ligand is water. Thus, $\mathrm{Fe}^{3+}(a q)$ consists largely of $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$. $\infty 00$ (Section 16.11) It is important to realize that ligands can undergo reaction. For example, we saw in Figure 16.18 that a water molecule in $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}(a q)$ can be deprotonated to yield $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}\right]^{2+}(a q)$ and $\mathrm{H}^{+}(a q)$. The iron ion retains its oxidation state; the coordinated hydroxide ligand, with a 1 - charge, reduces the complex charge to $2+$. Ligands can also be displaced from the coordination sphere by other ligands, if the incoming ligands bind more strongly to the metal ion than the original ones. For example, ligands such as $\mathrm{NH}_{3}, \mathrm{NCS}^{-}$, and $\mathrm{CN}^{-}$can replace $\mathrm{H}_{2} \mathrm{O}$ in the coordination sphere of metal ions.

## Charges, Coordination Numbers, and Geometries

The charge of a complex is the sum of the charges on the metal and on the ligands. In $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{SO}_{4}$ we can deduce the charge on the complex ion because we know that the charge of the sulfate ion is $2-$. Because the compound is electrically neutral, the complex ion must have a $2+$ charge, $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$. We can then use the charge of the complex ion to deduce the oxidation number of copper. Because the $\mathrm{NH}_{3}$ ligands are uncharged molecules, the oxidation number of copper must be +2 :

Recall that the number of atoms directly bonded to the metal atom in a complex is the coordination number of the complex. Thus, the silver ion in $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$has a coordination number of 2 , and the cobalt ion has a coordination number of 6 in all four complexes in Table 23.3.

Some metal ions have only one observed coordination number. The coordination number of chromium(III) and cobalt(III) is invariably 6 , for example, and that of platinum(II) is always 4 . For most metals, however, the coordination number is different for different ligands. In these complexes, the most common coordination numbers are 4 and 6 .

The coordination number of a metal ion is often influenced by the relative sizes of the metal ion and the ligands. As the ligand gets larger, fewer of them can coordinate to the metal ion. Thus, iron(III) is able to coordinate to six fluorides in $\left[\mathrm{FeF}_{6}\right]^{3-}$ but to

What is the oxidation number of the metal in $\left[\mathrm{Rh}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]\left(\mathrm{NO}_{3}\right)_{2}$ ?

## SOLUTION

Analyze We are given the chemical formula of a coordination compound and asked to determine the oxidation number of its metal atom.

Plan To determine the oxidation number of Rh, we need to figure out what charges are contributed by the other groups. The overall charge is zero, so the oxidation number of the metal must balance the charge due to the rest of the compound.

Solve The $\mathrm{NO}_{3}$ group is the nitrate anion, which has a 1- charge. The $\mathrm{NH}_{3}$ ligands carry zero charge, and the Cl is a coordinated chloride ion, which has a 1 - charge. The sum of all the charges must be zero:

The oxidation number of rhodium, $x$, must therefore be +3 .
Practice Exercise 1
In which of the following compounds does the transition-metal have the highest oxidation number?
(a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]$ (b) $\mathrm{K}_{2}\left[\mathrm{PtCl}_{6}\right]$ (c) $\mathrm{Rb}_{3}\left[\mathrm{MoO}_{3} \mathrm{~F}_{3}\right]$
(d) $\mathrm{Na}\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]\left(\right.$ e) $\mathrm{K}_{4}\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]$

Practice Exercise 2
What is the charge of the complex formed by a platinum(II) metal ion surrounded by two ammonia molecules and two bromide ions?
only four chlorides in $\left[\mathrm{FeCl}_{4}\right]^{-}$. Ligands that transfer substantial negative charge to the metal also produce reduced coordination numbers. For example, six ammonia molecules can coordinate to nickel(II), forming $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$, but only four cyanide ions can coordinate to this ion, forming $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$.

The most common coordination geometries for coordination complexes are shown in Figure 23.10. Complexes in which the coordination number is 4 have two geometries-tetrahedral and square planar. The tetrahedral geometry is the more common of the two and is especially prevalent among nontransition metals. The square planar geometry is characteristic of transition-metal ions with eight $d$ electrons in the valence shell, such as platinum(II) and gold(III). Complexes with a coordination number of 6 almost always have an octahedral geometry. Even though the octahedron can be drawn as a square with one ligand above and another below the plane, all six vertices are equivalent.

### 23.3 Common Ligands in Coordination Chemistry

The ligand atom that binds to the central metal ion in a coordination complex is called the donor atom of the ligand. Ligands having only one donor atom are called monodentate ligands (from the Latin, meaning "one-toothed"). These ligands are able to occupy only one site in a coordination sphere. Ligands having two donor atoms are bidentate ligands ("two-toothed"), and those having three or more donor atoms are polydentate ligands ("many-toothed"). In both bidentate and polydentate species, the multiple donor atoms can simultaneously bond to the metal ion, thereby occupying two or more sites in a coordination sphere. Table 23.4 gives examples of all three types of ligands.

Because they appear to grasp the metal between two or more donor atoms, bidentate and polydentate ligands are also known as chelating agents (pronounced "KEE-lay-ting"; from the Greek chele, "claw").

## Go Figure

In the drawings on the right-hand side, what does the solid wedge connecting atoms represent? What does the dashed wedge connecting atoms represent?

Square planar geometry

## Octahedral geometry

- Figure 23.10 Common geometries of coordination complexes. In complexes having coordination number 4, the geometry is typically either tetrahedral or square planar. In complexes having coordination number 6, the geometry is nearly always octahedral.

## TABLE 23.4 Some Common Ligands

Figure 23.11 The $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ ion. The ligand is ethylenediamine.

One common chelating agent is the bidentate ligand ethylenediamine, denoted en:

in which each donor nitrogen atom has one nonbonding electron pair. These donor atoms are sufficiently far apart to allow both of them to bond to the metal ion in adjacent positions. The $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ complex ion, which contains three ethylenediamine ligands in the octahedral coordination sphere of cobalt(III), is shown in Figure 23.11. Notice that in the image on the right the en is written in a shorthand notation as two nitrogen atoms connected by an arc.

$\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$

The ethylenediaminetetraacetate ion, [EDTA] ${ }^{4-}$, is an important polydentate ligand that has six donor atoms. It can wrap around a metal ion using all six donor atoms, as shown in Figure 23.12, although it sometimes binds to a metal using only five of its donor atoms.

## Give It Some Thought

Both $\mathrm{H}_{2} \mathrm{O}$ and ethylenediamine (en) have two nonbonding pairs of electrons. Why can en act as a bidentate ligand whereas water cannot?

In general, the complexes formed by chelating ligands (that is, bidentate and polydentate ligands) are more stable than the complexes formed by related monodentate ligands. The equilibrium formation constants for $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ and $\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}$ illustrate this observation:

$$
\begin{array}{r}
{\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(a q)+6 \mathrm{NH}_{3}(a q) \rightleftharpoons\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}(a q)+6 \mathrm{H}_{2} \mathrm{O}(l)} \\
\mathrm{K}_{f}=1.2 \times 10^{9} \\
{\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(a q)+3 \mathrm{en}(a q) \rightleftharpoons\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}(a q)+6 \mathrm{H}_{2} \mathrm{O}(l)} \\
K_{f}=6.8 \times 10^{17} \tag{23.5}
\end{array}
$$

Although the donor atom is nitrogen in both instances, $\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}$ has a formation constant that is more than $10^{8}$ times larger than that of $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$. This trend of generally larger formation constants for bidentate and polydentate ligands, known as the chelate effect, is examined in the "A Closer Look" essay on page 1045.

Chelating agents are often used to prevent one or more of the customary reactions of a metal ion without removing the ion from solution. For example, a metal ion that interferes with a chemical analysis can often be complexed and its interference thereby removed. In a sense, the chelating agent hides the metal ion. For this reason, scientists sometimes refer to these ligands as sequestering agents.

Phosphate ligands, such as sodium tripolyphosphate, $\mathrm{Na}_{5}\left[\mathrm{OPO}_{2} \mathrm{OPO}_{2} \mathrm{OPO}_{3}\right]$, are used to sequester $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ ions in hard water so that these ions cannot interfere with the action of soap or detergents.

Chelating agents are used in many prepared foods, such as salad dressings and frozen desserts, to complex trace metal ions that catalyze decomposition reactions. Chelating agents are used in medicine to remove toxic heavy metal ions that have been ingested, such as $\mathrm{Hg}^{2+}, \mathrm{Pb}^{2+}$, and $\mathrm{Cd}^{2+}$. One method of treating lead poisoning, for example, is to administer $\mathrm{Na}_{2} \mathrm{Ca}($ EDTA). The EDTA chelates the lead, allowing it to be removed from the body via urine.

## Give It Some Thought

Cobalt(III) has a coordination number of 6 in all its complexes. Is the carbonate ion a monodentate or bidentate ligand in the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{CO}_{3}\right)\right]^{+}$ion?

## Metals and Chelates in Living Systems

Ten of the 29 elements known to be necessary for human life are transition metals. $\infty \quad$ (Section 2.7, "Elements Required by Living Organisms") These 10 elements-V, Cr, $\mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}, \mathrm{Zn}, \mathrm{Mo}$, and Cd -form complexes with a variety of groups present in biological systems.

Although our bodies require only small quantities of metals, deficiencies can lead to serious illness. A deficiency of manganese, for example, can lead to convulsive disorders. Some epilepsy patients have been helped by the addition of manganese to their diets.

Figure 23.12 The complex ion
[Co(EDTA)]-. The ligand is the polydentate ethylenediaminetetraacetate ion, whose full representation is given in Table 23.2. This representation shows how the two N and four O donor atoms coordinate to cobalt.

## Go Figure

How many carbon atoms are there in porphine? How many have $s p^{3}$ hybridization? How many have $s p^{2}$ hybridization?

Porphine

Heme b

Figure 23.13 Porphine and two porphyrins, heme b and chlorophyll a. $\mathrm{Fe}(\mathrm{II})$ and $\mathrm{Mg}(\mathrm{II})$ ions replace the two blue H atoms in porphine and bond with all four nitrogens in heme $b$ and chlorophyll a, respectively.

Among the most important chelating agents in nature are those derived from the porphine molecule (Figure 23.13). This molecule can coordinate to a metal via its four nitrogen donor atoms. Once porphine bonds to a metal ion, the two H atoms on the nitrogens are displaced to form complexes called porphyrins. Two important porphyrins are hemes, in which the metal ion is Fe (II), and chlorophylls, with a Mg (II) central ion.

Figure 23.14 shows a schematic structure of myoglobin, a protein that contains one heme group. Myoglobin is a globular protein, one that folds into a compact, roughly spherical shape. Myoglobin is found in the cells of skeletal muscle, particularly in seals, whales, and porpoises. It stores oxygen in cells, one molecule of $\mathrm{O}_{2}$ per myoglobin, until it is needed for metabolic activities. Hemoglobin, the protein that transports oxygen in human blood, is made up of four heme-containing subunits, each of which is very similar to myoglobin. One hemoglobin can bind up to four $\mathrm{O}_{2}$ molecules.

In both myoglobin and hemoglobin, the iron is coordinated to the four nitrogen atoms of a porphyrin and to a nitrogen atom from the protein chain (Figure 23.15). In hemoglobin, the sixth position around the iron is occupied either by $\mathrm{O}_{2}$ (in oxyhemoglobin, the bright red form) or by water (in deoxyhemoglobin, the purplish red form). The oxy form is the one shown in Figure 23.15.

Carbon monoxide is poisonous because the equilibrium binding constant of human hemoglobin for CO is about 210 times greater than that for $\mathrm{O}_{2}$. As a result, a relatively small quantity of CO can inactivate a substantial fraction of the hemoglobin in the blood by displacing the $\mathrm{O}_{2}$ molecule from the heme-containing subunit. For example, a person breathing air that contains only $0.1 \%$ CO takes in enough CO after a few hours to convert up to $60 \%$ of the hemoglobin $(\mathrm{Hb})$ into COHb , thereby reducing the blood's normal oxygen-carrying capacity by $60 \%$.

Under normal conditions, a nonsmoker breathing unpolluted air has about 0.3 to $0.5 \% \mathrm{COHb}$ in her or his blood. This amount arises mainly from the production of small quantities of CO in the course of normal body chemistry and from the small amount of CO present in clean air. Exposure to higher concentrations of CO causes the COHb level to increase, which

Figure 23.14 Myoglobin. This ribbon diagram does not show most of the atoms.

## Go Figure

What is the coordination number of iron in the heme unit shown here? What is the identity of the blue donor atoms in the heme?

© Figure 23.15 Coordination sphere of the hemes in oxymyoglobin and oxyhemoglobin.
in turn leaves fewer Hb sites to which $\mathrm{O}_{2}$ can bind. If the level of COHb becomes too high, oxygen transport is effectively shut down and death occurs. Because CO is colorless and odorless, CO poisoning occurs with very little warning. Improperly ventilated combustion devices, such as kerosene lanterns and stoves, thus pose a potential health hazard.

## A CLOSER LOOK Entropy and the Chelate Effect

We learned in Section 19.5 that chemical processes are favored by positive entropy changes and by negative enthalpy changes. The special stability associated with the formation of chelates, called the chelate effect, can be explained by comparing the entropy changes that occur with monodentate ligands with the entropy changes that occur with polydentate ligands.

We begin with the reaction in which two $\mathrm{H}_{2} \mathrm{O}$ ligands of the square-planar $\mathrm{Cu}(\mathrm{II})$ complex $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ are replaced by monodentate $\mathrm{NH}_{3}$ ligands at $27^{\circ} \mathrm{C}$ :

$$
\begin{aligned}
& {\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}(a q)+2 \mathrm{NH}_{3}(a q) } \rightleftharpoons \\
& {\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}\right]^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) } \\
& \Delta H^{\circ}=-46 \mathrm{~kJ} ; \quad \Delta S^{\circ}=-8.4 \mathrm{~J} / \mathrm{K} ; \quad \Delta G^{\circ}=-43 \mathrm{~kJ}
\end{aligned}
$$

The thermodynamic data tell us about the relative abilities of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{NH}_{3}$ to serve as ligands in this reaction. In general, $\mathrm{NH}_{3}$ binds more tightly to metal ions than does $\mathrm{H}_{2} \mathrm{O}$, so this substitution reaction is exothermic $(\Delta H<0)$. The stronger bonding of the $\mathrm{NH}_{3}$ ligands also causes the $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}\right]^{2+}$ ion to be more rigid, which is probably the reason $\Delta S^{\circ}$ is slightly negative.

We can use Equation 19.20, $\Delta G^{\circ}=-R T \ln K$, to calculate the equilibrium constant of the reaction at $27^{\circ} \mathrm{C}$. The result, $K=3.1 \times 10^{7}$, tells us that the equilibrium lies far to the right, favoring replacement of $\mathrm{H}_{2} \mathrm{O}$ by $\mathrm{NH}_{3}$. For this equilibrium, therefore, the enthalpy change, $\Delta H^{\circ}=-46 \mathrm{~kJ}$, is large enough and negative enough to overcome the entropy change, $\Delta S^{\circ}=-8.4 \mathrm{~J} / \mathrm{K}$.

Now let's use a single bidentate ethylenediamine (en) ligand in our substitution reaction:

$$
\begin{gathered}
{\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}(a q)+\mathrm{en}(a q) \rightleftharpoons\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{en})\right]^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)} \\
\Delta H^{\circ}=-54 \mathrm{~kJ} ; \quad \Delta S^{\circ}=+23 \mathrm{~J} / \mathrm{K} ; \quad \Delta G^{\circ}=-61 \mathrm{~kJ}
\end{gathered}
$$

The en ligand binds slightly more strongly to the $\mathrm{Cu}^{2+}$ ion than two $\mathrm{NH}_{3}$ ligands, so the enthalpy change here ( -54 kJ ) is slightly more negative than for $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}\right]^{2+}(-46 \mathrm{~kJ})$. There is a big differ-
ence in the entropy change, however: $\Delta S^{\circ}$ is $-8.4 \mathrm{~J} / \mathrm{K}$ for the $\mathrm{NH}_{3}$ reaction but $+23 \mathrm{~J} / \mathrm{K}$ for the en reaction. We can explain the positive $\Delta S^{\circ}$ value using concepts discussed in Section 19.3. Because a single en ligand occupies two coordination sites, two molecules of $\mathrm{H}_{2} \mathrm{O}$ are released when one en ligand bonds. Thus, there are three product molecules in the reaction but only two reactant molecules. The greater number of product molecules leads to the positive entropy change for the equilibrium.

The slightly more negative value of $\Delta H^{\circ}$ for the en reaction ( -54 kJ versus -46 kJ ) coupled with the positive entropy change leads to a much more negative value of $\Delta G^{\circ}(-61 \mathrm{~kJ}$ for en, -43 kJ for $\mathrm{NH}_{3}$ ) and thus a larger equilibrium constant: $K=4.2 \times 10^{10}$.

We can combine our two equations using Hess's law 000 (Section 5.6) to calculate the enthalpy, entropy, and free-energy changes that occur for en to replace ammonia as ligands on $\mathrm{Cu}(\mathrm{II})$ :

$$
\begin{aligned}
& {\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}\right]^{2+}(a q)+\mathrm{en}(a q) } \rightleftharpoons \\
& {\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{en})\right]^{2+}(a q)+2 \mathrm{NH}_{3}(a q) } \\
& \Delta H^{\circ}=(-54 \mathrm{~kJ})-(-46 \mathrm{~kJ})=-8 \mathrm{~kJ} \\
& \Delta S^{\circ}=(+23 \mathrm{~J} / \mathrm{K})-(-8.4 \mathrm{~J} / \mathrm{K})=+31 \mathrm{~J} / \mathrm{K} \\
& \Delta G^{\circ}=(-61 \mathrm{~kJ})-(-43 \mathrm{~kJ})=-18 \mathrm{~kJ}
\end{aligned}
$$

Notice that at $27^{\circ} \mathrm{C}$, the entropic contribution $\left(-T \Delta S^{\circ}\right)$ to the free-energy change, $\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}$ (Equation 19.12), is negative and greater in magnitude than the enthalpic contribution $\left(\Delta H^{\circ}\right)$. The equilibrium constant for the $\mathrm{NH}_{3}$-en reaction, $1.4 \times 10^{3}$, shows that the replacement of $\mathrm{NH}_{3}$ by en is thermodynamically favorable.

The chelate effect is important in biochemistry and molecular biology. The additional thermodynamic stabilization provided by entropy effects helps stabilize biological metal-chelate complexes, such as porphyrins, and can allow changes in the oxidation state of the metal ion while retaining the structural integrity of the complex.

Related Exercises: 23.32, 23.98

## Go Figure

Which peak in this curve corresponds to the lowest-energy transition by an electron in a chlorophyll molecule?

Figure 23.16 The absorption of sunlight by chlorophyll.

The chlorophylls, which are porphyrins that contain Mg (II) (Figure 23.13), are the key components in the conversion of solar energy into forms that can be used by living organisms. This process, called photosynthesis, occurs in the leaves of green plants:

$$
\begin{equation*}
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)+6 \mathrm{O}_{2}(g) \tag{23.6}
\end{equation*}
$$

The formation of 1 mol of glucose, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, requires the absorption of 48 mol of photons from sunlight or other sources of light. Chlorophyllcontaining pigments in the leaves of plants absorb the photons. Figure 23.13 shows that the chlorophyll molecule has a series of alternating, or conjugated, double bonds in the ring surrounding the metal ion. This system of conjugated double bonds makes it possible for chlorophyll to absorb light strongly in the visible region of the spectrum. As Figure 23.16 shows, chlorophyll is green because it absorbs red light (maximum absorption at 655 nm ) and blue light (maximum absorption at 430 nm ) and transmits green light.

Photosynthesis is nature's solar energy-conversion machine, and thus all living systems on Earth depend on photosynthesis for continued existence.

## CHEMISTRY AND LIFE The Battle for Iron in Living Systems

Because living systems have difficulty assimilating enough iron to satisfy their nutritional needs, iron-deficiency anemia is a common problem in humans. Chlorosis, an iron deficiency in plants that makes leaves turn yellow, is also commonplace.

Living systems have difficulty assimilating iron because most iron compounds found in nature are not very soluble in water. Microorganisms have adapted to this problem by secreting an iron-binding compound, called a siderophore, that forms an extremely stable water-soluble complex with iron(III). One such complex is ferrichrome (Figure 23.17). The iron-binding strength of a siderophore is so great that it can extract iron from iron oxides.

A Figure 23.17 Ferrichrome.

When ferrichrome enters a living cell, the iron it carries is removed through an enzyme-catalyzed reaction that reduces the strongly bonding iron(III) to iron(II), which is only weakly complexed by the siderophore (Figure 23.18). Microorganisms thus acquire iron by excreting a siderophore into their immediate environment and then taking the resulting iron complex into the cell.

In humans, iron is assimilated from food in the intestine. A protein called transferrin binds iron and transports it across the intestinal wall to distribute it to other tissues in the body. The normal adult body contains about 4 g of iron. At any one time, about 3 g of this iron is in the blood, mostly in the form of hemoglobin. Most of the remainder is carried by transferrin.

A bacterium that infects the blood requires a source of iron if it is to grow and reproduce. The bacterium excretes a siderophore into the blood to compete with transferrin for iron. The equilibrium constants

A Figure 23.18 The iron-transport system of a bacterial cell.
for forming the iron complex are about the same for transferrin and siderophores. The more iron available to the bacterium, the more rapidly it can reproduce and thus the more harm it can do.

Several years ago, New Zealand clinics regularly gave iron supplements to infants soon after birth. However, the incidence of certain bacterial infections was eight times higher in treated than in untreated infants. Presumably, the presence of more iron in the blood than absolutely necessary makes it easier for bacteria to obtain the iron needed for growth and reproduction.

In the United States, it is common medical practice to supplement infant formula with iron sometime during the first year of life. However, iron supplements are not necessary for infants who breast-
feed because breast milk contains two specialized proteins, lactoferrin and transferrin, which provide sufficient iron while denying its availability to bacteria. Even for infants fed with infant formulas, supplementing with iron during the first several months of life may be ill-advised.

For bacteria to continue to multiply in the blood, they must synthesize new supplies of siderophores. Synthesis of siderophores in bacteria slows, however, as the temperature is increased above the normal body temperature of $37^{\circ} \mathrm{C}$ and stops completely at $40^{\circ} \mathrm{C}$. This suggests that fever in the presence of an invading microbe is a mechanism used by the body to deprive bacteria of iron.

### 23.4 Nomenclature and Isomerism in Coordination Chemistry

When complexes were first discovered, they were named after the chemist who originally prepared them. A few of these names persist, as, for example, with the dark red substance $\mathrm{NH}_{4}\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{NCS})_{4}\right]$, which is still known as Reinecke's salt. Once the structures of complexes were more fully understood, it became possible to name them in a more systematic manner. Let's use two substances to illustrate how coordination compounds are named:

## How to Name Coordination Compounds

1. In naming complexes that are salts, the name of the cation is given before the name of the anion. Thus, in $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$ we name the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$ cation and then the $\mathrm{Cl}^{-}$.
2. In naming complex ions or molecules, the ligands are named before the metal. Ligands are listed in alphabetical order, regardless of their charges. Prefixes that give the number of ligands are not considered part of the ligand name in determining alphabetical order. Thus, the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$ ion is pentaamminechlorocobalt(III). (Be careful to note, however, that the metal is written first in the chemical formula.)
3. The names of anionic ligands end in the letter $o$, but electrically neutral ligands ordinarily bear the name of the molecules (Table 23.5). Special names are used for $\mathrm{H}_{2} \mathrm{O}$ (aqua), $\mathrm{NH}_{3}$ (ammine), and CO (carbonyl). For example, $\left[\mathrm{Fe}(\mathrm{CN})_{2}\left(\mathrm{NH}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{+}$is the diamminediaquadicyanoiron(III) ion.
4. Greek prefixes (di-, tri-, tetra-, penta-, hexa-) are used to indicate the number of each kind of ligand when more than one is present. If the ligand contains a Greek prefix (for example, ethylenediamine) or is polydentate, the alternate prefixes bis-, tris-, tetrakis-, pentakis-, and hexakis- are used and the ligand name is placed in parentheses. For example, the name for $\left[\mathrm{Co}(\mathrm{en})_{3}\right] \mathrm{Br}_{3}$ is tris(ethylenediamine)cobalt(III) bromide.
5. If the complex is an anion, its name ends in -ate. The compound $\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$ is potassium hexacyanoferrate(II), for example, and the ion $\left[\mathrm{CoCl}_{4}\right]^{2-}$ is tetrachlorocobaltate(II) ion.
6. The oxidation number of the metal is given in parentheses in Roman numerals following the name of the metal.

Three examples for applying these rules are

| $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Br}_{2}$ | Hexaamminenickel(II) bromide |
| :--- | :--- |
| $\left[\mathrm{Co}(\mathrm{en})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{CN})\right] \mathrm{Cl}_{2}$ | Aquacyanobis(ethylenediamine)cobalt(III) chloride |
| $\mathrm{Na}_{2}\left[\mathrm{MoOCl}_{4}\right]$ | Sodium tetrachlorooxomolybdate(IV) |

TABLE 23.5 Some Common Ligands and Their Names

|  | Name in <br> Complexes | Ligand | Name in Complexes |
| :--- | :--- | :--- | :--- |
| Azide, $\mathrm{N}_{3}^{-}$ | Azido | Oxalate, $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$ | Oxalato |
| Bromide, $\mathrm{Br}^{-}$ | Bromo | Oxide, $\mathrm{O}^{2-}$ | Oxo |
| Chloride, $\mathrm{Cl}^{-}$ | Chloro | Ammonia, $\mathrm{NH}_{3}$ | Ammine |
| Cyanide, $\mathrm{CN}^{-}$ | Cyano | Carbon monoxide, CO | Carbonyl |
| Fluoride, $\mathrm{F}^{-}$ | Fluoro | Ethylenediamine, en | Ethylenediamine |
| Hydroxide, $\mathrm{OH}^{-}$ | Hydroxo | Pyridine, $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ | Pyridine |
| Carbonate, $\mathrm{CO}_{3}{ }^{2-}$ | Carbonato | Water, $\mathrm{H}_{2} \mathrm{O}$ | Aqua |

## Sample Exercise 23.3

Naming Coordination Compounds
Name the compounds (a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$, (b) $\mathrm{K}_{4}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]$.

## SOLUTION

Analyze We are given the chemical formulas for two coordination compounds and assigned the task of naming them.
Plan To name the complexes, we need to determine the ligands in the complexes, the names of the ligands, and the oxidation state of the metal ion. We then put the information together following the rules listed in the text.

## Solve

(a) The ligands are four water molecules-tetraaqua-and two chloride ions-dichloro. By assigning all the oxidation numbers we know for this molecule, we see that the oxidation number of Cr is +3 :

Thus, we have chromium(III). Finally, the anion is chloride. The name of the compound is tetraaquadichlorochromium(III) chloride.
(b) The complex has four cyanide ion ligands, $\mathrm{CN}^{-}$, which means tetracyano, and the oxidation state of the nickel is zero:

Because the complex is an anion, the metal is indicated as nickelate(0). Putting these parts together and naming the cation first, we have potassium tetracyanonickelate(0).

## Practice Exercise 1

What is the name of the compound $\left[\mathrm{Rh}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$ ?
(a) Rhodium(III) tetraamminedichloro chloride
(b) Tetraammoniadichlororhodium(III) chloride (c) Tetraamminedichlororhodium(III) chloride (d) Tetraamminetrichlororhodium(III) (e) Tetraamminedichlororhodium(II) chloride

Practice Exercise 2
Name the compounds (a) $\left[\mathrm{Mo}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Br}_{3}\right] \mathrm{NO}_{3}$,
(b) $\left(\mathrm{NH}_{4}\right)_{2}\left[\mathrm{CuBr}_{4}\right]$. (c) Write the formula for sodium diaquabis(oxalato)ruthenate(III).

Aigure 23.19 Forms of isomerism in coordination compounds.

## Isomerism

When two or more compounds have the same composition but a different arrangement of atoms, we call them isomers. 000 (Section 2.9) Here we consider two main kinds of isomers in coordination compounds: structural isomers (which have different bonds) and stereoisomers (which have the same bonds but different ways in which the ligands occupy the space around the metal center). Each of these classes also has subclasses, as shown in Figure 23.19.

## Structural Isomerism

Many types of structural isomerism are known in coordination chemistry, including the two named in Figure 23.19: linkage isomerism and coordination-sphere isomerism. Linkage isomerism is a relatively rare but interesting type that arises when a particular ligand is capable of coordinating to a metal in two ways. The nitrite ion, $\mathrm{NO}_{2}^{-}$, for example, can coordinate to a metal ion through either its nitrogen or one of its oxygens (Figure 23.20). When it coordinates through the nitrogen atom, the $\mathrm{NO}_{2}^{-}$ligand is called nitro; when it coordinates through the oxygen atom, it is called nitrito and is generally written $\mathrm{ONO}^{-}$. The isomers shown in Figure 23.20 have different properties. The nitro isomer is yellow, for example, whereas the nitrito isomer is red.

Another ligand capable of coordinating through either of two donor atoms is thiocyanate, $\mathrm{SCN}^{-}$, whose potential donor atoms are N and S .

## Go Figure

What are the chemical formula and name for each of the complex ions in this figure?

A Figure 23.20 Linkage isomerism.

Cl ligands adjacent to each other $\mathrm{NH}_{3}$ ligands adjacent to each other

trans
Cl ligands on opposite sides of central atom $\mathrm{NH}_{3}$ ligands on opposite sides of central atom

A Figure 23.21 Geometric isomerism.

## Give It Some Thought

Can the ammonia ligand engage in linkage isomerism?

Coordination-sphere isomers are isomers that differ in which species in the complex act as ligands, and which are outside the coordination sphere. For example, three isomers have the formula $\mathrm{CrCl}_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$. When the ligands are six $\mathrm{H}_{2} \mathrm{O}$ and the chloride ions are in the crystal lattice (as counterions), we have the violet compound $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{3}$. When the ligands are five $\mathrm{H}_{2} \mathrm{O}$ and one $\mathrm{Cl}^{-}$, with the sixth $\mathrm{H}_{2} \mathrm{O}$ and the two $\mathrm{Cl}^{-}$out in the lattice, we have the green compound $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O}$. The third isomer, $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, is also a green compound. In the two green compounds, either one or two water molecules have been displaced from the coordination sphere by chloride ions. The displaced $\mathrm{H}_{2} \mathrm{O}$ molecules occupy a site in the crystal lattice.

## Stereoisomerism

Stereoisomers have the same chemical bonds but different spatial arrangements. In the square-planar complex $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$, for example, the chloro ligands can be either adjacent to or opposite each other (Figure 23.21). (We saw an earlier example of this type of isomerism in the cobalt complex of Figure 23.8, and we will return to that complex in a moment.) This form of stereoisomerism, in which the arrangement of the atoms is different but the same bonds are present, is called geometric
isomerism. The isomer with like ligands in adjacent positions is the cis isomer, and the isomer with like ligands across from one another is the trans isomer.

Geometric isomers generally have different physical properties and may also have markedly different chemical reactivities. For example, cis- $\left[\operatorname{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$, also called cisplatin, is effective in the treatment of testicular, ovarian, and certain other cancers, whereas the trans isomer is ineffective. This is because cisplatin forms a chelate with two nitrogens of DNA, displacing the chloride ligands. The chloride ligands of the trans isomer are too far apart to form the $\mathrm{N}-\mathrm{Pt}-\mathrm{N}$ chelate with the nitrogen donors in DNA.

Geometric isomerism is also possible in octahedral complexes when two or more different ligands are present, as in the cis and trans tetraamminedichlorocobalt(III) ion in Figure 23.8. Because all four corners of a tetrahedron are adjacent to one another, cis-trans isomerism is not observed in tetrahedral complexes.

## Give It Some Thought

Can a trigonal planar complex exhibit geometric isomerism?

The second type of stereoisomerism listed in Figure 23.19 is optical isomerism. Optical isomers, called enantiomers, are mirror images that cannot be superimposed on each other. They bear the same resemblance to each other that your left hand bears to your right hand. If you look at your left hand in a mirror, the image is identical to your right hand (Figure 23.22). No matter how hard you try, however, you cannot superimpose your two hands on each other. An example of a complex that exhibits this type of isomerism is the $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ ion. Figure 23.22 shows the two enantiomers of this complex and their mirror-image relationship. Just as there is no way that we can twist or turn our right hand to make it look identical to our left, so also there is no way to rotate one of these enantiomers to make it identical to the other. Molecules or ions that are not superimposable on their mirror image are said to be chiral (pronounced KY-rul).

The properties of two optical isomers differ only if the isomers are in a chiral environ-ment-that is, an environment in which there is a sense of right- and left-handedness. A chiral enzyme, for example, might catalyze the reaction of one optical isomer but not the other. Consequently, one optical isomer may produce a specific physiological effect in the body, with its mirror image producing either a different effect or none at all. Chiral reactions are also extremely important in the synthesis of pharmaceuticals and other industrially important chemicals.

A Figure 23.22 Optical isomerism.

Optical isomers are usually distinguished from each other by their interaction with plane-polarized light. If light is polarized-for example, by being passed through a sheet of polarizing film—the electric-field vector of the light is confined to a single plane (Figure 23.23). If the polarized light is then passed through a solution containing one optical isomer, the plane of polarization is rotated either to the right or to the left. The isomer that rotates the plane of polarization to the right is dextrorotatory; it is the dextro, or $d$, isomer (Latin dexter, "right"). Its mirror image rotates the plane of polarization to the left; it is levorotatory and is the levo, or $l$, isomer (Latin laevus, "left"). The $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ isomer on the right in Figure 23.22 is found experimentally to be the $l$ isomer of this ion. Its mirror image is the $d$ isomer. Because of their effect on plane-polarized light, chiral molecules are said to be optically active.

## Sample Exercise 23.4

## Determining the Number of Geometric Isomers

The Lewis structure $: \mathrm{C} \equiv 0$ : indicates that the CO molecule has two lone pairs of electrons. When CO binds to a transition-metal atom, it nearly always does so by using the C lone pair. How many geometric isomers are there for tetracarbonyldichloroiron(II)?

## SOLUTION

Analyze We are given the name of a complex containing only monodentate ligands, and we must determine the number of isomers the complex can form.

Plan We can count the number of ligands to determine the coordination number of the Fe and then use the coordination number to predict the geometry. We can then either make a series of drawings with ligands in different positions to determine the number of isomers or deduce the number of isomers by analogy to cases we have discussed.
Solve The name indicates that the complex has four carbonyl (CO) ligands and two chloro $\left(\mathrm{Cl}^{-}\right)$ligands, so its formula is $\mathrm{Fe}(\mathrm{CO})_{4} \mathrm{Cl}_{2}$. The complex therefore has a coordination number of 6 , and we can assume an octahedral geometry. Like $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$(Figure 23.8), it has four ligands of one type and two of another. Consequently, there are two isomers possible: one with the $\mathrm{Cl}^{-}$ligands across the metal from each other, trans- $\left[\mathrm{Fe}(\mathrm{CO})_{4} \mathrm{Cl}_{2}\right]$, and one with the $\mathrm{Cl}^{-}$ligands adjacent to each other, cis-[ $\left.\mathrm{Fe}(\mathrm{CO})_{4} \mathrm{Cl}_{2}\right]$.

Comment It is easy to overestimate the number of geometric isomers. Sometimes different orientations of a single isomer are incorrectly thought to be different isomers. If two structures can be
rotated so that they are equivalent, they are not isomers of each other. The problem of identifying isomers is compounded by the difficulty we often have in visualizing three-dimensional molecules from their two-dimensional representations. It is sometimes easier to determine the number of isomers if we use three-dimensional models.

## Practice Exercise 1

Which of the following molecules does not have a geometric isomer?

Practice Exercise 2
How many isomers exist for the square-planar molecule $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{ClBr}\right]$ ?

Figure 23.23 Using polarized light to detect optical activity.

## Sample Exercise 23.5

Predicting Whether a Complex Has Optical Isomers
Does either cis- $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$or trans- $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{-}$have optical isomers?

## SOLUTION

Analyze We are given the chemical formula for two geometric isomers and asked to determine whether either one has optical isomers. Because en is a bidentate ligand, we know that both complexes are octahedral and both have coordination number 6.

Plan We need to sketch the structures of the cis and trans isomers and their mirror images. We can draw the en ligand as two N atoms connected by an arc. If the mirror image cannot be superimposed on the original structure, the complex and its mirror image are optical isomers.

## Solve

The trans isomer of $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$and its mirror image are shown here. Notice that the mirror image of the isomer is identical to the original. Consequently trans- $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$does not exhibit optical isomerism.

The cis isomer of $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$and its mirror image are shown here. In this case the two cannot be superimposed on each other. Thus, the two cis structures are optical isomers (enantiomers). We say that cis-[Co(en) $\left.)_{2} \mathrm{Cl}_{2}\right]^{+}$is a chiral complex.

Practice Exercise 1
Which of the following complexes has an optical isomer?
(a) Tetrahedral $\left[\mathrm{CdBr}_{2} \mathrm{Cl}_{2}\right]^{2-}(\mathbf{b})$ Octahedral $\left[\mathrm{CoCl}_{4}(\mathrm{en})\right]^{2-}$
(c) Octahedral $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{2+}(\mathbf{d})$ Tetrahedral
$\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right) \mathrm{BrClI}\right]^{-}$

## Practice Exercise 2

Does the square-planar complex ion $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)\left(\mathrm{N}_{3}\right) \mathrm{ClBr}\right]^{-}$have optical isomers? Explain your answer.

When a substance with optical isomers is prepared in the laboratory, the chemical environment during the synthesis is not usually chiral. Consequently, equal amounts of the two isomers are obtained, and the mixture is said to be racemic. A racemic mixture does not rotate polarized light because the rotatory effects of the two isomers cancel each other.

## Give It Some Thought

Which of the following physical properties of the $d$ and / enantiomers of a substance are different: (a) the melting point, (b) the way polarized light is rotated on passing through the substance, (c) the color, or (d) all of the above.

### 23.5 Color and Magnetism in Coordination Chemistry

Studies of the colors and magnetic properties of transition-metal complexes have played an important role in the development of modern models for metal-ligand bonding. We discussed the various types of magnetic behavior of the transition metals in Section 23.1, and we discussed the interaction of radiant energy with matter in Section 6.3. Let's briefly examine the significance of these two properties for transition-metal complexes before we develop a model for metal-ligand bonding.

## Color

In Figure 23.4, we saw the diverse range of colors seen in salts of transition-metal ions and their aqueous solutions. In general, the color of a complex depends on the identity of the metal ion, on its oxidation state, and on the ligands bound to it. Figure 23.24, for instance, shows how the pale blue color characteristic of $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ changes to deep blue-violet as $\mathrm{NH}_{3}$ ligands replace the $\mathrm{H}_{2} \mathrm{O}$ ligands to form $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$.

For a substance to have color we can see, it must absorb some portion of the spectrum of visible light. 000 (Section 6.1) Absorption happens, however, only if the energy needed to move an electron in the substance from its ground state to an excited state corresponds to the energy of some portion of the visible spectrum. ©oo (Section 6.3) Thus, the particular energies of radiation a substance absorbs dictate the color we see for the substance.

Figure 23.24 The color of a coordination complex changes when the ligand changes.

Figure 23.25 Two ways of perceiving the color orange. An object appears orange either when it reflects orange light to the eye (left) or when it transmits to the eye all colors except blue, the complement of orange (middle). Complementary colors lie opposite to each other on an artist's color wheel (right).

When an object absorbs some portion of the visible spectrum, the color we perceive is the sum of the unabsorbed portions, which are either reflected or transmitted by the object and strike our eyes. (Opaque objects reflect light, and transparent ones transmit it.) If an object absorbs all wavelengths of visible light, none reaches our eyes and the object appears black. If it absorbs no visible light, it is white if opaque or colorless if transparent. If it absorbs all but orange light, the orange light is what reaches our eye and therefore is the color we see.

An interesting phenomenon of vision is that we also perceive an orange color when an object absorbs only the blue portion of the visible spectrum and all the other colors strike our eyes. This is because orange and blue are complementary colors, which means that the removal of blue from white light makes the light look orange (and the removal of orange makes the light look blue).

Complementary colors can be determined with an artist's color wheel, which shows complementary colors on opposite sides (Figure 23.25).

The amount of light absorbed by a sample as a function of wavelength is known as the sample's absorption spectrum. The visible absorption spectrum of a transparent

## Sample Exercise 23.6

## Relating Color Absorbed to Color Observed

The complex ion trans- $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$absorbs light primarily in the red region of the visible spectrum (the most intense absorption is at 680 nm$)$. What is the color of the complex ion?

## SOLUTION

Analyze We need to relate the color absorbed by a complex (red) to the color observed for the complex.

Plan For an object that absorbs only one color from the visible spectrum, the color we see is complementary to the color absorbed. We can use the color wheel of Figure 23.25 to determine the complementary color.
Solve From Figure 23.25, we see that green is complementary to red, so the complex appears green.
Comment As noted in Section 23.2, this green complex was one of those that helped Werner establish his theory of coordination (Table 23.3). The other geometric isomer of this complex, cis- $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$, absorbs yellow light and therefore appears violet.

Practice Exercise 1
A solution containing a certain transition-metal complex ion has the absorption spectrum shown here.

What color would you expect a solution containing this ion to be? (a) violet (b) blue (c) green (d) orange (e) red

Practice Exercise 2
A certain transition-metal complex ion absorbs at 695 nm . Which color is this ion most likely to be-blue, yellow, green, or red?
sample can be determined using a spectrometer, as described in the "A Closer Look" box on page 620. The absorption spectrum of the ion $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ is shown in Figure 23.26. The absorption maximum is at 500 nm , but the graph shows that much of the yellow, green, and blue light is absorbed. Because the sample absorbs all of these colors, what we see is the unabsorbed red and violet light, which we perceive as purple (the color purple is classified as a tertiary color located between red and violet on an artist's color wheel).

## Magnetism of Coordination Compounds

Many transition-metal complexes exhibit paramagnetism, as described in Sections 9.8 and 23.1. In such compounds, the metal ions possess some number of unpaired electrons. It is possible to experimentally determine the number of unpaired electrons per metal ion from the measured degree of paramagnetism, and experiments reveal some interesting comparisons.

Compounds of the complex ion $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$ have no unpaired electrons, for example, but compounds of the $\left[\mathrm{CoF}_{6}\right]^{3-}$ ion have four unpaired electrons per metal ion. Both complexes contain $\mathrm{Co}(\mathrm{III})$ with a $3 d^{6}$ electron configuration. 000 (Section 7.4) Clearly, there is a major difference in the ways in which the electrons are arranged in these two cases. Any successful bonding theory must explain this difference, and we present such a theory in the next section.

## Give It Some Thought

What is the electron configuration for (a) the Co atom and (b) the $\mathrm{Co}^{3+}$ ion? How many unpaired electrons does each possess? (See Section 7.4 to review electron configurations of ions.)

## 23.6 | Crystal-Field Theory

Scientists have long recognized that many of the magnetic properties and colors of transition-metal complexes are related to the presence of $d$ electrons in the metal cation. In this section, we consider a model for bonding in transition-metal complexes, crystal-field theory, that accounts for many of the observed properties of these substances.* Because many predictions of crystal-field theory are qualitatively the same as those obtained with more advanced molecular-orbital theories, crystal-field theory is an excellent place to start in considering the electronic structure of coordination compounds.

The attraction of a ligand to a metal ion is essentially a Lewis acid-base interaction in which the base-that is, the ligand-donates a pair of electrons to an empty orbital on the metal ion (Figure 23.27). Much of the attractive interaction between the metal ion and the ligands is due, however, to the electrostatic forces between the positive charge on the metal ion and negative charges on the ligands. An ionic ligand, such as $\mathrm{Cl}^{-}$or $\mathrm{SCN}^{-}$, experiences the usual cation-anion attraction. When the ligand is a neutral molecule, as in the case of $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{NH}_{3}$, the negative ends of these polar molecules, which contain an unshared electron pair, are directed toward the metal ion. In this case, the attractive interaction is of the ion-dipole type. 000 (Section 11.2) In either case, the ligands are attracted strongly toward the metal ion. Because of the metal-ligand electrostatic attraction, the energy of the complex is lower than the combined energy of the separated metal ion and ligands.

Although the metal ion is attracted to the ligand electrons, the metal ion's $d$ electrons are repulsed by the ligands. Let's examine this effect more closely, specifically the case in which the ligands form an octahedral array around a metal ion that has coordination number 6.

[^63]
## Go Figure

How would this absorbance spectrum change if you decreased the concentration of the $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ in solution?

$\Delta$ Figure 23.26 The color of $\left[\mathrm{Ti}_{\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}}\right.$ A solution containing the $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion appears purple because, as its visible absorption spectrum shows, the solution does not absorb light from the violet and red ends of the spectrum. That unabsorbed light is what reaches our eyes.

A Figure 23.27 Metal-ligand bond formation. The ligand acts as a Lewis base by donating its nonbonding electron pair to an empty orbital on the metal ion. The bond that results is strongly polar with some covalent character.

## Go Figure

Which d orbitals have lobes that point directly toward the ligands in an octahedral crystal-field?

A Figure 23.28 Energies of $d$ orbitals in a free metal ion, a spherically symmetric crystal-field, and an octahedral crystal-field.

In crystal-field theory, we consider the ligands to be negative points of charge that repel the negatively charged electrons in the $d$ orbitals of the metal ion. The energy diagram in Figure 23.28 shows how these ligand point charges affect the energies of the $d$ orbitals. First, we imagine the complex as having all the ligand point charges uniformly distributed on the surface of a sphere centered on the metal ion. The average energy of the metal ion's $d$ orbitals is raised by the presence of this uniformly charged sphere. Hence, the energies of all five $d$ orbitals are raised by the same amount.

This energy picture is only a first approximation, however, because the ligands are not distributed uniformly on a spherical surface and, therefore, do not approach the metal ion equally from every direction. Instead, we envision the six ligands approaching along $x$-, $y$-, and $z$-axes, as shown on the right in Figure 23.28. This arrangement of ligands is called an octahedral crystal-field. Because the metal ion's $d$ orbitals have different orientations and shapes, they do not all experience the same repulsion from the ligands and, therefore, do not all have the same energy under the influence of the octahedral crystal-field. To see why, we must consider the shapes of the $d$ orbitals and how their lobes are oriented relative to the ligands.

Figure 23.28 shows that the lobes of the $d_{z^{2}}$ and $d_{x^{2}-y^{2}}$ orbitals are directed along the $x$-, $y$-, and $z$-axes and so point directly toward the ligand point charges. The lobes of the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals, however, are directed between the axes and so do not point directly toward the charges. The result of this difference in orientation- $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ lobes point directly toward the ligand charges; $d_{x y}, d_{x z}$, and $d_{y z}$ lobes do not-is that an electron residing in either the $d_{x^{2}-y^{2}}$ or $d_{z^{2}}$ orbitals feels more repulsion from the negatively charged ligands. Hence the energy of the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals is higher than the energy of the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals. This difference in energy is represented by the red boxes in the energy diagram of Figure 23.28.

It might seem like the energy of the $d_{x^{2}-y^{2}}$ orbital should be different from that of the $d_{z^{2}}$ orbital because the $d_{x^{2}-y^{2}}$ has four lobes pointing at ligands and the $d_{z^{2}}$ has only two lobes pointing at ligands. However, the $d_{z^{2}}$ orbital does have electron density in the $x y$ plane, represented by the ring encircling the point where the two lobes meet. More advanced calculations show that two orbitals do indeed have the same energy in the presence of the octahedral crystal-field.

## Go Figure

How would you calculate the energy gap between the $t_{2}$ and e orbitals from this diagram?

Because their lobes point directly at the negative ligand charges, electrons in the metal ion's $d_{z^{2}}$ and $d_{x^{2}-y^{2}}$ orbitals experience stronger repulsions than those in the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals. As a result, the energy splitting shown in Figure 23.28 occurs. The three lowerenergy $d$ orbitals are called the $t_{2}$ set of orbitals, and the two higher-energy ones are called the $e$ set.* The energy gap $\Delta$ between the two sets is called the crystal-field splitting energy.

Crystal-field theory helps us account for the colors observed in transition-metal complexes. The energy gap $\Delta$ between the $e$ and $t_{2}$ sets of $d$ orbitals is of the same order of magnitude as the energy of a photon of visible light. It is therefore possible for a transition-metal complex to absorb visible light that excites an electron from a lower-energy $\left(t_{2}\right) d$ orbital into a higher-energy $(e) d$ orbital. $\operatorname{In}\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$, for example, the $\mathrm{Ti}(\mathrm{III})$ ion has an $[\mathrm{Ar}] 3 d^{1}$ electron configuration. (Recall from Section 7.4 that when determining the electron configurations of transition-metal ions, we remove the $s$ electrons first.) $\mathrm{Ti}(\mathrm{III})$ is thus called a $d^{1}$ ion. In the ground state of $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$, the single $3 d$ electron resides in an orbital in the $t_{2}$ set (Figure 23.29). Absorption of $495-\mathrm{nm}$ light excites this electron up to an orbital in the $e$ set, generating the absorption spectrum shown in Figure 23.26. Because this transition involves exciting an electron from one set of $d$ orbitals to the other, we call it a $\boldsymbol{d}$ - $\boldsymbol{d}$ transition. As noted earlier, the absorption of visible radiation that produces this $d-d$ transition causes the $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion to appear purple.

## Give It Some Thought

Why are compounds of Ti(IV) colorless?

The magnitude of the crystal-field splitting energy and, consequently, the color of a complex depend on both the metal and the ligands. For example, we saw in Figure 23.4 that the color of $\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ complexes changes from reddish-pink when the metal ion is $\mathrm{Co}^{2+}$, to green for $\mathrm{Ni}^{2+}$, to pale blue for $\mathrm{Cu}^{2+}$. If we change the ligands in the $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ ion, the color also changes. $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ has a blue-violet color, while $\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}$ is purple (Figure 23.30). In a ranking called the spectrochemical series, ligands are arranged in order of their abilities to increase the crystal-field splitting energy, as in this abbreviated list:

$$
\begin{array}{cc}
\mathrm{Cl}^{-}<\mathrm{F}^{-}<\mathrm{H}_{2} \mathrm{O}<\mathrm{NH}_{3}<\text { en }<\mathrm{NO}_{2}^{-}(\mathrm{N} \text {-bonded })<\mathrm{CN}^{-}
\end{array}
$$

The magnitude of $\Delta$ increases by roughly a factor of 2 from the far left to the far right of the spectrochemical series. Ligands at the low- $\Delta$ end of the spectrochemical series are termed weak-field ligands; those at the high- $\Delta$ end are termed strong-field ligands.

[^64]4 Figure 23.29 The $d$ - $d$ transition in $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ is produced by the absorption of $495-\mathrm{nm}$ light.

Go Figure
If you were to use a ligand $L$ that was a stronger field ligand than ethylenediamine, what color would you expect the $\left[\mathrm{NiL}_{6}\right]^{2+}$ complex ion to have?

Figure 23.30 Effect of ligand on crystal-field splitting. The greater the crystal-field strength of the ligand, the greater the energy gap $\Delta$ it causes between the $t_{2}$ and $e$ sets of the metal ion's orbitals. This shifts the wavelength of the absorption maximum to shorter values.

Let's take a closer look at the colors and crystal-field splitting as we vary the ligands for the series of $\mathrm{Ni}^{2+}$ complexes discussed above. Because the Ni atom has an $[\mathrm{Ar}] 3 d^{8} 4 s^{2}$ electron configuration, $\mathrm{Ni}^{2+}$ has the configuration $[\mathrm{Ar}] 3 d^{8}$ and therefore is a $d^{8}$ ion. The $t_{2}$ set of orbitals holds six electrons, two in each orbital, while the last two electrons go into the $e$ set of orbitals. Consistent with Hund's rule, each $e$ orbital holds one electron and both electrons have the same spin. 000 (Section 6.8)

As the ligand changes from $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{NH}_{3}$ to ethylenediamine, the spectrochemical series tells us that the crystal-field, $\Delta$, exerted by the six ligands should increase. When there is more than one electron in the $d$ orbitals, interactions between the electrons make the absorption spectra more complicated than the spectrum shown for $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ in Figure 23.26, which complicates the task of relating changes in $\Delta$ with color. With $d^{8}$ ions like $\mathrm{Ni}^{2+}$ three peaks are observed in the absorption spectra. Fortunately, for $\mathrm{Ni}^{2+}$ complexes we can simplify the analysis because only one of these three peaks falls in the visible region of the spectrum.* Because the energy separation $\Delta$ is increasing, the wavelength of the absorption peak should shift to a shorter wavelength. 000 (Section 6.3) In the case of $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ the absorption peak in the visible part of the spectrum reaches a maximum near 720 nm , in the red region of the spectrum. So the complex ion takes the complementary color-green. For $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ the absorption peak reaches its maximum at 570 nm near the boundary between orange and yellow. The resulting color of the complex ion is a mixture of the complementary colors—blue and violet. Finally, for $\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}$ the peak shifts to an even shorter wavelength, 540 nm , which lies near the boundary between green and yellow. The resulting color purple is a mixture of the complementary colors red and violet.

[^65]

Figure 23.31 Two possibilities for adding a fourth electron to a $d^{3}$ octahedral complex. Whether the fourth electron goes into a $t_{2}$ orbital or into an $e$ orbital depends on the relative energies of the crystal-field splitting energy and the spin-pairing energy.

## Electron Configurations in Octahedral Complexes

Crystal-field theory helps us understand the magnetic properties and some important chemical properties of transition-metal ions. From Hund's rule, we expect electrons to always occupy the lowest-energy vacant orbitals first and to occupy a set of degenerate (same-energy) orbitals one at a time with their spins parallel. coo (Section 6.8) Thus, if we have a $d^{1}, d^{2}$, or $d^{3}$ octahedral complex, the electrons go into the lower-energy $t_{2}$ orbitals, with their spins parallel. When a fourth electron must be added, we have the two choices shown in Figure 23.31: The electron can either go into an $e$ orbital, where it will be the sole electron in the orbital or become the second electron in a $t_{2}$ orbital. Because the energy difference between the $t_{2}$ and $e$ sets is the splitting energy $\Delta$, the energy cost of going into an $e$ orbital rather than a $t_{2}$ orbital is also $\Delta$. Thus, the goal of filling lowest-energy available orbitals first is met by putting the electron in a $t_{2}$ orbital.

There is a penalty for doing this, however, because the electron must now be paired with the electron already occupying the orbital. The difference between the energy required to pair an electron in an occupied orbital and the energy required to place that electron in an empty orbital is called the spin-pairing energy. The spin-pairing energy arises from the fact that the electrostatic repulsion between two electrons that share an orbital (and so must have opposite spins) is greater than the repulsion between two electrons that are in different orbitals and have parallel spins.

In coordination complexes, the nature of the ligands and the charge on the metal ion often play major roles in determining which of the two electron arrangements shown in Figure 23.31 is used. In $\left[\mathrm{CoF}_{6}\right]^{3-}$ and $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$, both ligands have a 1 - charge. The $\mathrm{F}^{-}$ion, however, is on the low end of the spectrochemical series, so it is a weak-field ligand. The $\mathrm{CN}^{-}$ion is on the high end and so is a strong-field ligand, which means it produces a larger energy gap $\Delta$ than the $\mathrm{F}^{-}$ion. The splittings of the $d$-orbital energies in these two complexes are compared in Figure 23.32.

Cobalt(III) has an [Ar]3d $d^{6}$ electron configuration, so both complexes in Figure 23.32 are $d^{6}$ complexes. Let's imagine that we add these six electrons one at a time to the $d$ orbitals of the $\left[\mathrm{CoF}_{6}\right]^{3-}$ ion. The first three go into the $t_{2}$ orbitals with their spins parallel. The fourth electron could pair up in one of the $t_{2}$ orbitals. The $\mathrm{F}^{-}$ion is a weakfield ligand, however, and so the energy gap $\Delta$ between the $t_{2}$ set and the $e$ set is small. In this case, the more stable arrangement is the fourth electron in one of the $e$ orbitals. By the same energy argument, the fifth electron goes into the other $e$ orbital. With all five $d$ orbitals containing one electron, the sixth must pair up, and the energy needed to place the sixth electron in a $t_{2}$ orbital is less than that needed to place it in an $e$ orbital. We end up with four $t_{2}$ electrons and two $e$ electrons.

A Figure 23.32 High-spin and low-spin complexes. The high-spin $\left[\mathrm{CoF}_{6}\right]^{3-}$ ion has a weak-field ligand and so a small $\Delta$ value. The low-spin $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$ ion has a strong-field ligand and so a large $\Delta$ value. Because $\left[\mathrm{CoF}_{6}\right]^{3-}$ has unpaired electrons it is paramagnetic, while $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$ is diamagnetic.

Figure 23.32 shows that the crystal-field splitting energy $\Delta$ is much larger in the $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$ complex. In this case, the spin-pairing energy is smaller than $\Delta$, so the lowest-energy arrangement is to place all six electrons in the $t_{2}$ orbitals.

The $\left[\mathrm{CoF}_{6}\right]^{3-}$ complex is a high-spin complex; that is, the electrons are arranged so that they remain unpaired as much as possible. The $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$ ion is a low-spin complex; that is, the electrons are arranged so that they remain paired as much as possible while still following Hund's rule. These two electronic arrangements can be readily distinguished by measuring the magnetic properties of the complex. Experiments show that $\left[\mathrm{CoF}_{6}\right]^{3-}$ has four unpaired electrons and is paramagnetic, while $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$ has no unpaired electrons and is diamagnetic. The absorption spectrum also shows peaks corresponding to the different values of $\Delta$ in these two complexes.

## Give It Some Thought

In octahedral complexes, for which d electron counts with unpaired electrons is there no differentiation between high-spin and low-spin arrangements?

In the transition metal ions of periods 5 and 6 (which have $4 d$ and $5 d$ valence electrons), the $d$ orbitals are larger than in the period 4 ions (which have only $3 d$ electrons). Thus, ions from periods 5 and 6 interact more strongly with ligands, resulting in a larger crystal-field splitting. Consequently, metal ions in periods 5 and 6 are invariably low spin in an octahedral crystal-field.

## Sample Exercise 23.7

## The Spectrochemical Series, Crystal-Field Splitting, Color, and Magnetism

The compound hexaamminecobalt(III) chloride is diamagnetic and orange in color with a single absorption peak in its visible absorption spectrum. (a) What is the electron configuration of the cobalt(III) ion? (b) Is $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ a high-spin complex or a low-spin complex? (c) Estimate the wavelength where you expect the absorption of light to reach a maximum? (d) What color and magnetic behavior would you predict for the complex ion $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ ?

## SOLUTION

Analyze We are given the color and magnetic behavior of an octahedral complex containing Co with a +3 oxidation number. We need to use this information to determine its electron configuration, its spin state (low-spin or high-spin), and the color of light it absorbs. In part (d), we must use the spectrochemical series to predict how its properties will change if $\mathrm{NH}_{3}$ is replaced by ethylenediamine (en).

Plan (a) From the oxidation number and the periodic table we can determine the number of valence electrons for $\mathrm{Co}(\mathrm{III})$, and from that we can determine the electron configuration. (b) The magnetic behavior can be used to determine whether this compound is a low-spin or high-spin complex. (c) Since there is a single peak in the visible absorption spectrum, the color of the compound should be complementary to the color of light that is absorbed most strongly. (d) Ethylenediamine is a stronger field ligand than $\mathrm{NH}_{3}$, so we expect a larger $\Delta$ for $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ than for $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$.

## Solve

(a) Co has an electron configuration of $[\mathrm{Ar}] 4 s^{2} 3 d^{7}$, and $\mathrm{Co}^{3+}$ has three fewer electrons than Co. Because transition-metal ions always lose their valence shell $s$ electrons, the electron configuration of $\mathrm{Co}^{3+}$ is $[\mathrm{Ar}] 3 d^{6}$.
(b) There are six valence electrons in the $d$ orbitals. The filling of the $t_{2}$ and $e$ orbitals for both high-spin and low-spin complexes is shown below. Because the compound is diamagnetic, we know all of the electrons must be paired up, which allows us to determine that $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ is a low-spin complex.

(c) We are told that the compound is orange and has a single absorption peak in the visible region of the spectrum. The compound must therefore absorb the complementary color of orange, which is blue. The blue region of the spectrum ranges from approximately 430 nm to 490 nm . As an estimate we assume that the complex ion absorbs somewhere in the middle of the blue region, near 460 nm .
(d) Ethylenediammine is higher in the spectrochemical series than ammonia. Therefore, we expect a larger $\Delta$ for $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$. Because $\Delta$ was already greater than the spinpairing energy for $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$, we expect $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ to be a low-spin complex as well, with a $d^{6}$ configuration, so it will also be diamagnetic. The wavelength at which the complex absorbs light will shift to higher energy. If we assume a shift in the absorption maximum from blue to violet, the color of the complex will become yellow.
Comment The compound $\left[\mathrm{Co}(\mathrm{en})_{3}\right] \mathrm{Cl}_{3}$, which contains the $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ ion, was made and studied by Alfred Werner. This compound forms diamagnetic, golden-yellow crystals.

Practice Exercise 1
Which of the following octahedral complex ions will have the fewest number of unpaired electrons?
(a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$
(e) $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$
(b) $\left[\mathrm{V}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ (c) $\left[\mathrm{FeF}_{6}\right]^{3-}$
(d) $\left[\mathrm{RhCl}_{6}\right]^{3-}$
(e) $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$

## Practice Exercise 2

Consider the colors of the ammonia complexes of $\mathrm{Co}^{3+}$ given in Table 23.3. Based on the change in color would you expect $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$ to have a larger or smaller value of $\Delta$ than $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ ? Is this prediction consistent with the spectrochemical series?

## Tetrahedral and Square-Planar Complexes

Thus far we have considered crystal-field theory only for complexes having an octahedral geometry. When there are only four ligands in a complex, the geometry is generally tetrahedral, except for the special case of $d^{8}$ metal ions, which we will discuss in a moment.

The crystal-field splitting of $d$ orbitals in tetrahedral complexes differs from that in octahedral complexes. Four equivalent ligands can interact with a central metal ion most effectively by approaching along the vertices of a tetrahedron. In this geometry the lobes of the two $e$ orbitals point toward the edges of the tetrahedron, exactly in between the ligands (Figure 23.33). This orientation keeps the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ as far from the ligand point charges as possible. Consequently, these two $d$ orbitals experience less repulsion from the ligands and lie at lower energy than the other three $d$ orbitals. The three $t_{2}$ orbitals do not point directly at the ligand point charges, but they do come closer to the ligands than the $e$ set, and as a result they experience more repulsion and are higher in energy. As we see in Figure 23.33, the splitting of $d$ orbitals in a tetrahedral geometry is the opposite of what we find for the octahedral geometry, namely, the $e$ orbitals are now below the $t_{2}$ orbitals. The crystal-field splitting energy $\Delta$ is much smaller for tetrahedral complexes than it is for comparable octahedral complexes, in part because there are fewer ligand point charges in the tetrahedral geometry, and in part because neither set of orbitals has lobes that point directly at the ligands. Calculations show that for the same metal ion and ligand set, $\Delta$ for the tetrahedral complex is only four-ninths as large as for the octahedral complex. For this reason, nearly all tetrahedral complexes are high spin; the crystal-field splitting energy is never large enough to overcome the spin-pairing energies.

In a square-planar complex, four ligands are arranged about the metal ion such that all five species are in the $x y$ plane. The resulting energy levels of the $d$ orbitals are

In tetrahedral crystal field

$\Delta$ Figure 23.33 Energies of the $d$ orbitals in a tetrahedral crystal-field. The splitting of the $e$ and $t_{2}$ sets of orbitals is inverted with respect to the splitting associated with an octahedral crystal-field. The crystal-field splitting energy $\Delta$ is smaller than it is in an octahedral crystal-field.

## Go Figure

For which d orbital(s) do the lobes point directly at the ligands in a square-planar crystal-field?

Square planar
illustrated in Figure 23.34. Note in particular that the $d_{z^{2}}$ orbital is considerably lower in energy than the $d_{x^{2}-y^{2}}$ orbital. To understand why this is so, recall from Figure 23.28 that in an octahedral field the $d_{z^{2}}$ orbital of the metal ion interacts with the ligands positioned above and below the $x y$ plane. There are no ligands in these two positions in a squareplanar complex, which means that the $d_{z^{2}}$ orbital experiences less repulsion and so remains in a lower-energy, more stable state.

Square-planar complexes are characteristic of metal ions with a $d^{8}$ electron configuration. They are nearly always low spin, with the eight $d$ electrons spin-paired to form a diamagnetic complex. This pairing leaves the $d_{x^{2}-y^{2}}$ orbital empty. Such an electronic arrangement is particularly common among the $d^{8}$ ions of periods 5 and 6 , such as $\mathrm{Pd}^{2+}, \mathrm{Pt}^{2+}, \mathrm{Ir}^{+}$, and $\mathrm{Au}^{3+}$.

## Give It Some Thought

Why is the energy of the $d_{x z}$ and $d_{y z}$ orbitals in a square-planar complex lower than that of the $d_{x y}$ orbital?

## Sample Exercise 23.8

Populating $d$ Orbitals in Tetrahedral and Square-Planar Complexes
Nickel(II) complexes in which the metal coordination number is 4 can have either square-planar or tetrahedral geometry. $\left[\mathrm{NiCl}_{4}\right]^{2-}$ is paramagnetic, and $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ is diamagnetic. One of these complexes is square planar, and the other is tetrahedral. Use the relevant crystal-field splitting diagrams in the text to determine which complex has which geometry.

## SOLUTION

Analyze We are given two complexes containing $\mathrm{Ni}^{2+}$ and their magnetic properties. We are given two molecular geometry choices and asked to use crystal-field splitting diagrams from the text to determine which complex has which geometry.
Plan We need to determine the number of $d$ electrons in $\mathrm{Ni}^{2+}$ and then use Figure 23.33 for the tetrahedral complex and Figure 23.34 for the square-planar complex.
Solve Nickel(II) has the electron configuration $[\mathrm{Ar}] 3 d^{8}$. With very few exceptions tetrahedral complexes are high spin and square-planar complexes are low spin. Therefore, the population of the $d$ orbitals in the two geometries is

Tetrahedral

The tetrahedral complex has two unpaired electrons, and the square-planar complex has none. We know from Section 23.1 that the tetrahedral complex must be paramagnetic and the square planar must be diamagnetic. Therefore, $\left[\mathrm{NiCl}_{4}\right]^{2-}$ is tetrahedral, and $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ is square planar.

Comment Nickel(II) forms octahedral complexes more frequently than square-planar ones, whereas $d^{8}$ metals from periods 5 and 6 tend to favor square-planar coordination.

Practice Exercise 1
How many unpaired electrons do you predict for the tetrahedral $\left[\mathrm{MnCl}_{4}\right]^{2-}$ ion?
(a) 1, (b) 2, (c) 3, (d) 4, (e) 5 .

## Practice Exercise 2

Are there any diamagnetic tetrahedral complexes containing transition metal ions with partially filled $d$ orbitals? If so what electron count(s) leads to diamagnetism?

Crystal-field theory can be used to explain many observations in addition to those we have discussed. The theory is based on electrostatic interactions between ions and atoms, which essentially means ionic bonds. Many lines of evidence show, however, that the
bonding in complexes must have some covalent character. Therefore, molecular-orbital theory 000 (Sections 9.7 and 9.8) can also be used to describe the bonding in complexes, but the application of molecular-orbital theory to coordination compounds is beyond the scope of our discussion. Crystal-field theory, although not entirely accurate in all details, provides an adequate and useful first description of the electronic structure of complexes.

## A CLOSER LOOK Charge-Transfer Color

$\Delta$ Figure 23.35 The colors of compounds can arise from charge-transfer transitions. $\mathrm{KMnO}_{4}$ and $\mathrm{K}_{2} \mathrm{CrO}_{4}$ are colored due to ligand-to-metal charge-transfer transitions in their anions. Higher energy ultraviolet photons are needed to excite the charge-transfer transition in the perchlorate ion, therefore $\mathrm{KClO}_{4}$ is white.

In the laboratory portion of your course, you have probably seen many colorful transition-metal compounds, including those shown in Figure 23.35. Many of these compounds are colored because of $d-d$ transitions. Some colored complexes, however, including the violet permanganate ion, $\mathrm{MnO}_{4}^{-}$, and the yellow chromate ion, $\mathrm{CrO}_{4}{ }^{2-}$, derive their color from a different type of excitation involving the $d$ orbitals.

The permanganate ion strongly absorbs visible light, with a maximum absorption at 565 nm . Because violet is complementary to yellow, this strong absorption in the yellow portion of the visible spectrum is responsible for the violet color of salts and solutions of the ion. What is happening during this absorption of light? The $\mathrm{MnO}_{4}^{-}$ion is a complex of $\mathrm{Mn}(\mathrm{VII})$. Because $\mathrm{Mn}(\mathrm{VII})$ has a $[\mathrm{Ar}] 3 d^{0}$ electron configuration, the absorption cannot be due to a $d-d$ transition because there are no $d$ electrons to excite! That does not mean, however, that the $d$ orbitals are not involved in the transition. The excitation in the $\mathrm{MnO}_{4}^{-}$ion is due to a charge-transfer transition, in which an electron on one oxygen ligand is excited into a vacant $d$ orbital on the Mn ion (Figure 23.36). In essence, an electron is transferred from a ligand to the metal, so this transition is called a ligand-to-metal charge-transfer (LMCT) transition.

An LMCT transition is also responsible for the color of the $\mathrm{CrO}_{4}{ }^{2-}$, which contains the $\mathrm{Cr}(\mathrm{VI})$ ion with an $[\mathrm{Ar}] 3 d^{0}$ electron configuration.

Also shown in Figure 23.35 is a salt of the perchlorate ion $\left(\mathrm{ClO}_{4}^{-}\right)$. Like $\mathrm{MnO}_{4}^{-}, \mathrm{ClO}_{4}^{-}$is tetrahedral and has its central atom in the +7 oxidation state. However, because the Cl atom does not have low-lying $d$ orbitals, exciting an electron from O to Cl requires a more energetic photon than does it does in $\mathrm{MnO}_{4}^{-}$. The first absorption for
$\mathrm{ClO}_{4}^{-}$is in the ultraviolet portion of the spectrum, so no visible light is absorbed and the salt appears white.

Other complexes exhibit charge-transfer excitations in which an electron from the metal atom is excited to an empty orbital on a ligand. Such an excitation is called a metal-to-ligand charge-transfer (MLCT) transition.

Charge-transfer transitions are generally more intense than $d-d$ transitions. Many metal-containing pigments used for oil painting, such as cadmium yellow (CdS), chrome yellow $\left(\mathrm{PbCrO}_{4}\right)$, and red ochre $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$, have intense colors because of charge-transfer transitions.

Related Exercises: 23.84, 23.85

A Figure 23.36 Ligand-to-metal charge-transfer transition in $\mathrm{MnO}_{4}^{-}$. As shown by the blue arrow, an electron is excited from a nonbonding orbital on O into one of the empty $d$ orbitals on Mn .

## Sample Integrative Exercise

## Putting Concepts Together

The oxalate ion has the Lewis structure shown in Table 23.4. (a) Show the geometry of the complex formed when this ion complexes with cobalt(II) to form $\left[\mathrm{Co}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$. (b) Write the formula for the salt formed when three oxalate ions complex with $\mathrm{Co}(\mathrm{II})$, assuming that the charge-balancing cation is $\mathrm{Na}^{+}$. (c) Sketch all the possible geometric isomers for the cobalt complex formed in part (b). Are any of these isomers chiral? Explain. (d) The equilibrium constant for the formation of the
cobalt(II) complex produced by coordination of three oxalate anions, as in part (b), is $5.0 \times 10^{9}$, and the equilibrium constant for formation of the cobalt(II) complex with three molecules of ortho-phenanthroline (Table 23.4) is $9 \times 10^{19}$. From these results, what conclusions can you draw regarding the relative Lewis base properties of the two ligands toward cobalt(II)? (e) Using the approach described in Sample Exercise 17.14, calculate the concentration of free aqueous Co (II) ion in a solution initially containing 0.040 M oxalate (aq) and $0.0010 \mathrm{M} \mathrm{Co}^{2+}(a q)$.

## SOLUTION

(a) The complex formed by coordination of one oxalate ion is octahedral:

(b) Because the oxalate ion has a charge of 2-, the net charge of a complex with three oxalate anions and one $\mathrm{Co}^{2+}$ ion is $4-$. Therefore, the coordination compound has the formula: $\quad \mathrm{Na}_{4}\left[\mathrm{Co}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right]$
(c) There is only one geometric isomer. The complex is chiral, however, in the same way the $\left[\mathrm{Co}(\mathrm{en})_{3}\right]^{3+}$ complex is chiral (Figure 23.22). The two mirror images are not superimposable, so there are two enantiomers:

(d) The ortho-phenanthroline ligand is bidentate, like the oxalate ligand, so they both exhibit the chelate effect. Thus, we conclude that ortho-phenanthroline is a stronger Lewis base toward $\mathrm{Co}^{2+}$ than oxalate. This conclusion is consistent with what we learned about bases in Section 16.7, that nitrogen bases are generally stronger than oxygen bases. (Recall, for example, that $\mathrm{NH}_{3}$ is a stronger base than $\mathrm{H}_{2} \mathrm{O}$.)
(e) The equilibrium we must consider involves 3 mol of oxalate ion (represented as $\mathrm{Ox}^{2-}$ ).

$$
\mathrm{Co}^{2+}(a q)+3 \mathrm{Ox}^{2-}(a q) \rightleftharpoons\left[\mathrm{Co}(\mathrm{Ox})_{3}\right]^{4-}(a q)
$$

The formation-constant expression is: $\quad K_{f}=\frac{\left[\left[\mathrm{Co}(\mathrm{Ox})_{3}\right]^{4-}\right]}{\left[\mathrm{Co}^{2+}\right]\left[\mathrm{Ox}^{2-}\right]^{3}}$

Because $K_{f}$ is so large, we can assume that essentially all the $\mathrm{Co}^{2+}$ is converted to the oxalato complex. Under that assumption, the final concentration of
$\left[\mathrm{Co}(\mathrm{Ox})_{3}\right]^{4-}$ is 0.0010 M and that of oxalate ion is
$\left[\mathrm{Ox}^{2-}\right]=(0.040)-3(0.0010)=0.037 \mathrm{M}$ (three $\mathrm{Ox}^{2-}$ ions react with each $\mathrm{Co}^{2+}$ ion). We then have:

$$
\left[\mathrm{Co}^{2+}\right]=x M,\left[\mathrm{Ox}^{2-}\right] \cong 0.037 \mathrm{M},\left[\left[\mathrm{Co}(\mathrm{Ox})_{3}\right]^{4-}\right] \cong 0.0010 \mathrm{M}
$$

Inserting these values into the equilibrium-constant expression, and solving for $x$, we obtain $4 \times 10^{-9} M$. From this, we see that the oxalate has complexed all but a tiny fraction of the $\mathrm{Co}^{2+}$ in solution.

$$
\begin{aligned}
& K_{f}=\frac{(0.0010)}{x(0.037)^{3}}=5 \times 10^{9} \\
& x=4 \times 10^{-9} \mathrm{M}
\end{aligned}
$$

## Chapter Summary and Key Terms

THE TRANSITION METALS (SECTION 23.1) Metallic elements are obtained from minerals, which are solid inorganic compounds found in nature. Metallurgy is the science and technology of extracting metals from the earth and processing them for further use. Transition metals are characterized by incomplete filling of the $d$ orbitals. The presence of $d$ electrons in transition elements leads to multiple oxidation states. As we proceed through the transition metals in a given row of the periodic table, the attraction between the nucleus and the valence electrons increases more markedly for $d$ electrons than for $s$ electrons. As a result, the later transition elements in a period tend to have lower oxidation states.

The atomic and ionic radii of period 5 transition metals are larger than those of period 4 metals. The transition metals of periods 5 and 6 have comparable atomic and ionic radii and are also similar in other properties. This similarity is due to the lanthanide contraction.

The presence of unpaired electrons in valence orbitals leads to magnetic behavior in transition metals and their compounds. In ferromagnetic, ferrimagnetic, and antiferromagnetic substances, the unpaired electron spins on atoms in a solid are affected by spins on neighboring atoms. In a ferromagnetic substance the spins all point in the same direction. In an antiferromagnetic substance the spins point in opposite directions and cancel one another. In a ferrimagnetic substance the spins point in opposite directions but do not fully cancel. Ferromagnetic and ferrimagnetic substances are used to make permanent magnets.

TRANSITION-METAL COMPLEXES (SECTION 23.2) Coordination compounds are substances that contain metal complexes. Metal complexes contain metal ions bonded to several surrounding anions or molecules known as ligands. The metal ion and its ligands make up the coordination sphere of the complex. The number of atoms attached to the metal ion is the coordination number of the metal ion. The most common coordination numbers are 4 and 6; the most common coordination geometries are tetrahedral, square planar, and octahedral.

COMMON LIGANDS IN COORDINATION CHEMISTRY (SECTION 23.3) Ligands that occupy only one site in a coordination sphere are called monodentate ligands. The atom of the ligand that bonds to the metal ion is the donor atom. Ligands that have two donor atoms are bidentate ligands. Polydentate ligands have three or more donor atoms. Bidentate and polydendate ligands are also called chelating agents. In general, chelating agents form more stable complexes than do related monodentate ligands, an observation known as the chelate effect. Many biologically important molecules, such as the porphyrins, are complexes of chelating agents. A related group of plant pigments known as chlorophylls are important in photosynthesis, the process by which plants use solar energy to convert $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ into carbohydrates.

NOMENCLATURE AND ISOMERISM IN COORDINATION CHEMISTRY (SECTION 23.4) In naming coordination compounds, the number and type of ligands attached to the metal ion are specified, as is the oxidation state of the metal ion. Isomers are compounds with the same composition but different arrangements of atoms and therefore different properties. Structural isomers differ in the bonding arrangements of the ligands. Linkage isomerism occurs when a ligand can coordinate to a metal ion through different donor atoms. Coordination-sphere isomers contain different ligands in the
coordination sphere. Stereoisomers are isomers with the same chemical bonding arrangements but different spatial arrangements of ligands. The most common forms of stereoisomerism are geometric isomerism and optical isomerism. Geometric isomers differ from one another in the relative locations of donor atoms in the coordination sphere; the most common being cis and trans isomers. Geometric isomers differ from one another in their chemical and physical properties. Optical isomers are nonsuperimposable mirror images of each other. Optical isomers, or enantiomers, are chiral, meaning that they have a specific "handedness" and differ only in the presence of a chiral environment. Optical isomers can be distinguished from one another by their interactions with plane-polarized light; solutions of one isomer rotate the plane of polarization to the right (dextrorotatory), and solutions of its mirror image rotate the plane to the left (levorotatory). Chiral molecules, therefore, are optically active. A 50-50 mixture of two optical isomers does not rotate plane-polarized light and is said to be racemic.
COLOR AND MAGNETISM IN COORDINATION CHEMISTRY (SECTION 23.5) A substance has a particular color because it either reflects or transmits light of that color or absorbs light of the complementary color. The amount of light absorbed by a sample as a function of wavelength is known as its absorption spectrum. The light absorbed provides the energy to excite electrons to higher-energy states.

It is possible to determine the number of unpaired electrons in a complex from its degree of paramagnetism. Compounds with no unpaired electrons are diamagnetic.

CRYSTAL-FIELD THEORY (SECTION 23.6) Crystal-field theory successfully accounts for many properties of coordination compounds, including their color and magnetism. In crystal-field theory, the interaction between metal ion and ligand is viewed as electrostatic. Because some $d$ orbitals point directly at the ligands whereas others point between them, the ligands split the energies of the metal $d$ orbitals. For an octahedral complex, the $d$ orbitals are split into a lower-energy set of three degenerate orbitals (the $t_{2}$ set) and a higherenergy set of two degenerate orbitals (the e set). Visible light can cause a $d$ - $d$ transition, in which an electron is excited from a lower-energy $d$ orbital to a higher-energy $d$ orbital. The spectrochemical series lists ligands in order of their ability to increase the split in $d$-orbital energies in octahedral complexes.

Strong-field ligands create a splitting of $d$-orbital energies that is large enough to overcome the spin-pairing energy. The $d$ electrons then preferentially pair up in the lower-energy orbitals, producing a low-spin complex. When the ligands exert a weak crystal-field, the splitting of the $d$ orbitals is small. The electrons then occupy the higher-energy $d$ orbitals in preference to pairing up in the lowerenergy set, producing a high-spin complex. Transition metal ions from periods 5 and 6 have large crystal-field splitting energies and adopt low spin configurations in octahedral complexes.

Crystal-field theory also applies to tetrahedral and squareplanar complexes, which leads to different $d$-orbital splitting patterns. In a tetrahedral crystal-field, the splitting of the $d$ orbitals results in a higher-energy $t_{2}$ set and a lower-energy $e$ set, the opposite of the octahedral case. The splitting in a tetrahedral crystal-field is much smaller than that in an octahedral crystal-field, so tetrahedral complexes are nearly always high-spin complexes.

## Learning Outcomes After studying this chapter, you should be able to:

- Describe the periodic trends in radii and oxidation states of the transition-metal ions, including the origin and effect of the lanthanide contraction. (Section 23.1) Related Exercises: 23.1, 23.11, 23.12
- Determine the oxidation number and number of $d$ electrons for metal ions in complexes. (Section 23.2) Related Exercises: 23.13, 23.15, 23.16, 23.25
- Identify common ligands and distinguish between chelating and nonchelating ligands. (Section 23.3) Related Exercises: 23.27, 23.29, 23.30, 23.33
- Name coordination compounds given their formula and write their formula given their name. (Section 23.4)
Related Exercises: 23.35-23.38
- Define isomerism and differentiate between the various types of isomers. (Section 23.4) Related Exercises: 23.39, 23.40
- Recognize and draw the geometric isomers of a complex. (Section 23.4) Related Exercises: 23.41-23.44
- Recognize and draw the optical isomers of a complex. (Section 23.4) Related Exercises: 23.45, 23.46
- Use crystal-field theory to determine the number of unpaired electrons in a complex. (Sections 23.5 and 23.6)
Related Exercises: 23.49, 23.61, 23.63, 23.65
- Use the spectrochemical series to predict the relative crystalfield splitting energy and colors of metal complexes. (Sections 23.5 and 23.6) Related Exercises: 23.55, 23.56
- Differentiate between high-spin and low-spin ions, and identify the factors that stabilize each. (Section 23.6)
Related Exercises: 23.8, 23.59, 23.65, 23.66

## Exercises

## Visualizing Concepts

23.1 The three graphs below show the variation in radius, effective nuclear charge, and maximum oxidation state for the
transition metals of period 4. In each part below identify which property is being plotted. [Section 23.1]

23.2 Draw the structure for $\mathrm{Pt}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)\left(\mathrm{NH}_{3}\right)_{2}$ and use it to answer the following questions: (a) What is the coordination number for platinum in this complex? (b) What is the coordination geometry? (c) What is the oxidation state of the platinum? (d) How many unpaired electrons are there? [Sections 23.2 and 23.6]
23.3 Draw the Lewis structure for the ligand shown here. (a) Which atoms can serve as donor atoms? Classify this ligand as monodentate, bidentate, or polydentate. (b) How many of these ligands are needed to fill the coordination sphere in an octahedral complex? [Section 23.2]

$\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NHCH}_{2} \mathrm{CO}_{2}{ }^{-}$
23.4 Four-coordinate metals can have either a tetrahedral or a square-planar geometry; both possibilities are shown here
for $\left[\mathrm{PtCl}_{2}\left(\mathrm{NH}_{3}\right)_{2}\right]$. (a) What is the name of this molecule? (b) Would the tetrahedral molecule have a geometric isomer? (c) Would the tetrahedral molecule be diamagnetic or paramagnetic? (d) Would the square-planar molecule have a geometric isomer? (e) Would the square-planar molecule be diamagnetic or paramagnetic? (f) Would determining the number of geometric isomers help you distinguish between the tetrahedral and square-planar geometries? (g) Would measuring the molecule's response to a magnetic field help you distinguish between the two geometries? [Sections 23.4-23.6]

square planar

tetrahedral
23.5 There are two geometric isomers of octahedral complexes of the type $M A_{3} X_{3}$, where $M$ is a metal and $A$ and $X$ are monodentate ligands. Of the complexes shown here, which are identical to (1) and which are the geometric isomers of (1)? [Section 23.4]

23.6 Which of the complexes shown here are chiral? [Section 23.4]

(1)
$=\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$
$O=\mathrm{Cl}$
$=\mathrm{NH}_{3}$

(2)

(3)

(4)
23.7 The solutions shown here each have an absorption spectrum with a single absorption peak like that shown in Figure 23.26. What color does each solution absorb most strongly? [Section 23.5]

23.8 Which of these crystal-field splitting diagrams represents: (a) a weak-field octahedral complex of $\mathrm{Fe}^{3+}$, (b) a strongfield octahedral complex of $\mathrm{Fe}^{3+}$, (c) a tetrahedral complex of $\mathrm{Fe}^{3+},(\mathbf{d})$ a tetrahedral complex of $\mathrm{Ni}^{2+}$ ? (The diagrams do not indicate the relative magnitudes of $\Delta$.) [Section 23.6]

23.9 In the linear crystal-field shown here, the negative charges are on the $z$-axis. Using Figure 23.28 as a guide, predict which of the following choices most accurately describes the splitting of the $d$ orbitals in a linear crystal-field? [Section 23.6]

23.10 Two Co(III) complexes are both low spin but have different ligands. A solution of one is orange and a solution of the other is yellow. Which solution is likely to contain the complex that has the stronger-field ligand? [Section 23.6]

## The Transition Metals (Section 23.1)

23.11 The lanthanide contraction explains which of the following periodic trends? (a) The atomic radii of the transition metals first decrease and then increase when moving horizontally across each period. (b) When forming ions the period 4 transition metals lose their $4 s$ electrons before their 3d electrons. (c) The radii of the period 5 transition metals ( $\mathrm{Y}-\mathrm{Cd}$ ) are very similar to the radii of the period 6 transition metals (Lu-Hg).
23.12 Which periodic trend is partially responsible for the observation that the maximum oxidation state of the transi-tion-metal elements peaks near groups 7 and 8? (a) The number of valence electrons reaches a maximum at group 8. (b) The effective nuclear charge increases on moving left across each period. (c) The radii of the transition-metal elements reach a minimum for group 8 , and as the size of the atoms decreases it becomes easier to remove electrons.
23.13 For each of the following compounds, determine the electron configuration of the transition-metal ion. (a) CuO , (b) $\mathrm{Cu}_{2} \mathrm{O},(\mathbf{c}) \mathrm{V}_{2} \mathrm{O}_{5},($ d $) \mathrm{MnO}$.
23.14 Among the period 4 transition metals (Sc-Zn), which elements do not form ions where there are partially filled $3 d$ orbitals?
23.15 Write out the ground-state electron configurations of (a) $\mathrm{Sc}^{2+},(\mathbf{b}) \mathrm{Mo}^{2+},(\mathbf{c}) \mathrm{Rh}^{3+},(\mathbf{d}) \mathrm{Fe}^{3+}$.
23.16 How many electrons are in the valence $d$ orbitals in these transition-metal ions? (a) $\mathrm{Ru}^{3+}$, (b) $\mathrm{Pd}^{2+}$, (c) $\mathrm{Ti}^{2+}$, (d) $\mathrm{W}^{6+}$.
23.17 Which type of substance is attracted by a magnetic field, a diamagnetic substance or a paramagnetic substance?
23.18 Which type of magnetic material cannot be used to make permanent magnets, a ferromagnetic substance, an antiferromagnetic substance, or a ferrimagnetic substance?
23.19 What kind of magnetism is exhibited by this diagram:

23.20 The most important oxides of iron are magnetite, $\mathrm{Fe}_{3} \mathrm{O}_{4}$, and hematite, $\mathrm{Fe}_{2} \mathrm{O}_{3}$. (a) What are the oxidation states of iron in these compounds? (b) One of these iron oxides is ferrimagnetic, and the other is antiferromagnetic. Which iron oxide is more likely to be ferrimagnetic? Explain.

## Transition-Metal Complexes (Section 23.2)

23.21 (a) Using Werner's definition of valence, which property is the same as oxidation number, primary valence or secondary valence? (b) What term do we normally use for the other type of valence? (c) Why can $\mathrm{NH}_{3}$ serve as a ligand but $\mathrm{BH}_{3}$ cannot?
23.22 Which species are more likely to act as ligands? (a) Positively charged ions or negatively charged ions? (b) Neutral molecules that are polar or those that are nonpolar?
23.23 A complex is written as $\mathrm{NiBr}_{2} \cdot 6 \mathrm{NH}_{3}$. (a) What is the oxidation state of the Ni atom in this complex? (b) What is the likely coordination number for the complex? (c) If the complex is treated with excess $\mathrm{AgNO}_{3}(a q)$, how many moles of AgBr will precipitate per mole of complex?
23.24 Crystals of hydrated chromium(III) chloride are green, have an empirical formula of $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, and are highly soluble, (a) Write the complex ion that exists in this compound. (b) If the complex is treated with excess $\mathrm{AgNO}_{3}(a q)$, how many moles of AgCl will precipitate per mole of $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ dissolved in solution? (c) Crystals of anhydrous chromium(III) chloride are violet and insoluble in aqueous solution. The coordination geometry of chromium in these crystals is octahedral, as is almost always the case for $\mathrm{Cr}^{3+}$. How can this be the case if the ratio of Cr to Cl is not $1: 6$ ?
23.25 Indicate the coordination number and the oxidation number of the metal for each of the following complexes:
(a) $\mathrm{Na}_{2}[\mathrm{Co}($ EDTA $)]$
(b) $\mathrm{KMnO}_{4}$
(c) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}_{2}$
(d) $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}$
(e) $\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}$
(f) $\mathrm{Zn}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)\left(\mathrm{NH}_{3}\right)_{2}$
23.26 Indicate the coordination number and the oxidation number of the metal for each of the following complexes:
(a) $\mathrm{K}_{2} \mathrm{PtCl}_{4}$
(b) $\left[\mathrm{Ni}(\mathrm{CO})_{4}\right] \mathrm{Br}_{2}$
(c) $\mathrm{OsO}_{4}$
(d) $\left[\mathrm{Mn}(\mathrm{en})_{3}\right]\left(\mathrm{NO}_{3}\right)_{2}$
(e) $\left[\mathrm{Cr}(\mathrm{en})\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}_{3}$
(f) $\left[\mathrm{Zn}(\text { bipy })_{2}\right]\left(\mathrm{ClO}_{4}\right)_{2}$

## Common Ligands in Coordination Chemistry (Section 23.3)

23.27 For each of the following molecules or polyatomic ions, draw the Lewis structure and indicate if it can act as a monodentate ligand, a bidentate ligand, or is unlikely to act as a ligand at all: (a) ethylamine, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{2}$, (b) trimethylphosphine, $\mathrm{P}\left(\mathrm{CH}_{3}\right)_{3}$, (c) carbonate, $\mathrm{CO}_{3}{ }^{2-}$, (d) ethane, $\mathrm{C}_{2} \mathrm{H}_{6}$.
23.28 For each of the following polydentate ligands, determine (i) the maximum number of coordination sites that the ligand can occupy on a single metal ion and (ii) the number and type of donor atoms in the ligand: (a) acetylacetonate ion (acac), (b) phenanthroline (phen), (c) diethylenetriamine, (d) carbonate ion, (e) triphosphate ion.
23.29 Polydentate ligands can vary in the number of coordination positions they occupy. In each of the following, identify the polydentate ligand present and indicate the probable number of coordination positions it occupies:
(a) $\operatorname{Cr}(\mathrm{EDTA})^{-}$
(b) $\left[\mathrm{Ni}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \mathrm{Br}_{2}$
(c) $\left[\mathrm{Ru}(\mathrm{en})\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}_{3}$
(d) $\mathrm{K}_{2}\left[\mathrm{Fe}(\right.$ o-phen $\left.)(\mathrm{CN})_{4}\right]$
23.30 Indicate the likely coordination number of the metal in each of the following complexes:
(a) $\left[\mathrm{Ru}(\text { bipy })_{3}\right]\left(\mathrm{NO}_{3}\right)_{2}$
(b) $\mathrm{Re}(\text { o-phen })_{2}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}$
(c) $\mathrm{Pd}(\mathrm{PPh} 3)_{3} \mathrm{Cl}$
(d) $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Mn}($ EDTA $)$
23.31 For each of the following pairs, identify the molecule or ion that is more likely to act as a ligand in a metal complex: (a) carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ or carbonate $\left(\mathrm{CO}_{3}^{2-}\right)$, (b) water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ or hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$, (c) phosphine $\left(\mathrm{PH}_{3}\right)$ or phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$.
23.32 Pyridine $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)$, abbreviated py, is the molecule

(a) Would you expect pyridine to act as a monodentate or bidentate ligand? (b) For the equilibrium reaction

$$
\left[\mathrm{Ru}(\text { py })_{4}(\text { bipy })\right]^{2+}+2 \mathrm{py} \rightleftharpoons\left[\mathrm{Ru}(\mathrm{py})_{6}\right]^{2+}+\text { bipy }
$$

would you predict the equilibrium constant to be larger or smaller than one?
23.33 True or false? The following ligand can act as a bidentate ligand.

23.34 When silver nitrate is reacted with the molecular base ortho-phenanthroline, colorless crystals form that contain the transition-metal complex shown below. (a) What is the coordination geometry of silver in this complex? (b) Assuming no oxidation or reduction occurs during the reaction, what is charge of the complex shown here? (c) Do you expect any nitrate ions will be present in the crystal? (d) Write a formula for the compound that forms in this reaction. (e) Use the accepted nomenclature to write the name of this compound.

