Library of Congress Cataloging-in-Publication Data

Information communication technologies : concepts, methodologies, tools and applications / [compiled] by Craig Van Slyke.
p. cm.

Summary: "This collection meets these research challenges; compiling breaking research in the pivotal areas of social adaptation to information technology. It covers ad-hoc networks, collaborative environments, e-governance, and urban information systems, case studies, empirical analysis, and conceptual models. Over 300 chapters contributed by experts, this six-volume compendium will provide any library's collection with the definitive reference on ICTs"--Provided by publisher.

ISBN 978-1-59904-949-6 (hardcover) -- ISBN 978-1-59904-950-2 (e-book)

1. Information technology--Social aspects. 2. Information technology--Economic aspects. 3. Information technology--Political aspects. 4. Digital communications--Social aspects. 5. Information society. I. Van Slyke, Craig.

British Cataloguing in Publication Data

A Cataloguing in Publication record for this book is available from the British Library.

If a library purchased a print copy of this publication, please go to <http://www.igi-global.com/agreement> for information on activating the library's complimentary electronic access to this publication.

Editor-in-Chief

Mehdi Khosrow-Pour, DBA
Editor-in-Chief
Contemporary Research in Information Science and Technology, Book Series

Associate Editors

Steve Clarke
University of Hull, UK

Murray E. Jennex
San Diego State University, USA

Annie Becker
Florida Institute of Technology USA

Ari-Veikko Anttiroiko
University of Tampere, Finland

Editorial Advisory Board

Sherif Kamel
American University in Cairo, Egypt

In Lee
Western Illinois University, USA

Jerzy Kisielnicki
Warsaw University, Poland

Keng Siau
University of Nebraska-Lincoln, USA

Amar Gupta
Arizona University, USA

Craig van Slyke
University of Central Florida, USA

John Wang
Montclair State University, USA

Vishanth Weerakkody
Brunel University, UK

**Additional Research Collections found in the
“Contemporary Research in Information Science and Technology”
Book Series**

Data Mining and Warehousing: Concepts, Methodologies, Tools, and Applications
John Wang, Montclair University, USA • 6-volume set • ISBN 978-1-59904-951-9

Electronic Commerce: Concepts, Methodologies, Tools, and Applications
S. Ann Becker, Florida Institute of Technology, USA • 4-volume set • ISBN 978-1-59904-943-4

Electronic Government: Concepts, Methodologies, Tools, and Applications
Ari-Veikko Anttiroiko, University of Tampere, Finland • 6-volume set • ISBN 978-1-59904-947-2

End-User Computing: Concepts, Methodologies, Tools, and Applications
Steve Clarke, University of Hull, UK • 4-volume set • ISBN 978-1-59904-945-8

Global Information Technologies: Concepts, Methodologies, Tools, and Applications
Felix Tan, Auckland University of Technology, New Zealand • 6-volume set • ISBN 978-1-59904-939-7

Information Communication Technologies: Concepts, Methodologies, Tools, and Applications
Craig Van Slyke, University of Central Florida, USA • 6-volume set • ISBN 978-1-59904-949-6

Information Security and Ethics: Concepts, Methodologies, Tools, and Applications
Hamid Nemati, The University of North Carolina at Greensboro, USA • 6-volume set • ISBN 978-1-59904-937-3

Intelligent Information Technologies: Concepts, Methodologies, Tools, and Applications
Vijayan Sugumar, Oakland University, USA • 4-volume set • ISBN 978-1-59904-941-0

Knowledge Management: Concepts, Methodologies, Tools, and Applications
Murray E. Jennex, San Diego State University, USA • 6-volume set • ISBN 978-1-59904-933-5

Multimedia Technologies: Concepts, Methodologies, Tools, and Applications
Syad Mahbubur Rahman, Minnesota State University, USA • 3-volume set • ISBN 978-1-59904-953-3

Online and Distance Learning: Concepts, Methodologies, Tools, and Applications
Lawrence Tomei, Robert Morris University, USA • 6-volume set • ISBN 978-1-59904-935-9

Virtual Technologies: Concepts, Methodologies, Tools, and Applications
Jerzy Kisielnicki, Warsaw University, Poland • 3-volume set • ISBN 978-1-59904-955-7

Volume I

Section 1. Fundamental Concepts and Theories in Information Communication Technologies

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of information communication technology (ICT). Chapters found within these pages provide an excellent framework in which to position ICT within the field of information science and technology. Individual contributions provide insight into the critical incorporation of ICT into the global community and explore crucial stumbling blocks of the field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of ICT.