## Nomenclature and Isomerism in Coordination Chemistry (Section 23.4)

23.35 Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:
(a) triamminetriaquachromium(III) nitrate
(b) dichlorobis(ethylenediamine)platinum(II)
(c) pentacarbonyliron(0)
(d) ammonium diaquabis(oxalato) Co (II)
(e) tris(bipyridyl)cobalt(III) sulfate
23.36 Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:
(a) hexaammineiron(II) nitrate
(b) tetraaquadibromochromium(III) perchlorate
(c) ammonium hexachloropalladate(IV)
(d) diammineoxolatonickel(II)
(e) Hexaamminemolybdenum(III) tetrachlorocuprate(II)
23.37 Write the names of the following compounds, using the standard nomenclature rules for coordination complexes:
(a) $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right] \mathrm{NO}_{3}$
(b) $\mathrm{Hg}\left[\mathrm{Co}(\mathrm{SCN})_{4}\right]$
(c) $\left[\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{3}\right]$
(d) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{CO}_{3}\right]_{2} \mathrm{SO}_{4}$
23.38 Write names for the following coordination compounds:
(a) $\mathrm{Na}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{5} \mathrm{NO}\right]$
(b) $\left[\mathrm{CoO}\left(\mathrm{NH}_{3}\right)_{5}\right] \mathrm{Br}$
(c) $\mathrm{Na}_{2}\left[\mathrm{NiBr}_{4}\right]$
(d) $\left[\mathrm{Rh}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]_{3}$
23.39 Consider the following three complexes:
(Complex 1) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Br}_{2}\right] \mathrm{Cl}$
(Complex 2) $\left[\mathrm{Pd}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{ONO})_{2}\right]$
(Complex 3) $\left[\mathrm{V}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$,
Which of the three complexes can have (a) geometric isomers, (b) linkage isomers, (c) optical isomers, (d) coordinationsphere isomers?
23.40 Consider the following three complexes:
(Complex 1) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{SCN}\right]^{2+}$
(Complex 2) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right]^{2+}$
(Complex 3) $\mathrm{CoClBr} \cdot 5 \mathrm{NH}_{3}$
Which of the three complexes can have (a) geometric isomers, (b) linkage isomers, (c) optical isomers, (d) coordina-tion-sphere isomers?
23.41 A four-coordinate complex $\mathrm{MA}_{2} \mathrm{~B}_{2}$ is prepared and found to have two different isomers. Is it possible to determine from this information whether the complex is square planar or tetrahedral? If so, which is it?
23.42 Consider an octahedral complex, $\mathrm{MA}_{2} \mathrm{~B}_{4}$. How many geometric isomers are expected for this compound? Will any of the isomers be optically active? If so, which ones?
23.43 Determine if each of the following complexes exhibits geometric isomerism. If geometric isomers exist, determine how many there are. (a) tetrahedral $\left[\mathrm{Cd}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Cl}_{2}\right]$, (b) square-planar $\left[\mathrm{IrCl}_{2}\left(\mathrm{PH}_{3}\right)_{2}\right]^{-}$, (c) octahedral $\left[\mathrm{Fe}(o \text {-phen })_{2} \mathrm{Cl}_{2}\right]^{+}$.
23.44 Determine if each of the following complexes exhibits geometric isomerism. If geometric isomers exist, determine how many there are. (a) $\left[\mathrm{Rh} \text { (bipy) }(o \text {-phen })_{2}\right]^{3+}$, (b) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3}(\text { bipy }) \mathrm{Br}\right]^{2+}$, (c) square-planar $\left[\mathrm{Pd}(\mathrm{en})(\mathrm{CN})_{2}\right]$.
23.45 Determine if each of the following metal complexes is chiral and therefore has an optical isomer: (a) tetrahedral [ $\left.\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Cl}_{2}\right],(\mathbf{b})$ octahedral trans-[Ru(bipy) $\left.{ }_{2} \mathrm{Cl}_{2}\right],(\mathbf{c})$ octahedral cis-[Ru(bipy) $\left.{ }_{2} \mathrm{Cl}_{2}\right]$.
23.46 Determine if each of the following metal complexes is chiral and therefore has an optical isomer: (a) square planar $\left[\mathrm{Pd}(\mathrm{en})(\mathrm{CN})_{2}\right],(\mathbf{b})$ octahedral $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+},(\mathbf{c})$ octahedral cis-[V(en) $\left.{ }_{2} \mathrm{ClBr}\right]$.

## Color and Magnetism in Coordination Chemistry; Crystal-Field Theory (Sections 23.5 and 23.6)

23.47 (a) If a complex absorbs light at 610 nm , what color would you expect the complex to be? (b) What is the energy in joules of a photon with a wavelength of 610 nm ? (c) What is the energy of this absorption in $\mathrm{kJ} / \mathrm{mol}$ ?
23.48 (a) A complex absorbs photons with an energy of $4.51 \times 10^{-19} \mathrm{~J}$. What is the wavelength of these photons? (b) If this is the only place in the visible spectrum where the complex absorbs light, what color would you expect the complex to be?
23.49 Identify each of the following coordination complexes as either diamagnetic or paramagnetic:
(a) $\left[\mathrm{CoBr}\left(\mathrm{NH}_{3}\right)_{5}\right]^{2+}$
(b) $\left[\mathrm{W}(\mathrm{CN})_{6}\right]^{3-}$
(c) $\left[\mathrm{VF}_{6}\right]^{3-}$
(d) $\left[\mathrm{Rh}(\text { o-phen })_{3}\right]^{3+}$
23.50 Identify each of the following coordination complexes as either diamagnetic or paramagnetic:
(a) $\left.\left[\mathrm{ZnBr}_{4}\right)\right]^{2-}$
(b) $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$
(c) $\mathrm{OsO}_{4}$
(d) $\left[\mathrm{PtCl}_{4}\right]^{2-}$
23.51 If the lobes of a given $d$-orbital point directly at the ligands, will an electron in that orbital have a higher or lower energy than an electron in a $d$-orbital whose lobes do not point directly at the ligands?
23.52 The lobes of which $d$ orbitals point directly between the ligands in (a) octahedral geometry, (b) tetrahedral geometry?
23.53 (a) Sketch a diagram that shows the definition of the crystalfield splitting energy ( $\Delta$ ) for an octahedral crystal-field. (b) What is the relationship between the magnitude of $\Delta$ and the energy of the $d-d$ transition for a $d^{1}$ complex? (c) Calculate $\Delta$ in $\mathrm{kJ} / \mathrm{mol}$ if a $d^{1}$ complex has an absorption maximum at 545 nm .
23.54 As shown in Figure 23.26, the $d-d$ transition of $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ produces an absorption maximum at a wavelength of about 500 nm . (a) What is the magnitude of $\Delta$ for $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ in $\mathrm{kJ} / \mathrm{mol}$ ? (b) How would the magnitude of $\Delta$ change if the $\mathrm{H}_{2} \mathrm{O}$ ligands in $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ were replaced with $\mathrm{NH}_{3}$ ligands?
23.55 The colors in the copper-containing minerals malachite, which is green and has an empirical formula of $\mathrm{Cu}_{2} \mathrm{CO}_{3}$ $(\mathrm{OH})_{2}$, and azurite, which is blue and has an empirical formula of $\mathrm{Cu}_{3}\left(\mathrm{CO}_{3}\right)_{2}(\mathrm{OH})_{2}$, come from a single $d$ - $d$ transition in each compound. The compounds are sometimes found together in nature as shown here. (a) What is the electron configuration of the copper ion in each mineral? (b) Based on their colors, in which compound would you predict the crystal-field splitting $\Delta$ is larger?

23.56 The color and wavelength of the absorption maximum for $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+},\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$, and $\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}$ are given in Figure 23.30. The absorption maximum for the $\left[\mathrm{Ni}(\text { bipy })_{3}\right]^{2+}$ ion occurs at about 520 nm . (a) What color
would you expect for the $\left[\mathrm{Ni}(\text { bipy })_{3}\right]^{2+}$ ion? (b) Based on these data, where would you put bipy in the spectrochemical series?
23.57 Give the number of (valence) $d$ electrons associated with the central metal ion in each of the following complexes: (a) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2}$, (b) $\mathrm{K}_{2}\left[\mathrm{Cu}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}\right]$, (c) $\left[\mathrm{Os}(\mathrm{en})_{3}\right] \mathrm{Cl}_{3}$, (d) $[\mathrm{Cr}(\mathrm{EDTA})] \mathrm{SO}_{4},(\mathbf{e})\left[\mathrm{Cd}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{2}$.
23.58 Give the number of (valence) $d$ electrons associated with the central metal ion in each of the following complexes: (a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{3},(\mathbf{b})\left[\mathrm{Zr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{SO}_{4}$, (c) $\mathrm{Na}_{2}\left[\mathrm{CuCl}_{4}\right]$, (d) $\left(\mathrm{NH}_{4}\right)_{2}\left[\mathrm{Ni}\left(\mathrm{CO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right],\left(\right.$ e) $\mathrm{K}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$
23.59 A classmate says, "A weak-field ligand usually means the complex is high spin." Is your classmate correct? Explain.
23.60 For a given metal ion and set of ligands, is the crystal-field splitting energy larger for a tetrahedral or an octahedral geometry?
23.61 For each of the following metals, write the electronic configuration of the atom and its 2+ ion: (a) Mn, (b) Ru, (c) Rh. Draw the crystal-field energy-level diagram for the $d$ orbitals of an octahedral complex, and show the placement of the $d$ electrons for each $2+$ ion, assuming a strong-field complex. How many unpaired electrons are there in each case?
23.62 For each of the following metals, write the electronic configuration of the atom and its 3+ ion: (a) Fe, (b) Mo, (c) Co. Draw the crystal-field energy-level diagram for the $d$ orbitals of an octahedral complex, and show the placement of the $d$ electrons for each $3+$ ion, assuming a weak-field complex. How many unpaired electrons are there in each case?
23.63 Draw the crystal-field energy-level diagrams and show the placement of $d$ electrons for each of the following: (a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ (four unpaired electrons), (b) $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ (a high-spin complex), (c) $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]^{2+}$ (a low-spin complex), (d) $\left[\mathrm{IrCl}_{6}\right]^{2-}$ (a low-spin complex), (e) $\left[\mathrm{Cr}(\mathrm{en})_{3}\right]^{3+}$, (f) $\left[\mathrm{NiF}_{6}\right]^{4-}$.
23.64 Draw the crystal-field energy-level diagrams and show the placement of electrons for the following complexes: (a) $\left[\mathrm{VCl}_{6}\right]^{3-},(\mathbf{b})\left[\mathrm{FeF}_{6}\right]^{3-}$ (a high-spin complex), (c) $\left[\mathrm{Ru}(\text { bipy })_{3}\right]^{3+}$ (a low-spin complex), (d) $\left[\mathrm{NiCl}_{4}\right]^{2-}$ (tetrahedral), (e) $\left[\mathrm{PtBr}_{6}\right]^{2-},(\mathbf{f})\left[\mathrm{Ti}(\mathrm{en})_{3}\right]^{2+}$.
23.65 The complex $\left[\mathrm{Mn}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ contains five unpaired electrons. Sketch the energy-level diagram for the $d$ orbitals, and indicate the placement of electrons for this complex ion. Is the ion a high-spin or a low-spin complex?
23.66 The ion $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{3-}$ has one unpaired electron, whereas $\left[\mathrm{Fe}(\mathrm{NCS})_{6}\right]^{3-}$ has five unpaired electrons. From these results, what can you conclude about whether each complex is high spin or low spin? What can you say about the placement of $\mathrm{NCS}^{-}$in the spectrochemical series?

## Additional Exercises

23.67 The Curie temperature is the temperature at which a ferromagnetic solid switches from ferromagnetic to paramagnetic, and for nickel, the Curie temperature is $354^{\circ} \mathrm{C}$. Knowing this, you tie a string to two paper clips made of nickel and hold the paper clips near a permanent magnet. The magnet attracts the paper clips, as shown in the photograph on the left. Now you heat one of the paper clips with a cigarette lighter, and the clip drops (right photograph). Explain what happened.

23.68 Explain why the transition metals in periods 5 and 6 have nearly identical radii in each group.
23.69 Based on the molar conductance values listed here for the series of platinum(IV) complexes, write the formula for each complex so as to show which ligands are in the coordination sphere of the metal. By way of example, the molar conductances of 0.050 M NaCl and $\mathrm{BaCl}_{2}$ are $107 \mathrm{ohm}^{-1}$ and $197 \mathrm{ohm}^{-1}$, respectively.

| Complex | Molar Conductance $\left(\text { ohm }^{-1}\right)^{*}$ <br> of $0.050 ~$ <br> $M$ Solution |
| :--- | :---: |$|$

*The ohm is a unit of resistance; conductance is the inverse of resistance.
23.70 (a) A compound with formula $\mathrm{RuCl}_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ is dissolved in water, forming a solution that is approximately the same color as the solid. Immediately after forming the solution, the addition of excess $\mathrm{AgNO}_{3}(a q)$ forms 2 mol of solid AgCl per mole of complex. Write the formula for the compound, showing which ligands are likely to be present in the coordination sphere. (b) After a solution of $\mathrm{RuCl}_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ has stood for about a year, addition of $\mathrm{AgNO}_{3}(\mathrm{aq})$ precipitates 3 mol of AgCl per mole of complex. What has happened in the ensuing time?
23.71 Sketch the structure of the complex in each of the following compounds and give the full compound name:
(a) cis- $\left[\mathrm{PtBrCl}\left(\mathrm{NO}_{2}\right)_{2}\right]^{2-}$
(b) $\left[\mathrm{Mn}(\mathrm{CO})_{3}\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)\right]^{+}$
(c) cis- $\left.\left[\mathrm{CrCl}_{4}\right)\left(\mathrm{OH}_{2}\right)_{2}\right]^{-}$
(d) trans- $\left[\mathrm{Co}(\mathrm{OH})(\mathrm{en})_{2} \mathrm{Cl}\right]^{+}$
23.72 Does complex $d$ in Exercise 23.71 have optical isomers?
23.73 The molecule dimethylphosphinoethane $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2}\right.$ $\mathrm{P}\left(\mathrm{CH}_{3}\right)_{2}$, which is abbreviated dmpe] is used as a ligand for some complexes that serve as catalysts. A complex that contains this ligand is $\mathrm{Mo}(\mathrm{CO})_{4}(\mathrm{dmpe})$. (a) Draw the Lewis structure for dmpe, and compare it with ethylenediamine as a coordinating ligand. (b) What is the oxidation state of Mo in $\mathrm{Na}_{2}\left[\mathrm{Mo}(\mathrm{CN})_{2}(\mathrm{CO})_{2}(\mathrm{dmpe})\right]$ ? (c) Sketch the structure of the $\left[\mathrm{Mo}(\mathrm{CN})_{2}(\mathrm{CO})_{2}(\mathrm{dmpe})\right]^{2-}$ ion, including all the possible isomers.
23.74 The square-planar complex $\left[\mathrm{Pt}(\mathrm{en}) \mathrm{Cl}_{2}\right]$ only forms in one of two possible geometric isomers. Which isomer is not observed: cis or trans?
23.75 The acetylacetone ion forms very stable complexes with many metallic ions. It acts as a bidentate ligand, coordinating to the metal at two adjacent positions. Suppose that one of the $\mathrm{CH}_{3}$ groups of the ligand is replaced by a $\mathrm{CF}_{3}$ group, as shown here:

Sketch all possible isomers for the complex with three tfac ligands on cobalt(III). (You can use the symbol $\bullet$ to represent the ligand.)
23.76 Which transition metal atom is present in each of the following biologically important molecules: (a) hemoglobin, (b) chlorophylls, (c) siderophores, (d) hemocyanine.
23.77 Carbon monoxide, CO, is an important ligand in coordination chemistry. When CO is reacted with nickel metal, the product is $\left[\mathrm{Ni}(\mathrm{CO})_{4}\right]$, which is a toxic, pale yellow liquid. (a) What is the oxidation number for nickel in this compound? (b) Given that $\left[\mathrm{Ni}(\mathrm{CO})_{4}\right]$ is a diamagnetic molecule with a tetrahedral geometry, what is the electron configuration of nickel in this compound? (c) Write the name for $\left[\mathrm{Ni}(\mathrm{CO})_{4}\right]$ using the nomenclature rules for coordination compounds.
23.78 Some metal complexes have a coordination number of 5. One such complex is $\mathrm{Fe}(\mathrm{CO})_{5}$, which adopts a trigonal bipyramidal geometry (see Figure 9.8). (a) Write the name for $\mathrm{Fe}(\mathrm{CO})_{5}$, using the nomenclature rules for coordination compounds. (b) What is the oxidation state of Fe in this compound? (c) Suppose one of the CO ligands is replaced with a $\mathrm{CN}^{-}$ligand, forming $\left[\mathrm{Fe}(\mathrm{CO})_{4}(\mathrm{CN})\right]^{-}$. How many geometric isomers would you predict this complex could have?
23.79 Which of the following objects is chiral: (a) a pencil, (b) a computer keyboard, (c) a grand piano, (d) a molecular model of cis-Fe(bipy) ${ }_{2} \mathrm{Cl}_{2}$, (e) a piece of plane A4 paper?
23.80 The complexes $\left[\mathrm{CrBr}_{6}\right]^{3-}$ and $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ are both known. (a) Draw the $d$-orbital energy-level diagram for octahedral $\mathrm{Cr}(\mathrm{III})$ complexes. (b) What gives rise to the colors of these complexes? (c) Which of the two complexes would you expect to absorb light of higher energy?
[23.81] One of the more famous species in coordination chemistry is the Creutz-Taube complex:

It is named for the two scientists who discovered it and initially studied its properties. The central ligand is pyrazine, a planar six-membered ring with nitrogens at opposite sides. (a) How can you account for the fact that the complex, which has only neutral ligands, has an odd overall charge? (b) The metal is in a low-spin configuration in both cases. Assuming octahedral coordination, draw the $d$-orbital energy-level diagram for each metal. (c) In many experiments the two metal ions appear to be in exactly equivalent states. Can you think of a reason that this might appear to be so, recognizing that electrons move very rapidly compared to nuclei?
23.82 Solutions of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+},\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ (both octahedral), and $\left[\mathrm{CoCl}_{4}\right]^{2-}$ (tetrahedral) are colored. One is pink, one is blue, and one is yellow. Based on the spectrochemical series and remembering that the energy splitting in tetrahedral complexes is normally much less than that in octahedral ones, assign a color to each complex.
23.83 Oxyhemoglobin, with an $\mathrm{O}_{2}$ bound to iron, is a low-spin $\mathrm{Fe}(\mathrm{II})$ complex; deoxyhemoglobin, without the $\mathrm{O}_{2}$ molecule, is a high-spin complex. (a) Assuming that the coordination environment about the metal is octahedral, how many unpaired electrons are centered on the metal ion in each case? (b) What ligand is coordinated to the iron in place of $\mathrm{O}_{2}$ in deoxyhemoglobin? (c) Explain in a general way why the two forms of hemoglobin have different colors (hemoglobin is red, whereas deoxyhemoglobin has a bluish cast). (d) A 15 -minute exposure to air containing 400 ppm of CO causes about $10 \%$ of the hemoglobin in the
blood to be converted into the carbon monoxide complex, called carboxyhemoglobin. What does this suggest about the relative equilibrium constants for binding of carbon monoxide and $\mathrm{O}_{2}$ to hemoglobin? (e) CO is a strong-field ligand. What color might you expect carboxyhemoglobin to be?
[23.84] Consider the tetrahedral anions $\mathrm{VO}_{4}{ }^{3-}$ (orthovanadate ion), $\mathrm{CrO}_{4}{ }^{2-}$ (chromate ion), and $\mathrm{MnO}_{4}^{-}$(permanganate ion). (a) These anions are isoelectronic. What does this statement mean? (b) Would you expect these anions to exhibit $d-d$ transitions? Explain. (c) As mentioned in "A Closer Look" on charge-transfer color, the violet color of $\mathrm{MnO}_{4}^{-}$ is due to a ligand-to-metal charge transfer (LMCT) transition. What is meant by this term? (d) The LMCT transition in $\mathrm{MnO}_{4}^{-}$occurs at a wavelength of 565 nm . The $\mathrm{CrO}_{4}{ }^{2-}$ ion is yellow. Is the wavelength of the LMCT transition for chromate larger or smaller than that for $\mathrm{MnO}_{4}^{-}$? Explain. (e) The $\mathrm{VO}_{4}^{3-}$ ion is colorless. Do you expect the light absorbed by the LMCT to fall in the UV or the IR region of the electromagnetic spectrum? Explain your reasoning.
23.85 Given the colors observed for $\mathrm{VO}_{4}^{3-}$ (orthovanadate ion), $\mathrm{CrO}_{4}{ }^{2-}$ (chromate ion), and $\mathrm{MnO}_{4}^{-}$(permanganate ion) (see Exercise 23.84), what can you say about how the energy separation between the ligand orbitals and the empty $d$ orbitals changes as a function of the oxidation state of the transition metal at the center of the tetrahedral anion?
[23.86] The blue-green color of turquoise is due to the presence of $\mathrm{Cu}(\mathrm{II})$ ions at octahedral sites which is coordinated with $\mathrm{OH}^{-}$and $\mathrm{H}_{2} \mathrm{O}$. Assuming $\mathrm{Cu}(\mathrm{II})$ ions adopt an octahedral geometry, draw the crystal-field splitting diagram for $\mathrm{Cu}(\mathrm{II})$ in this environment. Suppose that the turquoise crystal is subjected to high pressure. What do you predict for the variation in the wavelength of absorption of the turquoise as a function of pressure? Explain.
23.87 In 2001, chemists at SUNY-Stony Brook succeeded in synthesizing the complex trans- $\left[\mathrm{Fe}(\mathrm{CN})_{4}(\mathrm{CO})_{2}\right]^{2-}$, which could be a model of complexes that may have played a role in the origin of life. (a) Sketch the structure of the complex. (b) The complex is isolated as a sodium salt. Write the complete name of this salt. (c) What is the oxidation state of Fe in this complex? How many $d$ electrons are associated with
the Fe in this complex? (d) Would you expect this complex to be high spin or low spin? Explain.
[23.88] When Alfred Werner was developing the field of coordination chemistry, it was argued by some that the optical activity he observed in the chiral complexes he had prepared was due to the presence of carbon atoms in the molecule. To disprove this argument, Werner synthesized a chiral complex of cobalt that had no carbon atoms in it, and he was able to resolve it into its enantiomers. Design a cobalt(III) complex that would be chiral if it could be synthesized and that contains no carbon atoms. (It may not be possible to synthesize the complex you design, but we will not worry about that for now.)
23.89 Generally speaking, for a given metal and ligand, the stability of a coordination compound is greater for the metal in the +3 rather than in the +2 oxidation state (for metals that form stable +3 ions in the first place). Suggest an explanation, keeping in mind the Lewis acid-base nature of the metal-ligand bond.
23.90 Many trace metal ions exist in the blood complexed with amino acids or small peptides. The anion of the amino acid glycine (gly),

can act as a bidentate ligand, coordinating to the metal through nitrogen and oxygen atoms. How many isomers are possible for (a) $\left[\mathrm{Zn}(\mathrm{gly})_{2}\right]$ (tetrahedral), (b) $\left[\mathrm{Pt}(\mathrm{gly})_{2}\right]$ (square planar), (c) $\left[\mathrm{Co}(\mathrm{gly})_{3}\right]$ (octahedral)? Sketch all possible isomers. Use the symbol $\curvearrowleft$ to represent the ligand.
23.91 The coordination complex $\left[\mathrm{Cr}(\mathrm{CO})_{6}\right]$ forms colorless, diamagnetic crystals that melt at $90^{\circ} \mathrm{C}$. (a) What is the oxidation number of chromium in this compound? (b) Given that $\left[\mathrm{Cr}(\mathrm{CO})_{6}\right]$ is diamagnetic, what is the electron configuration of chromium in this compound? (c) Given that $\left[\mathrm{Cr}(\mathrm{CO})_{6}\right]$ is colorless, would you expect CO to be a weak-field or strong-field ligand? (d) Write the name for $\left[\mathrm{Cr}(\mathrm{CO})_{6}\right]$ using the nomenclature rules for coordination compounds.

## Integrative Exercises

[23.92] Metallic elements are essential components of many important enzymes operating within our bodies. Carbonic anhydrase, which contains $\mathrm{Zn}^{2+}$ in its active site, is responsible for rapidly interconverting dissolved $\mathrm{CO}_{2}$ and bicarbonate ion, $\mathrm{HCO}_{3}^{-}$. The zinc in carbonic anhydrase is tetrahedrally coordinated by three neutral nitrogencontaining groups and a water molecule. The coordinated water molecule has a $\mathrm{p} K_{a}$ of 7.5 , which is crucial for the enzyme's activity. (a) Draw the active site geometry for the Zn (II) center in carbonic anhydrase, just writing " N " for the three neutral nitrogen ligands from the protein.
(b) Compare the $\mathrm{p} K_{a}$ of carbonic anhydrase's active site with that of pure water; which species is more acidic? (c) When the coordinated water to the Zn (II) center in carbonic anhydrase is deprotonated, what ligands are bound to the $\mathrm{Zn}(\mathrm{II})$ center? Assume the three nitrogen ligands are unaffected. (d) The $\mathrm{p} K_{a}$ of $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ is 10 . Suggest an explanation for the difference between this $\mathrm{p} K_{a}$ and that of carbonic anhydrase. (e) Would you expect carbonic anhydrase to have a deep color, like hemoglobin and other metal-ion-containing proteins do? Explain.
23.93 Two different compounds have the formulation $\mathrm{CoBr}\left(\mathrm{SO}_{4}\right) \cdot 5 \mathrm{NH}_{3}$. Compound A is dark violet, and compound B is red-violet. When compound A is treated with $\mathrm{AgNO}_{3}(a q)$, no reaction occurs, whereas compound B reacts with $\mathrm{AgNO}_{3}(a q)$ to form a white precipitate. When compound A is treated with $\mathrm{BaCl}_{2}(a q)$, a white precipitate is formed, whereas compound B has no reaction with $\mathrm{BaCl}_{2}(a q)$. (a) Is Co in the same oxidation state in these complexes? (b) Explain the reactivity of compounds A and B with $\mathrm{AgNO}_{3}(\mathrm{aq})$ and $\mathrm{BaCl}_{2}(a q)$. (c) Are compounds A and $B$ isomers of one another? If so, which category from Figure 23.19 best describes the isomerism observed for these complexes? (d) Would compounds A and B be expected to be strong electrolytes, weak electrolytes, or nonelectrolytes?
23.94 An iron complex formed from a solution containing hydrochloric acid and bipyridine is purified and analyzed. It contains $9.38 \% \mathrm{Fe}, 60.53 \%$ carbon, $4.06 \%$ hydrogen, and $14.12 \%$ nitrogen by mass. The remainder of the compound is chlorine. An aqueous solution of the complex has about the same electrical conductivity as an equimolar solution of $\mathrm{K}_{2}\left[\mathrm{CuCl}_{4}\right]$. Write the formula of the
compound, using brackets to denote the iron and its coordination sphere.
23.95 The $E^{\circ}$ values for two low-spin iron complexes in acidic solution are as follows:

$$
\begin{array}{ll}
{\left[\mathrm{Fe}(o \text {-phen })_{3}\right]^{3+}(a q)+\mathrm{e}^{-}} & \rightleftharpoons \\
{\left[\mathrm{Fe}(o \text {-phen })_{3}\right]^{2+}(a q)} & E^{\circ}=1.12 \mathrm{~V} \\
\left.[\mathrm{CN})_{6}\right]^{3-}(a q)+\mathrm{e}^{-} \rightleftharpoons & {\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}(a q)}
\end{array} E^{\circ}=0.36 \mathrm{~V} .
$$

(a) Is it thermodynamically favorable to reduce both Fe (III) complexes to their $\mathrm{Fe}(\mathrm{II})$ analogs? Explain. (b) Which complex, $\left[\mathrm{Fe}(o \text {-phen })_{3}\right]^{3+}$ or $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{3-}$, is more difficult to reduce? (c) Suggest an explanation for your answer to (b).
23.96 A platinum complex formed from a solution containing chloride ion and ammonia is found on elemental analysis to contain $23.63 \%$ chlorine, $9.34 \%$ nitrogen, $2.02 \%$ hydrogen by mass. The compound is slightly soluble in several organic solvents; its solutions in water or alcohol do not conduct electricity. It is found experimentally to have a net dipole moment. Write the chemical formula of this platinum complex, and indicate its probable structure.
23.97 (a) In early studies it was observed that when the complex $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Br}_{2}\right] \mathrm{Br}$ was placed in water, the electrical conductivity of a 0.05 M solution changed from an initial value of $191 \mathrm{ohm}^{-1}$ to a final value of $374 \mathrm{ohm}^{-1}$ over a period of an hour or so. Suggest an explanation for the observed results. (See Exercise 23.69 for relevant comparison data.) (b) Write a balanced chemical equation to describe the reaction. (c) A $500-\mathrm{mL}$ solution is made up by dissolving 3.87 g of the complex. As soon as the solution is formed, and before any change in conductivity has occurred, a $25.00-\mathrm{mL}$ portion of the solution is titrated with $0.0100 \mathrm{M} \mathrm{AgNO}_{3}$ solution. What volume of $\mathrm{AgNO}_{3}$ solution do you expect to be required to precipitate the free $\mathrm{Br}^{-}(a q)$ ? (d) Based on the response you gave to part (b), what volume of $\mathrm{AgNO}_{3}$ solution would be required to titrate a fresh $25.00-\mathrm{mL}$ sample
of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Br}_{2}\right] \mathrm{Br}$ after all conductivity changes have occurred?
23.98 The total concentration of $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ in a sample of hard water was determined by titrating a $0.100-\mathrm{L}$ sample of the water with a solution of EDTA ${ }^{4-}$. The EDTA ${ }^{4-}$ chelates the two cations:

$$
\begin{aligned}
\mathrm{Mg}^{2+}+[\mathrm{EDTA}]^{4-} & \longrightarrow[\mathrm{Mg}(\mathrm{EDTA})]^{2-} \\
\mathrm{Ca}^{2+}+[\mathrm{EDTA}]^{4-} & \longrightarrow[\mathrm{Ca}(\mathrm{EDTA})]^{2-}
\end{aligned}
$$

It requires 31.5 mL of 0.0104 M [EDTA] ${ }^{4-}$ solution to reach the end point in the titration. A second 0.100-L sample was then treated with sulfate ion to precipitate $\mathrm{Ca}^{2+}$ as calcium sulfate. The $\mathrm{Mg}^{2+}$ was then titrated with 18.7 mL of 0.0104 $M$ [EDTA] ${ }^{4-}$. Calculate the concentrations of $\mathrm{Mg}^{2+}$ and $\mathrm{Ca}^{2+}$ in the hard water in $\mathrm{mg} / \mathrm{L}$.
23.99 Carbon monoxide is toxic because it binds more strongly to the iron in hemoglobin $(\mathrm{Hb})$ than does $\mathrm{O}_{2}$, as indicated by these approximate standard free-energy changes in blood:

$$
\begin{gathered}
\mathrm{Hb}+\mathrm{O}_{2} \longrightarrow \mathrm{HbO}_{2} \quad \Delta G^{\circ}=-70 \mathrm{~kJ} \\
\mathrm{Hb}+\mathrm{CO} \longrightarrow \mathrm{HbCO} \quad \Delta G^{\circ}=-80 \mathrm{~kJ}
\end{gathered}
$$

Using these data, estimate the equilibrium constant at 298 $K$ for the equilibrium

$$
\mathrm{HbO}_{2}+\mathrm{CO} \rightleftharpoons \mathrm{HbCO}+\mathrm{O}_{2}
$$

23.100 The value of $\Delta$ for the $\left[\mathrm{MoI}_{6}\right]^{3-}$ complex is $198.58 \mathrm{~kJ} / \mathrm{mol}$. Calculate the expected wavelength of the absorption corresponding to promotion of an electron from the lower energy to the higher-energy $d$-orbital set in this complex. Should the complex absorb in the visible range?
[23.101] A Zn electrode is immersed in a solution that is 1.00 M in $\left[\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ and 1.00 M in $\mathrm{NH}_{3}$. When the cathode is a standard hydrogen electrode, the emf of the cell is found to be +1.04 V . What is the formation constant for $\left[\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ ?

## Design an Experiment

Following a procedure found in a scientific paper, you go into the lab and attempt to prepare crystals of dichlorobis(ethylenediamine) cobalt(III) chloride. The paper states that this compound can be made by reacting $\mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, an excess of ethylenediamine, $\mathrm{O}_{2}$ from the air (which acts as an oxidizing agent), water, and concentrated hydrochloric acid. At the end of the reaction, you filter off the solution and are left with a green, crystalline product. (a) What experiment(s) could you perform to confirm that you have prepared
$\left[\mathrm{CoCl}_{2}(\mathrm{en})_{2}\right] \mathrm{Cl}$ and not $\left[\mathrm{Co}(\mathrm{en})_{3}\right] \mathrm{Cl}_{3}$ ? (b) How could you verify that cobalt was present as $\mathrm{Co}^{3+}$ and determine the spin state of the cobalt complex in your product? (c) How many geometric isomers exist for $\left[\mathrm{CoCl}_{2}(\mathrm{en})_{2}\right] \mathrm{Cl}$ ? How could you determine if your product contains a single geometric isomer or a mixture of geometric isomers? (d) If the product does contain a single geometric isomer how would you determine which one was present? (Hint: You may find the information in Table 23.3 helpful.)

## THE CHEMISTRY OF LIFE: ORGANIC AND BIOLOGICAL CHEMISTRY

## We are all familiar with how chemical

substances can influence our health and behavior. Aspirin, also known as acetylsalicylic acid, relieves aches and pains. The caffeine that is in coffee and tea, and the ethanol that is in wine and beer, are well-known molecules that at the proper doses give us pleasure. Spices ontain a host of molecules such as capsaicin (in chili peppers) and vanillin (in the vanilla bean). Other plant-derived compounds include quinine, for treating malaria, and taxol, for treating many cancers.

Understanding how these molecules exert their effects and developing new molecules that can target disease and pain are enormous components of the modern chemical enterprise. This chapter is about the molecules, composed mainly of carbon, hydrogen, oxygen, and nitrogen, that bridge chemistry and biology.

More than 16 million carbon-containing compounds are known. Chemists make thousands of new compounds every year, about $90 \%$ of which contain carbon. The study of compounds whose molecules contain carbon constitutes the branch of chemistry known as organic chemistry. This term arose from the eighteenth-century belief that organic compounds could be formed only by living (that is, organic)

4 SPICE MARKET. The many colors and tastes of these chili peppers come from the organic compounds they contain.
24.1 General Characteristics of Organic Molecules Review the structures and properties of organic compounds.
24.2 Introduction to Hydrocarbons Consider hydrocarbons, compounds containing only C and H , including the hydrocarbons called alkanes, which contain only single C-C bonds. We also look at isomers, compounds with identical compositions but different molecular structures.

## WHAT'S AHEAD

Alkenes, Alkynes, and Aromatic Hydrocarbons Explore hydrocarbons with one or more $\mathrm{C}=\mathrm{C}$ bonds, called alkenes, and those with one or more $\mathrm{C} \equiv \mathrm{C}$ bonds, called alkynes. Aromatic hydrocarbons have at least one planar ring with delocalized $\pi$ electrons.

Organic Functional Groups
Recognize that a central organizing principle of organic chemistry is the functional group, a group of atoms at which most of the compound's chemical reactions occur.

Chirality in Organic Chemistry Learn that compounds with nonsuperimposable mirror images are chiral and that chirality plays important roles in organic and biological chemistry.

Introduction to Biochemistry Learn about the chemistry of living organisms, known as biochemistry, biological chemistry, or chemical biology. Important classes of compounds that occur in living systems are proteins, carbohydrates, lipids, and nucleic acids.

Proteins See that proteins are polymers of amino acids linked with amide (also called peptide) bonds. Proteins are used by organisms for structural support, as molecular transporters and as catalysts for biochemical reactions.

Carbohydrates Observe that carbohydrates are sugars and polymers of sugars used primarily as fuel by organisms (glucose) or as structural support in plants (cellulose).

Lipids Understand that lipids are a large class of molecules used primarily for energy storage in organisms.

Nucleic Acids Learn that nucleic acids are polymers of nucleotides that contain an organism's genetic information. Deoxyribonucleic acid (DNA) and ribonucleic acid (RNA) are polymers composed of nucleotides.
systems. This idea was disproved by the German chemist Friedrich Wöhler (1800-1882). In 1828 , he synthesized urea $\left(\mathrm{H}_{2} \mathrm{NCONH}_{2}\right)$, an organic substance found in the urine of mammals, by heating ammonium cyanate ( $\mathrm{NH}_{4} \mathrm{OCN}$ ), an inorganic (nonliving) substance. In chemistry, "organic compounds" are considered to be those that contain carbon and hydrogen. Therefore, compounds such as ammonia or carbon dioxide are generally considered "inorganic."

The study of the chemistry of living species is called biological chemistry, chemical biology, or biochemistry. In this chapter, we present some of the elementary aspects of both organic chemistry and biochemistry.

## 24.1 | General Characteristics of Organic Molecules

What is it about carbon that leads to the tremendous diversity in its compounds and allows it to play such crucial roles in biology and society? Let's consider some general features of organic molecules and, as we do, review principles we learned in earlier chapters.

## The Structures of Organic Molecules

Because carbon has four valence electrons ( $[\mathrm{He}] 2 s^{2} 2 p^{2}$ ), it forms four bonds in virtually all its compounds. When all four bonds are single bonds, the electron pairs are disposed in a tetrahedral arrangement. 000 (Section 9.2) In the hybridization model, the carbon $2 s$ and $2 p$ orbitals are then $s p^{3}$ hybridized. 000 (Section 9.5) When there is one double bond, the arrangement is trigonal planar ( $s p^{2}$ hybridization). With a triple bond, it is linear ( $s p$ hybridization). Examples are shown in Figure 24.1.

Almost every organic molecule contains C-H bonds. Because the valence shell of H can hold only two electrons, hydrogen forms only one covalent bond. As a result,

© Figure 24.1 Carbon geometries. The three common geometries around carbon are tetrahedral as in methane $\left(\mathrm{CH}_{4}\right)$, trigonal planar as in formaldehyde $\left(\mathrm{CH}_{2} \mathrm{O}\right)$, and linear as in acetonitrile $\left(\mathrm{CH}_{3} \mathrm{CN}\right)$. Notice that in all cases each carbon atom forms four bonds.
hydrogen atoms are always located on the surface of organic molecules whereas the $\mathrm{C}-\mathrm{C}$ bonds form the backbone, or skeleton, of the molecule, as in the propane molecule:

## The Stability of Organic Compounds

Carbon forms strong bonds with a variety of elements, especially $\mathrm{H}, \mathrm{O}, \mathrm{N}$, and the halogens. 000 (Sections 5.8 and 8.8) Carbon also has an exceptional ability to bond to itself, forming a variety of molecules made up of chains or rings of carbon atoms. Most reactions with low or moderate activation energy 000 (Section 14.5) begin when a region of high electron density in one molecule encounters a region of low electron density in another molecule. The regions of high electron density may be due to the presence of a multiple bond or to the more electronegative atom in a polar bond. Because of their strength (the $\mathrm{C}-\mathrm{C}$ single bond enthalpy is $348 \mathrm{~kJ} / \mathrm{mol}$, the $\mathrm{C}-\mathrm{H}$ bond enthalpy is $413 \mathrm{~kJ} / \mathrm{mol}$ coo Tables 5.4 and 8.3) and lack of polarity, both $\mathrm{C}-\mathrm{C}$ single bonds and $\mathrm{C}-\mathrm{H}$ bonds are relatively unreactive. To better understand the implications of these facts, consider ethanol:

The differences in the electronegativity values of $\mathrm{C}(2.5)$ and O (3.5) and of O and H (2.1) indicate that the $\mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{H}$ bonds are quite polar. Thus, many reactions of ethanol involve these bonds while the hydrocarbon portion of the molecule remains intact. A group of atoms such as the $\mathrm{C}-\mathrm{O}-\mathrm{H}$ group, which determines how an organic molecule reacts (in other words, how the molecule functions), is called a functional group. The functional group is the center of reactivity in an organic molecule.

## Give It Some Thought

Which bond is most likely to be the location of a chemical reaction: $\mathrm{C}=\mathrm{O}, \mathrm{C}-\mathrm{C}$, or $\mathrm{C}-\mathrm{H}$ ?

## Solubility and Acid-Base Properties of Organic Compounds

In most organic substances, the most prevalent bonds are carbon-carbon and carbonhydrogen, which are not polar. For this reason, the overall polarity of organic molecules is often low, which makes them generally soluble in nonpolar solvents and not very soluble in water. 000 (Section 13.3) Organic molecules that are soluble in polar solvents are those that have polar groups on the molecule surface, such as glucose and ascorbic acid (Figure 24.2). Organic molecules that have a long, nonpolar part bonded to a polar, ionic part, such as the stearate ion shown in Figure 24.2, function as surfactants and are used in soaps and detergents. 000 (Section 13.6) The nonpolar part of the molecule extends into a nonpolar medium such as grease or oil, and the polar part extends into a polar medium such as water.

Many organic substances contain acidic or basic groups. The most important acidic organic substances are the carboxylic acids, which bear the functional group- COOH . $\infty \quad$ (Sections 4.3 and 16.10) The most important basic organic substances are amines, which bear the $-\mathrm{NH}_{2},-\mathrm{NHR}$, or $-\mathrm{NR}_{2}$ groups, where R is an organic group made up of carbon and hydrogen atoms. 000 (Section 16.7)

## Go Figure

How would replacing OH groups on ascorbic acid with $\mathrm{CH}_{3}$ groups affect the substance's solubility in (a) polar solvents and (b) nonpolar solvents?

Glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$

Ascorbic acid $\left(\mathrm{HC}_{6} \mathrm{H}_{7} \mathrm{O}_{6}\right)$

Stearate $\left(\mathrm{C}_{17} \mathrm{H}_{35} \mathrm{COO}^{-}\right)$
Figure 24.2 Organic molecules that are soluble in polar solvents.

### 24.2 Introduction to Hydrocarbons

Because carbon compounds are so numerous, it is convenient to organize them into families that have structural similarities. The simplest class of organic compounds is the hydrocarbons, compounds composed of only carbon and hydrogen. The key structural feature of hydrocarbons (and of most other organic substances) is the presence of stable carbon-carbon bonds. Carbon is the only element capable of forming stable, extended chains of atoms bonded through single, double, or triple bonds.

Hydrocarbons can be divided into four types, depending on the kinds of carboncarbon bonds in their molecules.

- Alkanes contain only single $\mathrm{C}-\mathrm{C}$ bonds.
- Alkenes, also known as olefins, contain at least one $\mathrm{C}=\mathrm{C}$ double bond.
- Alkynes contain at least one $\mathrm{C} \equiv \mathrm{C}$ triple bond.
- Aromatic hydrocarbons have carbon atoms that are connected in a planar ring structure, joined by both $\sigma$ and delocalized $\pi$ bonds between carbon atoms. coo (Section 8.6)

An example of each type is shown in Table 24.1.
Each type of hydrocarbon exhibits different chemical behaviors, as we will see shortly. The physical properties of all four types, however, are similar in many ways. Because hydrocarbon molecules are relatively nonpolar, they are almost completely insoluble in water but dissolve readily in nonpolar solvents. Their melting points and boiling points are determined by dispersion forces. 000 (Section 11.2) As a result, hydrocarbons of very low molecular weight, such as $\mathrm{C}_{2} \mathrm{H}_{6}\left(\mathrm{bp}=-89^{\circ} \mathrm{C}\right)$, are gases at room temperature; those of moderate molecular weight, such as $\mathrm{C}_{6} \mathrm{H}_{14}\left(\mathrm{bp}=69^{\circ} \mathrm{C}\right)$, are liquids; and those of high molecular weight, such as $\mathrm{C}_{22} \mathrm{H}_{46}\left(\mathrm{mp}=44^{\circ} \mathrm{C}\right)$, are solids.

Table 24.2 lists the ten simplest alkanes. Many of these substances are familiar because they are used so widely. Methane is a major component of natural gas. Ethane is also a component of natural gas and is a feedstock for making polyethylene. 000 (Section 12.8) Propane is the major component of bottled gas used for home heating and

cooking in areas where natural gas is not available. Butane is used in disposable lighters and in fuel canisters for gas camping stoves and lanterns. Alkanes with 5 to 12 carbon atoms per molecule are used to make gasoline. Notice that each succeeding compound in Table 24.2 has an additional $\mathrm{CH}_{2}$ unit.

The formulas for the alkanes given in Table 24.2 are written in a notation called condensed structural formulas. This notation reveals the way in which atoms are bonded to one another but does not require drawing in all the bonds. For example, the structural formula and the condensed structural formulas for butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ are

## Give It Some Thought

How many $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}=\mathrm{C}$ bonds are formed by the carbon atom of ethene?

## Structures of Alkanes

According to the VSEPR model, the molecular geometry about each carbon atom in an alkane is tetrahedral. 000 (Section 9.2) The bonding may be described as involving $s p^{3}$-hybridized orbitals on the carbon, as pictured in Figure 24.3 for methane. 000 (Section 9.5)

Rotation about a carbon-carbon single bond is relatively easy and occurs rapidly at room temperature. To visualize such rotation, imagine grasping either methyl group of the propane molecule in Figure 24.4 and rotating the group relative to the rest of the molecule. Because motion of this sort occurs rapidly in alkanes, a long-chain alkane molecule is constantly undergoing motions that cause it to change its overall shape.

## Structural Isomers

The alkanes in Table 24.2 are called straight-chain or linear hydrocarbons because all the carbon atoms are joined in a continuous chain. Alkanes consisting of four or more carbon atoms can also form branched chains, and when they do, they are called branchedchain hydrocarbons. (The branches in organic molecules are often called side chains.) Table 24.3, for example, shows all the straight-chain and branched-chain alkanes containing four and five carbon atoms.

Figure 24.3 Bonds about carbon in methane. This tetrahedral molecular geometry is found around all carbons in alkanes.

before rotation

after rotation
Figure 24.4 Rotation about a C-C bond occurs easily and rapidly in all alkanes.

TABLE 24.3 Isomers of $\mathrm{C}_{4} \mathrm{H}_{10}$ and $\mathrm{C}_{5} \mathrm{H}_{12}$

| Systematic Name (Common Name) | Structural Formula | Condensed Structural Formula | Space-Filling <br> Model | Melting <br> Point ( ${ }^{\circ} \mathrm{C}$ ) | Boiling <br> Point ( ${ }^{\circ} \mathrm{C}$ ) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Butane ( $n$-butane) |  | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |  | -138 | -0.5 |
| 2-Methylpropane (isobutane) |  |  |  | -159 | -12 |

Compounds that have the same molecular formula but different bonding arrangements (and hence different structures) are called structural isomers. 000 (Section 2.9) Thus, $\mathrm{C}_{4} \mathrm{H}_{10}$ has two structural isomers and $\mathrm{C}_{5} \mathrm{H}_{12}$ has three. The structural isomers of a given alkane differ slightly from one another in physical properties, as the melting and boiling points in Table 24.3 indicate.

The number of possible structural isomers increases rapidly with the number of carbon atoms in the alkane. There are 18 isomers with the molecular formula $\mathrm{C}_{8} \mathrm{H}_{18}$, for example, and 75 with the molecular formula $\mathrm{C}_{10} \mathrm{H}_{22}$.

## Give It Some Thought

What evidence can you cite to support the fact that although isomers have the same molecular formula they are in fact different compounds?

## Nomenclature of Alkanes

In the first column of Table 24.3, the names in parentheses are called the common names. The common name of the isomer with no branches begins with the letter $n$
(indicating the "normal" structure). When one $\mathrm{CH}_{3}$ group branches off the major chain, the common name of the isomer begins with iso-, and when two $\mathrm{CH}_{3}$ groups branch off, the common name begins with neo-. As the number of isomers grows, however, it becomes impossible to find a suitable prefix to denote each isomer by a common name. The need for a systematic means of naming organic compounds was recognized as early as 1892 , when an organization called the International Union of Chemistry met in Geneva to formulate rules for naming organic substances. Since that time, the task of updating the rules for naming compounds has fallen to the International Union of Pure and Applied Chemistry (IUPAC). Chemists everywhere, regardless of their nationality, subscribe to a common system for naming compounds.

The IUPAC names for the isomers of butane and pentane are the ones given first in Table 24.3. These systematic names, as well as those of other organic compounds, have three parts:

The following steps summarize the procedures used to name alkanes, which all have names ending with -ane. We use a similar approach to write the names of other organic compounds.

## How to Name Alkanes

1. Find the longest continuous chain of carbon atoms, and use the name of this chain (given in Table 24.2) as the base name. Be careful in this step because the longest chain may not be written in a straight line, as in the following structure:

2-Methylhexane

Because the longest continuous chain contains six C atoms, this isomer is named as a substituted hexane. Groups attached to the main chain are called substituents because they are substituted in place of an H atom on the main chain. In this molecule, the $\mathrm{CH}_{3}$ group not enclosed by the blue outline is the only substituent in the molecule.
2. Number the carbon atoms in the longest chain, beginning with the end nearest a substituent. In our example, we number the C atoms beginning at the upper right because that places the $\mathrm{CH}_{3}$ substituent on C 2 of the chain. (If we had numbered from the lower right, the $\mathrm{CH}_{3}$ would be on C 5 .) The chain is numbered from the end that gives the lower number to the substituent position.
3. Name each substituent. A substituent formed by removing an $H$ atom from an alkane is called an alkyl group. Alkyl groups are named by replacing the -ane ending of the alkane name with $-y l$. The methyl group $\left(\mathrm{CH}_{3}\right)$, for example, is derived from methane $\left(\mathrm{CH}_{4}\right)$ and the ethyl group $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)$ is derived from ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$. Table 24.4 lists six common alkyl groups.
4. Begin the name with the number or numbers of the carbon or carbons to which each substituent is bonded. For our compound, the name 2-methylhexane indicates the presence of a methyl group on C 2 of a hexane (six-carbon) chain.

TABLE 24.4 Condensed Structural Formulas and Common Names for Several Alkyl Groups

| Group | Name |
| :---: | :---: |
| $\mathrm{CH}_{3}$ - | Methyl |
| $\mathrm{CH}_{3} \mathrm{CH}_{2}-$ | Ethyl |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2}$ - | Propyl |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}-$ | Butyl |
|  | Isopropyl |
|  | tert-Butyl |

5. When two or more substituents are present, list them in alphabetical order. The presence of two or more of the same substituent is indicated by the prefixes di- (two), tri- (three), tetra- (four), penta- (five), and so forth. The prefixes are ignored in determining the alphabetical order of the substituents:

3-Ethyl-2,4,5-trimethylheptane

## Sample Exercise 24.1

## Naming Alkanes

Give the systematic name for the following alkane:

## SOLUTION

Analyze We are given the condensed structural formula of an alkane and asked to give its name.
Plan Because the hydrocarbon is an alkane, its name ends in -ane. The name of the parent hydrocarbon is based on the longest continuous chain of carbon atoms. Branches are alkyl groups, named after the number of C atoms in the branch and located by counting $C$ atoms along the longest continuous chain.
Solve The longest continuous chain of C atoms extends from the upper left $\mathrm{CH}_{3}$ group to the lower left $\mathrm{CH}_{3}$ group and is seven C atoms long:

The parent compound is thus heptane. There are two methyl groups branching off the main chain. Hence, this compound is a dimethylheptane. To specify the location of the two methyl groups, we must number the C atoms from the end that gives the lower two numbers to the carbons bearing side chains. This means that we should start numbering at the upper left carbon. There is a methyl group on C3 and one on C4. The compound is thus 3,4-dimethylheptane.

Practice Exercise 1
What is the systematic name of this compound?

(a) 3-ethyl-3-methylbutane
(b) 2-ethyl-2-methylbutane
(c) 3,3-dimethylpentane
(d) isoheptane
(e) 1,2-dimethylneopentane

Practice Exercise 2
Name the following alkane:

## Sample Exercise 24.2

## Writing Condensed Structural Formulas

Write the condensed structural formula for 3-ethyl-2-methylpentane.

## SOLUTION

Analyze We are given the systematic name for a hydrocarbon and asked to write its condensed structural formula.

Plan Because the name ends in -ane, the compound is an alkane, meaning that all the carbon-carbon bonds are single bonds. The parent hydrocarbon is pentane, indicating five C atoms
(Table 24.2). There are two alkyl groups specified, an ethyl group (two carbon atoms, $\mathrm{C}_{2} \mathrm{H}_{5}$ ) and a methyl group (one carbon atom, $\mathrm{CH}_{3}$ ). Counting from left to right along the five-carbon chain, the name tells us that the ethyl group is attached to C3 and the methyl group is attached to C2.

Solve We begin by writing five C atoms attached by single bonds. These represent the backbone of the parent pentane chain:

$$
\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{C}
$$

We next place a methyl group on the second $C$ and an ethyl group on the third C of the chain. We then add hydrogens to all the other C atoms to make four bonds to each carbon:

The formula can be written more concisely as

$$
\mathrm{CH}_{3} \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{CH}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right) \mathrm{CH}_{2} \mathrm{CH}_{3}
$$

where the branching alkyl groups are indicated in parentheses.

Practice Exercise 1
How many hydrogen atoms are in 2,2-dimethylhexane?
(a) 6
(b) 8
(c) 16
(d) 18
(e) 20

Practice Exercise 2
Write the condensed structural formula for 2,3-dimethylhexane.

## Cycloalkanes

Alkanes that form rings, or cycles, are called cycloalkanes. As Figure 24.5 illustrates, cycloalkane structures are sometimes drawn as line structures, which are polygons in which each corner represents a $\mathrm{CH}_{2}$ group. This method of representation is similar to that used for benzene rings. $\infty$ (Section 8.6) (Remember from our benzene discussion that in aromatic structures each vertex represents a CH group, not a $\mathrm{CH}_{2}$ group.)

Carbon rings containing fewer than five carbon atoms are strained because the $\mathrm{C}-\mathrm{C}-\mathrm{C}$ bond angles must be less than the $109.5^{\circ}$ tetrahedral angle. The amount of strain increases as the rings get smaller. In cyclopropane, which has the shape of an equilateral triangle, the angle is only $60^{\circ}$; this molecule is therefore much more reactive than propane, its straight-chain analog.

## Go Figure The general formula for straight-chain alkanes is $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$. What is the general formula for cycloalkanes?

Cyclohexane
Each vertex represents one $\mathrm{CH}_{2}$ group

Cyclopentane
Five vertices $=$ five $\mathrm{CH}_{2}$ groups

Cyclopropane
Three vertices $=$ three $\mathrm{CH}_{2}$ groups

A Figure 24.5 Condensed structural formulas and line structures for three cycloalkanes.

Give It Some Thought
Are the $\mathrm{C}-\mathrm{C}$ bonds cyclopropane weaker than those in cyclohexane?

## Reactions of Alkanes

Because they contain only $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bonds, most alkanes are relatively unreactive. At room temperature, for example, they do not react with acids, bases, or strong
oxidizing agents. Their low chemical reactivity, as noted in Section 24.1, is due primarily to the strength and lack of polarity of $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bonds.

Alkanes are not completely inert, however. One of their most commercially important reactions is combustion in air, which is the basis of their use as fuels. 000 (Section 3.2) For example, the complete combustion of ethane proceeds according to this highly exothermic reaction:

$$
2 \mathrm{C}_{2} \mathrm{H}_{6}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H^{\circ}=-2855 \mathrm{~kJ}
$$

## CHEMISTRY PUT TO WORK Gasoline

Petroleum, or crude oil, is a mixture of hydrocarbons plus smaller quantities of other organic compounds containing nitrogen, oxygen, or sulfur. The tremendous demand for petroleum to meet the world's energy needs has led to the tapping of oil wells in such forbidding places as the North Sea and northern Alaska.

The usual first step in the refining, or processing, of petroleum is to separate it into fractions on the basis of boiling point (Table 24.5). Because gasoline is the most commercially important of these fractions, various processes are used to maximize its yield.

Gasoline is a mixture of volatile alkanes and aromatic hydrocarbons. In a traditional automobile engine, a mixture of air and gasoline vapor is compressed by a piston and then ignited by a spark plug. The burning of the gasoline should create a strong, smooth expansion of gas, forcing the piston outward and imparting force along the driveshaft of the engine. If the gas burns too rapidly, the piston receives a single hard slam rather than a strong, smooth push. The result is a "knocking" or "pinging" sound and a reduction in the efficiency with which energy produced by the combustion is converted to work.

The octane number of a gasoline is a measure of its resistance to knocking. Gasolines with high octane numbers burn more smoothly and are thus more effective fuels (Figure 24.6). Branched alkanes and aromatic hydrocarbons have higher octane numbers than straight-chain alkanes. The octane number of gasoline is obtained by comparing its knocking characteristics with those of isooctane (2,2,4-trimethylpentane) and heptane. Isooctane is assigned an octane number of 100 , and heptane is assigned 0 . Gasoline with the same knocking characteristics as a mixture of $91 \%$ isooctane and $9 \%$ heptane, for instance, is rated as 91 octane.

| TABLE 24.5 | Hydrocarbon Fractions from Petroleum |  |  |
| :--- | :--- | :--- | :--- |
| Fraction | Size Range of <br> Molecules | Boiling-Point <br> Range $\left({ }^{\circ} \mathrm{C}\right)$ | Uses |
| Gas | $\mathrm{C}_{1}$ to $\mathrm{C}_{5}$ | -160 to 30 | Gaseous fuel, <br> production of $\mathrm{H}_{2}$ |
| Straight-run <br> gasoline | $\mathrm{C}_{5}$ to $\mathrm{C}_{12}$ | 30 to 200 | Motor fuel |
| Kerosene, <br> fuel oil | $\mathrm{C}_{12}$ to $\mathrm{C}_{18}$ | 180 to 400 | Diesel fuel, <br> furnace fuel, <br> cracking |
| Lubricants | $\mathrm{C}_{16}$ and up | 350 and up | Lubricants |
| Paraffins | $\mathrm{C}_{20}$ and up | Low-melting <br> solids | Candles, <br> matches |
| Asphalt | $\mathrm{C}_{36}$ and up | Gummy <br> residues | Surfacing roads |

The gasoline obtained by fractionating petroleum (called straight-run gasoline) contains mainly straight-chain hydrocarbons and has an octane number around 50. To increase its octane rating, it is subjected to a process called reforming, which converts the straightchain alkanes into branched-chain ones.

Cracking is used to produce aromatic hydrocarbons and to convert some of the less volatile fractions of petroleum into compounds suitable for use as automobile fuel. In cracking, the hydrocarbons are mixed with a catalyst and heated to $400-500^{\circ} \mathrm{C}$. The catalysts used are either clay minerals or synthetic $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{SiO}_{2}$ mixtures. In addition to forming molecules more suitable for gasoline, cracking results in the formation of such low-molecular-weight hydrocarbons as ethylene and propene. These substances are used in a variety of reactions to form plastics and other chemicals.

Adding compounds called either antiknock agents or octane enhancers increases the octane rating of gasoline. Until the mid1970s, the principal antiknock agent was tetraethyl lead $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{~Pb}$. It is no longer used, however, because of the environmental hazards of lead and because it poisons catalytic converters. 000 (Section 14.7, "Catalytic Converters") Aromatic compounds such as toluene $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{3}\right)$ and oxygenated hydrocarbons such as ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$ are now generally used as antiknock agents.

### 24.3 Alkenes, Alkynes, and Aromatic Hydrocarbons

Because alkanes have only single bonds, they contain the largest possible number of hydrogen atoms per carbon atom. As a result, they are called saturated hydrocarbons. Alkenes, alkynes, and aromatic hydrocarbons contain multiple carbon-carbon bonds (double, triple, or delocalized $\pi$ bonds). As a result, they contain less hydrogen than an alkane with the same number of carbon atoms. Collectively, they are called unsaturated hydrocarbons. On the whole, unsaturated molecules are more reactive than saturated ones.

## Alkenes

Alkenes are unsaturated hydrocarbons that contain at least one $\mathrm{C}=\mathrm{C}$ bond. The simplest alkene is $\mathrm{CH}_{2}=\mathrm{CH}_{2}$, called ethene (IUPAC) or ethylene (common name), which plays important roles as a plant hormone in seed germination and fruit ripening. The next member of the series is $\mathrm{CH}_{3}-\mathrm{CH}=\mathrm{CH}_{2}$, called propene or propylene. Alkenes with four or more carbon atoms have several isomers. For example, the alkene $\mathrm{C}_{4} \mathrm{H}_{8}$ has the four structural isomers shown in Figure 24.7. Notice both their structures and their names.

The names of alkenes are based on the longest continuous chain of carbon atoms that contains the double bond. The chain is named by changing the ending of the name of the corresponding alkane from -ane to -ene. The compound on the left in Figure 24.7, for example, has a double bond as part of a three-carbon chain; thus, the parent alkene is propene.

The location of the double bond along an alkene chain is indicated by a prefix number that designates the double-bond carbon atom that is nearest an end of the chain. The chain is always numbered from the end that brings us to the double bond sooner and hence gives the smallest-numbered prefix. In propene, the only possible location for the double bond is between the first and second carbons; thus, a prefix indicating its location is unnecessary. For butene (Figure 24.7), there are two possible positions for the double bond, either after the first carbon (1-butene) or after the second carbon (2-butene).

## Give It Some Thought

How many distinct locations are there for a double bond in a five-carbon linear chain?

## Go Figure How many isomers are there for propene, $\mathrm{C}_{3} \mathrm{H}_{6}$ ?

Figure 24.7 The alkene $\mathrm{C}_{4} \mathrm{H}_{8}$ has four structural isomers.

Figure 24.8 Cis and trans isomers of alkenes. Geometric isomers of alkenes exist because rotation about a carbon-carbon double bond requires too much energy to occur at ordinary temperatures.

If a substance contains two or more double bonds, the location of each is indicated by a numerical prefix, and the ending of the name is altered to identify the number of double bonds: diene (two), triene (three), and so forth. For example, $\mathrm{CH}_{2}=\mathrm{CH}-\mathrm{CH}_{2}-\mathrm{CH}=\mathrm{CH}_{2}$ is 1,4-pentadiene.

The two isomers on the right in Figure 24.7 differ in the relative locations of their methyl groups. These two compounds are geometric isomers, compounds that have the same molecular formula and the same groups bonded to one another but differ in the spatial arrangement of these groups. $\infty 0$ (Section 23.4) In the cis isomer the two methyl groups are on the same side of the double bond, whereas in the trans isomer they are on opposite sides. Geometric isomers possess distinct physical properties and can differ significantly from each other in their chemical behavior.

Geometric isomerism in alkenes arises because, unlike the $\mathrm{C}-\mathrm{C}$ bond, the $\mathrm{C}=\mathrm{C}$ bond resists twisting. Recall from Section 9.6 that the double bond between two carbon atoms consists of a $\sigma$ and a $\pi$ bond. Figure 24.8 shows a cis alkene. The carbon-carbon bond axis and the bonds to the hydrogen atoms and to the alkyl groups (designated R ) are all in a plane, and the $p$ orbitals that form the $\pi$ bond are perpendicular to that plane. As Figure 24.8 shows, rotation around the carbon-carbon double bond requires the $\pi$ bond to be broken, a process that requires considerable energy (about $250 \mathrm{~kJ} / \mathrm{mol}$ ). Because rotation does not occur easily around the carbon-carbon bond, the cis and trans isomers of an alkene cannot readily interconvert and, therefore, exist as distinct compounds.

## Sample Exercise 24.3

## Drawing Isomers

Draw all the structural and geometric isomers of pentene, $\mathrm{C}_{5} \mathrm{H}_{10}$, that have an unbranched hydrocarbon chain.

## SOLUTION

Analyze We are asked to draw all the isomers (both structural and geometric) for an alkene with a five-carbon chain.
Plan Because the compound is named pentene and not pentadiene or pentatriene, we know that the five-carbon chain contains
only one carbon-carbon double bond. Thus, we begin by placing the double bond in various locations along the chain, remembering that the chain can be numbered from either end. After finding the different unique locations for the double bond, we consider whether the molecule can have cis and trans isomers.

## Solve

There can be a double bond after either the first carbon (1-pentene) or second carbon (2-pentene). These are the only two possibilities because the chain can be numbered from either end. Thus, what we might erroneously call 3-pentene is actually 2 -pentene, as seen by numbering the carbon chain from the other end:

renumbered as renumbered as

Because the first C atom in 1-pentene is bonded to two H atoms, there are no cistrans isomers. There are cis and trans isomers for 2-pentene, however. Thus, the three isomers for pentene are:
(You should convince yourself that cis-3pentene is identical to cis-2-pentene and that trans-3-pentene is identical to trans-2-pentene. However, cis-2-pentene and trans-2-pentene are the correct names because they have smaller numbered prefixes.)

1-Pentene

trans-2-Pentene

cis-2-Pentene

## Practice Exercise 1

Which compound does not exist?
(a) 1,2,3,4,5,6,7-octaheptaene (b) cis-2-butane
(c) trans-3-hexene (d) 1-propene $\quad$ (e) cis-4-decene
$\qquad$

## Alkynes

Alkynes are unsaturated hydrocarbons containing one or more $\mathrm{C} \equiv \mathrm{C}$ bonds. The simplest alkyne is acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right.$, systematic name ethyne), a highly reactive molecule. When acetylene is burned in a stream of oxygen in an oxyacetylene torch, the flame reaches about 3200 K . Because alkynes in general are highly reactive, they are not as widely distributed in nature as alkenes; alkynes, however, are important intermediates in many industrial processes.

Alkynes are named by identifying the longest continuous chain containing the triple bond and modifying the ending of the name of the corresponding alkane from -ane to -yne, as shown in Sample Exercise 24.4.

## Sample Exercise 24.4

Naming Unsaturated Hydrocarbons
Name the following compounds:
(b)

## Practice Exercise 2

How many straight-chain isomers are there of hexene, $\mathrm{C}_{6} \mathrm{H}_{12}$ ?
(a)

## SOLUTION

Analyze We are given the condensed structural formulas for an alkene and an alkyne and asked to name the compounds.

Plan In each case, the name is based on the number of carbon atoms in the longest continuous carbon chain that contains the multiple bond. In the alkene, care must be taken to indicate whether cistrans isomerism is possible and, if so, which isomer is given.

## Solve

(a) The longest continuous chain of carbons that contains the double bond is seven carbons long, so the parent hydrocarbon is heptene. Because the double bond begins at carbon 2 (numbering from the end closer to the double bond), we have 2-heptene. With a methyl group at carbon atom 4, we have 4-methyl-2-heptene. The geometrical configuration at the double bond is cis (that is, the alkyl groups are bonded to the double bond on the same side). Thus, the full name is 4-methyl-cis-2-heptene. the

(b) The longest continuous chain containing the triple bond has six carbons, so this compound is a derivative of hexyne. The triple bond comes after the first carbon (numbering from the right), making it 1-hexyne. The branch from the hexyne chain contains three carbon atoms, making it a propyl group. Because this substituent is located on C3 of the hexyne chain, the molecule is 3-propyl-1-hexyne.

Practice Exercise 1
If a compound has two carbon-carbon triple bonds and one carbon-carbon double bond, what class of compound is it?
(a) an eneyne
(b) a dieneyne
(c) a trieneyne
(d) an enediyne
(e) an enetriyne

Practice Exercise 2
Draw the condensed structural formula for 4-methyl-2-pentyne.

## Addition Reactions of Alkenes and Alkynes

The presence of carbon-carbon double or triple bonds in hydrocarbons markedly increases their chemical reactivity. The most characteristic reactions of alkenes and alkynes are addition reactions, in which a reactant is added to the two atoms that form the multiple bond. A simple example is the addition of elemental bromine to ethylene to produce 1,2-dibromoethane:

The $\pi$ bond in ethylene is broken, and the electrons that formed the bond are used to form two $\sigma$ bonds to the two bromine atoms. The $\sigma$ bond between the carbon atoms is retained.

Addition of $\mathrm{H}_{2}$ to an alkene converts it to an alkane:

$$
\begin{equation*}
\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{3}+\mathrm{H}_{2} \xrightarrow{\mathrm{Ni}, 500^{\circ} \mathrm{C}} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3} \tag{24.2}
\end{equation*}
$$

The reaction between an alkene and $\mathrm{H}_{2}$, referred to as hydrogenation, does not occur readily at ordinary temperatures and pressures. One reason for the lack of reactivity of $\mathrm{H}_{2}$ toward alkenes is the stability of the $\mathrm{H}_{2}$ bond. To promote the reaction, the reaction temperature must be raised $\left(500^{\circ} \mathrm{C}\right)$, and a catalyst (such as Ni ) is used to assist in rupturing the $\mathrm{H}-\mathrm{H}$ bond. We write such conditions over the reaction arrow to indicate they must be present in order for the reaction to occur. The most widely used catalysts are finely divided metals on which $\mathrm{H}_{2}$ is adsorbed. 000 (Section 14.7)

Hydrogen halides and water can also add to the double bond of alkenes, as in these reactions of ethylene:

$$
\begin{gather*}
\mathrm{CH}_{2}=\mathrm{CH}_{2}+\mathrm{HBr} \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Br}  \tag{24.3}\\
\mathrm{CH}_{2}=\mathrm{CH}_{2}+\mathrm{H}_{2} \mathrm{O} \xrightarrow{\mathrm{H}_{2} \mathrm{SO}_{4}} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \tag{24.4}
\end{gather*}
$$

The addition of water is catalyzed by a strong acid, such as $\mathrm{H}_{2} \mathrm{SO}_{4}$.
The addition reactions of alkynes resemble those of alkenes, as shown in these examples:

2-Butyne trans-2,3-Dichloro-2-butene

## Sample Exercise 24.5

## Predicting the Product of an Addition Reaction

Write the condensed structural formula for the product of the hydrogenation of 3-methyl-1-pentene.

## SOLUTION

Analyze We are asked to predict the compound formed when a particular alkene undergoes hydrogenation (reaction with $\mathrm{H}_{2}$ ) and to write the condensed structural formula of the product.
Plan To determine the condensed structural formula of the product, we must first write the condensed structural formula or Lewis structure of the reactant. In the hydrogenation of the alkene, $\mathrm{H}_{2}$ adds to the double bond, producing an alkane.

Solve The name of the starting compound tells us that we have a chain of five C atoms with a double bond at one end (position 1) and a methyl group on C3:

Hydrogenation-the addition of two H atoms to the carbons of the double bond-leads to the following alkane:

Comment The longest chain in this alkane has five carbon atoms; the product is therefore 3-methylpentane.

Practice Exercise 1
What product is formed from the hydrogenation of
2-methylpropene? (a) propane, (b) butane, (c) 2-methylbutane,
(d) 2-methylpropane, (e) 2-methylpropyne.

## Practice Exercise 2

Addition of HCl to an alkene forms 2-chloropropane. What is the alkene?

## A CLOSER LOOK Mechanism of Addition Reactions

As the understanding of chemistry has grown, chemists have advanced from simply cataloging reactions that occur to explaining how they occur, by drawing the individual steps of a reaction based upon experimental and theoretical evidence. The sum of these steps is termed a reaction mechanism. 000 (Section 14.6)

The addition reaction between HBr and an alkene, for instance, is thought to proceed in two steps. In the first step, which is rate determining 000 (Section 14.6), HBr attacks the electron-rich double bond, transferring a proton to one of the double-bond carbons. In the reaction of 2-butene with HBr , for example, the first step is

The electron pair that formed the $\pi$ bond is used to form the new $\mathrm{C}-\mathrm{H}$ bond.

The second, faster step is addition of $\mathrm{Br}^{-}$to the positively charged carbon. The bromide ion donates a pair of electrons to the carbon, forming the $\mathrm{C}-\mathrm{Br}$ bond:

Because the rate-determining step involves both the alkene and the acid, the rate law for the reaction is second order, first order in the alkene and first order in HBr :

Rate $=-\frac{\Delta\left[\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{3}\right]}{\Delta t}=k\left[\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{3}\right][\mathrm{HBr}]$

The energy profile for the reaction is shown in Figure 24.9. The first energy maximum represents the transition state in the first step, and the second maximum represents the transition state in the second step. The energy minimum represents the energies of the intermediate species, $\mathrm{CH}_{3} \stackrel{+}{\mathrm{C}} \mathrm{H}-\mathrm{CH}_{2} \mathrm{CH}_{3}$ and $\mathrm{Br}^{-}$.

To show electron movement in reactions like these, chemists often use curved arrows pointing in the direction of electron flow. For the addition of HBr to 2-butene, for example, the shifts in electron positions are shown as

## Go Figure

Is the reaction in Figure 24.9 spontaneous or not, assuming the change in energy equals the change in $\Delta G$ ?

A Figure 24.9 Energy profile for addition of HBr to 2-butene. The two maxima tell you that this is a two-step mechanism.

## Aromatic Hydrocarbons

The simplest aromatic hydrocarbon, benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, is shown in Figure 24.10 along with some other aromatic hydrocarbons. Benzene is the most important aromatic hydrocarbon, and most of our discussion focuses on it. When the $\mathrm{C}_{6} \mathrm{H}_{5}$-group is a substituent in a compound, it is known (confusingly) as the phenyl group.

A Figure 24.10 Line formulas and common names of several aromatic compounds. The aromatic rings are represented by hexagons with a circle inscribed inside to denote delocalized $\pi$ bonds. Each vertex represents a carbon atom. Each carbon is bound to three other atoms-either three carbons, or two carbons and a hydrogen-so that each carbon has the requisite four bonds.

## Stabilization of $\pi$ Electrons by Delocalization

If you draw one Lewis structure for benzene, you draw a ring that contains three CC double bonds and three single CC bonds. $0 \infty$ (Section 8.6) You might therefore expect benzene to resemble the alkenes and to be highly reactive. Benzene and the other aromatic hydrocarbons, however, are much more stable than alkenes because the $\pi$ electrons are delocalized in the $\pi$ orbitals. ©oo (Section 9.6)

We can estimate the stabilization of the $\pi$ electrons in benzene by comparing the energy released upon forming cyclohexane by adding hydrogen to benzene, to cyclohexene (one double bond), and to 1,4-cyclohexadiene (two double bonds):

From the second and third reactions, it appears that the energy released upon hydrogenation of each double bond is roughly $118 \mathrm{~kJ} / \mathrm{mol}$ for each bond. Benzene contains the equivalent of three double bonds. We might expect, therefore, the energy released upon hydrogenation of benzene to be about 3 times -118 , or $-354 \mathrm{~kJ} / \mathrm{mol}$, if benzene behaved as though it were "cyclohexatriene," that is, if it behaved as though it had three isolated double bonds in a ring. Instead, the energy released is 146 kJ less than this, indicating that benzene is more stable than would be expected for three double bonds. The difference of $146 \mathrm{~kJ} / \mathrm{mol}$ between the expected heat of hydrogenation ( $-354 \mathrm{~kJ} / \mathrm{mol}$ ) and the observed heat of hydrogenation ( $-208 \mathrm{~kJ} / \mathrm{mol}$ ) is due to stabilization of the $\pi$ electrons through delocalization in the $\pi$ orbitals that extend around the ring. Chemists call this stabilization energy the resonance energy.

## Substitution Reactions of Aromatic Hydrocarbons

Although aromatic hydrocarbons are unsaturated, they do not readily undergo addition reactions. The delocalized $\pi$ bonding causes aromatic compounds to behave quite differently from alkenes and alkynes. Benzene, for example, does not add $\mathrm{Cl}_{2}$ or $\mathrm{Br}_{2}$ to its double bonds under ordinary conditions. In contrast, aromatic hydrocarbons undergo substitution reactions relatively easily. In a substitution reaction, one hydrogen atom of the molecule is removed and replaced (substituted) by another atom or group of atoms. When benzene is warmed in a mixture of nitric and
sulfuric acids, for example, one of the benzene hydrogens is replaced by the nitro group, $\mathrm{NO}_{2}$ :

Benzene
Nitrobenzene

More vigorous treatment results in substitution of a second nitro group into the molecule:

There are three isomers of benzene that contain two nitro groups-the 1,2- or orthoisomer, the 1,3- or meta-isomer, and the 1,4- or para-isomer of dinitrobenzene:

In the reaction of Equation 24.11, the principal product is the meta isomer.
Bromination of benzene, carried out with $\mathrm{FeBr}_{3}$ as a catalyst, is another substitution reaction:

Benzene
Bromobenzene

In a similar substitution reaction, called the Friedel-Crafts reaction, alkyl groups can be substituted onto an aromatic ring by reacting an alkyl halide with an aromatic compound in the presence of $\mathrm{AlCl}_{3}$ as a catalyst:

Benzene
Ethylbenzene

## Give It Some Thought

When the aromatic hydrocarbon naphthalene, shown in Figure 24.10, reacts with nitric and sulfuric acids, two compounds containing one nitro group are formed. Draw the structures of these two compounds.

Figure 24.12 Everyday alcohols. Many of the products we use every dayfrom rubbing alcohol to hair spray and antifreeze-are composed either entirely or mainly of alcohols.

## $24.4 \mid$ Organic Functional Groups

The $\mathrm{C}=\mathrm{C}$ double bonds of alkenes and $\mathrm{C} \equiv \mathrm{C}$ triple bonds of alkynes are just two of many functional groups in organic molecules. As noted earlier, these functional groups each undergo characteristic reactions, and the same is true of all other functional groups. Each kind of functional group often undergoes the same kinds of reactions in every molecule, regardless of the size and complexity of the molecule. Thus, the chemistry of an organic molecule is largely determined by the functional groups it contains. Table 24.6 lists the most common functional groups. Notice that, except for $\mathrm{C}=\mathrm{C}$ and $\mathrm{C} \equiv \mathrm{C}$, they all contain either $\mathrm{O}, \mathrm{N}$, or a halogen atom, X .

We can think of organic molecules as being composed of functional groups bonded to one or more alkyl groups. The alkyl groups, which are made of $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ single bonds, are the less reactive portions of the molecules. In describing general features of organic compounds, chemists often use the designation $R$ to represent any alkyl group: methyl, ethyl, propyl, and so on. Alkanes, for example, which contain no functional group, are represented as $\mathrm{R}-\mathrm{H}$. Alcohols, which contain the functional group -OH , are represented as $\mathrm{R}-\mathrm{OH}$. If two or more different alkyl groups are present in a molecule, we designate them $R, R^{\prime}, R^{\prime \prime}$, and so forth.

## Alcohols

Alcohols are compounds in which one or more hydrogens of a parent hydrocarbon have been replaced by the functional group - OH, called either the hydroxyl group or the alcohol group. Note in Figure 24.11 that the name for an alcohol ends in -ol. The simple alcohols are named by changing the last letter in the name of the corresponding alkane to -ol-for example, ethane becomes ethanol. Where necessary, the location of the OH group is designated by a numeric prefix that indicates the number of the carbon atom bearing the OH group. Figure 24.12 shows several commercial products that consist entirely or in large part of an alcohol.

The $\mathrm{O}-\mathrm{H}$ bond is polar, so alcohols are more soluble in polar solvents than are hydrocarbons. The - OH functional group can also participate in hydrogen bonding. As a result, the boiling points of alcohols are higher than those of their parent alkanes.

A Figure 24.11 Condensed structural formulas of six important alcohols. Common names are given in blue.

TABLE 24.6 Common Functional Groups

|  |  |  | Example |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Functional Group | Compound <br> Type | Suffix | Structural <br> Formula | Ball-and-stick <br> Model | Systematic Name (Common Name) |
|  | Alkene | -ene |  |  | Ethene (Ethylene) |
| - $\mathrm{C} \equiv \mathrm{C}-$ | Alkyne | -yne | $\mathrm{H}-\mathrm{C} \equiv \mathrm{C}-\mathrm{H}$ |  | Ethyne (Acetylene) |
|  | Alcohol | -ol |  |  | Methanol (Methyl alcohol) |
|  | Ether | ether |  |  | Methoxymethane (Dimethyl ether) |
|  $(X=\text { halogen })$ | Alkyl halide or haloalkane | -ide |  |  | Chloromethane (Methyl chloride) |
|  | Amine | -amine |  |  | Ethylamine |
|  | Aldehyde | -al |  |  | Ethanal (Acetaldehyde) |
|  | Ketone | -one |  |  | Propanone (Acetone) |
|  | Carboxylic acid | -oic acid |  |  | Ethanoic acid (Acetic acid) |
|  | Ester | -oate |  |  | Methyl ethanoate (Methyl acetate) |
|  | Amide | -amide |  |  | Ethanamide (Acetamide) |

The simplest alcohol, methanol (methyl alcohol), has many industrial uses and is produced on a large scale by heating carbon monoxide and hydrogen under pressure in the presence of a metal oxide catalyst:

$$
\begin{equation*}
\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \xrightarrow{200-300 \mathrm{~atm}} \mathrm{CH}_{3} \mathrm{OH}(g) \tag{24.14}
\end{equation*}
$$

Because methanol has a very high octane rating as an automobile fuel, it is used as a gasoline additive and as a fuel in its own right.

Ethanol (ethyl alcohol, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ ) is a product of the fermentation of carbohydrates such as sugars and starches. In the absence of air, yeast cells convert these carbohydrates into ethanol and $\mathrm{CO}_{2}$ :

$$
\begin{equation*}
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q) \xrightarrow{\text { yeast }} 2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(a q)+2 \mathrm{CO}_{2}(g) \tag{24.15}
\end{equation*}
$$

In the process, the yeast cells derive energy necessary for growth. This reaction is carried out under carefully controlled conditions to produce beer, wine, and other beverages in which ethanol (called just "alcohol" in everyday language) is the active ingredient.

The simplest polyhydroxyl alcohol (an alcohol containing more than one OH group) is 1,2-ethanediol (ethylene glycol, $\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ ), the major ingredient in automobile antifreeze. Another common polyhydroxyl alcohol is 1,2,3-propanetriol (glycerol, $\mathrm{HOCH}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OH}$ ), a viscous liquid that dissolves readily in water and is used in cosmetics as a skin softener and in foods and candies to keep them moist.

Phenol is the simplest compound with an OH group attached to an aromatic ring. One of the most striking effects of the aromatic group is the greatly increased acidity of the OH group. Phenol is about 1 million times more acidic in water than a nonaromatic alcohol. Even so, it is not a very strong acid ( $K_{a}=1.3 \times 10^{-10}$ ). Phenol is used industrially to make plastics and dyes, and as a topical anesthetic in throat sprays.

Cholesterol, shown in Figure 24.11, is a biochemically important alcohol. The OH group forms only a small component of this molecule, so cholesterol is only slightly soluble in water ( $2.6 \mathrm{~g} / \mathrm{L}$ of $\mathrm{H}_{2} \mathrm{O}$ ). Cholesterol is a normal and essential component of our bodies; when present in excessive amounts, however, it may precipitate from solution. It precipitates in the gallbladder to form crystalline lumps called gallstones. It may also precipitate against the walls of veins and arteries and thus contribute to high blood pressure and other cardiovascular problems.

## Ethers

Compounds in which two hydrocarbon groups are bonded to one oxygen are called ethers. Ethers can be formed from two molecules of alcohol by eliminating a molecule of water. The reaction is catalyzed by sulfuric acid, which takes up water to remove it from the system:

A reaction in which water is eliminated from two substances is called a condensation reaction. 000 (Sections 12.8 and 22.8)

Both diethyl ether and the cyclic ether tetrahydrofuran, shown below, are common solvents for organic reactions. Diethyl ether was formerly used as an anesthetic (known simply as "ether" in that context), but it had significant side effects.

Diethyl ether

Tetrahydrofuran (THF)

## Aldehydes and Ketones

Several of the functional groups listed in Table 24.6 contain the carbonyl group, $\mathrm{C}=\mathrm{O}$. This group, together with the atoms attached to its carbon, defines several important functional groups that we consider in this section.

In aldehydes, the carbonyl group has at least one hydrogen atom attached:

Ethanal
Methanal Formaldehyde Acetaldehyde

In ketones, the carbonyl group occurs at the interior of a carbon chain and is therefore flanked by carbon atoms:

The systematic names of aldehydes contain -al and ketone names contain -one. Notice that testosterone has both alcohol and ketone groups; the ketone functional group dominates the molecular properties. Therefore, testosterone is considered a ketone first and an alcohol second, and its name reflects its ketone properties.

Many compounds found in nature contain an aldehyde or ketone functional group. Vanilla and cinnamon flavorings are naturally occurring aldehydes. Two isomers of the ketone carvone impart the characteristic flavors of spearmint leaves and caraway seeds.

Ketones are less reactive than aldehydes and are used extensively as solvents. Acetone, the most widely used ketone, is completely miscible with water, yet it dissolves a wide range of organic substances.

## Carboxylic Acids and Esters

Carboxylic acids contain the carboxyl functional group, often written COOH. 000 (Section 16.10) These weak acids are widely distributed in nature and are common in citrus fruits. 000 (Section 4.3) They are also important in the manufacture of polymers used to make fibers, films, and paints. Figure 24.13 shows the formulas of several carboxylic acids.

## Go Figure Which of these substances have both a carboxylic acid functional group and an alcohol functional group?

Lactic acid

Methanoic acid Formic acid

Acetylsalicylic acid Aspirin

Ethanoic acid
Acetic acid

Citric acid

Phenyl methanoic acid Benzoic acid

- Figure 24.13 Structural formulas of common carboxylic acids. The common names for these acids are given in blue type.

The common names of many carboxylic acids are based on their historical origins. Formic acid, for example, was first prepared by extraction from ants; its name is derived from the Latin word for "ant," formica.

Carboxylic acids can be produced by oxidation of alcohols. Under appropriate conditions, the aldehyde may be isolated as the first product of oxidation, as in the sequence

where ( O ) represents any oxidant that can provide oxygen atoms. The air oxidation of ethanol to acetic acid is responsible for causing wines to turn sour, producing vinegar.

The oxidation processes in organic compounds are related to those oxidation reactions we studied in Chapter 20. Instead of counting electrons, the number of $\mathrm{C}-\mathrm{O}$ bonds is usually considered to show the extent of oxidation of similar compounds. For example, methane can be oxidized to methanol, then formaldehye (methanal), then formic acid (methanoic acid):

Methane

Methanol

Formaldehyde

Formic acid

From methanol to formic acid, the number of C - O bonds increases from 0 to 3 (double bonds are counted as two). If you were to calculate the oxidation state of carbon in these compounds, it would range from -4 in methane (if H's are counted as +1 ) to +2 in formic acid, which is consistent with carbon being oxidized. The ultimate oxidation product of any organic compound, then, is $\mathrm{CO}_{2}$, which is indeed the product of combustion reactions of carbon-containing compounds $\left(\mathrm{CO}_{2}\right.$ has $4 \mathrm{C}-\mathrm{O}$ bonds, and C has the oxidation state +4 ).

Aldehydes and ketones can be prepared by controlled oxidation of alcohols. Complete oxidation results in formation of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, as in the burning of methanol:

$$
\mathrm{CH}_{3} \mathrm{OH}(g)+\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

Controlled partial oxidation to form other organic substances, such as aldehydes and ketones, is carried out by using various oxidizing agents, such as air, hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$, ozone $\left(\mathrm{O}_{3}\right)$, and potassium dichromate $\left(\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}\right)$.

## Give It Some Thought

Write the condensed structural formula for a compound that would result from oxidation of the alcohol

Acetic acid can also be produced by the reaction of methanol with carbon monoxide in the presence of a rhodium catalyst:

This reaction is not an oxidation; it involves, in effect, the insertion of a carbon monoxide molecule between the $\mathrm{CH}_{3}$ and OH groups. A reaction of this kind is called carbonylation.

Carboxylic acids can undergo condensation reactions with alcohols to form esters:

Esters are compounds in which the H atom of a carboxylic acid is replaced by a carboncontaining group:

## Give It Some Thought

What is the difference between an ether and an ester?

The name of any ester consists of the name of the group contributed by the alcohol followed by the name of the group contributed by the carboxylic acid, with the -ic replaced by -ate. For example, the ester formed from ethyl alcohol, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$, and butyric acid, $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{COOH}$, is

Notice that the chemical formula generally has the group originating from the acid written first, which is opposite of the way the ester is named. Another example is isoamyl acetate, the ester formed from acetic acid and isoamyl alcohol. Isoamyl acetate smells like bananas or pears.

Many esters such as isoamyl acetate have pleasant odors and are largely responsible for the pleasing aromas of fruit.

An ester treated with an acid or a base in aqueous solution is hydrolyzed; that is, the molecule is split into an alcohol and a carboxylic acid or its anion:

[24.21]

The hydrolysis of an ester in the presence of a base is called saponification, a term that comes from the Latin word for soap, sapon. Naturally occurring esters include fats and oils, and in making soap an animal fat or a vegetable oil is boiled with a strong base. The resultant soap consists of a mixture of salts of long-chain carboxylic acids (called fatty acids), which form during the saponification reaction.

## Sample Exercise 24.6

## Naming Esters and Predicting Hydrolysis Products

In a basic aqueous solution, esters react with hydroxide ion to form the salt of the carboxylic acid and the alcohol from which the ester is constituted. Name each of the following esters, and indicate the products of their reaction with aqueous base.
(a)

(b)

## SOLUTION

Analyze We are given two esters and asked to name them and to predict the products formed when they undergo hydrolysis (split into an alcohol and carboxylate ion) in basic solution.
Plan Esters are formed by the condensation reaction between an alcohol and a carboxylic acid. To name an ester, we must analyze its structure and determine the identities of the alcohol and acid from which it is formed. We can identify the alcohol by adding an OH to the alkyl group attached to the O atom of the carboxyl (COO) group. We can identify the acid by adding an H to the O atom of the carboxyl group. We have learned that the first part of an ester name indicates the alcohol portion and the second indicates the acid portion. The name conforms to how the ester undergoes hydrolysis in base, reacting with base to form an alcohol and a carboxylate anion.

## Solve

(a) This ester is derived from ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$ and benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$. Its name is therefore ethyl benzoate. The net ionic equation for reaction of ethyl benzoate with hydroxide ion is

The products are benzoate ion and ethanol.
(b) This ester is derived from phenol $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right)$ and butanoic acid (commonly called butyric acid) $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\right)$. The residue from the phenol is called the phenyl group. The ester is therefore named phenyl butyrate or phenyl butanoate. The net ionic equation for the reaction of phenyl butyrate with hydroxide ion is

The products are butyrate ion and phenol.

Practice Exercise 1
For the generic ester $\mathrm{RC}(\mathrm{O}) \mathrm{OR}^{\prime}$, which bond will hydrolyze under basic conditions?
(a) the R - C bond
(b) the $\mathrm{C}=\mathrm{O}$ bond
(c) the $\mathrm{C}-\mathrm{O}$ bond
(d) the $\mathrm{O}-\mathrm{R}^{\prime}$ bond
(e) more than one of the above

Practice Exercise 2
Write the condensed structural formula for the ester formed from propyl alcohol and propionic acid.

## Amines and Amides

Amines are compounds in which one or more of the hydrogens of ammonia $\left(\mathrm{NH}_{3}\right)$ are replaced by an alkyl group:

Amines are the most common organic bases. $0 \infty$ (Section 16.7) As we saw in the Chemistry Put to Work box in Section 16.8, many pharmaceutically active compounds are complex amines:

Cocaine

Morphine

Codeine

An amine with at least one H bonded to N can undergo a condensation reaction with a carboxylic acid to form an amide, which contains the carbonyl group ( $\mathrm{C}=\mathrm{O}$ ) attached to N (Table 24.6):

We may consider the amide functional group to be derived from a carboxylic acid with an $\mathrm{NRR}^{\prime}, \mathrm{NH}_{2}$, or $\mathrm{NHR}^{\prime}$ group replacing the OH of the acid, as in these examples:

Ethanamide Acetamide

Phenylmethanamide Benzamide

N -(4-hydroxyphenyl)ethanamide Acetaminophen

The amide linkage

where R and $\mathrm{R}^{\prime}$ are organic groups, is the key functional group in proteins, as we will see in Section 24.7.

### 24.5 Chirality in Organic Chemistry

A molecule possessing a nonsuperimposable mirror image is termed chiral (Greek cheir, "hand"). 000 (Section 23.4) Compounds containing carbon atoms with four different attached groups are inherently chiral. A carbon atom with four different attached groups is called a chiral center. For example, consider 2-bromopentane:

All four groups attached to the second carbon are different, making that carbon a chiral center. Figure 24.14 illustrates the nonsuperimposable mirror images of this molecule. Imagine moving the molecule shown to the left of the mirror over to the right of the mirror. If you then turn it in every possible way, you will conclude that it cannot be superimposed on the molecule shown to the right of the mirror. Nonsuperimposable mirror images are called either optical isomers or enantiomers. 000 (Section 23.4) Organic chemists use the labels $R$ and $S$ to distinguish the two forms. We will not go into the rules for deciding on the labels.

## Go Figure If you replace Br with $\mathrm{CH}_{3}$, will the compound be chiral?

Figure 24.14 The two enantiomeric forms of 2-bromopentane. The mirror-image isomers are not superimposable on each other.

The two members of an enantiomer pair have identical physical properties and identical chemical properties when they react with nonchiral reagents. Only in a chiral environment do they behave differently from each other. One interesting property of chiral substances is that their solutions may rotate the plane of polarized light, as explained in Section 23.4.

Chirality is common in organic compounds. It is often not observed, however, because when a chiral substance is synthesized in a typical reaction, the two enantiomers are formed in precisely the same quantity. The resulting mixture is called a racemic mixture, and it does not rotate the plane of polarized light because the two forms rotate the light to equal extents in opposite directions. 000 (Section 23.4)

Many drugs are chiral compounds. When a drug is administered as a racemic mixture, often only one enantiomer has beneficial results. The other is often inert, or nearly so, or may even have a harmful effect. For example, the drug ( $R$ )-albuterol (Figure $24.15(\mathbf{a})$ ) is a bronchodilator used to relieve the symptoms of asthma. The enantiomer $(S)$-albuterol is not only ineffective as a bronchodilator but also actually counters the effects of $(R)$-albuterol. As another example, the nonsteroidal analgesic ibuprofen is a chiral molecule usually sold as the racemic mixture. However, a preparation consisting of just the more active enantiomer, (S)-ibuprofen (Figure $24.15(\mathbf{b})$ ), relieves pain and reduces inflammation more rapidly than the racemic mixture. For this reason, the chiral version of the drug may in time come to replace the racemic one.

(a)
(R)-Albuterol

(S)-Ibuprofen
© Figure 24.15 ( $R$ )-Albuterol and (S)-Ibuprofen. (a) This compound, which acts as a bronchodilator in patients with asthma, is one member of an enantiomer pair. The other member, ( $(S)$-albuterol, has the OH group pointing down, and does not have the same physiological effect. (b) For relieving pain and reducing inflammation, the ability of this enantiomer far outweighs that of the $(R)$ isomer. In the $(R)$ isomer, the positions of the H and $\mathrm{CH}_{3}$ group on the far-right carbon are switched.

## Give It Some Thought

What are the requirements on the four groups attached to a carbon atom in order that it be a chiral center?

## 24.6 | Introduction to Biochemistry

The functional groups discussed in Section 24.4 generate a vast array of molecules with very specific chemical reactivities. Nowhere is this specificity more apparent than in bio-chemistry-the chemistry of living organisms.

Before we discuss specific biochemical molecules, we can make some general observations. Many biologically important molecules are quite large because organisms build biomolecules from smaller, simpler substances readily available in the biosphere. The synthesis of large molecules requires energy because most of the reactions are endothermic. The ultimate source of this energy is the Sun. Animals have essentially no capacity for using solar energy directly and so depend on plant photosynthesis to supply the bulk of their energy needs. 000 (Section 23.3)

In addition to requiring large amounts of energy, living organisms are highly organized. In thermodynamic terms, this high degree of organization means that the entropy of living systems is much lower than that of the raw materials from which the systems formed. Thus, living systems must continuously work against the spontaneous tendency toward increased entropy. 000 (Section 19.3)

In the "Chemistry and Life" essays that appear throughout this text, we have introduced some important biochemical applications of fundamental chemical ideas. The remainder of this chapter will serve as only a brief introduction to other aspects of biochemistry. Nevertheless, you will see some patterns emerging. Hydrogen bonding, 000 (Section 11.2), for example, is critical to the function of many biochemical systems, and the geometry of molecules 000 (Section 9.1) can govern their biological importance and activity. Many of the large molecules in living systems are polymers 000 (Section 12.8) of much smaller molecules. These biopolymers can be classified into three broad categories: proteins, polysaccharides (carbohydrates), and nucleic acids. Lipids are another common class of molecules in living systems, but they are usually large molecules, not biopolymers.

### 24.7 Proteins

Proteins are macromolecules present in all living cells. About 50\% of your body's dry mass is protein. Some proteins are structural components in animal tissues; they are a key part of skin, nails, cartilage, and muscles. Other proteins catalyze reactions, transport oxygen, serve as hormones to regulate specific body processes, and perform other tasks. Whatever their function, all proteins are chemically similar, being composed of smaller molecules called amino acids.

## Amino Acids

An amino acid is a molecule containing an amine group, $-\mathrm{NH}_{2}$, and a carboxylic acid group, - COOH . The building blocks of all proteins are $\alpha$-amino acids, where the $\alpha$ (alpha) indicates that the amino group is located on the carbon atom immediately adjacent to the carboxylic acid group. Thus, there is always one carbon atom between the amino group and the carboxylic acid group.

The general formula for an $\alpha$-amino acid is represented by

The doubly ionized form, called a zwitterion, usually predominates at near-neutral pH values. This form is a result of the transfer of a proton from the carboxylic acid group to the amine group. 000 (Section 16.10: "The Amphiprotic Behavior of Amino Acids")

Amino acids differ from one another in the nature of their R groups. Twenty-two amino acids occur naturally in proteins, and Figure 24.16 shows the 20 of these 22 found in humans. Our bodies can synthesize 11 of these 20 amino acids in sufficient amounts for our needs. The other 9 must be ingested and are called essential amino acids because they are necessary components of our diet.

Go Figure Which group of amino acids has a net positive charge at pH 7 ?

$\Delta$ Figure 24.16 The 20 amino acids found in the human body. The blue shading shows the different R groups for each amino acid. The acids are shown in the zwitterionic form in which they exist in water at near-neutral pH values. The amino acid names shown in bold are the nine essential ones. Three-letter and one-letter abbreviations for each amino acid are shown below its name.

The $\alpha$-carbon atom of the amino acids, which is the carbon between the amino and carboxylate groups, has four different groups attached to it. The amino acids are thus chiral (except for glycine, which has two hydrogens attached to the central carbon). For historical reasons, the two enantiomeric forms of amino acids are often distinguished by the labels D (from the Latin dexter, "right") and L (from the Latin laevus, "left"). Nearly all the chiral amino acids found in living organisms have the L configuration at the chiral center. The principal exceptions are the proteins that make up the cell walls of bacteria, which can contain considerable quantities of the $D$ isomers.

## Polypeptides and Proteins

Amino acids are linked together into proteins by amide groups (Table 24.6):

Each amide group is called a peptide bond when it is formed by amino acids. A peptide bond is formed by a condensation reaction between the carboxyl group of one amino acid and the amino group of another amino acid. Alanine and glycine, for example, form the dipeptide glycylalanine:

Glycylalanine (Gly-Ala; GA)
The amino acid that furnishes the carboxyl group for peptide-bond formation is named first, with a $-y l$ ending; then the amino acid furnishing the amino group is named. Using the abbreviations shown in Figure 24.16, we can abbreviate glycylalanine as either Gly-Ala or GA. In this notation, it is understood that the unreacted amino group is on the left and the unreacted carboxyl group on the right.

The artificial sweetener aspartame (Figure 24.17) is the methyl ester of the dipeptide formed from the amino acids aspartic acid and phenylalanine.

## Go Figure

How many chiral centers are there in one molecule of aspartame?

Aspartic acid (Asp)

Phenylalanine (Phe)

A Figure 24.17 Sweet stuff. The artificial sweetener aspartame is the methyl ester of a dipeptide.

## Sample Exercise 24.7

## Drawing the Structural Formula of a Tripeptide

Draw the structural formula for alanylglycylserine.

## SOLUTION

Analyze We are given the name of a substance with peptide bonds and asked to write its structural formula.

Plan The name of this substance suggests that three amino acids-alanine, glycine, and serine-have been linked together, forming a tripeptide. Note that the ending $-y l$ has been added to each amino acid except for the last one, serine. By convention, the sequence of amino acids in peptides and proteins is written from the nitrogen end to the carbon end: The first-named amino acid (alanine, in this case) has a free amino group and the last-named one (serine) has a free carboxyl group.
Solve We first combine the carboxyl group of alanine with the amino group of glycine to form a peptide bond and then the
carboxyl group of glycine with the amino group of serine to form another peptide bond:

We can abbreviate this tripeptide as either Ala-Gly-Ser or AGS.

Practice Exercise 1
How many nitrogen atoms are in the tripeptide Arg-Asp-Gly?
$\begin{array}{lllll}\text { (a) } 3 & \text { (b) } 4 & \text { (c) } 5 & \text { (d) } 6 & \text { (e) } 7\end{array}$
Practice Exercise 2
Name the dipeptide and give the two ways of writing its abbreviation.

Polypeptides are formed when a large number of amino acids ( $>30$ ) are linked together by peptide bonds. Proteins are linear (that is, unbranched) polypeptide molecules with molecular weights ranging from about 6000 to over 50 million u. Because up to 22 different amino acids are linked together in proteins and because proteins consist of hundreds of amino acids, the number of possible arrangements of amino acids within proteins is virtually limitless.

## Protein Structure

The sequence of amino acids from the "N terminus" (that is, the amino end) to the "C terminus" (the carboxylic acid end) along a protein chain is called its primary structure and gives the protein its unique identity. A change in even one amino acid can alter the biochemical characteristics of the protein. For example, sickle-cell anemia is a genetic disorder resulting from a single replacement in a protein chain in hemoglobin. The chain that is affected contains 146 amino acids. The substitution of an amino acid with a hydrocarbon side chain for one that has an acidic functional group in the side chain alters the solubility properties of the hemoglobin, and normal blood flow is impeded. 000 (Section 13.6, "Sickle-Cell Anemia")

Proteins in living organisms are not simply long, flexible chains with random shapes. Rather, the chains self-assemble into structures based on the intermolecular forces we learned about in Chapter 11. This self-assembling leads to a protein's secondary structure, which refers to how segments of the protein chain are oriented in a regular pattern, as seen in Figure 24.18.

One of the most important and common secondary structure arrangements is the $\boldsymbol{\alpha}($ alpha)-helix. The alpha helix is held in position by hydrogen bonds between amide H atoms and carbonyl O atoms in the main chain, not the side chains, of the protein. The pitch of the helix and its diameter must be such that (1) no bond angles are strained and (2) the $\mathrm{N}-\mathrm{H}$ and $\mathrm{C}=\mathrm{O}$ functional groups on adjacent turns are in proper position for hydrogen bonding. An arrangement of this kind is possible for some amino acids along the chain but not for others. Large protein molecules may contain segments of the chain that have the $\alpha$-helical arrangement interspersed with sections in which the chain is in a random coil.

The other common secondary structure of proteins is the $\boldsymbol{\beta}$ (beta)-sheet. Beta sheets are made of two or more strands of peptides that hydrogen-bond from an amide H in one strand to a carbonyl O in the other strand. Like the alpha helix, the hydrogen bonding in beta sheets is between the peptide backbones, not the side chains.

## Give It Some Thought

If you heat a protein to break the intramolecular hydrogen bonds, will you maintain the primary structure of the protein?

Proteins are not active biologically unless they are in a particular shape in solution. The process by which the protein adopts its biologically active shape is called folding. The shape of a protein in its folded form-determined by all the bends, kinks, and sections of rodlike $\alpha$-helical, $\beta$-sheet, or flexible coil components-is called the tertiary

## structure.

Globular proteins fold into a compact, roughly spherical shape. Globular proteins are generally soluble in water and are mobile within cells. They have nonstructural

A Figure 24.18 The four levels of protein structure. Amino acids, linked by amide bonds from the amine end to the acid end, can hydrogen-bond to form alpha helix or beta sheet secondary structures. These secondary structures fold into tertiary structures based on electrostatic and van der Waals interactions. Many proteins for quaternary structures in which multiple protein molecules associate to form dimers, trimers, or tetramers (as shown here).
functions, such as combating the invasion of foreign objects, transporting and storing oxygen (hemoglobin and myoglobin), and acting as catalysts. The fibrous proteins form a second class of proteins. In these substances, the long coils align more or less in parallel to form long, water-insoluble fibers. Fibrous proteins provide structural integrity and strength to many kinds of tissue and are the main components of muscle, tendons, and hair. The largest known proteins, in excess of 27,000 amino acids long, are muscle proteins.

The tertiary structure of a protein is maintained by many different interactions. Certain foldings of the protein chain lead to lower energy (more stable) arrangements than do other folding patterns. For example, a globular protein dissolved in aqueous solution folds in such a

A Figure 24.19 Linear structure of the carbohydrates glucose and fructose.
way that the nonpolar hydrocarbon portions are tucked within the molecule, away from the polar water molecules. Most of the more polar acidic and basic side chains, however, project into the solution, where they can interact with water molecules through iondipole, dipole-dipole, or hydrogen-bonding interactions.

Some proteins are assemblies of more than one polypeptide chain. Each chain has its own tertiary structure, and two or more of these tertiary subunits may aggregate into a larger functional macromolecule. The way the tertiary subunits are arranged is called the quaternary structure of the protein (Figure 24.18). For example, hemoglobin, the oxygen-carrying protein of red blood cells, consists of four tertiary subunits. Each subunit contains a component called a heme with an iron atom that binds oxygen as depicted in Figure 23.15. The quaternary structure is maintained by the same types of interactions that maintain the tertiary structure.

One of the most fascinating current hypotheses in biochemistry is that misfolded proteins can cause infectious disease. These infectious misfolded proteins are called prions. The best example of a prion is the one thought to be responsible for mad cow disease, which can be transmitted to humans.

### 24.8 Carbohydrates

Carbohydrates are an important class of naturally occurring substances found in both plant and animal matter. The name carbohydrate ("hydrate of carbon") comes from the empirical formulas for most substances in this class, which can be written as $\mathrm{C}_{x}\left(\mathrm{H}_{2} \mathrm{O}\right)_{y}$. For example, glucose, the most abundant carbohydrate, has the molecular formula $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$, or $\mathrm{C}_{6}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}$. Carbohydrates are not really hydrates of carbon; rather, they are polyhydroxy aldehydes and ketones. Glucose, for example, is a six-carbon aldehyde sugar, whereas fructose, the sugar that occurs widely in fruit, is a six-carbon ketone sugar (Figure 24.19).

The glucose molecule, having both alcohol and aldehyde functional groups and a reasonably long and flexible backbone, can form a six-member-ring structure, as shown in Figure 24.20. In fact, in an aqueous solution only a small percentage of the glucose molecules are in the open-chain form. Although the ring is often drawn as if it were planar, the molecules are actually nonplanar because of the tetrahedral bond angles around the C and O atoms of the ring.

Figure 24.20 shows that the ring structure of glucose can have two relative orientations. In the $\alpha$ form the OH group on C 1 and the $\mathrm{CH}_{2} \mathrm{OH}$ group on C 5 point in opposite directions, and in the $\beta$ form they point in the same direction. Although the difference

A Figure 24.20 Cyclic glucose has an $\alpha$ form and a $\beta$ form.
between the $\alpha$ and $\beta$ forms might seem small, it has enormous biological consequences, including the vast difference in properties between starch and cellulose.

Fructose can cyclize to form either five- or six-member rings. The five-member ring forms when the C 5 OH group reacts with the C 2 carbonyl group:

The six-member ring results from the reaction between the C6 OH group and the C2 carbonyl group.

## Sample Exercise 24.8

Identifying Functional Groups and Chiral Centers in Carbohydrates
How many chiral carbon atoms are there in the open-chain form of glucose (Figure 24.19)?

## SOLUTION

Analyze We are given the structure of glucose and asked to determine the number of chiral carbons in the molecule.

Plan A chiral carbon has four different groups attached (Section 24.5). We need to identify those carbon atoms in glucose.

Solve Carbons 2, 3, 4, and 5 each have four different groups attached to them:

Thus, there are four chiral carbon atoms in the glucose molecule.

Practice Exercise 1
How many chiral carbon atoms are there in the open-chain form of fructose (Figure 24.19)?
(a) 0
(b) 1
(c) 2
(d) $3 \quad$ (e) 4

## Practice Exercise 2

Name the functional groups present in the beta form of glucose.

## Disaccharides

Both glucose and fructose are examples of monosaccharides, simple sugars that cannot be broken into smaller molecules by hydrolysis with aqueous acids. Two monosaccharide units can be linked together by a condensation reaction to form a disaccharide. The structures of two common disaccharides, sucrose (table sugar) and lactose (milk sugar), are shown in Figure 24.21.

The word sugar makes us think of sweetness. All sugars are sweet, but they differ in the degree of sweetness we perceive when we taste them. Sucrose is about six times sweeter than lactose, slightly sweeter than glucose, but only about half as sweet as

Figure 24.21 Two disaccharides.
fructose. Disaccharides can be reacted with water (hydrolyzed) in the presence of an acid catalyst to form monosaccharides. When sucrose is hydrolyzed, the mixture of glucose and fructose that forms, called invert sugar,* is sweeter to the taste than the original sucrose. The sweet syrup present in canned fruits and candies is largely invert sugar formed from hydrolysis of added sucrose.

## Polysaccharides

Polysaccharides are made up of many monosaccharide units joined together. The most important polysaccharides are starch, glycogen, and cellulose, all three of which are formed from repeating glucose units.

Starch is not a pure substance. The term refers to a group of polysaccharides found in plants. Starches serve as a major method of food storage in plant seeds and tubers. Corn, potatoes, wheat, and rice all contain substantial amounts of starch. These plant products serve as major sources of needed food energy for humans. Enzymes in the digestive system catalyze the hydrolysis of starch to glucose.

Some starch molecules are unbranched chains, whereas others are branched. Figure $24.22(\mathbf{a})$ illustrates an unbranched starch structure. Notice, in particular, that the

(a)

(b)

Figure 24.22 Structures of (a) starch and (b) cellulose. Not all hydrogen atoms are shown.

[^66]glucose units are in the $\alpha$ form, with the bridging oxygen atoms pointing in one direction and the $\mathrm{CH}_{2} \mathrm{OH}$ groups pointing in the opposite direction.

Glycogen is a starch-like substance synthesized in the animal body. Glycogen molecules vary in molecular weight from about 5000 to more than 5 million u. Glycogen acts as a kind of energy bank in the body. It is concentrated in the muscles and liver. In muscles, it serves as an immediate source of energy; in the liver, it serves as a storage place for glucose and helps to maintain a constant glucose level in the blood.

Cellulose [Figure 24.22(b)] forms the major structural unit of plants. Wood is about $50 \%$ cellulose; cotton fibers are almost entirely cellulose. Cellulose consists of an unbranched chain of glucose units, with molecular weights averaging more than $500,000 \mathrm{u}$. At first glance, this structure looks very similar to that of starch. In cellulose, however, the glucose units are in the $\beta$ form with each bridging oxygen atom pointing in the same direction as the $\mathrm{CH}_{2} \mathrm{OH}$ group in the ring to its left.

Because the individual glucose units have different relationships to one another in starch and cellulose, enzymes that readily hydrolyze starches do not hydrolyze cellulose. Thus, you might eat a pound of cellulose and receive no caloric value from it even though the heat of combustion per unit mass is essentially the same for both cellulose and starch. A pound of starch, in contrast, would represent a substantial caloric intake. The difference is that the starch is hydrolyzed to glucose, which is eventually oxidized with the release of energy. However, enzymes in the body do not readily hydrolyze cellulose, so it passes through the digestive system relatively unchanged. Many bacteria contain enzymes, called cellulases, that hydrolyze cellulose. These bacteria are present in the digestive systems of grazing animals, such as cattle, that use cellulose for food.

## Give It Some Thought

Why are food with high content of dietary fiber usually low in calories?

### 24.9 Lipids

Lipids are a diverse class of nonpolar biological molecules used by organisms for longterm energy storage (fats, oils) and as elements of biological structures (phospholipids, cell membranes, waxes).

## Fats

Fats are lipids derived from glycerol and fatty acids. Glycerol is an alcohol with three OH groups. Fatty acids are carboxylic acids $(\mathrm{RCOOH})$ in which R is a hydrocarbon chain, usually 15 to 19 carbon atoms in length. Glycerol and fatty acids undergo condensation reactions to form ester linkages as shown in Figure 24.23. Three fatty acid molecules join to a glycerol. Although the three fatty acids in a fat can be the same, as they are in Figure 24.23, it is also possible that a fat contains three different fatty acids.

Lipids with saturated fatty acids are called saturated fats and are commonly solids at room temperature (such as butter and shortening). Unsaturated fats contain one or more double bonds in their carbon-carbon chains. The cis and trans nomenclature we learned for alkenes applies: Trans fats have H atoms on the opposite sides of the $\mathrm{C}=\mathrm{C}$ double bond, and cis fats have H atoms on the same sides of the $\mathrm{C}=\mathrm{C}$ double bond. Unsaturated fats (such as olive oil and peanut oil) are usually liquid at room temperature

## Go Figure

What structural features of a fat molecule cause it to be insoluble in water?

A Figure 24.23 Structure of a fat.
and are more often found in plants. For example, the major component (approximately 60 to $80 \%$ ) of olive oil is oleic acid, cis $-\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{7} \mathrm{CH}=\mathrm{CH}\left(\mathrm{CH}_{2}\right)_{7} \mathrm{COOH}$. Oleic acid is an example of a monounsaturated fatty acid, meaning it has only one carbon-carbon double bond in the chain. In contrast, polyunsaturated fatty acids have more than one carbon-carbon double bond in the chain.

For humans, trans fats are not nutritionally required, which is why some governments are moving to ban them in foods. How, then, do trans fats end up in our food? The process that converts unsaturated fats (such as oils) into saturated fats (such as shortening) is hydrogenation. $0 \infty$ (Section 24.3) The by-products of this hydrogenation process include trans fats.

Some of the fatty acids essential for human health must be available in our diets because our metabolism cannot synthesize them. These essential fatty acids are ones that have the carbon-carbon double bonds either three carbons or six carbons away from the $-\mathrm{CH}_{3}$ end of the chain. These are called omega- 3 and omega- 6 fatty acids, where omega refers to the last carbon in the chain (the carboxylic acid carbon is considered the first, or alpha, one).

## Phospholipids

Phospholipids are similar in chemical structure to fats but have only two fatty acids attached to a glycerol. The third alcohol group of glycerol is joined to a phosphate group (Figure 24.24). The phosphate group can also be attached to a small charged or polar group, such as choline, as shown in the figure. The diversity in phospholipids is based on differences in their fatty acids and in the groups attached to the phosphate group.

In water, phospholipids cluster together with their charged polar heads facing the water and their nonpolar tails facing inward. The phospholipids thus form a bilayer that is a key component of cell membranes (Figure 24.24).

## Go Figure

Why do phospholipids form bilayers but not monolayers in water?

A Figure 24.24 Structure of a phospholipid and a cell membrane. Living cells are encased in membranes typically made of phospholipid bilayers. The bilayer structure is stabilized by the favorable interactions of the hydrophobic tails of the phospholipids, which point away from both the water inside the cell and the water outside the cell, while the charged head groups face the two water environments.

### 24.10 $\mid$ Nucleic Acids

Nucleic acids are a class of biopolymers that are the chemical carriers of an organism's genetic information. Deoxyribonucleic acids (DNAs) are huge molecules whose molecular weights may range from 6 to 16 million $u$. Ribonucleic acids (RNAs) are smaller molecules, with molecular weights in the range of 20,000 to $40,000 \mathrm{u}$. Whereas DNA is found primarily in the nucleus of the cell, RNA is found mostly outside the nucleus in the cytoplasm, the nonnuclear material enclosed by the cell membrane. DNA stores the genetic information of the cell and specifies which proteins the cell can synthesize. RNA carries the information stored by DNA out of the cell nucleus into the cytoplasm, where the information is used in protein synthesis.

The monomers of nucleic acids, called nucleotides, are formed from a five-carbon sugar, a nitrogen-containing organic base, and a phosphate group. An example is shown in Figure 24.25.

a Figure 24.25 A nucleotide. Structure of deoxyadenylic acid, the nucleotide formed from phosphoric acid, the sugar deoxyribose, and the organic base adenine.

The five-carbon sugar in RNA is ribose, and that in DNA is deoxyribose:

Deoxyribose differs from ribose only in having one fewer oxygen atom at carbon 2. There are five nitrogen-containing bases in nucleic acids:

Adenine (A)
DNA RNA

Guanine (G) DNA RNA

Cytosine (C)
DNA
RNA

Thymine (T) DNA

Uracil (U)

The first three bases shown here are found in both DNA and RNA. Thymine occurs only in DNA, and uracil occurs only in RNA. In either nucleic acid, each base is attached to a five-carbon sugar through a bond to the nitrogen atom shown in color.

The nucleic acids RNA and DNA are polynucleotides formed by condensation reactions between a phosphoric acid OH group on one nucleotide and a sugar OH group on another nucleotide. Thus, the polynucleotide strand has a backbone consisting of alternating sugar and phosphate groups with the bases extending off the chain as side groups (Figure 24.26). The carbons in the sugars are numbered $1^{\prime}, 2^{\prime}$, and so forth, as shown in Figure 24.26. Just as proteins have a sequence of amino acids from the N terminus to the C terminus, nucleic acids have a sequence of bases that start from the $5^{\prime}$ end of the sugar-phosphate backbone and go to the 3 ' end.

The DNA strands wind together in an antiparallel double helix (Figure $24.27(\mathbf{a})$ ). The two strands are held together by attractions between bases (represented by T, A, C, and G). These attractions involve dispersion forces, dipole-dipole forces, and hydrogen bonds. $\infty$ (Section 11.2) As shown in Figure 24.27(b), the structures of thymine and adenine make them perfect partners for hydrogen bonding. Likewise, cytosine and guanine form ideal hydrogen-bonding partners. We say that thymine and adenine are complementary to each other and cytosine and guanine are complementary to each other. In the double-helix structure, therefore, each thymine on one strand is opposite an adenine on the other strand, and each cytosine is opposite a guanine. The double-helix structure with complementary bases on the two strands is the key to understanding how DNA functions.

The two strands of DNA unwind during cell division, and new complementary strands are constructed on the unraveling strands

Which pair of complementary bases, AT or GC, would you expect to be more difficult to dissociate from each other?

- Figure 24.27 DNA and bonding between complementary bases. (a) The DNA double helix, showing the sugar-phosphate backbone as a pair of ribbons and dotted lines to indicate hydrogen bonding between the complementary bases. (b) Structures of the complementary base pairs in DNA.
(Figure 24.28). This process results in two identical double-helix DNA structures, each containing one strand from the original structure and one new strand. This replication allows genetic information to be transmitted when cells divide.

The structure of DNA is also the key to understanding protein synthesis, the means by which viruses infect cells, and many other problems of central importance to modern biology. These themes are beyond the scope of this book. If you take courses in the life sciences, however, you will learn a good deal about such matters.

A Figure 24.28 DNA replication. The original DNA double helix partially unwinds, and new nucleotides line up on each strand in complementary fashion. Hydrogen bonds help align the new nucleotides with the original DNA chain. When the new nucleotides are joined by condensation reactions, two identical double-helix DNA molecules result.

## Sample Integrative Exercise

Putting Concepts Together
Pyruvic acid,

is formed in the body from carbohydrate metabolism. In muscles, it is reduced to lactic acid in the course of exertion. The acid-dissociation constant for pyruvic acid is $3.2 \times 10^{-3}$. (a) Why does pyruvic acid have a larger acid-dissociation constant than acetic acid? (b) Would you expect pyruvic acid to exist primarily as the neutral acid or as dissociated ions in muscle tissue, assuming a pH of 7.4 and an initial acid concentration of $2 \times 10^{-4} \mathrm{M}$ ? (c) What would you predict for the solubility properties of pyruvic acid? Explain. (d) What is the hybridization of each carbon atom in pyruvic acid? (e) Assuming H atoms as the reducing agent, write a balanced chemical equation for the reduction of pyruvic acid to lactic acid (Figure 24.13). (Although H atoms do not exist as such in biochemical systems, biochemical reducing agents deliver hydrogen for such reductions.)

## SOLUTION

(a) The acid-dissociation constant for pyruvic acid should be somewhat greater than that of acetic acid because the carbonyl function on the $\alpha$-carbon atom of pyruvic acid exerts an electron-withdrawing effect on the carboxylic acid group. In the $\mathrm{C}-\mathrm{O}-\mathrm{H}$ bond system, the electrons are shifted from H , facilitating loss of the H as a proton. 000 (Section 16.10)
(b) To determine the extent of ionization, we first set up the ionization equilibrium and equilibrium-constant expression. Using HPv as the symbol for the acid, we have

$$
\begin{gathered}
\mathrm{HPv} \rightleftharpoons \mathrm{H}^{+}+\mathrm{Pv}^{-} \\
K_{a}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{Pv}^{-}\right]}{[\mathrm{HPv}]}=3.2 \times 10^{-3}
\end{gathered}
$$

Let $\left[\mathrm{Pv}^{-}\right]=x$. Then the concentration of undissociated acid is $2 \times 10^{-4}-x$. The concentration of $\left[\mathrm{H}^{+}\right]$is fixed at $4.0 \times 10^{-8} \mathrm{M}$ (the antilog of the pH value). Substituting, we obtain

$$
3.2 \times 10^{-3}=\frac{\left(4.0 \times 10^{-8}\right)(x)}{\left(2 \times 10^{-4}-x\right)}
$$

Solving for $x$, we obtain

$$
x=\left[\mathrm{Pv}^{-}\right]=2 \times 10^{-4} M
$$

This is the initial concentration of acid, which means that essentially all the acid has dissociated. We might have expected this result because the acid is quite dilute and the aciddissociation constant is fairly high.
(c) Pyruvic acid should be quite soluble in water because it has polar functional groups and a small hydrocarbon component. We would predict it would be soluble in polar organic solvents, especially ones that contain oxygen. In fact, pyruvic acid dissolves in water, ethanol, and diethyl ether.
(d) The methyl group carbon has $s p^{3}$ hybridization. The carbon of the carbonyl group has $s p^{2}$ hybridization because of the double bond to oxygen. Similarly, the carboxylic acid carbon is $s p^{2}$ hybridized.
(e) The balanced chemical equation for this reaction is

Essentially, the ketonic functional group has been reduced to an alcohol.

## STRATEGIES FOR SUCCESS What Now?

If you are reading this box, you have made it to the end of our text. We congratulate you on the tenacity and dedication that you have exhibited to make it this far!

As an epilogue, we offer the ultimate study strategy in the form of a question: What do you plan to do with the knowledge of chemistry that you have gained thus far in your studies? Many of you will enroll in additional courses in chemistry as part of your required curriculum. For others, this will be the last formal course in chemistry that you will take. Regardless of the career path you plan to takewhether it is chemistry, one of the biomedical fields, engineering, the liberal arts, or another field-we hope that this text has increased your appreciation of the chemistry in the world around you. As you will observe, chemistry is everywhere, from food and pharmaceuticals to solar cells and sports equipment.

We have also tried to give you a sense that chemistry is a dynamic, continuously changing science. Research chemists
synthesize new compounds, develop new reactions, uncover chemical properties that were previously unknown, find new applications for known compounds, and refine theories. The understanding of biological systems in terms of the underlying chemistry has become increasingly important as new levels of complexity are uncovered. Solving the global challenges of sustainable energy and clean water requires the work of many chemists. We encourage you to participate in the fascinating world of chemical research by enrolling in an undergraduate research program. Given all the answers that chemists seem to have, you may be surprised at the large number of questions that they still find to ask.

Finally, we hope you have enjoyed using this textbook. We certainly enjoyed putting so many of our thoughts about chemistry on paper. We truly believe it to be the central science, one that benefits all who learn about it and from it.

## Chapter Summary and Key Terms

GENERAL CHARACTERISTICS OF ORGANIC COMPOUNDS (INTRODUCTION AND SECTION 24.1) This chapter introduces organic chemistry, which is the study of carbon compounds (typically compounds containing carbon-carbon bonds), and biochemistry, which is the study of the chemistry of living organisms. C-C single bonds and $\mathrm{C}-\mathrm{H}$ bonds tend to have low reactivity. Those bonds that have a high electron density (such as multiple bonds or bonds with an atom of high electronegativity) tend to be the sites of reactivity in an organic compound. These sites of reactivity are called functional groups.

INTRODUCTION TO HYDROCARBONS (SECTION 24.2) The simplest types of organic compounds are hydrocarbons, those composed of only carbon and hydrogen. There are four major kinds of hydrocarbons: alkanes, alkenes, alkynes, and aromatic hydrocarbons. Alkanes are composed of only $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{C}$ single bonds. Alkenes contain one or more carbon-carbon double bonds. Alkynes contain one or more carbon-carbon triple bonds. Aromatic hydrocarbons contain cyclic arrangements of carbon atoms bonded through both $\sigma$ and delocalized $\pi$ bonds. Alkanes are saturated hydrocarbons; the others are unsaturated.

Alkanes may form straight-chain, branched-chain, and cyclic arrangements. Isomers are substances that possess the same molecular formula but differ in the arrangements of atoms. In structural isomers, the bonding arrangements of the atoms differ. Different isomers are given different systematic names. The naming of hydrocarbons is based on the longest continuous chain of carbon atoms in the structure. The locations of alkyl groups, which branch off the chain, are specified by numbering along the carbon chain.

Alkanes with ring structures are called cycloalkanes. Alkanes are relatively unreactive. They do, however, undergo combustion in air, and their chief use is as sources of heat energy produced by combustion.

ALKENES, ALKYNES, AND AROMATIC HYDROCARBONS (SECTION 24.3) The names of alkenes and alkynes are based on the longest continuous chain of carbon atoms that contains the multiple bond, and the location of the multiple bond is specified by a numerical prefix. Alkenes exhibit not only structural isomerism but geometric (cis-trans) isomerism as well. In geometric isomers, the bonds are the same, but the molecules have different geometries. Geometric isomerism is possible in alkenes because rotation about the $\mathrm{C}=\mathrm{C}$ double bond is restricted.

Alkenes and alkynes readily undergo addition reactions to the carbon-carbon multiple bonds. Additions of acids, such as HBr, proceed via a rate-determining step in which a proton is transferred to one of the alkene or alkyne carbon atoms. Addition reactions are difficult to carry out with aromatic hydrocarbons, but substitution reactions are easily accomplished in the presence of catalysts.
ORGANIC FUNCTIONAL GROUPS (SECTION 24.4) The chemistry of organic compounds is dominated by the nature of their functional groups. The functional groups we have considered are

$R, R^{\prime}$, and $\mathrm{R}^{\prime \prime}$ represent hydrocarbon groups-for example, methyl $\left(\mathrm{CH}_{3}\right)$ or phenyl $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)$.

Alcohols are hydrocarbon derivatives containing one or more OH groups. Ethers are formed by a condensation reaction of two molecules of alcohol. Several functional groups contain the carbonyl $(\mathrm{C}=\mathrm{O})$ group, including aldehydes, ketones, carboxylic acids, esters, and amides. Aldehydes and ketones can be produced by the oxidation of certain alcohols. Further oxidation of the aldehydes produces carboxylic acids. Carboxylic acids can form esters by a condensation reaction with alcohols, or they can form amides by a condensation reaction with amines. Esters undergo hydrolysis (saponification) in the presence of strong bases.
CHIRALITY IN ORGANIC CHEMISTRY (SECTION 24.5) Molecules that possess nonsuperimposable mirror images are termed chiral. The two nonsuperimposable forms of a chiral molecule are called enantiomers. In carbon compounds, a chiral center is created when all four groups bonded to a central carbon atom are different. Many of the molecules occurring in living systems, such as the amino acids, are chiral and exist in nature in only one enantiomeric form. Many drugs of importance in human medicine are chiral, and the enantiomers may produce very different biochemical effects.

INTRODUCTION TO BIOCHEMISTRY; PROTEINS (SECTIONS 24.6 AND 24.7) Many of the molecules that are essential for life are large natural polymers that are constructed from smaller molecules called monomers. Three of these biopolymers are considered in this chapter: proteins, polysaccharides (carbohydrates), and nucleic acids.

Proteins are polymers of amino acids. They are the major structural materials in animal systems. All naturally occurring proteins are formed from 22 amino acids, although only 20 are common. The amino acids are linked by peptide bonds. A polypeptide is a polymer formed by linking many amino acids by peptide bonds.

Amino acids are chiral substances. Usually only one of the enantiomers is found to be biologically active. Protein structure is determined by the sequence of amino acids in the chain (its primary structure), the intramolecular interactions within the chain (its secondary structure), and the overall shape of the complete molecule (its tertiary structure). Two important secondary structures are the $\boldsymbol{\alpha}$-helix and the $\boldsymbol{\beta}$-sheet. The process by which a protein assumes its biologically active tertiary structure is called folding. Sometimes several proteins aggregate together to form a quaternary structure.
CARBOHYDRATES AND LIPIDS (SECTIONS 24.8 AND 24.9) Carbohydrates, which are polyhydroxy aldehydes and ketones, are the major structural constituents of plants and are a source of energy in both plants and animals. Glucose is the most common monosaccharide, or simple sugar. Two monosaccharides can be linked together by means of a condensation reaction to form a disaccharide. Polysaccharides are complex carbohydrates made up of many monosaccharide units joined together. The three most important polysaccharides are starch, which is found in plants; glycogen, which is found in mammals; and cellulose, which is also found in plants.

Lipids are compounds derived from glycerol and fatty acids and include fats and phospholipids. Fatty acids can be saturated, unsaturated, cis, or trans depending on their chemical formulas and structures.

NUCLEIC ACIDS (SECTION 24.10) Nucleic acids are biopolymers that carry the genetic information necessary for cell reproduction; they also control cell development through control of protein synthesis. The building blocks of these biopolymers are nucleotides.

There are two types of nucleic acids, ribonucleic acid (RNA) and deoxyribonucleic acid (DNA). These substances consist of a polymeric backbone of alternating phosphate and ribose or deoxyribose sugar groups with organic bases attached to the sugar molecules. The DNA polymer is a double-stranded helix (double helix) held together by hydrogen bonding between matching organic bases situated across from one another on the two strands. The hydrogen bonding between specific base pairs is the key to gene replication and protein synthesis.

## Learning Outcomes After studying this chapter, you should be able to:

- Distinguish among alkanes, alkenes, alkynes, and aromatic hydrocarbons. (Section 24.2) Related Exercises: 24.13, 24.14
- Draw hydrocarbon structures based on their names and name hydrocarbons based on their structures. (Sections 24.2 and 24.3) Related Exercises: 24.27, 24.28
- Predict the products of addition reactions and substitution reactions. (Section 24.3) Related Exercises: 24.35, 24.36
- Draw the structures of the functional groups (alkene, alkyne, alcohol, haloalkane, carbonyl, ether, aldehyde, ketone, carboxylic acid, ester, amine, and amide) and be able to identify functional groups in molecules from the structure or the name. (Section 24.4) Related Exercises: 24.43-24.46
- Understand what makes a compound chiral and be able to recognize a chiral substance. (Section 24.5)
Related Exercises: 24.57, 24.58
- Recognize the amino acids and understand how they form peptides and proteins via amide bond formation. (Section 24.7) Related Exercises: 24.59, 24.60
- Understand the differences among the primary, secondary, tertiary, and quaternary structures of proteins. (Section 24.7) Related Exercises: 24.65, 24.66
- Classify molecules as saccharides or lipids based on their structures. (Sections 24.8 and 24.9) Related Exercises: 24.67, 24.68
- Distinguish between starch and cellulose structures. (Section 24.8) Related Exercises: 24.69, 24.70
- Explain the difference between a saturated and unsaturated fat. (Section 24.9) Related Exercises: 24.73, 24.74
- Explain the structure of nucleic acids and the role played by complementary bases in DNA replication. (Section 24.10) Related Exercises: 24.77, 24.78

## Exercises

## Visualizing Concepts

24.1 All the structures shown here have the molecular formula $\mathrm{C}_{8} \mathrm{H}_{18}$. Which structures are the same molecule? (Hint: One way to answer this question is to determine the chemical name for each structure.) [Section 24.2]
(a)

(b)

(c)

(d)

24.2 Which of these molecules is unsaturated? [Section 24.3]

(a)

(b)

(c)

(d)
24.3 (a) Which of these molecules most readily undergoes an addition reaction? (b) Which of these molecules is aromatic? (c) Which of these molecules most readily undergoes a substitution reaction? [Section 24.3]

(i)

(iii)

(ii)

(iv)
24.4 (a) Which of these compounds below would you expect to have the highest boiling point? (b) Which of these compounds is the most oxidized? (c) Which of these compounds, if any, is an ether? (d) Which of these compounds, if any, is an ester? (e) Which of these compounds, if any, is a ketone? [Section 24.4]

24.5 For each of the compounds below, state its systematic name, its functional group(s), and whether or not it is chiral. [Sections 24.2, 24.4]

(a)

(c)

$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$
(d)
24.6 From examination of the molecular models i-v, choose the substance that (a) can be hydrolyzed to form a solution containing glucose, (b) is capable of forming a zwitterion, (c) is one of the four bases present in DNA, (d) reacts with an acid to form an ester, (e) is a lipid. [Sections 24.6-24.10]

(i)

(ii)

(iii)

(iv)

(v)

## Introduction to Organic Compounds; Hydrocarbons (Sections 24.1 and 24.2)

24.7 Indicate whether each statement is true or false. (a) All carbon atoms in propene are $s p^{2}$ hybridized. (b) Acetone is another name for propanone. (c) The phenyl group contains six $s p^{2}$-hybridized carbons. (d) A hydrocarbon containing only $s p^{3}$ carbons must be an alkane.
24.8 Indicate whether each statement is true or false. (a) Ethane has a higher molar mass than ethene. (b) For molecules of the same homologous family, the higher the molecular mass, the higher the boiling point. (c) The local geometry around the alkene group is T-shaped. (d) Butene has two structural isomers.
24.9 Predict the ideal values for the bond angles about each carbon atom in the following molecule. Indicate the hybridization of orbitals for each carbon.

## $\mathrm{CH}_{2} \mathrm{CHCOOCH}_{3}$

24.10 Identify the carbon atom(s) in the structure shown that has (have) each of the following hybridizations: (a) $s p$, (b) $s p^{2},(\mathbf{c}) s p^{3}$.

24.11 For each of the following hydrocarbons, state how many carbon atoms are in each molecule:
(a) t-butanol
(b) propanone
(c) 2-ethylpropane
(d) cyclohexane
(e) ethane
24.12 True or false: The weaker a single bond in a molecule, the greater the chance it will be the site of a reaction (compared to stronger single bonds in the molecule).
24.13 Indicate whether each statement is true or false. (a) Alkanes do not contain any carbon-carbon multiple bonds. (b) Cyclobutane contains a four-membered ring. (c) Alkenes contain carbon-carbon triple bonds. (d) Alkynes contain carbon-carbon double bonds. (e) Pentane is a saturated hydrocarbon but 1-pentene is an unsaturated hydrocarbon. (f) Cyclohexane is an aromatic hydrocarbon. (g) The methyl group contains one less hydrogen atom than methane.
24.14 What structural features help us identify a compound as (a) an alkane, (b) a cycloalkane, (c) an alkene, (d) an alkyne, (e) a saturated hydrocarbon, (f) an aromatic hydrocarbon?
24.15 Give the the name or condensed structural formula, as appropriate:
(a)

(b)

(c) 2-methylheptane
(d) 4-ethyl-2,3-dimethyloctane
(e) 1,2-dimethylcyclohexane
24.16 Give the name or condensed structural formula, as appropriate:
(a)

(b)

(c) 2,5,6-trimethylnonane
(d) 4-ethyl-5,6-dimethyldodecane
(e) 1-ethyl-3-methylcyclohexane
24.17 Give the name or condensed structural formula, as appropriate:
(a) $\mathrm{CH}_{3} \mathrm{CHCH}_{3}$

(b) 2,2-dimethylpentane
(c) 4-ethyl-1,1-dimethylcyclohexane
(d) $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHCH}_{2} \mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}$
(e) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right) \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$
24.18 Give the name or condensed structural formula, as appropriate:
(a) 3-phenylpentane
(b) 2,3-dimethylhexane
(c) 3,3-dimethyloctane
(d) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}$
(e)

24.19 What is the octane number of a mixture that is $35 \%$ heptane and 65\% isooctane?
24.20 Describe two ways in which the octane number of a gasoline consisting of alkanes can be increased.

## Alkenes, Alkynes, and Aromatic Hydrocarbons (Section 24.3)

24.21 (a) Can $\mathrm{C}_{6} \mathrm{H}_{12}$ be a saturated hydrocarbon?
(b) Are all molecules containing a benzene ring unsaturated?
24.22 (a) Is the compound $\mathrm{CBr}_{3} \mathrm{CH}=\mathrm{CHCH}_{3}$ saturated or unsaturated? Explain. (b) What is wrong with the formula $\mathrm{CH}_{2}=\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ ?
24.23 Give the molecular formula of a hydrocarbon containing five carbon atoms that is (a) an alkane, (b) a cycloalkane, (c) an alkene, (d) an alkyne.
24.24 Give the molecular formula of a hydrocarbon containing six carbon atoms that is (a) a cyclic alkane, (b) a cyclic alkene, (c) a linear alkyne, (d) an aromatic hydrocarbon.
24.25 Enediynes are a class of compounds that include some antibiotic drugs. Draw the structure of an "enediyne" fragment that contains six carbons in a row.
24.26 Give the general formula for any cyclic alkene, that is, a cyclic hydrocarbon with one double bond.
24.27 Write the condensed structural formulas for two alkenes and one alkyne that all have the molecular formula $\mathrm{C}_{6} \mathrm{H}_{10}$.
24.28 Draw all the possible noncyclic structural isomers of $\mathrm{C}_{5} \mathrm{H}_{10}$. Name each compound.
24.29 Name or write the condensed structural formula for the following compounds:
(a) cis-2-pentene
(b) 1,6-dichloro-3-hexyne
(c) $\mathrm{BrC} \equiv \mathrm{CBr}$
(d) 1,3-Benzenediol
(e) $\mathrm{CH}_{2}=\mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{CH}=\mathrm{CH}_{2}$
24.30 Name or write the condensed structural formula for the following compounds:
(a) para-dibromobenzene
(b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{C} \equiv \mathrm{CC}\left(\mathrm{CH}_{3}\right)_{3}$
(c) trans-2-butene
(d) cycloheptene
(e) methylcyclopentane
24.31 Indicate whether each statement is true or false. (a) The three isomers of dimethylbenzene are $o$-dimethylbenzene, $m$-dimethylbenzene, and $p$-dimethylbenzene. (b) Alkenes with at least three carbon atoms differing in the position of the $\mathrm{C}=\mathrm{C}$ double bond are called geometric isomers. (c) Substituted benzenes can form cis and trans isomers.
24.32 Draw all structural and geometric isomers of butene and name them.
24.33 Indicate whether each of the following molecules is capable of geometrical isomerism. For those that are, draw the structures: (a) 2-methylpropene, (b) 1,3-diiodobenzene, (c) 1,2-dichloropent-1-ene, (d) 3-methyl-1-butyne.
24.34 Draw the four distinct geometric isomers of 4-methyl-2, 4-heptadiene.
24.35 (a) True or false: Alkenes undergo addition reactions and aromatic hydrocarbons undergo substitution reactions. (b) Using condensed structural formulas, write the balanced equation for the reaction of 2-pentene with $\mathrm{Br}_{2}$ and name the resulting compound. Is this an addition or a substitution reaction? (c) Write a balanced chemical equation for the reaction of $\mathrm{Cl}_{2}$ with benzene to make paradichlorobenzene in the presence of $\mathrm{FeCl}_{3}$ as a catalyst. Is this an addition or a substitution reaction?
24.36 Using condensed structural formulas, write a balanced chemical equation for each of the following reactions: (a) hydrogenation of cyclohexene, (b) addition of $\mathrm{H}_{2} \mathrm{O}$ to trans-2-pentene using $\mathrm{H}_{2} \mathrm{SO}_{4}$ as a catalyst (two products), (c) reaction of 2-chloropropane with benzene in the presence of $\mathrm{AlCl}_{3}$.
24.37 (a) When cyclopropane is treated with HI, 1-iodopropane is formed. A similar type of reaction does not occur with cyclopentane or cyclohexane. Suggest an explanation for cyclopropane's reactivity. (b) Suggest a method of preparing ethylbenzene, starting with benzene and ethylene as the only organic reagents.
24.38 (a) One test for the presence of an alkene is to add a small amount of bromine, which is a red-brown liquid, and look for the disappearance of the red-brown color. This test does not work for detecting the presence of an aromatic hydrocarbon. Explain. (b) Write a series of reactions leading to para-bromoethylbenzene, beginning with benzene and using other reagents as needed. What isomeric side products might also be formed?
24.39 The rate law for addition of $\mathrm{Br}_{2}$ to an alkene is first order in $\mathrm{Br}_{2}$ and first order in the alkene. Does this information suggest that the mechanism of addition of $\mathrm{Br}_{2}$ to an alkene proceeds in the same manner as for addition of HBr ? Explain.
24.40 Describe the intermediate that is thought to form in the addition of a hydrogen halide to an alkene, using cyclohexene as the alkene in your description.
24.41 The molar heat of combustion of gaseous cyclopropane is $-2089 \mathrm{~kJ} / \mathrm{mol}$; that for gaseous cyclopentane is $-3317 \mathrm{~kJ} / \mathrm{mol}$. Calculate the heat of combustion per $\mathrm{CH}_{2}$ group in the two cases, and account for the difference.
24.42 The heat of combustion of decahydronaphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{18}\right)$ is $-6286 \mathrm{~kJ} / \mathrm{mol}$. The heat of combustion of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ is $-5157 \mathrm{~kJ} / \mathrm{mol}$. (In both cases $\mathrm{CO}_{2}(g)$ and $\mathrm{H}_{2} \mathrm{O}(l)$ are the products.) Using these data and data in Appendix C, calculate the heat of hydrogenation and the resonance energy of naphthalene.

## Functional Groups and Chirality (Sections 24.4 and 24.5)

24.43 (a) Which of the following compounds, if any, is an ether? (b) Which compound, if any, is an alcohol? (c) Which compound, if any, would produce a basic solution if dissolved in water? (Assume solubility is not a problem). (d) Which compound, if any, is a ketone? (e) Which compound, if any, is an aldehyde?
(i) $\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{2}-\mathrm{OH}$
(ii)

(v) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CHO}$
(ii)

(iv)

(vi) $\mathrm{CH}_{3} \mathrm{C} \equiv \mathrm{CCH}_{2} \mathrm{COOH}$
24.44 Identify the functional groups in each of the following compounds:
(a)

(b)

(c)

(d)

(e)

24.45 Draw the molecular structure for (a) a carboxylic acid that is an isomer of ethyl ethanoate, (b) an alcohol that is an isomer of dimethylether.
24.46 (a) Give the empirical formula and structural formula for a cyclic ether containing four carbon atoms in the ring. (b) Write the structural formula for a straight-chain compound that is a structural isomer of your answer to part (a).
24.47 The IUPAC name for a carboxylic acid is based on the name of the hydrocarbon with the same number of carbon atoms. The ending -oic is appended, as in ethanoic acid, which is the IUPAC name for acetic acid. Draw the structure of the following acids: (a) methanoic acid, (b) pentanoic acid, (c) 2-chloro-3-methyldecanoic acid.
24.48 Aldehydes and ketones can be named in a systematic way by counting the number of carbon atoms (including the carbonyl carbon) that they contain. The name of the aldehyde or ketone is based on the hydrocarbon with the same number of carbon atoms. The ending al for aldehyde or -one for ketone is added as appropriate. Draw the structural formulas for the following aldehydes or ketones: (a) 3-ethyl-2-pentanone, (b) 2,2-diethylbutanal, (c) pentanal, (d) 1-bromo-3-heptanone.
24.49 Draw the condensed structure of the compounds formed by condensation reactions between (a) benzoic acid and ethanol, (b) ethanoic acid and methylamine, (c) acetic acid and phenol. Name the compound in each case.
24.50 Draw the condensed structures of the compounds formed from (a) butanoic acid and methanol, (b) benzoic acid and 2-propanol, (c) propanoic acid and dimethylamine. Name the compound in each case.
24.51 Write a balanced chemical equation using condensed structural formulas for the saponification (base hydrolysis) of (a) methyl propionate, (b) phenyl acetate.
24.52 Write a balanced chemical equation using condensed structural formulas for ( $\mathbf{a}$ ) the formation of butyl propionate from the appropriate acid and alcohol, (b) the saponification (base hydrolysis) of methyl benzoate.
24.53 Pure acetic acid is a viscous liquid, with high melting and boiling points $\left(16.7^{\circ} \mathrm{C}\right.$ and $\left.118^{\circ} \mathrm{C}\right)$ compared to compounds of similar molecular weight. Suggest an explanation.
24.54 Acetic anhydride is formed from two acetic acid molecules, in a condensation reaction that involves the removal of a molecule of water. Write the chemical equation for this process, and show the structure of acetic anhydride.
24.55 Write the condensed structural formula for each of the following compounds: (a) 2-pentanol, (b) 1,2-propanediol, (c) ethyl acetate, (d) diphenyl ketone, (e) methyl ethyl ether.
24.56 Write the condensed structural formula for each of the following compounds: (a) 2-ethyl-1-hexanol, (b) methyl phenyl ketone, (c) para-bromobenzoic acid, (d) butyl ethyl ether, (e) $\mathrm{N}, \mathrm{N}$-dimethylbenzamide.
24.57 How many chiral carbons are in 4-bromo-2-chloro-2butanol? (a) 0, (b) 1, (c) 2, (d) 3, (e) 4 or more.
24.58 Is 2-butanol chiral?

## Introduction to Biochemistry; Proteins <br> (Sections 24.6 and 24.7)

24.59 (a) Draw the chemical structure of a generic amino acid, using $R$ for the side chain. (b) When amino acids react to form proteins, do they do so via substitution, addition, or condensation reactions? (c) Draw the bond that links amino acids together in proteins. What is this called?
24.60 Indicate whether each statement is true or false. (a) Tryptophan is an aromatic amino acid. (b) Lysine is positively charged at pH 7 . (c) Asparagine has two amide bonds. (d) Isoleucine and leucine are enantiomers. (e) Valine is probably more water-soluble than arginine.
24.61 Draw the two possible heterodimeric dipeptides formed by condensation reactions between glycine and alanine.
24.62 Write a chemical equation for the formation of threonylaspartic acid from the constituent amino acids, assuming that the reaction is made possible by enzymatic catalysis.
24.63 (a) Draw the condensed structure of the tripeptide Trp-Cys-Cys. (b) How many different tripeptides can be made consisting of one tryptophan and two cysteine units? Give the abbreviations for each of these tripeptides, using the three-letter and one-letter codes for the amino acids.
24.64 (a) What amino acids would be obtained by hydrolysis of the following tripeptide?

(b) How many different tripeptides can be made from glycine, serine, and glutamic acid? Give the abbreviation for each of these tripeptides, using the three-letter codes and one-letter codes for the amino acids.
24.65 Indicate whether each statement is true or false. (a) The sequence of amino acids in a protein, from the amine end to the acid end, is called the primary structure of the protein. (b) Alpha helix and beta sheet structures are examples of quaternary protein structure. (c) It is impossible for more than one protein to bind to another and make a higher order structure.
24.66 Indicate whether each statement is true or false: (a) In the alpha helical structure of proteins, ion-dipole and dipole-dipole interactions occur between the carbonyl groups of the protein backbone and polar side chains of the protein. (b) Only hydrogen bonding is involved in forming the tertiary structure of a protein.

## Carbohydrates and Lipids

(Sections 24.8 and 24.9)
24.67 Indicate whether each statement is true or false: (a) Maltose is a monosaccharide. (b) Polysaccharides are a type of carbohydrate. (c) All carbohydrates have an oxygen to hydrogen ratio of 1:2.
24.68 (a) Are $\alpha$-glucose and $\beta$-glucose enantiomers? (b) Show the condensation of two glucose molecules to form a disaccharide with an $\alpha$ linkage. (c) Repeat part (b) but with a $\beta$ linkage.
24.69 (a) What is the empirical formula of cellulose? (b) What is the monomer that forms the basis of the cellulose
polymer? (c) What bond connects the monomer units in cellulose: amide, acid, ether, ester, or alcohol?
24.70 (a) What is the empirical formula of starch? (b) What is the monomer that forms the basis of the starch polymer?
(c) What bond connects the monomer units in starch: amide, acid, ether, ester, or alcohol?
24.71 The structural formula for the open-chain form of D-mannose is

(a) Is this molecule a sugar? (b) How many chiral carbons are present in the molecule? (c) Draw the structure of the six-member-ring form of this molecule.
24.72 The structural formula for the open-chain form of fructose is

(a) Is this molecule a sugar? (b) How many chiral carbons are present in the open-chain form of this molecule? (c) Draw the structure of the five-member-ring form (furanose) of this molecule.
24.73 Indicate whether each statement is true or false: (a) Fat molecules must contain $\mathrm{C}=\mathrm{C}$ bonds. (b) Phosphoplipids have overall net charge. (c) Cis-monounsaturated fat molecules are bent in shape.
24.74 Indicate whether each statement is true or false: (a) If you use data from Table 8.3 on bond enthalpies, you can show that the more $\mathrm{C}-\mathrm{H}$ bonds a molecule has compared to $\mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{H}$ bonds, the more energy it can store. (b) Trans fats are saturated. (c) Fatty acids are long-chain carboxylic acids. (d) Monounsaturated fatty acids have one CC single bond in the chain, while the rest are double or triple bonds.

## Nucleic Acids (Section 24.10)

24.75 Adenine and guanine are members of a class of molecules known as purines; they have two rings in their structure. Thymine and cytosine, on the other hand, are pyrimidines, and have only one ring in their structure. Predict which have larger dispersion forces in aqueous solution, the purines or the pyrimidines.
24.76 A nucleoside consists of an organic base of the kind shown in Section 24.10, bound to ribose or deoxyribose. Draw the
structure for deoxyguanosine, formed from guanine and deoxyribose.
24.77 What is the DNA sequence for the molecule shown here?

24.78 You are working in a biotechnology lab and are analyzing DNA. You obtain a sample of a short dodecamer of DNA that contains 12 base pairs. (a) What must the ratio of adenine to thymine be in your sample? (b) What must the ratio of cytosine to guanine be in your sample? (c) Assume the counterions present in your DNA solution are sodium ions. How many sodium ions must there be per dodecamer? Assume the 5' end phosphates each bear a-1 charge.
24.79 Imagine a single DNA strand containing a section with the following base sequence: $5^{\prime}$-AGTTACTGG-3'. What is the base sequence of the complementary strand?
24.80 Which statement best explains the chemical differences between DNA and RNA? (a) DNA has two different sugars in its sugar-phosphate backbone, but RNA only has one. (b) Thymine is one of the DNA bases, whereas RNA's corresponding base is thymine minus a methyl group. (c) The RNA sugar-phosphate backbone contains fewer oxygen atoms than DNA's backbone. (d) DNA forms double helices but RNA cannot.

## Additional Exercises

24.81 Draw the condensed structural formulas for two different molecules with the formula $\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{O}$.
24.82 How many structural isomers are there for a five-member straight carbon chain with one double bond? For a six-member straight carbon chain with two double bonds?
24.83 (a) Draw the condensed structural formulas for the cis and trans isomers of 3-methyl-3-hexene. (b) Can cyclohexene exhibit cis-trans isomerism? Explain. (c) Does 2-hexyne have geometric isomers? Explain.
24.84 If a molecule is an "ene-ol," what functional groups must it have? The suffix -ene signifies an alkene, -ol an alcohol. The molecule has alkene and alcohol functional groups.
24.85 Identify each of the functional groups in these molecules:
(a)

(Responsible for the odor of almonds)
(b)

(Responsible for the odor of vanilla)
(c)

(serotonin, a neurotransmitter)
(d)

(citric acid, a weak acid naturally present in citric fruits)
24.86 For the molecules shown in 24.85, (a) Which one(s) of them, if any, would produce a basic solution if dissolved in water? (b) Which one(s) of them, if any, would produce an acidic solution if dissolved in water? (c) Which of them is the most water-soluble?
24.87 Write a condensed structural formula for each of the following: (a) an amide with the formula $\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{NO},(\mathbf{b})$ a cyclic ether with the formula $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O},(\mathbf{c})$ a diketone compound with the formula $\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{O}_{2},(\mathbf{d})$ a phenyl carboxylic acid with the formula $\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{2}$.
24.88 Draw each molecule given its name and the following information. (a) Nitroglycerin, also known as 1,2,3-trinitroxypropane, the active ingredient in dynamite
and a medication administered to people having a heart attack, (Hint: The nitroxy group is the conjugate base of nitric acid.) (b) Putrescine, also known as 1,4-diaminobutane, the compound responsible for the odor of putrefying fish, (c) Cyclohexanone, the precursor to Nylon, (d) 1,1,2,2-tetrafluoroethene, the precursor to Teflon, (e) Oleic acid, also known as cis-9-octanedecenoic acid, a monounsaturated fatty acid found in many fats and oils. Draw the correct isomer.
[24.89] Indole smells terrible in high concentrations but has a pleasant floral-like odor when highly diluted. Its structure is

The molecule is planar, and the nitrogen is a very weak base, with $K_{b}=2 \times 10^{-12}$. Explain how this information indicates that the indole molecule is aromatic.
24.90 For each molecule below, identify its functional groups and how many chiral centers it contains.
(a)

(b)

24.91 Which of the following peptides have a net positive charge at pH 7 ? (a) Asn-His-Arg, (b) Glu-Lys-Phe, (c) Thr-Leu-Ala.
24.92 Glutathione is a tripeptide found in most living cells. Partial hydrolysis yields Cys-Gly and Glu-Cys. What structures are possible for glutathione?
24.93 Monosaccharides can be categorized in terms of the number of carbon atoms (pentoses have five carbons and hexoses have six carbons) and according to whether they contain an aldehyde (aldo- prefix, as in aldopentose) or ketone group (keto- prefix, as in ketopentose). Classify glucose and fructose in this way.
24.94 Can a DNA strand bind to a complementary RNA strand? Explain.

## Integrative Exercises

24.95 You have samples of four compounds: diethyl ether, butane, 1 -chlorobutane, and ethylene glycol. You measure the boiling points of the compounds as $-0.5^{\circ} \mathrm{C}, 35^{\circ} \mathrm{C}$, $77^{\circ} \mathrm{C}$, and $195^{\circ} \mathrm{C}$, but then lose the labels for each sample. Make the following predictions: (a) Which compound boils at $-0.5^{\circ} \mathrm{C}$ ? (b) Which boils at $35^{\circ} \mathrm{C}$ ? (c) Which boils at $77^{\circ} \mathrm{C}$ ? (d) Which boils at $195^{\circ} \mathrm{C}$ ?
[24.96] An unknown organic compound is found on elemental analysis to contain $72.0 \%$ carbon, $12.0 \%$ hydrogen, and $16.0 \%$ oxygen by mass. It has a molecular weight of $100 \mathrm{~g} / \mathrm{mol}$ and is slightly soluble in water. Upon careful oxidation it is converted into a ketone which contains $73.4 \%$ carbon, $10.3 \%$ hydrogen, and $16.3 \%$ oxygen by mass. Indicate two or more reasonable structures for the unknown.
24.97 An organic compound is analyzed and found to contain $62.0 \%$ carbon, $10.4 \%$ hydrogen, and $27.6 \%$ oxygen by mass. The compound boils at $48.8^{\circ} \mathrm{C}$. At $25^{\circ} \mathrm{C}$ and 76.5 kPa , the vapor has a density of $1.8 \mathrm{~g} / \mathrm{L}$. The compound has a carbonyl group and can be oxidized to a carboxylic acid. Suggest a structure for the compound.
24.98 An unknown substance is found to contain only carbon and hydrogen. It is a liquid that boils at $49^{\circ} \mathrm{C}$ at 101.3 kPa pressure. Upon analysis it is found to contain $85.7 \%$ carbon and $14.3 \%$ hydrogen by mass. At $100^{\circ} \mathrm{C}$ and 97.99 kPa , the vapor of this unknown has a density of $2.21 \mathrm{~g} / \mathrm{L}$. When it is dissolved in hexane solution and bromine water is added, no reaction occurs. What is the identity of the unknown compound?
24.99 The standard free energy of formation of solid maltose is $-1334.42 \mathrm{~kJ} / \mathrm{mol}$, whereas that of solid glucose is $-910.56 \mathrm{~kJ} / \mathrm{mol}$. What is $\Delta G^{\circ}$ for the condensation of two glucose molecules to form maltose?
24.100 A typical amino acid with one amino group and one carboxylic acid group, such as serine, can exist in water in
several ionic forms. (a) Suggest the forms of the amino acid at low pH and at high pH . (b) Amino acids generally have two $\mathrm{p} K_{a}$ values, one in the range of 2 to 3 and the other in the range of 9 to 10 . Serine, for example, has $\mathrm{p} K_{a}$ values of 2.19 and 9.21 . Using species such as acetic acid and ammonia as models, suggest the origin of the two $\mathrm{p} K_{a}$ values. (c) Glutamic acid is an amino acid that has three $\mathrm{p} K_{a}$ 's: 2.10, 4.07, and 9.47. Draw the structure of glutamic acid, and assign each $\mathrm{p} K_{a}$ to the appropriate part of the molecule. (d) An unknown amino acid is titrated with strong base, producing the following titration curve. Which amino acids are likely candidates for the unknown?

[24.101] The protein ribonuclease A in its native, or most stable, form is folded into a compact globular shape:

Native ribonuclease A
(a) Does the native form have a lower or higher free energy than the denatured form, in which the protein is an extended chain? (b) What is the sign of the system's entropy change in going from the denatured to the folded form? (c) In the native form, the molecule has
four $-S-S$ - bonds that bridge parts of the chain. What effect do you predict these four linkages to have on the free energy and entropy of the native form relative to the free energy and entropy of a hypothetical folded structure that does not have any - $\mathrm{S}-\mathrm{S}-$ linkages? Explain. (d) A gentle reducing agent converts the four $-S-S-$ linkages in ribonuclease A to eight - S - H bonds. What effect do you predict this conversion to have on the tertiary structure and entropy of the protein? (e) Which amino acid must be present for -SH bonds to exist in ribonuclease A?
24.102 The amino acid glycine can act as a weak acid:

If the $1^{\text {st }} \mathrm{p} K_{a}$ for the protonated amino group of glycine is 9.8 , what is the ratio of the neutral to anionic form of glycine in blood at pH 7.4 ?

## Design an Experiment

Quaternary structures of proteins arise if two or more smaller polypeptides or proteins associate with each other to make a much larger protein structure. The association is due to the same hydrogen bonding, electrostatic, and dispersion forces we have seen before. Hemoglobin, the protein used to transport oxygen molecules in our blood, is an example of a protein that has quaternary structure.

Hemoglobin is a tetramer; it is made of four smaller polypeptides, two "alphas" and two "betas." (These names do not imply anything about the number of alpha helices or beta sheets in the individual polypeptides.) Design a set of experiments that would provide sound evidence that hemoglobin exists as a tetramer and not as one enormous polypeptide chain.

## MATHEMATICAL OPERATIONS

## A. 1 | Exponential Notation

The numbers used in chemistry are often either extremely large or extremely small. Such numbers are conveniently expressed in the form

$$
N \times 10^{n}
$$

where $N$ is a number between 1 and 10 , and $n$ is the exponent. Some examples of this exponential notation, which is also called scientific notation, follow.

$$
\begin{array}{ll}
1,200,000 \text { is } 1.2 \times 10^{6} & \text { (read "one point two multi ten to the sixth power") } \\
0.000604 \text { is } 6.04 \times 10^{-4} & \begin{array}{l}
\text { (read "six point zero four times ten to the negative fourth } \\
\text { power") }
\end{array}
\end{array}
$$

A positive exponent, as in the first example, tells us how many times a number must be multiplied by 10 to give the long form of the number:

$$
\begin{aligned}
1.2 \times 10^{6} & =1.2 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \quad(\text { six tens }) \\
& =1,200,000
\end{aligned}
$$

It is also convenient to think of the positive exponent as the number of places the decimal point must be moved to the left to obtain a number greater than 1 and less than 10. For example, if we begin with 3450 and move the decimal point three places to the left, we end up with $3.45 \times 10^{3}$.

In a related fashion, a negative exponent tells us how many times we must divide a number by 10 to give the long form of the number.

$$
6.04 \times 10^{-4}=\frac{6.04}{10 \times 10 \times 10 \times 10}=0.000604
$$

It is convenient to think of the negative exponent as the number of places the decimal point must be moved to the right to obtain a number greater than 1 but less than 10. For example, if we begin with 0.0048 and move the decimal point three places to the right, we end up with $4.8 \times 10^{-3}$.

In the system of exponential notation, with each shift of the decimal point one place to the right, the exponent decreases by 1 :

$$
4.8 \times 10^{-3}=48 \times 10^{-4}
$$

Similarly, with each shift of the decimal point one place to the left, the exponent increases by 1 :

$$
4.8 \times 10^{-3}=0.48 \times 10^{-2}
$$

Many scientific calculators have a key labeled EXP or EE, which is used to enter numbers in exponential notation. To enter the number $5.8 \times 10^{3}$ on such a calculator, the key sequence is

On some calculators the display will show 5.8 , then a space, followed by 03 , the exponent. On other calculators, a small 10 is shown with an exponent 3 .

To enter a negative exponent, use the key labeled $+/-$. For example, to enter the number $8.6 \times 10^{-5}$, the key sequence is

$$
8 \cdot 6 \sqrt{8} \cdot \sqrt{6 X P}+/-5
$$

When entering a number in exponential notation, do not key in the 10 if you use the EXP or EE button.

In working with exponents, it is important to recall that $10^{0}=1$. The following rules are useful for carrying exponents through calculations.

1. Addition and Subtraction In order to add or subtract numbers expressed in exponential notation, the powers of 10 must be the same.

$$
\begin{aligned}
\left(5.22 \times 10^{4}\right)+\left(3.21 \times 10^{2}\right) & =\left(522 \times 10^{2}\right)+\left(3.21 \times 10^{2}\right) \\
& =525 \times 10^{2}(3 \text { significant figures }) \\
& =5.25 \times 10^{4} \\
\left(6.25 \times 10^{-2}\right)-\left(5.77 \times 10^{-3}\right) & =\left(6.25 \times 10^{-2}\right)-\left(0.577 \times 10^{-2}\right) \\
& =5.67 \times 10^{-2} \quad(3 \text { significant figures })
\end{aligned}
$$

When you use a calculator to add or subtract, you need not be concerned with having numbers with the same exponents because the calculator automatically takes care of this matter.
2. Multiplication and Division When numbers expressed in exponential notation are multiplied, the exponents are added; when numbers expressed in exponential notation are divided, the exponent of the denominator is subtracted from the exponent of the numerator.

$$
\begin{aligned}
\left(5.4 \times 10^{2}\right)\left(2.1 \times 10^{3}\right) & =(5.4)(2.1) \times 10^{2+3} \\
& =11 \times 10^{5} \\
& =1.1 \times 10^{6} \\
\left(1.2 \times 10^{5}\right)\left(3.22 \times 10^{-3}\right) & =(1.2)(3.22) \times 10^{5+(-3)}=3.9 \times 10^{2} \\
\frac{3.2 \times 10^{5}}{6.5 \times 10^{2}} & =\frac{3.2}{6.5} \times 10^{5-2}=0.49 \times 10^{3}=4.9 \times 10^{2} \\
\frac{5.7 \times 10^{7}}{8.5 \times 10^{-2}} & =\frac{5.7}{8.5} \times 10^{7-(-2)}=0.67 \times 10^{9}=6.7 \times 10^{8}
\end{aligned}
$$

3. Powers and Roots When numbers expressed in exponential notation are raised to a power, the exponents are multiplied by the power. When the roots of numbers expressed in exponential notation are taken, the exponents are divided by the root.

$$
\begin{aligned}
\left(1.2 \times 10^{5}\right)^{3} & =(1.2)^{3} \times 10^{5 \times 3} \\
& =1.7 \times 10^{15} \\
\sqrt[3]{2.5 \times 10^{6}} & =\sqrt[3]{2.5} \times 10^{6 / 3} \\
& =1.3 \times 10^{2}
\end{aligned}
$$

Scientific calculators usually have keys labeled $x^{2}$ and $\sqrt{x}$ for squaring and taking the square root of a number, respectively. To take higher powers or roots, many calculators have $y^{x}$ and $\sqrt[x]{y}$ (or INV $y^{x}$ ) keys. For example, to perform the operation $\sqrt[3]{7.5} \times 10^{-4}$ on such a calculator, you would key in $7.5 \times 10^{-4}$, press the $\sqrt[x]{y}$ key (or the INV and then the $y^{x}$ keys), enter the root, 3 , and finally press $=$. The result is $9.1 \times 10^{-2}$.

## Sample Exercise 1

## Using Exponential Notation

Perform each of the following operations, using your calculator where possible:
(a) Write the number 0.0054 in standard exponential notation. (b) $\left(5.0 \times 10^{-2}\right)+\left(4.7 \times 10^{-3}\right)(c)\left(5.98 \times 10^{12}\right)$
$\left(2.77 \times 10^{-5}\right)(d) \sqrt[4]{1.75 \times 10^{-12}}$

## SOLUTION

(a) Because we move the decimal point three places to the right to convert 0.0054 to 5.4 , the exponent is -3 :

$$
5.4 \times 10^{-3}
$$

Scientific calculators are generally able to convert numbers to exponential notation using one or two keystrokes; frequently "SCI" for "scientific notation" will convert a number into exponential notation. Consult your instruction manual to see how this operation is accomplished on your calculator.
(b) To add these numbers longhand, we must convert them to the same exponent.

$$
\left(5.0 \times 10^{-2}\right)+\left(0.47 \times 10^{-2}\right)=(5.0+0.47) \times 10^{-2}=5.5 \times 10^{-2}
$$

(c) Performing this operation longhand, we have

$$
(5.98 \times 2.77) \times 10^{12-5}=16.6 \times 10^{7}=1.66 \times 10^{8}
$$

(d) To perform this operation on a calculator, we enter the number, press the $\sqrt[x]{y}$ key (or the INV and $y^{x}$ keys), enter 4 , and press the $=$ key. The result is $1.15 \times 10^{-3}$.

## Practice Exercise

Perform the following operations:
(a) Write 67,000 in exponential notation, showing two significant figures.
(b) $\left(3.378 \times 10^{-3}\right)-\left(4.97 \times 10^{-5}\right)$
(c) $\left(1.84 \times 10^{15}\right)\left(7.45 \times 10^{-2}\right)$
(d) $\left(6.67 \times 10^{-8}\right)^{3}$

## A. 2 | Logarithms

## Common Logarithms

The common, or base-10, logarithm (abbreviated $\log$ ) of any number is the power to which 10 must be raised to equal the number. For example, the common logarithm of 1000 (written log 1000) is 3 because raising 10 to the third power gives 1000 .

$$
10^{3}=1000, \text { therefore, } \log 1000=3
$$

Further examples are

$$
\begin{aligned}
\log 10^{5} & =5 \\
\log 1 & =0 \quad \text { Remember that } 10^{0}=1 \\
\log 10^{-2} & =-2
\end{aligned}
$$

In these examples the common logarithm can be obtained by inspection. However, it is not possible to obtain the logarithm of a number such as 31.25 by inspection. The logarithm of 31.25 is the number $x$ that satisfies the following relationship:

$$
10^{x}=31.25
$$

Most electronic calculators have a key labeled LOG that can be used to obtain logarithms. For example, on many calculators we obtain the value of $\log 31.25$ by entering 31.25 and pressing the LOG key. We obtain the following result:

$$
\log 31.25=1.4949
$$

Notice that 31.25 is greater than $10\left(10^{1}\right)$ and less than $100\left(10^{2}\right)$. The value for log 31.25 is accordingly between $\log 10$ and $\log 100$, that is, between 1 and 2 .

## Significant Figures and Common Logarithms

For the common logarithm of a measured quantity, the number of digits after the decimal point equals the number of significant figures in the original number. For example, if 23.5 is a measured quantity (three significant figures), then $\log 23.5=1.371$ (three significant figures after the decimal point).

## Antilogarithms

The process of determining the number that corresponds to a certain logarithm is known as obtaining an antilogarithm. It is the reverse of taking a logarithm. For example, we saw previously that $\log 23.5=1.371$. This means that the antilogarithm of 1.371 equals 23.5 .

$$
\begin{aligned}
\log 23.5 & =1.371 \\
\text { antilog } 1.371 & =23.5
\end{aligned}
$$

The process of taking the antilog of a number is the same as raising 10 to a power equal to that number.

$$
\operatorname{antilog} 1.371=10^{1.371}=23.5
$$

Many calculators have a key labeled $10^{x}$ that allows you to obtain antilogs directly. On others, it will be necessary to press a key labeled INV (for inverse), followed by the LOG key.

## Natural Logarithms

Logarithms based on the number $e$ are called natural, or base $e$, logarithms (abbreviated $\ln$ ). The natural $\log$ of a number is the power to which $e$ (which has the value 2.71828...) must be raised to equal the number. For example, the natural $\log$ of 10 equals 2.303.

$$
e^{2.303}=10, \text { therefore } \ln 10=2.303
$$

Your calculator probably has a key labeled LN that allows you to obtain natural logarithms. For example, to obtain the natural $\log$ of 46.8 , you enter 46.8 and press the LN key.

$$
\ln 46.8=3.846
$$

The natural antilog of a number is $e$ raised to a power equal to that number. If your calculator can calculate natural logs, it will also be able to calculate natural antilogs. On some calculators there is a key labeled $e^{x}$ that allows you to calculate natural antilogs directly; on others, it will be necessary to first press the INV key followed by the LN key. For example, the natural antilog of 1.679 is given by

$$
\text { Natural antilog } 1.679=e^{1.679}=5.36
$$

The relation between common and natural logarithms is as follows:

$$
\ln a=2.303 \log a
$$

Notice that the factor relating the two, 2.303 , is the natural $\log$ of 10 , which we calculated earlier.

## Mathematical Operations Using Logarithms

Because logarithms are exponents, mathematical operations involving logarithms follow the rules for the use of exponents. For example, the product of $z^{a}$ and $z^{b}$ (where $z$ is any number) is given by

$$
z^{a} \cdot z^{b}=z^{(a+b)}
$$

Similarly, the logarithm (either common or natural) of a product equals the sum of the logs of the individual numbers.

$$
\log a b=\log a+\log b \quad \ln a b=\ln a+\ln b
$$

For the $\log$ of a quotient,

$$
\log (a / b)=\log a-\log b \quad \ln (a / b)=\ln a-\ln b
$$

Using the properties of exponents, we can also derive the rules for the logarithm of a number raised to a certain power.

$$
\begin{aligned}
\log a^{n} & =n \log a & & \ln a^{n}=n \ln a \\
\log a^{1 / n} & =(1 / n) \log a & & \ln a^{1 / n}=(1 / n) \ln a
\end{aligned}
$$

## pH Problems

One of the most frequent uses for common logarithms in general chemistry is in working pH problems. The pH is defined as $-\log \left[\mathrm{H}^{+}\right]$, where $\left[\mathrm{H}^{+}\right]$is the hydrogen ion concentration of a solution. $0 \infty$ (Section 16.4) The following sample exercise illustrates this application.

## Sample Exercise 2

## Using Logarithms

(a) What is the pH of a solution whose hydrogen ion concentration is 0.015 M ?
(b) If the pH of a solution is 3.80, what is its hydrogen ion concentration?

## SOLUTION

(1) We are given the value of $\left[\mathrm{H}^{+}\right]$. We use the LOG key of our calculator to calculate the value of $\log \left[\mathrm{H}^{+}\right]$. The pH is obtained by changing the sign of the value obtained. (Be sure to change the sign after taking the logarithm.)

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =0.015 \\
\log \left[\mathrm{H}^{+}\right] & =-1.82 \quad(2 \text { significant figures }) \\
\mathrm{pH} & =-(-1.82)=1.82
\end{aligned}
$$

(2) To obtain the hydrogen ion concentration when given the pH , we must take the antilog of -pH .

$$
\begin{aligned}
\mathrm{pH} & =-\log \left[\mathrm{H}^{+}\right]=3.80 \\
\log \left[\mathrm{H}^{+}\right] & =-3.80 \\
{\left[\mathrm{H}^{+}\right] } & =\operatorname{antilog}(-3.80)=10^{-3.80}=1.6 \times 10^{-4} \mathrm{M}
\end{aligned}
$$

## Practice Exercise

Perform the following operations:
(a) $\log \left(2.5 \times 10^{-5}\right)$
(b) $\ln 32.7$
(c) antilog -3.47
(d) $e^{-1.89}$

## A. 3 | Quadratic Equations

An algebraic equation of the form $a x^{2}+b x+c=0$ is called a quadratic equation. The two solutions to such an equation are given by the quadratic formula:

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

Many calculators today can calculate the solutions to a quadratic equation with one or two keystrokes. Most of the time, $x$ corresponds to the concentration of a chemical species in solution. Only one of the solutions will be a positive number, and that is the one you should use; a "negative concentration" has no physical meaning.

## Sample Exercise 3

## Using the Quadratic Formula

Find the values of $x$ that satisfy the equation $2 x^{2}+4 x=1$.

## SOLUTION

To solve the given equation for x , we must first put it in the form

$$
a x^{2}+b x+c=0
$$

and then use the quadratic formula. If

$$
2 x^{2}+4 x=1
$$

then

$$
2 x^{2}+4 x-1=0
$$

Using the quadratic formula, where $a=2, b=4$, and $c=-1$, we have

$$
\begin{aligned}
x & =\frac{-4 \pm \sqrt{4^{2}-4(2)(-1)}}{2(2)} \\
& =\frac{-4 \pm \sqrt{16+8}}{4}=\frac{-4 \pm \sqrt{24}}{4}=\frac{-4 \pm 4.899}{4}
\end{aligned}
$$

The two solutions are

$$
x=\frac{0.899}{4}=0.225 \text { and } x=\frac{-8.899}{4}=-2.225
$$

If this was a problem in which $x$ represented a concentration, we would say $x=0.225$ (in the appropriate units), since a negative number for concentration has no physical meaning.

## A. 4 | Graphs

Often the clearest way to represent the interrelationship between two variables is to graph them. Usually, the variable that is being experimentally varied, called the independent variable, is shown along the horizontal axis ( $x$-axis). The variable that responds to the change in the independent variable, called the dependent variable,

A Figure A. 1 A graph of pressure versus temperature yields a straight line for the data.
is then shown along the vertical axis ( $y$-axis). For example, consider an experiment in which we vary the temperature of an enclosed gas and measure its pressure. The independent variable is temperature and the dependent variable is pressure. The data shown in Table A. 1 can be obtained by means of this experiment. These data are shown graphically in Figure A.1. The relationship between temperature and pressure is linear. The equation for any straight-line graph has the form

$$
y=m x+b
$$

where $m$ is the slope of the line and $b$ is the intercept with the $y$-axis. In the case of Figure A.1, we could say that the relationship between temperature and pressure takes the form

$$
P=m T+b
$$

where $P$ is pressure in kPa and $T$ is temperature in ${ }^{\circ} \mathrm{C}$. As shown in Figure A.1, the slope is $0.0403 \mathrm{kPa} /{ }^{\circ} \mathrm{C}$, and the intercept-the point where the line crosses the $y$-axis-is 11.35 kPa . Therefore, the equation for the line is

$$
P=\left(0.0403 \mathrm{kPa} /{ }^{\circ} \mathrm{C}\right) T+11.35 \mathrm{kPa}
$$

## A. 5 | Standard Deviation

The standard deviation from the mean, $s$, is a common method for describing precision in experimentally determined data. We define the standard deviation as

$$
s=\sqrt{\frac{\sum_{i=1}^{N}\left(x_{i}-\bar{x}\right)^{2}}{N-1}}
$$

where $N$ is the number of measurements, $\bar{x}$ is the average (also called the mean) of the measurements, and xi represent the individual measurements. Electronic calculators with built-in statistical functions can calculate $s$ directly by inputting the individual measurements.

A smaller value of $s$ indicates a higher precision, meaning that the data are more closely clustered around the average. The standard deviation has statistical significance. If a large number of measurements is made, $68 \%$ of the measured values is expected to be within one standard deviation of the average, assuming only random errors are associated with the measurements.

TABLE A. 1 Interrelation between Pressure and Temperature

| Temperature ( $\left.{ }^{\circ} \mathrm{C}\right)$ | Pressure (kPa) |
| :---: | :---: |
| 20.0 | 12.16 |
| 30.0 | 12.56 |
| 40.0 | 12.97 |
| 50.0 | 13.37 |

## Sample Exercise 4

Calculating an Average and Standard Deviation
The percent carbon in a sugar is measured four times: $42.01 \%, 42.28 \%, 41.79 \%$, and $42.25 \%$. Calculate (a) the average and (b) the standard deviation for these measurements.

## SOLUTION

(a) The average is found by adding the quantities and dividing by the number of measurements:

$$
\bar{x}=\frac{42.01+42.28+41.79+42.25}{4}=\frac{168.33}{4}=42.08
$$

(b) The standard deviation is found using the preceding equation:

$$
s=\sqrt{\frac{\sum_{i=1}^{N}\left(x_{i}-\bar{x}\right)^{2}}{N-1}}
$$

Let's tabulate the data so the calculation of $\sum_{i=1}^{N}\left(x_{i}-\bar{x}\right)^{2}$ can be seen
clearly.

> Difference between

Measurement
Square of

| Percent C | and Average, $\left(x_{i}-x\right)$ | Difference, $\left(x_{\mathrm{i}}-x\right)^{2}$ |
| :---: | :--- | ---: |
| 42.01 | $42.01-42.08=-0.07$ | $(-0.07)^{2}=0.005$ |
| 42.28 | $42.28-42.08=0.20$ | $(0.20)^{2}=0.040$ |
| 41.79 | $41.79-42.08=-0.29$ | $(-0.29)^{2}=0.084$ |
| 42.25 | $42.25-42.08=0.17$ | $(0.17)^{2}=0.029$ |

The sum of the quantities in the last column is

$$
\sum_{i=1}^{N}\left(x_{i}-\bar{x}\right)^{2}=0.005+0.040+0.084+0.029=0.16
$$

Thus, the standard deviation is

$$
s=\sqrt{\frac{\sum_{i=1}^{N}\left(x_{i}-\bar{x}\right)^{2}}{N-1}}=\sqrt{\frac{0.16}{4-1}}=\sqrt{\frac{0.16}{3}}=\sqrt{0.053}=0.23
$$

Based on these measurements, it would be appropriate to represent the measured percent carbon as $42.08 \pm 0.23$.

## AQUEOUS EQUILIBRIUM CONSTANTS

TABLE D. 1 Dissociation Constants for Acids at $25^{\circ} \mathrm{C}$

| Name | Formula | $K_{\text {a1 }}$ | $K_{\text {a2 }}$ | $K_{\text {a3 }}$ |
| :---: | :---: | :---: | :---: | :---: |
| Acetic acid | $\mathrm{CH}_{3} \mathrm{COOH}\left(\right.$ or $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ ) | $1.8 \times 10^{-5}$ |  |  |
| Arsenic acid | $\mathrm{H}_{3} \mathrm{AsO}_{4}$ | $5.6 \times 10^{-3}$ | $1.0 \times 10^{-7}$ | $3.0 \times 10^{-12}$ |
| Arsenous acid | $\mathrm{H}_{3} \mathrm{AsO}_{3}$ | $5.1 \times 10^{-10}$ |  |  |
| Ascorbic acid | $\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}$ | $8.0 \times 10^{-5}$ | $1.6 \times 10^{-12}$ |  |
| Benzoic acid | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\left(\right.$ or $\mathrm{HC}_{7} \mathrm{H}_{5} \mathrm{O}_{2}$ ) | $6.3 \times 10^{-5}$ |  |  |
| Boric acid | $\mathrm{H}_{3} \mathrm{BO}_{3}$ | $5.8 \times 10^{-10}$ |  |  |
| Butanoic acid | $\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{COOH}\left(\right.$ or $\mathrm{HC}_{4} \mathrm{H}_{7} \mathrm{O}_{2}$ ) | $1.5 \times 10^{-5}$ |  |  |
| Carbonic acid | $\mathrm{H}_{2} \mathrm{CO}_{3}$ | $4.3 \times 10^{-7}$ | $5.6 \times 10^{-11}$ |  |
| Chloroacetic acid | $\mathrm{CH}_{2} \mathrm{ClCOOH}$ (or $\mathrm{HC}_{2} \mathrm{H}_{2} \mathrm{O}_{2} \mathrm{Cl}$ ) | $1.4 \times 10^{-3}$ |  |  |
| Chlorous acid | $\mathrm{HClO}_{2}$ | $1.1 \times 10^{-2}$ |  |  |
| Citric acid | $\mathrm{HOOCC}(\mathrm{OH})\left(\mathrm{CH}_{2} \mathrm{COOH}\right)_{2}\left(\right.$ or $\left.\mathrm{H}_{3} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)$ | $7.4 \times 10^{-4}$ | $1.7 \times 10^{-5}$ | $4.0 \times 10^{-7}$ |
| Cyanic acid | HCNO | $3.5 \times 10^{-4}$ |  |  |
| Formic acid | $\mathrm{HCOOH}\left(\mathrm{or} \mathrm{HCHO}_{2}\right.$ ) | $1.8 \times 10^{-4}$ |  |  |
| Hydroazoic acid | $\mathrm{HN}_{3}$ | $1.9 \times 10^{-5}$ |  |  |
| Hydrocyanic acid | HCN | $4.9 \times 10^{-10}$ |  |  |
| Hydrofluoric acid | HF | $6.8 \times 10^{-4}$ |  |  |
| Hydrogen chromate ion | $\mathrm{HCrO}_{4}^{-}$ | $3.0 \times 10^{-7}$ |  |  |
| Hydrogen peroxide | $\mathrm{H}_{2} \mathrm{O}_{2}$ | $2.4 \times 10^{-12}$ |  |  |
| Hydrogen selenate ion | $\mathrm{HSeO}_{4}^{-}$ | $2.2 \times 10^{-2}$ |  |  |
| Hydrogen sulfide | $\mathrm{H}_{2} \mathrm{~S}$ | $9.5 \times 10^{-8}$ | $1 \times 10^{-19}$ |  |
| Hypobromous acid | HBrO | $2.5 \times 10^{-9}$ |  |  |
| Hypochlorous acid | HClO | $3.0 \times 10^{-8}$ |  |  |
| Hypoiodous acid | HIO | $2.3 \times 10^{-11}$ |  |  |
| Iodic acid | $\mathrm{HIO}_{3}$ | $1.7 \times 10^{-1}$ |  |  |
| Lactic acid | $\mathrm{CH}_{3} \mathrm{CH}(\mathrm{OH}) \mathrm{COOH}\left(\right.$ or $\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{3}$ ) | $1.4 \times 10^{-4}$ |  |  |
| Malonic acid | $\mathrm{CH}_{2}(\mathrm{COOH})_{2}\left(\right.$ or $\left.\mathrm{H}_{2} \mathrm{C}_{3} \mathrm{H}_{2} \mathrm{O}_{4}\right)$ | $1.5 \times 10^{-3}$ | $2.0 \times 10^{-6}$ |  |
| Nitrous acid | $\mathrm{HNO}_{2}$ | $4.5 \times 10^{-4}$ |  |  |
| Oxalic acid | $(\mathrm{COOH})_{2}\left(\right.$ or $\left.\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ | $5.9 \times 10^{-2}$ | $6.4 \times 10^{-5}$ |  |
| Paraperiodic acid | $\mathrm{H}_{5} \mathrm{IO}_{6}$ | $2.8 \times 10^{-2}$ | $5.3 \times 10^{-9}$ |  |
| Phenol | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\left(\right.$ or $\mathrm{HC}_{6} \mathrm{H}_{5} \mathrm{O}$ ) | $1.3 \times 10^{-10}$ |  |  |
| Phosphoric acid | $\mathrm{H}_{3} \mathrm{PO}_{4}$ | $7.5 \times 10^{-3}$ | $6.2 \times 10^{-8}$ | $4.2 \times 10^{-13}$ |
| Propionic acid | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{COOH}\left(\right.$ or $\mathrm{HC}_{3} \mathrm{H}_{5} \mathrm{O}_{2}$ ) | $1.3 \times 10^{-5}$ |  |  |
| Pyrophosphoric acid | $\mathrm{H}_{4} \mathrm{P}_{2} \mathrm{O}_{7}$ | $3.0 \times 10^{-2}$ | $4.4 \times 10^{-3}$ | $2.1 \times 10^{-7}$ |
| Selenous acid | $\mathrm{H}_{2} \mathrm{SeO}_{3}$ | $2.3 \times 10^{-3}$ | $5.3 \times 10^{-9}$ |  |
| Sulfuric acid | $\mathrm{H}_{2} \mathrm{SO}_{4}$ | Strong acid | $1.2 \times 10^{-2}$ |  |
| Sulfurous acid | $\mathrm{H}_{2} \mathrm{SO}_{3}$ | $1.7 \times 10^{-2}$ | $6.4 \times 10^{-8}$ |  |
| Tartaric acid | $\mathrm{HOOC}(\mathrm{CHOH})_{2} \mathrm{COOH}\left(\right.$ or $\mathrm{H}_{2} \mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}_{6}$ ) | $1.0 \times 10^{-3}$ |  |  |

## TABLE D. 2 Dissociation Constants for Bases at $25^{\circ} \mathrm{C}$

| Name | Formula | $K_{b}$ |
| :--- | :--- | :--- |
| Ammonia | $\mathrm{NH}_{3}$ | $1.8 \times 10^{-5}$ |
| Aniline | $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ | $4.3 \times 10^{-10}$ |
| Dimethylamine | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ | $5.4 \times 10^{-4}$ |
| Ethylamine | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{NH}_{2}$ | $6.4 \times 10^{-4}$ |
| Hydrazine | $\mathrm{H}_{2} \mathrm{NNH}_{2}$ | $1.3 \times 10^{-6}$ |
| Hydroxylamine | $\mathrm{HONH}_{2}$ | $1.1 \times 10^{-8}$ |
| Methylamine | $\mathrm{CH}_{3} \mathrm{NH}_{2}$ | $4.4 \times 10^{-4}$ |
| Pyridine | $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ | $1.7 \times 10^{-9}$ |
| Trimethylamine | $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$ | $6.4 \times 10^{-5}$ |

TABLE D. 3 Solubility-Product Constants for Compounds at $25^{\circ} \mathrm{C}$

| Name | Formula | $K_{s p}$ | Name | Formula | $K_{s p}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Barium carbonate | $\mathrm{BaCO}_{3}$ | $5.0 \times 10^{-9}$ | Lead(II) fluoride | $\mathrm{PbF}_{2}$ | $3.6 \times 10^{-8}$ |
| Barium chromate | $\mathrm{BaCrO}_{4}$ | $2.1 \times 10^{-10}$ | Lead(II) sulfate | $\mathrm{PbSO}_{4}$ | $6.3 \times 10^{-7}$ |
| Barium fluoride | $\mathrm{BaF}_{2}$ | $1.7 \times 10^{-6}$ | Lead(II) sulfide* | PbS | $3 \times 10^{-28}$ |
| Barium oxalate | $\mathrm{BaC}_{2} \mathrm{O}_{4}$ | $1.6 \times 10^{-6}$ | Magnesium hydroxide | $\mathrm{Mg}(\mathrm{OH})_{2}$ | $1.8 \times 10^{-11}$ |
| Barium sulfate | $\mathrm{BaSO}_{4}$ | $1.1 \times 10^{-10}$ | Magnesium carbonate | $\mathrm{MgCO}_{3}$ | $3.5 \times 10^{-8}$ |
| Cadmium carbonate | $\mathrm{CdCO}_{3}$ | $1.8 \times 10^{-14}$ | Magnesium oxalate | $\mathrm{MgC}_{2} \mathrm{O}_{4}$ | $8.6 \times 10^{-5}$ |
| Cadmium hydroxide | $\mathrm{Cd}(\mathrm{OH})_{2}$ | $2.5 \times 10^{-14}$ | Manganese(II) carbonate | $\mathrm{MnCO}_{3}$ | $5.0 \times 10^{-10}$ |
| Cadmium sulfide* | CdS | $8 \times 10^{-28}$ | Manganese(II) hydroxide | $\mathrm{Mn}(\mathrm{OH})_{2}$ | $1.6 \times 10^{-13}$ |
| Calcium carbonate (calcite) | $\mathrm{CaCO}_{3}$ | $4.5 \times 10^{-9}$ | Manganese(II) sulfide* | MnS | $2 \times 10^{-53}$ |
| Calcium chromate | $\mathrm{CaCrO}_{4}$ | $4.5 \times 10^{-9}$ | Mercury(I) chloride | $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$ | $1.2 \times 10^{-18}$ |
| Calcium fluoride | $\mathrm{CaF}_{2}$ | $3.9 \times 10^{-11}$ | Mercury(I) iodide | $\mathrm{Hg}_{2} \mathrm{I}_{2}$ | $1.1 \times 10^{-1.1}$ |
| Calcium hydroxide | $\mathrm{Ca}(\mathrm{OH})_{2}$ | $6.5 \times 10^{-6}$ | Mercury(II) sulfide* | HgS | $2 \times 10^{-53}$ |
| Calcium phosphate | $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ | $2.0 \times 10^{-29}$ | Nickel(II) carbonate | $\mathrm{NiCO}_{3}$ | $1.3 \times 10^{-7}$ |
| Calcium sulfate | $\mathrm{CaSO}_{4}$ | $2.4 \times 10^{-5}$ | Nickel(II) hydroxide | $\mathrm{Ni}(\mathrm{OH})_{2}$ | $6.0 \times 10^{-16}$ |

## ANSWERS TO SELECTED EXERCISES

## Chapter 1

1.1 (a) Pure element: i (b) mixture of elements: v, vi (c) pure compound: iv (d) mixture of an element and a compound: ii, iii $\mathbf{1 . 3}$ (a) Homogeneous mixture (b) Yes, brass is a solution. $\mathbf{1 . 5}$ Filtration 1.7 (a) The aluminum sphere is lightest, then nickel, then silver. (b) The platinum cube is smallest, then gold, then lead. 1.9 (a) 7.5 cm ; two significant figures (sig figs) (b) $72 \mathrm{mi} / \mathrm{hr}$ (inner scale, two significant figures) or $115 \mathrm{~km} / \mathrm{hr}$ (outer scale, three significant figures) 1.11464 jelly beans. The mass of an average bean has 2 decimal places and 3 sig figs. The number of beans then has 3 sig figs, by the rules for multiplication and division. 1.13 (a) Homogeneous mixture (b) homogeneous mixture (c) pure substance $(\mathbf{d})$ homogeneous mixture. 1.15 (a) $\mathrm{He}(\mathbf{b}) \mathrm{Pt}(\mathbf{c}) \mathrm{Co}(\mathbf{d}) \mathrm{Sn}(\mathbf{e}) \mathrm{Ag}(\mathbf{f})$ antimony $(\mathbf{g})$ lead (h) bromine (i) vanadium (j) mercury $\mathbf{1 . 1 7} \mathrm{C}$ is a compound; it contains both carbon and oxygen. A is a compound; it contains at least carbon and oxygen. B is not defined by the data given; it is probably also a compound because few elements exist as white solids. 1.19 Physical properties: silvery white; lustrous; melting point $=649{ }^{\circ} \mathrm{C}$, boiling point $=1105{ }^{\circ} \mathrm{C}$; density at $20^{\circ} \mathrm{C}=1.738 \mathrm{~g} / \mathrm{cm}^{3}$; pounded into sheets; drawn into wires; good conductor. Chemical properties: burns in air; reacts with $\mathrm{Cl}_{2}$. 1.21 (a) Physical (b) chemical (c) physical (d) chemical (e) chemical $\mathbf{1 . 2 3}$ Evaporation 1.25 (a) $1.08 \times 10^{2} \mathrm{~J}$ (b) $2.58 \times 10^{1} \mathrm{cal}$ (c) The kinetic energy is converted mostly to heat. 1.27 (a) Kinetic energy (b) Potential energy decreases. 1.29 (a) $E_{\mathrm{k}}=11 \mathrm{~J}$; $\mathrm{v}=6.6 \mathrm{~m} / \mathrm{s} 1.31$ (a) $3 \times 10^{12} \mathrm{~m}$ (b) $2.5 \times 10^{-15} \mathrm{~s}(\mathbf{c}) 5.7 \times 10^{-5} \mathrm{~m}$ (d) $8.3 \times 10^{3} \mathrm{~kg} 1.33$ (a) $28^{\circ} \mathrm{C}$ (b) $84^{\circ} \mathrm{F}$ (c) $567 \mathrm{~K}(\mathbf{d}) 559^{\circ} \mathrm{C}$ (e) $838^{\circ} \mathrm{F}$ (f) $275 \mathrm{~K} \mathbf{1 . 3 5}$ (a) $1.62 \mathrm{~g} / \mathrm{mL}$. Tetrachloroethylene, $1.62 \mathrm{~g} / \mathrm{mL}$, is more dense than water, $1.00 \mathrm{~g} / \mathrm{mL}$; tetrachloroethylene will sink rather than float on water. (b) 11.7 g 1.37 (a) Calculated density $=0.86 \mathrm{~g} / \mathrm{mL}$. The substance is probably toluene, density $=0.866 \mathrm{~g} / \mathrm{mL}$. (b) 40.4 mL ethylene glycol (c) Yes, the graduated cylinder in Figure 1.21 will provide the appropriate level of accuracy. (d) $1.11 \times 10^{3} \mathrm{~g}$ nickel $1.394 \mathrm{Tg} 1.411054 \mathrm{~J} /$ Btu 1.43 Exact: (b), (d), and (f) $\mathbf{1 . 4 5}$ (a) 4 (b) 1 (c) $2(\mathbf{d}) 3(\mathbf{e}) 4\left(\right.$ g) $61.47(\mathbf{a}) 2.04 \times 10^{6}(\mathbf{b}) 2.93 \times 10^{-4}(\mathbf{c})-8.25 \times 10^{4}$ (d) $9.42 \times 10^{3}(\mathbf{e})-3.25 \times 10^{-6} \mathbf{1 . 4 9}$ (a) 43.052 (b) 879.30 (c) $2.14 \times 10^{3}(\mathbf{d}) 0.101 \mathbf{1 . 5 1} 5$ significant figures
1.53 (a) $\frac{2.54 \mathrm{~cm}}{1 \mathrm{in}}$ (b) $\frac{1 \mathrm{~kg}}{2.2 \mathrm{lb}} \times \frac{1 \mathrm{~g}}{1 \times 10^{-3} \mathrm{~kg}}$
(c) $\frac{1 \mu \mathrm{~g}}{1 \times 10^{-6} \mathrm{~kg}}(\mathbf{d}) \frac{(12)^{2} \mathrm{in}^{2}}{1^{2} \mathrm{ft}^{2}} \times \frac{(2.54)^{2} \mathrm{~cm}^{2}}{1^{2} \mathrm{in}^{2}}$
1.55 (a) $54.7 \mathrm{~km} / \mathrm{hr}$ (b) $1.3 \times 10^{3} \mathrm{gal}$ (c) 46.0 m (d) $0.984 \mathrm{in} / \mathrm{hr}$ 1.57 (a) $4.32 \times 10^{5} \mathrm{~s}$ (b) 88.5 m (c) $\$ 0.499 / \mathrm{L}$ (d) $46.6 \mathrm{~km} / \mathrm{hr}$ (e) $1.420 \mathrm{~L} / \mathrm{s}$ (f) $707.9 \mathrm{~cm}^{3} \mathbf{1 . 5 9}$ (a) $1.2 \times 10^{2} \mathrm{~L}$ (b) $5 \times 10^{2} \mathrm{mg}$ (c) $19.9 \mathrm{mi} / \mathrm{gal}\left(2 \times 10^{1} \mathrm{mi} / \mathrm{gal}\right.$ for 1 significant figure) (d) 1.81 kg $\mathbf{1 . 6 1} 67 \mathrm{~kg}$ air $\mathbf{1 . 6 3} \$ 9 \times 10^{4} \mathbf{1 . 6 7} 8.47 \mathrm{~g} \mathrm{O} \mathbf{1 . 6 9}$ (a) Set I, 22.51; set II, 22.61. Based on the average, set I is more accurate. (b) The average deviation for both set I and set II is 0.02 . The two sets display the same precision. 1.71 (a) Volume (b) time (c) length (d) density (e) temperature (f) speed (g) pressure $\mathbf{1 . 7 4}$ Substances (b), (f), and (g) are pure or nearly pure. $\mathbf{1 . 7 5}(\mathbf{a}) 1.13 \times 10^{5}$ quarters (b) $6.41 \times 10^{5} \mathrm{~g}$ (c) $\$ 2.83 \times 10^{4}(\mathbf{d}) 5.74 \times 10^{8}$ stacks 1.79 The most dense liquid, acetic acid, sinks; the piece of oak wood floats on the surface of the acetic acid, in the liquid interphase. The hexane resides on top. $\mathbf{1 . 8 2}$ density of solid $=1.63 \mathrm{~g} / \mathrm{mL} 1.85$ (a) Density of peat $=0.13 \mathrm{~g} / \mathrm{cm}^{3}$,
density of soil $=2.5 \mathrm{~g} / \mathrm{cm}^{3}$. It is not correct to say that peat is "lighter" than topsoil. Volumes must be specified in order to compare masses. (b) Buy 16 bags of peat (more than 15 are needed). (Results to 1 significant figure are not meaningful.) $\mathbf{1 . 8 9}$ The inner diameter of the tube is $1.90 \mathrm{~cm} . \mathbf{1 . 9 1}$ The separation with distinctly separated red and blue spots is more successful. To quantify the characteristics of the separation, calculate a reference value for each spot: distance traveled by spot/distance traveled by solvent. If the values for the two spots are fairly different, the separation is successful. 1.94 (a) Volume $=0.050 \mathrm{~mL}(\mathbf{b})$ surface area $=12.4 \mathrm{~m}^{2}$ (c) $99.99 \%$ of the mercury was removed. (d) The spongy material weighs 17.7 mg after exposure to mercury.