Chapter 1.1. An Overview on Strategic ICT Implementations Toward Developing Knowledge Societies / <i>Hakikur Rahman</i>	1
Chapter 1.2. The Role of Information and Communication Technologies in Knowledge Management: A Classification of Knowledge Management Systems / <i>Irma Becerra-Fernandez and Rajiv Sabherwal</i>	36
Chapter 1.3. Postcolonial ICT Challenges / <i>Birgitta Rydhagen and Lena Trojer</i>	46
Chapter 1.4. Holistic Evaluation of the Roles of ICTs in Regional Development / <i>Chris Keen, Dean Steer, and Paul Turner</i>	54
Chapter 1.5. ICT in Regional Development / <i>Saundaryya Borbora and Mrinal Kanti Dutta</i>	66
Chapter 1.6. Digital Divide: Introduction to the Problem / <i>Liudmila Burtseva, Svetlana Cojocar, Constantin Gaidric, Galina Magariu, and Tatiana Verlan</i>	74
Chapter 1.7. The Evolution of ICT, Economic Development, and the Digitally-Divided Society / <i>Sadayoshi Takaya</i>	91

Chapter 1.8. Information Dynamics in Developing Countries / <i>Hakikur Rahman</i>	104
Chapter 1.9. Role of ICT in Development Process: A Review of Issues and Prospects in South Asia / <i>Dilip Dutta</i>	115
Chapter 1.10. Information and Communication Technology and Good Governance in Africa / <i>Godwin Onu</i>	132
Chapter 1.11. Telecommunications Sector and Internet Access in Africa / <i>Vanessa Phala</i>	144
Chapter 1.12. The Arab World, Culture, and Information Technology / <i>Mohamed El Louadi</i>	151
Chapter 1.13. ICT Growth and Diffusion: Concepts, Impacts, and Policy Issues in the Indian Experience with Reference to the International Digital Divide / <i>Saundarjya Borbora</i>	160
Chapter 1.14. ICT, Education, and Regional Development in Swiss Peripheral Areas / <i>Chiara Giorgi and Dieter Schürch</i>	174
Chapter 1.15. Applying for Government Grants for ICT in Australia / <i>Lynne H. De Weaver</i>	183
Chapter 1.16. Role of ICTs in Socioeconomic Development and Poverty Reduction / <i>Hakikur Rahman</i>	190
Chapter 1.17. Evolution of the Euro and Currency Competition in the Global ICT Age / <i>Sadayoshi Takaya</i>	226
Chapter 1.18. The Genesis, Political, and Economic Sides of the Internet / <i>Andrew Targowski</i>	238
Chapter 1.19. The Transformation of the Distribution Process in the Airline Industry Empowered by Information and Communication Technology / <i>Patrick S. Merten</i>	254
Chapter 1.20. Technological Innovation, Trade, and Development / <i>Laura Márquez-Ramos, Inmaculada Martínez-Zarzoso, and Celestino Suárez-Burquet</i>	284
Chapter 1.21. ICT and Business in the New Economy: Globalization and Attitudes Towards E-Commerce / <i>John Sagi, Elias Carayannis, Subhashish Dasgupta, and Gary Thomas</i>	304
Chapter 1.22. Collaboration Challenges in Community Telecommunication Networks / <i>Sylvie Albert and Rolland LeBrasseur</i>	323
Chapter 1.23. Patents and Standards in the ICT Sector: Are Submarine Patents a Substantive Problem or a Red Herring? / <i>Aura Soininen</i>	345
Chapter 1.24. Factors Influencing the Lifetime of Telecommunication and Information Technology Standards: Results of an Explorative Analysis of the PERINORM Database / <i>Knut Blind</i>	383

Chapter 1.25. Some Insights into the Impact of ICTs on Learning Agency and Seamless Learning / <i>Hitendra Pillay, John A. Clarke, and Peter G. Taylor</i>	405
Chapter 1.26. Learning Styles and Adaptive ICT Based Learning Environment / <i>Zlatko J. Kovačić</i>	413
Chapter 1.27. Behavioral, Cognitive, and Humanistic Theories: Which Theories do Online Instructors Utilize? / <i>MarySue Ciccirelli</i>	430
Chapter 1.28. ICT-Based Learning: A Basic Ingredient for Socio-Economic Empowerment / <i>Hakikur Rahman</i>	443
Chapter 1.29. Between Tradition and Innovation in ICT and Teaching / <i>Antonio Cartelli</i>	456
Chapter 1.30. Sociocultural Animation / <i>Marcus Foth</i>	464
Chapter 1.31. Biographical Stories of European Women Working in ICT / <i>Andrea Birbaumer, Marianne Tolar, and Ina Wagner</i>	472
Chapter 1.32. The Beijing World Conference on Women, ICT Policy, and Gender / <i>J. Ann Dumas</i>	480
Chapter 1.33. Gender Inequalities for Use and Access of ICTs in Developing Countries / <i>Sushil K. Sharma</i>	488
Chapter 1.34. WSIS Gender and ICT Policy / <i>J. Ann Dumas</i>	496
Chapter 1.35. Gender ICT and Millennium Development Goals / <i>J. Ann Dumas</i>	504

Section 2. Information Communication Technologies Development and Design Methodologies

This section provides in-depth coverage of conceptual architecture, enabling the reader to gain a comprehensive understanding of the emerging technological developments within the field of ICT. Research fundamentals imperative to the understanding of developmental processes within information management are offered. From broad examinations to specific discussions on electronic tools, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs as well as abstract developments are explained within these chapters, and frameworks for implementing ICT in education, healthcare, and government are explored.