## Chapter 2

$2.1(\mathbf{a})(-)(\mathbf{b})$ increase (c) decrease $\mathbf{2 . 4}$ The particle is an ion. ${ }_{16}^{32} \mathrm{~S}^{2-}$ 2.6 Formula: $\mathrm{IF}_{5}$; name: iodine pentafluoride; the compound is molecular. 2.8 Only $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$, calcium nitrate, is consistent with the diagram. $2.10(\mathbf{a})$ In the presence of an electric field, there is electrostatic attraction between the negatively charged oil drops and the positively charged plate as well as electrostatic repulsion between the negatively charged oil drops and the negatively charged plate. These electrostatic forces oppose the force of gravity and change the rate of fall of the drops. (b) Each individual drop has a different number of electrons associated with it. If the combined electrostatic forces are greater than the force of gravity, the drop moves up. $\mathbf{2 . 1 1}$ (a) mass O $/$ mass C $=2.66(\mathbf{b})$ mass O $/$ mass C $=1.33(\mathbf{c}) \mathrm{CO} 2.13$ (a) $0.5711 \mathrm{~g} \mathrm{O} / 1 \mathrm{~g} \mathrm{~N} ; 1.142 \mathrm{~g} \mathrm{O} / 1 \mathrm{~g} \mathrm{~N} ; 2.284 \mathrm{~g} \mathrm{O} / 1 \mathrm{~g} \mathrm{~N} ; 2.855 \mathrm{~g} \mathrm{O} / 1 \mathrm{~g} \mathrm{~N}$ (b) The numbers in part ( $\mathbf{a}$ ) obey the law of multiple proportions. Multiple proportions arise because atoms are the indivisible entities combining, as stated in Dalton's atomic theory. 2.15 The neutron was the most difficult to be discovered because it does not carry any charge. $\mathbf{2 . 1 7}$ The fraction of alpha particles deflected at a large angle is $2.7 \times 10^{-9}$. That is, 1 out of approximately 365 million alpha particles is deflected at a large angle. $\mathbf{2 . 1 9}(\mathbf{a}) 0.21 \mathrm{~nm} ; 2.10 \times 102 \mathrm{pm}(\mathbf{b}) 4.76 \times 106$ W atoms (c) $3.88 \times 10^{-29} \mathrm{~m}^{3} 2.21$ (a) Proton, neutron, electron (b) proton $=1+$, neutron $=0$, electron $=1-(\mathbf{c})$ The neutron is most massive. (The neutron and proton have very similar masses.) (d) The electron is least massive. 2.23 (a) 15 protons, 15 electrons, 17 neutrons $(\mathbf{b}){ }^{32} \mathrm{~S}(\mathbf{c}){ }^{33} \mathrm{P}(\mathbf{d}){ }^{33} \mathrm{P} \mathbf{2 . 2 5}$ (a) Atomic number is the number of protons in the nucleus of an atom. Mass number is the total number of nuclear particles, protons plus neutrons, in an atom. (b) mass number 2.27 (a) ${ }^{84} \mathrm{Kr}$ : $36 \mathrm{p}, 48 \mathrm{n}, 36$ e (b) ${ }^{200} \mathrm{Hg}: 80 \mathrm{p}, 120 \mathrm{n}, 80$ e (c) ${ }^{59} \mathrm{Co}: 27 \mathrm{p}, 32 \mathrm{n}, 27$ e (d) ${ }^{55} \mathrm{Mn}: 25 \mathrm{p}, 30 \mathrm{n}, 25$ e (e) ${ }^{239} \mathrm{U}: 92 \mathrm{p}, 147 \mathrm{n}$, $92 \mathrm{e}(\mathbf{f}){ }^{181} \mathrm{Ta}: 73 \mathrm{p}, 108 \mathrm{n}, 73 \mathrm{e}$

## Chapter 5

$5.1(\mathbf{a}) E_{\text {el }}=1.8 \times 10^{2} \mathrm{~J}(\mathbf{b})$ If the spheres are released, they will move away from each other. (c) $\mathrm{v}=19 \mathrm{~m} / \mathrm{s} 5.4$ (a) (iii) (b) none of them (c) all of them $5.7(\mathbf{a})$ The sign of $w$ is $(+)$. (b) The sign of $q$ is $(-)$. (c) The sign of $w$ is positive and the sign of $q$ is negative, so we cannot absolutely determine the sign of $\Delta E$. It is likely that the heat lost is much smaller than the work done on the system, so the sign of $\Delta E$ is probably positive. $\mathbf{5 . 1 0}(\mathbf{a}) \mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g)$. Since $\Delta V=0$, $w=0$. (b) $\Delta H=\Delta H_{f}=90.37 \mathrm{~kJ}$. The definition of a formation reaction is one where elements combine to form one mole of a single product. The enthalpy change for such a reaction is the enthalpy of formation. 5.13 (a) $E_{e l}=-1.0 \times 10^{-18} \mathrm{~J}$ (b) $\Delta E_{e l}=7.7 \times 10^{-19} \mathrm{~J}$ (c) The two objects carry opposite charges; they attract each other. As they move farther apart, their energy increases. 5.15 (a) $F_{\text {el }}=-4.4 \times 10^{-9} \mathrm{~N}(\mathbf{b}) F_{\mathrm{g}}=1.9 \times 10^{-48} \mathrm{~N}$ (c) The electrostatic force is $2.3 \times 10^{39}$ times larger than the gravitational force. Both forces are attractive, that is, they point in the same direction. $\mathbf{5 . 1 7}$ $w=2.6 \times 10^{-18} \mathrm{~J} .5 .19$ (a) Gravity; work is done because the force of gravity is opposed and the book is lifted. (b) Gas spring force; Work is done because the force of the pump is opposed as the gas is compressed into it. $\mathbf{5 . 2 1}$ (a) Matter cannot leave or enter a closed system. (b) Neither matter nor energy can leave or enter an isolated system. (c) Any part of the universe not part of the system is called the surroundings. 5.23 (a) According to the first law of thermodynamics, energy is conserved. (b) The internal energy $(\mathbf{E})$ of a system is the sum of all the kinetic and potential energies of the system components. (c) The internal energy of a closed system increases when work is done on the system and when heat is transferred to the system. 5.25 (a) $\Delta E=-0.077 \mathrm{~kJ}$, endothermic (b) $\Delta E=-22.1 \mathrm{~kJ}$, exothermic 5.27 (a) Since no work is done by the system in case (2), the gas will absorb most of the energy as heat; the case (2) gas will have the higher temperature. (b) In case (1) energy will be used to do work on the surroundings ( $-w$ ), but some will be absorbed as heat ( $+q$ ). In case (2) $w=0$ and $q$ is $(+)$. (c) $\Delta E$ is greater for case (2) because the entire 100 $J$ increases the internal energy of the system rather than a part of the energy doing work on the surroundings. $\mathbf{5 . 2 9}$ (a) A state function is a property that depends only on the physical state (pressure, temperature, etc.) of the system, not on the route used to get to the current state. (b) Internal energy is a state function; heat is not a state function. (c) Volume is a state function. The volume of a system depends only on conditions (pressure, temperature, amount of substance), not the route or method used to establish that volume. $\mathbf{5 . 3 1} w=203 \mathrm{~J}$ 5.33 (a) As $\Delta E=q+w$, measuring $\Delta E$ generally requires a means
to measure both q and w . While, at constant pressure, the measured heat $q_{p}$ is identical to the change in enthalpy $\Delta H$. (b) $E$ is a property of a thermodynamic system; it only depends on its conditions, e.g. its temperature and pressure. Heat $q$ is not a property of a system, $q$ describes energy transferred to or from the system. We can equate change in internal energy, $\Delta E$, with heat only for the specific conditions of constant volume and no work. (c) The process is exothermic. 5.35 (a) $w=7.4 \mathrm{~kJ}(\mathbf{b}) \Delta E=-476.2 \mathrm{~kJ}(\mathbf{c})$ Since the value of $\Delta n$ is negative, the quantity $(-P \Delta V)$ is positive. We add a positive quantity to $\Delta H$ to calculate $\Delta E$, so $\Delta E$ must be larger. $\mathbf{5 . 3 7} \Delta E=1.47 \mathrm{~kJ}$; $\Delta H=0.824 \mathrm{~kJ} 5.39$
(a) $\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) ; \quad \Delta H=-890 \mathrm{~kJ}$
(b)

(b) The estimate from part (a) is less negative or larger than the true reaction enthalpy.
(c) $\Delta H$ for the reaction calculated using enthalpies of formation is -572 kJ .5 .89 (a) Fuel value is the amount of energy produced when 1 g of a substance (fuel) is combusted. (b) 5 g of fat (c) These products of metabolism are expelled as waste via the alimentary tract, $\mathrm{H}_{2} \mathrm{O}(l)$ primarily in urine and feces, and $\mathrm{CO}_{2}(g)$ as gas when breathing. 5.91 (a) $228 \mathrm{cal} /$ serving (b) Potassium is not metabolized by the body, so it does not contribute to the calorie content of the food. $\mathbf{5 . 9 3}$ 59.7 Cal 5.95 (a) $\Delta H_{\text {comb }}=-1850 \mathrm{~kJ} / \mathrm{mol} \mathrm{C}_{3} \mathrm{H}_{4},-1926 \mathrm{~kJ} / \mathrm{mol}$ $\mathrm{C}_{3} \mathrm{H}_{6},-2044 \mathrm{~kJ} / \mathrm{mol} \mathrm{C}_{3} \mathrm{H}_{8}(\mathbf{b}) \Delta H_{\text {comb }}=-4.616 \times 10^{4} \mathrm{~kJ} / \mathrm{kg} \mathrm{C}_{3} \mathrm{H}_{4}$, $-4.578 \times 10^{4} \mathrm{~kJ} / \mathrm{kg} \mathrm{C}_{3} \mathrm{H}_{6},-4.635 \times 10^{4} \mathrm{~kJ} / \mathrm{kg} \mathrm{C}_{3} \mathrm{H}_{8}$ (c) These three substances yield nearly identical quantities of heat per unit mass, but propane is marginally higher than the other two. $5.971 .0 \times 10^{12} \mathrm{~kg} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6} /$ yr $\mathbf{5 . 9 9}$ The spontaneous air bag reaction is probably exothermic, with $-\Delta H$ and thus $-q$. When the bag inflates, work is done by the system, so the sign of $w$ is also negative.
5.103 $\Delta H=-11.73 \mathrm{~kJ} ; \Delta E=-14.21 \mathrm{~kJ} 5.1051 .8 \times 10^{4}$ bricks 5.108 (a) $\Delta H_{r x n}^{0}=-11.73 \mathrm{KJ}$ (b) 39.7 g Fe needed
5.112 (a) $\Delta H_{r x n}^{0}=82 \mathrm{KJ} / \mathrm{mol}$ (b) 1-hexene has greater enthalpy than cyclohexane. (c) 1-hexene will have the larger combustion enthalpy. 5.115 If all work is used to increase the man's potential energy, the stair climbing uses 70 Cal and will not compensate for the extra order of 245 Cal fries. (More than 70 Cal will be required to climb the stairs because some energy is used to move limbs and some will be lost as heat.) $\mathbf{5 . 1 2 0}$ (a) $1.479 \times 10^{-18} \mathrm{~J} /$ molecule (b) $1 \times 10^{-15} \mathrm{~J} /$ photon. The X-ray has approximately 1000 times more energy than is produced by the combustion of 1 molecule of $\mathrm{CH}_{4}(g)$. $\mathbf{5 . 1 2 2}$ (a) $\Delta H^{\circ}$ for neutralization of the acids is: $\mathrm{HNO}_{3},-55.8 \mathrm{~kJ} ; \mathrm{HCl},-56.1 \mathrm{~kJ} ; \mathrm{NH}_{4}{ }^{+},-4.1 \mathrm{~kJ}$. (b) $\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$ is the net ionic equation for the first two reactions. $\mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$ (c) The $\Delta H^{\circ}$ values for the first two reactions are nearly identical, -55.8 kJ and -56.1 kJ . Because spectator ions do not change during a reaction and these two reactions have the same net ionic equation, it is not surprising that they have the same $\Delta H^{\circ}$. (d) Strong acids are more likely than weak acids to donate $\mathrm{H}^{+}$. Neutralization of the two strong acids is energetically favorable, while the third reaction is barely so. $\mathrm{NH}_{4}{ }^{+}$is likely a weak acid. 5.124 (a) $\Delta H^{\circ}=-65.7 \mathrm{~kJ}(\mathbf{b}) \Delta H^{\circ}$ for the complete molecular equation will be the same as $\Delta H^{\circ}$ for the net ionic equation. Since the overall enthalpy change is the enthalpy of products minus the enthalpy of reactants, the contributions of spectator ions cancel. (c) $\Delta H_{f}^{\circ}$ for $\mathrm{AgNO}_{3}(\mathrm{aq})$ is $-100.4 \mathrm{~kJ} / \mathrm{mol}$.

## Chapter 6

6.2 (a) 0.1 m or 10 cm (b) No. Visible radiation has wavelengths much shorter than 0.1 m . (c) Energy and wavelength are inversely proportional. Photons of the longer 0.1-m radiation have less energy than visible photons. (d) Radiation with $\lambda=0.1 \mathrm{~m}$ is in the low-energy portion of the microwave region. The appliance is probably a microwave oven. 6.5 (a) Increase (b) decrease 6.9 (a) $l=1$ (b) $3 p_{\mathrm{y}}$ (c) (iii) 6.13 (a) $10^{7} 1 / \mathrm{cm}$ (b) $2 \times 10^{4} 1 / \mathrm{cm}$ (c) $101 / \mathrm{cm} 6.15$ (a) True (b) False. Ultraviolet light has shorter wavelengths than visible light. (c) False. Xrays travel at the same speed as microwaves. (d) False. Electromagnetic radiation and sound waves travel at different speeds. 6.17 Wavelength of X-rays $<$ ultraviolet $<$ green light $<$ red light $<$ infrared $<$ radio waves 6.19 (a) $3.0 \times 10^{13} \mathrm{~s}^{-1}$ (b) $5.45 \times 10^{-7} \mathrm{~m}=545 \mathrm{~nm}$. (c) The radiation in (b) is visible; the radiation in (a) is not. (d) $1.50 \times 10^{4} \mathrm{~m}$ $6.214 .6 \times 10^{14} \mathrm{~s}^{-1}$; red. $\mathbf{6 . 2 3}$ (iv) $\mathbf{6 . 2 5} \quad$ (a) $1.95 \times 10^{-19} \mathrm{~J}$ (b) $4.81 \times 10^{-19} \mathrm{~J}(\mathbf{c}) 328 \mathrm{~nm} 6.27$ (a) $\lambda=3.0 \mathrm{~mm}, E=6.6 \times 10^{-23} \mathrm{~J}$, $\lambda=3.0 \mathrm{~nm}, E=6.6 \times 10^{-16} \mathrm{~J}(\mathbf{b})$ The 3.0 mm photon is in the microwave region and the 0.3 nm photon is in the x -ray region. The x-ray photon has the greater energy. $\mathbf{6 . 2 9}$ (a) $6.11 \times 10^{-19} \mathrm{~J} /$ photon (b) $368 \mathrm{~kJ} / \mathrm{mol}(\mathbf{c}) 1.64 \times 10^{15}$ photons (d) $368 \mathrm{~kJ} / \mathrm{mol} 6.31$ (a) The $\sim 1 \times 10^{-6} \mathrm{~m}$ radiation is in the infrared portion of the spectrum.
(b) $8.1 \times 10^{16}$ photons $/ \mathrm{s} 6.33$ (a) $v=1.09 \times 10^{15} 1 / \mathrm{s}$
(b) $\lambda=275 \mathrm{~nm}(\mathbf{c}) E_{240}=8.28 \times 10^{-19} \mathrm{~J}$. The excess energy of the $240-\mathrm{nm}$ photon is converted into the kinetic energy of the emitted electron. $v=4.82 \times 10^{5} \mathrm{~m} / \mathrm{s} .6 .35$ When an electron in a hydrogen atom transitions from $n=1$ to $n=3$, the atom "expands". 6.37 (a) Emitted (b) emitted (c) emitted 6.39 (a)) $E_{3}=-2.42 \times 10^{-19} \mathrm{~J}$; $E_{6}=-6.06 \times 10^{-20} \mathrm{~J} ; \quad \Delta E=-1.82 \times 10^{-19} \mathrm{~J} ; \quad \lambda=1090 \mathrm{~nm} \quad$ (b) infrared 6.41 (a) (ii) (b) $n_{i}=3, n_{f}=2 ; \lambda=6.56 \times 10^{-7} \mathrm{~m}$; this is the red line at $656 \mathrm{~nm} . n_{i}=4, n_{f}=2 ; \lambda=4.86 \times 10^{-7} \mathrm{~m}$; this is the blue-green line at $486 \mathrm{~nm} . n_{i}=5, n_{f}=2 ; \lambda=4.34 \times 10^{-7} \mathrm{~m}$; this is the blue-violet line at $434 \mathrm{~nm} . \mathbf{6 . 4 3}$ (a) Ultraviolet region (b) $n_{i}=5, n_{f}=16.45$ The order of decreasing energy of light absorbed is: $n=1$ to $n=3 ; n=2$ to $n=5 ; n=3$ to $n=7 ; n=4$ to $n=8 \quad 6.47$ (a) $\lambda=5.6 \times 10^{-37} \mathrm{~m} \quad$ (b) $\lambda=2.65 \times 10^{-34} \mathrm{~m}$ (c) $\lambda=2.3 \times 10^{-13} \mathrm{~m}(\mathbf{d}) \lambda=1.51 \times 10^{-11} \mathrm{~m} 6.493 .16 \times 10^{3} \mathrm{~m} / \mathrm{s}$ 6.51 (a) $\Delta x \geq 4 \times 10^{-27} \mathrm{~m}$ (b) $\Delta x \geq 3 \times 10^{-10} \mathrm{~m} 6.53$ (a) False (b) false 6.55 (a) $n=4, l=3,2,1,0$ (b) $l=2, m_{l}=-2,-1,0,1,2$ (c) $m_{l}=2, l \geq 2$ or $l=2,3$ or $4 \mathbf{6 . 5 7}$ (a) $3 p: n=3, l=1$ (b) $2 s: n=2$, $l=0$ (c) $4 f: n=4, l=3$ (d) $5 d: n=5, l=26.59$ (a) $3,2,1,0,-1$, $-2,-3$ (b) $1 / 2,-1 / 26.61$ (a) Impossible, $1 p$ (b) possible (c) possible (d) impossible, $2 d 6.63$
(a)

(b)

(c)

6.65 (a) The hydrogen atom $1 s$ and $2 s$ orbitals have the same overall spherical shape, but the $2 s$ orbital has a larger radial extension and one more node than the $1 s$ orbital. (b) A single $2 p$ orbital is directional in that its electron density is concentrated along one of the three Cartesian axes of the atom. The $d_{x^{2}-y^{2}}$ orbital has electron density along both the $x$ - and $y$-axes, while the $p_{x}$ orbital has density only along the $x$-axis. (c) The average distance of an electron from the nucleus in a $3 s$ orbital is greater than for an electron in a $2 s$ orbital. (d) $1 s<2 p<3 d<4 f<6 s 6.67$ (a) For the $\mathrm{He}^{+}$ion, the $2 s$ and $2 p$ orbitals have the same energy. (b) Yes. In a helium atom, the $2 s$ orbital is lower in energy than the $2 p$ orbital. 6.69 (a) No. Both configurations follow the Pauli exclusion principle. (b) No. Both configurations follow Hund's rule. (c) No. In the absence of a magnetic field, we cannot say which configuration has the lower energy. 6.71 (a) 2 (b) 6 (c) 10 (d) 26.73 (a) "Valence electrons" are those involved in chemical bonding. They are part or all of the outer-shell electrons listed after the core. (b) "Core electrons" are inner-shell electrons that have the electron configuration of the nearest noblegas element. (c) Each box represents an orbital. (d) Each half-arrow in an orbital diagram represents an electron. The direction of the halfarrow represents electron spin. 6.75 (a) $\mathrm{Cs},[\mathrm{Xe}] 6 s^{1}(\mathbf{b}) \mathrm{Ni},[\mathrm{Ar}] 4 s^{2} 3 d^{8}$ (c) $\mathrm{Se},[\mathrm{Ar}] 4 s^{2} 3 d^{10} 4 p^{4}$ (d) $\mathrm{Cd},[\mathrm{Kr}] 5 s^{2} 4 d^{10}$ (e) $\mathrm{U},[\mathrm{Rn}] 5 f^{3} 6 d^{1} 7 s^{2}$ (f) $\mathrm{Pb},[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{10} 6 p^{2} 6.77$ (a) Be, 0 unpaired electrons (b) O, 2 unpaired electrons (c) $\mathrm{Cr}, 6$ unpaired electrons (d) Te, 2 unpaired electrons 6.79 (a) The $4 s$ subshell would fill before the $3 d$. (b) The $s$ subshell can hold only 2 electrons. (c) The third electron would fill the $2 s$ subshell before the $3 s$.
6.81 (a) $\lambda_{\mathrm{A}}=3.6 \times 10^{-8} \mathrm{~m}, \lambda_{\mathrm{B}}=8.0 \times 10^{-8} \mathrm{~m}$
(b) $\nu_{\mathrm{A}}=8.4 \times 10^{15} \mathrm{~s}^{-1}, \nu_{\mathrm{B}}=3.7 \times 10^{15} \mathrm{~s}^{-1}$ (c) A, ultraviolet; B, ultraviolet $\mathbf{6 . 8 4} 3.9 \mathrm{hr} \mathbf{6 . 8 6} 8.835 \times 10^{19}$ photons $\mathbf{6 . 9 1}$ (a) Lines with $n_{f}=1$ lie in the ultraviolet, lines with $n_{f}=2$ lie in the visible and lines with $n_{f}=3$ lie near the infrared. Lines with $n_{f}=4$ will have smaller energy differences and longer wavelengths and lie in the infrared. (b) $n_{i}=5, \Delta E=-4.905 \times 10^{-20} \mathrm{~J} ; \lambda=4050 \mathrm{~nm} ; n_{i}=6$,
$\Delta E=-7.569 \times 10^{-20} \mathrm{~J}, \quad \lambda=2624 \mathrm{~nm} ; \quad n_{i}=7, \quad \Delta E=-9.176 \times$ $10^{-20} \mathrm{~J}, \lambda=2165 \mathrm{~nm} 6.95 \lambda=12.3 \mathrm{pm} 6.99$ (a) The nodal plane of the $p_{z}$ orbital is the $x y$-plane. (b) The two nodal planes of the $d_{x y}$ orbital are the ones where $x=0$ and $y=0$. These are the $y z$ - and $x z$-planes. (c) The two nodal planes of the $d_{x^{2}-y^{2}}$ orbital are the ones that bisect the $x$ - and $y$-axes and contain the $z$-axis. 6.102 (a) $\mathrm{Cl}:[\mathrm{Ne}] 3 s^{2} 3 p^{5}, 1$ unpaired electron (b) Al: $[\mathrm{Ne}] 3 s^{2} 3 p^{1}$, 1 unpaired electron (c) $\mathrm{Zr}:[\mathrm{Kr}] 5 s^{2} 4 d^{2}, 2$ unpaired electrons (d) As: $[\operatorname{Ar}] 4 s^{2} 3 d^{10} 4 p^{3}, 3$ unpaired electrons (e) $\mathrm{Sb}:[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{3}$, 3 unpaired electrons (f) $\mathrm{W}:[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{4}, 4$ unpaired electrons 6.105 (a) $1.7 \times 10^{28}$ photons (b) 34 s 6.109 (a) Bohr's theory was based on the Rutherford nuclear model of the atom: a dense positive charge at the center and a diffuse negative charge surrounding it. Bohr's theory then specified the nature of the diffuse negative charge. The prevailing theory before the nuclear model was Thomson's plum pudding model: discrete electrons scattered about a diffuse positive charge cloud. Bohr's theory could not have been based on the Thomson model of the atom. (b) De Broglie's hypothesis is that electrons exhibit both particle and wave properties. Thomson's conclusion that electrons have mass is a particle property, while the nature of cathode rays is a wave property. De Broglie's hypothesis actually rationalizes these two seemingly contradictory observations about the properties of electrons.

## Chapter 7

7.2 The largest brown sphere is $\mathrm{Br}^{-}$, the intermediate blue one is Br , and the smallest red one is F. 7.5 (a) The bonding atomic radius of $\mathrm{A}, \mathrm{r}_{\mathrm{A}}$, is $d_{1} / 2 ; r_{x}=d_{2}-\left(d_{1} / 2\right)$. (b) The length of the $\mathrm{X}-\mathrm{X}$ bond is $2 r_{x}$ or $2 d_{2}-d_{1} .7 .8(\mathbf{a}) \mathrm{X}+2 \mathrm{~F}_{2} \longrightarrow \mathrm{XF}_{4}(\mathbf{b}) \mathrm{X}$ in the diagram has about the same bonding radius as F , so it is likely to be a nonmetal. If X were a metal, the compound would be ionic and the charge on X would be $4+$. The bonding (ionic) radius of $\mathrm{X}^{4+}$ would be much smaller than that of fluorine. 7.9 (a) The results are $2,8,18,32$. (b) The atomic numbers of the noble gases are $2,10,18,36,54$, and 86 . The differences between sequential pairs of these atomic numbers is $8,8,18,18$, and 32 . These differences correspond to the results in (a). They represent the filling of new subshells when moving across the next row of the periodic chart. (c) The Pauli exclusion principle is the source of the " 2 ". $\mathbf{7 . 1 1}$ (a) Of the elements listed, only Fe was known before 1700. (b) The seven metals known in ancient times, $\mathrm{Fe}, \mathrm{Cu}, \mathrm{Ag}$, $\mathrm{Sn}, \mathrm{Au}, \mathrm{Hg}$, and Pb , are mostly near the bottom of the activity series, Table 4.5. 7.13 For elements $\mathrm{N}, \mathrm{O}, \mathrm{P}$, and $\mathrm{S}, \mathrm{O}$ and S have the largest effective nuclear charge; N and P have the smallest effective nuclear charge. $\mathbf{7 . 1 5}$ (a) For both Na and $\mathrm{K}, Z_{\text {eff }}=1$. (b) For both Na and K , $Z_{\text {eff }}=2.2$. (c) Slater's rules give values closer to the detailed calculations: Na, 2.51; K, 3.49. (d) Both approximations give the same value of $Z_{\text {eff }}$ for Na and K; neither accounts for the gradual increase in $Z_{\text {eff }}$ moving down a group. (e) Following the trend from detailed calculations, we predict a $Z_{\text {eff }}$ value of approximately 4.5. 7.17 The $n=2$ electrons in F experience a greater effective nuclear charge and thus have a greater probability of being closer to the nucleus. $\mathbf{7 . 1 9}$ Quantity (b) must be measured to determine the bonding atomic radius of an atom. 7.21 (a) $137 \mathrm{pm}(\mathbf{b})$ The distance between W atoms will decrease. 7.23 From the bonding atomic radii, $\mathrm{P}-\mathrm{Cl}=107+102 \mathrm{pm}=$ 209 pm . It is very close to the experimental values of 204 pm in $\mathrm{PCl}_{3} .7 .25$ (a) $\mathrm{As}>\mathrm{Kr}>\mathrm{Ar}($ (b) $\mathrm{Rb}>\mathrm{Cd}>\mathrm{Te}($ (c) $\mathrm{Cu}>\mathrm{Cl}>\mathrm{C}$ 7.27 (a) False (b) true (c) false $7.29 \mathrm{H}^{-}$: $\mathrm{He}, \mathrm{Ca}^{2+}$ : $\mathrm{Ar}, \mathrm{ln}^{3+}$ : $\operatorname{Pd}, \quad \operatorname{Pd}\left([K r] 4 d^{10}\right.$, irregular), $\mathrm{Ge}^{2+}: \mathrm{Zn} \quad 7.31 \quad$ (a) $\mathrm{Na}^{+} \quad$ (b) $\mathrm{F}^{-}$, $Z_{\text {eff }}=7 ; \mathrm{Na}^{+}, \quad Z_{\text {eff }}=9 \quad$ (c) $\quad S=4.15 ; \quad \mathrm{F}^{-}, Z_{\text {eff }}=4.85 ; \mathrm{Na}^{+}$, $Z_{\text {eff }}=6.85$ (d) For isoelectronic ions, as nuclear charge $(Z)$ increases, effective nuclear charge $\left(\mathrm{Z}_{\text {eff }}\right)$ increases and ionic radius decreases. 7.33 (a) $\mathrm{Cl}<\mathrm{S}<\mathrm{K}$ (b) $\mathrm{K}^{+}<\mathrm{Cl}^{-}<\mathrm{S}^{2-}$ (c) The neutral K atom has the largest radius because the $n$-value of
its outer electron is larger than the $n$-value of valence electrons in S and Cl . The $\mathrm{K}^{+}$ion is smallest because, in an isoelectronic series, the ion with the largest $Z$ has the smallest ionic radius. 7.35 (a) $\mathrm{Cl}^{-}$is larger than Ar because the two are isoelectronic and Ar has the larger $Z$ and $\mathrm{Z}_{\text {eff. }}$. (b) $\mathrm{P}^{3-}$ is larger than $\mathrm{S}^{2-}$ because the two ions are isoelectronic and $\mathrm{S}^{2-}$ has the larger $Z$ and $\mathrm{Z}_{\text {eff }}$. (c) $\mathrm{K}^{+}$is larger than $\mathrm{Na}^{+}$because for particles with like charges, size increases going down a family. (d) $\mathrm{F}^{-}$is larger than F because the increase in electron repulsions that accompany addition of an electron causes the electron cloud to expand. $7.37 \mathrm{Cl}(g) \longrightarrow \mathrm{Cl}^{+}(g)+\mathrm{e}^{-}$; $\mathrm{Cl}^{+}(g) \longrightarrow \mathrm{Cl}^{2+}(g)+\mathrm{e}^{-} ; \mathrm{Cl}^{2+}(g) \longrightarrow \mathrm{Cl}^{3+}(g)+\mathrm{e}^{-}$. The process for the first ionization energy requires the least amount of energy. 7.39 Of these three elements, Li has the highest second ionization energy. Both $\mathrm{Li}^{+}$and $\mathrm{K}^{+}$have the stable electron configurations of noble gases, but the unshielded $1 s$ electron of $\mathrm{Li}^{+}$is much closer to the nucleus and requires more energy to remove. 7.41 (a) The smaller the atom, the larger its first ionization energy. (b) Of the nonradioactive elements, He has the largest and Cs has the smallest first ionization energy. $\mathbf{7 . 4 3}$ (a) $\mathrm{Br}(\mathbf{b}) \mathrm{Ca}(\mathbf{c}) \mathrm{Rb}(\mathbf{d}) \mathrm{Pb}(\mathbf{e}) \mathrm{Al} 7.45$ (a) $\mathrm{Cu}^{2+}:[\mathrm{Ar}] 3 d^{9}(\mathbf{b}) \mathrm{Ca}^{2+}:[\mathrm{Ar}]$, noble gas configuration (c) $\mathrm{N}^{3-}:[\mathrm{Ne}]$, noble gas configuration $(\mathbf{d}) \mathrm{Ru}^{2+}:[\mathrm{Kr}] 4 d^{6}(\mathbf{e}) \mathrm{H}^{-}$: $[\mathrm{He}]$, noble gas configuration $7.47 \mathrm{Zn}^{2+},[\mathrm{Ar}] 3 d^{10} ; \mathrm{Cd}^{2+},[\mathrm{Kr}] 4 d^{10} ; \mathrm{Hg}^{2+},[\mathrm{Xe}] 4 f^{14} 6 d^{10}$ 7.49 Second electron affinity of $\mathrm{Cl}: \mathrm{Cl}^{-}+1 \mathrm{e}^{-} \longrightarrow \mathrm{Cl}^{2-}(\mathrm{g})$. We predict that the second electron affinity of chlorine will be positive. It is probably not possible to directly measure this quantity, because a positive value indicates that $\mathrm{Cl}^{2-}$ ion is unstable and will not form. 7.51 The electron affinity of I will be negative. The electron-electron repulsions created by adding an electron to an $\mathrm{I}^{-}$ion causes the electron affinity of $\mathrm{I}^{-}$to be a positive value. 7.53 (a) Ionization energy $\left(\mathrm{I}_{1}\right)$ of $\mathrm{Ne}: \mathrm{Ne}(g) \longrightarrow \mathrm{Ne}^{+}(g)+1 \mathrm{e}^{-} ;[\mathrm{He}] 2 s^{2} 2 p^{6} \longrightarrow[\mathrm{He}] 2 s^{2} 2 p^{5}$; electron affinity $\left(E_{1}\right)$ of $\mathrm{F}: \mathrm{F}(g)+1 \mathrm{e}^{-} \longrightarrow \mathrm{F}^{-}(g)$; He$] 2 s^{2} 2 p^{5} \longrightarrow$ $[\mathrm{He}] 2 s^{2} 2 p^{6}$. (b) $I_{1}$ of Ne is positive; $E_{1}$ of F is negative. (c) One process is apparently the reverse of the other, with one important difference. Ne has a greater $Z$ and $Z_{\text {eff }}$, so we expect $I_{1}$ for Ne to be somewhat greater in magnitude and opposite in sign to $E_{1}$ for F . 7.55 (a) Decrease (b) Increase (c) The smaller the first ionization energy of an element, the greater the metallic character of that element. The trends in (a) and (b) are the opposite of the trends in ionization energy. 7.57 Agree. When forming ions, all metals form cations. The only nonmetallic element that forms cations is the metalloid Sb , which is likely to have significant metallic character. $\mathbf{7 . 5 9}$ Ionic: $\mathrm{ZnO}, \mathrm{K}_{2} \mathrm{O}, \mathrm{TiO}_{2}$; molecular: $\mathrm{SO}_{2}, \mathrm{SiO}_{2}, \mathrm{OF}_{2}$. Ionic compounds are formed by combining a metal and a nonmetal; molecular compounds are formed by two or more nonmetals. 7.61 ZrO will react more readily with $\mathrm{HCl}(\mathrm{aq}) . \mathbf{7 . 6 3}$ (a) Dichlorine heptoxide $(\mathbf{b}) 2 \mathrm{Cl}_{2}(g)+7 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Cl}_{2} \mathrm{O}_{7}(l)(\mathbf{c}) \mathrm{Cl}_{2} \mathrm{O}_{7}$ is an acidic oxide, so it will be more reactive to base, $\mathrm{OH}^{-}$. (d) The oxidation state of Cl in $\mathrm{Cl}_{2} \mathrm{O}_{7}$ is +7 ; the corresponding electron configuration for Cl is $[\mathrm{He}] 2 s^{2} 2 p^{6}$ or $[\mathrm{Ne}] .7 .65(\mathbf{a}) \mathrm{BCl}_{3}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{B}(\mathrm{OH})_{3}(a q)+$ $3 \mathrm{HCl}(a q)(\mathbf{b}) \mathrm{CoO}(s)+2 \mathrm{HNO}_{3}(a q) \longrightarrow \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$ (c) $\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}($ aq $)$ (d) $\mathrm{CO}_{2}(g)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \longrightarrow \mathrm{BaCO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)$
7.67 (a) The first and second ionization energies of calcium are less than those of beryllium. (b) The first ionization energy of calcium is higher than that of rubidium. $7.69(\mathbf{a}) 2 \mathrm{~K}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{KCl}(s)$ (b) $\mathrm{SrO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Sr}(\mathrm{OH})_{2}(a q)$
(c) $4 \mathrm{Li}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Li}_{2} \mathrm{O}(s)(\mathbf{d}) 2 \mathrm{Na}(s)+\mathrm{S}(t) \longrightarrow \mathrm{Na}_{2} \mathrm{~S}(s)$
7.71 (a) The reactions of the alkali metals with hydrogen and with a halogen are redox reactions. Both hydrogen and the halogen gain electrons and are reduced. (The alkali metal loses electrons and is oxidized.) $\mathrm{Ca}(s)+\mathrm{F}_{2}(g) \longrightarrow \mathrm{CaF}_{2}(s) ; \mathrm{Ca}(s)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{CaH}_{2}(s)$.
(b) The oxidation number of Ca in both products is +2 . The electron configuration is that of $\mathrm{Ar},[\mathrm{Ne}] 3 s^{2} 3 p^{6} .7 .73$ (a) $\mathrm{Br},[\mathrm{Ar}] 4 s^{2} 4 p^{5}$;
$\mathrm{Cl},[\mathrm{Ne}] 3 s^{2} 3 p^{5}(\mathbf{b}) \mathrm{Br}$ and Cl are in the same group, and both adopt a 1 - ionic charge. (c) The ionization energy of Br is smaller than that of Cl , because the $4 p$ valence electrons in Br are farther from to the nucleus and less tightly held than the $3 p$ electrons of Cl . (d) Both react slowly with water to form HX + HOX. (e) The electron affinity of Br is less negative than that of Cl , because the electron added to the $4 p$ orbital in Br is farther from the nucleus and less tightly held than the electron added to the $3 p$ orbital of Cl . (f) The atomic radius of Br is larger than that of Cl , because the $4 p$ valence electrons in Br are farther from the nucleus and less tightly held than the $3 p$ electrons of Cl. 7.75 (a) The term inert was dropped because it no longer described all the Group 18 elements. (b) In the 1960s, scientists discovered that Xe would react with substances having a strong tendency to remove electrons, such as $\mathrm{F}_{2}$. Thus, Xe could not be categorized as an "inert" gas. (c) The group is now called the noble gases. 7.77 (a) $\mathrm{P}_{4}(s)+6 \mathrm{Cl}_{2}(g) \longrightarrow 4 \mathrm{PCl}_{3}(l)\left(\right.$ b) $2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$ $\mathrm{H}_{2}(g)+2 \mathrm{NaOH}(a q)\left(\right.$ c) $2 \mathrm{HBr}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{HCl}(g)+\mathrm{Br}_{2}$ (d) $\mathrm{AlCl}_{3}(s)+3 \mathrm{NaOH}(a q) \longrightarrow \mathrm{Al}(\mathrm{OH})_{3}(s)+3 \mathrm{NaCl}(a q)$ 7.79 Up to $Z=82$, there are three instances where atomic weights are reversed relative to atomic numbers: Ar and K ; Co and Ni ; Te and I. 7.81 (a) $5+(\mathbf{b}) 4.8+$ (c) Shielding is greater for $3 p$ electrons, owing to penetration by $3 s$ electrons, so $Z_{\text {eff }}$ for $3 p$ electrons is less than that for $3 s$ electrons. (d) The first electron lost is a $3 p$ electron because it has a smaller $Z_{\text {eff }}$ and experiences less attraction for the nucleus than a $3 s$ electron does. 7.85 (a) The $\mathrm{P}-\mathrm{Cl}$ distance is 194 pm . (b) The predicted $\mathrm{P}-\mathrm{Cl}$ bond length is 209 pm .7 .87 (a) Chalcogens, -2 ; halogens, -1 . (b) The family with the larger value is: atomic radii, chalcogens; ionic radii of the most common oxidation state, chalcogens; first ionization energy, halogens; second ionization energy, halogens $7.91 \mathrm{C}: 1 s^{2} 2 s^{2} 2 p^{2}$. $I_{1}$ through $I_{4}$ represent loss of the $2 p$ and $2 s$ electrons in the outer shell of the atom. The values of $I_{1}-I_{4}$ increase as expected. $I_{5}$ and $I_{6}$ represent loss of the $1 s$ core electrons. These $1 s$ electrons are much closer to the nucleus and experience the full nuclear charge, so the values of $I_{5}$ and $I_{6}$ are significantly greater than $I_{1}-I_{4} .7 .96$ (a) $\mathrm{Mg}^{2+}(\mathbf{b}) \mathrm{Cu}^{2+}$ (c) $\mathrm{Pb}^{2+}$ 7.99 (a) For both H and the alkali metals, the added electron will complete an $n s$ subshell, so shielding and repulsion effects will be similar. For the halogens, the electron is added to an $n p$ subshell, so the energy change is likely to be quite different. (b) True. The electron configuration of H is $1 s^{1}$. The single $1 s$ electron experiences no repulsion from other electrons and feels the full unshielded nuclear charge. The outer electrons of all other elements that form compounds are shielded by a spherical inner core of electrons and are less strongly attracted to the nucleus, resulting in larger bonding atomic radii. (c) Both H and the halogens have large ionization energies. The relatively large effective nuclear charge experienced by $n p$ electrons of the halogens is similar to the unshielded nuclear charge experienced by the H $1 s$ electron. For the alkali metals, the $n s$ electron being removed is effectively shielded by the core electrons, so ionization energies are low. (d) ionization energy of hydride, $\mathrm{H}^{-}(g) \longrightarrow \mathrm{H}(g)+1 \mathrm{e}^{-}$ (e) electron affinity of hydrogen, $\mathrm{H}(\mathrm{g})+1 \mathrm{e}^{-} \longrightarrow \mathrm{H}^{-}(g)$. The value for the ionization energy of hydride is equal in magnitude but opposite in sign to the electron affinity of hydrogen. 7.102 The most likely product is (iii). 7.107 Electron configuration, $[\mathrm{Rn}] 7 s^{2} 5 f^{14} 6 d^{10} 7 p^{5}$; first ionization energy, $805 \mathrm{~kJ} / \mathrm{mol}$; electron affinity, $-235 \mathrm{~kJ} / \mathrm{mol}$; atomic size, $1.65 \AA$; common oxidation state, -1 . 7.110 (a) $\mathrm{Li},[\mathrm{He}] 2 s^{1} ; \mathrm{Z}_{\text {eff }} \approx 1+$ (b) $I_{1} \approx 5.45 \times 10^{-19} \mathrm{~J} /$ atom $\approx 328 \mathrm{~kJ} / \mathrm{mol}(\mathbf{c})$ The estimated value of $328 \mathrm{~kJ} / \mathrm{mol}$ is less than the Table 7.4 value of $520 \mathrm{~kJ} / \mathrm{mol}$. Our estimate for $Z_{\text {eff }}$ was a lower limit; the [He] core electrons do not perfectly shield the $2 s$ electron from the nuclear charge. (d) Based on the experimental ionization energy, $Z_{\text {eff }}=1.26$. This value is greater than the estimate from part (a) but agrees well with the "Slater"
value of 1.3 and is consistent with the explanation in part (c). $\mathbf{7 . 1 1 3}$ (a) $\mathrm{Mg}_{3} \mathrm{~N}_{2}$ (b) $\mathrm{Mg}_{3} \mathrm{~N}_{2}(s)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{MgO}(s)+2 \mathrm{NH}_{3}(g)$; the driving force is the production of $\mathrm{NH}_{3}(\mathrm{~g})$. (c) $17 \% \mathrm{Mg}_{3} \mathrm{~N}_{2}$ (d) $3 \mathrm{Mg}(\mathrm{s})+2 \mathrm{NH}_{3}(\mathrm{~g}) \longrightarrow \mathrm{Mg}_{3} \mathrm{~N}_{2}(\mathrm{~s})+3 \mathrm{H}_{2}(\mathrm{~g})$. $\mathrm{NH}_{3}$ is the limiting reactant and $0.46 \mathrm{~g} \mathrm{H}_{2}$ is formed. (e) $\Delta H_{\mathrm{rxn}}^{\circ}=-368.70 \mathrm{~kJ}$

## Chapter 8

8.1 (a) Group 14 (b) Group 2 (c) Group 158.4 (a) $\mathrm{Ru}(\mathbf{b})[\mathrm{Kr}] 5 s^{2} 4 d^{6}$. 8.7 (a) Four (b) In order of increasing bond length: $3<1<2$ (c) Bond 3 is the strongest $\mathrm{C}-\mathrm{C}$ bond in the hydrocarbon molecule. For the same pair of bonded atoms, the greater the number of shared pairs of electrons, the shorter and stronger the bond. 8.11 (a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{5}$ (b) seven (c) The $3 s$ and $3 p$ electrons are valence electrons. $\mathbf{8 . 1 3}(\mathbf{a}) \cdot \dddot{\mathrm{T}} \cdot(\mathbf{e}) \cdot \dot{\mathrm{Si}} \cdot(\mathbf{c}): \ddot{\mathrm{K}}:(\mathbf{d}) \cdot \ddot{\mathrm{P}}$.
$8.15+\quad+\stackrel{\mathrm{K}}{\mathrm{B}} \mathrm{r}: \longrightarrow \mathrm{K}^{+}+[: \ddot{\mathrm{B}} \mathrm{r}:]^{-}$
(b) one (c) K loses an electron. 8.17 (a) $\mathrm{AlCl}_{3}$ (b) MgO (c) $\mathrm{ZnCl}_{2}$ (d) $\mathrm{Li}_{2} \mathrm{O} 8.19$ (a) $\mathrm{Be}^{2+}: 1 s^{2}=[\mathrm{He}]$, noble-gas configuration (b) $\mathrm{Mn}^{2+}:[\mathrm{Ar}] 3 d^{5}$ (c) $\mathrm{Cd}^{2+}:[\mathrm{Kr}] 4 d^{10}$ (d) $\mathrm{Fe}^{3+}:[\mathrm{Ar}] 3 d^{5}(\mathbf{e}) \mathrm{Tl}^{+}$: $[\mathrm{Xe}] 4 f^{14} 5 d^{10} 6 s^{2}$ (f) $A t^{-}$: [Xe] $4 f^{14} 5 d^{10} 6 s^{2} 6 p^{6}=[\mathrm{Rn}]$, noble-gas configuration 8.21 (a) Endothermic $(\mathbf{b}) \mathrm{NaCl}(s) \longrightarrow \mathrm{Na}^{+}(g)+\mathrm{Cl}^{-}(g)$ (c) Salts like NaCl , that have singly charged ions, will have smaller lattice energies compared with salts like CaO , that have doubly charged ions. $8.23(\mathbf{a}) \mathrm{Na}^{+}, 1+; \mathrm{Ca}^{2+}, 2+(\mathbf{b}) \mathrm{F}^{-}, 1-; \mathrm{O}^{2-}, 2-(\mathbf{c}) \mathrm{CaO}$ will have the larger lattice energy. (d) We expect the lattice energy of ScN to be slightly less than $8.10 \times 10^{3} \mathrm{~kJ} 8.25$ (a) K-F, 271 pm ; Na-Cl, 283 pm; $\mathrm{Na}-\mathrm{Br}, 298 \mathrm{pm} ; \mathrm{Li}-\mathrm{Cl}, 257 \mathrm{pm}$ (b) $\mathrm{LiCl}>\mathrm{KF}>\mathrm{NaCl}>\mathrm{NaBr}$ (c) From Table 8.2: LiCl, $1030 \mathrm{~kJ} ; \mathrm{KF}, 808 \mathrm{~kJ} ; \mathrm{NaCl}, 788 \mathrm{~kJ} ; \mathrm{NaBr}, 732 \mathrm{~kJ}$. The predictions from ionic radii are correct. $\mathbf{8 . 2 7}$ Statement (a) is the best explanation. 8.29 The lattice energy of $\mathrm{RbCl}(s)$ is $+692 \mathrm{~kJ} / \mathrm{mol}$.
$\mathbf{8 . 3 1}$ (a) The bonding in (i) glucose, (ii) nitrogen and (iv) ammonia is likely to be covalent. (b) Ionic because it is a solid with a high melting point. 8.33

(a) 5 (b) 1 (c) 8 (d) 8 (e) 108.35 (a) : $\ddot{\mathrm{O}}=\mathrm{O}: \quad$ (b) four bonding electrons (two bonding electron pairs) (c) $\mathrm{An} \ddot{\mathrm{O}}=\mathrm{O}$ double bond is shorter than an $\mathrm{O}-\mathrm{O}$ single bond. The greater the number of shared electron pairs between two atoms, the shorter the distance between the atoms. 8.37 Statement (b) is false. $\mathbf{8 . 3 9}$ (a) Mg (b) S (c) C (d) As 8.41 The bonds in (a), (b) and (d) are polar. The more electronegative atom in each polar bond is: (a) O, (b) F (d) Cl. 8.43 (a) The calculated charge on H and Br is $0.12 e$. (b) Decrease $\mathbf{8 . 4 5}$ (a) $\mathrm{SiF}_{4}$, molecular, silicon tetrachloride; $\mathrm{LaF}_{3}$, ionic, lanthanum(III) fluoride (b) $\mathrm{FeCl}_{2}$, ionic, iron(II) chloride; $\mathrm{ReCl}_{6}$, molecular (metal in high oxidation state), rhenium hexachloride. (c) $\mathrm{PbCl}_{4}$, molecular (by contrast to the distinctly ionic RbCl ), lead tetrachloride; RbCl , ionic, rubidium chloride 8.47
(a)

(b) $: \mathrm{N} \equiv \mathrm{C}-\ddot{\mathrm{C}} \mathrm{C}:$

(d)

(e)

8.49 Statement (b) is most true. Keep in mind that when it is necessary to place more than an octet of electrons around an atom in order to minimize formal charge, there may not be a "best" Lewis structure. 8.51 Formal charges are shown on the Lewis structures; oxidation numbers are listed below each structure.
(a)

(b)

$$
\mathrm{S},+4 ; \mathrm{Cl},-1 ; \mathrm{O},-2
$$

(c)

$$
\mathrm{Cl},+3 ; \mathrm{H},+1 ; \mathrm{O},-2
$$

$$
\mathrm{Br},+5 ; \mathrm{O},-2
$$

### 8.53 (a) $[\ddot{O}=\ddot{\mathrm{N}}-\ddot{O}:]^{-} \longleftrightarrow[: \ddot{O}-\dot{N}=\ddot{O}]^{-}$

(b) $\mathrm{O}_{3}$ is isoelectronic with $\mathrm{NO}_{2}^{-}$; both have 18 valence electrons. (c) Since each $\mathrm{N}-\mathrm{O}$ bond has partial double-bond character, the $\mathrm{N}-\mathrm{O}$ bond length in $\mathrm{NO}_{2}^{-}$should be shorter than an $\mathrm{N}-\mathrm{O}$ single bond but longer than an $\mathrm{N}=\mathrm{O}$ double bond. 8.55 The more electron pairs shared by the atoms, the shorter the bond. Thus, the bond length of $\mathrm{O}_{2}$ is shorter than that of $\mathrm{H}_{2} \mathrm{O}_{2} .8 .57$ (a) False (b) false $\mathbf{8 . 5 9}$ (a) $\mathrm{AsF}_{5}$ is an exception to the octet rule. (b) $\mathrm{BCl}_{3}$ is an exception to the octet rule. 8.61 Assume that the dominant structure is the one that minimizes formal charge. Following this guideline, only $\mathrm{ClO}^{-}$obeys the octet rule. $\mathrm{ClO}, \mathrm{ClO}_{2}^{-}, \mathrm{ClO}_{3}^{-}$, and $\mathrm{ClO}_{4}^{-}$do not obey the octet rule.

8.63
${ }^{(a)} \mathrm{H}-\ddot{\mathrm{C}} \mathrm{C}$ :
Does not obey the octet rule. $H$ has 2 electrons.
(b)

Does not obey the octet rule. Central I has 12 electrons.
(c) $\dot{\mathrm{N}}=\ddot{\mathrm{O}}$

Does not obey the octet rule. N has only 7 electrons.
(d)

(e) $[: \ddot{\mathrm{I}} \dot{\mathrm{I}} \dot{\mathrm{I}}-\ddot{\mathrm{I}}:]^{-}$
Does not obey the octet rule. Central I has 10 electrons.

This structure violates the octet rule.

(c) Formal charges are minimized on the structure that violates the octet rule; this form is probably dominant.
$8.6732 \mathrm{e}^{-}, 16 \mathrm{e}^{-} \mathrm{pr}$
(a)

8.69 (a) $\Delta H=-304 \mathrm{~kJ} \quad$ (b) $\Delta H=-82 \mathrm{~kJ} \mathrm{\quad(c)} \quad \Delta H=-467 \mathrm{~kJ}$ 8.71 (a) False (b) false (c) false (d) false (e) false 8.73 The Ca-O bond will be stronger than the $\mathrm{Na}-\mathrm{Cl}$ bond, because the ion charges are greater. 8.75 (a) $\mathrm{CH}_{2}, 6 \mathrm{e}^{-}, 3 \mathrm{e}^{-}$pr $\mathrm{H}-\ddot{\mathrm{C}}-\mathrm{H} 2 \mathrm{CH}_{2}, \rightarrow \mathrm{C}_{2} \mathrm{H}_{4}$. (b) The product of this reaction, $\mathrm{C}_{2} \mathrm{H}_{4}$, contains a $\mathrm{C}-\mathrm{C}$ double bond, with a typical bond length of $134 \mathrm{pm} . \mathbf{8 . 7 7}$ A double $\mathrm{C}-\mathrm{O}$ bond $\mathbf{8 . 8 5}$ (a) B-O. The most polar bond will be formed by the two elements with the greatest difference in electronegativity. (b) As-I. These elements have the two largest covalent radii among this group of elements. (c) $\mathrm{BCI}_{3}$. B has three valence electron and participates in three covalent bonds. The Octet rule is satisfied by all three chlorine atoms. (d) O. O has 6 valence electrons and it needs to participate in two covalent bonds in order to satisfy the octet rule. $8.90(\mathbf{a})+1(\mathbf{b})-1$ $(\mathbf{c})+1$ (assuming the odd electron is on $N)(\mathbf{d}) 0(\mathbf{e})+3 \mathbf{8 . 9 5}$ (a) False. One possible example is ozone $\mathrm{O}_{3}$. (b) False. $\mathrm{O}_{3}$ does not have an odd electron. $8.98(\mathbf{a}) \mathrm{Ti}^{2+},[\mathrm{Ar}] 3 d^{2}$; $\mathrm{Ca},[\mathrm{Ar}] 4 s^{2}$. (b) Ca has no unpaired electrons and $\mathrm{Ti}^{2+}$ has two. (c) In order to be isoelectronic with $\mathrm{Ca}^{2+}$, Ti would have a $4+$ charge. $\mathbf{8 . 1 0 4}$ (a) Potassium peroxide is $\mathrm{K}_{2} \mathrm{O}_{2}$. (b) $14 \mathrm{e}^{-}, 7 \mathrm{e}^{-}$pairs $(\mathbf{c})^{-}: \ddot{\mathrm{O}}-\ddot{\mathrm{O}}:^{-}(\mathbf{d})$ Based on the Lewis structure, it is a single bond in the peroxide ion, whereas a double bond for the oxygen molecule. Therefore, the $\mathrm{O}-\mathrm{O}$ in peroxide ion is longer than that of the oxygen molecule.

### 8.109

(a) $\mathrm{NH}_{3} \mathrm{BF}_{3}, 32 \mathrm{e}^{-}, 16 \mathrm{e}^{-} \mathrm{pr} \quad$ (b) $\boldsymbol{\delta}^{\boldsymbol{\delta}+-} \boldsymbol{\delta}^{--}$

(c) Chlorine is less electronegative and less electron withdrawing than fluorine. The $\mathrm{B}-\mathrm{N}$ bond in $\mathrm{NH}_{3} \mathrm{BCl}_{3}$ is less polar than the $\mathrm{B}-\mathrm{N}$ bond in $\mathrm{NH}_{3} \mathrm{BF}_{3}$.

## Chapter 9

9.1 Removing an atom from the equatorial plane of the trigonal bipyramid in Figure 9.3 creates a seesaw shape. 9.3 (a) Two elec-tron-domain geometries, linear and trigonal bipyramidal (b) one electron-domain geometry, trigonal bipyramidal (c) one electrondomain geometry, octahedral (d) one electron domain geometry, octahedral (e) one electron domain geometry, octahedral (f) one electron-domain geometry, trigonal bipyramidal (This triangular pyramid is an unusual molecular geometry not listed in Table 9.3. It could occur if the equatorial substituents on the trigonal bipyramid were extremely bulky, causing the nonbonding elec-
tron pair to occupy an axial position.) 9.5 (a) Zero. Moving from left to right along the x-axis of the plot, the distance between the Cl atoms increases. At very large separation, the potential energy of interaction approaches zero. (b) The $\mathrm{Cl}-\mathrm{Cl}$ bond distance is approximately 200 pm . The $\mathrm{Cl}-\mathrm{Cl}$ bond energy is approximately $240 \mathrm{~kJ} / \mathrm{mol}$. (c) Weaker. Under extreme pressure, the $\mathrm{Cl}-\mathrm{Cl}$ bond gets shorter. The potential energy of the atom pair increases and the bond gets weaker. 9.11 (a) i, Two $s$ atomic orbitals; ii, two $p$ atomic orbitals overlapping end to end; iii, two $p$ atomic orbitals overlapping side to side (b) i, $\sigma$-type MO; ii, $\sigma$-type MO; iii, $\pi$-type MO (c) i, antibonding; ii, bonding; iii, antibonding (d) i, the nodal plane is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. ii, there are two nodal planes; both are perpendicular to the interatomic axis. One is left of the left atom and the second is right of the right atom. iii, there are two nodal planes; one is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. The second contains the interatomic axis and is perpendicular to the first. 9.13 (a) In a linear $\mathrm{AB}_{2}$ molecule, there can be either 0 or 3 nonbonding electron pairs. (b) three (c) yes 9.15 A molecule with tetrahedral molecular geometry has an atom at each vertex of the tetrahedron. A trigonal-pyramidal molecule has one vertex of the tetrahedron occupied by a nonbonding electron pair rather than an atom. 9.17 (a) Octahedral (b) octahedral (c) square planar 9.19 (a) No effect (b) no effect (c) 2 nonbonding pairs on the central O influence the molecular shape. (d) no effect (e) no effect 9.21 (a) 1 (b) 2 (c) 9 (d) 59.23 (a) Tetrahedral, tetrahedral (b) trigonal bipyramidal, T-shaped (c) octahedral, square pyramidal (d) octahedral, square planar 9.25 (a) Linear, linear (b) trigonal bipyramidal, trigonal bipyramidal (c) trigonal planar, bent (d) linear, linear (e) trigonal bipyridimal, seesaw (f) octahedral, square pyridimal 9.27 (a) i, trigonal planar; ii, tetrahedral; iii, trigonal bipyramidal (b) i, 0 ; ii, 1 ; iii, 2 (c) N and $\mathrm{P}(\mathbf{d}) \mathrm{Cl}$ (or Br or I). This T-shaped molecular geometry arises from a trigonal-bipyramidal electron-domain geometry with 2 nonbonding domains. Assuming each F atom has 3 nonbonding domains and forms only single bonds with A, A must have 7 valence electrons and be in or below the third row of the periodic table to produce these electron-domain and molecular geometries. 9.29 (a) 1 , less than $109.5^{\circ} ; 2$, close to $120^{\circ} ; 3$, less than $109.5^{\circ}$ (b) 4 , close to $120^{\circ}$ (c) 5 , close to $120^{\circ}$; 6 , close to $180^{\circ}$ (d) 7 , less than $109.5^{\circ} ; 8$, close to $120^{\circ} 9.31$ (a) $\mathrm{NH}_{4}^{+}$has zero nonbonding electron pairs on N and the largest bond angles. (b) $\mathrm{NH}_{2}^{-}$has two nonbonding electron pairs on N and the smallest bond angles. 9.33 (a) Although both ions have 4 bonding electron domains, the 6 total domains around Br require octahedral domain geometry and square-planar molecular geometry, while the 4 total domains about B lead to tetrahedral domain and molecular geometry. (b) The angles will vary as $\mathrm{H}_{2} \mathrm{O}>\mathrm{H}_{2} \mathrm{~S}>\mathrm{H}_{2} \mathrm{Se}$. The less electronegative the central atom, the larger the nonbonding electron domain, and the greater the effect of repulsive forces on adjacent bonding domains. The less electronegative the central atom, the greater the deviation from ideal tetrahedral angles. 9.35 A bond dipole is the asymmetric charge distribution between two bonded atoms with unequal electronegativities. A molecular dipole moment is the three-dimensional sum of all the bond dipoles in a molecule. 9.37 (a) No. $\mathrm{CS}_{2}$ does not have a dipole moment. (b) Yes. The net dipole moment vector points along the $\mathrm{O}-\mathrm{S}-\mathrm{O}$ angle bisector. 9.39 (a) Nonpolar. The polar B-F bonds are arranged in a symmetrical trigonal planar geometry. (b) No. The added nonbonding electron pair requires that the electron domain geometry is tetrahedral and the shape is a trigonal pyramid. (c) Yes. In $\mathrm{BF}_{2} \mathrm{Cl}$, the bond dipoles do not cancel. 9.41 (a) IF (d) $\mathrm{PCl}_{3}$ and (f) $\mathrm{IF}_{5}$ are polar. 9.43 (a) Lewis structures

Molecular geometries

Polar

Nonpolar

Polar
(b) The middle isomer has a zero net dipole moment. (c) $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}$ has only one isomer, and it has a dipole moment. 9.45 (a) True (b) false (c) true (d) false (e) true $\mathbf{9 . 4 7}$ (a) False (b) true (c) false (d) false 9.49 (a) B, $[\mathrm{He}] 2 s^{2} 2 p^{1}(\mathbf{b}) \mathrm{F},[\mathrm{He}] 2 s^{2} 2 p^{5}$ (c) $s p^{2}(\mathbf{d})$ A single $2 p$ orbital is unhybridized. It lies perpendicular to the trigonal plane of the $s p^{2}$ hybrid orbitals. 9.51 (a) $s p^{3}$ (b) $s p^{3} d^{2}$ (c) $s p^{3}$ (d) $s p^{2} 9.53$ Left, no hybrid orbitals discussed in this chapter form angles of $90^{\circ}$ with each other; $p$ atomic orbitals are perpendicular to each other; center, $109.5^{\circ}, s p^{3}$; right, $120^{\circ}, s p^{2}$
9.55 (a)

(b)

(c) A $\sigma$ bond is generally stronger than a $\pi$ bond because there is more extensive orbital overlap. (d) No. Overlap of two $s$ orbitals results in electron density along the internuclear axis, while a $\pi$ bond has none.

### 9.57

(a)

$$
\mathrm{Cl}-\mathrm{C} \equiv \mathrm{C}-\mathrm{H}
$$

(b) $s p^{3}, s p^{2}, s p(\mathbf{c})$ nonplanar, planar, planar (d) $4 \sigma, 0 \pi ; 5 \sigma, 1 \pi ; 3 \sigma$, $2 \pi 9.59$ (a) 18 valence electrons (b) 10 valence electrons make $\sigma$ bonds. (c) 2 valence electrons make $\pi$ bonds. (d) 6 valence electrons are nonbonding. (e) Both carbon atoms in the molecule are $s p^{2}$ hybridized. 9.61 (a) $\sim 109^{\circ}$ bond angles about the leftmost $\mathrm{C}, s p^{3} ; \sim 120^{\circ}$ bond angles about the right-hand C, $s p^{2}$. (b) The doubly bonded O can be viewed as $s p^{2}$, the other as $s p^{3}$; the bond angle of the $s p^{3} \mathrm{O}$ is somewhat less than $109.5^{\circ}$. (c) Seven $\sigma$ bonds, one $\pi$ bond. 9.63 (a) In a localized $\pi$ bond, the electron density is concentrated between the two atoms forming the bond. In a delocalized $\pi$ bond, the electron density is spread over all the atoms that contribute $p$ orbitals to the network. (b) The existence of more than one resonance form is a good indication that a molecule will have delocalized $\pi$ bonding. (c) delocalized

### 9.65

(a)

(b) $s p^{3}$
(c) Yes, there are five equivalent resonance structures of the type shown in (a).
(d) There are four electrons in the $\pi$ system of the molecule.
9.67 (a) Linear (b) The two central C atoms each have trigonal planar geometry with $\sim 120^{\circ}$ bond angles about them. The C and O atoms lie in a plane with the H atoms free to rotate in and out of this plane.
(c) The molecule is planar with $\sim 120^{\circ}$ bond angles about the two N atoms. 9.69 (a) Hybrid orbitals are mixtures of atomic orbitals from a single atom and remain localized on that atom. Molecular orbitals are combinations of atomic orbitals from two or more atoms and are delocalized over at least two atoms. (b) Each MO can hold a maximum of two electrons. (c) Antibonding molecular orbitals can have electrons in them.

### 9.71

(a)

$\mathrm{H}_{2}{ }^{+}$
(b) There is one electron in $\mathrm{H}_{2}{ }^{+}$. $(\mathbf{c}) \sigma_{1 s}{ }^{1}(\mathbf{d}) \mathrm{BO}=\frac{1}{2}(\mathbf{e})$ Fall apart. If the single electron in $\mathrm{H}_{2}{ }^{+}$is excited to the $\sigma_{1 \text { s }}^{*}$ orbital, its energy is higher than the energy of an $\mathrm{H} 1 s$ atomic orbital and $\mathrm{H}_{2}^{+}$will decompose into a hydrogen atom and a hydrogen ion. (f) Statement (i) is correct.
9.73

(a) $1 \sigma$ bond (b) $2 \pi$ bonds (c) $1 \sigma^{*}$ and $2 \pi^{*} 9.75$ (a) When comparing the same two bonded atoms, as bond order increases, bond energy increases. As bond order increases, bond length decreases. When comparing different bonded nuclei, there are no simple relationships. (b) $\mathrm{Be}_{2}$ is not expected to exist; it has a bond order of zero and is not energetically favored over isolated Be atoms. $\mathrm{Be}_{2}{ }^{+}$has a bond order of 0.5 and is slightly lower in energy than isolated Be atoms. It will probably exist under special experimental conditions. 9.77 (a) Diamagnetic (b) $\mathrm{F}_{2}, \mathrm{O}_{2}{ }^{2+} 9.79$ (a) $\mathrm{B}_{2}{ }^{+}, \sigma_{2 \mathrm{~s}}{ }^{2} \sigma_{2 s}^{*}{ }^{2} \pi_{2 p}{ }^{1}$, increase (b) $\mathrm{Li}_{2}{ }^{+}, \sigma_{1 s}{ }^{2} \sigma_{1 s}{ }^{*}{ }^{2} \sigma_{2 s}{ }^{1}$, increase (c) $\mathrm{N}^{+}{ }^{+}, \sigma_{2 s}{ }^{2} \sigma_{2 s}{ }^{2}{ }^{2} \pi_{2 p}{ }^{4} \sigma_{2 p}{ }^{1}$, increase (d) $\mathrm{Ne}_{2}{ }^{2+}, \sigma_{2 s}{ }^{2} \sigma_{2 s}^{*}{ }^{2} \sigma_{2 p}{ }^{2} \pi_{2 p}{ }^{4} \pi_{2 p}^{*}{ }^{4}$, decrease $\mathbf{9 . 8 1} \mathrm{CN}, \sigma_{2 s}{ }^{2} \sigma_{2 s}^{*}{ }^{2} \sigma_{2 p}{ }^{2} \pi_{2 p}{ }^{3}$, bond order $=2.5 ; \mathrm{CN}^{+}, \sigma_{2 s}{ }^{2} \sigma_{2 s}^{*}{ }^{2} \sigma_{2 p}{ }^{2} \pi_{2 p}^{2}$, bond order $=2.0 ; \mathrm{CN}^{-}$, $\sigma_{2 s}{ }^{2} \sigma_{2 s}^{*}{ }^{2} \sigma_{2 p}{ }^{2} \pi_{2 p}{ }^{4}$, bond order $=3.0$. (a) $\mathrm{CN}^{-}(\mathbf{b}) \mathrm{CN}, \mathrm{CN}^{+} \mathbf{9 . 8 3}$ (a) $3 s$, $3 p_{x}, 3 p_{y}, 3 p_{z}(\mathbf{b}) \pi_{3 p}(\mathbf{c}) 2(\mathbf{d})$ If the MO diagram for $\mathrm{P}_{2}$ is similar to that of $\mathrm{N}_{2}, \mathrm{P}_{2}$ will have no unpaired electrons and be diamagnetic. $\mathbf{9 . 8 7}$ (a) $\mathrm{PF}_{4}^{-}, \mathrm{BrF}_{4}^{-}$and $\mathrm{ClF}_{4}^{-}(\mathbf{b}) \mathrm{AlF}_{4}^{-}$(c) $\mathrm{BrF}_{4}^{-}(\mathbf{d}) \mathrm{PF}_{4}^{-}$and $\mathrm{ClF}_{4}^{+}$

9.91 (a) $5 \sigma$ bonds (b) $2 \sigma$ bonds $2 \pi$ bonds (c) $3 \sigma$ bonds $3 \pi$ bonds (d) $2 \sigma$ bonds $1 \pi$ bond

(a) The molecule is nonplanar. (b) Allene has no dipole moment. (c) The bonding in allene would not be described as delocalized. The $\pi$ electron clouds of the two adjacent $\mathrm{C}=\mathrm{C}$ are mutually perpendicular, so there is no overlap and no delocalization of $\pi$ electrons. 9.101 (a) All O atoms have $s p^{2}$ hybridization. (b) The two $\sigma$ bonds are formed by overlap of $s p^{2}$ hybrid orbitals, the $\pi$ bond is formed by overlap of atomic $p$ orbitals, one nonbonded pair is in a $p$ atomic orbital and the other five nonbonded pairs are in $s p^{2}$ hybrid orbitals. (c) unhybridized $p$ atomic orbitals (d) four, two from the $\pi$ bond and two from the nonbonded pair in the $p$ atomic orbital 9.104 (a) Ground state, $\sigma_{2 s}{ }^{2} \sigma^{*}{ }_{2 s}{ }^{2} \pi_{2 p}{ }^{4} \sigma_{2 p}{ }^{2}$; excited state, $\sigma_{2 s}{ }^{2} \sigma^{*}{ }_{2 s}{ }^{2} \pi_{2 p}{ }^{4} \sigma_{2 s}{ }^{1} \pi^{*}{ }_{2 p}{ }^{1}$ (b) paramagnetic (c) $\sigma_{2 \mathrm{p}}$ to $\pi^{*}{ }_{2 p}(\mathbf{d}) 7.0 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}(\mathbf{e})$ The bond order of the $\mathrm{N}-\mathrm{N}$ bond in the first excited state is smaller and the bond is weaker than in the ground state. The silicon analogs would have the same hybridization as the C compounds. Silicon, which is in the row below C , has a larger bonding atomic radius and atomic orbitals than C . The close approach of Si atoms required to form strong, stable $\pi$ bonds in $\mathrm{Si}_{2} \mathrm{H}_{4}$ and $\mathrm{Si}_{2} \mathrm{H}_{2}$ is not possible and these Si analogs do not readily form. 9.108 The yellow curcumin has the larger HOMOLUMO gap because it absorbs visible violet light and appears yellow.
9.114(a) $2 \mathrm{SF}_{4}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{OSF}_{4}(g)$
(b)

(c) $\Delta H=-551 \mathrm{~kJ}$, exothermic (d) The electron-domain geometry is trigonal bipyramidal. The O atom can be either equatorial or axial.

(e) In the structure on the left, there are 3 equatorial and 1 axial fluorine atoms. In the structure on the right, there are 2 equatorial and 2 axial fluorine atoms. 9.118 (a) $8462 \mathrm{~kJ} / \mathrm{mol}$ (b) $8778 \mathrm{~kJ} / \mathrm{mol}$ (c) Because the $\pi$ electrons are delocalized, the molecule has a lower overall energy than that predicted for the presence of localized $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}=\mathrm{C}$ bonds.

### 9.122

(The structure on the right does not minimize formal charges and will make a minor contribution to the true structure.)
(b)

Both resonance structures predict the same bond angles. (c) The two extreme Lewis structures predict different bond lengths. These bond length estimates assume that the structure minimizing formal charge makes a larger contribution to the true structure. $\mathrm{C}-\mathrm{O}, 1.28 \AA$; $\mathrm{C}=\mathrm{N}, 1.33 \AA ; \mathrm{C}-\mathrm{N}, 1.43 \AA ; \mathrm{C}-\mathrm{H}, 1.07 \AA(\mathbf{d})$ The molecule will have a dipole moment. The $\mathrm{C}=\mathrm{N}$ and $\mathrm{C}=\mathrm{O}$ bond dipoles are opposite each other, but they are not equal. And, there are nonbonding electron pairs that are not directly opposite each other and will not cancel.

## Chapter 10

10.1 It would be much easier to drink from a straw on Mars. When a straw is placed in a glass of liquid, the atmosphere exerts equal pressure inside and outside the straw. When we drink through a straw, we withdraw air, thereby reducing the pressure on the liquid inside. If only 709 Pa is exerted on the liquid in the glass, a very small reduction in pressure inside the straw will cause the liquid to rise.10.3 At the same temperature, volume and the lower pressure, the container would have half as many particles as at the higher pressure. 10.5 For a fixed amount of ideal gas at constant volume, if the pressure is doubled, the temperature also doubles. 10.7 (a) $P_{\text {red }}<P_{\text {yellow }}<P_{\text {blue }}(\mathbf{b}) P_{\text {red }}=28.4 \mathrm{kPa}$;
$P_{\text {yellow }}=42.6 \mathrm{kPa} ; P_{\text {blue }}=71.0 \mathrm{kPa} 10.9$ (a) Curve B is helium. (b) Curve B corresponds to the higher temperature. (c) The root mean square speed is highest. $\mathbf{1 0 . 1 1}$ The $\mathrm{NH}_{4} \mathrm{Cl}(s)$ ring will form at location a. $\mathbf{1 0 . 1 3}$ Statement (c) is false. Gaseous molecules are so far apart that there is no barrier to mixing, regardless of the identity of the molecules. $\mathbf{1 0 . 1 5}$ (a) 14.72 bar (b) $14.52 \mathrm{~atm}(\mathbf{c})$ $213.5 \mathrm{lb} / \mathrm{in}^{2} \mathbf{1 0 . 1 7}$ (a) 1.72 m (b) $1.96 \mathrm{~atm} \mathbf{1 0 . 1 9}$ (a) 1.084 atm (b) $823.7 \mathrm{~mm} \mathrm{Hg}(\mathbf{c}) 1.098 \times 10^{5} \mathrm{~Pa}$ (d) $1.098 \mathrm{bar}(\mathbf{e}) 15.93 \mathrm{psi}$ 10.21 (a) $P=773.4$ torr (b) $P=1.018 \mathrm{~atm}$ (c) The pressure in Chicago is greater than standard atmospheric pressure, and so it makes sense to classify this weather system as a "high-pressure system." 10.23 (i) 0.31 atm (ii) 1.88 atm (iii) $0.136 \mathrm{~atm} \mathbf{1 0 . 2 5}$ The action in (c) would double the pressure $\mathbf{1 0 . 2 7}$ (a) Boyle's Law, $P V=$ constant or $P_{1} V_{1}=P_{2} V_{2}$, at constant $V, P_{1} / P_{2}=1$; Charles' Law, $V / T=$ constant or $V_{1} / T_{1}=V_{2} / T_{2}$, at constant $V, T_{1} / T_{2}=1$; then $P_{1} / T_{1}=P_{2} / T_{2}$ or $P / T=$ constant. Amonton's law is that pressure and Kelvin temperature are directly proportional at constant volume. (b) 239.2 kPa 10.29 (a) STP stands for standard temperature, $0^{\circ} \mathrm{C}$ (or 273 K ), and standard pressure, 101.3 kPa . (b) 22.4 L (c) 24.5 L (d) $0.08315 \mathrm{~L}-\mathrm{bar} /$ mol-K 10.31 Flask A contains the gas with a molar mass of $28 \mathrm{~g} / \mathrm{mol}$ and flask B contains the gas with a molar mass of $56 \mathrm{~g} / \mathrm{mol}$.
10.33

$\mathbf{1 0 . 3 5} 8.2 \times 10^{2} \mathrm{~kg} \mathrm{He} \mathbf{1 0 . 3 7}$ (a) $5.15 \times 10^{22}$ molecules (b) 6.5 kg air $\mathbf{1 0 . 3 9}$ (a) $16.72 \mathrm{MPa}(\mathbf{b}) 1.91 \times 10^{3} \mathrm{~L} \mathbf{1 0 . 4 1} 567.4 \mathrm{kPa} \mathbf{1 0 . 4 3}$ (a) 29.8 $\mathrm{g} \mathrm{Cl}_{2}(\mathbf{b}) 9.42 \mathrm{~L}(\mathbf{c}) 501 \mathrm{~K}(\mathbf{d}) 231.3 \mathrm{kPa} 10.45$ (a) $1 \times 10^{-2} \mathrm{~mol} \mathrm{O}_{2}(\mathbf{b})$ The roach needs $72 \%$ of the available $\mathrm{O}_{2}$ in the jar. 10.47 The density
of a gas increases with increasing molar mass. The order of increasing density is: $\mathrm{NH}^{3}(17 \mathrm{~g} / \mathrm{mol})<\mathrm{O}_{2}(32 \mathrm{~g} / \mathrm{mol})<\mathrm{HCl}(36.5 \mathrm{~g} / \mathrm{mol})$ $\operatorname{Ar}(40 \mathrm{~g} / \mathrm{mol}) \mathbf{1 0 . 4 9}$ (c) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The balloon thus weighs less than the air displaced by its volume. $\mathbf{1 0 . 5 1}$ (a) $d=4.52 \mathrm{~g} / \mathrm{L}$ (b) molar mass $=84.1 \mathrm{~g} / \mathrm{mol} \quad \mathbf{1 0 . 5 3}$ molar mass $=89.4 \mathrm{~g} / \mathrm{mol}$ $\mathbf{1 0 . 5 5} 5.1 \times 10^{-7} \mathrm{~g} \mathrm{Mg} \quad \mathbf{1 0 . 5 7}$ (a) $8.47 \mathrm{LCO}_{2} \quad$ (b) $12.4 \mathrm{~L} \mathrm{O}_{2}$ $\mathbf{1 0 . 5 9} 0.0786 \mathrm{~g} \mathrm{Zn} 10.61$ (a) When the stopcock is opened, the volume occupied by $\mathrm{N}_{2}(g)$ increases from 2.0 L to $5.0 \mathrm{~L} . P_{\mathrm{N}_{2}}=40.53 \mathrm{kPa}$ (b) When the gases mix, the volume of $\mathrm{O}_{2}(g)$ increases from 3.0 L to $5.0 \mathrm{~L} . P_{\mathrm{O}_{2}}=121.6 \mathrm{kPa}(\mathbf{c}) P_{t}=162.1 \mathrm{kPa} 10.63$ (a) $P_{\mathrm{t}}=495.5 \mathrm{kPa}(\mathbf{b})$ $P_{\mathrm{H}_{2}}=49.6 \mathrm{kPa}, P_{\mathrm{O}_{2}}=99.3 \mathrm{kPa}, P_{\mathrm{N}_{2}}=346.5 \mathrm{kPa}$
10.65 $\quad X_{\mathrm{CO}_{2}}=0.00040710 .67 P_{\mathrm{CO}_{2}}=45.04 \mathrm{kPa}, P_{\mathrm{t}}=95.70 \mathrm{kPa}$ $10.69 P_{\mathrm{CO}_{2}}=91.0 \mathrm{kPa} 10.71 P_{\mathrm{O}_{2}}=232.3 \mathrm{kPa} 10.73 P_{\mathrm{t}}=250.27 \mathrm{kPa}$ 10.75 (a) Decrease (b) increase (c) decrease 10.77 The root-meansquare speed of Rn is approximately 7.5 times slower than that of He . $\mathbf{1 0 . 7 9}$ (a) Average kinetic energy of the molecules increases. (b) Root mean square speed of the molecules increases. (c) Strength of an average impact with the container walls increases. (d) Total collisions of molecules with walls per second increases. $\mathbf{1 0 . 8 1}$ (a) In order of increasing speed and decreasing molar mass: $\mathrm{Ar}<\mathrm{HCl},<\mathrm{O}_{2}<\mathrm{CO}<\mathrm{CH}_{4}$ (b) $u_{\mathrm{rms}}=515 \mathrm{~m} / \mathrm{s}$ (c) The most probable speed of an argon atom in the stratosphere is $337 \mathrm{~m} / \mathrm{s} . \quad \mathbf{1 0 . 8 3}$ Statements (a) and (d) are true. 10.85 The order of increasing rate of effusion is ${ }^{2} \mathrm{H}^{37} \mathrm{Cl}<{ }^{1} \mathrm{H}^{37} \mathrm{Cl}<{ }^{2} \mathrm{H}^{35} \mathrm{Cl}<{ }^{1} \mathrm{H}^{35} \mathrm{Cl}$. 10.87 $\mathrm{As}_{4} \mathrm{~S}_{6}$
$\mathbf{1 0 . 8 9}$ (a) Non-ideal-gas behavior is observed at very high pressures and low temperatures. (b) The real volumes of gas molecules and attractive intermolecular forces between molecules cause gases to behave nonideally. 10.91 Statement (b) is true. $\mathbf{1 0 . 9 3}$ (a) $P=495.48 \mathrm{kPa}$ (b) $P=475.21 \mathrm{kPa}$ (c) Qualitatively, molecular attractions are more important as the amount of free space decreases and the number of molecular collisions increases. Molecular volume is a larger part of the total volume as the container volume decreases. 10.95 From the value of $b$ for Xe , the nonbonding radius is 272 pm . From Figure 7.7, the bonding atomic radius of Xe is 140 pm . We expect the bonding radius of an atom to be smaller than its nonbonding radius, but our calculated value is nearly twice as large. $\mathbf{1 0 . 9 8} V_{f}=2.2 \mathrm{~mm}^{3} \mathbf{1 0 . 1 0 0}$ $P=74.7 \mathrm{~Pa} \mathbf{1 0 . 1 0 2}(\mathbf{a}) 5.73 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}(g)(\mathbf{b}) 2.68 \times 10^{2} \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}(l)$ (c) The ratio of moles liquid to moles gas is 47 . Many more molecules and moles of liquid fit in a container of fixed volume because there is much less space between molecules in the liquid phase. 10.104 (a) Molar mass of the unknown gas is $100.4 \mathrm{~g} / \mathrm{mol}(\mathbf{b})$ We assume that the gases behave ideally, and that $P, V$ and $T$ are constant. 10.106 (a) $0.00378 \mathrm{~mol} \mathrm{O}_{2}(\mathbf{b}) 0.0345 \mathrm{~g} \mathrm{C}_{8} \mathrm{H}_{18} \mathbf{1 0 . 1 0 8} 0.552 \mathrm{~g} \mathrm{H}_{2}$ 10.110 (a) Molar mass of the unknowngas is $50.46 \mathrm{~g} / \mathrm{mol}(\mathbf{b})$ The ratio $\mathrm{d} / \mathrm{P}$ varies with pressure because of the finite volumes of gas molecules and attractive intermolecular forces. $\mathbf{1 0 . 1 1 2} T_{2}=687^{\circ} \mathrm{C} \mathbf{1 0 . 1 1 4}$ (a) More significant (b) less significant $\mathbf{1 0 . 1 1 6}$ (a) At STP, argon atoms occupy $0.0359 \%$ of the total volume. (b) At 20.27 MPa pressure and $0^{\circ} \mathrm{C}$, argon atoms occupy $7.19 \%$ of the total volume. $\mathbf{1 0 . 1 1 8}$ (a) The molecular formula of cyclopropane is $\mathrm{C}_{3} \mathrm{H}_{6}$. (b) Although the molar masses of Ar and $\mathrm{C}_{3} \mathrm{H}_{6}$ are similar, we expect intermolecular attractions to be more significant for the more complex $\mathrm{C}_{3} \mathrm{H}_{6}$ molecules, and that $\mathrm{C}_{3} \mathrm{H}_{6}$ will deviate more from ideal behavior at the conditions listed. If the pressure is high enough for the volume correction in the van der Waals equation to dominate behavior, the larger $\mathrm{C}_{3} \mathrm{H}_{6}$ molecules definitely deviate more than Ar atoms from ideal behavior. (c) Cyclopropane would effuse through a pinhole slower than methane, because it has the greater molar mass. $\mathbf{1 0 . 1 2 0}$ (a) $44.58 \%$ C, $6.596 \% \mathrm{H}, 16.44 \% \mathrm{Cl}, 32.38 \% \mathrm{~N}(\mathbf{b}) \mathrm{C}_{8} \mathrm{H}_{14} \mathrm{~N}_{5} \mathrm{Cl}(\mathbf{c})$ Molar mass of the compound is required in order to determine molecular formula when
the empirical formula is known. $\mathbf{1 0 . 1 2 2}$ (a) $\mathrm{NH}_{3}(\mathrm{~g})$ remains after reaction. (b) $96.97 \mathrm{kPa}(\mathbf{c}) 7.33 \mathrm{~g} \mathrm{NH}_{4} \mathrm{Cl}$

### 10.124

(a) : $\ddot{\mathrm{O}}-\dot{\mathrm{C}} \mathrm{l}-\mathrm{O}:$
(b) $\mathrm{ClO}_{2}$ is very reactive because it is an odd-electron molecule. Adding an electron pairs the odd electron and completes the octet of Cl . $\mathrm{ClO}_{2}$ has a strong tendency to gain an electron and be reduced.

(d) The bond angle is less than $109^{\circ}$. (e) $11.2 \mathrm{~g} \mathrm{ClO}_{2}$
10.126 (a) $P_{\mathrm{IF}_{3}}=52.18 \mathrm{kPa}(\mathbf{b}) X_{\mathrm{IF}_{5}}=0.544$
(c)

(d) Total mass in the flask is 20.00 g ; mass is conserved.