Chapter 2.1. Connecting the First Mile: A Best Practice Framework for ICT-Based Knowledge Sharing Initiatives / <i>Surmaya Talyarkhan, David J. Grimshaw, and Lucky Lowe</i>	513
Chapter 2.2. A Framework to Build Process Theories of Anticipatory Information and Communication Technology (ICT) Standardizing / <i>Kalle Lyytinen, Thomas Keil, and Vladislav Fomin</i>	534

Chapter 2.3. How the National E-Strategy Shapes Competitiveness in the Information Economy / <i>Alf Neumann</i>	574
Chapter 2.4. An Explanatory Approach to the Political Uses of ICT Initiatives for Participation: Institutions, Context, and Characteristics of the Actors / <i>Rosa Borge</i>	582
Chapter 2.5. B2B E-Commerce Diffusion: The Efficacy of Institutional Discourse / <i>Kim Virborg Andersen and Helle Zinner Henriksen</i>	600
Chapter 2.6. Enabling Strategy Formulation by ICT: A Viable Systems Approach / <i>Dirk Vriens and Jan Achterbergh</i>	617
Volume II	
Chapter 2.7. Media Life Cycle and Consumer-Generated Innovation / <i>Yuichi Wasida, Shenja van der Graaf, Eva Keeris</i>	638
Chapter 2.8. Participatory Design and Creativity in Development of Information and Communication Technologies / <i>Nette Schultz, Lene Sørensen, and Dan Saugstrup</i>	656
Chapter 2.9. ICT and Developing Social Capital / <i>Kate Sutcliffe</i>	672
Chapter 2.10. A Taxonomy of Stakeholders: Human Roles in System Development / <i>Ian F. Alexander</i>	679
Chapter 2.11. A Practitioner-Centered Assessment of a User-Experience Framework / <i>John McCarthy, Peter Wright, and Lisa Meekison</i>	712
Chapter 2.12. Different Levels of Information Systems Designers' Forms of Thought and Potential for Human-Centered Design / <i>Hannakaisa Isomäki</i>	734
Chapter 2.13. A Method to Quantify Corpus Similarity and its Application to Quantifying the Degree of Literally in a Document / <i>Etienne Denoual</i>	751
Chapter 2.14. Digital Access, ICT Fluency, and the Economically Disadvantaged: Approaches to Minimize the Digital Divide / <i>Ellen Whybrow</i>	764
Chapter 2.15. Delivering More Effective Community Consultation and Support for Regional ICT Programs / <i>Lynne De Weaver and Allan H. Ellis</i>	778
Chapter 2.16. Developing a Global Perspective for Knowledge Management / <i>Martin A. Schell</i>	793
Chapter 2.17. Deconstructing the South African Government's ICT for Development Discourse / <i>Sagren Moodley</i>	816

Chapter 2.18. E Bario Project: In Search of a Methodology to Provide Access to Information Communication Technologies for Rural Communities in Malaysia / <i>Poline Bala, Roger W. Harris, and Peter Songan</i>	826
Chapter 2.19. ICTs and the Communicative Conditions for Democracy: A Local Experiment with Web-Mediated Civic Publicness / <i>Seija Ridell</i>	840
Chapter 2.20. The Creation of a Commercial Software Development Company in a Developing Country for Outsourcing Purposes / <i>Sam Lubbe</i>	862
Chapter 2.21. The Information Society in Ukraine / <i>Serge S. Azarov</i>	870
Chapter 2.22. Telecommunication Problems in Rural Areas of Armenia / <i>Gevorg Melkonyan</i>	877
Chapter 2.23. ICT as an Example of Industrial Policy in EU / <i>Morten Falch and Anders Henten</i>	882
Chapter 2.24. Information Literacy for Telecenter Users in Low-Income Regional Mexican Communities / <i>Antonio Santos</i>	889
Chapter 2.25. Gender and ICT Policies and Programmes in an Indian State / <i>Malathi Subramania and Anupama Saxena</i>	897
Chapter 2.26. Crossing the Digital Divide in a Women’s Community ICT Centre / <i>Clem Herman</i>	904
Chapter 2.27. Developing Regional Tourism Using Information Communications Technology / <i>Dean Carson</i>	911
Chapter 2.28. A Framework for Ontology-Based Tourism Application Generator / <i>Roopa Jakkilinki and Nalin Sharda</i>	920
Chapter 2.29. Developing Visual Tourism Recommender Systems / <i>Mohan Ponnada, Roopa Jakkilinki, and Nalin Sharda</i>	938
Chapter 2.30. Design and Implementation Approaches for Location-Based, Tourism-Related Services / <i>George Kakalettris, Dimitris Varoutas,</i> <i>Dimitris Katsianis, and Thomas Sphicopoulos</i>	951
Chapter 2.31. Collaborative Commerce and the Hotel Industry / <i>Michelle Rowe and Alfred Ogle</i>	988
Chapter 2.32. Peering into the Black Box: A Holistic Framework for Innovating at the Intersection of ICT & Health / <i>Ben Bellows, Aman Bhandar, Mahad Ibrahim, and</i> <i>Jaspal S. Sandhu</i>	1002
Chapter 2.33. Analysing a Rural Community’s Reception of ICT in Ghana / <i>Paula F. Saddler</i>	1029

Chapter 2.34. Factors Motivating the Acceptance of New Information and Communication Technologies in UK Healthcare: A Test of Three Models / <i>Janice A Osbourne and Malcolm Clarke</i>	1036
Chapter 2.35. Information and Communication Technologies: Towards a Mediated Learning Context / <i>Glenn Finger, Maret McGlasson, and Paul Finger</i>	1047
Chapter 2.36. Learning-Supported Decision-Making: ICTs as Feedback Systems / <i>Elena P. Antonacopoulou and K. Nadia Papamichail</i>	1066
Chapter 2.37. Reframing Information System Design as Learning Across Communities of Practice / <i>Kevin Gallagher and Robert M. Mason</i>	1083
Chapter 2.38. The Transformation Model / <i>Kathleen P. King</i>	1102
Chapter 2.39. The Influence of Constructivist E-Learning System on Student Learning Outcomes / <i>Thanakorn Wangpipatwong and Borworn Papasratorn</i>	1109
Chapter 2.40. A Wireless Networking Curriculum Model for Network Engineering Technology Programs / <i>Raymond A. Hansen, Anthony H. Smith, and Julie R. Mariga</i>	1122
Chapter 2.41. Agent-Based Architecture of a Distributed Laboratory System / <i>Hong Lin</i>	1130
Chapter 2.42. A Project-Based Learning Approach: Online Group Collaborative Learning / <i>Jianxia Du, Byron Havard, James Adams, and Heng Li</i>	1143
Chapter 2.43. Task-Oriented Online Discussion: A Practical Model for Student Learning / <i>Byron Havard, Jianxia Du, and Anthony Olinzock</i>	1153
Chapter 2.44. An Analysis of Student Persistence in Online Education / <i>Steven F. Tello</i>	1163
Chapter 2.45. Transitioning from Face-to-Face to Online Instruction: How to Increase Presence and Cognitive/Social Interaction in an Online Information Security Risk Assessment Class / <i>Cindy S. York, Dazhi Yang, and Melissa Dark</i>	1179
Chapter 2.46. Project-Based Online Group Collaborative Learning Characteristics / <i>Jianxia Du, Byron Havard, James Adams, Gang Ding, and Wei -Chieh Yu</i>	1190
Chapter 2.47. Using “Blended Learning” to Develop Tertiary Students’ Skills of Critique / <i>Paul Lajbcyier and Christine Spratt</i>	1202
Chapter 2.48. Using a Blended Model to Improve Delivery of Teacher Education Curriculum in Global Settings / <i>Vivian H. Wright, Ronnie Stanford, Jon Beedle</i>	1216
Chapter 2.49. Developing Staff Training in Virtual High Schools / <i>Chris Thompson and Zane L. Berge</i>	1225

Chapter 2.50. A Model for Effectively Integrating Technology Across the Curriculum: A Three-Step Staff Development Program for Transforming Practice / <i>John Graham and George W. Semich</i>	1234
Chapter 2.51. Putting Enterprise Systems in a Larger ICT Context: A Pedagogical Framework / <i>Thomas Rienzo, J. Michael Tarn, and James Danenburg</i>	1244
Chapter 2.52. An Embedded Collaborative Systems Model for Implementing ICT-Based Multimedia Cartography Teaching and Learning / <i>Shivanand Balram and Suzana Dragicevic</i>	1254
Chapter 2.53. Computing Curricula: A Comparison of Models / <i>Anthony Scime and Christine Wania</i>	1270

Volume III

Chapter 2.54. ICT-Enabled Education in Africa: A Sober Reflection on the Development Challenges / <i>Shafika Isaacs</i>	1284
--	------

Section 3. Information Communication Technologies Tools and Technologies

This section presents extensive coverage of various ICT-related tools and technologies that researchers, practitioners, and students alike can implement in their daily lives. These chapters educate readers about fundamental tools such as the Internet and mobile technology, while also providing insight into new and upcoming technologies and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with countless examples of the tools and technologies essential to the field of ICT. In addition, the impact of these various tools, as well as the current issue of ensuring equal access to them, is discussed within this collection of chapters.