## Chapter 11

11.1 (a) The diagram best describes a liquid. (b) In the diagram, particles are close together, mostly touching, but there is no regular arrangement or order. This rules out a gaseous sample, where the particles are far apart, and a crystalline solid, which has a regular repeating structure in all three directions. 11.4 In its final state, methane is a gas at $185^{\circ} \mathrm{C} .11 .6$ (a) Propanol can engage in hydrogen bonding. (b) While both molecules are somewhat polar, we expect propanol to have a larger dipole moment because of its O-H bond. (c) Propanol boils at $97.2^{\circ} \mathrm{C}$, while ethyl methyl ether boils at $10.8^{\circ} \mathrm{C}$. The stronger intermolecular forces in propanol cause it to have the higher boiling point. 11.9 (a) Solid $<$ liquid $<$ gas (b) gas $<$ liquid $<$ solid (c) Matter in the gaseous state is most easily compressed because particles are far apart and there is much empty space. 11.11 (a) It increases. Kinetic energy is the energy of motion. As melting occurs, the motion of atoms relative to each other increases. (b) It increases somewhat. The density of liquid lead is less than the density of solid lead. The smaller density means a greater sample volume and greater average distance between atoms in three dimensions. 11.13 (a) The molar volumes of $\mathrm{Cl}_{2}$ and $\mathrm{NH}_{3}$ are nearly the same because they are both gases. (b) On cooling to 160 K , both compounds condense from the gas phase to the solid-state, so we expect a significant decrease in the molar volume. (c) The molar volumes are $0.0351 \mathrm{~L} / \mathrm{mol} \mathrm{Cl}_{2}$ and $0.0203 \mathrm{~L} / \mathrm{mol} \mathrm{NH}_{3}(\mathbf{d})$ Solid-state molar volumes are not as similar as those in the gaseous state, because most of the empty space is gone and molecular characteristics determine properties. $\mathrm{Cl}_{2}(s)$ is heavier, has a longer bond distance and weaker intermolecular forces, so it has a significantly larger molar volume than $\mathrm{NH}_{3}(s)$. (e) There is little empty space between molecules in the liquid state, so we expect their molar volumes to be closer to those in the solid state than those in the gaseous state. $\mathbf{1 1 . 1 5}$ (a) London dispersion forces (b) dipole-dipole forces (c) hydrogen bonding 11.17 (a) $\mathrm{SO}_{2}$, London dispersion forces (b) $\mathrm{NH}_{3}$, London dispersion, dipole-dipole, and hydrogen-bonding ( $\mathrm{N}-\mathrm{H}$ bonds) forces (c) $\mathrm{BCl}_{3}$, non-polar covalent molecule $\mathbf{1 1 . 1 9}$ (a) In order of increasing polarizability: $\mathrm{CH}_{4}<\mathrm{SiH}_{4}<\mathrm{SiCl}_{4}<\mathrm{GeCl}_{4}<\mathrm{GeBr}_{4}$ (b) The magnitudes of London dispersion forces and thus the boiling points of molecules increase as polarizability increases. The order of increasing boiling points is the order of increasing polarizability given in (a). $\mathbf{1 1 . 2 1}$ (a) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(\mathbf{b}) \mathrm{N}\left(\mathrm{CH}_{3}\right)_{3}(\mathbf{c}) \mathrm{CH}_{2} \mathrm{Br}_{2} \mathbf{1 1 . 2 3}$ Both rodlike butane
molecules and spherical 2-methylpropane molecules experience dispersion forces. The larger contact surface between butane molecules facilitates stronger forces and produces a higher boiling point. 11.25 (a) A molecule must contain H atoms, bound to either $\mathrm{N}, \mathrm{O}$, or F atoms, in order to participate in hydrogen bonding with like molecules. (b) $\mathrm{CH}_{3} \mathrm{NH}_{2}$ and $\mathrm{CH}_{3} \mathrm{OH} \mathbf{1 1 . 2 7}$ (a) Replacing a hydroxyl hydrogen with a $\mathrm{CH}_{3}$ group eliminates hydrogen bonding in that part of the molecule. This reduces the strength of intermolecular forces and leads to a lower boiling point. (b) $\mathrm{CH}_{3} \mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{OCH}_{3}$ is a larger, more polarizable molecule with stronger London dispersion forces and thus a higher boiling point.
11.29

| Physical Property | $\mathbf{H}_{2} \mathbf{O}$ | $\mathbf{H}_{2} \mathbf{S}$ |
| :--- | :--- | :--- |
| Normal boiling point, ${ }^{\circ} \mathrm{C}$ | 100.00 | -60.7 |
| Normal melting point, ${ }^{\circ} \mathrm{C}$ | 0.00 | -85.5 |

(a) Based on its much higher normal melting point and boiling point, $\mathrm{H}_{2} \mathrm{O}$ has much stronger intermolecular forces. (b) $\mathrm{H}_{2} \mathrm{O}$ has hydrogen bonding, while $\mathrm{H}_{2} \mathrm{~S}$ has dipole-dipole forces. Both molecules have London dispersion forces. $11.31 \mathrm{SO}_{4}{ }^{2-}$ has a greater negative charge than $\mathrm{BF}_{4}^{-}$, so ion-ion electrostatic attractions are greater in sulfate salts and they are less likely to form liquids. $\mathbf{1 1 . 3 3}$ (a) As temperature increases, surface tension decreases; they are inversely related. (b) As temperature increases, viscosity decreases; they are inversely related. (c) The same attractive forces that cause surface molecules to be difficult to separate (high surface tension) cause molecules elsewhere in the sample to resist movement relative to each other (high viscosity). 11.35 (a) Diagram (ii) shows stronger adhesive forces between the surface and the liquid. (b) Diagram (i) represents water on a nonpolar surface. (c) Diagram (ii) represents water on a polar surface. 11.37 (a) The three molecules have similar structures and experience the same types of intermolecular forces. As molar mass increases, the strength of dispersion forces increases and the boiling points, surface tension, and viscosities all increase. (b) Ethylene glycol has an -OH group at both ends of the molecule. This greatly increases the possibilities for hydrogen bonding; the overall intermolecular attractive forces are greater and the viscosity of ethylene glycol is much greater. (c) Water has the highest surface tension but lowest viscosity because it is the smallest molecule in the series. There is no hydrocarbon chain to inhibit their strong attraction to molecules in the interior of the drop, resulting in high surface tension. The absence of an alkyl chain also means the molecules can move around each other easily, resulting in the low viscosity. 11.39 (a) Fusion, endothermic (b) vaporization, endotermic (c) condensation exothermic (d) condensation exothermic 11.41 (a) vaporization (l) $\rightarrow$ (g) (b) endothermic (c) Same numerical value. $11.432 .3 \times 10^{3} \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \mathbf{1 1 . 4 5}$ (a) 14.3 kJ (b) $25.1 \mathrm{~kJ} \mathbf{1 1 . 4 7}$ (a) False (b) true (c) false (d) true $\mathbf{1 1 . 4 9}$ Properties (c) intermolecular attractive forces, (d) temperature and (e) density of the liquid affect vapor pressure of a liquid.
11.51 (a) $\mathrm{CBr}_{4}<\mathrm{CHBr}_{3}<\mathrm{CH}_{2} \mathrm{Br}_{2}<\mathrm{CH}_{2} \mathrm{Cl}_{2}<\mathrm{CH}_{3} \mathrm{Cl}<\mathrm{CH}_{4}$. (b) $\mathrm{CH}_{4}<\mathrm{CH}_{3} \mathrm{Cl}<\mathrm{CH}_{2} \mathrm{Cl}_{2}<\mathrm{CH}_{2} \mathrm{Br}_{2}<\mathrm{CHBr}_{3}<\mathrm{CBr}_{4}$ (c) By analogy to attractive forces in HCl , the trend will be dominated by dispersion forces, even though four of the molecules are polar. The order of increasing boiling point is the order of increasing molar mass and increasing strength of dispersion forces. 11.53 (a) The temperature of the water in the two pans is the same. (b) Vapor pressure does not depend on either volume or surface area of the liquid. At the same temperature, the vapor pressures of water in the two containers are the same. 11.55 (a) Approximately $40^{\circ} \mathrm{C}$ (b) approximately 7 kPa
(c) approximately $50^{\circ} \mathrm{C}(\mathbf{d})$ approximately 51 kPa 11.57 (a) The critical point is the temperature and pressure beyond which the gas and liquid phases are indistinguishable. (b) The line that separates the gas and liquid phases ends at the critical point because at conditions beyond the critical temperature and pressure, there is no distinction between gas and liquid. In experimental terms a gas cannot be liquefied at temperatures higher than the critical temperature, regardless of pressure. At conditions beyond the critical point, a substance is known as a supercritical fluid. 11.59 (a) $\mathrm{H}_{2} \mathrm{O}(g)$ will condense to $\mathrm{H}_{2} \mathrm{O}(s)$ at approximately 530 Pa ; at a higher pressure, perhaps 500 kPa or so, $\mathrm{H}_{2} \mathrm{O}(s)$ will melt to form $\mathrm{H}_{2} \mathrm{O}(l)$. (b) At $100{ }^{\circ} \mathrm{C}$ and 50.7 kPa , water is in the vapor phase. As it cools, water vapor condenses to the liquid at approximately $82{ }^{\circ} \mathrm{C}$, the temperature where the vapor pressure of liquid water is 50.7 kPa . Further cooling results in freezing at approximately $0^{\circ} \mathrm{C}$. The freezing point of water increases with decreasing pressure, so at 50.7 kPa the freezing temperature is very slightly above $0^{\circ} \mathrm{C} .11 .61$ (a) 24 K (b) Neon sublimes at pressures less than the triple point pressure, approximately 50.7 kPa . (c) No 11.63 (a) Methane on the surface of Titan is likely to exist in both solid and liquid forms. (b) As pressure decreases upon moving away from the surface of Titan, $\mathrm{CH}_{4}(\mathrm{l})\left(\right.$ at $\left.-178{ }^{\circ} \mathrm{C}\right)$ will vaporize to $\mathrm{CH}_{4}(\mathrm{~g})$, and $\mathrm{CH}_{4}(s)$ (at temperatures below $-180^{\circ} \mathrm{C}$ ) will sublime to $\mathrm{CH}_{4}(\mathrm{~g})$. 11.65 In a nematic liquid crystalline phase, molecules are aligned along their long axes, but the molecular ends are not aligned. Molecules are free to translate in all dimensions, but they cannot tumble or rotate out of the molecular plane, or the order of the nematic phase is lost and the sample becomes an ordinary liquid. In an ordinary liquid, molecules are randomly oriented and free to move in any direction. 11.67 (a) True (b) false (c) true (d) false (e) false (f) true 11.69 Because order is maintained in at least one dimension, the molecules in a liquid-crystalline phase are not totally free to change orientation. This makes the liquid-crystalline phase more resistant to flow, more viscous, than the isotropic liquid. 11.71 Melting provides kinetic energy sufficient to disrupt molecular alignment in one dimension in the solid, producing a smectic phase with ordering in two dimensions. Additional heating of the smectic phase provides kinetic energy sufficient to disrupt alignment in another dimension, producing a nematic phase with one-dimensional order. 11.73 (a) Decrease (b) increase (c) increase (d) increase (e) increase (f) increase (g) increase $\mathbf{1 1 . 7 6}$ (a) The trans isomer will have stronger intermolecular hydrogen bonding, but the cis isomer will have stronger intramolecular hydrogen bonding. (b) The trans isomer melts at $287^{\circ} \mathrm{C}$ and the cis isomer melts at $135^{\circ} \mathrm{C}$. 11.78 (a) All of these compounds exhibit dispersion interactions. (b) ) All of these compounds are polar and exhibit dipole-dipole interactions. (c) Only methanoic acid and ethanoic acid exhibit hydrogen bonding. (d) Methanoic acid and ethanoic acid both exhibit hydrogen bonding, but ethanoic acid has a higher molecular weight. Thus, it has a higher total intermolecular force resulting in a higher boiling point. (e) Ethanal does not exhibit hydrogen bonding and it has the lowest molecular weight. Therefore, it has the lowest boiling point. 11.81 A plot of number of carbon atoms versus boiling point indicates that the boiling point of $\mathrm{C}_{8} \mathrm{H}_{18}$ is approximately $130^{\circ} \mathrm{C}$. The more carbon atoms in the hydrocarbon, the longer the chain, the more polarizable the electron cloud, the higher the boiling point. 11.83 (a) Evaporation is an endothermic process. The heat required to vaporize sweat is absorbed from your body, helping to keep it cool. (b) The vacuum pump reduces the pressure of the atmosphere above the water until atmospheric pressure equals the vapor pressure of water and the water boils. Boiling is an endothermic process, and the temperature drops if the system is not able to absorb heat from the surroundings fast enough. As the temperature of the water
decreases, the water freezes. 11.88 At low Antarctic temperatures, molecules in the liquid crystalline phase have less kinetic energy due to temperature, and the applied voltage may not be sufficient to overcome orienting forces among the ends of molecules. If some or all of the molecules do not rotate when the voltage is applied, the display will not function properly.

### 11.92

$$
\text { (i) } M=44
$$

(ii) $\mathbf{M}=72$
(iii) $\mathbf{M}=123$

(iv) $\mathbf{M}=58$

(v) $\mathbf{M}=123$

(vi) $M=60$
(a) Molar mass: Compounds (i) and (ii) have similar rodlike structures. The longer chain in (ii) leads to greater molar mass, stronger London dispersion forces, and higher heat of vaporization. (b) Molecular shape: Compounds (iii) and (v) have the same chemical formula and molar mass but different molecular shapes. The more rodlike shape of (v) leads to more contact between molecules, stronger dispersion forces, and higher heat of vaporization. (c) Molecular polarity: Compound (iv) has a smaller molar mass than (ii) but a larger heat of vaporization, which must be due to the presence of dipole-dipole forces. (d) Hydrogen bonding interactions: Molecules (v) and (vi) have similar structures. Even though (v) has larger molar mass and dispersion forces, hydrogen bonding causes (vi) to have the higher heat of vaporization.
11.96 $P$ (hexane vapor) $=25,278 \mathrm{~Pa}$

## Chapter 12

12.1 The red-orange compound is more likely to be a semiconductor and the white one an insulator. The red-orange compound absorbs light in the visible spectrum (red-orange is reflected, so blue-green is absorbed), while the white compound does not. This indicates that the red-orange compound has a lower energy electron transition than the white one. Semiconductors have lower energy electron transitions than insulators. 12.5 (a) The structure is hexagonal closepacked. (b) The coordination number, CN, is twelve. (c) $\mathrm{CN}(1)=9$, $\mathrm{CN}(2)=6$. 12.7 Fragment $(\mathbf{b})$ is more likely to give rise to electrical conductivity. Arrangement (b) has a delocalized $\pi$ system, in which electrons are free to move. Mobile electrons are required for electrical conductivity. 12.9 We expect linear polymer (a), with ordered regions, to be more crystalline and to have a higher melting point than branched polymer (b). $\mathbf{1 2 . 1 1}$ Statement $(\mathbf{b})$ is the best explanation. 12.13 (a) Hydrogen bonding, dipole-dipole forces, London dispersion forces (b) covalent chemical bonds (c) ionic bonds (d) metallic bonds $\mathbf{1 2 . 1 5}$ (a) Covalent-network (b) metallic (c) ionic (d) molecular (e) molecular (f) ionic $\mathbf{1 2 . 1 7}$ Metallic, because of its melting point, conductivity, and insolubility in water
12.19 (a)

Crystalline
(b)

Amorphous
12.21

12.23 Tetragonal $\mathbf{1 2 . 2 5}$ (e) Triclinic and rhombohedral $\mathbf{1 2 . 2 7}$ (b) 212.29 (a) Primitive hexagonal unit cell (b) NiAs $\mathbf{1 2 . 3 1}$ Copper. A body-centered cubic structure has more empty space than a facecentered cubic one. The more empty space, the less dense the solid. We expect the element with the highest density, copper, to adopt the face-centered cubic structure. $\mathbf{1 2 . 3 3}$ (a) Structure types A and C have equally dense packing and are more densely packed than structure type B. (b) Structure type B is least densely packed. 12.35 (a) The radius of an Rh atom is 135 pm . (b) The density of Rh is $12.4 \mathrm{~g} / \mathrm{cm}^{3}$. $\mathbf{1 2 . 3 7}$ (a) The radius of a Ca atom is 197.6 pm . (b) The density of Ca is $1.526 \mathrm{~g} / \mathrm{cm}^{3} \mathbf{1 2 . 3 9}$ (a) 4 Al atoms per unit cell (b) coordination number $=12$ (c) $a=4.04 \times 10^{-8} \mathrm{~cm}$ (d) density $=2.71 \mathrm{~g} / \mathrm{cm}^{3}$ 12.41 Statement (b) is false. 12.43 (a) Interstitial alloy (b) substitutional alloy (c) intermetallic compound $\mathbf{1 2 . 4 5}$ (a) True (b) false (c) false $\mathbf{1 2 . 4 7}$ (a) Nickel or palladium, substitutional alloy (b) copper, substitutional alloy (c) silver, substitutional alloy 12.49 (a) True (b) false (c) false (d) false
12.51

(a) Six AOs require six MOs (b) zero nodes in the lowest energy orbital (c) five nodes in highest energy orbital (d) two nodes in the HOMO (e) three nodes in the LUMO (f) The HOMO-LUMO energy gap for the six-atom diagram is smaller than the one for the four-atom diagram. In general, the more atoms in the chain, the smaller the HOMO-LUMO energy gap. 12.53 (a) Ag is more ductile. Cr has stronger metallic bonding, a stiffer lattice, and is less susceptible to distortion. (b) Zn is more ductile. Ge is a metalloid semi-conductor solid with a stiffer lattice than metallic Zn . 12.55 The order of increasing melting points is $\mathrm{La}<\mathrm{Hf}<$ $\mathrm{Ta}<\mathrm{W}$. Moving from La to W , the number of valence electrons, occupancy of the bonding band, and strength of metallic bonding increase. Stronger metallic bonding requires more energy
to break bonds and mobilize atoms, resulting in higher melting points from La to W. $\mathbf{1 2 . 5 7}$ (a) $\mathrm{SrTiO}_{3}$ (b) Six (c) Each Sr atom is coordinated to a total of twelve O atoms in the eight unit cells that contain the Sr atom. 12.59 The density of PbS is $7.60 \mathrm{~g} / \mathrm{cm}^{3}$. 12.61 (a) $2.90 \mathrm{~g} / \mathrm{cm}^{3}$ (b) We expect $\mathrm{As}^{3-}$ to have a larger ionic radius than $\mathrm{P}^{3-}$, so BAs will occupy a larger volume and the unit cell edge will be longer. (c) The density of BAs is $5.21 \mathrm{~g} / \mathrm{cm}^{3}$. The greater mass of As accounts for the greater density of BAs. $\mathbf{1 2 . 6 3}$ (a) $\mathrm{Cs}^{+}$and $\mathrm{I}^{-}$have the most similar radii and will adopt the CsCl-type structure. The radii of $\mathrm{Na}^{+}$and $\mathrm{I}^{-}$are somewhat different; NaI will adopt the NaCl -type structure. The radii of $\mathrm{Cu}^{+}$and $\mathrm{I}^{-}$are very different; CuI has the ZnS-type structure. (b) CsI, 8; NaI, 6; CuI, 412.65 (a) 6 (b) 3 (c) $6 \mathbf{1 2 . 6 7}$ (a) False (b) true $\mathbf{1 2 . 6 9}$ (a) Ionic solids are much more likely to dissolve in water. (b) Covalent-network solids can become considerably better conductors of electricity via chemical substitution. $\mathbf{1 2 . 7 1}$ (a) CdS (b) GaN (c) GaAs $\mathbf{1 2 . 7 3} \mathrm{Ge}$ or Si ( Ge is closer to Ga in bonding atomic radius.) $\mathbf{1 2 . 7 5}$ (a) A 1.1 eV photon corresponds to a wavelength of $1.1 \times 10^{-6} \mathrm{M}(\mathbf{b})$ According to the figure, Si can absorb all wavelengths in the visible portion of the solar spectrum. (c) Si absorbs wavelengths less than 1,100 nm . This corresponds to approximately $80-90 \%$ of the total area under the curve. 12.77 The emitted light has a wavelength of 365 nm . This is radiation in the ultraviolet region of the electromagnetic spectrum. 12.79 The band gap is approximately 2.09 eV , which corresponds to a wavelength of 593 nm .12 .81 (a) A monomer is a small molecule with low molecular mass that can be joined with other monomers to form a polymer. They are the repeating units of a polymer. (b) ethene (also known as ethylene) $\mathbf{1 2 . 8 3}$ Reasonable values for a polymer's molecular weight are $10,000 u, 100,000 u$, and $1,000,000 \mathrm{u}$.

### 12.85

If a dicarboxylic acid and a dialcohol are combined, there is the potential for propagation of the polymer chain at both ends of both monomers.

### 12.87

12.89

12.91 (a) Flexibility of the molecular chains causes flexibility of the bulk polymer. Flexibility is enhanced by molecular features that inhibit order, such as branching, and diminished by features that encourage order, such as cross-linking or delocalized $\pi$ electron density. (b) Less flexible $\mathbf{1 2 . 9 3}$ Low degree of crystallinity 12.95 If a solid has nanoscale dimensions of $1-10 \mathrm{~nm}$, there may
not be enough atoms contributing atomic orbitals to produce continuous energy bands of molecular orbitals. 12.97 (a) False. As particle size decreases, the band gap increases. (b) False. As particle size decreases, wavelength decreases. $\mathbf{1 2 . 9 9} 2.47 \times 10^{5} \mathrm{Au}$ atoms 12.101 Statement (b) is correct. $\mathbf{1 2 . 1 0 9} 3 \mathrm{Ni}$ atoms, 1 Al atom; 6 Nb atoms, 2 Sn atoms; 1 Sm atom, 5 Co atoms. In each case, the atom ratio matches the empirical formula given in the exercise. 12.111 The wavelength that corresponds to a photon with this energy is 477 nm .12 .113 (a) Zinc sulfide, $\mathrm{ZnS}(\mathbf{b})$ covalent (c) In the solid, each Si is bound to four C atoms in a tetrahedral arrangement, and each C is bound to four Si atoms in a tetrahedral arrangement, producing an extended three-dimensional network. SiC is highmelting because melting requires breaking covalent $\mathrm{Si}-\mathrm{C}$ bonds, which takes a huge amount of thermal energy. It is hard because the three-dimensional lattice resists any deformation that would weaken the $\mathrm{Si}-\mathrm{C}$ bonding network. 12.120 The distance between planes in crystalline silicon is 313 pm .12 .126 (a) $109^{\circ}$ (b) $120^{\circ}$ (c) atomic $p$ orbitals $\mathbf{1 2 . 1 3 0}$ (a) $2.50 \times 10^{22} \mathrm{Si}$ atoms (To 1 sig fig, the result is $2 \times 10^{22} \mathrm{Si}$ atoms.) (b) $1.29 \times 10^{-3} \mathrm{mg} \mathrm{P}(1.29 \mu \mathrm{~g} \mathrm{P})$ 12.132 63 Si atoms

## Chapter 13

13.1 (a) $<$ (b) $<$ (c) $\mathbf{1 3 . 3}$ (a) No (b) The ionic solid with the smaller lattice energy will be more soluble in water. $\mathbf{1 3 . 7}$ Vitamin $B_{6}$ is more water soluble. Vitamin E is more fat soluble. 13.9 (a) Yes, the molarity changes with a change in temperature. (b) No, molality does not change with change in temperature. 13.11 The volume inside the balloon will be 0.5 L , assuming perfect osmosis across the semipermeable membrane. 13.13 (a) False (b) false (c) true $\mathbf{1 3 . 1 5}$ (a) Dispersion (b) hydrogen bonding (c) ion-dipole (d) dipole-dipole $\mathbf{1 3 . 1 7}$ Very soluble (b) $\Delta H_{\text {mix }}$ will be the largest negative number. In order for $\Delta H_{\text {soln }}$ to be negative, the magnitude of $\Delta H_{\text {mix }}$ must be greater than the magnitude of ( $\Delta H_{\text {solute }}+\Delta H_{\text {solvent }}$ ). 13.19 (a) $\Delta H_{\text {solute }}$ (b) $\Delta H_{\text {mix }} 13.21$ (a) $\Delta H_{\text {soln }}$ is nearly zero. Because the solute and solvent in this case experience very similar London dispersion forces, the energy required to separate them individually and the energy released when they are mixed are approximately equal. $\Delta \mathrm{H}_{\text {mix }} \approx-\left(\Delta \mathrm{H}_{\text {solute }}+\Delta \mathrm{H}_{\text {solvent }}\right)$. (b) The entropy of the system increases when benzene and toluene form a solution. The change involves taking two pure liquids and forming a (homogeneous) mixture. The result is an increase in randomness or disorder. From part (a), the enthalpy of mixing is nearly zero, so the increase in entropy is the driving force for mixing in all proportions. 13.23 (a) Supersaturated (b) The bits of glass scraped from the vessel act as a seed crystal, which provides a nucleus of already aligned molecules, so that ordering of the dissolved particles is more facile. The excess alum is crystallizing out. (c) 86 g alum form 13.25 (a) Saturated (b) unsaturated (c) saturated (d) unsaturated $\mathbf{1 3 . 2 7}$ (a) We expect the liquids water and glycerol to be miscible in all proportions. (b) Hydrogen bonding, dipoledipole forces, London dispersion forces $\mathbf{1 3 . 2 9}$ Toluene, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{3}$, is the best solvent for nonpolar solutes. Without polar groups or nonbonding electron pairs, it forms only dispersion interactions with itself and other molecules. 13.31 (a) Carbon tetrachloride (b) water 13.33 (a) $\mathrm{CCl}_{4}$ is more soluble because dispersion forces among nonpolar $\mathrm{CCl}_{4}$ molecules are similar to dispersion forces in hexane. (b) $\mathrm{C}_{6} \mathrm{H}_{6}$ is a nonpolar hydrocarbon and will be more soluble in the similarly nonpolar hexane. (c) The long, rodlike hydrocarbon chain of octanoic acid forms strong dispersion interactions and causes it to be more soluble in hexane. 13.35 (a) False (b) true (c) false (d) true $13.37 S_{\mathrm{H}_{2}}=2.0 \times 10^{-3} \mathrm{M}, S_{\mathrm{Ar}}=3.5 \times 10^{-3} \mathrm{M}$ 13.39 (a) $1.60 \%$ of $\mathrm{NaNO}_{3}(\mathbf{b}) 28.6 \mathrm{ppm}$ 13.41(a) $X_{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}=0.0192$ (b) $4.76 \% \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ by mass
(c) $1.09 \mathrm{~m}_{2} \mathrm{H}_{5} \mathrm{OH} 13.43$ (a) $8.63 \times 10^{-3} \mathrm{MMg}\left(\mathrm{NO}_{3}\right)_{2}$ (b) 1.25 M $\mathrm{LiClO}_{4} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (c) $0.375 \mathrm{M} \mathrm{HNO}_{3} 13.45$ (a) $2.56 m \mathrm{C}_{6} \mathrm{H}_{6}$ (b) $0.858 m$ NaCl 13.47 (a) $50.01 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ by mass (b) $X_{\mathrm{H}_{2} \mathrm{SO}_{4}}=0.155$
(c) $10.20 \mathrm{~m} \mathrm{H}_{2} \mathrm{SO}_{4}$ (d) $7.112 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4} 13.49$ (a) $X_{\mathrm{CH}_{3} \mathrm{OH}}=0.244$
(b) $7.85 \mathrm{~m} \mathrm{CH}_{3} \mathrm{OH}$ (c) $4.94 \mathrm{M} \mathrm{CH}_{3} \mathrm{OH} 13.51$ (a) $0.0900 \mathrm{~mol} \mathrm{SrBr}_{2}$
(b) $1.40 \times 10^{-2} \mathrm{~mol} \mathrm{KCl}(\mathbf{c}) 8.63 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$
13.53 (a) Weigh out 1.3 g KBr , dissolve in water, dilute with stirring to 0.75 L . (b) Weigh out 2.62 g KBr , dissolve it in $122.38 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ to make exactly 125 g of 0.180 m solution. (c) Dissolve 244 g KBr in water, dilute with stirring to 1.85 L . (d) Weigh 10.1 g KBr , dissolve it in a small amount of water, and dilute to $0.568 \mathrm{~L} .13 .5521 \% \mathrm{HNO}_{3}$ by mass $\mathbf{1 3 . 5 7}$ (a) 8.23 m Zn (b) $45.3 \mathrm{M} \mathrm{Zn} \mathbf{1 3 . 5 9}$ (a) 4.66 kPa (b) $1.8 \times 10^{-3} M \mathrm{CO}_{2} 13.61$ (a) False (b) true (c) true (d) false 13.63 The vapor pressure of the first solution, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)$, is 3.10 kPa . The vapor pressure of the second solution, $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(\mathrm{aq})$, is 3.14 kPa . Generally, the less concentrated solution, the one with fewer moles of solute per kilogram of solvent, will have the higher vapor pressure. 13.65 (a) $\mathrm{P}_{\mathrm{H}_{2} \mathrm{O}}=24.85 \mathrm{kPa}(\mathbf{b}) 78.9 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{2} \mathbf{1 3 . 6 7}$ (a) $X_{\text {Eth }}=0.2812$ (b) $P_{\text {soln }}=31.7 \mathrm{kPa}(\mathbf{c}) X_{\text {Eth }}$ in vapor $=0.47213 .69$ (a) Because KCl is a strong electrolyte, one mole of KCl produces twice as many dissolved particles as one mole of the molecular solute urea. Freezingpoint depression is directly related to total moles of dissolved particles. The 0.10 m KCl has more dissolved particles so its freezing point is lower than that of $0.10 \mathrm{~m} \mathrm{CO}\left(\mathrm{NH}_{2}\right)_{2}$. (b) In solutions of strong electrolytes like KCl , ion pairing reduces the effective number of particles in solution, decreasing the change in freezing point. The actual freezing point is then higher than the calculated freezing point for a $0.10 m$ solution. (b) In solutions of strong electrolytes like NaCl , ion pairing reduces the effective number of particles in solution, decreasing the change in boiling point. The actual boiling point is then lower than the calculated boiling point for a 0.10 m solution. $13.710 .130 m$ urea $<0.080 m \mathrm{KBr}<0.070 m \mathrm{Mg}\left(\mathrm{NO}_{2}\right)_{2} \mathbf{1 3 . 7 3}$ (a) $T_{f}=-115.0^{\circ} \mathrm{C}, T_{b}=78.7^{\circ} \mathrm{C} \quad$ (b) $T_{f}=-67.3^{\circ} \mathrm{C}, T_{b}=64.2^{\circ} \mathrm{C}$ (c) $T_{f}=-0.4^{\circ} \mathrm{C}, T_{b}=100.1^{\circ} \mathrm{C} \quad$ (d) $\quad T_{f}=-0.6^{\circ} \mathrm{C}, T_{b}=100.2^{\circ} \mathrm{C}$ $13.75667 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2} \quad 13.77 \Pi=7.15 \mathrm{kPa}$ 13.79 The approximate molar mass of adrenaline is $1.8 \times 10^{2} \mathrm{~g}$. $\mathbf{1 3 . 8 1}$ Molar mass of lysozyme $=1.39 \times 10^{4} \mathrm{~g} \mathbf{1 3 . 8 3} i=2.8 \mathbf{1 3 . 8 5}(\mathbf{a})$ No. In the gaseous state, particles are far apart and intermolecular attractive forces are small. When two gases combine, all terms in Equation 13.1 are essentially zero and the mixture is always homogeneous. (b) To determine whether Faraday's dispersion is a true solution or a colloid, shine a beam of light on it. If light is scattered, the dispersion is a colloid. 13.87 Choice $(\mathbf{d}), \mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{11} \mathrm{COONa}$, is the best emulsifying agent. The long hydrocarbon chain will interact with the hydrophobic component, while the ionic end will interact with the hydrophilic component, as well as stabilize the colloid. 13.89 (a) No. The hydrophobic or hydrophilic nature of the protein will determine which electrolyte at which concentration will be the most effective precipitating agent. (b) Stronger. If a protein has been "salted out", protein-protein interactions are stronger than protein-solvent interactions and solid protein forms. (c) The first hypothesis seems plausible, since ion-dipole interactions among electrolytes and water molecules are stronger than dipole-dipole and hydrogen bonding interactions between water and protein molecules. But, we also know that ions adsorb on the surface of a hydrophobic colloid; the second hypothesis also seems plausible. If we could measure the charge and adsorbed water content of protein molecules as a function of salt concentration, then we could distinguish between these two hypotheses. 13.91 (a) Hydrochloride (b) free base (c) 0.492 M free base (d) 7.36 M hydrochloride (e) 275 mL of 12.0 M HCl 13.94 (a) $k_{\mathrm{Rn}}=7.17 \times 10^{-3} \mathrm{~mol} / \mathrm{L}-\mathrm{kPa}$ (b) $\quad P_{\mathrm{Rn}}=23 \mathrm{~Pa} ; \quad S_{\mathrm{Rn}}=1.6 \times 10^{-6} M \quad \mathbf{1 3 . 9 8} \quad$ (a) $2.69 \quad m \quad \mathrm{LiBr}$ (b) $X_{\mathrm{LiBr}}=0.0994(\mathbf{c}) 81.1 \% \mathrm{LiBr}$ by mass $13.100 X_{\mathrm{H}_{2} \mathrm{O}}=0.95$; 0.0263 mol ions; $0.0132 \mathrm{~mol} \mathrm{NaCl} ; 0.769 \mathrm{~g} \mathrm{NaCl} 13.103$ (a) $-0.6^{\circ} \mathrm{C}$
(b) $-0.4{ }^{\circ} \mathrm{C} \quad \mathbf{1 3 . 1 0 6} \quad$ (a), $\mathrm{CF}_{4}, 1.7 \times 10^{-4} \mathrm{~m}$; $\mathrm{CClF}_{3}, 9 \times 10^{-4} \mathrm{~m}$; $\mathrm{CCl}_{2} \mathrm{~F}_{2}, 2.3 \times 10^{-2} \mathrm{~m} ; \mathrm{CHClF}_{2}, 3.5 \times 10^{-2} m(\mathbf{b})$ dipole moment (c) $3.9 \times 10^{-4} \mathrm{~mol} \mathrm{O}_{2} \mathbf{1 3 . 1 0 9}$ (a) The central atom and the number of electron-pair domains about it are: (i) $\mathrm{Cl}, 4$; (ii) B, 4 ; (iii) P, 6; (iv) Al, 4; (v) B, 4 (b) tetrahedral (c) The central P atom in anion (iii) has an expanded octet. As drawn, the central Cl atom in anion (i) also has an expanded octet. Note that multiple resonance structures for $\mathrm{ClO}_{4}^{-}$ can be drawn, including one where Cl obeys the octet rule. The structure shown in this exercise is one that minimizes formal charge. (d) BARF 13.113 (a) $P_{t}=56.34 \mathrm{kPa}(\mathbf{b})$ Endothermic. Repulsive forces lead to an overall lowering of the energy of the system. $\Delta H_{\text {soln }}>0$.

## Chapter 14

14.1 The rate of the combustion reaction in the cylinder depends on the surface area of the droplets in the spray. The smaller the droplets, the greater the surface area exposed to oxygen, the faster the combustion reaction. In the case of a clogged injector, larger droplets lead to slower combustion. Uneven combustion in the various cylinders can cause the engine to run roughly and decrease fuel economy. 14.3 Equation (iv) (b) rate $=-\Delta[\mathrm{B}] / \Delta t=1 / 2 \Delta[\mathrm{~A}] / \Delta t \mathbf{1 4 . 9}$ (1) Total potentialenergyofthereactants(2) $E_{a}$, activationenergyofthereaction (3) $\Delta E$, netenergychangeforthereaction(4)totalpotentialenergyofthe products 14.12 (a) $\mathrm{NO}_{2}+\mathrm{F}_{2} \longrightarrow \mathrm{NO}_{2} \mathrm{~F}+\mathrm{F} ; \mathrm{NO}_{2}+\mathrm{F} \longrightarrow \mathrm{NO}_{2} \mathrm{~F}$ (b) $2 \mathrm{NO}_{2}+\mathrm{F}_{2} \longrightarrow 2 \mathrm{NO}_{2} \mathrm{~F}$ (c) F (atomic fluorine) is the intermediate (d) rate $=k\left[\mathrm{NO}_{2}\right]\left[\mathrm{F}_{2}\right] \quad 14.15$ (a) Net reaction: $\mathrm{AB}+\mathrm{AC} \longrightarrow \mathrm{BA}_{2}+\mathrm{C}(\mathbf{b}) \mathrm{A}$ is the intermediate. $(\mathbf{c}) \mathrm{A}_{2}$ is the catalyst. 14.17 (a) Reaction rate is the change in the amount of products or reactants in a given amount of time. (b) Rates depend on concentration of reactants, surface area of reactants, temperature, and activation energy/presence of catalyst. (c) No. The stoichiometry of the reaction (mole ratios of reactants and products) must be known to relate rate of disappearance of reactants to rate of appearance of products.

(b) $P_{\text {total }}$ decreases by $30 \mathrm{kPa} / \mathrm{min} . \mathbf{1 4 . 2 7}$ (a) If [B] doubles, there is no change in the rate or the rate constant. (b) The reaction is third order in A, zero order in B, and third order overall. (c) units of $k=M^{-2} \mathrm{~s}^{-1} 14.29(\mathbf{a})$ Rate $=k\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right](\mathbf{b})$ Rate $=2.06 \times 10^{-4} \mathrm{M} / \mathrm{s}$ (c) When the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ triples, the rate of the reaction triples. (d) When the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ is reduced by $10 \%$, the rate of the reaction is reduced by $10 \% . \mathbf{1 4 . 3 1}$ (a) $5.2 \times 10^{2} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ (b) If $\left[\mathrm{OH}^{-}\right]$is cut in half, the rate decreases by a factor of $1 / 2$. (c) If both $\left[\mathrm{OH}^{-}\right]$and $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}\right]$ are cut in half, the rate decreases by a factor of 114.14 .33 (a) Rate $=k\left[\mathrm{OCl}^{-}\right]\left[\mathrm{I}^{-}\right]$(b) $k=60 \mathrm{M}^{-1} \mathrm{~s}^{-1}$. (c) Rate $=6.0 \times 10^{-5} \mathrm{M} / \mathrm{s} \mathbf{1 4 . 3 5}$ (a) Rate $=k\left[\mathrm{BF}_{3}\right]\left[\mathrm{NH}_{3}\right]$ (b) The reaction is second order overall. (c) $k_{\text {avg }}=3.41 \mathrm{M}^{-1} \mathrm{~s}^{-1}$ (d) $0.170 \mathrm{M} / \mathrm{s}$ 14.37 (a) Rate $=k[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right] \quad$ (b) $\quad k_{\text {avg }}=1.2 \times 10^{4} \mathrm{M}^{-2} \mathrm{~s}^{-1}$ (c) $\frac{1}{2} \Delta[\mathrm{NOBr}] / \Delta t=-\Delta\left[\mathrm{Br}_{2}\right] / \Delta t(\mathbf{d})-\Delta\left[\mathrm{Br}_{2}\right] / \Delta t=8.4 \mathrm{M} / \mathrm{s} \mathbf{1 4 . 3 9}$ (a) A graph of $\ln [\mathrm{A}]$ versus time yields a straight line for a first-order reaction. (b) On a graph of $\ln [A]$ versus time, the rate constant is the (-slope) of the straight line. $\mathbf{1 4 . 4 1 ( a )} k=3.2 \times 10^{-6} s^{-1}\left(0.28 d^{-1}\right)$ (b) $t_{1 / 2}=2.2 \times 10^{2} \mathrm{~s}(3.7 \mathrm{~min}) \mathbf{1 4 . 4 3}$ (a) $P=4 \mathrm{kPa}(\mathbf{b}) t=51 \mathrm{~s}$
14.45 Plot ( $\ln P_{\mathrm{SO}_{2} \mathrm{Cl}_{2}}$ ) versus time, $k=-$ slope $=2.19 \times 10^{-5} \mathrm{~s}^{-1}$
$\mathbf{1 4 . 4 7}$ (a) The plot of $1 /[\mathrm{A}]$ versus time is linear, the reaction is second order in [A]. (b) 281 seconds (c) $t_{1 / 2}=38 \mathrm{~min} \mathbf{1 4 . 4 9}$ (a) The plot of $1 /\left[\mathrm{NO}_{2}\right]$ versus time is linear, so the reaction is second order in $\mathrm{NO}_{2}$. (b) $k=$ slope $=10 \mathrm{M}^{-1} \mathrm{~s}^{-1}(\mathbf{c})$ rate at $0.200 \mathrm{M}=0.400 \mathrm{M} / \mathrm{s}$, rate at $0.100 \mathrm{M}=0.100 \mathrm{M} / \mathrm{s}$; rate at $0.050 \mathrm{M}=0.025 \mathrm{M} / \mathrm{s}$
14.51 (a) The energy of the collision and the orientation of the molecules when they collide determine whether a reaction will occur. (b) The rate constant usually increases with an increase in reaction temperature. (c) The fraction of molecules with energy greater than the activation energy changes most dramatically with temperature. Frequency of collision and the orientation factor are lumped into the frequency factor, A , which is considered to be constant with temperature. $\mathbf{1 4 . 5 3} f=1.81 \times 10^{-2}$. At 300 K , approximately 2 out of 100 molecules have this kinetic energy.

(b) $E_{a}($ reverse $)=73 \mathrm{~kJ} \mathbf{1 4 . 5 7}$ (a) False (b) false (c) true $\mathbf{1 4 . 5 9}$ The order of slowest reaction to fastest reaction is: rate $(\mathbf{b})<$ rate (c) < rate (a) $\mathbf{1 4 . 6 1}$ (a) $k=1.1 \mathrm{~s}^{-1}$ (b) $k=13 \mathrm{~s}^{-1}$ (c) The method in parts (a) and (b) assumes that the collision model and thus the Arrhenius equation describe the kinetics of the reactions. That is, activation energy is constant over the temperature range under consideration. 14.63 A plot of $\ln k$ versus $1 / T$ has a slope of $-5.64 \times 10^{3} ; E_{a}=-R$ (slope) $=47.5 \mathrm{~kJ} / \mathrm{mol} 14.65$ (a) An elementary reaction is a process that occurs as a single event; the order is given
by the coefficients in the balanced equation for the reaction. (b) A unimolecular elementary reaction involves only one reactant molecule; a bimolecular elementary reaction involves two reactant molecules. (c) A reaction mechanism is a series of elementary reactions that describes how an overall reaction occurs and explains the experimentally determined rate law. (d) A rate-determining step is the slow step in a reaction mechanism. It limits the overall reaction rate. 14.67 (a) Bimolecular, rate $=k\left[\mathrm{H}_{2} \mathrm{O}\right]\left[\mathrm{CN}^{-}\right](\mathbf{b})$ bimolecular, rate $=k\left[\mathrm{CH}_{3} \mathrm{Cl}\right]\left[\mathrm{OH}^{-}\right](\mathbf{c})$ unimolecular, rate $=k\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right] \mathbf{1 4 . 6 9}$ (a) Two intermediates, B and C. $(\mathbf{b})$ three transition states $(\mathbf{c}) \mathrm{C} \longrightarrow \mathrm{D}$ is fastest. (d) $\Delta E$ is positive. $14.71(\mathbf{a}) \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{ICl}(\mathrm{g}) \rightarrow \mathrm{I}_{2}(\mathrm{~g})+2 \mathrm{HCl}(\mathrm{g})(\mathbf{b}) \mathrm{HI}$ is the intermediate. (c) If the first step is slow, the observed rate law is rate $=k\left[\mathrm{H}_{2}\right][\mathrm{ICI}]$. 14.73 (a) The two-step mechanism is consistent with the data, assuming that the second step is rate determining. (b) No. The linear plot guarantees that the overall rate law will include $[\mathrm{NO}]^{2}$. Since the data were obtained at constant $\left[\mathrm{Cl}_{2}\right]$, we have no information about reaction order with respect to $\left[\mathrm{Cl}_{2}\right] .14 .75$ (a) A catalyst is a substance that changes (usually increases) the speed of a chemical reaction without undergoing a permanent chemical change itself. (b) A homogeneous catalyst is in the same phase as the reactants, while a hetereogeneous catalyst is in a different phase. (c) A catalyst has no effect on the overall enthalpy change for a reaction, but it does affect activation energy. It can also affect the frequency factor.

14.79 (a) Multiply the coefficients in the first reaction by 2 and sum. (b) $\mathrm{NO}_{2}(\mathbf{g})$ is a catalyst. (c) $\mathrm{NO}(\mathbf{g})$ is an intermediate. (d) This is a homogeneous catalysis. $\mathbf{1 4 . 8 1}$ (a) Use of chemically stable supports makes it possible to obtain very large surface areas per unit mass of the precious metal catalyst because the metal can be deposited in a very thin, even monomolecular, layer on the surface of the support. (b) The greater the surface area of the catalyst, the more reaction sites, the greater the rate of the catalyzed reaction. $\mathbf{1 4 . 8 3}$ To put two $D$ atoms on a single carbon, it is necessary that one of the already existing $\mathrm{C}-\mathrm{H}$ bonds in ethylene be broken while the molecule is adsorbed, so that the H atom moves off as an adsorbed atom and is replaced by a D atom. This requires a larger activation energy than simply adsorbing $\mathrm{C}_{2} \mathrm{H}_{4}$ and adding one D atom to each carbon. 14.85 The enzyme lowers the activation energy of the reaction by $44 \mathrm{~kJ} / \mathrm{mol} . \mathbf{1 4 . 8 7}$ (a) The catalyzed reaction is approximately $10,000,000$ times faster at $25^{\circ} \mathrm{C}(\mathbf{b})$ The catalyzed reaction is 180,000 times faster at $125^{\circ} \mathrm{C}$. $\mathbf{1 4 . 9 1}$ (a) Rate $=4.7 \times 10^{-5} \mathrm{M} / \mathrm{s}$ (b, c) $k=0.84 \mathrm{M}^{-2} \mathrm{~s}^{-1}(\mathbf{d})$ If the $[\mathrm{NO}]$ is increased by a factor of 1.8 , the rate would increase by a factor of 3.2. $\mathbf{1 4 . 9 5}$ (a) The reaction is second order in $\mathrm{C}_{2} \mathrm{~F}_{4}$. (b) 889 seconds $\mathbf{1 4 . 9 9 \text { (a) The half-life of cobalt- } 6 0 \text { is } { } ^ { 2 } \text { (b) }}$ 5.29 years, that of iron- 59 is 44.7 days. (b) Iron- 59 decays at a faster rate. (c) 0.13 mg remains after three half-lives. (d) 0.925 mg remains after five days. $\mathbf{1 4 . 1 0 3}(\mathbf{a})$ The plot of $1 /\left[\mathrm{C}_{5} \mathrm{H}_{6}\right]$ versus time is linear and the reaction is second order. (b) $k=0.167 M^{-1} \mathrm{~s}^{-1} \mathbf{1 4 . 1 0 7}$ (a) When the two elementary reactions are added, $\mathrm{N}_{2} \mathrm{O}_{2}(\mathrm{~g})$ appears on both sides and cancels, resulting in the overall reaction. $2 \mathrm{NO}(g)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}(g)+\mathrm{H}_{2} \mathrm{O}(g) \quad(b) \quad$ First reaction, $-[\mathrm{NO}] / \Delta t=k[\mathrm{NO}]^{2}$, second reaction, $-\left[\mathrm{H}_{2}\right] / \Delta t=k\left[\mathrm{H}_{2}\right]\left[\mathrm{N}_{2} \mathrm{O}_{2}\right]$
(c) $\mathrm{N}_{2} \mathrm{O}_{2}$ is the intermediate. (d) Because $\left[\mathrm{H}_{2}\right]$ appears in the rate law, the second step must be slow relative to the first.
14.110 (a) $\mathrm{Cl}_{2}(g)+\mathrm{CHCl}_{3}(g) \longrightarrow \mathrm{HCl}(g)+\mathrm{CCl}_{4}(g)$ (b) $\mathrm{Cl}(\mathbf{g})$, $\mathrm{CCl}_{3}(\mathrm{~g})$ (c) reaction 1, unimolecular; reaction 2, bimolecular; reaction 3, bimolecular (d) Reaction 2 is rate determining. (e) Rate $=k\left[\mathrm{CHCl}_{3}\right]\left[\mathrm{Cl}_{2}\right]^{1 / 2}$. $\mathbf{1 4 . 1 1 5}$ The enzyme must lower the activation energy by 22 kJ in order to make it useful. 14.120 (a) $k=8 \times 10^{7} M^{-1} \mathrm{~s}^{-1}$
(b) $: \dot{\mathrm{N}}=\ddot{\mathrm{O}}:$

(c) NOF is bent with a bond angle of approximately $120^{\circ}$

(e) The electron-deficient NO molecule is attracted to electron-rich $\mathrm{F}_{2}$ so the driving force for formation of the transition state is greater than simple random collisions.
14.123 (a)

(b) A reactant that is attracted to the lone pair of electrons on nitrogen will produce a tetrahedral intermediate. This can be a moiety with a full, partial, or even transient positive charge.

## Chapter 15

15.1 (a) $k_{f}>k_{r}$ (b) The equilibrium constant is greater than one. 15.3 $K$ is greater than one. 15.5 $\mathrm{A}(g)+\mathrm{B}(g) \rightleftharpoons \mathrm{AB}(g)$ has the larger equilibrium constant. 15.6 From the smallest to the largest equilibrium constant, $(\mathbf{c})<(\mathbf{b})<(\mathbf{a})$. 15.7 Statement $(\mathbf{b})$ is true. $\mathbf{1 5 . 9}$ Two B atoms should be added to the diagram. 15.11 $K_{c}$ decreases as $T$ increases, so the reaction is exothermic. 15.13 (a) $K=0.1$ (b) At equilibrium, the partial pressure of A is greater than the partial pressure of B
15.15 (a) $K_{c}=\left[\mathrm{I}^{2}\right] /\left[\mathrm{I}_{2}\right]$; homogeneous
(b) $K_{c}=\left[\mathrm{SO}_{3}\right]^{2} /\left[\mathrm{SO}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]$; homogeneous
(c) $K_{c}=[\mathrm{CO}]^{2} /[\mathrm{CO}]$; heterogeneous
(d) $K_{c}=\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right] /\left[\mathrm{H}_{2} \mathrm{O}\right][\mathrm{CO}]$; homogeneous
(e) $K_{c}=\left[\mathrm{HCO}_{3}^{-}\right]\left[\mathrm{H}^{+}\right] /\left[\mathrm{CO}_{2}\right]$; homogeneous (f) $K_{c}=\left[\mathrm{Zn}^{2+}\right]\left[\mathrm{Fe}^{2^{+}}\right]$; heterogeneous (g) $K_{c}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{CO}_{3}^{2-}\right]$; heterogeneous 15.17 (a) Mostly products (b) at low total pressure, mostly reactants $\mathbf{1 5 . 1 9}$ (a) True (b) false (c) false $\mathbf{1 5 . 2 1} K_{p}=1.6 \times 10^{-9} \mathbf{1 5 . 2 3}$ (a) The equilibrium favors NO and $\mathrm{Br}_{2}$ at this temperature. (b) $K_{c}=77$ (c) $K_{c}=8.8 \mathbf{1 5 . 2 5}$ (a) $K_{p}=5.44$ (b) $K_{p}=0.034$ (c) $K_{c}=283 \mathbf{1 5 . 2 7}$ $K_{c}=2.9 \times 10^{-3} \mathbf{1 5 . 2 9}$ (a) $K_{p}=P_{\mathrm{O}_{2}}(\mathbf{b}) K_{c}=[\mathrm{Hg}(\text { solv })]^{4}\left[\mathrm{O}_{2}(\right.$ solv $\left.)\right]$ $15.31 K_{c}=10.5 \mathbf{1 5 . 3 3}$ (a) $K_{p}=0.61$ (b) $K_{c}=2.8 \times 10^{3} \mathbf{1 5 . 3 5}$ (a) $[\mathrm{NO}]=0.050,\left[\mathrm{~N}_{2}\right]=0.010,\left[\mathrm{H}_{2} \mathrm{O}\right]=0.150(\mathbf{b}) K_{c}=9.0 \times 10^{2}$
15.37 (a) $\quad P_{\mathrm{H}_{2} \mathrm{O}}=326 \mathrm{kPa}, P_{\mathrm{H}_{2}}=203 \mathrm{kPa}, P_{\mathrm{CO}_{2}}=405 \mathrm{kPa} \quad$ (b) $P_{\mathrm{H}_{2} \mathrm{O}}=347 \mathrm{kPa}, P_{\mathrm{H}_{2} \mathrm{O}}=182 \mathrm{kPa}, P_{\mathrm{CO}_{2}}=384 \mathrm{kPa}, P_{\mathrm{CO}}=21 \mathrm{kPa} \quad$ (c) $K_{p}=0.10(\mathbf{d}) K_{c}=0.10 \mathbf{1 5 . 3 9} K_{c}=2.0 \times 10^{4} \mathbf{1 5 . 4 1}(\mathbf{a})$ The value of $Q_{c}$ is zero. (b) As the reaction proceeds, the value of $Q_{c}$ will increase. (c) The reaction must be at equilibrium. 15.43 (a) $Q=7.2 \times 10^{-6}$, the reaction will proceed to the left. (b) $Q=3.0 \times 10^{-11}$, the reaction will proceed to the right. (c) $Q=5.18 \times 10^{-9}$, the reaction will proceed to the left. $\mathbf{1 5 . 4 5} P_{\mathrm{Cl}_{2}}=395 \mathrm{kPa}$
$15.47\left[\mathrm{Br}_{2}\right]=0.00939 \mathrm{M},[\mathrm{Br}]=0.00312 \mathrm{M}, 0.250 \mathrm{~g} \mathrm{Br}(\mathrm{g})$
$15.49[\mathrm{I}]=4.73 \times 10^{-5} \mathrm{M},\left[\mathrm{I}_{2}\right]=7.2 \times 10^{-5} \mathrm{M}, 0.092 \mathrm{~g} \mathrm{I}_{2}$
$\mathbf{1 5 . 5 1}[\mathrm{NO}]=0.003 \mathrm{M},\left[\mathrm{N}_{2}\right]=\left[\mathrm{O}_{2}\right]=0.12 \mathrm{M}$
15.53 The equilibrium pressure of $\mathrm{Br}_{2}(g)$ is 205 kPa .
$15.55(\mathbf{a})\left[\mathrm{Ca}^{2+}\right]=\left[\mathrm{SO}_{4}^{2-}\right]=4.9 \times 10^{-3} \mathrm{M}(\mathbf{b})$ A bit more than 1.0 g $\mathrm{CaSO}_{4}$ is needed in order to have some undissolved $\mathrm{CaSO}_{4}$ (s) in equilibrium with 1.4 L of saturated solution.
$\mathbf{1 5 . 5 7}[\mathrm{IBr}]=0.180 \mathrm{M},\left[\mathrm{I}_{2}\right]=\left[\mathrm{Br}_{2}\right]=0.0102 \mathrm{M}$
15.59 (a) $P_{\mathrm{CH}_{3} \mathrm{I}}=\mathrm{P}_{\mathrm{HI}}=130 \mathrm{~Pa}, P_{\mathrm{CH}_{4}}=13.2 \mathrm{kPa}, P_{\mathrm{I}_{2}}=6.5 \mathrm{kPa} 15.61$ (a) No effect (b) shift equilibrium to the left (c) shift equilibrium to the right $(\mathbf{d})$ shift equilibrium to the left $(\mathbf{e})$ shift equilibrium to the left ( $\mathbf{f}$ ) no effect $\mathbf{1 5 . 6 3}$ (a) No effect $(\mathbf{b})$ no effect $(\mathbf{c})$ increase $K_{P}(\mathbf{d})$ no effect $(\mathbf{e})$ decrease $K_{P} \mathbf{1 5 . 6 5}$ (a) $\Delta H^{\circ}=-155.7 \mathrm{~kJ}$ (b) The reaction is exothermic, so the equilibrium constant will decrease with increasing temperature. (c) $\Delta n$ does not equal zero, so a change in volume at constant temperature will affect the fraction of products in the equilibrium mixture. 15.67 An increase in pressure favors formation of ozone. 15.69 (a) Endothermic (b) The equilibrium constant increases. (c) The forward rate constant increases by a larger amount than the reverse rate constant. $\mathbf{1 5 . 7 3} K_{p}=2.5 \times 10^{5} ; K_{c}=3.67 \times 10^{-3} \mathbf{1 5 . 7 6}$ (a) $P_{\mathrm{Br}_{2}}=16.3 \mathrm{kPa} \quad P_{\mathrm{NO}}=63.6 \mathrm{kPa}, P_{\mathrm{NOBr}}=18.1 \mathrm{kPa} ; K_{c}=0.0643(\mathbf{b})$ $P_{t}=98.1 \mathrm{kPa},(\mathbf{c}) 10.49 \mathrm{~g} \mathrm{NOBr} \mathbf{1 5 . 7 9}$ At equilibrium, $P_{1 \mathrm{~B} r}=4.3 \mathrm{kPa}$, $P_{\mathrm{I}_{2}}=P_{\mathrm{Br}_{2}}=0.395 \mathrm{kPa} 15.82 K_{p}=897, K_{c}=0.107$
$15.85\left[\mathrm{CO}_{2}\right]=\left[\mathrm{H}_{2}\right]=0.264 \mathrm{M},[\mathrm{CO}]=\left[\mathrm{H}_{2} \mathrm{O}\right]=0.236 \mathrm{M}$
15.93 $Q=8 \times 10^{-6} . Q>K_{p}$, so the system is not at equilibrium; it will shift left to attain equilibrium. A catalyst that speeds up the reaction and thereby promotes the attainment of equilibrium would decrease the CO concentration in the exhaust. 15.95 At equilibrium, $\left[\mathrm{H}_{4} \mathrm{IO}_{6}^{-}\right]=0.0015 \mathrm{M}$

## Chapter 16

16.1 (a) HCl , the $\mathrm{H}^{+}$donor, is the Brønsted-Lowry acid. $\mathrm{NH}_{3}$, the $\mathrm{H}^{+}$acceptor, is the Brønsted-Lowry base. (b) HCl , the electron pair acceptor, is the Lewis acid. $\mathrm{NH}_{3}$, the electron pair donor, is the Lewis base. $\mathbf{1 6 . 5}$ (a) HY is a strong acid. There are no neutral HY molecules in solution, only $\mathrm{H}^{+}$cations and $\mathrm{Y}^{-}$anions. (b) HX has the smallest $K_{a}$ value. It has most neutral acid molecules and fewest ions. (c) HX has fewest $\mathrm{H}^{+}$and highest pH .16 .11 (a) Molecule (b) is more acidic because its conjugate base is resonance-stabilized and the ionization equilibrium favors the more stable products. (b) Increasing the electronegativity of $X$ increases the strength of both acids. As X becomes more electronegative and attracts more electron density, the $\mathrm{O}-\mathrm{H}$ bond becomes weaker, more polar, and more likely to be ionized. An electronegative X group also stabilizes the anionic conjugate bases by delocalizing the negative charge. The equilibria favor products and the values of $K_{a}$ increase. $\mathbf{1 6 . 1 3}$ HCl is the Brønsted-Lowry acid; $\mathrm{NH}_{3}$ is the Brønsted-Lowry base. 16.15 (a) (i) $\mathrm{HPO}_{4}^{2-}$ (ii) $\mathrm{Br}^{-}$(b) (i) HCN (ii) $\mathrm{H}_{2} \mathrm{SO}_{4}$

$16.63(\mathbf{a})\left[\mathrm{H}^{+}\right]=2.8 \times 10^{-3} \mathrm{M}, 0.69 \%$ ionization
(b) $\left[\mathrm{H}^{+}\right]=1.4 \times 10^{-3} \mathrm{M}, 1.4 \%$ ionization
(c) $\left[\mathrm{H}^{+}\right]=8.7 \times 10^{-4} \mathrm{M}, 2.2 \%$ ionization
$16.65(\mathbf{a})\left[\mathrm{H}^{+}\right]=5.1 \times 10^{-3} \mathrm{M}, \mathrm{pH}=2.30$. (b) Yes. We started the calculation by assuming that only the first step made a significant contribution to $\left[\mathrm{H}^{+}\right]$and pH . Calculation proved this assumption to be true. Next we assumed $\left[\mathrm{H}^{+}\right]$from the first ionization was small relative to 0.040 M citric acid; this assumption was not valid. Finally we assumed that additional ionization of $\left[\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}^{2-}\right]$ was small, which was true. (c) $\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}{ }^{3-}\right]$ is much less than $\left[\mathrm{H}^{+}\right]$. $\mathbf{1 6 . 6 7}$ (a) $\mathrm{HONH}_{3}{ }^{+}$ (b) When hydroxylamine acts as a base, the nitrogen atom accepts a proton. (c) In hydroxylamine, O and N are the atoms with nonbonding electron pairs; in the neutral molecule both have zero formal charges. Nitrogen is less electronegative than oxygen and more likely to share a lone pair of electrons with an incoming (and electrondeficient) $\mathrm{H}^{+}$. The resulting cation with the +1 formal charge on N is more stable than the one with the +1 formal charge on O . $\mathbf{1 6 . 6 9}$ (a) $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons\left(\mathrm{CH}_{3}\right)_{3} \mathrm{NH}^{+}(a q)+\mathrm{OH}^{-}(a q)$;

$K_{b}=\left[\mathrm{HSO}_{3}^{-}\right]\left[\mathrm{OH}^{-}\right] /\left[\mathrm{SO}_{3}^{2-}\right]$
(c) $\mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HCN}(a q)+\mathrm{OH}^{-}(a q)$;
$K_{b}=[\mathrm{HCN}]\left[\mathrm{OH}^{-}\right] /\left[\mathrm{CN}^{-}\right]$
16.71 From the quadratic formula, $\left[\mathrm{OH}^{-}\right]=5.4 \times 10^{-3} \mathrm{M}$,
$\mathrm{pH}=11.7316 .73(\mathbf{a})\left[\mathrm{C}_{10} \mathrm{H}_{15} \mathrm{ON}\right]=0.033 \mathrm{M},\left[\mathrm{C}_{10} \mathrm{H}_{15} \mathrm{ONH}^{+}\right]=$ $\left[\mathrm{OH}^{+}\right]=2.1 \times 10^{-3} \mathrm{M}(\mathbf{b}) K_{b}=1.4 \times 10^{-4}$
16.75 (a) $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}(a q)$
(b) $K_{b}=7.7 \times 10^{-5}(\mathbf{c})$ Phenol is a stronger acid than water.
16.77 (a) Hydrofluoric acid is stronger. (b) Cyanate ion is the stronger base. (c) For $\mathrm{NCO}^{-}, K_{b}=2.9 \times 10^{-11}$; for $\mathrm{F}^{-}, K_{b}=1.5 \times 10^{-11}$ 16.79 (a) $\left[\mathrm{OH}^{-}\right]=5.7 \times 10^{-4} \mathrm{M}, \mathrm{pH}=10.75$
(b) $\left[\mathrm{OH}^{-}\right]=1.3 \times 10^{-4} \mathrm{M}, \mathrm{pH}=10.10$
(c) $\left[\mathrm{OH}^{-}\right]=3.5 \times 10^{-6} \mathrm{M}, \mathrm{pH}=8.54 \quad \mathbf{1 6 . 8 1} \quad 0.11 \quad \mathrm{M} \mathrm{KCH} 33 \mathrm{COO}$ $\mathbf{1 6 . 8 3}$ (a) Acidic (b) acidic (c) basic (d) neutral (e) acidic $\mathbf{1 6 . 8 5} K_{b}$ for the anion of the unknown salt is $1.4 \times 10^{-11} ; K_{b}$ for $\mathrm{F}^{-}$is $1.5 \times 10^{-11}$; The unknown salt is $\mathrm{NaF} \mathbf{1 6 . 8 7}$ (a) $\mathrm{HNO}_{3}$ is a stronger acid than $\mathrm{HNO}_{2}$ (b) $\mathrm{H}_{2} \mathrm{~S}$ is a stronger acid than $\mathrm{H}_{2} \mathrm{O}$. (c) $\mathrm{H}_{2} \mathrm{SO}_{4}$ is a stronger acid than $\mathrm{H}_{2} \mathrm{SeO}_{4}$. (d) $\mathrm{CCl}_{3} \mathrm{COOH}$ is stronger than $\mathrm{CH}_{3} \mathrm{COOH}$ 16.89 (a) $\mathrm{BrO}^{-}(\mathbf{b}) \mathrm{BrO}^{-}(\mathbf{c}) \mathrm{HPO}_{4}{ }^{2-} \mathbf{1 6 . 9 1}$ (a) True (b) False. In a series of acids that have the same central atom, acid strength increases with the number of nonprotonated oxygen atoms bonded to the central atom. (c) False. $\mathrm{H}_{2} \mathrm{Te}$ is a stronger acid than $\mathrm{H}_{2} \mathrm{~S}$ because the $\mathrm{H}-\mathrm{Te}$ bond is longer, weaker, and more easily ionized than the $\mathrm{H}-\mathrm{S}$ bond. $16.93 \mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)$. Ammonia, $\mathrm{NH}_{3}$, acts as an Arrhenius base because it increases the concentration of hydroxide ion, $\mathrm{OH}^{-}$, in aqueous solution. It acts like a BrønstedLowry base because it is a proton, $\mathrm{H}^{+}$, acceptor. It acts like a Lewis base because it is an electron pair donor. 16.95 (a) Acid, $\mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{3}$ or $\mathrm{Fe}^{3+}$, base, $\mathrm{H}_{2} \mathrm{O}\left(\right.$ b) Acid, $\mathrm{H}_{2} \mathrm{O}$; base, $\mathrm{CN}^{-}(\mathbf{c})$ Acid, BF 3 ; base, $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$ (d) Acid, HIO; base, $\mathrm{NH}_{2}^{-} 16.97$ (a) $\mathrm{Cu}^{2+}$, higher cation charge (b) $\mathrm{Fe}^{3+}$, higher cation charge (c) $\mathrm{Al}^{3+}$, smaller cation radius, same charge $\mathbf{1 6 . 1 0 1} K=3.3 \times 10^{7} \mathbf{1 6 . 1 0 6} \mathrm{pH}=7.03$ ( $\operatorname{not} 6.1$, from the typical calculation, which does not make sense). Usually we assume that $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$from the autoprotolysis of water do not contribute to the overall $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$. However, for acid or base solute concentrations less than $1.0 \times 10^{-6} \mathrm{M}$, the autoprotolysis of water produces significant $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$and we must consider it when calculating pH . 16.109 (a) $\mathrm{p} K_{a}=4.84$ (b) $\mathrm{pH}=2.98$ (c) $\mathrm{pH}=8.86$ 16.113 Nicotine, protonated; caffeine, neutral base; strychnine, protonated; quinine, protonated $\mathbf{1 6 . 1 1 6} 6.0 \times 10^{13} \mathrm{H}^{+}$ions 16.119 (a) To the precision of the reported data, the pH of rainwater 40 years ago was 5.4 , no different from the pH today. With extra significant figures, $\left[\mathrm{H}^{+}\right]=3.61 \times 10^{-6} \mathrm{M}, \mathrm{pH}=5.443$ (b) A 20.0-L bucket of today's rainwater contains 0.02 L (with extra significant figures, 0.0200 L ) of dissolved $\mathrm{CO}_{2}$. $16.123 \mathrm{Rx} 1, \Delta H=104 \mathrm{~kJ}$; Rx $2, \Delta H=-32 \mathrm{~kJ}$. Reaction 2 is exothermic while reaction 1 is endothermic. For binary acids with heavy atoms ( X ) in the same family, the longer and weaker the $\mathrm{H}-\mathrm{X}$ bond, the stronger the acid (and the more exothermic the ionization reaction). 16.126 (a) $K(\mathrm{i})=5.6 \times 10^{3}, K(\mathrm{ii})=10(\mathbf{b})$ Both (i) and (ii) have $K>1$, so both could be written with a single arrow.

## Chapter 17

17.1 The middle box has the highest pH . For equal amounts of acid HX, the greater the amount of conjugate base $X^{-}$, the smaller the amount of $\mathrm{H}^{+}$and the higher the $\mathrm{pH} . \mathbf{1 7 . 7}$ (a) The red curve corresponds to the more concentrated acid solution. (b) On the titration curve of a weak acid, $\mathrm{pH}=\mathrm{p} K_{a}$ at the volume halfway to the equivalence point. Reading the $p K_{a}$ values from the two curves, the red curve has the smaller $p K_{a}$ and the larger $K_{a} . \mathbf{1 7 . 0 9}$ (a) The
right-most diagram represents the solubility of $\mathrm{BaCO}_{3}$ as $\mathrm{HNO}_{3}$ is added. (b) The left-most diagram represents the solubility of $\mathrm{BaCO}_{3}$ as $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is added. (c) The center diagram represents the solubility of $\mathrm{BaCO}_{3}$ as $\mathrm{NaNO}_{3}$ is added. 17.13 Statement (a) is most correct. 17.15 (a) $\left[\mathrm{H}^{+}\right]=1.58 \times 10^{-5} \mathrm{M}, \mathrm{pH}=4.80$ (b) $\left[\mathrm{OH}^{-}\right]=5.44 \times 10^{-5} \mathrm{M}$, $\mathrm{pH}=9.74(\mathbf{c})\left[\mathrm{H}^{+}\right]=1.44 \times 10^{-5} \mathrm{M}, \mathrm{pH}=4.8417 .17$ (a) $4.2 \%$ ionization (b) 0.020 \% ionization 17.19 Only solution (b) is a buffer $17.21(\mathbf{a}) \mathrm{pH}=3.76$ (b) $\mathrm{pH}=3.28 \mathbf{1 7 . 2 3}$ (a) $\mathrm{pH}=5.31$

CdS will precipitate; ZnS will not. (b) Add excess base; $\mathrm{Fe}\left(\mathrm{OH}_{3}\right)(s)$ precipitates, but $\mathrm{Cr}^{3+}$ forms the soluble complex $\mathrm{Cr}(\mathrm{OH})_{4}^{-}$. (c) Add $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4} ; \mathrm{Mg}^{2+}$ precipitates as $\mathrm{MgNH}_{4} \mathrm{PO}_{4} ; K^{+}$remains soluble. (d) Add 6 M HCl ; precipitate $\mathrm{Ag}^{+}$as $\mathrm{AgCl}(s) ; \mathrm{Mn}^{2+}$ remains soluble. $\mathbf{1 7 . 8 1}$ (a) Base is required to increase $\left[\mathrm{PO}_{4}^{3-}\right]$ so that the solubility product of the metal phosphates of interest is exceeded and the phosphate salts precipitate. (b) $K_{s p}$ for the cations in group 3 is much larger; to exceed $K_{s p}$, a higher [ $\mathrm{S}^{2-}$ ] is required. (c) They should all redissolve in strongly acidic solution. $\mathbf{1 7 . 8 3}$ $\mathrm{pOH}=\mathrm{p} K_{b}+\log \left\{\left[\mathrm{BH}^{-}\right] /[\mathrm{B}]\right\} \mathbf{1 7 . 8 9}$ (a) 6.5 mL glacial acetic acid, $5.25 \mathrm{~g} \mathrm{CH}_{3} \mathrm{COONa} 17.91$ (a) The molar mass of the acid is $121 \mathrm{~g} / \mathrm{mol}$. (b) $K_{a}=6.3 \times 10^{-5} \mathbf{1 7 . 9 7}$ (a) $\left[\mathrm{Pb}^{2+}\right]=2.7 \times 10^{-7} M$ (b) 56 ppb $\mathrm{Pb}^{2+}$ (c) The solubility of $\mathrm{PbCO}_{3}$ increases as pH is lowered. (d) A saturated solution of lead carbonate, with a lead concentra-
tion of 56 ppb , exceeds the EPA acceptable lead level of 15 ppb . 17.102 The solubility of $\mathrm{Fe}(\mathrm{OH})_{2}$ in $0.50 \mathrm{MNH}_{4} \mathrm{Cl}$ is $5.34 \times 10^{-3} \mathrm{~mol} / \mathrm{L}$ $\mathbf{1 7 . 1 0 8}\left[\mathrm{OH}^{-}\right] \geq 1.0 \times 10^{-2} \mathrm{M}$ or $\mathrm{pH} \geq 12.02 \mathbf{1 7 . 1 1 1}$ (a) The molar mass of the acid is $94.5 \mathrm{~g} / \mathrm{mol}$. (b) $K_{a}=1.3 \times 10^{-5}(\mathbf{c})$ From Appendix D , butanoic acid is the closest match for $K_{a}$ and molar mass, but the agreement is not exact. $\mathbf{1 7 . 1 1 3}$ (a) At the conditions given for the stomach, $99.7 \%$ of the aspirin is present as neutral molecules. $\mathbf{1 7 . 1 1 7}(\mathbf{a})\left[\mathrm{Ag}^{+}\right]$from AgCl is $1.4 \times 10^{3} \mathrm{ppb}$ or 1.4 ppm . (b) $\left[\mathrm{Ag}^{+}\right]$ from AgBr is 76 ppb . (c) $\left[\mathrm{Ag}^{+}\right]$from AgI is 0.98 ppb . AgBr would maintain $\left[\mathrm{Ag}^{+}\right]$in the correct range.

## Chapter 18

18.1 (a) A volume greater than 22.4 L (b) No. The relative volumes of one mole of an ideal gas at 50 km and 85 km depend on the temperature and pressure at the two altitudes. From Figure 18.1, the gas will occupy a much larger volume at 85 km than at 50 km . (c) We expect gases to behave most ideally in the thermosphere, around the stratopause and in the troposphere at low altitude. 18.3 (a) $\mathrm{A}=$ troposphere, $0-10 \mathrm{~km} ; \mathrm{B}=$ stratosphere, $12-50 \mathrm{~km}$; $\mathrm{C}=$ mesosphere, $50-85 \mathrm{~km}(\mathbf{b})$ Ozone is a pollutant in the troposphere and filters UV radiation in the stratosphere. (c) The troposphere (d) Only region C in the diagram is involved in an aurora borealis, assuming a narrow "boundary" between the stratosphere and mesosphere at 50 km . (e) The concentration of water vapor is greatest near Earth's surface in region A and decreases with altitude. Water's single bonds are susceptible to photodissociation in regions B and $C$, so its concentration is likely to be very low in these regions. The relative concentration of $\mathrm{CO}_{2}$, with strong double bonds, increases in regions B and C , because it is less susceptible to photodissociation. 18.5 The Sun $18.7 \mathrm{CO}_{2}(g)$ dissolves in seawater to form $\mathrm{H}_{2} \mathrm{CO}_{3}(a q)$. The basic pH of the ocean encourages ionization of $\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})$ to form $\mathrm{HCO}_{3}^{-}(a q)$ and $\mathrm{CO}_{3}{ }^{2-}(a q)$. Under the correct conditions, carbon is removed from the ocean as $\mathrm{CaCO}_{3}(s)$ (sea shells, coral, chalk cliffs). As carbon is removed, more $\mathrm{CO}_{2}(g)$ dissolves to maintain the balance of complex and interacting acid-base and precipitation equilibria. 18.9 Above ground, evaporation of petroleum gases and hydrogen sulfide at the well head, evaporation of volatile petroleum products and organic compounds from waste ponds, as well as leakage and overflow from the ponds are potential sources of contamination. Below ground, petroleum gases and fracking liquid can migrate into groundwater, both deep and shallow aquifers. 18.11 (a) Its temperature profile (b) troposphere, 0 to 12 km ; stratosphere, 12 to 50 km; mesosphere, 50 to 85 km ; thermosphere, 85 to 110 km
18.13 (a) The partial pressure of $\mathrm{O}_{3}$ is $8.5 \times 10^{-3} \mathrm{~Pa}$. (b) $2.0 \times 10^{15} \mathrm{O}_{3}$ molecules/1.0 L air $\mathbf{1 8 . 1 5} 7.3 \times 10^{16} \mathrm{CO}$ molecules/1.0 L air $\mathbf{1 8 . 1 7}$ (a) 499 nm (b) visible electromagnetic radiation 18.19 (a) Photodissociation is cleavage of a bond such that two neutral species are produced. Photoionization is absorption of a photon with sufficient energy to eject an electron, producing an ion and the ejected electron. (b) Photoionization of $\mathrm{O}_{2}$ requires $1205 \mathrm{~kJ} / \mathrm{mol}$. Photodissociation requires only $495 \mathrm{~kJ} / \mathrm{mol}$. At lower elevations, high-energy short-wavelength solar radiation has already been absorbed. Below 90 km , the increased concentration of $\mathrm{O}_{2}$ and the availability of longer-wavelength radiation cause the photodissociation process to dominate. 18.21 (a) 127 nm (b) A wavelength of 127 nm is in the ultraviolet portion of the electromagnetic spectrum. The energy is not enough energy to photoionize $\mathrm{N}_{2}$. 18.23 Ozone depletion reactions, which involve only $\mathrm{O}_{3}, \mathrm{O}_{2}$, or O (oxidation state $=0$ ), do not involve a change in oxidation state for oxygen atoms. Reactions involving ClO and one of the oxygen species with a zero oxidation state do involve a change in the oxidation state of oxygen atoms. $\mathbf{1 8 . 2 5}$ (a) A chlorofluorocarbon is a compound that contains chlorine, fluorine, and carbon, while a hydrofluorocarbon is
a compound that contains hydrogen, fluorine, and carbon. An HFC contains hydrogen in place of the chlorine present in a CFC. (b) HFCs are potentially less harmful to the ozone layer than CFCs because their photodissociation does not produce Cl atoms, which catalyze the destruction of ozone. $\mathbf{1 8 . 2 7}$ (a) The maximum wavelength of a single photon that will break a $\mathrm{C}-\mathrm{C}$ bond is 344 nm . The maximum wavelength of a single photon that will break a $\mathrm{C}-\mathrm{H}$ bond is 291 nm . (b) The photodissociation of both C-C bonds and C-H bonds will be significant.
$18.292 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HNO}_{2}+\mathrm{HNO}_{3}(a q)$;
$2 \mathrm{NO}(g)+\mathrm{O}_{2}+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HNO}_{2}(a q)+\mathrm{HNO}_{3}$
$18.31(\mathbf{a}) \mathrm{H}_{2} \mathrm{SO}_{4}(a q)+\mathrm{Fe}(\mathrm{s}) \longrightarrow \mathrm{FeSO}_{4}(a q)+\mathrm{H}_{2}(\mathrm{~g})(\mathbf{b})$ As copper is a much more noble metal than iron, acid alone cannot attack copper. But the combination of acid and oxygen is a very corrosive medium, that can dissolve copper: $\mathrm{H}_{2} \mathrm{SO}_{4}(a q)+\frac{1}{2} \mathrm{O}_{2}(g)+$ $\mathrm{Cu}(s) \longrightarrow \mathrm{CuSO}_{4}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \mathbf{1 8 . 3 3}$ (a) Ultraviolet (b) $357 \mathrm{~kJ} / \mathrm{mol}$ (c) The average $\mathrm{C}-\mathrm{H}$ bond energy from Table 8.3 is $413 \mathrm{~kJ} / \mathrm{mol}$. The $\mathrm{C}-\mathrm{H}$ bond energy in $\mathrm{CH}_{2} \mathrm{O}, 357 \mathrm{~kJ} / \mathrm{mol}$, is less than the "average" $\mathrm{C}-\mathrm{H}$ bond energy.

18.35 (a) $235 \mathrm{~W} / \mathrm{m}^{2}$. (b) Four sources, surface radiation, evapotranspiration, incoming solar radiation and convective heating, transfer energy to the atmosphere. Surface radiation makes the largest contribution and convective heating the smallest. (c) Of the $519 \mathrm{~W} / \mathrm{m}^{2}$ absorbed by the atmosphere, $324 \mathrm{~W} / \mathrm{m}^{2}$ are radiated back to the surface. The percentage is $62.4 \%$. $\mathbf{1 8 . 3 7} 0.445 \mathrm{M}$ 18.39 (a) $3.22 \times 10^{3} \mathrm{gH}_{2} \mathrm{O}$ (b) The final temperature is $43.4^{\circ} \mathrm{C}$. 18.41961 .4 kg CaO 18.43 (a) The total cation charge is $5.866=5.9$ C ; the total anion charge is $5.847=5.8 \mathrm{C}$. The two numbers vary in the third significant figure. This is not surprising, because the molarities of the various ions are given to two significant figures. 18.45 The minimum pressure required to initiate reverse osmosis is greater than 599 kPa .
18.47 (a) $\mathrm{CO}_{2}(g), \mathrm{HCO}_{3}^{-}, \mathrm{H}_{2} \mathrm{O}(l), \mathrm{SO}_{4}{ }^{2-}, \mathrm{NO}_{3}^{-}, \mathrm{HPO}_{4}{ }^{2-}, \mathrm{H}_{2} \mathrm{PO}_{4}^{-}$ (b) $\mathrm{CH}_{4}(g), \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}), \mathrm{NH}_{3}(\mathrm{~g}), \mathrm{PH}_{3}(\mathrm{~g}), 18.498 .1 \mathrm{~g} \mathrm{O}_{2}$
$18.515 \mathrm{Ca}^{2+}(a q)+4 \mathrm{OH}^{-}(a q)+3 \mathrm{HPO}_{4}^{2-}(a q) \longrightarrow \mathrm{Ca}_{5}(\mathrm{OH})$
$\left(\mathrm{PO}_{4}\right)_{3}(s)+3 \mathrm{H}_{2} \mathrm{O}(l) \mathbf{1 8 . 5 3}$ (a) Trihalomethanes are the by-products of water chlorination; they contain one central carbon atom bound to one hydrogen and three halogen atoms.
(b)

18.55 The fewer steps in a process, the less waste is generated. Processes with fewer steps require less energy at the site of the process and for subsequent cleanup or disposal of waste. $\mathbf{1 8 . 5 7}$ (a) $\mathrm{H}_{2} \mathrm{O}$ (b) It is better to prevent waste than to treat it. Atom economy. Less hazardous chemical synthesis and inherently safer for accident prevention. Catalysis and design for energy efficiency. Raw materials should be renewable. 18.59 (a) Vegetable oil as a raw material, by criteria 5,7 , and 12 . (b) Water as a solvent, by criteria 5, 7, and 12. (c) Catalyzed reaction, by criteria 6, 9 and 12. 18.64 Multiply equations 18.7 and 18.9 by a factor of 2 . Add these two equations to a third equation, $\mathrm{O}(g)+\mathrm{O}(g) \longrightarrow \mathrm{O}_{2}(g) \cdot 2 \mathrm{Cl}(g)$ and $2 \mathrm{ClO}(g)$ cancel from each side of the resulting equation to produce equation 18.10. $\mathbf{1 8 . 6 7}$ (a) A CFC has $\mathrm{C}-\mathrm{Cl}$ bonds and C-F bonds. In an HFC , the $\mathrm{C}-\mathrm{Cl}$ bonds are replaced by $\mathrm{C}-\mathrm{H}$ bonds. (b) Stratospheric lifetime is significant because, the longer a hal-ogen-containing molecule exists in the stratosphere, the greater
the likelihood that it will encounter light with energy sufficient to dissociate a carbon-halogen bond. Free halogen atoms are the bad actors in ozone destruction. (c) HFCs have replaced CFCs because it is infrequent that light with energy sufficient to dissociate a C-F bond will reach an HFC molecule. F atoms are much less likely than Cl atoms to be produced by photodissociation in the stratosphere. (d) The main disadvantage of HFCs as replacements for CFCs is that they are potent greenhouse gases. 18.69 (a) $\mathrm{C}_{3} \mathrm{H}_{8}(l)+5 \mathrm{O}_{2}(g) \longrightarrow 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)$
(b) $\mathrm{C}_{3} \mathrm{H}_{8}(l)+\frac{7}{2} \mathrm{O}_{2}(g) \longrightarrow 3 \mathrm{CO}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)$
(c) 66 L of dry air $\mathbf{1 8 . 7 3} 20 \mathrm{~m}^{2} \mathbf{1 8 . 7 5}(\mathbf{a}) \mathrm{CO}_{3}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$ $\mathrm{HCO}_{3}^{-}(a q)+\mathrm{OH}^{-}(a q) ; \mathrm{Mg}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow$
$\mathrm{Mg}(\mathrm{OH})_{2}(s)(\mathbf{b})$ At these ion concentrations, $\mathrm{Q}>K_{s p}$ and $\mathrm{Mg}(\mathrm{OH})_{2}$ will precipitate.
18.79 (a) $4.2 \times 10^{6}$ ton $\mathrm{CO}_{2}, 8.6 \times 10^{4}$ ton $\mathrm{SO}_{2}$
(b) $8.0 \times 10^{4}$ ton $\mathrm{CaSO}_{3}$
$\mathbf{1 8 . 8 2 ( \mathbf { a } )} \mathrm{H}-\ddot{\mathrm{O}}-\mathrm{H} \longrightarrow \mathrm{H}+\cdot \ddot{\mathrm{O}}-\mathrm{H}(\mathbf{b}) 258 \mathrm{~nm}$
(c) The overall reaction is $\mathrm{O}_{3}(g)+\mathrm{O}(g) \xrightarrow{\bullet} 2 \mathrm{O}_{2}(g) . \mathrm{OH}(g)$ is the catalyst in the overall reaction because it is consumed and then reproduced. 18.84 The enthalpy change for the first step is -141 kJ , for the second step, -249 kJ , for the overall reaction, -390 kJ . 18.87 (a) Rate $=k\left[\mathrm{O}_{3}\right][\mathrm{H}]$ (b) $k_{\text {avg }}=1.11 \times 10^{44} \mathrm{M}^{-1} \mathrm{~s}^{-1} 18.91$ (a) Process (i) is greener because it involves neither the toxic reactant phosgene nor the by-product HCl . (b) Reaction (i): C in $\mathrm{CO}_{2}$ is linear with $s p$ hybridization; C in $\mathrm{R}-\mathrm{N}=\mathrm{C}=\mathrm{O}$ is linear with $s p$ hybridization; C in the urethane monomer is trigonal planar with $s p^{2}$ hybridization. Reaction (ii): C in $\mathrm{COCl}_{2}$ is trigonal planar with $s p^{2}$ hybridization; C in $\mathrm{R}-\mathrm{N}=\mathrm{C}=\mathrm{O}$ is linear with $s p$ hybridization; C in the urethane monomer is trigonal planar with $s p^{2}$ hybridization. (c) The greenest way to promote formation of the isocyanate is to remove by-product, either water or HCl , from the reaction mixture.

## Chapter 19

(b) $\Delta H=0$ for mixing ideal gases. $\Delta S$ is positive because the disorder of the system increases. (c) The process is spontaneous and therefore irreversible. (d) Since $\Delta H=0$, the process does not affect the entropy of the surroundings. 19.4 Both $\Delta H$ and $\Delta S$ are positive. The net change in the chemical reaction is the breaking of five blue-blue bonds. Enthalpies for bond breaking are always positive. There are twice as many molecules of gas in the products, so $\Delta S$ is positive for this reaction. $\mathbf{1 9 . 7}$ (a) At $300 \mathrm{~K}, \Delta G=0$, and the system is at equilibrium. (b) The reaction is spontaneous at temperatures above $300 \mathrm{K}$.19.10 (a) True (b) false (c) false (d) false (e) true 19.11 Spontaneous: a, d; nonspontaneous: b, c, e 19.13 (a) True, assuming that the forward and reverse processes occur at the same conditions. (b) false (c) false (d) true (e) false 19.15 (a) Endothermic (b) above $0^{\circ} \mathrm{C}$ (c) below $0^{\circ} \mathrm{C}$ (d) at $0^{\circ} \mathrm{C} 19.17$ (a) No. An isothermal process occurs at constant temperature. (b) No. Temperature is a state function, so a change in temperature does not depend on pathway. (c) No. $\Delta E$ is a state function. 19.19 (a) An ice cube can melt reversibly at the conditions of temperature and pressure where the solid and liquid are in equilibrium. (b) No. We know that $\Delta H$ is a state function, and that melting is endothermic. Whether the ice cube melts reversibly or irreversibly, $\Delta H$ for the process is not zero. 19.21 (a) False (b) true (c) true (d) false 19.23 (a) Entropy increases (b) $188 \mathrm{~J} / \mathrm{K} 19.25$ (a) True (b) false (c) false 19.27 (a) Positive $\Delta S$ (b) $\Delta S=1.02 \mathrm{~J} / \mathrm{K}$ (c) Temperature need not be specified to calculate $\Delta S$, as long as the
expansion is isothermal. 19.29 (a) Yes, the expansion is spontaneous. (b) As the ideal gas expands into the vacuum, there is nothing for it to "push back," so no work is done. Mathematically, $w=-P_{\text {ext }} \Delta V$. Since the gas expands into a vacuum, $P_{\text {ext }}=0$ and $w=0$. (c) The "driving force" for the expansion of the gas is the increase in entropy. 19.31 (a) An increase in temperature produces more available microstates for a system. (b) A decrease in volume produces fewer available microstates for a system. (c) Going from liquid to gas, the number of available microstates increases. 19.33 (a) $\Delta S$ is negative. (b) $S$ of the system increases in 19.11 (a), (b) and (c). 19.35 $S$ increases in (a) and (c); $S$ decreases in (b). 19.37 (a) False (b) true (c) false (d) true 19.39 (a) $\mathrm{I}_{2}(g)(\mathbf{b}) \mathrm{O}_{2}(g)$ at 50.7 kPa pressure (d) $\mathrm{CH}_{3} \mathrm{OH}(l)$ (c) 1 mol of $\mathrm{N}_{2}$ in 44.8 L 19.41 (a) $\Delta S<0$ (b) $\Delta S<0$ (c) $\Delta S>0$ (d) $\Delta S<0$

### 19.43

(b) Boiling water, at $100^{\circ} \mathrm{C}$, has a much larger entropy change than melting ice at $0^{\circ} \mathrm{C} .19 .45$ (a) $\mathrm{C}_{4} \mathrm{H}_{10}(g)$ (b) $\mathrm{C}_{4} \mathrm{H}_{10}(g) \mathbf{1 9 . 4 7}$ (a) $\mathrm{HNO}_{3}(\mathrm{~g})$ will have the higher standard entropy at $25^{\circ} \mathrm{C} . \mathrm{HNO}_{3}(\mathrm{~g})$, $266.4 \mathrm{~J} / \mathrm{mol} \mathrm{K} ; \mathrm{HNO}_{3}(a q), 146 \mathrm{~J} / \mathrm{mol} \mathrm{K}(\mathbf{b}) \mathrm{PCl}_{3}(\mathrm{~g})$ will have the higher standard entropy at $25^{\circ} \mathrm{C} . \mathrm{PCl}_{3}(l), 217 \mathrm{~J} / \mathrm{mol} \mathrm{K} ; \mathrm{PCl}_{3}(\mathrm{~g})$, $311.7 \mathrm{~J} / \mathrm{mol} \mathrm{K}(\mathbf{c}) \mathrm{Fe}_{3} \mathrm{O}_{4}(\mathrm{~s})$ will have the higher standard entropy at $25^{\circ} \mathrm{C} . \mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s}), 89.96 \mathrm{~J} / \mathrm{mol} \mathrm{K} ; \mathrm{Fe}_{3} \mathrm{O}_{4}(\mathrm{~s}), 146.4 \mathrm{~J} / \mathrm{mol} \mathrm{K} .(\mathbf{d}) \mathrm{Li}(\mathrm{g})$ will have the higher standard entropy at $25{ }^{\circ} \mathrm{C} . \mathrm{Li}(\mathrm{s}), 29.09 \mathrm{~J} / \mathrm{mol}$ K; $\operatorname{Li}(\mathrm{g}), 138.8 \mathrm{~J} / \mathrm{mol}$ K. $\mathbf{1 9 . 4 9}$ For elements with similar structures, the heavier the atoms, the lower the vibrational frequencies at a given temperature. This means that more vibrations can be accessed at a particular temperature, resulting in greater absolute entropy for the heavier elements. 19.51 (a) $\Delta S^{\circ}=+75.3 \mathrm{~J} / \mathrm{K}$. $\Delta S^{\circ}$ is positive because the product contains more total particles with more motional freedom. (b) $\Delta S^{\circ}=+221.46 \mathrm{~J} / \mathrm{K} . \Delta S^{\circ}$ is positive because there are more moles of gas in the products. (c) $\Delta S^{\circ}=5.04 \mathrm{~J} / \mathrm{K} . \Delta S^{\circ}$ is almost zero, as there are equal moles of gas in the products and in the reactants. (d) $\Delta S^{\circ}=242.88 \mathrm{~J} / \mathrm{K} . \Delta S^{\circ}$ is negative because there are fewer moles of gas in the products. 19.53 (a) Yes. $\Delta G=\Delta H-T \Delta S(\mathbf{b})$ No. If $\Delta G$ is positive, the process is nonspontaneous. (c) No. There is no relationship between $\Delta G$ and rate of reaction. 19.55 (a) $\Delta S^{\circ}$ is negative; the reaction leads to a decrease in disorder of the system. (b) $\Delta H^{\circ}$ is negative; the reaction leads to an increase in disorder of the surroundings. (c) $\Delta G^{\circ}=+4.7 \mathrm{~kJ}(\mathbf{d})$ If all reactants and products are present in their standard states, the reaction is nonspontaneous in the forward direction at this temperature.
19.57 (a) $\Delta H^{\circ}=-804.2 \mathrm{~kJ}, \Delta S^{\circ}=-254.8 \mathrm{~J} / \mathrm{K}, \Delta G^{\circ}=-728.1 \mathrm{~kJ}$, $\Delta G^{\circ}=\Delta H^{\circ}-T \Delta G^{\circ}=-728.3 \mathrm{~kJ}$
(b) $\Delta H^{\circ}=-56.1 \mathrm{~kJ}, \Delta \mathrm{~S}^{\circ}=79.1 \mathrm{~J} / \mathrm{K}, \Delta \mathrm{G}^{\circ}=-79.7 \mathrm{~kJ}$,
$\Delta G^{\circ}=\Delta H^{\circ}-T \Delta G^{\circ}=-79.7 \mathrm{~kJ}$
(c) $\Delta H^{\circ}=-394.5 \mathrm{~kJ}, \Delta S^{\circ}=176.3 \mathrm{~J} / \mathrm{K}, \Delta G^{\circ}=-447.7 \mathrm{~kJ}$,
$\Delta G^{\circ}=\Delta H^{\circ}-T \Delta G^{\circ}=-447.1 \mathrm{~kJ}(\mathbf{d}) \Delta H^{\circ}=-27.6 \mathrm{~kJ}$,
$\Delta S^{\circ}=269.5 \mathrm{~J} / \mathrm{K}, \Delta G^{\circ}=-107.6 \mathrm{~kJ}$,
$\Delta G^{\circ}=\Delta H^{\circ}-T \Delta G^{\circ}=-107.9 \mathrm{~kJ}$. The discrepancy in $\Delta G^{\circ}$ values is due to experimental uncertainties in the tabulated thermodynamic data. 19.59 (a) $\Delta G^{\circ}=-636.4 \mathrm{~kJ}$, spontaneous (b) $\Delta G^{\circ}=856.3 \mathrm{~kJ}$, nonspontaneous (c) $\Delta G^{\circ}=44.2 \mathrm{~kJ}$, nonspontaneous (d) $\Delta G^{\circ}=159.2 \mathrm{~kJ}$, nonspontaneous 19.61 (a) $\mathrm{C}_{31} \mathrm{H}_{64}(\mathrm{~s})+47 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 31 \mathrm{CO}_{2}(\mathrm{~g})+32 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ (b) Because $\Delta \mathrm{S}^{\circ}$ is positive, $\Delta G^{\circ}$ is more negative than $\Delta H^{\circ} .19 .63$ (a) The forward reaction is spontaneous at low temperatures but becomes nonspontaneous at higher temperatures. (b) The reaction is nonspontaneous in the forward direction at all temperatures. (c) The forward reaction is nonspontaneous at low temperatures but becomes spontaneous at higher temperatures. $19.65 \Delta S>47.5 \mathrm{~J} / \mathrm{K}$ 19.67 (a) $T=333 \mathrm{~K}$ (b) spontaneous 19.69 (a) $\Delta H^{\circ}=155.7 \mathrm{~kJ}$, $\Delta S^{\circ}=171.4 \mathrm{~kJ}$. Since $\Delta S^{\circ}$ is positive, $\Delta G^{\circ}$ becomes more negative with increasing temperature. (b) $\Delta G^{\circ}=19 \mathrm{~kJ}$. The reaction is not spontaneous under standard conditions at $800 \mathrm{~K}(\mathbf{c}) \Delta G^{\circ}=-15.7 \mathrm{~kJ}$. The reaction is spontaneous under standard conditions at 1000 K . 19.71 (a) $T_{b}=57^{\circ} \mathrm{C}(\mathbf{b})$ From the Handbook of Chemistry and Physics, 74th Edition, $T_{b}=58.8^{\circ} \mathrm{C}$. The values are remarkably close; the small difference is primarily due to the fact that we used thermodynamic data at $25^{\circ} \mathrm{C}$ for our calculation.
19.73 (a) $\mathrm{C}_{2} \mathrm{H}_{2}(g)+\frac{5}{2} \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$
(b) -1299.5 kJ of heat produced $/ \mathrm{mol} \mathrm{C}_{2} \mathrm{H}_{2}$ burned
(c) $w_{\text {max }}=-1235.1 \mathrm{~kJ} / \mathrm{mol} \mathrm{C}_{2} \mathrm{H}_{2} 19.75$ (a) $\Delta G$ increases; it becomes more positive. (b) $\Delta G$ decreases; it becomes more negative. (c) $\Delta G$ increases; it becomes more positive. 19.77 (a) $\Delta G^{\circ}=-69.74 \mathrm{~kJ}$ (b) $\Delta G=-67 \mathrm{~kJ} 19.79$ (a) $\Delta G^{\circ}=-16.77 \mathrm{~kJ}, K=870$
(b) $\Delta G^{\circ}=8.0 \mathrm{~kJ}, K=0.039$ (c) $\Delta G^{\circ}=-497.9 \mathrm{~kJ}, K=2 \times 10^{87}$ $19.81 \Delta H^{\circ}=269.3 \mathrm{~kJ}, \Delta \mathrm{~S}^{\circ}=0.1719 \mathrm{~kJ} / \mathrm{K}$ (a) $P_{\mathrm{CO}_{2}}=6.1 \times 10^{-37}$ $\mathrm{kPa}(\mathbf{b}) P_{\mathrm{CO}_{2}}=1.6 \times 10^{-2} \mathrm{kPa}$
19.83 (a) $\mathrm{HNO}_{2}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{NO}_{2}^{-}(a q)(\mathbf{b}) \Delta G^{\circ}=19.1 \mathrm{~kJ}$ (c) $\Delta G=0$ at equilibrium (d) $\Delta G=-2.7 \mathrm{~kJ} 19.85$ (a) The thermodynamic quantities $P, H$ and $G$ are state functions (b) $w_{\text {rev }}<w_{\text {irrev }}$ (c) $q_{\text {rev }}>q_{\text {irrev }}$ (d) $\Delta H=q_{r e v}+w_{\text {rev }}+\mathrm{p} \Delta V, \quad \Delta G=w_{r e v}+\mathrm{p} \Delta V$ 19.94 (a) $\mathrm{C}(s)+2 \mathrm{H}_{2}(g) \rightarrow \mathrm{CH}_{4}(g) ; \mathrm{Na}(s)+\frac{1}{2} \mathrm{Cl}_{2}(g) \rightarrow \mathrm{NaCl}(s)(\mathbf{b})$ In both reactions, $\Delta G_{f}^{0}$ will be more positive (less negative) than $\Delta H_{f}^{0}$. (c) Condition (iii), when $\Delta S_{f}^{0}$ is negative. 19.99 (a) For the oxidation of glucose in the body, $\Delta G^{\circ}=-2878.8 \mathrm{~kJ}, K=5 \times 10^{504}$; for the anaerobic decomposition of glucose, $\Delta G^{\circ}=-228.0 \mathrm{~kJ}, K=9 \times 10^{39}$
(b) A greater maximum amount of work at standard conditions can be obtained from the oxidation of glucose in the body, because $\Delta G^{\circ}$ is much more negative. 19.103 (a) Acetone, $\Delta S_{\text {vap }}^{\circ}=88.4 \mathrm{~J} / \mathrm{mol} \mathrm{K}$; dimethyl ether, $\Delta S_{\text {vap }}^{\circ}=86.6 \mathrm{~J} / \mathrm{mol} \mathrm{K}$; ethanol, $\Delta S_{\text {vap }}^{\circ}=110 \mathrm{~J} / \mathrm{mol} \mathrm{K}$; octane, $\Delta S_{\text {vap }}^{\circ}=86.3 \mathrm{~J} / \mathrm{mol} \mathrm{K}$; pyridine, $\Delta S_{\text {vap }}^{\circ}=90.4 \mathrm{~J} / \mathrm{mol} \mathrm{K}$. Ethanol does not obey Trouton's rule. (b) Hydrogen bonding (in ethanol and other liquids) leads to more ordering in the liquid state and a greater than usual increase in entropy upon vaporization. Liquids that experience hydrogen bonding are probably exceptions to Trouton's rule. (c) Owing to strong hydrogen bonding interactions, water probably does not obey Trouton's rule. $\Delta S_{\text {vap }}^{\circ}=109.0 \mathrm{~J} / \mathrm{mol} \mathrm{K}$. (d) $\Delta H_{\text {vap }}$ for $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl} \approx 36 \mathrm{~kJ} / \mathrm{mol} 19.110$ (a) 682 K or $409^{\circ} \mathrm{C}$ (b) 782 K or $509^{\circ} \mathrm{C}$

## Chapter 20

20.1 In this analogy, the electron is analogous to the proton $\left(\mathrm{H}^{+}\right)$. Redox reactions can be viewed as electron-transfer reactions, just
as acid-base reactions can be viewed as proton-transfer reactions. Oxidizing agents are themselves reduced; they gain electrons. A strong oxidizing agent would be analogous to a strong base. $\mathbf{2 0 . 3}$ (a) The process represents oxidation. (b) The electrode is the anode. (c) When a neutral atom loses a valence electron, the radius of the resulting cation is smaller than the radius of the neutral atom. 20.7 (a) The sign of $\Delta G^{\circ}$ is positive. (b) The equilibrium constant is less than one. (c) No. An electrochemical cell based on this reaction cannot accomplish work on its surroundings. $\mathbf{2 0 . 1 0}$ (a) Zinc is the anode. (b) The energy density of the silver oxide battery is most similar to the nickel-cadmium battery. The molar masses of the electrode materials and the cell potentials for these two batteries are most similar. 20.13 (a) Oxidation is the loss of electrons. (b) Electrons appear on the products' side (right side). (c) The oxidant is the reactant that is reduced. (d) An oxidizing agent is the substance that promotes oxidation; it is the oxidant. 20.15 (a) True (b) false (c) true 20.17 (a) (i) Reactants: $\mathrm{H},+1$; Mn, +2 ; $\mathrm{Na},+1$; $\mathrm{Bi},+5$; $\mathrm{O},-2$. Products: $\mathrm{H},+1 ; \mathrm{O},-2 ; \mathrm{Mn},+7 ; \mathrm{Bi},+3, \mathrm{Na},+1$ (ii) The total number of electrons transferred is 10 . (b) Reactants: $\mathrm{K},+1 ; \mathrm{Mn},+7 ; \mathrm{O},-2$; $\mathrm{Na},+1 ; \mathrm{S},+4 ; \mathrm{O},-2 ; \mathrm{H},+1$. Products: $\mathrm{Mn},+4 ; \mathrm{O},-2 ; \mathrm{Na},+1 ; \mathrm{S}$, $+6, \mathrm{~K},+1 ; \mathrm{H},+1$ (ii) The total number of electrons transferred is 6. (c) (i) Reactants: $\mathrm{Cu}, 0 ; \mathrm{Ag},+1 ; \mathrm{N},+5$; $\mathrm{O},-2$. Products: $\mathrm{Ag}, 0$; $\mathrm{Cu},+2 ; \mathrm{N},+5 ; \mathrm{O},-2$. (ii) The total number of electrons transferred is 2.20 .19 (a) Nitrogen is oxidized from +4 to +5 ; oxygen is reduced from -1 to -2 . $20.59 w_{\text {max }}=1.3 \times 10^{2} \mathrm{~kJ} / \mathrm{mol} \mathrm{Sn} ; 8.3 \times 10^{4} \mathrm{~J} / 75.0 \mathrm{~g} \mathrm{Sn}$
20.61 (a) In the Nernst equation, $Q=1$ if all reactants and products are at standard conditions. (b) Yes. The Nernst equation is applicable to cell emf at nonstandard conditions, so it must be applicable at temperatures other than 298 K . Values of $E^{\circ}$ at temperatures other than 298 K are required. And, there is a variable for T in the second term. If the short-hand form of the equation, Equation 20.18, is used, a coefficient other than 0.0592 is required. 20.63 (a) $E$ decreases (b) $E$ increases (c) no effect (d) $E$ decreases 20.65 (a) $E^{\circ}=0.48 \mathrm{~V}$ (b) $E=0.52 \mathrm{~V}$ (c) $E=0.46 \mathrm{~V} 20.67$ (a) $E^{\circ}=0.46 \mathrm{~V}$ (b) $E=0.37 \mathrm{~V}$ 20.69 (a) The compartment with $\left[\mathrm{Cu}^{2+}\right]=0.100 \mathrm{M}$ is the cathode. (b) $E^{\circ}=0$ (c) $E=0.0888 \mathrm{~V}$ (d) In the anode compartment $\left[\mathrm{Cu}^{2+}\right]$ increases; in the cathode compartment $\left[\mathrm{Cu}^{2+}\right]$ decreases. $20.71 E^{\circ}=0.76 \mathrm{~V}, \mathrm{pH}=2.2 \mathbf{2 0 . 7 3}$ (a) $260 \mathrm{~g} \mathrm{~Pb}(\mathbf{b}) 2.42 \times 10^{5} \mathrm{C}$ 20.75 (a) The anode (b) $E^{\circ}=3.50 \mathrm{~V}$ (c) The emf of the battery, 3.5 V , is exactly the standard cell potential calculated in part (b). (d) At ambient conditions, $E \approx E^{\circ}$, so $\log Q \approx 1$. Assuming that the value of $E^{\circ}$ is relatively constant with temperature, the value of the second term in the Nernst equation is approximately zero at $37^{\circ} \mathrm{C}$, and $E \approx 3.5 \mathrm{~V} .20 .77$ (a) The cell emf will have a smaller value. (b) NiMH batteries use an alloy such as $\mathrm{ZrNi}_{2}$ as the anode material. This eliminates the use and disposal problems associated
with Cd, a toxic heavy metal. 20.79 (a) When the battery is fully charged, the mole ratio of the elements in the cathode is: 0.5 mol $\mathrm{Li}^{+}$to $0.5 \mathrm{~mol} \mathrm{Co}^{3+}$ to $0.5 \mathrm{~mol} \mathrm{Co}^{4+}$ to $2 \mathrm{~mol} \mathrm{O}^{2-}$. The material is $\mathrm{LiCo}_{2} \mathrm{O}_{4}(\mathbf{b}) 4.9 \times 10^{3} \mathrm{C}$ of electricity delivered on full discharge of a fully charged battery $\mathbf{2 0 . 8 1}$ (a) The spontaneous reaction in the hydrogen fuel cell is hydrogen gas plus oxygen gas makes water. (b) $E^{\circ}=1.23 \mathrm{~V} 20.83(\mathbf{a})$ anode: $\mathrm{Fe}(s) \longrightarrow \mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-}$; cathode: $\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)(\mathbf{b}) 2 \mathrm{Fe}^{2+}(a q)+$ $3 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}(s)+6 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-}$;
$\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \mathbf{2 0 . 8 5}(\mathbf{a}) \mathrm{Al}$ is called a "sacrificial anode" because it has a more negative $E_{\text {red }}^{0}$ than the pipeline metal and is preferentially oxidized when the two are coupled. It is sacrificed to preserve the pipeline. (b) $E_{\text {red }}^{0}$ for $\mathrm{Al}^{3+}$ is -1.66 V , more negative than most metals present in pipelines, including Fe and Zn . 20.87 (a) +3 (b) $+8 / 3$ or +2.67 (c) 2 Fe (III) and 1 Fe (II) 20.89 (a) Electrolysis is an electrochemical process driven by an outside energy source. (b) By definition, electrolysis reactions are nonspontaneous. (c) $2 \mathrm{Cl}^{-}(l) \longrightarrow \mathrm{Cl}_{2}(g)+2 \mathrm{e}^{-}(\mathbf{d})$ When an aqueous solution of NaCl undergoes electrolysis, sodium metal is not formed because $\mathrm{H}_{2} \mathrm{O}$ is preferentially reduced to form $\mathrm{H}_{2}(\mathrm{~g}) \mathbf{2 0 . 9 1}$ (a) $236 \mathrm{~g} \mathrm{Cr}(s)$ (b) 2.51 A 20.93 (a) $4.0 \times 10^{5} \mathrm{~g} \mathrm{Li}(\mathbf{b})$ The minimum voltage required to drive the electrolysis is +4.41 V . $\mathbf{2 0 . 9 5}$ Gold is less active than copper and thus more difficult to oxidize. When a mixture of copper and gold is refined by electrolysis, Cu is oxidized from the anode, but any metallic gold present in the mixture is not oxidized, so it accumulates near the anode, available for collection.
20.97(a) $3 \mathrm{Fe}^{2+}(a q) \rightarrow \mathrm{Fe}(s)+2 \mathrm{Fe}^{3+}(a q)$
(b) $3 \mathrm{Br}_{2}(l)+3 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow 6 \mathrm{H}^{+}(a q)+5 \mathrm{Br}^{-}(a q)+\mathrm{BrO}_{3}^{-}(a q)$
(c) $4 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow 14 \mathrm{H}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+2 \mathrm{Cr}(s)$
(d) $5 \mathrm{NO}_{2}^{-}(a q)+2 \mathrm{H}^{+}(a q) \rightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{N}_{2}(g)+3 \mathrm{NO}_{3}^{-}(a q)$
20.99 (a) $E^{\circ}=0.226 \mathrm{~V}$, spontaneous (b) $E^{\circ}=-0.44 \mathrm{~V}$, nonspontaneous (c) $E^{\circ}=-0.144 \mathrm{~V}$, nonspontaneous (d) $E^{\circ}=-0.434 \mathrm{~V}$, nonspontaneous $20.103 K=1.22 \times 10^{-41} \mathbf{2 0 . 1 0 6}$ (a) By analogy to O in hydroxide $\left(\mathrm{OH}^{-}\right)$and in alcohol $(\mathrm{R}-\mathrm{OH})$, the oxidation state of $S$ in a thiol ( $\mathrm{R}-\mathrm{SH}$ ) is -2 . (b) By analogy to O in peroxide ( $-\mathrm{O}-\mathrm{O}-$ ), the oxidation state of S in a disulfide $(-\mathrm{S}-\mathrm{S}-$ ) is -1 . (c) The oxidation number of $S$ becomes more positive and the thiols are oxidized. (d) Converting a disulfide to two thiols is the reverse of the process described in part (c). In order to reduce the disulfide, a reducing agent must be added to the solution. (e) When two thiols ( $\mathrm{R}-\mathrm{SH}$ ) react to form a disulfide ( $\mathrm{R}-\mathrm{S}-\mathrm{S}-\mathrm{R}$ ), the H atoms are probably removed by base before the oxidizing agent does its work. $\mathbf{2 0 . 1 0 9} 1.5 \times 10^{4} \mathrm{kWh}$ required $\mathbf{2 0 . 1 1 4}(\mathbf{a}) E^{\circ}=0.728 \mathrm{~V}$, (b) cathode: $\mathrm{Br}_{2}(l)+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{Br}^{-}(a q)$; anode: $\mathrm{Cu}(s) \rightarrow \mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-}$
(c) $\Delta S^{\circ}=-123.78 \mathrm{~J}$. Because $\Delta S^{\circ}$ is negative, $\Delta G^{\circ}$ will become more positive and $E^{\circ}$ will become more negative as temperature is increased. 20.117 $K_{s p}$ for AgCl is $1.8 \times 10^{-10}$.