Chapter 3.1. Internet: A Right to Use and Access Information, or a Utopia? / <i>Inban Naicker</i>	1306
Chapter 3.2. The Nearest Some of Us Will Ever Come to Information Heaven / <i>Buyile Ngubane</i>	1328
Chapter 3.3. Establishing a “Knowledge Network” of Local and Regional Development Subjects / <i>Olexandr Molodtsov</i>	1352
Chapter 3.4. Sex Tourism and the Internet: Information, Amplification, and Moral Panics / <i>Jerry Eades</i>	1360
Chapter 3.5. Cultural Knowledge Management and Broadband Content in Development: Open Content Platforms, Copyright and Archives / <i>David Rooney, Elizabeth Ferrier, Phil Graham, and Ashley Jones</i>	1379
Chapter 3.6. The Right of Interpretation: Who Decides the Success of Picture Mail? / <i>Michael Björn</i>	1395

Chapter 3.7. The Role of Information and Communication Technology in Competitive Intelligence / <i>Dirk Vriens</i>	1414
Chapter 3.8. Information and Communication Technology Tools for Competitive Intelligence / <i>Dirk Vriens</i>	1437
Chapter 3.9. It's All in the Game: How to Use Simulation-Games for Competitive Intelligence and How to Support Them by ICT / <i>Jan Achterbergh and Dirk Vriens</i>	1445
Chapter 3.10. Assessing Online Discussion Forum Participation / <i>Matthew Shaul</i>	1459
Chapter 3.11. E-News: Community Interaction through Journalism / <i>Matthew Simpson, Jay Burmeister, and Michael Docherty</i>	1468
Chapter 3.12. Role of ICT in Establishing E-Government System for Disadvantaged Communities / <i>Hakikur Rahman</i>	1482
Chapter 3.13. The Role of Place: Tasmanian Insights on ICT and Regional Development / <i>Dean Steer and Paul Turner</i>	1494
Chapter 3.14. Radio for Social Development / <i>Patrick Craddock and Peggy Duncan</i>	1506
Chapter 3.15. Digital Bridges: Extending ICT To Rural Communities Using Space Technologies / <i>Phillip Olla</i>	1513
Chapter 3.16. Voice Over IP for Rural Telecommunication Provision / <i>Thomas Wilsdon and Jill Slay</i>	1530
Chapter 3.17. ICTs as Tools for Poverty Reduction: The Tanzanian Experience / <i>Zaipuna O. Yonah and Baanda A. Salim</i>	1538
Chapter 3.18. Information Technology Standards in China / <i>Michelle Rowe</i>	1551
Chapter 3.19. ICT and Distance Learning for Agricultural Extension in Low Income Countries / <i>Colin R. Latchem and Ajit Maru</i>	1554
Chapter 3.20. ICT for Knowledge and Intellectual Capital Management in Organizations / <i>Jacques Bulchand and Jorge Rodríguez</i>	1561
Chapter 3.21. Digital Business Portfolios: Categories, Content, and Production / <i>Eleanor J. Flanigan and Susan Amirian</i>	1581
Chapter 3.22. A Socio-Technical Analysis of Factors Affecting the Integration of ICT in Primary and Secondary Education / <i>Charoula Angeli, Nicos Valanides</i>	1590
Chapter 3.23. Satellite Technology in Schools / <i>Anneleen Cosemans</i>	1611

Chapter 3.24. The Use of Online Technologies in the Teaching and Learning Process: WebCT-Communication or Technology Turn-Off? / <i>Maggie Ferguson and Adrian Ibbetson</i>	1616
Chapter 3.25. The Didactical Potential of Robotics for Education with Digital Media / <i>Andreas Wiesner-Steiner, Heidi Schelhowe, and Heike Wiesner</i>	1630
Chapter 3.26. Students' Perceptions of the Laptop Program: What Factors Should be Considered Before Implementing the Program? / <i>Chuleeporn Changchit,</i> <i>Robert Cutshall, and Susan Elwood</i>	1639
Chapter 3.27. Game Mods: Customizable Learning in a K16 Setting / <i>Elizabeth Fanning</i>	1647
Chapter 3.28. A Statewide Analysis of Student Web Portfolios in New York Colleges and Universities / <i>John DiMarco</i>	1655
Chapter 3.29. Innovative Technologies for Education and Learning: Education and Knowledge-Oriented Applications of Blogs, Wikis, Podcasts, and More / <i>Jeffrey Hsu</i>	1666
Chapter 3.30. Introducing GIS for Business in Higher Education / <i>David Gadish</i>	1688
Chapter 3.31. CAL Student Coaching Environment and Virtual Reality in Mechanical Engineering / <i>S. Manjit Sidhu, N. Selvanathan, and S. Ramesh</i>	1696
Chapter 3.32. Assessing the Effectiveness of Programmed Instruction and Collaborative Peer Tutoring in Teaching Java / <i>Henry H. Emurian</i>	1712
Chapter 3.33. An Interactive Tool for Teaching and Learning LAN Design / <i>Nurul I. Sarkar</i>	1726
Chapter 3.34. LAN-Designer: A Software Tool to Enhance Learning and Teaching Server-Based LAN Design / <i>Nurul I. Sarkar</i>	1741
Chapter 3.35. Mobile ICT / <i>Dermott McMeel</i>	1752
Chapter 3.36. Innovation in Wireless Technologies / <i>Diego Ragazzi</i>	1758
Chapter 3.37. New Challenges for Smart Organizations: Demands for Mobility—Wireless Communication Technologies / <i>István Mezgár</i>	1765
Chapter 3.38. Foreseeing the Future Lifestyle with Digital Music: A Comparative Study Between Mobile Phone Ring Tones and Hard-Disk Music Players Like iPod / <i>Masataka Yoshikawa</i>	1809
Chapter 3.39. Screening in High Standard: Innovating Film and Television in a Digital Age through High Definition / <i>Bas Agterberg</i>	1820
Chapter 3.40. Digital Cinema as Disruptive Technology: Exploring New Business Models in the Age of Digital Distribution / <i>Nigel Culkin, Keith Randle, and Norbert Morawetz</i>	1832

Chapter 3.41. Access to the Living Room: Triple Play and Interactive Television Reshaping the Producer/Consumer Relation / <i>Eggo Müller</i>	1846
Chapter 3.42. Beauty and the Nerd: Ethnographical Analyses in the Japanese Digitalization / <i>Gaby Anne Wildenbos and Yuichi Washida</i>	1855
Chapter 3.43. Digital Imaging Trek: A Practical Model for Managing the Demand of the Digitally Enabled Traveller / <i>Stephen C. Andrade and Hilary Mason</i>	1867
Chapter 3.44. Adaptive Use of ICT in Response to Disintermediation / <i>Pramod Sharma, Dean Carson, and Andrew Taylor</i>	1889
Chapter 3.45. Virtual Reality Mapping Revisited: IT Tools for the Divide Between Knowledge and Action in Tourism / <i>Malcolm Cooper and Neil MacNeil</i>	1896
Chapter 3.46. USE IT to Create Patient-Relation Management for Multiple Sclerosis Patients / <i>Margreet B. Michel-Verkerke, Roel W. Schuring, and Ton A. M. Spil</i>	1909

Volume IV

Chapter 3.47. Participatory 3D Modelling / <i>Giacomo Rambaldi</i>	1925
--	------

Section 4. Utilization and Application of Information Communication Technologies

This section introduces and discusses a variety of the existing applications of ICT that have influenced government, culture, and education and also proposes new ways in which ICT can be implemented in society. Within these selections, particular issues related to ICT utilization, such as the existence of a cross-cultural digital divide and the existence of a gender barrier, are explored and debated. Contributions included in this section provide excellent coverage of today's IT community and insight into how ICT impacts the social fabric of our present-day global village.

Chapter 4.1. A Dissemination Strategy for the Management of Knowledge in Rural Communities / <i>Ken Stevens</i>	1934
Chapter 4.2. ICTs for Intercultural Dialogue (ICT4ID) / <i>Victor Giner Minana</i>	1951
Chapter 4.3. Information and Communication Technologies Provision to Rural Communities: The Case of Gutu World Links Telecenter in Zimbabwe / <i>Shirley Chikowore-Kabwato and Isola Ajiferuke</i>	1954
Chapter 4.4. Indigenous Peoples and the Cultural Constructions of Information and Communication Technology (ICT) in Latin America / <i>Juan Francisco Salazar</i>	1966
Chapter 4.5. Assessing Universal Access to ICT in Ghana / <i>Godfred Frempong and Imoro Braimah</i>	1976

Chapter 4.6. Caribbean Companies and the Information Superhighway / <i>Simon Fraser</i>	1986
Chapter 4.7. Technology Leapfrogging in Thailand / <i>Louis Sanzogni and Heather Arthur-Gray</i>	1995
Chapter 4.8. An ICT Enabled “Community” in Rural Nigeria and the UK / <i>Pamela McLean</i>	2003
Chapter 4.9. ICT in Medical Education in Trinidad and Tobago / <i>Marilyn Lewis</i>	2008
Chapter 4.10. Clustering Dynamics of the ICT Sector in South Africa / <i>Sagren Moodley</i>	2014
Chapter 4.11. ICT and the Tourism Information Marketplace in Australia / <i>Andrew Taylor</i>	2022
Chapter 4.12. Potential Challenges of ICT Implementations in Sri Lanka / <i>Kennedy D. Gunawardana</i>	2032
Chapter 4.13. The E-Pabelan National ICT4PR Pilot Project: Experiences and Challenges of Implementation in an Indonesian Context / <i>Alex Robinson</i>	2052
Chapter 4.14. Determining Whether ICT Improves Social Interactions / <i>Raj Gururajan</i>	2069
Chapter 4.15. Formation of a Knowledge-Based Society through Utilization of Information Networking / <i>Hakikur Rahman</i>	2076
Chapter 4.16. Transforming the K-12 Classroom with ICT: Recognizing and Engaging new Configurations of Student Learning / <i>Colin Baskin</i>	2084
Chapter 4.17. Strategies for the Cooperation of Higher Education Institutions in ICT / <i>Juha Kettunen</i>	2104
Chapter 4.18. Integrating ICT in Universities: Some Actual Problems and Solutions / <i>Vassilios Dagdilelis</i>	2118
Chapter 4.19. Diffusion of Educational Technology and Education Reform: Examining Perceptual Barriers to Technology Integration / <i>LeAnne K. Robinson</i>	2130
Chapter 4.20. Evaluating the Learning Effectiveness of Using Web-Based Instruction: An Individual Differences Approach / <i>Sherry Y. Chen</i>	2143
Chapter 4.21. Quality of Online Learning Applications: Impact on Student Enjoyment, Motivation, and Anxiety / <i>Leping Liu</i>	2154
Chapter 4.22. Virtual Reality & Immersive Technology in Education / <i>Patrick E. Connolly</i>	2168
Chapter 4.23. E-Learning: An Investigation into Students’ Reactions to Investment into IT at Tertiary Institutions / <i>Solitaire Maherry-Lubbe</i>	2173