## Chapter 22

22.1 Statement (c) is correct. 22.3 Molecules (b) and (d) will have the seesaw structure shown in the figure. 22.6 The graph shows the trend in (c) density for the group 16 elements. Going down the family, atomic mass increases faster than atomic volume (radius), and density increases. 22.9 The compound on the left, with the strained three-membered ring, will be the most generally reactive. The larger the deviation from ideal bond angles, the more strain in the molecule and the more generally reactive it is. $\mathbf{2 2 . 1 1}$ Metals: (b) $\mathrm{Ba}(\mathbf{d}) \mathrm{Cs},(\mathbf{e}) \mathrm{Y}$; nonmetals: (c) Ar, (f) At; metalloids: (a) B 22.13 (a) $\mathrm{F}(\mathbf{b}) \mathrm{Te}(\mathbf{c}) \mathrm{Rb}(\mathbf{d}) \mathrm{N}(\mathbf{e}) \operatorname{Ir}(\mathbf{f}) \operatorname{Si} 22.15$ Statements $(\mathbf{b})$ and $(\mathbf{d})$ are true. 22.17 (a) $\mathrm{NaOCH}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{NaOH}(a q)+\mathrm{CH}_{3} \mathrm{OH}(a q)$

(b) $\mathrm{NH}_{4}^{+},-3$ (c) $\mathrm{HNO}_{2},+3(\mathbf{d}) \mathrm{Mg}_{3} \mathrm{~N}_{2},-3$ (e) $\mathrm{N}_{2} \mathrm{H}_{2},-1$ (f) $\mathrm{NaNO}_{3},+5$ (g) $\mathrm{NF}_{3},+3$ (h) $\mathrm{HNO}_{3},+5$
$22.51(\mathbf{a}): \ddot{\mathrm{O}}=\ddot{\mathrm{N}}-\ddot{\mathrm{O}}-\mathrm{H} \longleftrightarrow: \ddot{\mathrm{O}}-\ddot{\mathrm{N}}=\ddot{\mathrm{O}}-\mathrm{H}$
The molecule is bent around the central oxygen and nitrogen atoms; the four atoms need not be coplanar. The right-most form does not minimize formal charges and is less important in the actual bonding model. The oxidation state of N is +3 .
(b)

The molecule is linear. The oxidation state of N is $-1 / 3$.

The geometry is tetrahedral around the left nitrogen, trigonal pyramidal around the right. The oxidation state of N is -2 .

The ion is trigonal planar; it has three equivalent resonance forms. The oxidation state of N is +5 .
$22.53(\mathbf{a}) \mathrm{Mg}_{3} \mathrm{~N}_{2}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{NH}_{3}($ aq $)$
(b) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$, redox reaction
(c) $\mathrm{N}_{2} \mathrm{O}_{5}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{H}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)$
(d) $\mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{NH}_{4}^{+}(a q)$
$(\mathbf{e}) \mathrm{N}_{2} \mathrm{H}_{4}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)$, redox reaction
22.55 (a) $\mathrm{HNO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{NO}_{3}^{-}(a q)+2 \mathrm{e}^{-}$
(b) $\mathrm{N}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{N}_{2} \mathrm{O}(a q)+2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-}$
22.57 (a) $\mathrm{SbF}_{6}^{-},+5$ (b) $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2},+5$ (c) $\mathrm{KH}_{2} \mathrm{PO}_{4},+5$ (d) $\mathrm{As}_{2} \mathrm{O}_{3},+3$ (e) $\mathrm{P}_{4} \mathrm{O}_{6},+3(\mathbf{f}) \mathrm{AsF}_{3},+322.59$ (a) Phosphorus is a larger atom than nitrogen, and P has energetically available $3 d$ orbitals, which participate in the bonding, but nitrogen does not. (b) Only one of the three hydrogens in $\mathrm{H}_{3} \mathrm{PO}_{2}$ is bonded to oxygen. The other two are bonded directly to phosphorus and are not easily ionized. (c) $\mathrm{PH}_{3}$ is a weaker base than $\mathrm{H}_{2} \mathrm{O}$ so any attempt to add $\mathrm{H}^{+}$to $\mathrm{PH}_{3}$ in the presence of $\mathrm{H}_{2} \mathrm{O}$ causes protonation of $\mathrm{H}_{2} \mathrm{O}$. (d) The $\mathrm{P}_{4}$ molecules in white phosphorus have more severely strained bond angles than the chains in red phosphorus, causing white phosphorus to be more reactive.
22.61
(a) $2 \mathrm{Ca}_{3} \mathrm{PO}_{4}(s)+6 \mathrm{SiO}_{2}(s)+10 \mathrm{C}(s) \longrightarrow \mathrm{P}_{4}(g)+6 \mathrm{CaSiO}_{3}(l)$

(e) $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{4}, \mathrm{~Pb}:+4$ (f) $\mathrm{SnO}_{2},+422.71$ (a) Carbon (b) silicon (c) lead 22.73 (a) Tetrahedral (b) Metasilicic acid will probably adopt the single-strand silicate chain structure shown in Figure 22.32 (b). The Si to O ratio is correct and there are two terminal O atoms per Si that can accommodate the two H atoms associated with each Si atom of the acid. 22.75 (a) Two $\mathrm{Ca}^{2+}(\mathbf{b})$ two $\mathrm{OH}^{-}$ 22.77 (a) Diborane has bridging $H$ atoms linking the two $B$ atoms. The structure of ethane has the C atoms bound directly, with no bridging atoms. (b) $\mathrm{B}_{2} \mathrm{H}_{6}$ is an electron-deficient molecule. The 6 valence electron pairs are all involved in $\mathrm{B}-\mathrm{H}$ sigma bonding, so the only way to satisfy the octet rule at B is to have the bridging H atoms shown in Figure 22.35. (c) The term hydridic indicates that the H atoms in $\mathrm{B}_{2} \mathrm{H}_{6}$ have more than the usual amount of electron density for a covalently bound H atom. 22.79 (a) False (b) true (c) false (d) true (e) true (f) true (g) false 22.82 (a) $\mathrm{SO}_{3}(\mathbf{b}) \mathrm{Cl}_{2} \mathrm{O}_{5}$ (c) $\mathrm{N}_{2} \mathrm{O}_{3}$ (d) $\mathrm{CO}_{2}$ (e) $\mathrm{P}_{2} \mathrm{O}_{5} 22.85$ (a) $\mathrm{PO}_{6}{ }^{-}{ }^{+} 5 ; \mathrm{NF}_{3},+3$ (b) According to the Octet rule, because N is a period 2 element which has 5 valance electrons, it can only form 4 covalent bonds at the most. Therefore, it cannot form an $\mathrm{NF}_{6}{ }^{-}$anion. In contrast, P is a period 3 element which can use the d orbitals in hybridization to form covalent bonds with 6 fluorine atoms. Therefore, a stable $\mathrm{PF}_{6}^{-}$anion can be formed.
22.91 (a) $1.94 \times 10^{3} \mathrm{~g} \mathrm{H}_{2}(\mathbf{b}) 2.16 \times 10^{4} \mathrm{~L} \mathrm{H}_{2}(\mathbf{c}) 2.76 \times 10^{5} \mathrm{~kJ} 22.93$ (a) $-285.83 \mathrm{~kJ} / \mathrm{mol} \mathrm{H}_{2} ;-890.4 \mathrm{~kJ} / \mathrm{mol} \mathrm{CH}_{4}$ (b) $-141.79 \mathrm{~kJ} / \mathrm{g} \mathrm{H}_{2}$; $-55.50 \mathrm{~kJ} / \mathrm{g} \mathrm{CH}_{4}$ (c) $1.276 \times 10^{4} \mathrm{~kJ} / \mathrm{m}^{3} \mathrm{H}_{2} ; 3.975 \times 10^{4} \mathrm{~kJ} / \mathrm{m}^{3} \mathrm{CH}_{4}$ 22.95 (a) $[\mathrm{HClO}]=0.036 \mathrm{M}(\mathbf{b}) \mathrm{pH}=1.4$
$22.98(\mathbf{a}) \mathrm{CaCO}_{3}(s)+\mathrm{SO}_{2}(g) \longrightarrow \mathrm{CaSO}_{3}(s)+\mathrm{CO}_{2}(g)$
(b) 249.7 kg (c) $55.9 \mathrm{~m}^{3} \mathbf{2 2 . 1 0 0}$ The average bond enthalpies are H—O, 463 kJ; H—S, 367 kJ; H—Se, 317 kJ; H—Te, 267 kJ. The H—X bond enthalpy decreases steadily in the series. The origin of this effect is probably the increasing size of the orbital from X with which the hydrogen $1 s$ orbital must overlap. 22.103 Dimethyl-
hydrazine produces 0.0369 mol gas per gram of reactants, while methylhydrazine produces 0.0388 mol gas per gram of reactants. Methylhydrazine has marginally greater thrust. 22.104 (a) $3 \mathrm{~B}_{2} \mathrm{H}_{6}(g)+6 \mathrm{NH}_{3}(g) \longrightarrow 2(\mathrm{BH})_{3}(\mathrm{NH})_{3}(l)+12 \mathrm{H}_{2}(g)$; $3 \mathrm{LiBH}_{4}(s)+3 \mathrm{NH}_{4} \mathrm{Cl}(s) \longrightarrow 2(\mathrm{BH})_{3}(\mathrm{NH})_{3}(l)+9 \mathrm{H}_{2}(\mathrm{~g})+$ $3 \mathrm{LiCI}(s)$
(b)

(c) $2.40 \mathrm{~g}(\mathrm{BH})_{3}(\mathrm{NH})_{3}$

## Chapter 23

23.2

(a) Coordination number is 4 (b) coordination geometry is square planar $(\mathbf{c})$ oxidation state is $+2(\mathbf{d})$ no unpaired electrons $23.6 \mathrm{Mol}-$ ecules (1), (3), and (4) are chiral because their mirror images are not superimposible on the original molecules. 23.8 (a) Diagram (4) (b) diagram (1) (c) diagram (3) (d) diagram (2) 23.11 The lanthanide contraction explains trend (c). The lanthanide contraction is the name given to the decrease in atomic size due to the build-up in effective nuclear charge as we move through the lanthanides and beyond them. This effect offsets the expected increase in atomic size going from period 5 to period 6 transition elements. $23.13(\mathbf{a}) \mathrm{Cu}^{2+}$, $[\mathrm{Ar}] 3 \mathrm{~d}^{9}$ (b) $\mathrm{Cu}^{+},[\mathrm{Ar}] 3 \mathrm{~d}^{10}(\mathbf{c}) \mathrm{V}^{5+},[\mathrm{Ar}](\mathbf{d}) \mathrm{Mn}^{2+},[\mathrm{Ar}] 3 \mathrm{~d}^{5} 23.15$ (a) $\mathrm{Sc}^{2+}$, $[\mathrm{Ar}] 3 \mathrm{~d}^{1}(\mathbf{b}) \mathrm{Mo}^{2+},[\mathrm{Kr}] 4 \mathrm{~d}^{4}(\mathbf{c}) \mathrm{Rh}^{3+},[\mathrm{Kr}] 4 \mathrm{~d}^{6}(\mathbf{d}) \mathrm{Fe}^{3+},[\mathrm{Ar}] 3 \mathrm{~d}^{5} 23.17$ (a) The unpaired electrons in a paramagnetic material cause it to be weakly attracted into a magnetic field. 23.19 The diagram shows a material with misaligned spins that become aligned in the direction of an applied magnetic field. This is a paramagnetic material. 23.21 (a) Primary valence is roughly the same as oxidation number. Oxidation number is a broader term than ionic charge, but Werner's complexes contain metal ions where cation charge and oxidation number are equal. (b) Coordination number is the modern term for secondary valence. (c) $\mathrm{NH}_{3}$ can serve as a ligand because it has an unshared electron pair, while $\mathrm{BH}_{3}$ does not. Ligands are the Lewis base in metal-ligand interactions. As such, they must possess at least one unshared electron pair. 23.23 (a) +2 (b) 6 (c) 2 mol $\mathrm{AgBr}(\mathrm{s})$ will precipitate per mole of complex. 23.25 (a) Coordination number $=6$, oxidation number $=+2$ (b) $4,+7$ (c) $4,+2$ (d) $6,+3(\mathbf{e}) 4,+1$ (f) $4,+223.27$ (a) Monodentate ligand

(b) monodentate ligand

(c) either monodentate or bidentate ligand

(d) unlikely to act as a ligand

23.29 (a) Ethylenediaminetetraacetate, EDTA is hexadentate (b) oxalate, $\mathrm{C}_{2} \mathrm{O}_{4}^{2-}$, is bidentate (c) ethylenediamine, en, is bidentate (d) ortho-Phenanthroline, o-phen, is bidentate. 23.31 (a) $\mathrm{CO}_{3}{ }^{2-}$ (b) $\mathrm{H}_{2} \mathrm{O}$ (c) $\mathrm{PH}_{3}$ 23.33 True. The ligand shown in the figure can act as a bidentate ligand for a single metal center. The $\mathrm{CH}_{2}$ groups between the two oxygen atoms are $s p^{3}$ hybridized and allow some bending in the molecule so that the two oxygen atoms can approach one single metal center simultaneously for chelation. 23.35 (a) $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right]\left(\mathrm{NO}_{3}\right)_{3}$ (b) $\left[\mathrm{Pt}(\mathrm{en}) \mathrm{Cl}_{2}\right] \quad(\mathbf{c}) \quad\left[\mathrm{Fe}(\mathrm{CO})_{5}\right] \quad$ (d) $\quad\left(\mathrm{NH}_{4}\right)_{2}\left[\mathrm{CO}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (e) $\left[\mathrm{Co}(\text { bipy })_{3}\right]_{2}\left(\mathrm{SO}_{4}\right)_{3} \quad 23.37$ (a) diamminesilver(I) nitrate (b) mercury(II) tetrathiocyanatocobaltate(II) (c) trichlorotris (triphenylphosphine)ruthenium(III) (d) pentaamminecarbonatocobalt( III) sulphate 23.39(a) Complexes 1, 2 and 3 can have geometric isomers; they each have cis-trans isomers. (b) Complex 2 can have linkage isomers, owing to the presence of the nitrite ligand. (c) The cis geometric isomer of complex 3 can have optical isomers (d) Complex 1 can have coordination sphere isomers. It is the only complex with a counter ion that can also be a ligand. $\mathbf{2 3 . 4 1}$ Yes. No structural or stereoisomers are possible for a tetrahedral complex of the form $\mathrm{MA}_{2} \mathrm{~B}_{2}$. The complex must be square planar with cis and trans geometric isomers. 23.43 (a) Unique structure, no other isomers (b) two geometric isomers, trans and cis isomers with $180^{\circ}$ and $90^{\circ} \mathrm{Cl}-\mathrm{Ir}-\mathrm{Cl}$ angles, respectively (c) three geometric isomers; trans and cis isomers with $180^{\circ}$ and $90^{\circ} \mathrm{Cl}-\mathrm{Fe}-\mathrm{Cl}$ angles, respectively; the cis isomer has enantiomers 23.45 (a) Not chiral (b) not chiral (c) chiral, has optical isomers 23.47 (a) Blue (b) $E=3.26 \times 10^{-19} \mathrm{~J} /$ photon (c) $E=196 \mathrm{~kJ} / \mathrm{mol} 23.49$ (a) $\mathrm{Co}^{3+}$, $[\mathrm{Ar}] 3 \mathrm{~d}^{6}$. No unpaired electrons. (b) $\mathrm{W}^{3+},[\mathrm{Xe}] 4 \mathrm{f}^{14} \mathrm{~d}^{3}$. Paramagnetic. (c) $\mathrm{V}^{3+},[\mathrm{Ar}] 3 \mathrm{~d}^{2}$. Paramagnetic. (d) $\mathrm{Rh}^{3+},[\mathrm{Kr}] 4 \mathrm{~d}^{6}$ Diamagnetic. 23.51 An electron in a $d$ orbital with lobes that point directly at the ligands will have higher energy than an electron in a $d$ orbital with lobes that do not point directly at the ligands.

(b) The magnitude of $\Delta$ and the energy of the $d$ - $d$ transition for a $d^{1}$ complex are equal. (c) $\Delta=220 \mathrm{~kJ} / \mathrm{mol} 23.55$ (a) Both minerals contain $\mathrm{Cu}^{2+},[\mathrm{Ar}] 3 \mathrm{~d}^{9}$. (b) Azurite will probably have the
larger $\Delta$. It absorbs orange visible light, which has shorter wavelengths than the red light absorbed by malachite. 23.57 (a) $\mathrm{Pt}^{3+}, d^{8}$ (b) $\mathrm{Cu}^{2+}, d^{9}(\mathbf{c}) \mathrm{Os}^{3+}, d^{5}(\mathbf{d}) \mathrm{Cr}^{2+}, d^{4}(\mathbf{e}) \mathrm{Cd}^{2+}, d^{10} 23.59$ Yes. A weakfield ligand leads to a small $\Delta$ value and a small $d$-orbital splitting energy. If the splitting energy of a complex is smaller than the energy required to pair electrons in an orbital, the complex is high spin. 23.61 (a) $\mathrm{Mn},[\mathrm{Ar}] 4 s^{2} 3 d^{5} ; \mathrm{Mn}^{2+},[\mathrm{Ar}] 3 d^{5}$; 1 unpaired electron

(b) $\mathrm{Ru},[\mathrm{Kr}] 5 s^{1} 4 d^{7} ; \mathrm{Ru}^{2+},[\mathrm{Kr}] 4 d^{6} ; 0$ unpaired electrons

(c) Rh, $[\mathrm{Kr}] 5 s^{1} 4 d^{8} ; \mathrm{Rh}^{2+},[\mathrm{Kr}] 4 d^{7} ; 1$ unpaired electron

23.63 All complexes in this exercise are six-coordinate octahedral.

> 23.69 $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{4} ;\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2} ;\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right] \mathrm{Cl}$ $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{4}\right] ; \mathrm{K}\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}_{5}\right]$
23.73

Both dmpe and en are bidentate ligands, binding through P and N , respectively. Because phosphorus is less electronegative than N , dmpe is a stronger electron pair donor and Lewis base than en. Dmpe creates a stronger ligand field and is higher on the spectrochemical series. Structurally, dmpe occupies a larger volume than en. M-P bonds are longer than $\mathrm{M}-\mathrm{N}$ bonds and the two $-\mathrm{CH}_{3}$ groups on each P atom in dmpe create more steric hindrance than the H atoms on N in en. (b) The oxidation state of Mo is zero. (c) The symbol P P represents the bidentate dmpe ligand.

optical isomers
23.76 (a) Iron (b) magnesium (c) iron (d) copper 23.78 (a) Pentacarbonyliron (0) (b) The oxidation state of iron must be zero. (c) Two. One isomer has CN in an axial position and the other has it in an equatorial position.

### 23.80

(a)

(b) These complexes are colored because the crystal-field splitting energy, $\Delta$, is in the visible portion of the electromagnetic spectrum. Visible light with $\lambda=h c / \Delta$ is absorbed, promoting one of the $d$-electrons into a higher energy $d$-orbital. The remaining wavelengths of visible light are reflected or transmitted; the combination of these wavelengths is the color we see. (c) $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ will absorb light with higher energy. $\mathrm{NH}_{3}$ is in the middle of the spectrochemical series, and causes a larger $\Delta$ than $\mathrm{Br}^{-}$, a weak-field ligand. Because $\Delta$ and $\lambda$ are inversely related, larger $\Delta$ corresponds to higher energy and shorter $\lambda$. $23.82\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$, yellow; $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$, pink; $\left[\mathrm{CoCl}_{4}\right]^{2-}$, blue
23.83 (a)

(b) sodium dicarbonyltetracyanoferrate(II) (c) $+2,6 d$-electrons (d) We expect the complex to be low spin. Cyanide (and carbonyl) are high on the spectrochemical series, which means the complex will have a large $\Delta$ splitting, characteristic of low-spin complexes. 23.93 (a) Yes, the oxidation state of Co is +3 in both complexes. (b) Compound A has $\mathrm{SO}_{4}{ }^{2-}$ outside the coordination sphere and coordinated $\mathrm{Br}^{-}$, so it forms a precipitate with $\mathrm{BaCl}_{2}(a q)$ but not $\mathrm{AgNO}_{3}(a q)$. Compound B has $\mathrm{Br}^{-}$outside the coordination sphere and coordinated $\mathrm{SO}_{4}^{2-}$ so it forms a precipitate with $\mathrm{AgNO}_{3}(\mathrm{aq})$ but not $\mathrm{BaCl}_{2}(a q)$. (c) Compounds A and B are coordination sphere isomers. (d) Both compounds are strong electrolytes. 23.96 The chemical formula is $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$. This should be a neutral square-planar complex of $\mathrm{Pt}(\mathrm{II})$, a nonelectrolyte. Because it has a net dipole moment, we can infer that it must be the cis isomer. $23.9847 .3 \mathrm{mg} \mathrm{Mg}^{2+} / \mathrm{L}$,
$53.4 \mathrm{mg} \mathrm{Ca}^{2+} / \mathrm{L} \mathbf{2 3 . 1 0 0} \Delta E=3.30 \times 10^{-19} \mathrm{~J} /$ photon, $\lambda=602 \mathrm{~nm}$. The complex will absorb in the visible around 600 nm and appear blue.

$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}(\mathrm{Br}) \mathrm{CH}(\mathrm{Br}) \mathrm{CH}_{3}$ 2, 3-dibromopentane

This is an addition reaction.

(c)

This is an substitution reaction.
24.37 The $60^{\circ} \mathrm{C}-\mathrm{C}-\mathrm{C}$ angles in the cyclopropane ring cause strain that provides a driving force for reactions that result in ring opening. There is no comparable strain in the five-membered or six-membered rings. (b) $\mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{HBr}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Br}(l)$;
$\mathrm{C}_{6} \mathrm{H}_{6}(l)+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Br}(l) \xrightarrow{\mathrm{AICl}_{3}} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{2} \mathrm{CH}_{3}(l)+\mathrm{HBr}(g)$
24.39 Yes, this information suggests (but does not prove) that the reactions proceed in the same manner. That the two rate laws are first order in both reactants and second order overall indicates that the activated complex in the rate-determining step in each mechanism is bimolecular and contains one molecule of each reactant. This is usually an indication that the mechanisms are the same, but it does not rule out the possibility of different fast steps or a different order of elementary steps. $24.41 \Delta H_{\text {comb }} / \mathrm{mol} \mathrm{CH}_{2}$ for cyclopropane $=696.3 \mathrm{~kJ}$, for cyclopentane $=663.4 \mathrm{~kJ} . \Delta H_{\text {comb }} / \mathrm{CH}_{2}$ group for cyclopropane is greater because $\mathrm{C}_{3} \mathrm{H}_{6}$ contains a strained ring. When combustion occurs, the strain is relieved and the stored energy is released.

## ANSWERS TO GIVE IT SOME THOUGHT

## Chapter 1

page $49(\mathbf{a}) 100(\mathbf{b})$ atoms page 54 Water is composed of two types of atoms: hydrogen and oxygen. Hydrogen is composed only of hydrogen atoms, and oxygen is composed only of oxygen atoms. Therefore, hydrogen and oxygen are elements and water is a compound. page 56 Weight is an extensive property, which changes when the size of the matter changes. page 57 (a) Chemical change: Iron reacts with water and oxygen to form hydrated iron(III) oxide. (b) Physical change: Dry ice does not melt; it changes directly from solid to gas through a process called sublimation. (c) Chemical change: The acid and the base in the tablet react with water and $\mathrm{CO}_{2}$ is released. page 59 Doubling its speed will increase the kinetic energy by a factor of four, while doubling its mass will only double the kinetic energy. page 60 The chemical potential energy of the battery increases as it is recharged. page 61 The candela, cd. page $6310^{9}$ page $652.5 \times 10^{2} \mathrm{~m}^{3}$ is, because it has units of length to the third power. page 68 (c) Volume of liquid that a disposable dropper delivers page 69 The mass should be reported to four significant figures, two figures to the left of the decimal point and two to the right. page 71 The mass of the water can be reported as 10.08 g with a total of four significant figures. The number of significant figures to the right of the decimal point is limited by the precision to which the mass of the empty beaker is known. page 74 Conversions (ii) and (iii) involve exact numbers and therefore do not alter the number of significant figures in a calculation, but conversion (i) has the potential to affect the number of significant figures in a calculation.

## Chapter 2

page 89 (a) The law of multiple proportions. (b) The second compound must contain two oxygen atoms for each carbon atom (that is, twice as many carbon atoms as the first compound). page 91 (b) The particles that make up cathode rays must be present in all metals. page 93 As the thickness of the gold foil increases there is a higher probability that the alpha particle will collide with a nucleus as it passes through the foil, increasing the number of alpha particles scattered at large angles. page 94 (a) The atom has 8 protons because atoms have equal numbers of electrons and protons. (b) The protons reside in the nucleus of the atom. page 97 The mass of an electron is $5.5 \times 10^{-4} \mathrm{u}$, so you would need to express the mass of an oxygen atom to four places past the decimal, giving a total of six significant figures, to detect a change in mass upon losing an electron. page 97 The atomic weight of lithium, 6.941 u , is closer to ${ }^{7} \mathrm{Li}$, which means ${ }^{7} \mathrm{Li}$ is the more abundant isotope. page $101(\mathbf{a}) \mathrm{Be},(\mathbf{b})$ second period and group 2 , (c) 4 , (d) metal page $103 \mathrm{~N}_{2} \mathrm{O}_{4}$ and $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$ can be only molecular formulas; their empirical formulas would be $\mathrm{NO}_{2}$ and $\mathrm{CH}_{2} \mathrm{O} . \mathrm{NH}_{3}$ and $\mathrm{CO}_{2}$ could be empirical formulas or molecular formulas. No formula can be only an empirical formula; there would always be a molecule of that composition. page 104 (a) $\mathrm{C}_{2} \mathrm{H}_{6}$, (b) $\mathrm{CH}_{3}$, (c) No, you cannot determine bond angles or relative bond distances from a structural formula. page $108 \mathrm{PbO}_{2}$ page 110 FeO page 111 The endings convey the number of oxygen atoms bound to the nonmetallic element page 113 (a) $\mathrm{NaHCO}_{3}$, (b) $\mathrm{Ca}\left(\mathrm{HSO}_{4}\right)_{2}$, (c) $\mathrm{NaH}_{2} \mathrm{PO}_{4}$ page 114 Bromic acid, by analogy to the relationship between the chlorate ion and chloric acid. page 115 Yes, it contains two different elements. page 116

## Chapter 3

page 128 Each $\mathrm{Na}_{2} \mathrm{CO}_{3}$ has $2 \mathrm{Na}, 1 \mathrm{C}$ and 3 O ; thus $2 \mathrm{Na}_{2} \mathrm{CO}_{3}$ represents $4 \mathrm{Na}, 2 \mathrm{C}$, and 6 O . page 133 The product is an ionic compound involving $\mathrm{Zn}^{2+}$ and $\mathrm{I}^{-}$, and its chemical formula is therefore $\mathrm{Znl}_{2}$. page 138 (a) A mole of sucrose. By inspecting their chemical formulas we find that sucrose has more atoms of $\mathrm{H}, \mathrm{C}$, and O than methanol. Thus, a molecule of sucrose has a greater mass than a molecule of methanol. (b) The molar masses of methanol and sucrose are $32.04 \mathrm{~g} / \mathrm{mol}$ and $342.30 \mathrm{~g} / \mathrm{mol}$ respectively. Therefore, there are two moles of methanol and one mole of sucrose. The number of molecules of methanol is twice as large as the number of molecules of sucrose. page 143 No, chemical analysis cannot distinguish compounds that have different molecular formulas but the same empirical formula. page $\mathbf{1 4 7} 3.14 \mathrm{~mol}$ because $2 \mathrm{~mol}_{2} \cong 1$ $\mathrm{mol} \mathrm{O}_{2}$ based on the coefficients in the balanced equation page 148 To obey the law of conservation of mass the mass of the products consumed must equal the mass of reactants formed, therefore the mass of $\mathrm{H}_{2} \mathrm{O}$ produced is $1.00 \mathrm{~g}+3.59 \mathrm{~g}-3.03 \mathrm{~g}=1.56 \mathrm{~g} \mathrm{H} 2 \mathrm{O}$.

## Chapter 4

page $167(\mathbf{a}) \mathrm{K}^{+}(a q)$ and $\mathrm{NO}_{3}^{-}(a q)(\mathbf{b}) \mathrm{NH}_{4}^{+}(a q)$ and $\mathrm{SO}_{4}^{2-}(a q)$ page 169 NaOH because it is the only solute that is a strong electrolyte page $173 \mathrm{Mg}^{2+}(a q)$ and $\mathrm{NO}_{3}^{-}(a q)$ page 175 Three. Each COOH group will partially ionize in water to form $\mathrm{H}^{+}(a q)$.
page 176 Only soluble metal hydroxides are classified as strong bases and $\mathrm{Al}(\mathrm{OH})_{3}$ is insoluble. page $180 \mathrm{SO}_{2}(g)$ page 183 (a) -1 , (b) +3 page 186 (a) Yes, nickel is below zinc in the activity series so $\mathrm{Ni}^{2+}(a q)$ will oxidize Zns to form Nis and $\mathrm{Zn}^{2+}(a q)$.
(b) No reaction will occur because the $\mathrm{Zn}^{2+}(a q)$ ions cannot be further oxidized. page 191 The concentration is halved to 0.05 M .

## Chapter 5

page 211 Open system. Humans exchange matter and energy with their surroundings. page 214 Endothermic page 216 Height of the mountain page 217 No. If $\Delta V$ is zero, then the expression $w=-P \Delta V$ is also zero. page $218 \Delta H$ is negative; the fact that the heating pad (part of the surroundings) gets hot means the system is releasing heat, meaning that $q_{P}$ is negative. (See figure 5.8) Because the process occurs at constant pressure $q_{p}=\Delta H$. page 220 No. Because only half as much matter is involved, the value of $\Delta H$ would be $\frac{1}{2}(-483.6 \mathrm{~kJ})=-241.8 \mathrm{~kJ}$. page $223 \mathrm{Hg}(l)$. Rearranging Equation 5.22 gives $\Delta T=\frac{q}{C_{s} \times m}$. When $q$ and $m$ are constant for a series of substances, then $\Delta T=\frac{\text { constant }}{C_{s}}$. Therefore, the element with the smallest $C_{s}$ in Table 5.2 has the largest $\Delta T$, $H g l$. page 228 (a) The sign of $\Delta H$ changes. (b) The magnitude of $\Delta H$ doubles. page 232 No. Because $\mathrm{O}_{3}(g)$ is not the most stable form of oxygen at $25^{\circ} \mathrm{C}, 1$ $\operatorname{atm}\left[\mathrm{O}_{2}(g)\right.$ is $], \Delta H_{f}^{\circ}$ for $\mathrm{O}_{3}(g)$ is not necessarily zero. In Appendix C
we see that it is $142.3 \mathrm{~kJ} / \mathrm{mol}$. page 235 To transform a $\mathrm{Cl}_{2}$ molecule into two separate Cl atoms the $\mathrm{Cl}-\mathrm{Cl}$ bond must be broken which requires an input of energy. Therefore, the $\mathrm{Cl}_{2}$ molecule will have a lower energy and be more stable. The difference in energy between the two is the $\mathrm{Cl}-\mathrm{Cl}$ bond dissociation energy, $242 \mathrm{~kJ} / \mathrm{mol}$.
page 239 Reacting 1 mol of glucose releases 2803 kJ of energy. The molar mass of glucose is 180.6 g , so the amount of energy released when 1 g is reacted is $2803 \mathrm{~kJ} / 18.6 \mathrm{~g}=15.56 \mathrm{~kJ} / \mathrm{g}$. This value is close to the average value for carbohydrates $(17 \mathrm{~kJ} / \mathrm{g})$ as expected.
page 240 Fats, because they have the largest fuel value of the three

## Chapter 6

page 258 No. Both visible light and X-rays are forms of electromagnetic radiation. They therefore both travel at the speed of light, $c$. Their differing ability to penetrate skin is due to their different energies, which we will discuss in the next section. page 261 The notes on a piano go in "jumps"; for example, one can't play a note between B and C on a piano. In this analogy, a violin is continu-ous-in principle, one can play any note (such as a note halfway between B and C). page 262 (a) Electrons will be ejected. If photons of red light have sufficient energy to eject electrons, then photons of green light, which have a higher frequency and hence energy than red light, will also be able to eject electrons. page 262 Wavelike behavior. page 265 The energies in the Bohr model have only certain specific allowed values, much like the positions on the steps in Figure 6.6. page 265 As the potential energy of the electron decreases (becomes more negative) it's attraction to the nucleus increases and the radius of its orbit decreases. page $266 \Delta E<0$ suggests that energy is released. The energy of the final state (possibly the ground state) is lower than that of the excited state. page 267 True. The energy of the emitted photon increases as the initial value of $n$ increases and the final value of $n$ decreases. In the limit $\mathrm{n}_{\mathrm{f}}=1$ and $\mathrm{n}_{\mathrm{i}}$ goes to infinity, which gives a photon energy, $\mathrm{E}_{\text {photon }}=h c R_{\mathrm{H}}$. page 269 Yes, all moving objects produce matter waves. They can be observed by neutron diffraction. page 271 Less important. page 272 In the first statement, we know exactly where the electron is. In the second statement, we are saying that we know the probability of the electron being at a point, but we don't know exactly where it is. The second statement is consistent with the Uncertainty Principle. page 273 In the Bohr model electrons move in orbits, each of which has a specific fixed distance from the nucleus. In the modern picture of the atom electrons are found in orbitals and cannot be said to orbit the nucleus at a specific distance. page 278 The two orbitals have the same orbital angular momentum quantum number, $l=0$ and the same magnetic quantum number since $l=0$ has only one magnetic quantum number. They have different values of the principal quantum number. page 280 In hydrogen, the energy of an orbital depends only on its principal quantum number, $n$. Therefore, $3 p$, and $3 d$ subshells of a hydrogen atom all have the same energy. In a many-electron atom, for a given value of $n$, the energy of an orbital increases with the increasing value of $l$, as illustrated in Figure 6.25. Therefore, in a many-electron atom the energy level of $3 p<3 d$. page 285 The $5 s$ orbital, which starts to hold electrons at element 37, Rb. page 289 The three elements have the following valence electron configurations for their $n d$ and $(n+1) s$ subshells: For Fe, $3 d^{6} 4 s^{2}$; for Ru, $4 d^{7} 5 s^{1}$; and for Os, $4 f^{14} 5 d^{6} 6 s^{2}$. Thus, we conclude that the energy level of the respective $(n+1) s$ subshell is slightly below that of the $n d$ subshell, because the s orbital is occupied with at least one electron before all $d$ orbitals are filled.

## Chapter 7

page 303 Co and Ni as well as Te and I are other pairs of elements whose atomic weights are out of order compared to their
atomic numbers. page 306 The $3 p$ electron in an Ar atom would experience a larger $Z_{\text {eff }}$ than the $4 s$ electron in Ca , due to the greater shielding of the $4 s$ electron of the Ca atom by all the $3 s$ and $3 p$ electrons. page 308 These trends work against each other: $Z_{\text {eff }}$ increasing would imply that the valence electrons are pulled tighter in to make the atom smaller, while orbital size "increasing" would imply that atomic size would also increase. The orbital size effect is larger: As you go down a column in the periodic table, atomic size generally increases. page 312 It is harder to remove another electron from $\mathrm{Al}^{+}$, so the process in Equation 7.3 would require more energy and, hence, shorter-wavelength light (see Sections 6.1 and 6.2). page $312 I_{2}$ for a carbon atom corresponds to ionizing an electron from $\mathrm{C}^{+}$, which has the same number of electrons as a neutral B atom. $Z_{\text {eff }}$ will be greater for $\mathrm{C}^{+}$ than for B, so $I_{2}$ for a carbon atom will be greater than $I_{1}$ for a boron atom. page 315 The same, $[\mathrm{Ar}] 3 d^{6}$. page 317 The magnitudes are the same, but they have opposite signs. page 319 No. The oxidation state of As will be positive when combined with Cl , and negative when combined with Mg. page 321 Because the melting point is so low, we would expect a molecular rather than ionic compound. Thus, A is more likely to be S than Mg because $\mathrm{SCl}_{2}$ is a compound of two nonmetals and is therefore more likely to be molecular. page 324 Its low first ionization energy. page 327 In the acidic environment of the stomach, metal carbonates can react to give carbonic acid, which decomposes to water and carbon dioxide gas. Thus, calcium carbonate is much more soluble in acidic solution than it is in neutral water. page 329 (b) The fact that bromine is a liquid and chlorine is a gas. page 330 Based on the trends in the table, we might expect the radius to be about 150 pm , and the first ionization energy to be about $900 \mathrm{~kJ} / \mathrm{mol}$. In fact, its bonding radius is indeed 150 pm , and the experimental ionization energy is $920 \mathrm{~kJ} / \mathrm{mol}$.

## Chapter 8

page 344 No. P has five valence electrons. The first Lewis symbol is correct-it shows five valence electrons, and it doesn't matter which of the four sides has the paired electron. The second symbol shows six electrons and is incorrect. The third symbol shows that there are two electron pairs, which is incorrect. page 347 No. This reaction corresponds to the lattice energy for KCl , which is a large positive number. Therefore, the reaction will cost energy, not release energy. page 350 Molybdenum, Mo page 351 Weaker. In both $\mathrm{H}_{2}$ and $\mathrm{H}_{2}^{+}$the two H atoms are principally held together by the electrostatic attractions between the nuclei and the electrons concentrated between them. $\mathrm{H}_{2}{ }^{+}$has only one electron between the nuclei whereas $\mathrm{H}_{2}$ has two and this results in the $\mathrm{H}-\mathrm{H}$ bond in $\mathrm{H}_{2}$ being stronger. page 353 Triple bond. $\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}$ has a $\mathrm{C}-\mathrm{C}$ double bond. Because the $\mathrm{C}-\mathrm{C}$ bond in acetylene is shorter, it is likely to have a triple bond. page 353 Electron affinity measures the energy released when an isolated atom gains an electron to form a 1 - ion and has units of energy. Electronegativity has no units, and is the ability of the atom in a molecule to attract electrons to itself within that molecule. page 356 IF; because the difference in electronegativity between $I$ and $F$ is greater than that between Cl and F , the magnitude of Q should be greater for IF. In addition, because I has a larger atomic radius than Cl , the bond length in IF is longer than that in CIF. Thus, both Q and $r$ are larger for IF and, therefore, $\mu=Q r$ will be larger for IF. page 357 Smaller dipole moment for $\mathrm{C}-\mathrm{H}$. The magnitude of Q should be similar for $\mathrm{C}-\mathrm{H}$ and H - I bonds because the difference in electronegativity for each bond is 0.4 . The $\mathrm{C}-\mathrm{H}$ bond length is 110 pm and the $\mathrm{H}-\mathrm{I}$ bond length is 160 pm . Therefore $\mu=Q r$ will be greater for H -I because it has a longer bond (larger $r$ ). page $359 \mathrm{WCl}_{6}$. The data suggest
that the dark purple substance is a molecular species with its low melting and boiling points. W in $\mathrm{WCl}_{6}$ has an oxidation number of +6 and Mg in $\mathrm{MgCl}_{2}$ has an oxidation number of +2 . In Section 8.4, we learn that a compound with a metal in a high oxidation state should show a high degree of covalence and $\mathrm{WCl}_{6}$ fits this situation. page 362 There is probably a better choice of Lewis structure than the one chosen. Because the formal charges must add up to 0 and the formal charge on the Cl atom is +1 , there must be another atom that has a negative formal charge. Because Cl is the most electronegative element when compared to C and H , we don't expect it to carry a positive formal charge. page 364 The ozone OO bond length should be longer than the OO bond in oxygen. page 365 Weaker. page 366 No, it will not have multiple resonance structures. We can't "move" the double bonds, as we did in benzene, because the positions of the hydrogen atoms dictate specific positions for the double bonds. We can't write any other reasonable Lewis structures for the molecule. page 367 The formal charge of each atom is shown here:

The first structure shows each atom with a zero formal charge and therefore it is the dominant Lewis structure. The second one shows a positive formal charge for an oxygen atom, which is a highly electronegative atom, and this is not a favorable situation.

## Chapter 9

page 386 Removal of two opposite atoms from an octahedral arrangement would lead to square-planar shape. page $\mathbf{3 8 7}$ No. The molecule does not satisfy the octet rule because there are only six electrons around the atom B on the right. The atom B on the left and atom A both satisfy the octet rule. There are three electron domains around A: One single bond, one double bond, and one nonbonding electron pair. page 391 Yes. Because there are three equivalent dominant resonance structures, each of which puts the double bond between the N and a different O , the average structure has the same bond order for all three $\mathrm{N}-\mathrm{O}$ bonds. Thus, each electron domain is the same and the angles are predicted to be $120^{\circ}$. page 393 In a square planar arrangement of electron domains, each domain is $90^{\circ}$ from two other domains (and $180^{\circ}$ from the third domain). In a tetrahedral arrangement, each domain is $109.5^{\circ}$ from the other three domains. Domains always try to minimize the number of $90^{\circ}$ interactions, so the tetrahedral arrangement is favored. page 397 No. Although the bond dipoles are in opposite directions, they will not have the same magnitude because the $\mathrm{C}-\mathrm{S}$ bond is not as polar as the $\mathrm{C}-\mathrm{O}$ bond. Thus, the sum of the two vectors will not equal zero and the molecule is polar. page 401 They are both oriented perpendicular to the $\mathrm{F}-\mathrm{Be}-\mathrm{F}$ axis. page 402 None. All of the $2 p$ orbitals are used in constructing the $s p^{3}$ hybrid orbitals. page 408 There are four electron domains about each O atom, so we expect $s p^{3}$ hybridization at each of the O atoms. The $\mathrm{H}-\mathrm{O}-\mathrm{O}$ angles should therefore be roughly $109^{\circ}$, and the molecule is not expected to be linear. Although a planar structure might be possible, a non-planar structure is more favorable in view of the repulsion of lone pairs. page 412 $s p$ hybridization. page 415 The molecule would fall apart. It would have an electron configuration $\sigma 1 s^{2} \sigma^{*} 1 s^{2}$ and therefore a bond order of 0 . The energy of the molecule would actually even be higher than that of the two atoms because the destabilization energy of the antibonding orbitals would be greater than that of the stabilization energy of the bonding orbital. page 416 Yes, it will have a bond order of $1 \frac{1}{2}$. page 422 No. If the $\sigma_{2 p}$ MO were lower in energy than the $\pi_{2 p}$ MOs we would expect the last two electrons to go into the $\pi_{2 p} \mathrm{MOs}$ with the same spin, which would cause $\mathrm{C}_{2}$ to be paramagnetic.

## Chapter 10

page 441 No. The heaviest gas in Table 10.1 is $\mathrm{SO}_{2}$, whose molar mass, $64 \mathrm{~g} / \mathrm{mol}$, is less than half that of Xe , whose molar mass is $131 \mathrm{~g} / \mathrm{mol}$. page $442(\mathbf{a}) 6.32 \times 10^{3} \mathrm{~N}$, (b) $5.07 \times 10^{3} \mathrm{~N}$ page 442 (a) 0.303 atm , (b) 4.45 psi , (c) 30.7 kPa , (d) 0.307 bar page 445 It would be halved. page 446 No because the absolute temperature is not halved, it only decreases from 373 K to 323 K . page 448 17.5 cm page 452 Less dense because water has a smaller molar mass, $18 \mathrm{~g} / \mathrm{mol}$, than $\mathrm{N}_{2}, 28 \mathrm{~g} / \mathrm{mol}$. page 455 The partial pressure of $\mathrm{N}_{2}$ is not affected by the introduction of another gas, but the total pressure will increase. page $\mathbf{4 5 8}$ Slowest $\mathrm{kr}<\mathrm{N}_{2}<\mathrm{NH}_{3}$ fastest. page $460 u_{\mathrm{rms}} / u_{\mathrm{mp}}=\sqrt{3 / 2}$. This ratio will not change as the temperature changes and it will be the same for all gases. page 463 (a) Decrease, (b) have no effect. page 464 (b) 70 K and 506.6 kPa page 465 The negative deviation is due to attractive intermolecular forces.

## Chapter 11

page $482 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$; during boiling, energy is provided to overcome intermolecular forces between $\mathrm{H}_{2} \mathrm{O}$ molecules allowing the vapor to form. page $\mathbf{4 8 4} \mathrm{CH}_{4}<\mathrm{CCl}_{4}<\mathrm{CBr}_{4}$. Because all three molecules are nonpolar, the strength of dispersion forces determines the relative boiling points. Polarizability increases in order of increasing molecular size and molecular weight, $\mathrm{CH}_{4}<\mathrm{CCl}_{4}<\mathrm{CBr}_{4}$; hence, the dispersion forces and boiling points increase in the same order. page 488 Mainly hydrogen bonds, which hold the individual $\mathrm{H}_{2} \mathrm{O}$ molecules together in the liquid. page $\mathbf{4 8 8} \mathrm{Na}_{2} \mathrm{CO}_{3}$ in water, because sodium carbonate is a strong electrolyte that forms ions and water is a polar molecule with a dipole moment. Ion-dipole forces cannot be present in a $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{O} / \mathrm{H}_{2} \mathrm{O}$ mixture because $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{O}$ does not form ions. page 492 Decrease. page 494 Sublimation, endothermic page 496 The intermolecular attractive forces in $\mathrm{H}_{2} \mathrm{O}$ are much stronger than those in $\mathrm{H}_{2} \mathrm{~S}$ because $\mathrm{H}_{2} \mathrm{O}$ can form hydrogen bonds. The stronger intermolecular forces results in a higher critical temperature and pressure. page $498 \mathrm{CCl}_{4}$. Both compounds are nonpolar; therefore, only dispersion forces exist between the molecules. Because dispersion forces are stronger for the larger, heavier $\mathrm{CBr}_{4}$, it has a lower vapor pressure than $\mathrm{CCl}_{4}$. The substance with the larger vapor pressure at a given temperature is more volatile.

## Chapter 12

page 520 Tetragonal. There are two three-dimensional lattices that have a square base with a third vector perpendicular to the base, tetragonal and cubic, but in a cubic lattice the $a, b$, and $c$ lattice vectors are all of the same length. page 523 Ionic solids are composed of ions. Oppositely-charged ions slipping past each other could create electrostatic repulsions, so ionic solids are brittle. page 527 The packing efficiency decreases as the number of nearest neighbors decreases. The structures with the highest packing efficiency, hexagonal and cubic close packing, both have atoms with a coordination number of 12 . Body-centered cubic packing, where the coordination number is 8 , has a lower packing efficiency, and primitive cubic packing, where the coordination number is 6, has a lower packing efficiency still. page 528 Substitutional, because zinc atoms occupy positions normally occupied by a copper atom. page 533 Platinum, Pt should have more electrons in antibonding orbitals. Rhenium, Re, lies near the middle of the transition metal series where the bands arising from the $d$ orbitals and the $s$ orbital are approximately half-filled. This electron count should fill the bonding orbitals and leave the antibonding orbitals mostly empty. Because both elements have similar numbers of electrons in the bonding orbitals but rhenium has fewer electrons in
antibonding orbitals, it will have a higher melting point. page 534 No. In a crystal the lattice points must be identical. Therefore, if an atom lies on top of a lattice point, then the same type of atom must lie on all lattice points. In an ionic compound there are at least two different types of atoms, and only one can lie on the lattice points. page 537 Six. The empirical formula of titanium dioxide is $\mathrm{TiO}_{2}$. Rearranging Equation 12.1 we can determine the titanium coordination number to be anion coordination number $\times$ (number of anions per formula unit/number of cations per formula unit) $=3(2 / 1)=6$. page 548 A condensation polymer. The presence of both -COOH and -OH groups allows molecules to react with one another forming $\mathrm{C}-\mathrm{O}$ ester bonds and eliminating $\mathrm{H}_{2} \mathrm{O}$ to form a polyester. page 549 As the vinyl acetate content increases more side chain branching occurs which inhibits the formation of crystalline regions thereby lowering the melting point. page 551 No. The emitted photons have energies that are similar in energy to the band gap of the semiconductor. If the size of the crystals is reduced into the nanometer range, the band gap will increase. However, because 340-nm light falls in the UV region of the electromagnetic spectrum, increasing the energy of the band gap will only shift the light deeper into the UV.

## Chapter 13

page 571 Entropy increases as the ink molecules disperse into water. page 572 The lattice energy of $\mathrm{MgCl}_{2}(\mathrm{~s})$ must be overcome to separate $\mathrm{Mg}^{2+}$ and $\mathrm{Cl}^{-}$ions and disperse them into a solvent. $\mathrm{C}_{6} \mathrm{H}_{14}$ is nonpolar. Interactions between ions and nonpolar molecules tend to be very weak. Thus, the energy required to separate the ions in $\mathrm{MgCl}_{2}$ is not recovered in the form of ion- $\mathrm{C}_{6} \mathrm{H}_{14}$ interactions. page 574 (a) Breaking solute-solvent interactions to form separated particles requires energy and is therefore endothermic. (b) Separating solute molecules from each other requires energy and is therefore endothermic. page 575 The added solute provides a template for the solid to begin to crystallize from solution, and a precipitate will form. page 578 The solubility in water would be considerably lower because there would no longer be hydrogen bonding with water, which promotes solubility. page 5820.042 ppm ( 1 ppm is 1 part in $10^{6}$, the mass of 1 liter of water is 1000 g ); 42 ppb (1 ppb is 1 part in $10^{9}$ ). page $\mathbf{5 8 4}$ Molality is the number of moles of solute per kilogram of solvent, whereas molarity is the number moles of solute per liter of solution. Because the density of water at $90^{\circ} \mathrm{C}$ is less than $1 \mathrm{~kg} / \mathrm{L}$, the number of liters of solution is slightly larger than the number of kilograms of solvent. Therefore, molality is slightly larger than molarity. page 587 A greater extent, lowering of the vapor pressure depends on the total solute concentration (Equation 13.11). One mole of $\mathrm{NaHCO}_{3}$ (a strong electrolyte) provides 2 mol of particles ( 1 mol of $\mathrm{Na}^{+}$and $1 \mathrm{~mol} \mathrm{HCO}_{3}^{-}$), whereas one mole of sucrose (a nonelectrolyte) provides only 1 mol particles. page 590 Not necessarily; if the solute is a strong or weak electrolyte, it could have a lower molality and still cause an increase of $0.51^{\circ} \mathrm{C}$. The total molality of all the particles in the solution is 1 m . page 592 The $0.1-M$ solution is hypotonic with respect to the $0.25-M$ solution. (A hypotonic solution will have a lower total concentration and hence a lower osmotic pressure.) page 594 Both $\mathrm{NaNO}_{3}$ and $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ are strong electrolytes with $0.3 \mathrm{~mol} / \mathrm{L}$ of total ions. They would have the same osmotic pressure because they have the same concentration of particles. page 597 Hydrophilic groups would face the ions to make contact through ion-dipole interaction.

## Chapter 14

page 614 Increasing the partial pressure increases the number of collisions between molecules. For any reaction that depends on collisions (which is nearly all of them), we would expect the rate
to increase with increasing partial pressure. page 618 You can see visually that the slope of the line connecting 0 s and 600 s is smaller than the slope at 0 s and larger than the slope at 600 s . The order from fastest to slowest is therefore (ii) $>$ (i) $>$ (iii). page 621 No, the reaction rate usually depends on concentration but the rate constant does not. page 621 Generally no. Rate always has units of $M / s$. The units of the rate constant depend on the specific rate law, as we shall see throughout this chapter.
page 622 The reaction rate will remain the same because the rate law is zero order in $\left[\mathrm{CH}_{3} \mathrm{OH}\right]$. page 629 After 3 half-lives, the concentration will be $1 / 8$ of its original value, so 80 g of substance A were present before the start of the reaction. page $631 \mathrm{Yes}$, using $t=t_{1 / 2}$ and $[\mathrm{A}]_{t}=[\mathrm{A}]_{0} / 2$ the half life of a zero-order reaction is $\mathrm{t}_{1 / 2}=[\mathrm{A}]_{0} / 2 \mathrm{k}$. page 633 According to the figure, the energy barrier is lower in the forward direction than in the reverse. Thus, more molecules will have energy sufficient to cross the barrier in the forward direction. The forward rate will be greater page 634 No. If B can be isolated, it can't correspond to the top of the energy barrier. There would be transition states for each of the individual reactions above page 637 Unimolecular page 642 The likelihood of three molecules colliding at exactly the same time is vanishingly small. page 647 A heterogeneous catalyst is in a different phase than the reactants and is therefore fairly easy to remove from the mixture. The removal of a homogeneous catalyst can be much more difficult as it exists in the same phase as the reactants. page 649 False. The yield of a reaction does not depend on the energy of the transition state.

## Chapter 15

page $670(b)$ the forward and reverse reaction rates page 671 False page 674 It does not depend on starting concentrations. page 675 Yes, $K_{c}=K_{p}$ when the number of moles of gaseous products and the number of moles of gaseous reactants are equal. page 6760.00220 page $678 K_{c}=169$ page 678 It is squared. page $680 K_{p}=\frac{P_{\mathrm{NH}_{3}}^{2}}{P_{\mathrm{N}_{2}} \times P_{\mathrm{H}_{2}}^{3}}$ page $682 K_{c}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Cl}^{-}\right]$
page 691 (a) to the right (b) to the right page 692 (bottom) It will shift to the left, the side with a larger number of moles of gas. page 694 Endothermic. Raising the temperature of an endothermic reaction shifts the equilibrium to the right, increasing the vapor pressure of the gaseous product. page 696 It will stay the same. The presence of a catalyst can accelerate the reaction but does not alter the value of K , which is what limits the amount of product produced.

## Chapter 16

page 710 The $\mathrm{H}^{+}$ion for acids and the $\mathrm{OH}^{-}$ion for bases. page $712 \mathrm{NH}_{3}$ is the base because it accepts a $\mathrm{H}^{+}$from $\mathrm{CH}_{3} \mathrm{COOH}$ as the reaction moves from the left-hand to the right-hand side of the equation. page $\mathbf{7 1 5}$ As the conjugate base of a strong acid, we would classify $\mathrm{Br}^{-}$as having negligible basicity. page 719 pH is defined as $-\log \left[\mathrm{H}^{+}\right]$. This quantity will become negative if the $\mathrm{H}^{+}$concentration exceeds 1 M , which is possible. Such a solution would be highly acidic. page $721 \mathrm{pH}=14.00-1.50=12.5$. This solution is basic because $\mathrm{pH}>7.0$. page 723 Both CsOH and $\mathrm{Sr}(\mathrm{OH})_{2}$ are soluble hydroxides and strong bases. Therefore, the hydroxide concentrations will be 0.001 M for CsOH and 0.002 $M$ for $\mathrm{Sr}(\mathrm{OH})_{2}$. Because the $\mathrm{Sr}(\mathrm{OH})_{2}$ solution has a higher $\left[\mathrm{OH}^{-}\right]$, it is more basic and has a higher pH . page $724 \mathrm{Because}^{\mathrm{CH}_{3}{ }^{-} \text {is }}$ the conjugate base of a substance that has negligible acidity, $\mathrm{CH}_{3}{ }^{-}$ must be a strong base. Bases stronger than $\mathrm{OH}^{-}$abstract $\mathrm{H}^{+}$from water molecules: $\mathrm{CH}_{3}^{-}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{CH}_{4}+\mathrm{OH}^{-}$. page 725 Oxygen. page $728 p H>7$. We must consider the $\left[\mathrm{OH}^{-}\right]$that is
due to the autodissociation of water. The additional $\left[\mathrm{OH}^{-}\right]$from the very dilute alkaline solution will make the solution slightly basic. page $732 \mathrm{HPO}_{4}{ }^{2-}(a q) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{PO}_{4}{ }^{3-}(a q)$ page 738 4. page $\mathbf{7 4 0}$ Nitrate is the conjugate base of nitric acid, $\mathrm{HNO}_{3}$. The conjugate base of a strong acid does not act as a base, so $\mathrm{NO}_{3}^{-}$ ions will not affect the pH . Carbonate is the conjugate base of hydrogen carbonate, $\mathrm{HCO}_{3}^{-}$, which is a weak acid. The conjugate base of a weak acid acts as a weak base, so $\mathrm{CO}_{3}^{2-}$ ions will increase the pH . page $746 \mathrm{HCIO}_{4}$. For an oxyacid, acidity increases as the electronegativity of the central ion increases, which would make $\mathrm{HCIO}_{4}$ more acidic than $\mathrm{HIO}_{4}$. Acidity also increases as the number of oxygens bound to the central atom increases, which would make $\mathrm{HIO}_{4}$ more acidic than $\mathrm{HIO}_{3}$. Combining these two relationships we can order these acids in terms of increasing acid-dissociation constant, $\mathrm{HIO}_{3}<\mathrm{HIO}_{4}<\mathrm{HCIO}_{4}$. page 747 Basic. page 748 It must have an empty orbital that can interact with the lone pair on a Lewis base.

## Chapter 17

page $\mathbf{7 6 5}$ (top) $\mathrm{The}^{-1}{ }^{-}$ion is the only spectator ion. The pH is determined by the equilibrium

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{OH}^{-}(a q)+\mathrm{NH}_{4}^{+}(a q)
$$

page 765 (bottom) HBr and $\mathrm{Br}^{-}$. To form a buffer we need comparable concentrations of a weak acid and its conjugate base. HBr and $\mathrm{Br}^{-}$will not form a buffer because HBr is a strong acid and the $\mathrm{Br}^{-}$ion is merely a spectator ion. page $767(\mathbf{a})$ The $\mathrm{OH}^{-}$of NaOH (a strong base) reacts with the acid member of the buffer $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ abstracting a proton. Thus, $\mathrm{H}_{2} \mathrm{CO}_{3}$ decreases and $\mathrm{HCO}_{3}^{-}$increases. (b) The $\mathrm{H}^{+}$ of $\mathrm{HNO}_{3}$ (a strong acid) reacts with the base member of the buffer $\left(\mathrm{HCO}_{3}^{-}\right)$. Thus, $\mathrm{HCO}_{3}^{-}$decreases and $\mathrm{H}_{2} \mathrm{CO}_{3}$ increases. page 770 $\mathrm{H}_{2} \mathrm{CO}_{3}$ would be more suitable for a pH $=7.0$ buffer solution. To make a buffer we would also need a salt containing $\mathrm{HCO}_{3}^{-}$, such as $\mathrm{NaHCO}_{3}$. page $776 \mathrm{The} \mathrm{pH}=7$. The neutralization of a strong base with a strong acid gives a salt solution at the equivalence point. The salt contains ions that do not change the pH of water. page $\mathbf{7 8 0}$ The conjugate base of the weak acid is the majority species in solution at the equivalence point, and this conjugate base reacts with water in a $K_{b}$ reaction to produce $\mathrm{OH}^{-}$. Therefore, the pH at the equivalence point for a weak acid/strong base titration is greater than 7.00. page 783 The

above titration curve shows the titration of 25 mL of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ with HCl , both with 0.1 M concentrations. The overall reaction between the two is

$$
\mathrm{Na}_{2} \mathrm{CO}_{3}(a q)+\mathrm{HCl}(a q) \longrightarrow 2 \mathrm{NaCl}(a q)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

The initial ( pH sodium carbonate in water only) is near 11 because $\mathrm{CO}_{3}{ }^{2-}$ is a weak base in water. The graph shows two equivalence points, $\mathbf{A}$ and $\mathbf{B}$. The first point, $\mathbf{A}$, is reached at a pH of about 9 :

$$
\mathrm{Na}_{2} \mathrm{CO}_{3}(a q)+\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{NaHCO}_{3}(a q)
$$

$\mathrm{HCO}_{3}^{-}$is weakly basic in water and is a weaker base than the carbonate ion. The second point, $\mathbf{B}$, is reached at a pH of about 4:

$$
\mathrm{NaHCO}_{3}(a q)+\mathrm{HCl}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

$\mathrm{H}_{2} \mathrm{CO}_{3}$, a weak acid, forms and decomposes to carbon dioxide and water. page $\mathbf{7 8 5} \mathrm{PbSO}_{4}$. Because all three compounds produce the same number of ions, their relative solubilities correspond directly to the $K_{s p}$ values, with the compound with the largest $K_{s p}$ value being the most soluble. page 799 Lead, because $\mathrm{PbBr}_{2}$ is relatively insoluble.

## Chapter 18

page 813 We would expect that helium is relatively more abundant at the higher elevation, because Earth's gravitational field would exert a greater downward force on the heavier argon atoms. As a result the helium to argon ratio would be higher in the mesosphere than in the troposphere. page 816 Photoionization causes an electron to be ejected from an atom or molecule leading to the formation of a cation. It does not generally result in the breaking of a bond. page 818 From their Lewis structures we predict bond orders of 2 and 1.5 for $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$, respectively. Bond strength increases with increasing bond order so we would expect stronger $\mathrm{O}-\mathrm{O}$ bonds in $\mathrm{O}_{2}$. page $819 \mathrm{Yes} ; \mathrm{Cl}$ is neither a product nor a reactant in the overall reaction, and its presence does speed the reaction up. page 823 $\mathrm{SO}_{3}$ page $824 \mathrm{NO}_{2}$ photodissociates to NO and O ; the O atoms react with $\mathrm{O}_{2}$ in the atmosphere to form ozone, which is a key ingredient in photochemical smog. page 827 Higher humidity means there is more water in the air. Water absorbs infrared light, which we feel as heat. After sundown, the ground that has been warmed earlier in the day reradiates heat out. In locations with higher humidity, this energy is absorbed somewhat by the water and in turn is reradiated to some extent back to the Earth, resulting in warmer temperatures compared to a low-humidity location. page 828 You can see from the phase diagram that to pass from the solid to the gaseous state we need to be below water's critical point. Therefore, to sublime water we need to be below 608 Pa . A wide range of temperatures will work for sublimation at this pressure-the most environmentally relevant ones are $-50^{\circ} \mathrm{C}$ to $0^{\circ} \mathrm{C}$. page 832 Nitrogen and phosphorous. page 837 With a catalyst, the reaction is always faster, therefore costing less energy to run. In addition, with a catalyst the reaction may occur readily at a lower temperature, also costing less energy. page 839 Because the by-products of the reaction can be used to synthesize additional reactants in principle no atoms are wasted. page $840 s p$ before reaction; $s p^{2}$ after reaction.

## Chapter 19

page 854 No. Just because the system is restored to its original condition doesn't mean that the surroundings have likewise been restored to their original condition, so it is not necessarily reversible. page $856 \Delta S$ depends not merely on $q$ but on $q_{\text {rev }}$. Although there are many possible paths that could take a system from its initial to final state, there is always only one reversible isothermal path between two states. Thus, $\Delta S$ has only one particular value regardless of the path taken between states. page 859 Because the formation of sodium chloride is a spontaneous process, $\Delta S_{\text {univ }}$ must be positive. Therefore, the entropy of the surroundings must increase, and that increase must be larger than the entropy decrease of the system. page $861 S=0$, based on Equation 19.5 and the fact that $\ln 1=0$. page 862 No. Argon atoms are not attached to other atoms, so they cannot undergo vibrational motion. page $869 \Delta S_{\text {surr }}$ always increases. For simplicity, assume that the process is isothermal.

The change in entropy of the surroundings in an isothermal process is $\Delta S_{\text {surr }}=\frac{-q_{\text {sys }}}{T}$. Because the reaction is exothermic, $-q_{\text {sys }}$ is a positive number. Thus, $\Delta S_{\text {surr }}$ is a positive number and the entropy of the surroundings increases. page 870 (a) In any spontaneous process the entropy of the universe increases. (b) In any spontaneous process operating at constant temperature, the free energy of the system decreases. page 872 It indicates that the process to which the thermodynamic quantity refers has taken place under standard conditions, as summarized in Table 19.2. page 875 Below the boiling point, vaporization is non-spontaneous, and $\Delta G>0$. Therefore, $\Delta H-T \Delta S>0$, and $\Delta H>T \Delta S$. Therefore $\Delta H$ is greater in magnitude. page 878 No. $K$ is the ratio of product concentration to reactant concentration at equilibrium; $K$ could be very small but is not zero.

## Chapter 20

page 895 Oxygen is first assigned an oxidation number of -2 . Chlorine must then have a +7 oxidation number for the sum of oxidation numbers to equal -1 , the charge of the ion. page 898 No. Electrons should appear in the two half-reactions but cancel when the half-reactions are added properly. page 905 No . A redox reaction with a negative standard cell potential is non-spontaneous under standard conditions. page 906101.3 kPa pressure of $\mathrm{O}_{2}(\mathrm{~g})$, 1 M concentration of $\mathrm{H}^{+}(\mathrm{aq})$ and pure liquid (at 101.3 kPa pressure) of $\mathrm{H}_{2} \mathrm{O}(l)$; temperature 298.15 K . page 909 Ni page $913 \mathrm{Sn}^{2+}$ page $928 \mathrm{Al}, \mathrm{Zn}$. Both are easier to oxidize than Fe.

## Chapter 21

page $\mathbf{9 4 7}$ The mass number decreases by 4. page 949 Beta decay page 953 From Figure 21.3 we can see that each of these four elements has only one stable isotope, and from their atomic numbers we see that they each have an odd number of protons. Given the rarity of stable isotopes with odd numbers of neutrons and protons, we expect that each isotope will possess an even number of neutrons. From their atomic weights we see that this is the case: Mn ( 30 neutrons), Co ( 32 neutrons), Rh ( 58 neutrons), and I (74 neutrons). page 959 It doubles as well. The number of disintegrations per second is proportional to the number of atoms or the radioactive isotope. page 962 Any process that depends on the mass of the molecule, such as the rate of gaseous effusion (Section 10.8) page 965 The values in Table 21.7 only reflect the mass of the nucleus, while the atomic mass is the sum of the mass of the nucleus and the electrons. So the atomic mass of iron-56 is $26 \times m_{e}$ larger than the nuclear mass. page 966 No. Stable nuclei having mass numbers around 100 are the most stable nuclei. They could not form a still more stable nucleus with an accompanying release of energy. page 975 The absorbed dose is equal to $0.010 \mathrm{~J} \times\left(1 \mathrm{rad} / 1 \times 10^{-2} \mathrm{~J}\right)=1 \mathrm{rad}$. The effective dosage is calculated by multiplying the absorbed dose by the relative biological effectiveness (RBE) factor, which is 10 for alpha radiation. Thus, the effective dosage is 10 rems.

## Chapter 22

page 989 No. There is a double bond between the C atom and each O atom. Si rarely forms double bonds as it would have to in order to form $\mathrm{SiO}_{2}(\mathrm{~g})$. Instead Si forms 4 single bonds with the O atoms; $\mathrm{so}, \mathrm{SiO}_{2}$ is a solid with a giant covalent network. page $991 \mathrm{H}^{-}$, hydride.
page $992+1$ for everything except $\mathrm{H}_{2}$, for which the oxidation state of H is 0 . page 9980 for $\mathrm{Cl}_{2} ;-1$ for $\mathrm{Cl}^{-} ;+1$ for $\mathrm{ClO}^{-}$page 999 They should both be strong, since both iodine and nitrogen are in the +5 oxidation state. We need to look up the redox potentials to see which ion, $\mathrm{IO}_{3}^{-}$or $\mathrm{NO}_{3}^{-}$, has the larger reduction potential. The ion with the larger reduction potential is the stronger oxidizing agent. $\mathrm{IO}_{3}^{-}$is the stronger oxidizing agent on this basis $(+1.20 \mathrm{~V}$ standard
reduction potential in acid compared to +0.96 V for $\mathrm{NO}_{3}^{-}$).
page $1001 \mathrm{HClO}_{3}$ page $1004 \mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(l)$ page $1009(\mathbf{a})+3(\mathbf{b})+5$ page 1011 In $\mathrm{PF}_{3}$, phosphorus in the +3 oxidation state. The reaction with water produces the oxyacid with phosphorus in that oxidation state, $\mathrm{H}_{3} \mathrm{PO}_{3}$. Thus, the reaction is analogous to Equation 22.48, which also shows a trihalide reacting with water. page 1015 Fermentation; glucose is converted into ethanol and carbon dioxide. page 1020 Silicon is the element, Si. Silica is $\mathrm{SiO}_{2}$. Silicones are polymers that have an $\mathrm{O}-\mathrm{Si}-\mathrm{O}$ backbone and hydrocarbon groups on the Si. page $1020+3$

## Chapter 23

page 1033 Ti has the largest radius. page 1035 Because titanium only has 4 valence electrons you would have to remove a core electron to create a $\mathrm{Ti}^{5+}$ ion. page 1036 The larger the distance, the weaker the spin-spin interactions. page 1037 Yes, it is a Lewis acid-base interaction; the metal ion is the Lewis acid (electron pair acceptor). page 1043 The nonbonding electron pairs in $\mathrm{H}_{2} \mathrm{O}$ are both located on the same atom, which makes it impossible for both pairs to be donated to the same metal atom. To act as a chelating agent the nonbonding electron pairs need to be on different atoms that are not connected to each other. page 1043 Bidentate. page 1050 No, ammonia cannot engage in linkage isomerism-the only atom that can coordinate to a metal is the nitrogen. page 1050 No, a trigonal planar molecule cannot exhibit geometrical isomerism. page 1053 (b) The way polarized light is rotated on passing through the substance. page 1055 (a) Co is $[\mathrm{Ar}] 4 s^{2} 3 d^{7}$. (b) $\mathrm{Co}^{3+}$ is $[\mathrm{Ar}] 3 d^{6}$. The Co atom has 3 unpaired electrons and the $\mathrm{Co}^{3+}$ ion has 4 unpaired electrons, assuming all five d orbitals have the same energy. page 1057 Because Ti(IV) ions have an $[\mathrm{Ar}] 3 d^{0}$ electron configuration there are no $d-d$ transitions that can absorb photons of visible light. page 1060 $d^{1}, d^{2}, d^{3}, d^{8}, d^{9}$ page 1062 Because the ligands are located in the $x y$ plane, electrons in a $d_{x y}$ orbital, which has its lobes in the $x y$ plane, feel more repulsion than electrons in the $d_{x z}$ and $d_{y z}$ orbitals.

## Chapter 24

page $1077 \mathrm{C}=\mathrm{O}$, because it is a polar double bond. $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{C}$ bonds are relatively unreactive. (The CO double bond does not have to fully break to be reactive.) page 1079 Four $\mathrm{C}-\mathrm{H}$ bonds and one $\mathrm{C}=\mathrm{C}$ bond page 1080 The isomers have different properties, as seen in Table 24.3 (e.g., different melting points and different boiling points). page 1083 Yes, since cyclopropane is more strained. page 1085 Only two of the four possible $\mathrm{C}=\mathrm{C}$ bond sites are distinctly different in the linear chain of five carbon atoms with one double bond. page 1091

page $1096\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}_{\mathrm{O}}$ page 1097 The generic formula of an ether is ROR', while an ester is RCOOR'. If you carbonylate or oxidize an ether, you can get an ester. page 1101 All four groups must be different from one another. page 1104 Yes. Breaking the hydrogen bonds within a protein by heating does not cause the amino acid sequence to change because the amino acids are held together by strong amide bonds. page 1109 Dietary fiber comes from plant materials, such as cellulose, which is resistant to enzymatic digestion. Therefore, our body cannot metabolize dietary fiber to produce calories.

## ANSWERS TO GO FIGURE

## Chapter 1

Figure 1.1 Aspirin. It contains 9 carbon atoms. Figure 1.4 Vapor (gas) Figure 1.5 Molecules of a compound are composed of more than one type of atom, and molecules of an element are composed of only one type of atom. Figure 1.6 It would get larger because hydrogen atoms are lighter than the atoms of any other element. Figure 1.7 (c) Each water molecule contains one oxygen atom and two hydrogen atoms. Figure 1.14 The separations are due to physical processes of adsorption of the materials onto the column Figure 1.19 True Figure 1.20 1000 Figure 1.24 The darts would be scattered widely (poor precision) but their average position would be at the center (good accuracy).

## Chapter 2

Figure 2.3 Cathode rays would still be generated but without the fluorescent screen you would not be able to see them.
Figure 2.4 The electron beam would be deflected downward because of repulsion by the upper negative plate and attraction toward the positive plate. Figure 2.5 No, the electrons are of negligible mass compared with an oil drop. Figure 2.7 Beta rays are equivalent to electrons. (a) They are lighter. Figure 2.9 The beam consists of alpha particles, which carry a +2 charge. They are repelled from the positively charged gold nuclei. Figure $2.1010^{-2}$ pm Figure 2.13 Based on the periodic trend, we expect that elements that precede a nonreactive gas, as F does, will also be reactive nonmetals. The elements fitting this pattern are H and Cl .
Figure 2.16 All of the metals shown here are solids, that exhibit varying degrees of luster to their appearance. In contrast, bromine is a liquid and none of the nonmetals shown here are lustrous.
Figure 2.18 The ball-and-stick model. Figure 2.19 The elements are in the following groups: $\mathrm{Ag}^{+}$is $11, \mathrm{Zn}^{2+}$ is 12 , and $\mathrm{Sc}^{3+}$ is 3 . Only $\mathrm{Sc}^{3+}$ has the same number of electrons as a noble gas, Ar (element
18). Figure 2.20 No it is not, ionic solids like NaCl do not contain discrete molecules. Figure 2.23 Removing one $O$ atom from the perbromate ion gives the bromate ion, $\mathrm{BrO}_{3}{ }^{-}$.

## Chapter 3

Figure 3.4 There are two $\mathrm{CH}_{4}$ and four $\mathrm{O}_{2}$ molecules on the reactant side, which contain 2 C atoms, 8 H atoms and 8 O atoms. The number of each type of atom remains the same on the product side as it must. Figure 3.8 The flame gives off heat and therefore the reaction must release heat. Figure 3.9 Avogadro's number Figure $3.12 \mathrm{~g} / \mathrm{mol}^{2}$ and $\mathrm{mol}^{-1}$ Figure 3.17 If the amount of $\mathrm{H}_{2}$ is doubled then $\mathrm{O}_{2}$ becomes the limiting reactant. In that case $\left(7 \mathrm{~mol} \mathrm{O}_{2}\right) \times\left(2 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O} / 1 \mathrm{~mol} \mathrm{O}_{2}\right)=14 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}$ would be produced.

## Chapter 4

Figure 4.3 $\mathrm{NaCl}($ aq $)$ Figure $4.4 \mathrm{~K}^{+}$and $\mathrm{NO}_{3}{ }^{-}$Figure 4.9 Mg $\left(\mathrm{NO}_{3}\right)_{2}$ and water Figure 4.12 Two. Each O atom becomes an $\mathrm{O}^{2-}$ ion. Figure 4.13 One, based on the reaction stoichiometry.
Figure 4.14 Because the $\mathrm{Cu}(\mathrm{II})$ ion produces a blue color in aqueous solution. Figure 4.18 The volume needed to reach the end point if $\mathrm{Ba}(\mathrm{OH})_{2}(\mathrm{aq})$ were used would be one-half the volume needed for titration with $\mathrm{NaOH}(\mathrm{aq})$, because there are two hydroxide ions for every barium ion.

## Chapter 5

Figure 5.2 The electrostatic potential energy of two oppositely charged particles is negative (Equation 5.2). As the particles become closer, the electrostatic potential energy becomes even more negative-that is, it decreases. Figure 5.3 Attractions between oppositely charged ions would cause the ions to move closer together reducing the potential energy of the system. The lost potential energy is converted to kinetic energy needed to move the ions. Figure 5.4 The number of molecules will change because three reactant molecules ( $2 \mathrm{H}_{2}$ and $1 \mathrm{O}_{2}$ ) are needed to make two product $\left(\mathrm{H}_{2} \mathrm{O}\right)$ molecules. However, in a closed system like this one the total mass will not change. Figure 5.5 If $E_{\text {final }}=E_{\text {initial }}$, then $\Delta E=0 . \quad$ Figure 5.6

Figure 5.7 $\Delta E=50 \mathrm{~J}+(-85 \mathrm{~J})=-35 \mathrm{~J} \quad$ Figure 5.10 The battery is doing work on the surroundings, so $w<0$. Figure 5.11 The system does work on the surroundings to move the piston upward, so $w<0$. Figure 5.17 Endothermic-heat is being added to the system to raise the temperature of the water. Figure $\mathbf{5 . 1 8}$ Two cups provide more thermal insulation so less heat will escape the system. Figure 5.19 In a calorimeter the system is defined as the reactants and products, so the water inside the calorimeter is part of the surroundings. Figure 5.21 The condensation of $2 \mathrm{H}_{2} \mathrm{O}(g)$ to $2 \mathrm{H}_{2} \mathrm{O}(l)$ Figure 5.22 Yes, $\Delta H_{3}$ would remain the same as it is the enthalpy change for the process $\mathrm{CO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)$. Figure 5.24 Exothermic, because the enthalpy of the products is lower than that of the reactants. Figure 5.25 Grams of fat

## Chapter 6

Figure 6.3 Wavelength $=1.0 \mathrm{~m}$, frequency $=3.0 \times 10^{8} \mathrm{cycles} / \mathrm{s}$. Figure 6.4 Longer by 3 to 5 orders of magnitude (depending on what part of the microwave spectrum is considered). Figure 6.5 The part of the nail glowing yellow is hotter than the part glowing red. Figure 6.7 As the frequency of the incoming light is increased the photon energy will increase and the kinetic energy of the ejected electrons will increase. Figure 6.12 The $n=2$ to $n=1$ transition involves a larger energy change than the $n=3$ to $n=2$ transition. (Compare the lengths of the arrows connecting the states in the figure.) If the $n=3$ to $n=2$ transition produces visible light, the $n=2$ to $n=1$ transition must produce radiation of greater energy. Of the two choices only ultraviolet radiation has higher frequency and greater energy than visible light. Figure 6.13 The $n=4$ to $n=3$ transition involves a smaller energy difference and will therefore emit light of longer wavelength. Figure 6.17 The region of highest electron density is where the density of dots
is highest, which is near the nucleus. Figure 6.18 For a single electron atom like hydrogen the energies of the orbitals are the same as the energies of the orbits in the Bohr model. Figure 6.19 There would be four maxima and three nodes. Figure 6.23 The $p_{x}$ orbital. Figure 6.24 There are two nodal planes for each of the $d$-orbitals. For the $d_{x y}$ orbital the nodal planes are the $x z$ and $y z$ planes. Figure 6.25 The $4 d$ and $4 f$ subshells are not shown.
Figure 6.31 Osmium

## Chapter 7

Figure 7.1 These three metals do not readily react with other elements, especially oxygen, so they are often found in nature in the elemental form as metals (such as gold nuggets) Figure 7.4 Because of the peak near the nucleus in the $2 s$ curve there is a higher probability of finding a $2 s$ within 50 pm of the nucleus. In a multielectron atom an electron in a $2 s$ orbital will have a lower energy than one in a $2 p$ orbital. Figure 7.7 Bottom and left Figure 7.8 They get larger, just like the atoms do. Figure $7.10900 \mathrm{~kJ} / \mathrm{mol}$
Figure 7.11 There is more electron-electron repulsion in the case of oxygen because two electrons have to occupy the same orbital.
Figure 7.12 The added electron for the Group 14 elements leads to a half-filled $n p^{3}$ configuration. For the Group 15 elements, the added electron leads to an $n p^{4}$ configuration, so the electron must be added to an orbital that already has one electron in it, and thus experiences more electron-electron repulsion. Figure 7.13 They are opposite: As ionization energy increases, metallic character decreases, and vice versa. Figure 7.15 Anions are above and to the right of the line; cations are below and to the left of the line. Figure 7.16 No. The $\mathrm{Na}^{+}$and $\mathrm{NO}_{3}^{-}$ions will simply be spectator ions. The $\mathrm{H}^{+}$ions of an acid are needed in order to dissolve NiO. Figure 7.17 No. As seen in the photo, sulfur crumbles as it is hit with a hammer, typical of a solid nonmetal. Figure 7.21 Because Rb is below K in the periodic table, and has a lower first ionization energy we expect Rb to be more reactive with water than K. Figure 7.23 Lilac (see Figure 7.22). Figure 7.25 The bubbles are due to $\mathrm{H}_{2}(g)$. This could be confirmed by carefully testing the bubbles with a flamethere should be popping as the hydrogen gas ignites. Figure 7.26 Yes, because water does not decompose on sitting the way that hydrogen peroxide does. Figure 7.27 A regular octagon.
Figure $7.28 \mathrm{I}_{2}$ is a solid whereas $\mathrm{Cl}_{2}$ is a gas. Molecules are more closely packed together in a solid than they are in a gas, as will be discussed in detail in Chapter 11.

## Chapter 8

Figure 8.1 We would draw the chemical structure of sugar molecules (which have no charges and have covalent bonding between atoms in each molecule) and indicate weak intermolecular forces (especially hydrogen bonding) between sugar molecules.
Figure 8.3 Yes. Figure 8.4 Cations have a smaller radius than their neutral atoms and anions have a larger radius. Because Na and Cl are in the same row of the periodic table, we would expect $\mathrm{Na}^{+}$ to have a smaller radius than $\mathrm{Cl}^{-}$, so we would infer that the larger green spheres represent the chloride ions and the smaller purple spheres represent the sodium ions. Figure 8.5 The distance between ions in KF should be larger than that in NaF and smaller than that in KCl . We would thus expect the lattice energy of KF to be between 701 and $910 \mathrm{~kJ} / \mathrm{mol}$. Figure 8.7 The repulsions between the nuclei would decrease, the attractions between the nuclei and the electrons would decrease, and the repulsions between the electrons would be unaffected. Figure 8.8 The electronegativity decreases with increasing atomic number. Figure $8.10 \mu$ will decrease. Figure 8.11 The bonds are not polar enough to cause enough excess electron density on the halogen atom to lead to a
red shading. Figure 8.13 The lengths of the bonds of the outer O atoms to the inner O atom are the same. Figure 8.14 Yes. The electron densities on the left and right parts of the molecule are the same, indicating that resonance has made the two $\mathrm{O}-\mathrm{O}$ bonds equivalent to one another. Figure 8.15 The dashed bonds represent the delocalized electrons that result when the two resonance structures are averaged. Figure 8.16 It should be halfway between the values for single and double bonds, which we can estimate to be about $280 \mathrm{~kJ} / \mathrm{mol}$ from the graph.

## Chapter 9

Figure 9.1 The radii of the atoms involved (see Section 7.3).
Figure 9.2 $\mathrm{NF}_{3}$ Figure 9.3 Octahedral. Figure 9.4 No. We will get the same bent-shaped geometry regardless of which two atoms we remove. Figure $9.890^{\circ}$. Figure 9.9 The $\mathrm{C}-\mathrm{O}-\mathrm{H}$ bond involving the right O because of the greater repulsions due to the nonbonding electron domains. The angle should be less than the ideal value of $109.5^{\circ}$. Figure 9.10 Zero. Because they are equal in magnitude but opposite in sign, the vectors cancel upon addition. Figure 9.1374 pm is the bond length, $436 \mathrm{~kJ} /$ mol is the bond strength. Figure $9.16120^{\circ}$ Figure 9.17 The $p_{z}$ orbital. Figure 9.18 No. All four hybrids are equivalent and the angles between them are all the same, so we can use any of the two to hold the nonbonding pairs. Figure 9.19 Because the P $3 p$ orbitals are larger than the $\mathrm{N} 2 p$ orbitals, we would expect somewhat larger lobes on the hybrid orbitals in the right-most drawing. Other than that, the molecules are entirely analogous. Figure 9.22 They have to lie in the same plane in order to allow the overlap of the $\pi$ orbitals to be effective in forming the $\pi$ bond. Figure 9.23 Acetylene should have the higher carbon-carbon bond energy because it has a triple bond as compared to the double bond in ethylene. Figure 9.25 It has six $\mathrm{C}-\mathrm{C} \sigma$ and $\operatorname{six} \mathrm{C}-\mathrm{H} \sigma$ bonds. Figure 9.31 Zero. A node, by definition, is the place where the value of the wave function is zero. Figure 9.32 The energy of $\sigma_{1 s}$ would rise (but would still be below the energy of the H $1 s$ atomic orbitals). Figure $9.34 \sigma_{1 s}{ }^{2}, \sigma_{1 s}^{*}{ }^{1}$. Figure $9.35 \sigma_{1 s}^{*}$ and $\sigma_{2 s}^{*}$. Figure 9.36 The end-on overlap in the $\sigma_{2 p} \mathrm{MO}$ is greater than the sideways overlap in the $\pi_{2 p}$. Figure 9.42 The $\sigma_{2 p}$ and $\pi_{2 p}$ MOs have switched order. Figure $9.43 \mathrm{O}_{2}$ and $\mathrm{F}_{2}$ Figure $9.45 \mathrm{~N}_{2}$ is diamagnetic so it would not be attracted to the magnetic field. The liquid nitrogen would simply pour through the poles of the magnet without "sticking." Figure 9.46 11. All the electrons in the $n=2$ level are valenceshell electrons.

## Chapter 10

Figure 10.2 It will increase. Figure 10.4 Decreases Figure 10.5 1520 torr or 2 atm Figure 10.8 One Figure 10.9 Chlorine, $\mathrm{Cl}_{2}$. Figure 10.12 About one-sixth Figure $10.13 \mathrm{O}_{2}$ has the largest molar mass, $32 \mathrm{~g} / \mathrm{mol}$, and $\mathrm{H}_{2}$ has the smallest, $2.0 \mathrm{~g} / \mathrm{mol}$.
Figure $10.15 n$, moles of gas Figure 10.19 True Figure 10.21 It would increase.