Chapter 4.24. Guiding Our Way: Needs and Motivations of Teachers in Online Learning Modeling Responsive Course Design / <i>Kathleen P. King, Frank J. Melia, and Marlene D. Dunham</i>	2193
Chapter 4.25. Computer-Based Health Information Systems: Projects for Computerization or Health Management? Empirical Experiences from India / <i>Ranjini C. R. and Sundeep Sahay</i>	2209
Chapter 4.26. Current and Future State of ICT Deployment and Utilization in Healthcare: An Analysis of Cross-Cultural Ethical Issues / <i>Bernd Carsten Stahl, Simon Rogerson, and Amin Kashmeery</i>	2232

Section 5. Organizational and Social Implications of Information Communication Technologies

This section includes a wide range of research pertaining to the social and organizational impact of ICT around the world. Chapters introducing this section illustrate the intersection of ICT and culture and the impact this has upon individuals and entire communities. Other contributions discuss ICT's potential for empowerment among disenfranchised individuals and societies as well as the ways in which ICT can transform education and the modern workplace. Particular selections debate the use of ICT for web-based learning, while others discuss how ICT has been utilized in the field of tourism. The debates and inquires presented in this section offer research into the integration of global ICT as well as implementation of ethical considerations for all organizations.

Chapter 5.1. Convergence of ICT and Culture / <i>Matthew Mitchell</i>	2248
Chapter 5.2. Addressing the Cultural Dimensions of E-Learning: Where to Begin? / <i>Andrea L. Edmundson</i>	2252
Chapter 5.3. Group Process and Trust in Group Discussion / <i>Lorna Uden and Linda Wojnar</i>	2268
Chapter 5.4. Community (Information and Communication) Technology: Policy, Partnership and Practice / <i>Peter Day</i>	2282
Chapter 5.5. Mind the Gap!: New ‘Literacies’ Create New Divides / <i>Andrew D. Madden, J. Miguel Baptista Nunes, M. A. McPherson, Nigel Ford, and Dave Miller</i>	2297
Chapter 5.6. A New Generation Gap? Some Thoughts on the Consequences of Early ICT First Contact / <i>Andrew D. Madden, J.Miguel Baptista Nunes, M. McPherson, Nigel Ford, David Miller, and M. Rico</i>	2311
Chapter 5.7. Behavior Change through ICT Use: Experiences from Relatively Healthy Populations / <i>Marieke W. Verheijden</i>	2323
Chapter 5.8. Articulating ICT Use Narratives in Everyday Life / <i>Deirdre Hynes, Tarja Tiainen, Emma-Reetta Koivunen, and Minna-Kristiina Paakki</i>	2341
Chapter 5.9. ICT, CoLs, CoPs, and Virtual Communities / <i>Antonio Cartelli</i>	2350

Chapter 5.10. “You’re in My World Now.” Ownership and Access in the Proprietary Community of an MMOG / <i>Sal Humphreys</i>	2357
Chapter 5.11. Digital Petri Dishes: LiveJournal User Icons as a Space and Medium of Popular Cultural Production / <i>Alek Tarkowski</i>	2372
Chapter 5.12. Competent Web Dialogue: Thoughts Linked in Digital Conversations / <i>Eva Fåhræus and Marianne Döös</i>	2387
Chapter 5.13. Differential Impacts of Social Presence on the Behavior Modeling Approach / <i>Charlie C. Chen, Lorne Olfman, and Albert Harris</i>	2398
Chapter 5.14. Exploring the Behavioral Dimension of Client/Server Technology Implementation: An Empirical Investigation / <i>Eitel J. M. Lauría</i>	2417
Chapter 5.15. A Capacity Building Approach to Health Literacy through ICTs / <i>Lyn Simpson, Melinda Stockwell, Susan Leggett, Leanne Wood, and Danielle Penn</i>	2434
Chapter 5.16. Transforming Democracy through ICT / <i>Andy Williamson</i>	2441
Chapter 5.17. ICTs, Empowerment, and Development: Articulating Grassroots Analysis Through Participatory Approaches / <i>Hannah Beardon</i>	2450
Chapter 5.18. Enacting and Interpreting Technology- From Usage to Well-Being: Experiences of Indigenous Peoples with ICTs / <i>Björn-Sören Gigler</i>	2464
Chapter 5.19. ICTs and Educational Benefits in Regional Development / <i>James J. Rennie</i>	2495
Chapter 5.20. Support Networks for Rural and Regional Communities / <i>Tom Denison</i>	2514
Chapter 5.21. Digital Divide: A Glance at the Problem in Moldova / <i>Liudmila Burtseva, Svetlana Cojocar, Constantin Gaidric, Galina Magariu, and Tatiana Verlan</i>	2531