## Chapter 11

Figure 11.2 The density in a liquid is much closer to a solid than it is to a gas. Figure 11.3 The distance within the molecule (the covalent bond distance) represented by the solid black line is smaller than the intermolecular distance represented by the red dotted line. Figure 11.5 The halogens are diatomic molecules and have much greater size and mass, and therefore greater polarizability, than the noble gases, which are monatomic. Figure 11.8 They stay roughly the same because the molecules have roughly the
same molecular weights. Thus, the change in boiling point moving left to right is due mainly to the increasing dipole-dipole attractions. Figure 11.9 Both compounds are nonpolar and incapable of forming hydrogen bonds. Therefore, the boiling point is determined by the dispersion forces, which are stronger for the larger, heavier $\mathrm{AsH}_{3}$. Figure 11.10 The non-hydrogen atom must possess a nonbonding electron pair. Figure 11.11 There are four electron pairs surrounding oxygen in a water molecule. Two of the electron pairs are used to make covalent bonds to hydrogen within the $\mathrm{H}_{2} \mathrm{O}$ molecule, while the other two are available to make hydrogen bonds to neighboring molecules. Because the electron-pair geometry is tetrahedral (four electron domains around the central atom), the $\mathrm{H}-\mathrm{O} \cdots \mathrm{H}$ bond angle is approximately $109^{\circ}$. Figure 11.13 The O atom is the negative end of the polar $\mathrm{H}_{2} \mathrm{O}$ molecule; the negative end of the dipole is attracted to the positive ion. Figure 11.14 Yes, although not likely. Figure 11.19 Wax is a hydrocarbon that cannot form hydrogen bonds. Therefore, coating the inside of tube with wax will dramatically decrease the adhesive forces between water and the tube and change the shape of the water meniscus to an inverted U-shape. Neither wax nor glass can form metallic bonds with mercury so the shape of the mercury meniscus will be qualitatively the same, an inverted U-shape. Figure 11.20 Because energy is a state function, the energy to convert a gas to a solid is the same regardless of whether the process occurs in one or two steps. Thus, the energy of deposition equals the energy of condensation plus the energy of freezing. Figure 11.21 Because water has stronger intermolecular interactions. Figure 11.22 The temperature of the liquid water is increasing. Figure 11.24 Increases, because the molecules have more kinetic energy as the temperature increases and can escape more easily Figure 11.25 All liquids including ethylene glycol reach their normal boiling point when their vapor pressure is equal to atmospheric pressure, 101.3 kPa . Figure 11.27 It must be lower than the temperature at the triple point.

## Chapter 12

Figure 12.5 There is not a centered square lattice, because if you tile squares and put lattice points on the corners and the center of each square it would be possible to draw a smaller square (rotated by $45^{\circ}$ ) that only has lattice points on the corners. Hence a "centered square lattice" would be indistinguishable from a primitive square lattice with a smaller unit cell. Figure 12.12 Face-centered cubic, assuming similar size spheres and cell edge lengths, since there are more atoms per volume for this unit cell compared to the other two. Figure 12.13 A hexagonal lattice Figure 12.15 The solvent is the majority component and the solute the minority component. Therefore, there will be more solvent atoms than solute atoms.
Figure 12.17 The samarium atoms sit on the corners of the unit cell so there is only $8 \times(1 / 8)=1 \mathrm{Sm}$ atom per unit cell. Eight of the nine cobalt atoms sit on faces of the unit cell, and the other sits in the middle of the unit cell so there are $8 \times(1 / 2)+1=5 \mathrm{Co}$ atoms per unit cell. Figure $12.19 \mathrm{P}_{4}, \mathrm{~S}_{8}$, and $\mathrm{Cl}_{2}$ are all molecules, because they have strong chemical bonds between atoms and have well-defined numbers of atoms per molecule. Figure 12.21 In the fourth period, vanadium and chromium have very similar melting points. Molybdenum and tungsten have the highest melting points in the fifth and sixth periods, respectively. All of these elements are located near the middle of the period where the bonding orbitals are mostly filled and the antibonding orbitals mostly empty.
Figure 12.22 The molecular orbitals become more closely spaced in energy. Figure 12.23 Potassium has only one valence electron per atom $\left(4 s^{1}\right)$. Therefore we expect the $4 s$ band to be approximately half full. If we fill the $4 s$ band halfway a small amount of electron
density might leak over and start to fill the $3 d$ orbitals as well. The $4 p$ orbitals should be empty. Figure 12.24 Ionic substances cleave because the nearest neighbor interactions switch from attractive to repulsive if the atoms slide so that ions of like charge (cation-cation and anion-anion) touch each other. Metals don't cleave because the atoms are attracted to all other atoms in the crystal through metallic bonding. Figure 12.25 No, ions of like charge do not touch in an ionic compound because they are repelled from one another. In an ionic compound the cations touch the anions. Figure 12.27 In NaF there are four $\mathrm{Na}^{+}$ions $(12 \times 1 / 4)$ and four $\mathrm{F}^{-}$ions $(8 \times 1 / 8+6 \times 1 / 2)$ per unit cell. In $\mathrm{MgF}_{2}$ there are two $\mathrm{Mg}^{2+}$ ions $(8 \times 1 / 8+1)$ and four $\mathrm{F}^{-}$ions $(4 \times 1 / 2+2)$ per unit cell. In $\mathrm{ScF}_{3}$ there is one $\mathrm{Sc}^{3+}$ ion $(8 \times 1 / 8)$ and three $\mathrm{F}^{-}$ions $(12 \times 1 / 4)$ per unit cell. Figure 12.28 The intermolecular forces are stronger in toluene, as shown by its higher boiling point. The molecules pack more efficiently in benzene, which explains its higher melting point, even though the intermolecular forces are weaker.
Figure 12.30 The band gap for an insulator would be larger than the one for a semiconductor. Figure 12.31 If you doubled the amount of doping in panel (b), the amount of blue shading the conduction band would also double. Figure 12.45 Decrease. As the quantum dots get smaller, the band gap increases and the emitted light shifts to shorter wavelength. Figure 12.49 Each carbon atom in $\mathrm{C}_{60}$ is bonded to three neighboring carbon atoms through covalent bonds. Thus, the bonding is more like graphite, where carbon atoms also bond to three neighbors, than diamond, where carbon atoms bond to four neighbors.

## Chapter 13

Figure 13.1 Gas molecules move in constant random motion. Figure 13.2 Opposite charges attract. The electronrich O atom of the $\mathrm{H}_{2} \mathrm{O}$ molecule, which is the negative end of the dipole, is attracted to the positive $\mathrm{Na}^{+}$ion. Figure 13.4 For exothermic solution processes the magnitude of $\Delta H_{m i x}$ will be larger than the magnitude of $\Delta H_{\text {solute }}+\Delta H_{\text {solvent }}$ Figure 13.746 g .
Figure 13.12 If the partial pressure of a gas over a solution is doubled, the concentration of gas in the solution would double.
Figure 13.13 The highest. Figure 13.15 Looking at where the solubility curves for KCl and NaCl intersect the $80^{\circ} \mathrm{C}$ line, we see that the solubility of KCl is about $51 \mathrm{~g} / 100 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$, whereas NaCl has a solubility of about $39 \mathrm{~g} / 100 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. Thus, KCl is more soluble than NaCl at this temperature. Figure $13.16 \mathrm{~N}_{2}$ has the same molecular weight as CO but is nonpolar, so we can predict that its curve will be just below that of CO. Figure 13.22 The water will move through the semipermeable membrane toward the more concentrated solution. Thus, the liquid level in the left arm will increase. Figure 13.23 Water will move toward the more concentrated solute solution, which is inside the red blood cells, causing them to undergo hemolysis. Figure 13.26 The negatively charged groups both have the composition $-\mathrm{CO}_{2}^{-}$. Figure 13.28 Recall the rule that likes dissolve likes. The oil drop is composed of nonpolar molecules, which interact with the nonpolar part of the stearate ion via dispersion forces.

## Chapter 14

Figure 14.1 No. The surface area of a steel nail is much smaller than that for the same mass of steel wool, so the reaction with $\mathrm{O}_{2}$ would not be as vigorous. Depending on how hot it is, it might not burn at all. Figure 14.2 Our first guess might be half way between the values at 20 s and 40 s , namely 0.42 mol A . However, we also see that the change in the number of moles of $A$ between 0 s and 20 s is
greater than that between 20 s and 40 s -in other words, the rate of conversion gets smaller as the amount of A decreases. So we would guess that the change from 20 s to 30 s is greater than the change from 30 s to 40 s , and we would estimate that the number of moles of $A$ is between 0.42 and 0.30 mol . Figure 14.3 The instantaneous rate decreases as the reaction proceeds. Figure 14.7 The reaction is first order. Figure 14.9 At the beginning of the reaction when both plots are linear or nearly so. Figure $\mathbf{1 4 . 1 3}$ No, it will not turn down. The rate constant increases monotonically with increasing temperature because the kinetic energy of the colliding molecules continues to increase. Figure 14.15 The difference in height between the ball and the top of the barrier. Figure 14.16 As shown, the magnitude of energy needed to overcome the energy barrier is greater than the magnitude of the energy change in the reaction. Figure 14.17 It would be more spread out, the maximum of the curve would be lower and to the right of the maximum of the red curve, and a greater fraction of molecules would have kinetic energy greater than $E_{\mathrm{a}}$ than for the red curve. Figure 14.19 The rate of converting intermediates to products will be faster, because this reaction has a lower barrier than the reaction that converts intermediates back to reactants. Figure 14.20 No, because the bottleneck, or rate determining step, is passing through toll plaza A. Figure 14.21 The color is characteristic of molecular bromine, $\mathrm{Br}_{2}$, which is an intermediate in this reaction. Figure 14.22 There is one valley corresponding to the formation of intermediates, so the reaction has a total of two steps. Figure 14.25 Grinding increases the surface area, exposing more of the catalase to react with the hydrogen peroxide. Figure 14.26 Substrates must be held more tightly so that they can undergo the desired reaction. Products are released from the active site.

## Chapter 15

Figure 15.2 The same because once the system reaches equilibrium the concentrations of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ stop changing.
Figure 15.3 Because the concentration of reactants is decreasing, which reduces the frequency of collisions and hence the rate of the forward reaction. Figure 15.4 Yes. The reaction stoichiometry dictates that $\mathrm{H}_{2}$ disappears at three times the rate that $\mathrm{N}_{2}$ disappears. Figure 15.6 Experiment 4 Figure 15.7 The boxes would be approximately the same size. Figure 15.8 It would decrease. To reestablish equilibrium the concentration of $\mathrm{CO}_{2}(g)$ would need to return to its previous value. The only way to do that would be for more $\mathrm{CaCO}_{3}$ to decompose to produce enough $\mathrm{CO}_{2}(g)$ to replace what was lost. Figure 15.10 High pressure and low temperature, 500 atm and $400^{\circ} \mathrm{C}$ in this figure. Figure 15.11 Nitrogen must react with some of the added hydrogen to create ammonia and restore equilibrium. Figure 15.16 (a) the energy difference between the initial state and the transition state.
Figure 15.17 About $5 \times 10^{-4}$

## Chapter 16

Figure 16.2 Hydrogen bonds. Figure 16.4 $\mathrm{O}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{OH}^{-}(a q)$. Figure 16.5 Basic. The mixture of the two solutions will still have $\left[\mathrm{H}^{+}\right]<\left[\mathrm{OH}^{-}\right]$.
Figure 16.6 Lemon juice. It has a pH of about 2 whereas black coffee has a pH of about 5 . The lower the pH , the more acidic the solution. Figure 16.8 Phenolphthalein changes from colorless, for pH values less than 8 , to pink for pH values greater than 10. A pink color indicates $\mathrm{pH}>10$. Figure 16.9 Bromthymol blue would be most suitable because it changes pH over a range that brackets $\mathrm{pH}=7$. Methyl red is not sensitive to pH changes when $\mathrm{pH}>6$, while phe-
nolphthalein is not sensitive to pH changes when $\mathrm{pH}<8$, so neither changes color at $\mathrm{pH}=7$. Figure 16.12 Yes. The equilibrium of interest is $\mathrm{H}_{3} \mathrm{CCOOH} \rightleftharpoons \mathrm{H}^{+}+\mathrm{H}_{3} \mathrm{CCOO}^{-}$. If the percent dissociation remained constant as the acid concentration increased, the concentration of all three species would increase at the same rate. However, because there are two products and only one reactant, the product of the concentrations of products would increase faster than the concentration of the reactant. Because the equilibrium constant is constant, the percent dissociation decreases as the acid concentration increases. Figure 16.13 3. Figure 16.15 The nitrogen atom in hydroxylamine accepts a proton to form $\mathrm{NH}_{3} \mathrm{OH}^{+}$. As a general rule, nonbonding electron pairs on nitrogen atoms are more basic than nonbonding electron pairs on oxygen atoms.
Figure 16.17 The range of pH values is so large that we can't show the effects using a single indicator (see Figure 16.8). Figure 16.20 The HOY molecule on the left because it is a weak acid. Most of the HOY molecules remain undissociated.

## Chapter 17

Figure 17.6 The pH will increase upon addition of the base.
Figure 17.725 .00 mL . The number of moles of added base needed to reach the equivalence point remains the same. Therefore, by doubling the concentration of added base the volume needed to reach the equivalence point is halved. Figure 17.9 The volume of base needed to reach the equivalence point would not change because this quantity does not depend on the strength of the acid. However, the pH at the equivalence point, which is greater than 7 for a weak acid-strong base titration, would decrease to 7 because hydrochloric acid is a strong acid. Figure 17.11 The pH at the equivalence point increases (becomes more basic) as the acid becomes weaker. The volume of added base needed to reach the equivalence point remains unchanged. Figure 17.12 No; it would change color by pH 6 and miss pH 7. Figure $\mathbf{1 7 . 1 5} \mathrm{H}_{2} \mathrm{PO}_{3}^{-}$at first equivalence point, $\mathrm{HPO}_{3}{ }^{2-}$ at the second. Figure 17.22 Because the solution is basic. Figure 17.23 Yes. CuS would precipitate in step 2 on addition of $\mathrm{H}_{2} \mathrm{~S}$ to an acidic solution, while the $\mathrm{Zn}^{2+}$ ions remained in solution.

## Chapter 18

Figure 18.1 About 85 km , at the mesopause. Figure 18.3 The atmosphere absorbs a significant fraction of solar radiation. Figure 18.4 (c) UV Figure 18.5 The peak value is about $5 \times 10^{12}$ molecules per $\mathrm{cm}^{3}$. If we use Avogradro's number to convert molecules to moles, and the conversion factor of $1000 \mathrm{~cm}^{3}=1000 \mathrm{~mL}=1 \mathrm{~L}$, we find that the concentration of ozone at the peak is $8 \times 10^{-9} \mathrm{~mol} / \mathrm{L}$. Figure 18.8 The major sources of sulfur dioxide emission are located in the eastern half of the United States, and prevailing winds carry emissions in an eastward direction. Figure $18.10 \mathrm{CaSO}_{3}(s)$ Figure 18.12 The Earth's surface absorbs $492 \mathrm{~W} / \mathrm{m}^{2}$. Of that amount $390 \mathrm{~W} / \mathrm{m}^{2}$ or 79\% is radiated back toward the atmosphere. Figure 18.14 The increasing slope corresponds to an increasing rate of addition of $\mathrm{CO}_{2}$ to the atmosphere, probably as a result of ever-increasing burning of fossil fuels worldwide. Figure 18.16 Evaporation from sea water, evaporation from freshwater; evaporation and transpiration from land. Figure 18.17 As the temperature of water goes down its density increases. Therefore, density increases as depth increases (note the pressure also increases which also results in an increase in density). Figure 18.21 To reduce concentrations of dissolved iron and manganese, remove $\mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{NH}_{3}$, and reduce bacterial levels.

## Chapter 19

Figure 19.1 Yes, the potential energy of the eggs decreases as they fall. Figure 19.2 The freezing of liquid water to form ice is exothermic. Figure 19.3 To be truly reversible, the temperature change $\delta T$ must be infinitesimally small. Figure 19.5 Because the final volume would be less than twice the volume of Flask A, the final pressure would be greater than 50.7 kPa . Figure 19.8 There are two other independent rotational motions of the $\mathrm{H}_{2} \mathrm{O}$ molecule:

Figure 19.9 Ice, because it is the phase in which the molecules are held most rigidly Figure 19.11 The decrease in the number of molecules due to the formation of new bonds. Figure 19.12 During a phase change, the temperature remains constant but the entropy change can be large as molecules increase their degrees of freedom and motion. Figure 19.13 Based on the three molecules shown, the addition of each C increases $S^{\circ}$ by $40-45 \mathrm{~J} / \mathrm{mol} \mathrm{K}$. Based on this observation, we would predict that $S^{\circ}\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ would 310-315 J/mol K. Appendix C confirms that this is a good prediction: $S^{\circ}\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)=310.0 \mathrm{~J} / \mathrm{mol}$ K. Figure 19.14 Spontaneous Figure 19.15 If we plot progress of the reaction versus free energy, equilibrium is at a minimum point in free energy, as shown in the figure. In that sense, the reaction runs "downhill" until it reaches that minimum point.

## Chapter 20

Figure 20.1 Exothermic. Figure 20.2 The permanganate ion, $\mathrm{MnO}_{4}^{-}$, is reduced, as the half-reactions in the text show. The oxalate ion, $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$, acts as the reducing agent. Figure 20.3 The blue color is due to $\mathrm{Cu}^{2+}(a q)$. As this ion is reduced, forming $\mathrm{Cu}(s)$, its concentration decreases and the blue color fades. Figure 20.4 The Zn is oxidized and, therefore, serves as the anode of the cell. Figure 20.5 The electrical balance is maintained in two ways: Anions migrate into the half-cell, and cations migrate out via the salt bridge. Figure 20.9 As the cell operates, $\mathrm{H}^{+}$is reduced to $\mathrm{H}_{2}$ in the cathode half-cell. As $\mathrm{H}^{+}$is depleted, the positive $\mathrm{Na}^{+}$ions are drawn into the half-cell to maintain electrical balance in the solution.
Figure 20.11 Yes. Figure 20.13 The variable $n$ is the number of moles of electrons transferred in the process. Figure 20.14 The cathode. Figure 20.19 The cathode consists of $\mathrm{PbO}_{2}(s)$. Because each oxygen has an oxidation state of -2 , lead must have an oxidation state of +4 in this compound. Figure 20.20 Zn Figure 20.21 $\mathrm{Co}^{3+}$. The oxidation number increases as the battery charges. Figure $20.24 \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)$
Figure 20.25 The oxidizing agent of $\mathrm{O}_{2}(g)$ from the air.
Figure 20.290 V

## Chapter 21

Figure 21.1 From Figure 21.1 we see that the belt of stability for a nucleus containing 70 protons lies at approximately 102 neutrons. Figure $21.2{ }_{90}^{234} \mathrm{Th} \longrightarrow{ }_{91}^{234} \mathrm{~Pa}+{ }_{-1}^{0} \mathrm{e}$ Figure 21.3 Only three of the elements with an even number of protons have fewer than three isotopes: $\mathrm{He}, \mathrm{Be}$, and C. Note that these three elements are the lightest elements that have an even atomic number. Because they are so light, any change in the number of neutrons will change the neutron/proton ratio significantly. This helps to explain why they do not have more stable isotopes. None of the elements in

Figure 21.3 that have an odd number of protons have more than two stable isotopes. Figure 21.66 .25 g . After one half-life, the amount of the radioactive material will have dropped to 25.0 g . After two half-lives, it will have dropped to 12.5 g . After three half-lives, it will have dropped to 6.25 g . Figure 21.7 Plants convert ${ }^{14} \mathrm{CO}_{2}$ to ${ }^{14} \mathrm{C}$-containing sugars via photosynthesis. When mammals eat the plants, they metabolize the sugars, thereby incorporating ${ }^{14} \mathrm{C}$ in their bodies. Figure 21.8 Gamma rays. Both X rays and gamma rays consist of high-energy electromagnetic radiation, whereas alpha and beta rays are streams of particles. Figure 21.9 Ionization energy. Detection depends on the ability of the radiation to cause ionization of the gas atoms. Figure 21.14 The mass numbers are equal on both sides. Remember that this does not mean that mass is conserved-mass is lost during the reaction, which appears as energy released. Figure 21.15 16. Each of the eight neutrons would split another uranium- 235 nucleus, releasing two more neutrons.
Figure 21.16 Critical without being supercritical so that the release of energy is controlled. Figure 21.23 Alpha rays are less dangerous when outside the body because they cannot penetrate the skin. However, once inside the body they can do great harm to any cells that are nearby.

## Chapter 22

Figure 22.5 Beaker on the right is warmer. Figure 22.6 HF is the most stable, $\mathrm{SbH}_{3}$ the least stable. Figure 22.8 More soluble in $\mathrm{CCl}_{4}$ - the colors are deeper. Figure $22.9 \mathrm{CF}_{2}$ Figure 22.12 No Figure 22.14 Based on this structure-yes, it would have a dipole moment. In fact, if you look it up, hydrogen peroxide's dipole moment is larger than water's! Figure 22.19 Formally they could both be +2 . If we consider that the central sulfur is like $\mathrm{SO}_{4}{ }^{2-}$, however, then the central sulfur would be +6 , like $\mathrm{SO}_{4}{ }^{2-}$, and the terminal sulfur would be -2. Figure 22.21 Nitrite Figure 22.22 Longer. (There is a triple bond in $\mathrm{N}_{2}$.) Figure 22.24 The NO double bond Figure 22.26 In both compounds the electron domains around the P atoms are tetrahedral. In $\mathrm{P}_{4} \mathrm{O}_{10}$ all the electron domains around the P atoms are bonding. In $\mathrm{P}_{4} \mathrm{O}_{6}$ one of the electron domains about each P atom is nonbonding. Figure 22.31 The minimum temperature should be the melting point of silicon; the temperature of the heating coil should not be so high that the silicon rod starts to melt outside the zone of the heating coil.

## Chapter 23

Figure 23.3 No. The radius decreases first and then flattens out before increasing on moving past group 8B, while the effective nuclear charge increases steadily on moving left to right across the transition metal series. Figure $23.4 \mathrm{Zn}^{2+}$. Figure 23.5 The $4 s$ orbitals are always empty in transition metal ions, so all of the ions shown in this table have empty $4 s$ orbitals. The $3 d$ orbitals are only empty for those ions that have lost all of their valence electrons: $\mathrm{Sc}^{3+}, \mathrm{Ti}^{4+}, \mathrm{V}^{5+}, \mathrm{Cr}^{6+}$, and $\mathrm{Mn}^{7+}$. Figure 23.6 The electron spins would tend to align with the direction of the magnetic field.
Figure 23.8 No. If you start with a chloride ion on one vertex of the octahedron and then generate structures by placing the second chloride ion on any of the other five vertices you will get one complex that is the trans isomer and four complexes that are equivalent to the cis isomer shown in this figure. Figure 23.9 Neither the coordination number nor the oxidation state of iron change in this reaction. Figure 23.10 The solid wedge represents a bond coming out of the plane of the page. The dashed wedge represents a bond that is going into the plane of the page. Figure 23.13 There
are 20 carbon atoms in porphine, all of which have sp ${ }^{2}$ hybridization. Figure 23.15 The coordination number is 6 . The blue atoms in the heme are nitrogen atoms. Figure 23.16 The peak at 660 nm . Figure $23.20\left[\mathrm{Fe}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{NO}_{2}\right)\right]^{2+}$ and pentaamminenitroiron(III) ion for the complex on the left. $\left[\mathrm{Fe}\left(\mathrm{NH}_{3}\right)_{5}(\mathrm{ONO})\right]^{2+}$ and pentaamminenitritoiron(III) ion for the complex on the right. Figure 23.21 The cis isomer. Figure 23.24 Larger, since ammonia can displace water. Figure 23.26 The peak would stay in the same position in terms of wavelength, but its absorbance would decrease. Figure $23.28 d_{x^{2}-y^{2}}$ and $d_{z^{2}}$. Figure 23.29 Convert the wavelength of light, 495 nm , into energy in joules using the relationship $E=h c / \lambda$. Figure 23.30 The absorption peak would shift to shorter wavelengths absorbing green light and the color of the complex ion would become red. An even larger shift would move the absorption peak into the blue region of the spectrum and the color would become orange. Figure 23.34 Only the $d_{x^{2}-y^{2}}$ orbital points directly at the ligands.

## Chapter 24

Figure 24.1 Tetrahedral Figure 24.2 The OH group is polar whereas the $\mathrm{CH}_{3}$ group is nonpolar. Hence, adding $\mathrm{CH}_{3}$ will (a) reduce the substance's solubility in polar solvents and (b) increase its solubility in nonpolar solvents. Figure $24.5 \mathrm{C}_{n} \mathrm{H}_{2 n}$, because there are no $\mathrm{CH}_{3}$ groups, each carbon has two hydrogens. Figure 24.7 Just one Figure 24.9 Yes, spontaneous. Figure 24.13 Both lactic acid and citric acid Figure 24.14 No, because there are not four different groups around any carbon Figure 24.16 Those labeled "basic amino acids," which have basic side groups that are protonated at pH 7 Figure 24.17
Two. Figure 24.23 The long hydrocarbon chains, which are nonpolar Figure 24.24 The polar parts of the phospholipids seek to interact with water whereas the nonpolar parts seek to interact with other nonpolar substances and to avoid water. Figure 24.26 1-2-3-4 Figure 24.27 GC because each base has three hydrogen bonding sites, whereas there are only two in AT.

## ANSWERS TO SELECTED PRACTICE EXERCISES

## Chapter 1

## Sample Exercise 1.1

Practice Exercise 2: It is a compound because it has constant composition and can be separated into several elements.

## Sample Exercise 1.2

Practice Exercise 2: (a) $10^{12} \mathrm{pm}$, (b) 6.0 km , (c) $4.22 \times 10^{-3} \mathrm{~g}$, (d) 0.00422 g .

Sample Exercise 1.3
Practice Exercise 2: (a) 261.7 K , (b) $11.3^{\circ} \mathrm{F}$
Sample Exercise 1.4
Practice Exercise 2: (a) $8.96 \mathrm{~g} / \mathrm{cm}^{3}$, (b) 19.0 mL , (c) 340 g .
Sample Exercise 1.5
Practice Exercise 2: $2.29 \times 10^{6} \mathrm{~J}$

## Sample Exercise 1.6

Practice Exercise 2: No. The number of $\mathrm{cm}^{3}$ in a liter is a defined quantity and is therefore exact, but the volume represented by one $\mathrm{cm}^{3}$ is not exact, although it is known to high accuracy.

Sample Exercise 1.7
Practice Exercise 2: (a) four, (b) two, (c) three.
Sample Exercise 1.8
Practice Exercise 2: $9.52 \mathrm{~m} / \mathrm{s}$ (three significant figures).
Sample Exercise 1.9
Practice Exercise 2: No. Even though the mass of the gas would then be known to four significant figures, the volume of the container would still be known to only three.

Sample Exercise 1.10
Practice Exercise 2: 804.7 km
Sample Exercise 1.11
Practice Exercise 2: $12 \mathrm{~km} / \mathrm{L}$.
Sample Exercise 1.12
Practice Exercise 2: $1.2 \times 10^{4} \mathrm{ft}$.
Sample Exercise 1.13
Practice Exercise 2: 832 g

## Chapter 2

Sample Exercise 2.1
Practice Exercise 2: (a) 154 pm , (b) $1.3 \times 10^{6} \mathrm{C}$ atoms
Sample Exercise 2.2
Practice Exercise 2: (a) 56 protons, 56 electrons, and 82 neutrons, (b) 15 protons, 15 electrons, and 16 neutrons.

Sample Exercise 2.3
Practice Exercise 2: ${ }_{82}^{208} \mathrm{~Pb}$

## Sample Exercise 2.4

Practice Exercise 2: 28.09 u

## Sample Exercise 2.5

Practice Exercise 2: Na, atomic number 11, is a metal; Br , atomic number 35 , is a nonmetal.

Sample Exercise 2.6
Practice Exercise 2: $\mathrm{B}_{5} \mathrm{H}_{7}$

## Sample Exercise 2.7

Practice Exercise 2: 34 protons, 45 neutrons, and 36 electrons
Sample Exercise 2.8
Practice Exercise 2: (a) 3+, (b) 1-

## Sample Exercise 2.9

Practice Exercise 2: (a) Rb is from group 1, and readily loses one electron to attain the electron configuration of the nearest noble gas element, Kr. (b) Nitrogen and the halogens are all nonmetallic elements, which form molecular compounds with one another. (c) Krypton, Kr , is a noble gas element and is chemically inactive except under special conditions. (d) Na and K are both from group 1 and adjacent to one another in the periodic table. They would be expected to behave very similarly. (e) Calcium is an active metal and readily loses two electrons to attain the noble gas configuration of Ar.

Sample Exercise 2.10
Practice Exercise 2: (a) $\mathrm{Na}_{3} \mathrm{PO}_{4}$, (b) $\mathrm{ZnSO}_{4}$, (c) $\mathrm{Fe}_{2}\left(\mathrm{CO}_{3}\right)_{3}$
Sample Exercise 2.11
Practice Exercise 2: $\mathrm{BrO}^{-}$and $\mathrm{BrO}_{2}^{-}$
Sample Exercise 2.12
Practice Exercise 2: (a) ammonium bromide, (b) chromium(III) oxide, (c) cobalt(II) nitrate

Sample Exercise 2.13
Practice Exercise 2: (a) HBr , (b) $\mathrm{H}_{2} \mathrm{CO}_{3}$
Sample Exercise 2.14
Practice Exercise 2: (a) $\mathrm{SiBr}_{4}$, (b) $\mathrm{S}_{2} \mathrm{Cl}_{2}$, (c) $\mathrm{P}_{2} \mathrm{O}_{6}$.
Sample Exercise 2.15
Practice Exercise 2: No, they are not isomers because they have different molecular formulas. Butane is $\mathrm{C}_{4} \mathrm{H}_{10}$, whereas cyclobutane is $\mathrm{C}_{4} \mathrm{H}_{8}$.

## Chapter 3

## Sample Exercise 3.1

Practice Exercise 2: $(\mathbf{a}) \mathrm{C}_{2} \mathrm{H}_{4}+3 \mathrm{O}_{2} \longrightarrow 2 \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}$.
(b) Nine $\mathrm{O}_{2}$ molecules

## Sample Exercise 3.2

Practice Exercise 2: (a) $4,3,2$; (b) $2,6,2,3$; (c) $1,2,1,1,1$
Sample Exercise 3.3
Practice Exercise 2: $(\mathbf{a}) \mathrm{HgS}(s) \longrightarrow \mathrm{Hg}(l)+\mathrm{S}(s)$, or $\frac{1}{8} \mathrm{~S}_{8}(s)$
(b) $4 \mathrm{Al}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)$

Sample Exercise 3.4
Practice Exercise 2: $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(g)$
Sample Exercise 3.5
Practice Exercise 2: (a) 78.0 u , (b) 32.0 u , (c) 211.0 u
Sample Exercise 3.6
Practice Exercise 2: 16.1\%

## Sample Exercise 3.7

Practice Exercise 2: $1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}\left(6 \times 10^{23} \mathrm{O}\right.$ atoms $)<3 \times 10^{23}$ molecules $\mathrm{O}_{3}\left(9 \times 10^{23} \mathrm{O}\right.$ atoms $)<1 \mathrm{~mol} \mathrm{CO}_{2}\left(12 \times 10^{23} \mathrm{O}\right.$ atoms $)$

## Sample Exercise 3.8

Practice Exercise 2: (a) $9.0 \times 10^{23}$, (b) $2.71 \times 10^{24}$
Sample Exercise 3.9
Practice Exercise 2: $164.1 \mathrm{~g} / \mathrm{mol}$
Sample Exercise 3.10
Practice Exercise 2: $55.5 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}$.
Sample Exercise 3.11
Practice Exercise 2: (a) 6.0 g , (b) 8.29 g .
Sample Exercise 3.12
Practice Exercise 2: (a) $4.01 \times 10^{22}$ molecules $\mathrm{HNO}_{3}$,
(b) $1.20 \times 10^{23}$ atoms O

Sample Exercise 3.13
Practice Exercise 2: $\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{O}$
Sample Exercise 3.14
Practice Exercise 2: (a) $\mathrm{CH}_{3} \mathrm{O}$, (b) $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}$
Sample Exercise 3.15
Practice Exercise 2: (a) $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{O}$, (b) $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{2}$
Sample Exercise 3.16
Practice Exercise 2: 1.77 g
Sample Exercise 3.17
Practice Exercise 2: 26.5 g
Sample Exercise 3.18
Practice Exercise 2: (a) Al, (b) 1.50 mol , (c) $0.75 \mathrm{~mol} \mathrm{Cl}_{2}$
Sample Exercise 3.19
Practice Exercise 2: (a) $\mathrm{AgNO}_{3}$, (b) 1.59 g , (c) 1.39 g ,
(d) 1.52 g Zn

Sample Exercise 3.20
Practice Exercise 2: (a) 105 g Fe , (b) $83.7 \%$

## Chapter 4

## Sample Exercise 4.1

Practice Exercise 2: (a) 6, (b) 12, (c) 2, (d) 9
Sample Exercise 4.2
Practice Exercise 2: (a) insoluble, (b) soluble, (c) soluble
Sample Exercise 4.3
Practice Exercise 2: (a) $\mathrm{Fe}(\mathrm{OH})_{3}$,
(b) $\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3}(a q)+6 \mathrm{LiOH}(a q) \xrightarrow{\longrightarrow} 2 \mathrm{Fe}(\mathrm{OH})_{3}(s)+3 \mathrm{Li}_{2} \mathrm{SO}_{4}(a q)$

Sample Exercise 4.4
Practice Exercise 2: $3 \mathrm{Ag}^{+}(a q)+\mathrm{PO}_{4}{ }^{3-}(a q) \longrightarrow \mathrm{Ag}_{3} \mathrm{PO}_{4}(s)$
Sample Exercise 4.5
Practice Exercise 2: The diagram would show $10 \mathrm{Na}^{+}$ions, $2 \mathrm{OH}^{-}$ions, $8 \mathrm{Y}^{-}$ions, and $8 \mathrm{H}_{2} \mathrm{O}$ molecules.

## Sample Exercise 4.6

Practice Exercise 2: $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6}$ (nonelectrolyte) $<\mathrm{CH}_{3} \mathrm{COOH}$ (weak electrolyte, existing mainly in the form of molecules with few ions) $<\mathrm{NaCH}_{3} \mathrm{COO}$ (strong electrolyte that provides two ions, $\mathrm{Na}^{+}$and $\mathrm{CH}_{3} \mathrm{COO}^{-}$) $<\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ (strong electrolyte that provides three ions, $\mathrm{Ca}^{2+}$ and $2 \mathrm{NO}_{3}^{-}$)

## Sample Exercise 4.7

Practice Exercise 2:
(a) $\mathrm{H}_{3} \mathrm{PO}_{3}(a q)+2 \mathrm{KOH}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{K}_{2} \mathrm{HPO}_{3}(a q)$,
(b) $\mathrm{H}_{3} \mathrm{PO}_{3}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{HPO}_{3}^{2-} .\left(\mathrm{H}_{3} \mathrm{PO}_{3}\right.$ is a weak acid and therefore a weak electrolyte, whereas KOH , a strong base, and $\mathrm{K}_{3} \mathrm{PO}_{3}$, an ionic compound, are strong electrolytes. In spite of its formula, $\mathrm{H}_{3} \mathrm{PO}_{3}$ is a diprotic acid, better written as $\mathrm{H}_{2}\left(\mathrm{HPO}_{3}\right)$.

## Sample Exercise 4.8

Practice Exercise 2: $(\mathbf{a})+5, \quad(\mathbf{b})-1, \quad(\mathbf{c})+6, \quad(\mathbf{d})+4, \quad(\mathbf{e})-1$
Sample Exercise 4.9
Practice Exercise 2:
(a) $\mathrm{Mg}(s)+\mathrm{CoSO}_{4}(a q) \longrightarrow \mathrm{MgSO}_{4}(a q)+\mathrm{Co}(s)$;
$\mathrm{Mg}(s)+\mathrm{Co}^{2+}(a q) \longrightarrow \mathrm{Mg}^{2+}(a q)+\mathrm{Co}(s)$,
(b) Mg is oxidized and $\mathrm{Co}^{2+}$ is reduced.

Sample Exercise 4.10
Practice Exercise 2: Zn and Fe
Sample Exercise 4.11
Practice Exercise 2: 0.278 M
Sample Exercise 4.12
Practice Exercise 2: 0.030 M
Sample Exercise 4.13
Practice Exercise 2: (a) 1.1 g , (b) 76 mL
Sample Exercise 4.14
Practice Exercise 2: (a) $0.0200 \mathrm{~L}=20.0 \mathrm{~mL}$, (b) 5.0 mL ,
(c) 0.40 M

Sample Exercise 4.15
Practice Exercise 2: (a) 0.240 g , assuming you only need to neutralize one proton per sulfuric acid molecule, (b) 0.400 L

## Sample Exercise 4.16

Practice Exercise 2: 0.210 M
Sample Exercise 4.17
Practice Exercise 2: (a) $1.057 \times 10^{-3} \mathrm{~mol} \mathrm{MnO}_{4}^{-}$,
(b) $5.286 \times 10^{-3} \mathrm{~mol} \mathrm{Fe}^{2+}$,
(c) 0.2952 g ,
(d) $33.21 \%$

## Chapter 5

Sample Exercise 5.1
Practice Exercise 2: +55 J
Sample Exercise 5.2
Practice Exercise 2: 70 J

## Sample Exercise 5.3

Practice Exercise 2: In order to solidify, the gold must cool to below its melting temperature. It cools by transferring heat to its surroundings. The air around the sample would feel hot because heat is transferred to it from the molten gold, meaning the process is exothermic. (You may notice that solidification of a liquid is the reverse of the melting we analyzed in the exercise. As we will see, reversing the direction of a process changes the sign of the heat transferred.)

## Sample Exercise 5.4

Practice Exercise 2: - 14.4 kJ
Sample Exercise 5.5
Practice Exercise 2: (a) $4.9 \times 10^{5} \mathrm{~J}$,
(b) 11 K decrease $=11^{\circ} \mathrm{C}$ decrease

## Sample Exercise 5.6

Practice Exercise 2: $-68,000 \mathrm{~J} / \mathrm{mol}=-68 \mathrm{~kJ} / \mathrm{mol}$

Sample Exercise 5.7
Practice Exercise 2: (a) $-15.2 \mathrm{~kJ} / \mathrm{g}$, (b) $-1370 \mathrm{~kJ} / \mathrm{mol}$

## Sample Exercise 5.8

Practice Exercise 2: +1.9 kJ
Sample Exercise 5.9
Practice Exercise 2: -304.1 kJ
Sample Exercise 5.10
Practice Exercise 2: C (graphite) $+2 \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{CCl}_{4}(l)$;
$\Delta H_{f}^{\circ}=-106.7 \mathrm{~kJ} / \mathrm{mol}$.
Sample Exercise 5.11
Practice Exercise 2: -1367 kJ
Sample Exercise 5.12
Practice Exercise 2: - $156.1 \mathrm{~kJ} / \mathrm{mol}$
Sample Exercise 5.13
Practice Exercise 2: -1255 kJ
Sample Exercise 5.14
Practice Exercise 2: (a) $15 \mathrm{~kJ} / \mathrm{g}$, (b) 100 min

## Chapter 6

## Sample Exercise 6.1

Practice Exercise 2: The expanded visible-light portion of Figure 6.4 tells you that red light has a longer wavelength than blue light.

## Sample Exercise 6.2

Practice Exercise 2: (a) $1.43 \times 10^{14} \mathrm{~s}^{-1}$, (b) 2.899 m
Sample Exercise 6.3
Practice Exercise 2: (a) $3.11 \times 10^{-19} \mathrm{~J}$, (b) 0.16 J ,
(c) $4.2 \times 10^{16}$ photons

Sample Exercise 6.4
Practice Exercise 2: (a) $\Delta E<0$, photon emitted, (b) $\Delta E>0$, photon absorbed

Sample Exercise 6.5
Practice Exercise 2: $7.83 \times 10^{2} \mathrm{~m} / \mathrm{s}$

## Sample Exercise 6.6

Practice Exercise 2: (a) $5 p$; (b) 3; (c) $1,0,-1$
Sample Exercise 6.7
Practice Exercise 2: (a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{2}$, (b) two
Sample Exercise 6.8
Practice Exercise 2: group 14
Sample Exercise 6.9
Practice Exercise 2: (a) $[\mathrm{Ar}] 4 s^{2} 3 d^{7}$ or $[\mathrm{Ar}] 3 d^{7} 4 s^{2}$,
(b) $[\mathrm{Kr}] 5 s^{2} 4 d^{10} 5 p^{1}$ or $[\mathrm{Kr}] 4 d^{10} 5 s^{2} 5 p^{1}$

## Chapter 7

Sample Exercise 7.1
Practice Exercise 2: $\mathrm{P}-\mathrm{Br}$
Sample Exercise 7.2
Practice Exercise 2: $\mathrm{C}<\mathrm{Be}<\mathrm{Ca}<\mathrm{K}$

## Sample Exercise 7.3

Practice Exercise 2: $\mathrm{S}^{2-}$
Sample Exercise 7.4
Practice Exercise 2: $\mathrm{Cs}^{+}$

## Sample Exercise 7.5

Practice Exercise 2: Ca
Sample Exercise 7.6
Practice Exercise 2: Al lowest, C highest
Sample Exercise 7.7
Practice Exercise 2: (a) $[\operatorname{Ar}] 3 \mathrm{~d}^{10}$, (b) $[\operatorname{Ar}] 3 \mathrm{~d}^{3}$, (c) $[\operatorname{Ar}] 4 \mathrm{~s}^{2} 3 \mathrm{~d}^{10} 4 \mathrm{p}^{6}$
Sample Exercise 7.8
Practice Exercise 2: $\mathrm{CuO}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{CuSO}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
Sample Exercise 7.9
Practice Exercise 2: $\mathrm{P}_{4} \mathrm{O}_{6}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{3}(a q)$
Sample Exercise 7.10
Practice Exercise 2: $2 \mathrm{~K}(s)+\mathrm{S}(s) \longrightarrow \mathrm{K}_{2} \mathrm{~S}(s)$

## Chapter 8

## Sample Exercise 8.1

Practice Exercise 2: $\mathrm{ZrO}_{2}$
Sample Exercise 8.2
Practice Exercise 2: $\mathrm{Mg}^{2+}$ and $\mathrm{N}^{3-}$

## Sample Exercise 8.3

Practice Exercise 2: They both show 8 valence electrons; methane has 4 bonding pairs and neon has 4 nonbonding pairs

Sample Exercise 8.4
Practice Exercise 2: Se-Cl
Sample Exercise 8.5
Practice Exercise 2: (a) F, (b) 0.11-
Sample Exercise 8.6
Practice Exercise 2: (a) 20, (b)

## Sample Exercise 8.7

Practice Exercise 2: (a) [: $\mathrm{N} \equiv \mathrm{O}:]^{+}$,

Sample Exercise 8.8
Practice Exercise 2: (a)

(b)

## Sample Exercise 8.9

Practice Exercise 2:
(a) $\begin{array}{lll}-2 & 0 & +1\end{array}$

(i)

(ii)

(iii)
(b) Structure (iii), which places a negative charge on oxygen, the most electronegative element in the ion, is the dominant Lewis structure.

Sample Exercise 8.10
Practice Exercise 2: $\left[\begin{array}{c}\mathrm{H}-\mathrm{C}=\ddot{\mathrm{O}} \\ : \mathrm{O}:\end{array}\right]^{-} \longleftrightarrow\left[\begin{array}{c}\mathrm{H}-\mathrm{C}-\ddot{\mathrm{O}}: \\ \mathrm{U}: \\ \mathrm{O}:\end{array}\right]^{-}$

Sample Exercise 8.11
Practice Exercise 2: (a) C,

## Chapter 9

## Sample Exercise 9.1

Practice Exercise 2: (a) tetrahedral, bent; (b) trigonal planar, trigonal planar

## Sample Exercise 9.2

Practice Exercise 2: (a) trigonal bipyramidal, T-shaped; (b) trigonal bipyramidal, trigonal bipyramidal.

## Sample Exercise 9.3

Practice Exercise 2: $109.5^{\circ}, 180^{\circ}$

## Sample Exercise 9.4

Practice Exercise 2: (a) polar because polar bonds are arranged in a seesaw geometry, (b) nonpolar because polar bonds are arranged in a tetrahedral geometry

## Sample Exercise 9.5

Practice Exercise 2: tetrahedral, $s p^{3}$

## Sample Exercise 9.6

Practice Exercise 2: (a) approximately $109^{\circ}$ around the left C and $180^{\circ}$ around the right C; (b) $s p^{3}$, $s p$; (c) five $\sigma$ bonds and two $\pi$ bonds

## Sample Exercise 9.7

Practice Exercise 2: $\mathrm{SO}_{2}$ and $\mathrm{SO}_{3}$, as indicated by the presence of two or more resonance structures involving $\pi$ bonding for each of these molecules.

## Sample Exercise 9.8

Practice Exercise 2: $\sigma_{1 s}{ }^{2} \sigma_{1 s}^{\star 1} ; \frac{1}{2}$
Sample Exercise 9.9
Practice Exercise 2: (a) diamagnetic, 1; (b) diamagnetic, 3

## Chapter 10

## Sample Exercise 10.1

Practice Exercise 2: (d) 1.6 M
Sample Exercise 10.2
Practice Exercise 2: 107.6 kPa
Sample Exercise 10.3
Practice Exercise 2: $5.30 \times 10^{3} \mathrm{~L}$

## Sample Exercise 10.4

Practice Exercise 2: 202.65 kPa
Sample Exercise 10.5
Practice Exercise 2: $3.83 \times 10^{3} \mathrm{~m}^{3}$

## Sample Exercise 10.6

Practice Exercise 2: $27^{\circ} \mathrm{C}$

## Sample Exercise 10.7

Practice Exercise 2: $5.9 \mathrm{~g} / \mathrm{L}$
Sample Exercise 10.8
Practice Exercise 2: $29.0 \mathrm{~g} / \mathrm{mol}$

## Sample Exercise 10.9

Practice Exercise 2: 14.8 L
Sample Exercise 10.10
Practice Exercise 2: 289.8 kPa

## Sample Exercise 10.11

Practice Exercise 2: $133.3 \mathrm{kPa} \mathrm{N}_{2}, 20 \mathrm{kPa} \mathrm{Ar}$, and $9.733 \mathrm{kPa} \mathrm{CH}_{4}$
Sample Exercise 10.12
Practice Exercise 2: (a) increases, (b) no effect, (c) no effect
Sample Exercise 10.13
Practice Exercise 2: $1.36 \times 10^{3} \mathrm{~m} / \mathrm{s}$
Sample Exercise 10.14
Practice Exercise 2: $\mathrm{N}_{\mathrm{N}_{2}} / r_{\mathrm{O}_{2}}=1.07$
Sample Exercise 10.15
Practice Exercise 2: (a) 756.6 kPa , (b) 727.1 kPa

## Chapter 11

Sample Exercise 11.1
Practice Exercise 2: chloramine, NHCl
Sample Exercise 11.2
Practice Exercise 2: (a) $\mathrm{CH}_{3} \mathrm{CH}_{3}$ has only dispersion forces, whereas the other two substances have both dispersion forces and hydrogen bonds, (b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$

Sample Exercise 11.3
Practice Exercise 2: $-20.9 \mathrm{~kJ}-33.4 \mathrm{~kJ}-6.09 \mathrm{~kJ}=-60.4 \mathrm{~kJ}$
Sample Exercise 11.4
Practice Exercise 2: about 45 kPa
Sample Exercise 11.5
Practice Exercise 2: (a) $-162^{\circ} \mathrm{C}$; (b) It sublimes whenever the pressure is less than 10 kPa ; (c) The highest temperature at which a liquid can exist is defined by the critical temperature. So we do not expect to find liquid methane when the temperature is higher than $-80^{\circ} \mathrm{C}$.

## Sample Exercise 11.6

Practice Exercise 2: Because rotation can occur about carbon-carbon single bonds, molecules whose backbone consists predominantly of C - C single bonds are too flexible; the molecules tend to coil in random ways and, thus, are not rodlike.

## Chapter 12

Sample Exercise 12.1
Practice Exercise 2: 0.68 or 68\%
Sample Exercise 12.2
Practice Exercise 2: $a=402 \mathrm{pm}$ and density $=4.31 \mathrm{~g} / \mathrm{cm}^{3}$
Sample Exercise 12.3
Practice Exercise 2: smaller.
Sample Exercise 12.4
Practice Exercise 2: A group 15 element could be used to replace Se.

## Chapter 13

Sample Exercise 13.1
Practice Exercise 2: $\mathrm{C}_{5} \mathrm{H}_{12}<\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{Cl}<\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{OH}<\mathrm{C}_{5} \mathrm{H}_{10}(\mathrm{OH})_{2}$ (in order of increasing polarity and hydrogen-bonding ability)

Sample Exercise 13.2
Practice Exercise 2: $1.0 \times 10^{-5} \mathrm{M}$

## Sample Exercise 13.3

Practice Exercise 2: 90.5 g of NaOCl
Sample Exercise 13.4
Practice Exercise 2: 0.670 m
Sample Exercise 13.5
Practice Exercise 2: (a) $9.00 \times 10^{-3}$, (b) 0.505 m
Sample Exercise 13.6
Practice Exercise 2: (a) 10.9 m , (b) $X_{\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}}=0.163$,
(c) 5.97 M

Sample Exercise 13.7
Practice Exercise 2: 0.290
Sample Exercise 13.8
Practice Exercise 2: $-65.6^{\circ} \mathrm{C}$
Sample Exercise 13.9
Practice Exercise 2: 4.86 kPa
Sample Exercise 13.10
Practice Exercise 2: $110 \mathrm{~g} / \mathrm{mol}$
Sample Exercise 13.11
Practice Exercise 2: $4.20 \times 10^{4} \mathrm{~g} / \mathrm{mol}$

## Chapter 14

Sample Exercise 14.1
Practice Exercise 2: $1.8 \times 10^{-2} \mathrm{M} / \mathrm{s}$
Sample Exercise 14.2
Practice Exercise 2: $1.1 \times 10^{-4} \mathrm{M} / \mathrm{s}$
Sample Exercise 14.3
Practice Exercise 2: (a) $8.4 \times 10^{-7} \mathrm{M} / \mathrm{s}$, (b) $2.1 \times 10^{-7} \mathrm{M} / \mathrm{s}$
Sample Exercise 14.4
Practice Exercise 2: $2=3<1$
Sample Exercise 14.5
Practice Exercise 2: (a) 1, (b) $M^{-1} \mathrm{~s}^{-1}$.
Sample Exercise 14.6
Practice Exercise 2: (a) rate $=k[\mathrm{NO}]^{2}\left[\mathrm{H}_{2}\right]$, (b) $k=1.2 \mathrm{M}^{-2} \mathrm{~s}^{-1}$
(c) rate $=4.5 \times 10^{-4} \mathrm{M} / \mathrm{s}$

Sample Exercise 14.7
Practice Exercise 2:
Sample Exercise 14.8
Practice Exercise 2: $\left[\mathrm{NO}_{2}\right]=1.00 \times 10^{-3} \mathrm{M}$
Sample Exercise 14.9
Practice Exercise 2: (a) $0.478 \mathrm{yr}=1.51 \times 10^{7} \mathrm{~s}, \quad$ (b) it takes two half-lives, $2(0.478 \mathrm{yr})=0.956 \mathrm{yr}$

Sample Exercise 14.10
Practice Exercise 2: $2<1<3$ because, if you approach the barrier from the right, the $E_{a}$ values are $40 \mathrm{~kJ} / \mathrm{mol}$ for reverse reaction 2, $25 \mathrm{~kJ} / \mathrm{mol}$ for reverse reaction 1 , and $15 \mathrm{~kJ} / \mathrm{mol}$ for reverse reaction 3 .

## Sample Exercise 14.11

Practice Exercise 2: $3 \times 10^{13} \mathrm{~s}^{-1}$
Sample Exercise 14.12
Practice Exercise 2: (a) Yes, the two equations add to yield the equation for the reaction. (b) The first elementary reaction is unimolecular, and the second one is bimolecular. (c) $\mathrm{Mo}(\mathrm{CO})_{5}$.

## Sample Exercise 14.13

Practice Exercise 2: (a) Rate $=k[\mathrm{NO}]^{2}\left[\mathrm{Br}_{2}\right]$, (b) No, because termolecular reactions are very rare.

## Sample Exercise 14.14

Practice Exercise 2: Because the rate law conforms to the molecularity of the first step, the first step must be the rate-determining step. The second step must be much faster than the first one.

## Sample Exercise 14.15

Practice Exercise 2: $[\mathrm{Br}]=\left(\frac{k_{1}}{k_{-1}}\left[\mathrm{Br}_{2}\right]\right)^{1 / 2}$

## Chapter 15

## Sample Exercise 15.1

Practice Exercise 2: (a) $K_{c}=\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}$, (b) $K_{c}=\frac{\left[\mathrm{CdBr}_{4}{ }^{2-}\right]}{\left[\mathrm{Cd}^{2+}\right]\left[\mathrm{Br}^{-}\right]^{4}}$
Sample Exercise 15.2
Practice Exercise 2: 33.9

## Sample Exercise 15.3

Practice Exercise 2: At the lower temperature because $K_{p}$ is larger at the lower temperature

## Sample Exercise 15.4

Practice Exercise 2: $\frac{(54.0)^{3}}{1.04 \times 10^{-4}}=1.51 \times 10^{9}$

## Sample Exercise 15.5

Practice Exercise 2: (a) $K_{c}=\frac{\left[\mathrm{Cr}^{3+}\right]}{\left[\mathrm{Ag}^{+}\right]^{3}}, \quad$ (b) $K_{p}=\frac{\left(P_{\mathrm{H}_{2}}\right)^{4}}{\left(P_{\mathrm{H}_{2} \mathrm{O}}\right)^{4}}$
Sample Exercise 15.6
Practice Exercise 2: $\mathrm{H}_{2}(\mathrm{~g})$
Sample Exercise 15.7
Practice Exercise 2: $1.79 \times 10^{-5}$
Sample Exercise 15.8
Practice Exercise 2: 32.3

## Sample Exercise 15.9

Practice Exercise 2: $Q_{p}=16 ; Q_{p}>K_{p}$, and so the reaction will proceed from right to left, forming more $\mathrm{SO}_{3}$.

## Sample Exercise 15.10

Practice Exercise 2: 127.5 kPa
Sample Exercise 15.11
Practice Exercise 2: $P_{\mathrm{PCl}_{5}}=97.94 \mathrm{kPa}, P_{\mathrm{PCl}_{3}}=P_{\mathrm{Cl}_{2}}=70.26 \mathrm{kPa}$
Sample Exercise 15.12
Practice Exercise 2: (a) right, (b) left, (c) right, (d) left

## Chapter 16

## Sample Exercise 16.1

Practice Exercise 2: $\mathrm{H}_{2} \mathrm{SO}_{3}, \mathrm{HF}, \mathrm{HPO}_{4}{ }^{2-}, \mathrm{HCO}^{+}$
Sample Exercise 16.2
Practice Exercise 2: $\mathrm{O}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{OH}^{-}(a q)+\mathrm{OH}^{-}(a q)$. The $\mathrm{OH}^{-}$is both the conjugate acid of $\mathrm{O}^{2-}$ and the conjugate base of $\mathrm{H}_{2} \mathrm{O}$.

Sample Exercise 16.3
Practice Exercise 2: (a) left, (b) right

## Sample Exercise 16.4

Practice Exercise 2: (a) basic, (b) neutral, (c) acidic

## Sample Exercise 16.5

Practice Exercise 2: (a) $5 \times 10^{-9} \mathrm{M}$, (b) $1.0 \times 10^{-7} \mathrm{M}$,
(c) $7.1 \times 10^{-9} \mathrm{M}$

Sample Exercise 16.6
Practice Exercise 2: (a) 3.42, (b) $\left[\mathrm{H}^{+}\right]=5.3 \times 10^{-9} \mathrm{M}$, so $\mathrm{pH}=8.28$
Sample Exercise 16.7
Practice Exercise 2: $\left[\mathrm{H}^{+}\right]=6.6 \times 10^{-10}$
Sample Exercise 16.8
Practice Exercise 2: 0.0046 M
Sample Exercise 16.9
Practice Exercise 2: (a) $7.8 \times 10^{-3} \mathrm{M}, \quad$ (b) $2.4 \times 10^{-3} \mathrm{M}$
Sample Exercise 16.10
Practice Exercise 2: $1.5 \times 10^{-5}$
Sample Exercise 16.11
Practice Exercise 2: 2.7\%
Sample Exercise 16.12
Practice Exercise 2: 3.41
Sample Exercise 16.13
Practice Exercise 2: (a) $3.9 \%$, (b) $12 \%$
Sample Exercise 16.14
Practice Exercise 2: (a) $\mathrm{pH}=1.80, \quad$ (b) $\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\right]=6.4 \times 10^{-5} \mathrm{M}$

## Sample Exercise 16.15

Practice Exercise 2: Methylamine (because it has the larger $K_{b}$ value of the two amine bases in the list)

Sample Exercise 16.16
Practice Exercise 2: 0.12 M
Sample Exercise 16.17
Practice Exercise 2: (a) $\mathrm{PO}_{4}{ }^{3-}\left(K_{b}=2.4 \times 10^{-2}\right)$,
(b) $K_{b}=7.9 \times 10^{-10}$

Sample Exercise 16.18
Practice Exercise 2: (a) $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$,
(b) KBr ,
(c) $\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}$,
(d) $\mathrm{NH}_{4} \mathrm{NO}_{3}$

Sample Exercise 16.19
Practice Exercise 2: acidic
Sample Exercise 16.20
Practice Exercise 2: (a) HBr , (b) $\mathrm{H}_{2} \mathrm{~S}$, (c) $\mathrm{HNO}_{3}$, (d) $\mathrm{H}_{2} \mathrm{SO}_{3}$

## Chapter 17

## Sample Exercise 17.1

Practice Exercise 2: 3.42
Sample Exercise 17.2
Practice Exercise 2: $\left[\mathrm{HCOO}^{-}\right]=9.0 \times 10^{-5}, \mathrm{pH}=1.00$

## Sample Exercise 17.3

Practice Exercise 2: 4.50

## Sample Exercise 17.4

Practice Exercise 2: 4.62 (using quadratic).

## Sample Exercise 17.5

Practice Exercise 2: 0.13 M

Sample Exercise 17.6
Practice Exercise 2: (a) 4.68, (b) 1.70
Sample Exercise 17.7
Practice Exercise 2: (a) 10.30, (b) 3.70
Sample Exercise 17.8
Practice Exercise 2: (a) 4.20, (b) 9.26
Sample Exercise 17.9
Practice Exercise 2: (a) 8.21, (b) 5.28
Sample Exercise 17.10
Practice Exercise 2:
(a) $K_{\text {sp }}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{CO}_{3}^{2-}\right]=5.0 \times 10^{-9}$,
(b) $K_{s p}=\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{SO}_{4}^{2-}\right]=1.5 \times 10^{-5}$

Sample Exercise 17.11
Practice Exercise 2: $1.6 \times 10^{-12}$
Sample Exercise 17.12
Practice Exercise 2: $9 \times 10^{-6} \mathrm{~mol} / \mathrm{L}$
Sample Exercise 17.13
Practice Exercise 2: $4.0 \times 10^{-10} \mathrm{M}$
Sample Exercise 17.14
Practice Exercise 2:
(a) $\mathrm{CuS}(s)+\mathrm{H}^{+}(a q) \rightleftharpoons \mathrm{Cu}^{2+}(a q)+\mathrm{HS}^{-}(a q)$,
(b) $\mathrm{Cu}\left(\mathrm{N}_{3}\right)_{2}(s)+2 \mathrm{H}^{+}(a q) \rightleftharpoons \mathrm{Cu}^{2+}(a q)+2 \mathrm{HN}_{3}(a q)$

Sample Exercise 17.15
Practice Exercise 2: $1 \times 10^{-16} \mathrm{M}$
Sample Exercise 17.16
Practice Exercise 2: Yes, $\mathrm{CaF}_{2}$ precipitates because $\mathrm{Q}=4.6 \times 10^{-7}$ is larger than $K_{s p}=3.9 \times 10^{-11}$

Sample Exercise 17.17
Practice Exercise 2: $\mathrm{Cu}(\mathrm{OH})_{2}$ precipitates first, beginning when $\left[\mathrm{OH}^{-}\right]>1.5 \times 10^{-9} \mathrm{M} . \mathrm{Mg}(\mathrm{OH})_{2}$ begins to precipitate when $\left[\mathrm{OH}^{-}\right]>1.9 \times 10^{-5} \mathrm{M}$.

## Chapter 18

Sample Exercise 18.1
Practice Exercise 2: $4.0 \times 10^{-4} \mathrm{kPa}$
Sample Exercise 18.2
Practice Exercise 2: 127 nm
Sample Exercise 18.3
$1.5 \times 10^{4} \mathrm{~g} \mathrm{CO}_{2}$ or $15 \mathrm{~kg} \mathrm{CO}_{2}$

## Chapter 19

Sample Exercise 19.1
Practice Exercise 2: No, the reverse process is spontaneous at this temperature.

Sample Exercise 19.2
Practice Exercise 2: -163 J/K
Sample Exercise 19.3
Practice Exercise 2: no
Sample Exercise 19.4
Practice Exercise 2: (a) 1 mol of $\mathrm{SO}_{2}(g)$ at STP, (b) 2 mol of $\mathrm{NO}_{2}(g)$ at STP

## Sample Exercise 19.5

Practice Exercise 2: $180.39 \mathrm{~J} / \mathrm{K}$
Sample Exercise 19.6
Practice Exercise 2: $\Delta G^{\circ}=-14.7 \mathrm{~kJ}$; the reaction is spontaneous.
Sample Exercise 19.7
Practice Exercise 2: -800.7 kJ
Sample Exercise 19.8
Practice Exercise 2: More negative
Sample Exercise 19.9
Practice Exercise 2:
(a) $\Delta H^{\circ}=-196.6 \mathrm{~kJ}, \Delta S^{\circ}=-189.6 \mathrm{~J} / \mathrm{K}$;
(b) $\Delta G^{\circ}=-120.8 \mathrm{~kJ}$

Sample Exercise 19.10
Practice Exercise 2: 330 K
Sample Exercise 19.11
Practice Exercise 2: $-49.0 \mathrm{~kJ} / \mathrm{mol}$
Sample Exercise 19.12
Practice Exercise 2: $\Delta G^{\circ}=-106.4 \mathrm{~kJ} / \mathrm{mol}, K=4 \times 10^{18}$

## Chapter 20

Sample Exercise 20.1
Practice Exercise 2: $\mathrm{Al}(s)$ is the reducing agent; $\mathrm{MnO}_{4}^{-}(a q)$ is the oxidizing agent.

Sample Exercise 20.2
Practice Exercise 2: $\mathrm{Cu}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q) \longrightarrow$
$\mathrm{Cu}^{2+}(a q)+2 \mathrm{NO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$
Sample Exercise 20.3
Practice Exercise 2: $2 \mathrm{Cr}(\mathrm{OH})_{3}(s)+6 \mathrm{ClO}^{-}(a q) \longrightarrow$
$2 \mathrm{CrO}_{4}{ }^{2-}(a q)+3 \mathrm{Cl}_{2}(g)+2 \mathrm{OH}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)$
Sample Exercise 20.4
Practice Exercise 2: (a) The first reaction occurs at the anode and the second reaction at the cathode. (b) Zinc is oxidized to form $\mathrm{Zn}^{2+}$ as the reaction proceeds and therefore the zinc electrode loses mass. (c) The platinum electrode is not involved in the reaction and none of the products of the reaction at the cathode are solids, so the mass of platinum electrode does not change. (d) The platinum cathode is positive.

Sample Exercise 20.5
Practice Exercise 2: -0.40 V
Sample Exercise 20.6
Practice Exercise 2: 2.20 V
Sample Exercise 20.7
Practice Exercise 2: (a) Co $\longrightarrow \mathrm{Co}^{2+}+2 \mathrm{e}^{-} ;(\mathbf{b})+0.50 \mathrm{~V}$
Sample Exercise 20.8
Practice Exercise 2: $\mathrm{Al}(s)>\mathrm{Fe}(s)>\mathrm{I}^{-}(a q)$
Sample Exercise 20.9
Practice Exercise 2: Reactions (b) and (c) are spontaneous.
Sample Exercise 20.10
Practice Exercise 2: $+77 \mathrm{~kJ} / \mathrm{mol}$
Sample Exercise 20.11
Practice Exercise 2: It would increase.

## Sample Exercise 20.12

Practice Exercise 2: $\mathrm{pH}=4.23$ (using data from Appendix E to obtain $E^{\circ}$ to three significant figures)

## Sample Exercise 20.13

Practice Exercise 2: (a) The anode is the half-cell in which $\left[\mathrm{Zn}^{2+}\right]=$ $3.75 \times 10^{-4} \mathrm{M}$. (b) The emf is 0.105 V .
Sample Exercise 20.14
Practice Exercise 2: (a) 30.2 g of Mg , (b) $3.97 \times 10^{3} \mathrm{~s}$

## Chapter 21

Sample Exercise 21.1
Practice Exercise 2: ${ }_{84}^{212} \mathrm{Po}$
Sample Exercise 21.2
Practice Exercise 2: ${ }_{8}^{15} \mathrm{O} \longrightarrow{ }_{7}^{15} \mathrm{~N}+{ }_{+1}^{0} \mathrm{e}$
Sample Exercise 21.3
Practice Exercise 2: (a) $\alpha$ emission, (b) $\beta^{-}$emission
Sample Exercise 21.4
Practice Exercise 2: ${ }_{8}^{16} \mathrm{O}(\mathrm{p}, \alpha){ }_{7}^{13} \mathrm{~N}$
Sample Exercise 21.5
Practice Exercise 2: 3.12\%
Sample Exercise 21.6
Practice Exercise 2: 2200 yr
Sample Exercise 21.7
Practice Exercise 2: 15.1\%
Sample Exercise 21.8
Practice Exercise 2: $-3.19 \times 10^{-3} \mathrm{~g}$

## Chapter 22

Sample Exercise 22.1
Practice Exercise 2: (a) Cs, (b) Cl, (c) C, (d) Sb
Sample Exercise 22.2
Practice Exercise 2: $\mathrm{NaH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)$
Sample Exercise 22.3
Practice Exercise 2: trigonal bipyramidal, linear
Sample Exercise 22.4
Practice Exercise 2: $2 \mathrm{Br}^{-}(a q)+\mathrm{Cl}_{2}(a q) \longrightarrow \mathrm{Br}_{2}(a q)+2 \mathrm{Cl}^{-}(a q)$
Sample Exercise 22.5
Practice Exercise 2: $5 \mathrm{~N}_{2} \mathrm{O}_{4}(l)+4 \mathrm{~N}_{2} \mathrm{H}_{3} \mathrm{CH}_{3}(l) \longrightarrow 9 \mathrm{~N}_{2}(g)+$ $4 \mathrm{CO}_{2}(g)+12 \mathrm{H}_{2} \mathrm{O}(g)$
Sample Exercise 22.6
Practice Exercise 2: 6-

## Chapter 23

Sample Exercise 23.1
Practice Exercise 2: three: $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ and two $\mathrm{Cl}^{-}$
Sample Exercise 23.2
Practice Exercise 2: zero
Sample Exercise 23.3
Practice Exercise 2: (a) triamminetribromomolybdenum(IV) nitrate, (b) ammonium tetrabromocuprate(II), (c) $\mathrm{Na}\left[\mathrm{Ru}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{2}\right]$

## Sample Exercise 23.4

Practice Exercise 2: two

## Sample Exercise 23.5

Practice Exercise 2: No, because the complex is flat. This complex ion does, however, have geometric isomers (for example, the Cl and Br ligands could be cis or trans).

## Sample Exercise 23.6

Practice Exercise 2: Green, because it absorbs the green's complimentary color, red.

Sample Exercise 23.7
Practice Exercise 2: $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$ is purple which means it must absorb light near the boundary between the yellow and green regions of the spectrum. $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ is orange which means it absorbs blue light. Because yellow-green photons have a lower energy (longer wavelength) than blue photons, $\Delta$ is smaller for $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$. This prediction is consistent with the spectrochemical series because $\mathrm{Cl}^{-}$ligands are at the low end of the spectrochemical series. Thus replacing $\mathrm{NH}_{3}$ with $\mathrm{Cl}^{-}$should make $\Delta$ smaller.

## Sample Exercise 23.8

Practice Exercise 2: No it is not possible to have a diamagnetic complex with partially filled $d$ orbitals if the complex is high spin, and all tetrahedral complexes are high spin.

## Sample Exercise 24.3

Practice Exercise 2: five (1-hexene, cis-2-hexene, trans-2-hexene, cis-3-hexene, trans-3-hexene)

## Sample Exercise 24.4

Practice Exercise 2:

Sample Exercise 24.5
Practice Exercise 2: propene
Sample Exercise 24.6
Practice Exercise 2:

## Sample Exercise 24.7

Practice Exercise 2: serylaspartic acid; Ser-Asp, SD
Sample Exercise 24.8
Practice Exercise 2: alcohol, ether

## Chapter 24

## Sample Exercise 24.1

Practice Exercise 2: 2,4-dimethylpentane
Sample Exercise 24.2
Practice Exercise 2:

## GLOSSARY

absolute zero The temperature at which all thermal motion ceases: 0 K on the Kelvin scale and $-273.15^{\circ} \mathrm{C}$ on the Celsius scale. (Section 1.5)
absorption spectrum A pattern of variation in the amount of light absorbed by a sample as a function of wavelength. (Section 23.5)
accuracy A measure of how closely individual measurements agree with the correct, or "true," value. (Section 1.6)
acid A substance that is able to donate a $\mathrm{H}^{+}$ion (a proton) and, hence, increases the concentration of $\mathrm{H}^{+}(a q)$ when it dissolves in water. (Section 4.3)
acid-dissociation constant ( $K_{\mathrm{a}}$ ) An equilibrium constant that expresses the extent to which an acid transfers a proton to solvent water. (Section 16.6)
acidic anhydride (acidic oxide) An oxide that forms an acid when added to water; soluble nonmetal oxides are acidic anhydrides. (Section 22.5)
acidic oxide (acidic anhydride) An oxide that reacts either with a base to form a salt or with water to form an acid. (Section 22.5)
acid rain Rainwater that has become excessively acidic because of absorption of pollutant oxides, notably $\mathrm{SO}_{3}$, produced by human activities. (Section 18.2)
actinide element Element in which the 5 forbitals are only partially occupied. (Section 6.8)
activated complex (transition state) The particular arrangement of atoms found at the top of the potential-energy barrier as a reaction proceeds from reactants to products. (Section 14.5)
activation energy ( $E_{\mathrm{a}}$ ) The minimum energy needed for reaction; the height of the energy barrier to formation of products. (Section 14.5)
active site Specific site on a heterogeneous catalyst or an enzyme where catalysis occurs. (Section 14.7)
activity The decay rate of a radioactive material, generally expressed as the number of disintegrations per unit time. (Section 21.4)
activity series A list of metals in order of decreasing ease of oxidation. (Section 4.4)
addition polymerization Polymerization in which monomers are coupled through their multiple bonds. (Section 12.8)
addition reaction A reaction in which a reagent adds to the two carbon atoms of a carbon-carbon multiple bond. (Section 24.3) adsorption The binding of molecules to a surface. (Section 14.7)
alcohol An organic compound obtained by substituting a hydroxyl group ( -OH ) for a hydrogen on a hydrocarbon. (Sections 2.9 and 24.4)
aldehyde An organic compound that contains a carbonyl group $(\mathrm{C}=\mathrm{O})$ to which at least one hydrogen atom is attached. (Section 24.4)
alkali metals Members of group 1 in the periodic table. (Section 7.7)
alkaline earth metals Members of group 2 in the periodic table. (Section 7.7)
alkanes Compounds of carbon and hydrogen containing only carbon-carbon single bonds. (Sections 2.9 and 24.2)
alkenes Hydrocarbons containing one or more carbon-carbon double bonds. (Section 24.2)
alkyl group A group that is formed by removing a hydrogen atom from an alkane. (Section 24.2)
alkynes Hydrocarbons containing one or more carbon-carbon triple bonds. (Section 24.2)
alloy A substance that has the characteristic properties of a metal and contains more than one element. Often there is one principal metallic component, with other elements present in smaller amounts. Alloys may be homogeneous or heterogeneous. (Section 12.3)
alpha emission A type of radioactive decay in which an atomic nucleus emits an alpha particle and thereby transforms (or "decays") into an atom with a mass number 4 less and atomic number 2 less. (Section 21.1)
alpha $(\alpha)$ helix A protein structure in which the protein is coiled in the form of a helix with hydrogen bonds between $\mathrm{C}=\mathrm{O}$ and $\mathrm{N}-\mathrm{H}$ groups on adjacent turns. (Section 24.7)
alpha particles Particles that are identical to helium-4 nuclei, consisting of two protons and two neutrons, symbol ${ }_{2}^{4} \mathrm{He}$ or ${ }_{2}^{4} \alpha$. (Section 21.1)
amide An organic compound that has an $\mathrm{NR}_{2}$ group attached to a carbonyl, where R may be H or a hydrocarbon group.
(Section 24.4)
amine A compound that has the general formula $\mathrm{R}_{3} \mathrm{~N}$, where R may be H or a hydrocarbon group. (Section 16.7)
amino acid A carboxylic acid that contains an amino ( $-\mathrm{NH}_{2}$ ) group attached to the carbon atom adjacent to the carboxylic acid ( -COOH ) functional group. (Section 24.7)
amorphous solid A solid whose molecular arrangement lacks the order (regularly repeating long-range pattern) of a crystal. (Section 12.2)
amphiprotic Refers to the capacity of a substance to either add or lose a proton $\left(\mathrm{H}^{+}\right)$. (Section 16.2)
amphoteric oxides and hydroxides Oxides and hydroxides that are only slightly soluble in water but that dissolve in either acidic or basic solutions. (Section 17.5)
angstrom A common non-SI unit of length, denoted $\AA$, that is used to measure atomic dimensions: $1 \AA=10^{-10} \mathrm{~m}$. (Section 2.3)
anion A negatively charged ion. (Section 2.7)
anode An electrode at which oxidation occurs. (Section 20.3)
antibonding molecular orbital A molecular orbital in which electron density is concentrated outside the region between the two nuclei of bonded atoms. Such orbitals, designated as $\sigma^{*}$ or $\pi^{*}$, are less stable (of higher energy) than bonding molecular orbitals. (Section 9.7)
antiferromagnetism A form of magnetism in which unpaired electron spins on adjacent sites point in opposite directions and cancel each other's effects. (Section 23.1)
aqueous solution A solution in which water is the solvent.
(Chapter 4: Introduction)
aromatic hydrocarbons Hydrocarbon compounds that contain a planar, cyclic arrangement of carbon atoms linked by both $\sigma$ and delocalized $\pi$ bonds. (Section 24.2)

Arrhenius equation An equation that relates the rate constant for a reaction to the frequency factor, $A$, the activation energy, $E_{a}$, and the temperature, $T: k=A e^{-E_{a} / R T}$. In its logarithmic form it is written $\ln k=-E_{a} / R T+\ln A$. (Section 14.5)
atmosphere (atm) A unit of pressure equal to 760 torr; $1 \mathrm{~atm}=101.325 \mathrm{kPa}$. (Section 10.2)
atom The smallest representative particle of an element. The almost infinitesimally small building blocks of matter. (Sections 1.1 and 2.1)
atomic mass unit (amu) A unit based on the value of exactly 12 amu for the mass of the isotope of carbon that has six protons and six neutrons in the nucleus; $1 \mathrm{amu}=1.66054 \times 10^{-24} \mathrm{~g}$. (Sections 2.3 and 2.4)
atomic number The number of protons in the nucleus of an atom of an element. (Section 2.3)
atomic radius An estimate of the size of an atom. See bonding atomic radius. (Section 7.3)
atomic weight The average mass of the atoms of an element in atomic mass units (amu); it is numerically equal to the mass in grams of one mole of the element. (Section 2.4)
autoionization The process whereby water spontaneously forms low concentrations of $\mathrm{H}^{+}(a q)$ and $\mathrm{OH}^{-}(a q)$ ions by proton transfer from one water molecule to another. (Section 16.3)
Avogadro's hypothesis A statement that equal volumes of gases at the same temperature and pressure contain equal numbers of molecules. (Section 10.3)

Avogadro's law A statement that the volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas. (Section 10.3)

Avogadro's number ( $N_{A}$ ) The number of ${ }^{12} \mathrm{C}$ atoms in exactly 12 g of ${ }^{12} \mathrm{C}$; it equals $6.022 \times 10^{23} \mathrm{~mol}^{-1}$. (Section 3.4)
ball-and-stick model Model that depicts atoms as spheres and bonds as sticks. (Section 2.6)
band An array of closely spaced molecular orbitals occupying a continuous range of energy. (Section 12.4)
band gap The energy gap between a fully occupied valence band and an empty conduction band. (Section 12.7)
band structure The electronic structure of a bulk solid.
(Section 12.4)
bar A unit of pressure equal to $10^{5} \mathrm{~Pa}$. (Section 10.2)
base A substance that is an $\mathrm{H}^{+}$acceptor; a base produces an excess of $\mathrm{OH}^{-}(a q)$ ions when it dissolves in water. (Section 4.3)
base-dissociation constant ( $K_{\mathrm{b}}$ ) An equilibrium constant that expresses the extent to which a base reacts with solvent water, accepting a proton and forming $\mathrm{OH}^{-}(a q)$. (Section 16.7)
basic anhydride (basic oxide) An oxide that forms a base when added to water; soluble metal oxides are basic anhydrides.
(Section 22.5)
basic oxide (basic anhydride) An oxide that either reacts with water to form a base or reacts with an acid to form a salt and water. (Section 22.5)
battery A portable, self-contained electrochemical power source that contains one or more voltaic cells. (Section 20.7)
becquerel The SI unit of radioactivity. It corresponds to one nuclear disintegration per second. (Section 21.4)

Beer's law The light absorbed by a substance $(A)$ equals the product of its extinction coefficient ( $\varepsilon$ ), the path length through which the light passes (b), and the molar concentration of the substance (c): $A=\varepsilon b c$. (Section 14.3)
beta emission A nuclear decay process where a beta particle is emitted from the nucleus; also called beta decay. (Section 21.1)
beta particles Energetic electrons emitted from the nucleus, symbol ${ }_{1} \mathrm{e}$ or $\beta^{-}$. (Section 21.1)
beta sheet A structural form of protein in which sheets are made of two or more strands of peptides that hydrogen-bond from an amide H in one strand to a carbonyl O in the other strand. (Section 24.7)
bidentate ligand A ligand in which two linked coordinating atoms are bound to a metal. (Section 23.3)
bimolecular reaction An elementary reaction that involves two molecules. (Section 14.6)
biochemistry The study of the chemistry of living systems. (Chapter 24: Introduction)
biodegradable Organic material that bacteria are able to oxidize. (Section 18.4)
biopolymers Three broad categories of polymers: proteins, polysaccharides (carbohydrates), and nucleic acids.
(Section 24.6)
body-centered lattice A crystal lattice in which the lattice points are located at the center and corners of each unit cell. (Section 12.2)
bomb calorimeter A device for measuring the heat evolved in the combustion of a substance under constant-volume conditions. (Section 5.5)
bond angles The angles made by the lines joining the nuclei of the atoms in a molecule. (Section 9.1)
bond dipole The dipole moment that is due only to unequal electron sharing between two atoms in a covalent bond. (Section 9.3)
bond enthalpy The enthalpy change, $\Delta H$, required to break a particular bond when the substance is in the gas phase. (Section 5.8)
bonding atomic radius The radius of an atom as defined by the distances separating it from other atoms to which it is chemically bonded. (Section 7.3)
bonding molecular orbital A molecular orbital in which the electron density is concentrated in the internuclear region. The energy of a bonding molecular orbital is lower than the energy of the separate atomic orbitals from which it forms. (Section 9.7)
bonding pair In a Lewis structure, a pair of electrons that is shared by two atoms. (Section 8.3)
bond length The distance between the centers of two bonded atoms. (Section 8.3)
bond order The number of bonding electron pairs shared between two atoms, minus the number of antibonding electron pairs: bond order $=$ (number of bonding electrons - number of antibonding electrons)/2. (Section 9.7)
bond polarity A measure of the degree to which the electrons are shared unequally between two atoms in a chemical bond. (Section 8.4)
boranes Molecules containing only boron and hydrogen; covalent hydrides of boron. (Section 22.11)
Born-Haber cycle A thermodynamic cycle based on Hess's law that relates the lattice energy of an ionic substance to its enthalpy of formation and to other measurable quantities. (Section 8.2)

Boyle's law A law stating that at constant temperature, the product of the volume and pressure of a given amount of gas is a constant. (Section 10.3)

Brønsted-Lowry acid A substance (molecule or ion) that acts as a proton donor. (Section 16.2)
Brønsted-Lowry base A substance (molecule or ion) that acts as a proton acceptor. (Section 16.2)
Brownian motion The random motion of colloidal particles in solution due to collisions with solvent molecules. (Section 13.6)
buffer capacity The amount of acid or base a buffer can neutralize before the pH begins to change appreciably. (Section 17.2)
buffered solution (buffer) A solution that undergoes a limited change in pH upon addition of a small amount of acid or base. (Section 17.2)
calorie A unit of energy; it is the amount of energy needed to raise the temperature of 1 g of water by $1^{\circ} \mathrm{C}$ from $14.5^{\circ} \mathrm{C}$ to $15.5^{\circ} \mathrm{C}$. A related unit is the joule: $1 \mathrm{cal}=4.184 \mathrm{~J}$. (Section 1.5)
calorimeter An apparatus that measures the heat released or absorbed in a chemical or physical process. (Section 5.5)
calorimetry The experimental measurement of heat produced in chemical and physical processes. (Section 5.5)
capillary action The process by which a liquid rises in a tube because of a combination of adhesion to the walls of the tube and cohesion between liquid particles. (Section 11.3)
carbide A binary compound of carbon with a metal or metalloid. (Section 22.9)
carbohydrates A class of substances formed from polyhydroxy aldehydes or ketones. (Section 24.8)
carbon black An amorphous form of carbon. (Section 22.9)
carbonyl group The $\mathrm{C}=\mathrm{O}$ double bond, a characteristic feature of several organic functional groups, such as ketones and aldehydes. (Section 24.4)
carboxylic acid An acid that contains the -COOH functional group. (Sections 16.10 and 24.4)
catalyst A substance that changes the speed of a chemical reaction without itself undergoing a permanent chemical change in the process. (Section 14.7)
cathode An electrode at which reduction occurs. (Section 20.3)
cathode rays Streams of electrons that are produced when a high voltage is applied to electrodes in an evacuated tube. (Section 2.2)
cathodic protection A means of protecting a metal against corrosion by making it the cathode in a voltaic cell. This can be achieved by attaching a more easily oxidized metal, which serves as an anode, to the metal to be protected. (Section 20.8)
cation A positively charged ion. (Section 2.7)
cell potential The potential difference between the cathode and anode in an electrochemical cell; it is measured in volts: $1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}$. Also called electromotive force. (Section 20.4)
cellulose A polysaccharide of glucose; it is the major structural element in plant matter. (Section 24.8)

Celsius scale A temperature scale on which water freezes at $0^{\circ}$ and boils at $100^{\circ}$ at sea level. (Section 1.5)
chain reaction A series of reactions in which one reaction initiates the next. (Section 21.7)
changes of state Physical changes of matter from one state to a different one, for example, from a gas to a liquid. (Section 1.3)
charcoal An amorphous form of carbon produced when wood is heated strongly in a deficiency of air. (Section 22.9)

Charles's law A law stating that at constant pressure, the volume of a given quantity of gas is proportional to absolute temperature. (Section 10.3)
chelate effect The generally larger formation constants for bidentate and polydentate ligands as compared with the corresponding monodentate ligands. (Section 23.3)
chelating agent Bidentate and polydentate ligands capable of occupying two or more sites in the coordination sphere. (Section 23.3)
chemical bond A strong attractive force that exists between atoms in a molecule. (Chapter 8: Introduction)
chemical changes Processes in which a substance is transformed into a chemically different substance; also called chemical reactions. (Section 1.3)
chemical equation A representation of a chemical reaction using the chemical formulas of the reactants and products; a balanced chemical equation contains equal numbers of atoms of each element on both sides of the equation. (Section 3.1)
chemical equilibrium A state of dynamic balance in which the rate of formation of the products of a reaction from the reactants
equals the rate of formation of the reactants from the products; at equilibrium the concentrations of the reactants and products remain constant. (Section 4.1; Chapter 15: Introduction)
chemical formula A notation that uses chemical symbols with numerical subscripts to convey the relative proportions of atoms of the different elements in a substance. (Section 2.6)
chemical kinetics The area of chemistry concerned with the speeds, or rates, at which chemical reactions occur. (Chapter 14: Introduction)
chemical nomenclature The rules used in naming substances. (Section 2.8)
chemical properties Properties that describe the way a substance may change, or react, to form other substances. (Section 1.3)
chemical reactions Processes in which a substance is transformed into a chemically different substance; also called chemical changes. (Section 1.3)
chemistry The scientific discipline that studies matter, its properties, and the changes that matter undergoes. (Chapter 1: Introduction)
chiral A term describing a molecule or an ion that cannot be superimposed on its mirror image. (Sections 23.4 and 24.5)
chlorofluorocarbons Ozone-damaging substances, principally $\mathrm{CFCl}_{3}$ and $\mathrm{CF}_{2} \mathrm{Cl}_{2}$, that were once widely used as propellants in spray cans. They do not occur in nature. (Section 18.3)
chlorophyll A plant pigment that plays a major role in conversion of solar energy to chemical energy in photosynthesis. (Section 23.3)
cholesteric liquid crystal A liquid crystal having molecules arranged in layers, with their long axes parallel to the other molecules within the same layer. Moving from one layer to the next, the orientation of the molecules rotates by a fixed angle, resulting in a spiral pattern. (Section 11.7)
coal A naturally occurring solid containing hydrocarbons of high molecular weight, as well as compounds containing sulfur, oxygen, and nitrogen. (Section 5.8)
colligative property A property of a solvent (vapor-pressure lowering, freezing-point lowering, boiling-point elevation, osmotic pressure) that depends on the total concentration of solute particles present. (Section 13.5)
collision model A model of reaction rates based on the idea that molecules must collide to react; it explains the factors influencing reaction rates in terms of the frequency of collisions, the number of collisions with energies exceeding the activation energy, and the probability that the collisions occur with suitable orientations. (Section 14.5)
colloids (colloidal dispersions) Mixtures containing particles larger than normal solutes but small enough to remain suspended in the dispersing medium. (Section 13.6)
combination reaction A chemical reaction in which two or more substances combine to form a single product. (Section 3.2)
combustion reaction A chemical reaction that proceeds with evolution of heat and usually also a flame; most combustion
involves reaction with oxygen, as in the burning of a match. (Section 3.2)
common-ion effect A shift of an equilibrium induced by an ion common to the equilibrium. Whenever a weak electrolyte and a strong electrolyte containing a common ion are together in solution, the weak electrolyte ionizes less than it would if it were alone in solution. (Section 17.1)
complementary colors Colors that, when mixed in proper proportions, appear white or colorless. For example, orange and blue are complementary colors that form white light when mixed; when blue is removed, the light looks orange. (Section 23.5)
complete ionic equation A chemical equation in which dissolved strong electrolytes (such as dissolved ionic compounds) are written as separate ions. (Section 4.2)
complex ion (complex) An assembly of a metal ion and the Lewis bases bonded to it. (Section 17.5)
compound A substance composed of two or more elements united chemically in definite proportions. (Section 1.2)
concentration The quantity of solute present in a given quantity of solvent or solution. (Section 4.5)
concentration cell A voltaic cell containing the same electrolyte and the same electrode materials in both the anode and cathode compartments. The emf of the cell is derived from a difference in the concentrations of the same electrolyte solutions in the compartments. (Section 20.6)
condensation polymerization Polymerization in which two molecules are joined to form a larger molecule by elimination of a small molecule, such as $\mathrm{H}_{2} \mathrm{O}$. (Section 12.8)
condensation reaction A reaction in which two molecules are joined to form a larger molecule by elimination of a small molecule, such as $\mathrm{H}_{2} \mathrm{O}$. (Section 12.8)
conduction band A band of unoccupied antibonding molecular orbitals lying higher in energy than the occupied valence band and distinctly separated from it. (Section 12.7)
conjugate acid A substance formed by addition of a proton to a Brønsted-Lowry base. (Section 16.2)
conjugate acid-base pair An acid and a base, such as $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{OH}^{-}$, that differ only in the presence or absence of a proton. (Section 16.2)
conjugate base A substance formed by the loss of a proton from a Brønsted-Lowry acid. (Section 16.2)
continuous spectrum A spectrum that contains radiation distributed over all wavelengths. (Section 6.3)
conversion factor A fraction whose numerator and denominator are the same quantity expressed in different units. (Section 1.7)
coordination compound A compound containing a complex. (Section 23.2)
coordination number The number of adjacent atoms in a crystal structure to which an atom is directly bonded. In a complex, the coordination number of the metal ion is the number of atoms bonded to the metal ion. (Sections 12.3 and 24.2)
coordination sphere The central metal ion and its surrounding ligands. (Section 23.2)
coordination-sphere isomers Structural isomers that differ in which species in the complex are ligands and which are outside the coordination sphere in the solid. (Section 23.4)
copolymer A complex polymer resulting from the polymerization of two or more chemically different monomers. (Section 12.8)
core electrons The electrons that are not in the outermost shell of an atom. (Section 6.8)
corrosion Spontaneous redox reactions in which a metal is attacked by some substance in its environment and converted to an unwanted compound. (Section 20.8)
covalent bond A bond formed between two or more atoms by a sharing of electrons. (Chapter 8: Introduction)
covalent-network solids Solids that are held together by an extended network of covalent bonds. (Sections 12.1 and 12.7)
critical mass The amount of fissionable material necessary to maintain a nuclear chain reaction. (Section 21.7)
critical point The temperature and pressure beyond which the liquid and gas phases are indistinguishable from each other. (Section 11.6)
critical pressure The pressure at which a gas at its critical temperature is converted to a liquid state. (Section 11.4)
critical temperature The highest temperature at which a distinct liquid phase can form. The critical temperature increases with an increase in the magnitude of intermolecular forces. (Section 11.4)
cross-linking A method of stiffening polymers by introducing chemical bonds between chains. (Section 12.8)
crystal-field theory A theory that accounts for the colors and the magnetic and other properties of transition-metal complexes in terms of the splitting of the energies of metal ion $d$ orbitals by the electrostatic interaction with the ligands. (Section 23.6)
crystal lattice The geometrical pattern of points on which the unit cells are arranged; in effect, an abstract (that is, not real) scaffolding for the crystal structure. (Section 12.2)
crystalline solid (crystal) A solid whose internal arrangement of atoms, molecules, or ions possesses a regularly repeating pattern in any direction through the solid. (Section 12.2)
crystallinity A measure of the extent of short-range ordering in a polymer where chains line up in regular arrays. (Section 12.8)
crystallization The process in which molecules, ions, or atoms come together to form a crystalline solid. The opposite of the solution process. (Section 13.2)
cubic close packing A crystal structure where the atoms are packed together as close as possible, and the close-packed layers of atoms adopt a three-layer repeating pattern that leads to a face-centered cubic unit cell. (Section 12.3)
curie A measure of radioactivity: 1 curie $=3.7 \times 10^{10}$ nuclear disintegrations per second. (Section 21.4)
cycloalkanes Saturated hydrocarbons of general formula $\mathrm{C}_{n} \mathrm{H}_{2 n}$ in which the carbon atoms form a closed ring. (Section 24.2)

Dalton's law of partial pressures A law stating that the total pressure of a mixture of gases is the sum of the pressures that each gas would exert if it were present alone. (Section 10.6)
$d-d$ transition The transition of an electron in a transition-metal compound from a lower-energy $d$ orbital to a higher-energy $d$ orbital. (Section 23.6)
decomposition reaction A chemical reaction in which a single compound reacts to give two or more products. (Section 3.2)
degenerate A situation in which two or more orbitals have the same energy. (Section 6.7)
delocalized electrons Electrons that are spread over a number of atoms in a molecule or a crystal rather than localized on a single atom or a pair of atoms. (Section 9.6)
density The amount of mass in a unit volume of a substance. (Section 1.5)
deoxyribonucleic acid (DNA) A polynucleotide in which the sugar component is deoxyribose. (Section 24.10)
derived unit An SI unit obtained by multiplication or division of one or more of the SI base units. (Section 1.5)
desalination The removal of salts from seawater, brine, or brackish water to make it fit for human consumption. (Section 18.4)
deuterium The isotope of hydrogen whose nucleus contains a proton and a neutron: ${ }_{1}^{2} \mathrm{H}$. (Section 22.2)
dextrorotatory, or merely dextro or $d$ A term used to label a chiral molecule that rotates the plane of polarization of planepolarized light to the right (clockwise). (Section 23.4)
diamagnetism A type of magnetism that causes a substance with no unpaired electrons to be weakly repelled from a magnetic field. (Section 9.8)
diatomic molecule A molecule composed of only two atoms. (Section 2.6)
diffusion The spreading of one substance throughout a space or throughout a second substance. (Section 10.8)
dilution The process of preparing a less concentrated solution from a more concentrated one by adding solvent. (Section 4.5)
dimensional analysis A method of problem solving in which units are multiplied together or divided into each other along with the numerical values. Dimensional analysis ensures that the final answer of a calculation has the desired units. (Section 1.7)
dipole A molecule with one end having a partial negative charge and the other end having a partial positive charge; a polar molecule. (Section 8.4)
dipole-dipole interactions A force that becomes significant when polar molecules come in close contact with one another. The force is attractive when the positive end of one polar molecule approaches the negative end of another. (Section 11.2)
dipole moment A measure of the separation and magnitude of the positive and negative charges in polar molecules. (Section 8.4)
disaccharide Two monosaccharide units linked together by a condensation reaction. (Section 24.8)
dispersion forces Intermolecular forces resulting from attractions between induced dipoles. Also called London dispersion forces. (Section 11.2)
displacement reaction A reaction in which an ion in solution is displaced (replaced) through oxidation of an element. (Section 4.4)
disproportionation reaction A reaction in which an element is simultaneously oxidized and reduced. (Section 22.5)
distillation A separation process that depends on the different abilities of substances to form gases. (Section 1.3)
donor atom The atom of a ligand that bonds to the central metal ion in a coordination complex. (Section 23.2)
doping The process of adding controlled amounts of impurity atoms to a material. For example, incorporation of P into Si . (Section 12.7)
double bond A covalent bond involving two electron pairs. (Section 8.3)
double helix The structure for DNA that involves the winding of two DNA polynucleotide chains together in a helical arrangement. The two strands of the double helix are complementary in that the organic bases on the two strands are paired for optimal hydrogen bond interaction. (Section 24.10)
dynamic equilibrium A state of balance in which opposing processes occur at the same rate. (Section 11.5)
effective nuclear charge The net positive charge experienced by an electron in a many-electron atom; this charge is not the full nuclear charge because there is some shielding of the nucleus by the other electrons in the atom. (Section 7.2)
effusion The escape of a gas through an orifice or hole. (Section 10.8)
elastomer A material that can undergo a substantial change in shape via stretching, bending, or compression and return to its original shape upon release of the distorting force. (Section 12.8)
electrochemistry The branch of chemistry that deals with the relationships between electricity and chemical reactions. (Chapter 20: Introduction)
electrolysis reaction A reaction in which a nonspontaneous redox reaction is brought about by the passage of current under a sufficient external electrical potential. The devices in which electrolysis reactions occur are called electrolytic cells. (Section 20.9)
electrolyte A solute that produces ions in solution; an electrolytic solution conducts an electric current. (Section 4.1)
electrolytic cell A device in which a nonspontaneous oxidationreduction reaction is caused to occur by passage of current under a sufficient external electrical potential. (Section 20.9)
electromagnetic radiation (radiant energy) A form of energy that has wave characteristics and that propagates through a vacuum at the characteristic speed of $3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$. (Section 6.1)
electrometallurgy The use of electrolysis to reduce or refine metals. (Section 20.9)
electromotive force (emf) A measure of the driving force, or electrical pressure, for the completion of an electrochemical
reaction. Electromotive force is measured in volts: $1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}$. Also called the cell potential. (Section 20.4)
electron A negatively charged subatomic particle found outside the atomic nucleus; it is a part of all atoms. (Section 2.2)
electron affinity The energy change that occurs when an electron is added to a gaseous atom or ion. (Section 7.5)
electron capture A mode of radioactive decay in which an innershell orbital electron is captured by the nucleus. (Section 21.1)
electron configuration The arrangement of electrons in the orbitals of an atom or molecule (Section 6.8)
electron density The probability of finding an electron at any particular point in an atom; this probability is equal to $\psi^{2}$, the square of the wave function. Also called the probability density. (Section 6.5)
electron domain In the VSEPR model, a region about a central atom in which an electron pair is concentrated. (Section 9.2)
electron-domain geometry The three-dimensional arrangement of the electron domains around an atom according to the VSEPR model. (Section 9.2)
electronegativity A measure of the ability of an atom that is bonded to another atom to attract electrons to itself. (Section 8.4)
electronic charge The negative charge carried by an electron; it has a magnitude of $1.602 \times 10^{-19} \mathrm{C}$. (Section 2.3)
electronic structure The arrangement of electrons in an atom or molecule. (Chapter 6: Introduction)
electron-sea model A model for the behavior of electrons in metals. (Section 12.4)
electron shell A collection of orbitals that have the same value of $n$. For example, the orbitals with $n=3$ (the $3 s, 3 p$, and $3 d$ orbitals) comprise the third shell. (Section 6.5)
electron spin A property of the electron that makes it behave as though it were a tiny magnet. The electron behaves as if it were spinning on its axis; electron spin is quantized. (Section 6.7)
element A substance that cannot be decomposed into simpler substances. (Sections 1.1 and 1.2)
elemental composition The percentage composition of an element in a substance. (Section 3.3)
elementary reaction A process in a chemical reaction that occurs in a single step. An overall chemical reaction consists of one or more elementary reactions or steps. (Section 14.6)
empirical formula A chemical formula that shows the kinds of atoms and their relative numbers in a substance in the smallest possible whole-number ratios. (Section 2.6)
enantiomers Two mirror-image molecules of a chiral substance. The enantiomers are nonsuperimposable. (Section 23.4)
endothermic process A process in which a system absorbs heat from its surroundings. (Section 5.2)
energy The capacity to do work or to transfer heat. (Section 1.4)
energy-level diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which
they are derived. Also called a molecular-orbital diagram. (Section 9.7)
enthalpy A quantity defined by the relationship $H=E+P V$; the enthalpy change, $\Delta H$, for a reaction that occurs at constant pressure is the heat evolved or absorbed in the reaction: $\Delta H=q_{p}$. (Section 5.3)
enthalpy of formation The enthalpy change that accompanies the formation of a substance from the most stable forms of its component elements. (Section 5.7)
enthalpy of reaction The enthalpy change associated with a chemical reaction. (Section 5.4)
entropy A measure of the tendency for energy to spread or disperse, thereby reducing its ability to accomplish work. In a general sense, it reflects the degree of randomness or disorder associated with the particles that carry the energy. (Section 19.2)
enzyme A protein molecule that acts to catalyze specific biochemical reactions. (Section 14.7)
equilibrium constant The numerical value of
the equilibrium-constant expression for a system at equilibrium. The equilibrium constant is most usually denoted by $\kappa_{p}$ for gasphase systems or $K_{c}$ for solution-phase systems. (Section 15.2)
equilibrium-constant expression The expression that describes the relationship among the concentrations (or partial pressures) of the substances present in a system at equilibrium. The numerator is obtained by multiplying the concentrations of the substances on the product side of the equation, each raised to a power equal to its coefficient in the chemical equation. The denominator similarly contains the concentrations of the substances on the reactant side of the equation. (Section 15.2)
equivalence point The point in a titration at which the added solute reacts completely with the solute present in the solution. (Section 4.6)
ester An organic compound that has an OR group attached to a carbonyl; it is the product of a reaction between a carboxylic acid and an alcohol. (Section 24.4)
ether A compound in which two hydrocarbon groups are bonded to one oxygen. (Section 24.4)
exchange (metathesis) reaction A reaction between compounds that when written as a molecular equation appears to involve the exchange of ions between the two reactants. (Section 4.2)
excited state A higher energy state than the ground state.
(Section 6.3)
exothermic process A process in which a system releases heat to its surroundings. (Section 5.2)
extensive property A property that depends on the amount of sample considered; for example, mass or volume. (Section 1.3)
face-centered lattice A crystal lattice in which the lattice points are located at the faces and corners of each unit cell. (Section 12.2)

Faraday constant (F) The magnitude of charge of one mole of electrons: 96,500 C/mol. (Section 20.5)
$f$-block metals Lanthanide and actinide elements in which the $4 f$ or $5 f$ orbitals are partially occupied. (Section 6.9)
ferrimagnetism A substance that has both ferromagnetic and antiferromagnetic characteristics. A form of magnetism in which unpaired electron spins on different-type ions point in opposite directions but do not fully cancel out. (Section 23.1)
ferromagnetism A form of magnetism in which unpaired electron spins align parallel to one another. (Section 23.1)
first law of thermodynamics A statement that energy is conserved in any process. One way to express the law is that the change in internal energy, $\Delta E$, of a system in any process is equal to the heat, $q$, added to the system, plus the work, $w$, done on the system by its surroundings: $\Delta E=q+w$. (Section 5.2)
first-order reaction A reaction in which the reaction rate is proportional to the concentration of a single reactant, raised to the first power. (Section 14.4)
fission The splitting of a large nucleus into two smaller ones. (Section 21.6)
folding The process by which a protein adopts its biologically active shape. (Section 24.7)
force A push or a pull. (Section 1.4)
formal charge The charge an atom (in a molecule) would have if each bonding electron pair in the molecule were shared equally between its two atoms. (Section 8.5)
formation constant For a metal ion complex, the equilibrium constant for formation of the complex from the metal ion and base species present in solution. It is a measure of the tendency of the complex to form. (Section 17.5)
formula weight The sum of the atomic weights (AW) of the atoms in the chemical formula of the substance. For example, the formula weight of $\mathrm{NO}_{2}(46.0 \mathrm{amu})$ is the sum of the masses of one nitrogen atom and two oxygen atoms. (Section 3.3)
fossil fuels Coal, oil, and natural gas, which are presently our major sources of energy. (Section 5.8)
fracking The practice in which water laden with sand and other materials is pumped at high pressure into rock formations to release natural gas and other petroleum materials. (Section 18.4)
free energy (Gibbs free energy, G) A thermodynamic state function that gives a criterion for spontaneous change in terms of enthalpy and entropy: $G=H-T S$. (Section 19.5)
free radical A substance with one or more unpaired electrons. (Section 21.9)
frequency The number of times per second that one complete wavelength passes a given point. (Section 6.1)
frequency factor (A) A term in the Arrhenius equation that is related to the frequency of collision and the probability that the collisions are favorably oriented for reaction. (Section 14.5)
fuel cell A voltaic cell that utilizes the oxidation of a conventional fuel, such as $\mathrm{H}_{2} \mathrm{Or}_{\mathrm{CH}}^{4}$, in the cell reaction. (Section 20.7)
fuel value The energy released when 1 g of a substance is combusted. (Section 5.9)
functional group An atom or group of atoms that imparts characteristic chemical properties to an organic compound.
(Section 24.1)
fusion The joining of two light nuclei to form a more massive one. (Section 21.6)
galvanic cell See voltaic (galvanic) cell. (Section 20.3)
gamma radiation Energetic electromagnetic radiation emanating from the nucleus of a radioactive atom. (Section 21.1)
gas Matter that has no fixed volume or shape; it uniformly fills its container. (Section 1.2)
gas constant ( $R$ ) The constant of proportionality in the ideal-gas equation. (Section 10.4)
geometric isomerism A form of isomerism in which compounds with the same type and number of atoms and the same chemical bonds have different spatial arrangements of these atoms and bonds. (Sections 23.4 and 24.3)

Gibbs free energy A thermodynamic state function that combines enthalpy and entropy, in the form $G=H-T S$. For a change occurring at constant temperature and pressure, the change in free energy is $\Delta G=\Delta H-T \Delta S$. (Section 19.5)
glass An amorphous solid formed by fusion of $\mathrm{SiO}_{2}, \mathrm{CaO}$, and $\mathrm{Na}_{2} \mathrm{O}$. Other oxides may also be used to form glasses with differing characteristics. (Section 22.10)
glucose A polyhydroxy aldehyde whose formula is $\mathrm{CH}_{2} \mathrm{OH}(\mathrm{CHOH})_{4} \mathrm{CHO}$; it is the most important of the monosaccharides. (Section 24.8)
glycogen The general name given to a group of polysaccharides of glucose that are synthesized in mammals and used to store energy from carbohydrates. (Section 24.7)
Graham's law A law stating that the rate of effusion of a gas is inversely proportional to the square root of its molecular weight. (Section 10.8)
gray (Gy) The SI unit for radiation dose corresponding to the absorption of 1 J of energy per kilogram of biological material; $1 \mathrm{~Gy}=100$ rads. (Section 21.9)
green chemistry Chemistry that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. (Section 18.5)
greenhouse gases Gases in an atmosphere that absorb and emit infrared radiation (radiant heat), "trapping" heat in the atmosphere. (Section 18.2)
ground state The lowest-energy, or most stable, state. (Section 6.3)
group Elements that are in the same column of the periodic table; elements within the same group or family exhibit similarities in their chemical behavior. (Section 2.5)
Haber process The catalyst system and conditions of temperature and pressure developed by Fritz Haber and coworkers for the formation of $\mathrm{NH}_{3}$ from $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$. (Section 15.2)
half-life The time required for the concentration of a reactant substance to decrease to half its initial value; the time required for half of a sample of a particular radioisotope to decay. (Sections 14.4 and 21.4)
half-reaction An equation for either an oxidation or a reduction that explicitly shows the electrons involved, for example,
$\mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn}(s)$. (Section 20.2)
halogens Members of group 17 in the periodic table.
(Section 7.8)
heat The energy that causes the temperature of an object to increase. The flow of energy from a body at higher temperature to one at lower temperature when they are placed in thermal contact. (Sections 1.4 and 1.5)
heat capacity The quantity of heat required to raise the temperature of a sample of matter by $1^{\circ} \mathrm{C}$ (or 1 K ). (Section 5.5)
heat of fusion The enthalpy change, $\Delta H$, for melting a solid. (Section 11.4)
heat of sublimation The enthalpy change, $\Delta H$, for vaporization of a solid. (Section 11.4)
heat of vaporization The enthalpy change, $\Delta H$, for vaporization of a liquid. (Section 11.4)
Henderson-Hasselbalch equation The relationship among the $\mathrm{pH}, \mathrm{p}{ }_{a}$, and the concentrations of acid and conjugate base in an aqueous solution: $\mathrm{pH}=\mathrm{p} K_{a}+\log \frac{[\text { base }]}{[\text { acid }]}$. . Section 17.2)
Henry's law A law stating that the concentration of a gas in a solution, $S_{\mathrm{g}}$, is proportional to the pressure of gas over the solution: $S_{\mathrm{g}}=k P_{g}$. (Section 13.3)
Hess's law If a reaction is carried out in a series of steps, $\Delta H$ for the overall reaction equals the sum of the enthalpy changes for the individual steps. (Section 5.6)
heterogeneous alloy An alloy in which the components are not distributed uniformly; instead, two or more distinct phases with characteristic compositions are present. (Section 12.3)
heterogeneous catalyst A catalyst that is in a different phase from that of the reactant substances. (Section 14.7)
heterogeneous equilibrium The equilibrium established between substances in two or more different phases, for example, between a gas and a solid or between a solid and a liquid.
(Section 15.4)
hexagonal close packing A crystal structure where the atoms are packed together as closely as possible. The close-packed layers adopt a two-layer repeating pattern, which leads to a primitive hexagonal unit cell. (Section 12.3)
high-spin complex A complex whose electrons are arranged to give the maximum number of unpaired electrons. (Section 23.6)
hole A vacancy in the valence band of a semiconductor, created by doping. (Section 12.7)
homogeneous catalyst A catalyst that is in the same phase as the reactant substances. (Section 14.7)
homogeneous equilibrium The equilibrium established between reactant and product substances that are all in the same phase. (Section 15.4)
Hund's rule A rule stating that electrons occupy degenerate orbitals in such a way as to maximize the number of electrons with the same spin. In other words, each orbital has one
electron placed in it before pairing of electrons in orbitals occurs. (Section 6.8)
hybridization The mathematical mixing of different types of atomic orbitals to produce a set of equivalent hybrid orbitals. (Section 9.5)
hybrid orbital An orbital that results from the mixing of different kinds of atomic orbitals on the same atom. For example, an $s p^{3}$ hybrid results from the mixing, or hybridizing, of one s orbital and three $p$ orbitals. (Section 9.5)
hydration Solvation when the solvent is water. (Section 13.1)
hydride ion An ion formed by the addition of an electron to a hydrogen atom: $\mathrm{H}^{-}$. (Section 7.7)
hydrocarbons Compounds composed of only carbon and hydrogen. (Section 2.9)
hydrogen bonding Bonding that results from intermolecular attractions between molecules containing hydrogen bonded to an electronegative element. The most important examples involve OH, NH, and HF. (Section 11.2)
hydrolysis A reaction with water. When a cation or anion reacts with water, it changes the pH. (Sections 16.9 and 24.4)
hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$The predominant form of the proton in aqueous solution. (Section 16.2)
hydrophilic Water attracting. The term is often used to describe a type of colloid. (Section 13.6)
hydrophobic Water repelling. The term is often used to describe a type of colloid. (Section 13.6)
hypervalent A compound with more than an octet of electrons around the central atom. (Section 9.5)
hypothesis A model or tentative explanation of a series of observations. (Section 1.5)
ideal gas A hypothetical gas whose pressure, volume, and temperature behavior is completely described by the ideal-gas equation. (Section 10.4)
ideal-gas equation An equation of state for gases that embodies Boyle's law, Charles's law, and Avogadro's hypothesis in the form $P V=n R T$. (Section 10.4)
ideal solution A solution that obeys Raoult's law. (Section 13.5) immiscible liquids Liquids that do not dissolve in one another to a significant extent. (Section 13.3)
indicator A substance added to a solution that changes color when the added solute has reacted with all the solute present in solution. The most common type of indicator is an acid-base indicator whose color changes as a function of pH . (Section 4.6)
instantaneous rate The reaction rate at a particular time as opposed to the average rate over an interval of time. (Section 14.2)
insulators Materials that do not conduct electricity. (Section 12.7)
intensive property A property that does not depend on the amount of sample being examined, for example, density. (Section 1.3)
interhalogens Compounds formed between two different halogen elements. Examples include $\mathrm{IBr}^{2}$ and $\mathrm{BrF}_{3}$. (Section 22.4)
intermediate A substance formed in one elementary step of a multistep mechanism and consumed in another; it is neither a reactant nor an ultimate product of the overall reaction.
(Section 14.6)
intermetallic compound A homogeneous alloy with definite properties and a fixed composition. (Section 12.3)
intermolecular forces Forces that exist between molecules. (Chapter 11: Introduction)
internal energy The sum of all the kinetic and potential energies of the components of the system. When a system undergoes a change, the change in internal energy, $\Delta E$, is defined as the heat, $q$, added to the system, plus the work, $w$, done on the system by its surroundings: $\Delta E=q+w$. (Section 5.2)
interstitial alloy An alloy formed when solute atoms occupy interstitial positions in the "holes" between solvent atoms. (Section 12.3)
ion Electrically charged atom or group of atoms (polyatomic ion); ions can be positively or negatively charged, depending on whether electrons are lost (positive) or gained (negative) by the atoms. (Section 2.7)
ion-dipole force The force that exists between an ion and a polar molecule that possesses a permanent dipole moment. (Section 11.2)
ionic bond A bond formed by the electrostatic attractions between oppositely charged ions. The ions are formed from atoms by transfer of one or more electrons. (Chapter 8: Introduction)
ionic compound A compound composed of cations and anions. (Section 2.7)
ionic hydrides Compounds formed when hydrogen reacts with alkali metals and also the heavier alkaline earths ( $\mathrm{Ca}, \mathrm{Sr}$, and Ba ); these compounds contain the hydride ion, $\mathrm{H}^{-}$. (Section 22.2)
ionic solids Solids that are held together by the mutual electrostatic attraction between cations and anions. (Sections 12.1 and 12.5)
ionization energy The minimum energy required to remove an electron from the ground state of an isolated gaseous atom or ion. (Section 7.4)
ionizing radiation Radiation that has sufficient energy to remove an electron from a molecule, thereby ionizing it. (Section 21.9)
ion-product constant For water, $K_{w}$ is the product of the aquated hydrogen ion and hydroxide ion concentrations: $\left[\mathrm{H}^{+}\right]\left[\mathrm{OH}^{-}\right]=K_{\mathrm{w}}=1.0 \times 10^{-14}$ at $25^{\circ} \mathrm{C}$. (Section 16.3)
irreversible process A process that leaves the surroundings somehow changed when the system is restored to its original state. (Section 19.1)
isoelectronic series A series of atoms, ions, or molecules having the same number of electrons. (Section 7.3)
isomers Compounds whose molecules have the same overall composition but different structures. (Sections 2.9 and 23.4)
isothermal process A process that occurs at constant
temperature. (Section 19.1)
isotopes Atoms of the same element containing different numbers of neutrons and therefore having different masses. (Section 2.3)
joule (J) The SI unit of energy, $1 \mathrm{~kg}-\mathrm{m}^{2} / \mathrm{s}^{2}$. A related unit is the calorie: $4.184 \mathrm{~J}=1 \mathrm{cal}$. (Section 1.5)
Kelvin scale The SI temperature scale; the SI unit for temperature is the kelvin. Zero on the Kelvin scale corresponds to $-273.15^{\circ} \mathrm{C}$. (Section 1.5)
ketone A compound in which the carbonyl group $(C=O)$ occurs at the interior of a carbon chain and is therefore flanked by carbon atoms. (Section 24.4)
kinetic energy The energy that an object possesses by virtue of its motion. (Section 1.4)
kinetic-molecular theory of gases A set of assumptions about the nature of gases. These assumptions, when translated into mathematical form, yield the ideal-gas equation. (Section 10.7)
lanthanide contraction The gradual decrease in atomic and ionic radii with increasing atomic number among the lanthanide elements, atomic numbers 57 through 70. The decrease arises because of a gradual increase in effective nuclear charge through the lanthanide series. (Section 23.1)
lanthanide (rare earth) element Element in which the $4 f$ subshell is only partially occupied. (Sections 6.8 and 6.9)
lattice energy The energy required to separate completely the ions in an ionic solid into its gaseous ions. (Section 8.2)
lattice points Points in a crystal, all of which have identical environments. (Section 12.2)
lattice vectors The vectors $\boldsymbol{a}, \boldsymbol{b}$, and $\boldsymbol{c}$ that define each lattice point in a crystal lattice. Beginning from any lattice point, it is possible to move to any other lattice point by adding together whole-number multiples of the two lattice vectors. (Section 12.2)
law of conservation of mass The total mass of materials present after a chemical reaction is the same as the total mass present before the reaction. (Section 2.1)
law of constant composition A law that states that the elemental composition of a compound is always the same; also called the law of definite proportions. (Section 1.2)
law of definite proportions A law that states that the elemental composition of a substance is always the same; also called the
law of constant composition. (Section 1.2)
law of mass action The rules by which the equilibrium constant is expressed in terms of the concentrations of reactants and products, in accordance with the balanced chemical equation for the reaction. (Section 15.2)
law of multiple proportions if two elements $A$ and $B$ combine to form more than one compound, the masses of $B$ that can combine with a given mass of $A$ are in the ratio of small whole numbers.
Le Châtelier's principle A principle stating that when we disturb a system at chemical equilibrium, the relative concentrations of reactants and products shift so as to partially undo the effects of the disturbance. (Section 15.7)
levorotatory, or merely levo or I A term used to label a chiral molecule that rotates the plane of polarization of planepolarized light to the left (counterclockwise). (Section 24.4)

Lewis acid An electron-pair acceptor. (Section 16.11)
Lewis base An electron-pair donor. (Section 16.11)
Lewis structure A representation of covalent bonding in a molecule that is drawn using Lewis symbols. Shared electron pairs are shown as lines, and unshared electron pairs are shown as pairs of dots. Only the valence-shell electrons are shown. (Section 8.3)
Lewis symbol (electron-dot symbol) The chemical symbol for an element, with a dot for each valence electron. (Section 8.1)
ligand An ion or molecule that coordinates to a metal atom or to a metal ion to form a complex. (Section 23.2)
limiting reactant (limiting reagent) The reactant that is completely consumed in a reaction; the amount of product that can form is limited by the complete consumption of the limiting reactant. (Section 3.7)
line spectrum A spectrum that contains radiation at only certain specific wavelengths. (Section 6.3)
linkage isomers Structural isomers of coordination compounds in which a ligand is capable of coordinating to a metal in two ways. (Section 23.4)
lipid A nonpolar biological molecule used by organisms for longterm energy storage or as a structural component. (Section 24.9)
liquid Matter that has a distinct volume independent of its container. (Section 1.2)
liquid crystal A substance that exhibits a viscous, milky state between the liquid and solid states. (Section 11.7)
lock-and-key model A model of enzyme action in which the substrate molecule is pictured as fitting rather specifically into the active site on the enzyme. It is assumed that in being bound to the active site, the substrate is somehow activated for reaction. (Section 14.7)
low-spin complex A metal complex in which the electrons are paired in lower-energy orbitals. (Section 23.6)
macroporous Solids having pores that are visible to the naked eye. (Section 12.9)
magic numbers Numbers of protons and neutrons that result in very stable nuclei. (Section 21.2)
main-group elements Elements in the $s$ and $p$ blocks of the periodic table. (Section 6.9)
mass A measure of the amount of material in an object. In SI units, mass is measured in kilograms. (Section 1.5)
mass defect The difference between the mass of a nucleus and the total masses of the individual nucleons that it contains. (Section 21.6)
mass number The sum of the number of protons and neutrons in the nucleus of a particular atom. (Section 2.3)
mass percentage The number of grams of solute in each 100 g of solution. (Section 13.4)
mass spectrometer An instrument used to measure the precise masses and relative amounts of atomic and molecular ions. (Section 2.4)
matter Anything that occupies space and has mass; the physical material of the universe. (Section 1.1)
matter waves The term used to describe the wave characteristics of a moving particle. (Section 6.4)
mean free path The average distance traveled by a gas molecule between collisions. (Section 10.8)
mesoporous Solids having pore sizes in the range 2 to 50 nm . (Section 12.9)
metal complex Species that are assemblies of a central transitionmetal ion bonded to a group of surrounding molecules or ions, such as $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$and $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$. (Section 23.2)
metallic bond Bonding, usually in solid metals, in which the bonding electrons are relatively free to move throughout the three-dimensional structure. (Chapter 8: Introduction)
metallic character The extent to which an element exhibits the physical and chemical properties characteristic of metals, for example, luster, malleability, ductility, and good thermal and electrical conductivity. (Section 7.6)
metallic elements (metals) Elements that are usually solids at room temperature, exhibit high electrical and heat conductivity, and appear lustrous. Most of the elements in the periodic table are metals. (Sections 2.5 and 12.1)
metallic hydrides Compounds formed when hydrogen reacts with transition metals; these compounds contain the hydride ion, $\mathrm{H}^{-}$. (Section 22.2)
metallic solids Solids that are composed of metal atoms held together by a delocalized "sea" of collectively shared valence electrons. (Sections 12.1 and 12.3)
metalloids Elements that lie along the diagonal line separating the metals from the nonmetals in the periodic table; the properties of metalloids are intermediate between those of metals and nonmetals. (Section 2.5)
metallurgy The science of extracting metals from their natural sources by a combination of chemical and physical processes.
It is also concerned with the properties and structures of metals and alloys. (Section 23.1)
metathesis (exchange) reaction A reaction in which two substances react through an exchange of their component ions: $A X+B Y \longrightarrow A Y+B X$. Precipitation and acid-base neutralization reactions are examples of metathesis reactions. (Section 4.2)
metric system A system of measurement used in science and in most countries. The meter and the gram are examples of metric units. (Section 1.5)
microporous Refers to solids that have pores up to 2 nm in size. (Section 12.9)
microstate A single possible arrangement of the positions and kinetic energies of the molecules when the molecules are in a specific thermodynamic state. (Section 19.3)
mineral A solid, inorganic substance occurring in nature, such as calcium carbonate, which occurs as calcite. (Section 23.1)
miscible liquids Liquids that mix in all proportions. (Section 13.3)
mixture A combination of two or more substances in which each substance retains its own chemical identity. (Section 1.2)
molal boiling-point-elevation constant ( $\boldsymbol{K}_{\mathrm{b}}$ ) A constant characteristic of a particular solvent that gives the increase in boiling point as a function of solution molality: $\Delta T_{b}=i K_{b} m$. (Section 13.5)
molal freezing-point-depression constant ( $K_{f}$ ) A constant characteristic of a particular solvent that gives the decrease in freezing point as a function of solution molality: $\Delta T_{\mathrm{f}}=-i K_{\mathrm{f}} m$. (Section 13.5)
molality The concentration of a solution expressed as moles of solute per kilogram of solvent; abbreviated $m$. (Section 13.4)
molar heat capacity The heat required to raise the temperature of one mole of a substance by $1^{\circ} \mathrm{C}$. (Section 5.5)
molarity The concentration of a solution expressed as moles of solute per liter of solution; abbreviated $M$. (Section 4.5)
molar mass The mass of one mole of a substance in grams; it is numerically equal to the formula weight in atomic mass units. (Section 3.4)
mole A collection of Avogadro's number ( $6.022 \times 10^{23}$ ) of objects; for example, a mole of $\mathrm{H}_{2} \mathrm{O}$ is $6.022 \times 10^{23} \mathrm{H}_{2} \mathrm{O}$ molecules. (Section 3.4)
molecular compound A compound that consists of molecules. (Section 2.6)
molecular equation A chemical equation in which the formula for each substance is written without regard for whether it is an electrolyte or a nonelectrolyte. (Section 4.2)
molecular formula A chemical formula that indicates the actual number of atoms of each element in one molecule of a substance. (Section 2.6)
molecular geometry The arrangement in space of the atoms of a molecule. (Section 9.2)
molecular hydrides Compounds formed when hydrogen reacts with nonmetals and metalloids. (Section 22.2)
molecularity The number of molecules that participate as reactants in an elementary reaction. (Section 14.6)
molecular orbital (MO) An allowed state for an electron in a molecule. According to molecular-orbital theory, a molecular orbital is entirely analogous to an atomic orbital, which is an allowed state for an electron in an atom. Most bonding molecular orbitals can be classified as $\sigma$ or $\pi$, depending on the disposition of electron density with respect to the internuclear axis. (Section 9.7)
molecular-orbital diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived; also called an energy-level diagram.
(Section 9.7)
molecular-orbital theory A theory that accounts for the allowed states for electrons in molecules by using specific wave functions. (Section 9.7)
molecular solids Solids that are composed of molecules held together by their intermolecular forces. (Sections 12.1 and 12.6)
molecular weight The sum of the atomic weights (AW) of the atoms represented by their chemical formula for a molecule. (Section 3.3)
molecule A chemical combination of two or more atoms. (Sections 1.1 and 2.6)
mole fraction The ratio of the number of moles of one component of a mixture to the total moles of all components; abbreviated $X$, with a subscript to identify the component. (Section 10.6)
momentum The product of the mass, $m$, and velocity, $v$, of an object. (Section 6.4)
monodentate ligand A ligand that binds to the metal ion via a single donor atom. It occupies one position in the coordination sphere. (Section 23.3)
monomers Molecules with low molecular weights, which can be joined together (polymerized) to form a polymer. (Section 12.8)
monosaccharide A simple sugar, most commonly containing six carbon atoms. The joining together of monosaccharide units by condensation reactions results in formation of polysaccharides. (Section 24.8)
motif In a crystal, the group of atoms associated with each lattice point. (Section 12.2)
nanomaterial A solid whose dimensions range from 1 to 100 nm and whose properties differ from those of a bulk material with the same composition. (Sections 12.1 and 12.9)
natural gas A naturally occurring mixture of gaseous hydrocarbon compounds composed of hydrogen and carbon. (Section 5.8)
nematic liquid crystalline phase A liquid crystal in which the molecules are aligned in the same general direction, along their long axes, but in which the ends of the molecules are not aligned. (Section 11.7)
Nernst equation An equation that relates the cell emf, $E$, to the standard emf, $E^{\circ}$, and the reaction quotient, $Q: E=E^{\circ}-(R T / n F) \ln Q .($ Section 20.6)
net ionic equation A chemical equation for a solution reaction in which soluble strong electrolytes are written as ions and spectator ions are omitted. (Section 4.2)
neutralization reaction A reaction in which an acid and a base react in stoichiometrically equivalent amounts; the neutralization reaction between an acid and a metal hydroxide produces water and a salt. (Section 4.3)
neutron An electrically neutral particle found in the nucleus of an atom; it has approximately the same mass as a proton. (Section 2.2)
noble gases Members of group 18 in the periodic table. (Section 7.8)
nodal plane In an antibonding orbital, the plane in the region between the nuclei where the electron density is zero. (Section 9.7)
node Points in an atom at which the electron density is zero. For example, the node in a $2 s$ orbital is a spherical surface. (Section 6.6)
nonbonding pair In a Lewis structure a pair of electrons assigned completely to one atom; also called a lone pair. (Section 8.3)
nonelectrolyte A substance that does not ionize in water and consequently gives a nonconducting solution. (Section 4.1)
nonionizing radiation Radiation that does not have sufficient energy to remove an electron from a molecule. (Section 21.9)
nonmetallic elements (nonmetals) Elements in the upper right corner of the periodic table; nonmetals differ from metals in their physical and chemical properties. (Section 2.5)
nonpolar covalent bond A covalent bond in which the electrons are shared equally. (Section 8.4)
normal boiling point The boiling point at 1 atm pressure.
(Section 11.5)
normal melting point The melting point at 1 atm pressure. (Section 11.6)
nuclear binding energy The energy required to decompose an atomic nucleus into its component protons and neutrons. (Section 21.6)
nuclear disintegration series A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one; also called a radioactive series. (Section 21.2)
nuclear model Model of the atom with a very small and extremely dense nucleus containing most of the mass (protons and neutrons) and with electrons in the space outside the nucleus. (Section 2.2)
nuclear reaction Reaction in which transformations of atomic nuclei occur.
(Chapter 21: Introduction)
nuclear transmutation A conversion of one kind of nucleus to another. (Section 21.3)
nucleic acids Polymers of high molecular weight that carry genetic information and control protein synthesis. (Section 24.10)
nucleon Particles found in the nucleus of an atom; protons and neutrons. (Section 21.1)
nucleotide Monomers of nucleic acids formed from a fivecarbon sugar, a nitrogen-containing organic base, and a phosphate group. Nucleotides form linear polymers called DNA and RNA, which are involved in protein synthesis and cell reproduction. (Section 24.10)
nucleus The very small, very dense, positively charged portion of an atom; it is composed of protons and neutrons. (Section 2.2)
octet rule A rule stating that atoms tend to gain, lose, or share electrons until they are surrounded by eight valence electrons. (Section 8.1)
optical isomerism A form of isomerism in which the two forms of a compound (stereoisomers) are nonsuperimposable mirror images. Also called enantiomers. (Section 23.4)
optically active Possessing the ability to rotate the plane of polarized light. (Section 23.4)
orbital An allowed energy state of an electron in the quantummechanical model of the atom; the term orbital is also used to describe the spatial distribution of the electron. An orbital is
defined by the values of three quantum numbers: $n, l$, and $m_{l}$ (Section 6.5)
orbital diagram A representation of an atomic orbital drawn as a box with one or two half-arrows inside representing electrons. (Section 6.8)
organic chemistry The study of carbon-containing compounds, typically containing carbon-carbon bonds. (Section 2.9; Chapter 24: Introduction)
osmosis The net movement of solvent through a semipermeable membrane toward the solution with greater solute concentration. (Section 13.5)
osmotic pressure The pressure that must be applied to a solution to stop osmosis from pure solvent into the solution. (Section 13.5)
Ostwald process An industrial process used to make nitric acid from ammonia. The $\mathrm{NH}_{3}$ is catalytically oxidized by $\mathrm{O}_{2}$ to form $\mathrm{NO} ; \mathrm{NO}$ in air is oxidized to $\mathrm{NO}_{2} ; \mathrm{HNO}_{3}$ is formed in a disproportionation reaction when $\mathrm{NO}_{2}$ dissolves in water. (Section 22.7)
overall reaction order The sum of the reaction orders of all the reactants appearing in the rate expression when the rate can be expressed as rate $=k[\mathrm{~A}]^{a}[\mathrm{~B}]^{b} \ldots$. (Section 14.3)
overlap The extent to which atomic orbitals on different atoms share the same region of space. When the overlap between two orbitals is large, a strong bond may be formed. (Section 9.4)
oxidation A process in which a substance loses one or more electrons. (Section 4.4)
oxidation number (oxidation state) A positive or negative whole number assigned to an element in a molecule or ion on the basis of a set of formal rules; to some degree it reflects the positive or negative character of that atom. (Section 4.4)
oxidation-reduction (redox) reaction A reaction in which electrons are transferred from one reactant to another and the oxidation states of these atoms change. (Section 4.4; Chapter 20: Introduction)
oxidizing agent, or oxidant The substance that is reduced and thereby causes the oxidation of some other substance in an oxidation-reduction reaction. (Section 20.1)
oxyacid A compound in which one or more OH groups, and possibly additional oxygen atoms, are bonded to a central atom. (Section 16.10)
oxyanion A polyatomic anion that contains one or more oxygen atoms. (Section 2.8)
ozone The name given to $\mathrm{O}_{3}$, an allotrope of oxygen. (Section 7.8)
paramagnetism A property that a substance possesses if it contains one or more unpaired electrons. A paramagnetic substance is drawn into a magnetic field. (Section 9.8)
partial pressure The pressure exerted by a particular gas in a mixture. (Section 10.6)
particle accelerator A device that uses strong magnetic and electrostatic fields to accelerate charged particles. (Section 21.3)
parts per billion (ppb) The concentration of a solution in grams of solute per $10^{9}$ (billion) grams of solution; equals micrograms of solute per liter of solution for aqueous solutions. (Section 13.4)
parts per million (ppm) The concentration of a solution in grams of solute per $10^{6}$ (million) grams of solution; equals milligrams of solute per liter of solution for aqueous solutions. (Section 13.4)
pascal ( Pa ) The SI unit of pressure: $1 \mathrm{~Pa}=1 \mathrm{~N} / \mathrm{m}^{2}$. (Section 10.2)
Pauli exclusion principle A rule stating that no two electrons in an atom may have the same four quantum numbers ( $n, l, m_{l}$, and $\left.m_{s}\right)$. As a reflection of this principle, there can be no more than two electrons in any one atomic orbital. (Section 6.7)
peptide bond An amide group formed by amino acids. A bond formed between two amino acids. (Section 24.7)
percent ionization The percent of a substance that undergoes ionization on dissolution in water. The term applies to solutions of weak acids and bases. (Section 16.6)
percent yield The ratio of the actual (experimental) yield of a product to its theoretical (calculated) yield, multiplied by 100. (Section 3.7)
period The row of elements that lie in a horizontal row in the periodic table. (Section 2.5)
periodic table The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns. (Section 2.5)
perspective drawing A model that uses wedges and dashed lines to depict bonds that are not in the plane of the paper. (Section 2.6)
petroleum A naturally occurring combustible liquid composed of hundreds of hydrocarbons and other organic compounds. (Section 5.8)
pH The negative log in base 10 of the aquated hydrogen ion concentration: $\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]$. (Section 16.4)
pH titration curve A graph of pH as a function of added titrant. (Section 17.3)
phase change The conversion of a substance from one state of matter to another. The phase changes we consider are melting and freezing (solid $\rightleftharpoons$ liquid), sublimation and deposition, and vaporization and condensation (liquid $\rightleftharpoons$ gas). (Section 11.4)
phase diagram A graphic representation of the equilibria among the solid, liquid, and gaseous phases of a substance as a function of temperature and pressure. (Section 11.6)
phospholipid A form of lipid molecule that contains charged phosphate groups. (Section 24.9)
photochemical smog A complex mixture of undesirable substances produced by the action of sunlight on an urban atmosphere polluted with automobile emissions. The major starting ingredients are nitrogen oxides and organic substances. (Section 18.2)
photodissociation The rupture of a chemical bond resulting from absorption of a photon by a molecule. (Section 18.1)
photoelectric effect The emission of electrons from a metal surface induced by light. (Section 6.2)
photoionization The removal of an electron from an atom or molecule by absorption of light. (Section 18.1)
photon The smallest increment (a quantum) of radiant energy; a photon of light with frequency $\nu$ has an energy equal to $h \nu$. (Section 6.2)
photosynthesis The process that occurs in plant leaves by which light energy is used to convert carbon dioxide and water to carbohydrates and oxygen. (Section 23.3)
physical changes Changes in physical appearance (such as a phase change) that occur with no change in chemical composition. (Section 1.3)
physical properties Properties that can be measured without changing the composition of a substance, for example, color and freezing point. (Section 1.3)
pi ( $\pi$ ) bond A covalent bond in which electron density is concentrated above and below the internuclear axis; produced by the sideways overlap of $p$ orbitals. (Section 9.6)
pi $(\pi)$ molecular orbital A molecular orbital that concentrates the electron density on opposite sides of an imaginary line that passes through the nuclei. (Section 9.8)

Planck constant ( $h$ ) The constant that relates the energy and frequency of a photon, $E=h \nu$. Its value is $6.626 \times 10^{-34} \mathrm{~J}-\mathrm{s}$. (Section 6.2)
plastic A polymeric solid that can be formed into particular shapes by application of heat and pressure. (Section 12.8)
polar covalent bond A covalent bond in which the electrons are not shared equally. (Section 8.4)
polarizability The ease with which the electron cloud of an atom or a molecule is distorted by an outside influence, thereby inducing a dipole moment. (Section 11.2)
polar molecule A molecule in which the centers of positive and negative charge do not coincide; a molecule that possesses a nonzero dipole moment. (Section 8.4)
polyatomic ion An electrically charged group of two or more atoms. (Section 2.7)
polydentate ligand A ligand in which two, three, or more donor atoms can coordinate to the same metal ion. (Section 23.3)
polymer Large molecules with long chains of atoms (usually carbon), where the atoms within a given chain are connected by covalent bonds and adjacent chains are held to one another largely by weaker intermolecular forces. (Sections 12.1 and 12.8)
polypeptide A polymer of amino acids formed when a large number of amino acids ( $>30$ ) are linked together by peptide bonds. (Section 24.7)
polyprotic acid A substance capable of dissociating more than one proton in water; $\mathrm{H}_{2} \mathrm{SO}_{4}$ is an example. (Section 16.6)
polysaccharide A substance made up of many monosaccharide units joined together. (Section 24.8)
porphyrin A complex derived from the porphine molecule. (Section 23.3)
positron A particle with the same mass as an electron but with a positive charge, ${ }_{+1}^{0}$ e, or $\beta^{+}$. (Section 21.1)
positron emission A nuclear decay process where a positron, a particle with the same mass as an electron but with a positive charge, symbol ${ }_{+1}^{0} \mathrm{e}$, or $\beta^{+}$, is emitted from the nucleus. (Section 21.1)
potential energy The energy that an object possesses as a result of its position with respect to another object. (Section 1.4)
precipitate An insoluble substance that forms in, and separates from, a solution. (Section 4.2)
precipitation reaction A reaction that occurs between substances in solution in which one of the products is insoluble. (Section 4.2)
precision The closeness of agreement among several measurements of the same quantity. (Section 1.6)
pressure A measure of the force exerted on a unit area. In chemistry, pressure is often expressed in units of atmospheres $(\mathrm{atm})$ or torr: 760 torr $=1 \mathrm{~atm}$; in SI units pressure is expressed in pascals (Pa). (Section 10.2)
pressure-volume (PV) work Work performed by expansion of a gas against a resisting pressure. (Section 5.3)
primary cell A voltaic cell that cannot be recharged.
(Section 20.7)
primary structure The sequence of amino acids along a protein chain. (Section 24.7)
primitive lattice A crystal lattice in which the lattice points are located only at the corners of each unit cell. (Section 12.2)
principal quantum number The integer, $n$, associated with orbits and energy levels in the Bohr atom. (Section 6.3)
probability density $\left(\psi^{2}\right)$ A value that represents the probability that an electron will be found at a given point in space. Also called electron density. (Section 6.5)
product A substance produced in a chemical reaction; it appears to the right of the arrow in a chemical equation. (Section 3.1)
property Any characteristic that allows us to recognize a particular type of matter and to distinguish it from other types. (Section 1.1)
protein Macromolecules present in all living cells; a biopolymer formed from amino acids. (Section 24.7)
protium The most common isotope of hydrogen. (Section 22.2)
proton A positively charged subatomic particle found in the nucleus of an atom. (Section 2.2)
pure substance Matter that has a fixed composition and distinct properties. (Section 1.2)
qualitative analysis The determination of the presence or absence of a particular substance in a mixture. (Section 17.7)
quantitative analysis The determination of the amount of a given substance that is present in a sample. (Section 17.7)
quantum The smallest increment of radiant energy that may be absorbed or emitted; the magnitude of radiant energy is $h \nu$. (Section 6.2)
quaternary structure The structure of a protein resulting from the clustering of several individual protein chains into a final specific shape. (Section 24.7)
racemic mixture A mixture of equal amounts of the dextrorotatory and levorotatory forms of a chiral molecule. A racemic mixture will not rotate the plane of polarized light. (Section 23.4)
rad A measure of the energy absorbed from radiation by tissue or other biological material; $1 \mathrm{rad}=$ transfer of $1 \times 10^{-2} \mathrm{~J}$ of energy per kilogram of material. (Section 21.9)
radial probability function The probability that the electron will be found at a certain distance from the nucleus. (Section 6.6)
radioactive Possessing radioactivity, the spontaneous disintegration of an unstable atomic nucleus with accompanying emission of radiation. (Section 2.2; Chapter 21: Introduction)
radioactive decay chain A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one. Also called nuclear disintegration series. (Section 21.2)
radioisotope An isotope that is radioactive; that is, it is undergoing nuclear changes with emission of radiation. (Section 21.1)
radionuclide A radioactive nuclide. (Section 21.1)
radiotracer A radioisotope that can be used to trace the path of an element in a chemical system. (Section 21.5)
Raoult's law A law stating that the partial pressure exerted by solvent vapor above the solution, $P_{\text {solution }}$, equals the product of the mole fraction of the solvent, $X_{\text {solvent }}$, and the vapor pressure of the pure solvent, $P_{\text {solvent }}^{\circ} \cdot P_{\text {solution }}=X_{\text {solvent }} P_{\text {solvent }}^{\circ}$. (Section 13.5)
rare earth element See lanthanide (rare earth) element. (Sections 6.8 and 6.9)
rate constant A constant of proportionality between the reaction rate and the concentrations of reactants that appear in the rate law. (Section 14.3)
rate-determining step The slowest elementary step in a reaction mechanism. (Section 14.6)
rate law An equation that relates the reaction rate to the concentrations of reactants (and sometimes of products also). (Section 14.3)
reactant A starting substance in a chemical reaction; it appears to the left of the arrow in a chemical equation. (Section 3.1)
reaction mechanism A detailed picture, or model, of how the reaction occurs; that is, the order in which bonds are broken and formed and the changes in relative positions of the atoms as the reaction proceeds. (Section 14.6)
reaction order The power to which the concentration of a reactant is raised in a rate law. (Section 14.3)
reaction quotient ( $Q$ ) The value that is obtained when concentrations of reactants and products are inserted into the equilibrium expression. If the concentrations are equilibrium concentrations, $Q=K$; otherwise, $Q \neq K$. (Section 15.6)
reaction rate The speed at which a chemical reaction occurs; a measure of the decrease in concentration of a reactant or the increase in concentration of a product with time. (Chapter 14: Introduction and Section 14.2)
redox (oxidation-reduction) reaction A reaction in which certain atoms undergo changes in oxidation states. The substance increasing in oxidation state is oxidized; the substance decreasing in oxidation state is reduced. (Section 4.4; Chapter 20: Introduction)
reducing agent, or reductant The substance that is oxidized and thereby causes the reduction of some other substance in an oxidation-reduction reaction. (Section 20.1)
reduction A process in which a substance gains one or more electrons. (Section 4.4)
rem A measure of the biological damage caused by radiation; rems $=$ rads $\times$ RBE. (Section 21.9)
renewable energy sources Energy such as solar energy, wind energy, and hydroelectric energy derived from essentially inexhaustible sources. (Section 5.8)
representative (main-group) element An element from within the $s$ and $p$ blocks of the periodic table (Figure 6.30). (Section 6.9)
resonance structures (resonance forms) Individual Lewis structures in cases where two or more Lewis structures are equally good descriptions of a single molecule. The resonance structures in such an instance are "averaged" to give a more accurate description of the real molecule. (Section 8.6)
reverse osmosis The process by which water molecules move under high pressure through a semipermeable membrane from the more concentrated to the less concentrated solution. (Section 18.4)
reversible process A process in which the system can be restored to its original condition with no change to the surroundings. (Section 19.1)
ribonucleic acid (RNA) A polynucleotide in which ribose is the sugar component. (Section 24.10)
root-mean-square (rms) speed ( $\mu_{\mathrm{m}}$ ) The square root of the average of the squared speeds of the gas molecules in a gas sample. (Section 10.7)
rotational motion Movement of a molecule as it spins about an axis. (Section 19.3)
salinity A measure of the salt content of seawater, brine, or brackish water. It is equal to the mass in grams of dissolved salts present in 1 kg of seawater. (Section 18.3)
salt Any ionic compound whose cation comes from a base (for example, $\mathrm{Na}^{+}$from NaOH ) and whose anion comes from an acid (for example, $\mathrm{Cl}^{-}$from HCl ). (Section 4.3)
saponification Hydrolysis of an ester in the presence of a base. (Section 24.4)
saturated solution A solution in which undissolved solute and dissolved solute are in equilibrium. (Section 13.2)
scientific law A statement of what is always observed to happen, to the best of our knowledge. (Section 1.5)
scientific method The general process of advancing scientific knowledge by making experimental observations and by formulating hypotheses, theories, and laws. (Figure 1.18)
secondary cell A voltaic cell that can be recharged.
(Section 20.7)
secondary structure Refers to how segments of the protein chain are oriented in a regular pattern. (Section 24.7)
second law of thermodynamics A statement of our experience that there is a direction to the way events occur in nature. When a process occurs spontaneously in one direction, it is nonspontaneous in the reverse direction. It is possible to state the second law in many different forms, but they all relate back to the same idea about spontaneity. One of the most common statements found in chemical contexts is that in any spontaneous process the entropy of the universe increases. (Section 19.2)
second-order reaction A reaction in which the rate depends either on a reactant concentration raised to the second power or on the concentrations of two reactants each raised to the first power. (Section 14.4)
semiconductor A material that has electrical conductivity between that of a metal and that of an insulator. (Section 12.7)
sigma ( $\boldsymbol{\sigma}$ ) bond A covalent bond in which electron density is concentrated along the internuclear axis. (Section 9.6)
sigma ( $\boldsymbol{\sigma}$ ) molecular orbital A molecular orbital that centers the electron density about an imaginary line passing through two nuclei. (Section 9.7)
significant figures The digits that indicate the precision with which a measurement is made; all digits of a measured quantity are significant, including the last digit, which is uncertain.
(Section 1.6)
silica Common name for silicon dioxide. (Section 22.4)
silicates Compounds containing silicon and oxygen, structurally based on $\mathrm{SiO}_{4}$ tetrahedra. (Section 22.10)
single bond A covalent bond involving one electron pair. (Section 8.3)
SI units The preferred metric units for use in science.
(Section 1.5)
smectic A and smectic C liquid crystals Liquid crystals in which the molecules maintain the long-axis alignment seen in nematic crystals, but in addition pack into layers. (Section 11.7)
solid Matter that has both a definite shape and a definite volume. (Section 1.2)
solubility The amount of a substance that dissolves in a given quantity of solvent at a given temperature to form a saturated solution. (Sections 4.2 and 13.2)
solubility-product constant (solubility product) ( $K_{\text {sp }}$ ) An equilibrium constant related to the equilibrium between a solid salt and its ions in solution. It provides a quantitative measure of the solubility of a slightly soluble salt. (Section 17.4)
solute A substance dissolved in a solvent to form a solution; it is normally the component of a solution present in the smaller amount. (Section 4.1)
solution A mixture of substances that has a uniform composition; a homogeneous mixture. (Section 1.2)
solvation The clustering of solvent molecules around a solute particle. (Section 13.1)
solvent The dissolving medium of a solution; it is normally the component of a solution present in the greater amount. (Section 4.1)
space-filling model Model that shows relative sizes of the atoms. (Section 2.6)
specific heat $\left(C_{\mathrm{s}}\right)$ The heat capacity of 1 g of a substance; the heat required to raise the temperature of 1 g of a substance by $1^{\circ} \mathrm{C}$. (Section 5.5)
spectator ions Ions that go through a reaction unchanged and that appear on both sides of the complete ionic equation. (Section 4.2)
spectrochemical series A list of ligands arranged in order of their abilities to increase the crystal-field splitting energy. (Section 23.6)
spectrum The distribution among various wavelengths of the radiant energy emitted or absorbed by an object. (Section 6.3)
spin magnetic quantum number ( $m_{s}$ ) A quantum number associated with the electron spin; it may have values of $+\frac{1}{2}$ or $-\frac{1}{2}$. (Section 6.7)
spin-pairing energy The difference between the energy required to pair an electron in an occupied orbital and the energy required to place that electron in an empty orbital. (Section 23.6)
spontaneous process A process that is capable of proceeding in a given direction, as written or described, without needing to be driven by an outside source of energy. A process may be spontaneous even though it is very slow. (Section 19.1)
standard atmospheric pressure Defined as 760 torr or, in SI units, 101.325 kPa . (Section 10.2)
standard emf, also called the standard cell potential ( $E^{\circ}$ ) The emf of a cell when all reagents are at standard conditions. (Section 20.4)
standard enthalpy change ( $\Delta \boldsymbol{H}^{\circ}$ ) The change in enthalpy in a process when all reactants and products are in their stable forms at 1 atm pressure and a specified temperature, commonly $25^{\circ} \mathrm{C}$. (Section 5.7)
standard enthalpy of formation $\left(\boldsymbol{\Delta H}_{\boldsymbol{f}}^{\circ}\right)$ The change in enthalpy that accompanies the formation of one mole of a substance from its elements, with all substances in their standard states. (Section 5.7)
standard free energy of formation $\left(\Delta G_{f}^{\circ}\right)$ The change in free energy associated with the formation of a substance from its elements under standard conditions. (Section 19.5)
standard hydrogen electrode (SHE) An electrode based on the half-reaction $2 \mathrm{H}^{+}(1 \mathrm{M})+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(1 \mathrm{~atm})$. The standard
electrode potential of the standard hydrogen electrode is defined as 0 V. (Section 20.4)
standard molar entropy ( $S^{\circ}$ ) The entropy value for a mole of a substance in its standard state. (Section 19.4)
standard reduction potential ( $E_{\text {red }}^{\circ}$ ) The potential of a reduction half-reaction under standard conditions, measured relative to the standard hydrogen electrode. A standard reduction potential is also called a standard electrode potential. (Section 20.4)
standard solution A solution of known concentration.
(Section 4.6)
standard temperature and pressure (STP) Defined as $0^{\circ} \mathrm{C}$ and 1 atm pressure; frequently used as reference conditions for a gas. (Section 10.4)
starch The general name given to a group of polysaccharides that acts as energy-storage substances in plants. (Section 24.8)
state function A property of a system that is determined by its state or condition and not by how it got to that state; its value is fixed when temperature, pressure, composition, and physical form are specified; $P, V, T, E$, and $H$ are state functions. (Section 5.2)
states of matter The three forms that matter can assume: solid, liquid, and gas. (Section 1.2)
stereoisomers Compounds possessing the same formula and bonding arrangement but differing in the spatial arrangements of the atoms. (Section 23.4)
stoichiometry The relationships among the quantities of reactants and products involved in chemical reactions.
(Chapter 3: Introduction)
stratosphere The region of Earth's atmosphere from 10 km to 50 km above the surface. (Section 18.1)
strong acid An acid that ionizes completely in water. (Section 4.3)
strong base A base that ionizes completely in water. (Section 4.3)
strong electrolyte A substance (strong acids, strong bases, and most salts) that is completely ionized in solution. (Section 4.1)
structural formula A formula that shows not only the number and kinds of atoms in the molecule but also the arrangement (connections) of the atoms. (Section 2.6)
structural isomers Compounds possessing the same formula but differing in the bonding arrangements of the atoms. (Sections 23.4 and 24.2)
subatomic particles Particles such as protons, neutrons, and electrons that are smaller than an atom. (Section 2.2)
subshell One or more orbitals with the same set of quantum numbers $n$ and $l$. For example, we speak of the $2 p$ subshell ( $n=2, l=1$ ), which is composed of three orbitals ( $2 p_{x}, 2 p_{y}$, and $\left.2 p_{z}\right)$. (Section 6.5)
substitutional alloy An alloy formed when atoms of the solute in a solid solution occupy positions normally occupied by a solvent atom. (Section 23.6)
substitution reactions Reactions in which one atom (or group of atoms) replaces another atom (or group) within a molecule;
substitution reactions are typical for alkanes and aromatic hydrocarbons. (Section 24.3)
substrate A substance that undergoes a reaction at the active site in an enzyme. (Section 14.7)
supercritical fluid The state that exists when liquid and gas phases are indistinguishable from each other as the temperature exceeds the critical temperature and the pressure exceeds the critical pressure. (Section 11.4)
supercritical mass An amount of fissionable material larger than the critical mass. (Section 21.7)
supersaturated solution A solution containing more solute than an equivalent saturated solution. (Section 13.2)
surface tension The energy required to increase the surface area of a liquid by a unit amount. (Section 11.3)
surroundings In thermodynamics, everything that lies outside the system that we study. (Section 5.2)
system In thermodynamics, the portion of the universe that we single out for study. We must be careful to state exactly what the system contains and what transfers of energy it may have with its surroundings. (Section 5.2)
temperature A measure of the hotness or coldness of an object; a physical property that determines the direction of heat flow. (Section 1.5)
termolecular reaction An elementary reaction that involves three molecules. Termolecular reactions are rare. (Section 14.6)
tertiary structure The overall shape of a large protein, specifically, the manner in which sections of the protein fold back upon themselves or intertwine. (Section 24.7)
theoretical yield The quantity of product that is calculated to form when all of the limiting reagent reacts. (Section 3.7)
theory A tested model or explanation that has predictive powers and that accounts for all available observations. (Section 1.3)
thermochemistry The relationship between chemical reactions and energy changes.
(Chapter 5: Introduction)
thermodynamics The study of energy and its transformation. (Chapter 5: Introduction)
thermonuclear reaction Another name for fusion reactions; reactions in which two light nuclei are joined to form a more massive one. (Section 21.8)
thermoplastic A polymeric material that can be readily reshaped by application of heat and pressure. (Section 12.8)
thermosetting plastic A plastic that is formed by irreversible chemical processes and therefore is not readily reshaped by application of heat and pressure. (Section 12.8)
third law of thermodynamics A law stating that the entropy of a pure, crystalline solid at absolute zero temperature is zero: $s(0 \mathrm{~K})=0$. (Section 19.3)
titration The process of reacting a solution of unknown concentration with one of known concentration (a standard solution). (Section 4.6)
torr A unit of pressure ( 1 torr $=1 \mathrm{~mm} \mathrm{Hg}$ ). (Section 10.2)
transition elements (transition metals) Elements in which the $d$ orbitals are partially occupied. (Section 6.8)
transition state (activated complex) The particular arrangement of reactant and product molecules at the point of maximum energy in the rate-determining step of a reaction. (Section 14.5)
translational motion Movement in which an entire molecule moves in a definite direction. (Section 19.3)
transuranium elements Elements that follow uranium in the periodic table. (Section 21.3)
triple bond A covalent bond involving three electron pairs. (Section 8.3)
triple point The temperature at which solid, liquid, and gas phases coexist in equilibrium. (Section 11.6)
tritium The isotope of hydrogen whose nucleus contains a proton and two neutrons. (Section 22.2)
troposphere The region of Earth's atmosphere extending from the surface to about 10 km altitude. (Section 18.1)

Tyndall effect The scattering of a beam of visible light by the particles in a colloidal dispersion. (Section 13.6)
uncertainty principle A principle stating there is an inherent uncertainty in the precision with which we can simultaneously specify the position and momentum of a particle. This uncertainty is significant only for particles of extremely small mass, such as electrons. (Section 6.4)
unimolecular reaction An elementary reaction that involves a single molecule. (Section 14.6)
unit cell The smallest portion of a crystal that reproduces the structure of the entire crystal when repeated in different directions in space. It is the repeating unit or building block of the crystal lattice. (Section 12.2)
unsaturated solution A solution containing less solute than a saturated solution. (Section 13.2)
valence band A band of closely spaced bonding molecular orbitals that is essentially fully occupied by electrons.
(Section 12.7)
valence-bond theory A model of chemical bonding in which an electron-pair bond is formed between two atoms by the overlap of orbitals on the two atoms. (Section 9.4)
valence electrons The outermost electrons of an atom; those that occupy orbitals not occupied in the nearest noble-gas element of lower atomic number. The valence electrons are the ones the atom uses in bonding. (Section 6.8)
valence orbitals Orbitals that contain the outer-shell electrons of an atom. (Chapter 7: Introduction)
valence-shell electron-pair repulsion (VSEPR) model A model that accounts for the geometric arrangements of shared and unshared electron pairs around a central atom in terms of the repulsions between electron pairs. (Sections 9.1 and 9.2)
van der Waals equation An equation of state for nonideal gases that is based on adding corrections to the ideal-gas equation. The correction terms account for intermolecular forces of attraction and for the volumes occupied by the gas molecules themselves. (Section 10.9)
van't Hoff factor The number of fragments that a solute breaks into for a particular solvent. (Section 13.5)
vapor Gaseous state of any substance that normally exists as a liquid or solid. (Section 10.1)
vapor pressure The pressure exerted by a vapor in equilibrium with its liquid or solid phase. (Section 11.5)
vibrational motion Movement of the atoms within a molecule in which they move periodically toward and away from one another. (Section 19.3)
viscosity A measure of the resistance of fluids to flow. (Section 11.3)
volatile Refers to liquids that evaporate readily. (Section 11.5)
voltaic (galvanic) cell A device in which a spontaneous oxidation-reduction reaction occurs with the passage of electrons through an external circuit. (Section 20.3)
vulcanization The process of cross-linking polymer chains in rubber. (Section 12.8)
watt A unit of power; $1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s}$. (Section 20.5)
wave function A mathematical description of an allowed energy state (an orbital) for an electron in the quantum-mechanical model of the atom; it is usually symbolized by the Greek letter $\psi$. (Section 6.5)
wavelength The distance between identical points (such as two adjacent peaks or two adjacent troughs) on successive waves. (Section 6.1)
weak acid An acid that only partly ionizes in water. (Section 4.3)
weak base A base that only partly ionizes in water. (Section 4.3)
weak electrolyte A substance that only partly ionizes in solution. (Section 4.1)
work The energy transferred when a force exerted on an object causes a displacement of that object. (Section 1.4)
zeolite A class of aluminosilicates that occur naturally and can also be synthesized. (Section 12.9)
zero-order reaction A reaction in which the rate of disappearance of $A$ is independent of $[A]$. (Section 14.4)

## E

Earth
acid rain, 820-822, 820t, 821f, 822f
atmosphere, components, 812-814, 812f, 813ft, 814tf
atmosphere, ozone in, 817-820, 817f, 818f, $819 f$
atmosphere, photochemical reactions in, $814-816,815,817 t$
crust, components of, $52,52 f$
greenhouse gases, 824-827, 824f, 825f, 826f, 827f
smog, 823-824, 823f
water on, 828-831, 828f, 829t, 830f, $831 f$
water quality, $831-835,832 f, 833 f$, 834f, 835f
EDTA (ethylenediaminetetraacetate ion), 1042-1043, 1042ft, 1043f
Effective nuclear charge, 303-306, 304f, 305f
Effusion, molecular, 459-463, 460f, $462 f, 463 f$
Einstein, Albert, 61-62, 261-262, 273, 599, 969
Elastomers, 544-545, 544ft, 545f. See also Polymers
Electrical charge. See also Electrochemistry
Faraday constant ( $F$ ), 913-915, $914 f$
SI unit, coulomb, 90n
transition metal complexes, 10401041, 1041f
voltaic cells, 901-903, 901f, 902f, $903 f$
Electric current. See also
Electrochemistry
electrolyte solutions, 166-167, 167f
electron-sea model, 530-531
graphene, 554
lithium-ion batteries, 311, 311f
metals, conductivity of, 523
polymers and, 550, 550f
semiconductors, overview of, 539541, 540f, $541 t$
SI units, 61-63, $61 t, 62 t$
Electric eels, 919, $919 f$
Electric vehicles, 924-925, 924f, 925f

Electrocardiography, 920, 920 f
Electrochemistry
batteries and fuel cells, 921-926, 921f, 922f, 924f, 925f, 926f
batteries for hybrid and electric vehicles, $924-925,924 f, 925 f$
cell potentials, nonstandard conditions, 915-921, 918f, 919f, $920 f$
cell potentials, standard conditions, 904-911, 904f, 905f, 906f, 907t, 909f, 911f
concentration cells, 918-921, 918f, $919 f$
corrosion, 926-928, 927f, $928 f$
defined, 893
electrical work, 915
electrolysis, overview of, 928-932, 929f, 932f
electroplating, 929-930, $929 f$
free energy and redox reactions, 912-915, $914 f$
Hall-Héroult process, 931-932, 931f, $932 f$
heartbeat and electrocardiography, 920, 920f
hydrogen fuel cells, 923, 925-926, $926 f$
lead-acid batteries, 922, $922 f$
lithium-ion batteries, 923, $924 f$
nickel-cadmium (nicad) batteries, 895, 922-923
oxidation-reduction equations, balancing of, 896-900, 897f
oxidation-reduction reactions, 894-895, $894 f$
oxidizing and reducing agent strength, 910-911, 911f
voltaic cells, 901-903, 901f, 902f, $903 f$
Electrodes. See also Electrochemistry
alkaline batteries, 922 , $922 f$
batteries, overview, 921, 921f
concentration cells, 918-921, 918f, 919f
corrosion, 926-928, 927f, $928 f$
electrolysis reactions, 928-932, 929f, 932f
hydrogen fuel cells, 925-926, $926 f$
lithium-ion batteries, $923,924 f$
nickel-cadmium (nicad) batteries, 922-923
nickel-metal hydride (NiMH) battery, 923
voltaic cells, 901-903, 901f, 902f, 903f
Electrolysis, 53-54, 53f, 54t, 928-932,
929f, 932f

Electrolytes, 166-167, 167f
acids, 174-175
common-ion effect, 762-765
concentration of solutions, 188192, 188f, $191 f$
dilutions, 191-192, 191f
salt bridge, 902-903, 902f, $903 f$
strong and weak acids and bases, 176-177, 176t, 177t, 722-725, $724 f, 725 t$
weak and strong, 168-169
Electrolytic cells, 928-932, 929f, 932f
Electromagnetic force, 95
Electromagnetic radiation
ionizing and nonionizing radiation, 974-976, 974t, 975ft, 976ft
light, wave nature of, 258-260, 258f, $259 f$
line spectra and Bohr model, 263-268, 263f, 264f, 265f, 266f
wave behavior of matter, 268-271, 269f, 270f
Electromagnetic spectrum, 258, $259 f$
Electrometallurgy, 931-932, 931f, 932f
Electromotive force (emf), 904-911, 904f, 905f, 906f, 907t, 909f, 911f
Electron capture, 947t, 948-949, 948t, $949 t$
Electron density, 272
Electron domain, 386-387, $387 f$
Electron-domain geometry, defined, 387
Electronegativity
bond polarity and, 353-355, 354f, $355 f$
defined, 353
Group 5A elements, 1009-1010, 1010ft
halogens, 996
nonmetals, periodic trends, 988990, 988f, $989 f$
oxyacids, 745-746, 745f
Electronic band structure, 532-533, 532f
Electronic charge. See also Ions and ionic compounds
defined, 93
predicting ionic charges, 105-106, $106 f$
Electronic structure, atoms. See

hydrogen, overview of, 990-994, 993f, $994 f$
ionic compounds, names and formulas, 109-113, 109f, 110t, $111 f, 112 t$
metallic character, 317-318, 318ft
molecular hydrides, $994,994 f$
nitrogen, overview of, 1006-1009, 1006ft, 1007f, 1008f
noble gases, overview of, 994-996, 995ft
oxidation number, 183
oxygen, overview of, 999-1002, 1000f, 1001f, 1002ft
periodic table, 320-322, 321f
periodic trends and reactions, 988990, 988f, $989 f$
Nonpolar covalent bond, 353
dipole moment, 355-358, 356f, $357 t, 358 f$
electronegativity and bond polarity, 354-355, 355f
Nonpolar molecules
molecular shape and polarity, 396398, 396f, 397f
organic compounds, 1077
solute-solvent interactions, 576578, 576ft, 577ft, $578 f$
solution formation, 573
Nonvolatile solutions, 586-588, 586f, $588 f$
Normal boiling point, 499-500, $499 f$
Normal melting point, 500-503, 500f, 501f, $502 f$
Novoselov, Konstantin, 554
$n p$ orbitals, 1034-1035, 1034f, 1035f
$n s$ orbitals, 1034-1035, 1034f, 1035f
n-type semiconductors, 541-542, 542f

Nuclear disintegration series, 951-952, $952 f$
Nuclear energy, 241-243, 241ft, 949951, $950 f$
Nuclear forces, 95
Nuclear magnetic resonance (NMR), 281, $281 f$
Nuclear model, atom, 92-93, 93f
Nuclear reactions
energy changes in, 963-966, 965t, $966 f$
fission, nuclear power, 966-972, 967f, 968f, 969f, 970f
fusion, 966, 972
nuclear binding energies, 965-966, 965t, $966 f$
nuclear equations, 946-947
nuclear reactors, 969-971, 970f
nuclear transmutations, 953-956, 954f, 955f
nuclear waste, 971-972
nuclei, magic numbers, 952-953, 952t, $953 f$
overview of, 945-946
particle accelerators, $954-955,954 f$, 955f
patterns of stability, 949-953, 950f, 952ft, 953f
radiation in environment, 973-976, 973f, 974t, 975ft, 976ft
radiation therapy, $976,976 t$
radioactive decay, rate calculations, 956-960, 956f, 957t, 958f
radioactive decay, types of, 947-949, $947 t, 948 t, 949 t$
radioactive decay chains, 951-952, 952f
radioactivity, detection of, 961-963, 961f, 962f, $963 f$
Nuclear spin, 281, 281f
Nucleic acids, 1111-1113, 1111f, 1112f, $1113 f$
Nucleons, 946
Nucleosomes, 850f, 851
Nucleotides, 1111-1113, 1111f, 1112f, 1113f
Nucleus, atom, 92-93, 93f, 946
effective nuclear charge, 303-306, 304f, 305f
magic number, 952-953, 952t, 953f
neutron-to-proton ratio, 949-951, $950 f$
nuclear binding energies, 965-966, 965t, $966 f$
nuclear fission, 966-972, 967f, 968f, 969f, 970f
nuclear transmutations, 953-956, 954f, $955 f$
Nylon, 545-546, 546f, $546 t$

Oblique lattice, 519-521, 519f, 520f, 521f
Obsidian, 519, $519 f$
Ocean water, $829,829 t, 830 f, 836,836 f$
Octahedral molecules, 386-394, 386f, $387 f, 388 t, 389 t, 392 t, 393 f$
coordination compounds, 10591061, $1059 f$
transition metal complexes, 1041, $1041 f$
Octane, 116, 1079t
Octane number, gasoline, 1084, $1084 f$
Octet rule, 344-345, 344f, 349
exceptions to, 366-369
Lewis structures, drawing of, 359363, 363f
Ogallala Aquifer, 831, $831 f$
Oil, crude, 1084, 1084f
Omega-3 fatty acids, 1110, $1110 f$
Omega-6 fatty acids, 1110, 1110 f
Open systems, 210-211, 211f
Opsin, 411-412, 411f
Optical isomers, 1050-1052, 1051f, 1052f, 1099-1100, 1100f
Optically active molecules, 1051-1052, 1052f
Orbitals, atomic, 271-275, 271f, 272f, 274ft
alkali metals, 322-326, 323ft, 324f, $325 f$
alkaline earth metals, 326-327, $326 t, 327 f$
covalent bonding and orbital overlap, 398-399, 398f, 399f
crystal-field theory, 1055-1063, $1055 f, 1056 f, 1057 f, 1058 f$, 1059f, 1061f, 1062f
effective nuclear charge, 303-306, 304f, 305f
electron affinity, 316-317, 317f
electron configuration, 280-282
electron configurations and periodic table, 284-289, 285t, 286f, 288f, $289 f$
electronic band structure, 532-533, $532 f$
energy and, 425-426, 425f
halogens, Group 7A, 329-330, 329t, $330 f$
Hund's rule, 282-283
hybrid orbitals, 399-405, 400f, 401f, 402f, 403f, 404ft
hypervalent molecules, 403-404, 404ft
ionization energy, 312-316, 312t, $314 f$
magnetism and, 421-423, 422f, 423f
many-electron atoms, orbital
energies, 279-280, 279f
metalloids, 322
metals, 318-320, 319f, 320f
molecular orbital theory, 412-415, $413 f, 414 f$
multiple bonds, sigma and pi, 405$412,405 f, 406 f, 407 f, 408 f, 409 f$, 410f, 411f, 412f
noble gases, 331 , $331 t$
nonmetals, 320-322, 321f, 988-990, 988f, 989 f
orbital diagrams, 282-283, $282 t$
organic molecules, 1076-1077, $1076 f$
oxygen group, Group 6A, 328-329, $328 t$
Period 2, diatomic molecule bonds, 415-425, 415f-425f
phases in, 418-420, 418f, 419f, 420f
$p$ orbital, 277-278, 278f
$s$ orbitals, 275-277, 276f, 277f
spin-pairing energy, 1059-1061, 1059f
transition elements, 1033t, 10341035, 1034f, 1035f
Ores, 1033
Organic chemistry
acid-base properties of compounds, 1077, 1077f
addition reactions, alkenes and alkynes, 1088-1089, 1089f

## Useful Conversion Factors and Relationships

## Length

$$
\text { SI unit: meter } \begin{aligned}
(m) & \\
1 \mathrm{~km} & =0.62137 \mathrm{mi} \\
1 \mathrm{mi} & =5280 \mathrm{ft} \\
& =1.6093 \mathrm{~km} \\
1 \mathrm{~m} & =1.0936 \mathrm{yd} \\
1 \mathrm{in} . & =2.54 \mathrm{~cm} \text { (exactly) } \\
1 \mathrm{~cm} & =0.39370 \mathrm{in} . \\
1 \AA & =10^{-10} \mathrm{~m}
\end{aligned}
$$

## Mass

SI unit: kilogram (kg)

$$
\begin{aligned}
1 \mathrm{~kg} & =2.2046 \mathrm{lb} \\
1 \mathrm{lb} & =453.59 \mathrm{~g} \\
& =16 \mathrm{oz} \\
1 \mathrm{amu} & =1.660538921 \times 10^{-27} \mathrm{~kg}
\end{aligned}
$$

Temperature

$$
\begin{aligned}
& \text { SI unit: Kelvin (K) } \\
& 0 \begin{aligned}
\mathrm{K} & =-273.15^{\circ} \mathrm{C} \\
& =-459.67^{\circ} \mathrm{F} \\
\mathrm{~K} & ={ }^{\circ} \mathrm{C}+273.15 \\
{ }^{\circ} \mathrm{C} & =\frac{5}{9}\left({ }^{\circ} \mathrm{F}-32^{\circ}\right) \\
{ }^{\circ} \mathrm{F} & =\frac{9}{5}{ }^{\circ} \mathrm{C}+32^{\circ}
\end{aligned}
\end{aligned}
$$

Energy (derived)
SI unit: Joule (J)

$$
\begin{aligned}
1 \mathrm{~J} & =1 \mathrm{~kg}-\mathrm{m}^{2} / \mathrm{s}^{2} \\
& =0.2390 \mathrm{cal} \\
& =1 \mathrm{C}-\mathrm{V} \\
1 \mathrm{cal} & =4.184 \mathrm{~J} \\
1 \mathrm{eV} & =1.602 \times 10^{-19} \mathrm{~J}
\end{aligned}
$$

Pressure (derived)
SI unit: Pascal (Pa)

$$
\begin{aligned}
1 \mathrm{~Pa} & =1 \mathrm{~N} / \mathrm{m}^{2} \\
& =1 \mathrm{~kg} / \mathrm{m}-\mathrm{s}^{2} \\
1 \mathrm{~atm} & =1.01325 \times 10^{5} \mathrm{~Pa} \\
& =760 \mathrm{torr} \\
& =14.70 \mathrm{lb} / \mathrm{in}^{2} \\
1 \mathrm{bar} & =10^{5} \mathrm{~Pa} \\
1 \text { torr } & =1 \mathrm{~mm} \mathrm{Hg}
\end{aligned}
$$

Volume (derived)
SI unit: cubic meter ( $m^{3}$ )

$$
\begin{aligned}
1 \mathrm{~L} & =10^{-3} \mathrm{~m}^{3} \\
& =1 \mathrm{dm}^{3} \\
& =10^{3} \mathrm{~cm}^{3} \\
& =1.0567 \mathrm{qt} \\
1 \mathrm{gal} & =4 \mathrm{qt} \\
& =3.7854 \mathrm{~L} \\
1 \mathrm{~cm}^{3} & =1 \mathrm{~mL} \\
1 \mathrm{in}^{3} & =16.4 \mathrm{~cm}^{3}
\end{aligned}
$$

## Color Chart for Common Elements

${ }^{\text {a }}$ Mass of longest-lived or most important isotope.
List of Elements with Their Symbols and Atomic Weights

| Element | Symbol | Atomic Number | Atomic Weight | Element | Symbol | Atomic Number | Atomic Weight | Element | Symbol | Atomic Number | Atomic Weight |

## Common Ions

## Positive Ions (Cations)

## $1+$

ammonium $\left(\mathrm{NH}_{4}{ }^{+}\right)$
cesium ( $\mathrm{Cs}^{+}$)
copper(I) or cuprous ( $\mathrm{Cu}^{+}$)
hydrogen $\left(\mathrm{H}^{+}\right)$
lithium ( $\mathrm{Li}^{+}$)
potassium $\left(\mathrm{K}^{+}\right)$
silver $\left(\mathrm{Ag}^{+}\right)$
sodium $\left(\mathrm{Na}^{+}\right)$
$2+$
barium ( $\mathrm{Ba}^{2+}$ )
cadmium $\left(\mathrm{Cd}^{2+}\right)$
calcium $\left(\mathrm{Ca}^{2+}\right)$
chromium(II) or chromous $\left(\mathrm{Cr}^{2+}\right)$
cobalt(II) or cobaltous $\left(\mathrm{Co}^{2+}\right)$
copper(II) or cupric $\left(\mathrm{Cu}^{2+}\right)$
iron(II) or ferrous ( $\mathrm{Fe}^{2+}$ )
lead(II) or plumbous $\left(\mathrm{Pb}^{2+}\right)$
magnesium $\left(\mathrm{Mg}^{2+}\right)$
manganese(II) or manganous $\left(\mathrm{Mn}^{2+}\right)$
mercury(I) or mercurous $\left(\mathrm{Hg}_{2}{ }^{2+}\right)$
mercury(II) or mercuric $\left(\mathrm{Hg}^{2+}\right)$
strontium $\left(\mathrm{Sr}^{2+}\right)$
nickel(II) $\left(\mathrm{Ni}^{2+}\right)$
$\operatorname{tin}$ (II) or stannous $\left(\mathrm{Sn}^{2+}\right)$
zinc $\left(\mathrm{Zn}^{2+}\right)$
$3+$
aluminum $\left(\mathrm{Al}^{3+}\right)$
chromium(III) or chromic $\left(\mathrm{Cr}^{3+}\right)$
iron(III) or ferric $\left(\mathrm{Fe}^{3+}\right)$

## Negative Ions (Anions)

1 -
acetate $\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right.$or $\left.\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}^{-}\right)$
bromide ( $\mathrm{Br}^{-}$)
chlorate $\left(\mathrm{ClO}_{3}^{-}\right)$
chloride $\left(\mathrm{Cl}^{-}\right)$
cyanide ( $\mathrm{CN}^{-}$)
dihydrogen phosphate $\left(\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right)$
fluoride ( $\mathrm{F}^{-}$)
hydride ( $\mathrm{H}^{-}$)
hydrogen carbonate or bicarbonate $\left(\mathrm{HCO}_{3}{ }^{-}\right)$
hydrogen sulfite or bisulfite $\left(\mathrm{HSO}_{3}{ }^{-}\right)$
hydroxide $\left(\mathrm{OH}^{-}\right)$
iodide ( $\mathrm{I}^{-}$)
nitrate $\left(\mathrm{NO}_{3}{ }^{-}\right)$
nitrite $\left(\mathrm{NO}_{2}^{-}\right)$
perchlorate $\left(\mathrm{ClO}_{4}^{-}\right)$
permanganate $\left(\mathrm{MnO}_{4}^{-}\right)$
thiocyanate $\left(\mathrm{SCN}^{-}\right)$
2 -
carbonate $\left(\mathrm{CO}_{3}{ }^{2-}\right)$
chromate $\left(\mathrm{CrO}_{4}{ }^{2-}\right)$
dichromate $\left(\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}\right)$
hydrogen phosphate $\left(\mathrm{HPO}_{4}{ }^{2-}\right)$
oxide ( $\mathrm{O}^{2-}$ )
peroxide $\left(\mathrm{O}_{2}{ }^{2-}\right)$
sulfate $\left(\mathrm{SO}_{4}{ }^{2-}\right)$
sulfide ( $\mathrm{S}^{2-}$ )
sulfite $\left(\mathrm{SO}_{3}{ }^{2-}\right)$
3 -
arsenate $\left(\mathrm{AsO}_{4}{ }^{3-}\right)$
phosphate $\left(\mathrm{PO}_{4}{ }^{3-}\right)$

## Fundamental Constants*

| Atomic mass constant | 1 amu | $=1.660539040 \times 10^{-27} \mathrm{~kg}$ |
| :--- | :--- | :--- |
|  | lg | $=6.022140859 \times 10^{23} \mathrm{amu}$ |
| Avogadro's number ${ }^{\dagger}$ | $N_{\mathrm{A}}$ | $=6.022140857 \times 10^{23} / \mathrm{mol}$ |
| Boltzmann Constant | $k$ | $=1.3806485 \times 10^{-23} \mathrm{~J} / \mathrm{K}$ |
| Electron charge | $e$ | $=1.6021766208 \times 10^{-19} \mathrm{C}$ |
| Faraday constant | $F$ | $=9.648533289 \times 10^{4} \mathrm{C} / \mathrm{mol}$ |
| Gas constant | $R$ | $=0.0820582 \mathrm{~L}-\mathrm{atm} / \mathrm{mol}-\mathrm{K}$ |
|  |  | $=8.3144598 \mathrm{~J} / \mathrm{mol}-\mathrm{K}$ |
| Mass of electron | $m_{e}$ | $=5.4857990946 \times 10^{-4} \mathrm{amu}$ |
|  |  | $=9.10938356 \times 10^{-31} \mathrm{~kg}$ |
| Mass of neutron | $m_{n}$ | $=1.008664916 \mathrm{amu}$ |
|  |  | $=1.674927471 \times 10^{-27} \mathrm{~kg}$ |
| Mass of proton | $m_{p}$ | $=1.007276466 \mathrm{amu}$ |
|  |  | $=1.672621898 \times 10^{-27} \mathrm{~kg}$ |
| Pi | $\pi$ | $=3.1415926535$ |
| Planck constant | $h$ | $=6.626070040 \times 10^{-34} \mathrm{~J}-\mathrm{s}$ |
| Speed of light in vacuum | $c$ | $=2.99792458 \times 10^{8} \mathrm{~m} / \mathrm{s}$ |

*Fundamental constants are listed at the National Institute of Standards and Technology (NIST) Web site: http://physics.nist.gov/cuu/Constants/index.html
${ }^{\dagger}$ Avogadro's number is also referred to as the Avogadro constant. The latter term is the name adopted by agencies such as the International Union of Pure and Applied Chemistry (IUPAC) and the National Institute of Standards and Technology (NIST), but "Avogadro's number" remains in widespread usage and is used in most places in this book.
Periodic Table of the Elements

${ }^{\text {a }}$ The labels on top ( $1 \mathrm{~A}, 2 \mathrm{~A}$, etc.) are common American usage. The labels below these ( 1,2 , etc.) are those recommended by the International Union of Pure and Applied Chemistry (IUPAC).
Except for elements 114 and 116, the names and symbols for elements abo
Except for elements 114 and 116, the names and symbols for elements above 113 have not yet been decided.
Atomic weights in brackets are the names of the longest-lived or most important isotope of radioactive elements.
Further information is available at http://www.webelements.com
** Discovered in 2010, element 117 is currently under review by IUPAC.

[^0]:    4 THE MANUFACTURE OF SYNTHETIC PIGMENTS is one of the oldest
    examples of industrial chemistry. The impressionist artists made extensive use of the bold colors of the newly available pigments, as exemplified in van Gogh's painting Glass with Roses.

[^1]:    *U.S. Geological Survey Circular 285, U.S Department of the Interior.

[^2]:    *Remsen, The Principles of Theoretical Chemistry, 1887.

[^3]:    *In using this equation, only the component of the force that is acting parallel to the distance traveled is used. That will generally be the case for problems we will encounter in this chapter.
    **Strictly speaking, velocity is a vector quantity that has a direction; that is, it tells you how fast an object is moving and in what direction. Speed is a scalar quantity that tells you how fast an object is moving but not the direction of the motion. Unless otherwise stated, we will not be concerned with the direction of motion, and thus velocity and speed are interchangeable quantities for the treatment in this book.

[^4]:    *Mass and weight are not the same. Mass is a measure of the amount of matter; weight is the force exerted on this mass by gravity. For example, an astronaut weighs less on the Moon than on Earth because the Moon's gravitational force is less than Earth's. The astronaut's mass on the Moon, however, is the same as it is on Earth.

[^5]:    *Your instructor may want you to use a slight variation on the rule when the leftmost digit to be removed is exactly 5 , with no following digits or only zeros following. One common practice is to round up to the next higher number if that number will be even and down to the next lower number otherwise. Thus, 4.7350 would be rounded to 4.74 , and 4.7450 would also be rounded to 4.74 .

[^6]:    4 A FLOWER GARDEN. A staggering diversity of form and function can be achieved in plants and animals despite the fact that only a half dozen or so elements account for the vast majority of molecules found in living organisms.

[^7]:    *Dalton, "Atomic Theory" 1844.
    **The short chainlike symbol ( $\infty$ ) that precedes the section reference indicates a link to ideas presented earlier in the text.

[^8]:    *The electron is an elementary particle that cannot be divided into smaller particles, whereas protons and neutrons are made up of smaller particles called quarks.

[^9]:    ${ }^{a}$ The ions we use most often are in boldface. Learn them first.

[^10]:    ⓉHESE STAINLESS STEEL REACTORS are where the chemistry happens to make the carbonated alcoholic beverage known as beer.

[^11]:    *Lavoisier, Antoine. "Elements of Chemistry." 1790.

[^12]:    *When there is an insufficient quantity of $\mathrm{O}_{2}$ present, carbon monoxide $(\mathrm{CO})$ is produced along with $\mathrm{CO}_{2}$; this is called incomplete combustion. If the quantity of $\mathrm{O}_{2}$ is severely restricted, the fine particles of carbon we call soot are produced. Complete combustion produces only $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. Unless stated to the contrary, we will always take combustion to mean complete combustion.

[^13]:    *Avogadro's number is also referred to as the Avogadro constant. The latter term is the name adopted by agencies such as the National Institute of Standards and Technology (NIST), but Avogadro's number remains in widespread usage and is used in most places in this book.

[^14]:    \& WATER IS THE MOST ABUNDANT liquid on our planet. The
    composition of seawater closely matches the composition of the body fluids of almost all life forms, suggesting that life arose in the seas.

[^15]:    *The chemical formula of acetic acid is sometimes written $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ so that the formula looks like that of other common acids such as HCl . The formula $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ conforms to the molecular structure of acetic acid, with the acidic H on the O atom at the end of the formula.

[^16]:    THERMITE REACTION. The reaction between aluminum metal and iron oxide produces aluminum oxide and iron metal. It also generates enough heat to melt the iron metal formed in the reaction. The thermite reaction is a dramatic illustration of how potential energy stored in chemical bonds can be converted to heat.

[^17]:    *We read the combined units $\mathrm{J}-\mathrm{m} / \mathrm{C}^{2}$ as joule-meters per coulomb squared. You may see combinations of units such as $\mathrm{J}-\mathrm{m} / \mathrm{C}^{2}$ expressed with dots separating units instead of short dashes, $\mathrm{J} \cdot \mathrm{m} / \mathrm{C}^{2}$, or with dashes and dots totally absent, $\mathrm{J} \mathrm{m} / \mathrm{C}^{2}$.

[^18]:    *You are probably familiar with the notion of atmospheric pressure from a previous course in chemistry. We will discuss it in detail in Chapter 10. Here we need realize only that the atmosphere exerts a pressure on the surface of Earth that is nearly constant.

[^19]:    ${ }^{\text {a }}$ Beer typically contains $3.5 \%$ ethanol, which has fuel value.

[^20]:    *Annual Energy Review 2015, U.S Energy Information Administration, U. S. Department of Energy.

[^22]:    *Hermanns, William, Einstein and the Poet: In Search of the Cosmic Man, 1st edition, Branden Books, 1983.
    **The letters come from the words sharp, principal, diffuse, and fundamental, which were used to describe certain features of spectra before quantum mechanics was developed.

[^23]:    *In the quantum-mechanical model, the most probable distance at which to find the electron in the $1 s$ orbital is actually 52.9 pm , the same as the radius of the orbit predicted by Bohr for $n=1$. The distance 52.9 pm is often called the Bohr radius.

[^24]:    *We cannot make a simple correspondence between the subscripts ( $x, y$, and $z$ ) and the allowed $m_{l}$ values $(1,0$, and -1$)$. To explain why this is so is beyond the scope of an introductory text.

[^25]:    *Two sign conventions are used for electron affinity. In most introductory texts, including this one, the thermodynamic sign convention is used: A negative sign indicates that addition of an electron is an exothermic process, as in the electron affinity for chlorine, $-349 \mathrm{~kJ} / \mathrm{mol}$. Historically, however, electron affinity has been defined as the energy released when an electron is added to a gaseous atom or ion. Because $349 \mathrm{~kJ} / \mathrm{mol}$ is released when an electron is added to $\mathrm{Cl}(\mathrm{g})$, the electron affinity by this convention would be $+349 \mathrm{~kJ} / \mathrm{mol}$.

[^26]:    7.9 (a) Evaluate the expressions $2 \times 1,2 \times(1+3)$, $2 \times(1+3+5)$, and $2 \times(1+3+5+7)$. (b) How do the

[^27]:    «GIANT CRYSTALS. These gypsum crystals, large enough for people to walk on, are composed of $\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. The ionic bonding between calcium and sulfate ions at the atomic scale leads to the characteristic crystal shape at the human scale.

[^28]:    * There are some exceptions to this statement, such as network solids, including diamond, silicon, and germanium, where an extended structure is formed even though the bonding is clearly covalent. These substances are discussed in Section 12.7.

[^29]:    

[^30]:    

[^31]:    

[^32]:    \& SHAPE MATTERS. These two compounds at first glance appear identical. But a very small change at one carbon atom makes one compound an anti-pain medication and the other a liver toxin.

[^33]:    *The mathematical development of this three-dimensional function (and its square) is beyond the scope of this book, and, as is typically done by chemists, we have used lobes that are the same shape as in Figure 6.23.

[^34]:    4 A TORNADO is a violent, rotating column of air characterized by a funnel-shaped cloud. A tornado can be more than 3 km in diameter, with wind speeds approaching $500 \mathrm{~km} / \mathrm{hr}$.

[^35]:    ⒷECAUSE THE LEAVES OF THE LOTUS PLANT are highly water repellent,
    any water on a leaf beads up to minimize contact with the leaf surface.

[^36]:    *The atoms in a solid are able to vibrate in place. As the temperature of the solid increases, the vibrational motion increases.

[^37]:    *The $n$ in $n$-pentane is an abbreviation for the word normal. A normal hydrocarbon is one in which the carbon atoms are arranged in a straight chain. ©oo (Section 2.9)

[^38]:    *Cholesteric liquid crystals are sometimes called chiral nematic phases because the molecules within each plane adopt an arrangement similar to a nematic liquid crystal.

[^39]:    4 PHOTOVOLTAIC SYSTEMS Photovoltaic cells utilize light energy to generate electricity. Photovoltaic arrays utilize linked modules of these cells to supply usable solar power.

[^40]:    *A vector is a quantity involving both a direction and a magnitude. The magnitudes of the vectors in Figure 12.3 are indicated by their lengths, and their directions are indicated by the arrowheads.
    **You may wonder why the hexagonal unit cell is not shaped like a hexagon. Remember that the unit cell is by definition a parallelogram whose size and shape are defined by the lattice vectors $a$ and $b$.

[^41]:    *This is strictly true only for chains with an even number of atoms.

[^42]:    *This movement is analogous to watching people changing seats in a classroom; you can watch the people (electrons) move about the seats (atoms), or you can watch the empty seats (holes) "move."

[^43]:    4 COLORED FLOW. This microfluidic chip is similar to the one used in many medical diagnostic laboratories. The colored dye solutions are used to test the flow in each channel for proper functioning.

[^44]:    
    (a) Hexane
    
    (c) Acetone
    
    (b) Benzene
    
    (d) Carbon tetrachloride
    
    (e) Water

    Practice Exercise 2
    Arrange the following substances in order of increasing solubility in water:

[^45]:    $\triangleleft$ ARCTIC GROUND SQUIRRELS can hibernate for more than half the year by allowing their bodies to fall to temperatures near the freezing point of water. Every 2 to 3 weeks they shiver involuntarily to raise the temperature back to $36^{\circ} \mathrm{C}$ in order to minimize brain damage caused by the low-temperature hibernation.

[^46]:    *Equation 14.4 does not hold true if substances other than C and D are formed in significant amounts. For example, sometimes intermediate substances build in concentration before forming the final products. In that case, the relationship between the rate of disappearance of reactants and the rate of appearance of products is not given by Equation 14.4. All reactions whose rates we consider in this chapter obey Equation 14.4.

[^47]:    ${ }^{*}$ Note the rate constants $k_{1}$ and $k_{2}$ written above the reaction arrows. The subscript on each rate constant identifies the elementary step involved. Thus, $k_{1}$ is the rate constant for step 1 , and $k_{2}$ is the rate constant for step 2. A negative subscript refers to the rate constant for the reverse of an elementary step. For example, $k_{-1}$ is the rate constant for the reverse of the first step.

[^48]:    4 A LEAKY BOAT. A state of dynamic equilibrium, where the water level reaches a constant level, is eventually attained by bailing water from a small boat that has sprung a leak.

[^49]:    * Pronounced "le-SHOT-lee-ay."

[^50]:    *Because $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$are used interchangeably, you might see pH defined as $-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$.

[^51]:    - GREAT BARRIER REEF These structures are made of calcium carbonate, $\mathrm{CaCO}_{3}$.

[^52]:    *This is strictly true only for very dilute solutions, for $K_{s p}$ values change somewhat when the concentration of ionic substances in water is increased. However, we will ignore these effects, which are taken into consideration only for work that requires exceptional accuracy.

[^53]:    *Notice that the term amphoteric is applied to the behavior of insoluble oxides and hydroxides that dissolve in acidic or basic solutions. The similar term amphiprotic (Section 16.2) relates more generally to any molecule or ion that can either gain or lose a proton.

[^54]:    4 MINNERIYA NATIONAL PARK IN SRI LANKA is home to an extraordinarily diverse range of flora and fauna. Built around the ancient Minneriya Tank, the park comprises a mix of scrub land and evergreen forests.

[^55]:    *Adapted from P. T. Anastas and J. C. Warner, Green Chemistry: Theory and Practice. New York: Oxford University Press 1998, p. 30. See also Mike Lancaster, Green Chemistry: An Introductory Text. Cambridge, UK: RSC Publishing, 2010, Second Edition, Chapter 1.

[^56]:    4THE NUCLEOSOME Inside the nucleus of a living cell, DNA (the gray outer double-helical portion) surrounds eight protein molecules (the colored molecular models). This overall DNA/protein structure, called the nucleosome, is the basic unit of chromosomes in the nuclei of our cells. These structures are highly ordered, yet also must be unraveled for gene expression to take place. Both packaging and unpackaging of DNA in the nucleosome involve changes in the energy of the system.

[^57]:    $\triangleleft$ THE TESLA GIGAFACTORY, under construction in Nevada, will be the largest lithium-ion battery production facility in the world once completed in 2017. These batteries will be used in a wide variety of applications, including Tesla's all-electric vehicles.

[^58]:    *The positron has a very short life because it is annihilated when it collides with an electron, producing gamma rays: ${ }_{+1}^{0} \mathrm{e}+{ }_{-1}^{0} \mathrm{e} \longrightarrow 2{ }_{0}^{0} \gamma$.

[^59]:    *Other heavy nuclei can also undergo fission. However, these three are the only ones of practical importance.

[^60]:    *Historically, a nuclear weapon that relies solely on a fission process to release energy is called an atomic bomb, whereas one that also releases energy via a fusion reaction is called a hydrogen bomb.

[^61]:    *Fluorine forms one oxyacid, HOF. Because the electronegativity of fluorine is greater than that of oxygen, we must consider fluorine to be in a -1 oxidation state and oxygen to be in the 0 oxidation state in this compound.

[^62]:    $\triangle$ HORSESHOE CRAB BLOOD is harvested by bleeding out about one-third of the arthropod's blue blood.

[^63]:    *The name crystal-field arose because the theory was first developed to explain the properties of solid crystalline materials. The theory applies equally well to complexes in solution, however.

[^64]:    *The labels $t_{2}$ for the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals and $e$ for the $d_{z^{2}}$ and $d_{x^{2} 2 y^{2}}$ orbitals come from the application of a branch of mathematics called group theory to crystal-field theory. Group theory can be used to analyze the effects of symmetry on molecular properties.

[^65]:    *The other two peaks fall in the infrared (IR) and ultraviolet (UV) regions of the spectrum. For $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ the IR peak is found at 1176 nm and the UV peak at 388 nm .

[^66]:    *The term invert sugar comes from the fact that rotation of the plane of polarized light by the glucosefructose mixture is in the opposite direction, or inverted, from that of the sucrose solution.