Volume V

Chapter 5.22. Digital Opportunities, Equity, and Poverty in Latin America / <i>Simone Cecchini</i>	2566
Chapter 5.23. Integrating ICTs in African Development: Challenges and Opportunities in Sub-Saharan Africa / <i>Bobak Rezaian</i>	2586
Chapter 5.24. Poverty Reduction through Community-Compatible ICTs: Examples from Botswana and other African Countries / <i>Rebecca Lekoko and Bantu Morolong</i>	2617
Chapter 5.25. Interactions among Thai Culture, ICT, and IT Ethics / <i>Pattarasinee Bhattarakosol</i>	2637

Chapter 5.26. The Use of Information and Communication Technology for the Preservation of Aboriginal Culture: The Badimaya People of Western Australia / <i>Katina Michael and Leone Dunn</i>	2652
Chapter 5.27. ICT and the Orang Asli in Malaysia / <i>Pauline Hui Ying Ooi</i>	2656
Chapter 5.28. Information and Communication Technology and Economic Development in Malaysia / <i>Mohamed Aslam</i>	2659
Chapter 5.29. Urban Information Systems in Turkish Local Governments / <i>Koray Velibeyoglu</i>	2673
Chapter 5.30. Human Rights Movements and the Internet: From Local Contexts to Global Engagement / <i>John Lannon and Edward Halpin</i>	2682
Chapter 5.31. Learning IT: Where do Lectures Fit? / <i>Tanya McGill and Samantha Bax</i>	2708
Chapter 5.32. Information Technology Certification: A Student Perspective / <i>Tanya McGill and Michael Dixon</i>	2718
Chapter 5.33. The Effects of Human Factors on the Use of Web-Based Instruction / <i>Sherry Y. Chen</i>	2728
Chapter 5.34. Exploring the Rhetoric on Representing the User: Discourses on User Involvement in Academia and the IT Artifact Product Development Industry / <i>Netta Iivari</i>	2741
Chapter 5.35. E-Government Practices in Regional Context: Turkish Case / <i>Derya Altunbas and Elif Karakurt Tosun</i>	2771
Chapter 5.36. Information Security in Small Businesses / <i>Kishore Singh</i>	2791
Chapter 5.37. Impact of Organisational Intranets on Profitability in Organisations / <i>Udo Richard Averweg</i>	2817
Chapter 5.38. Training Sequences and their Effects on Task Performance and User Outcomes / <i>Clive Sanford and Anol Bhattacharjee</i>	2845
Chapter 5.39. CareerQuesting: Evaluating Web-Based Resources for Interesting Girls in STEM Careers / <i>Karen F. White and Mara H. Wasburn</i>	2863
Chapter 5.40. Feeling Welcome: Internet Tourism Marketing Across Cultures / <i>Wolfgang Georg Artl</i>	2877
Chapter 5.41. ICT and the Travel Industry: Opportunities and Challenges for New Zealand Travel Agents / <i>Vladimir Garkavenko and Simon Milne</i>	2898

Section 6. Managerial Impact of Information Communication Technologies

This section presents contemporary coverage of the more formal implications of ICT, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be facilitated within organizations. Core ideas such as IT-related training and continuing education as well as the efficiency and effectiveness of ICT in modern organizations are discussed throughout these chapters. Contributions within this section seek to answer the fundamental question of ICT implementation in organizations—how can particular technologies best be integrated into businesses and at what cost? Particular chapters provide methods for integrating ICT into the workforce and offer feedback from employees and employers regarding the future of ICT in the modern organizations.

Chapter 6.1. Holistic Approach to Align ICT Capabilities with Business Integration / <i>Marc Rabaey, Herman Tromp, and Koenraad Vandenborre</i>	2918
Chapter 6.2. A Framework for Business Performance Management / <i>Marco van der Kooij</i>	2933
Chapter 6.3. Neural Data Mining System for Trust-Based Evaluation in Smart Organizations / <i>T. T. Wong</i>	2950
Chapter 6.4. E-Commerce and Small Tourism Firms / <i>Patrice Braun</i>	2968
Chapter 6.5. Towards Improved Business Planning Decision Support for Small-to-Medium Tourism Enterprise Operators / <i>G. Michael McGrath</i>	2976
Chapter 6.6. Investing in Online Privacy Policy for Small Business as Part of B2C Web Site Management: Issues and Challenges / <i>Geoff Erwin and Mike Moncrieff</i>	2998
Chapter 6.7. The Use of IT in Small Business: Efficiency and Effectiveness in South Africa / <i>Sam Lubbe</i>	3007
Chapter 6.8. Information Technology Investment Evaluation and Measurement Methodology: A Case Study and Action Research of the Dimensions and Measures of IT-Business-Value in Financial Institutions / <i>Johan Nel</i>	3021
Chapter 6.9. Examining the Approach Used for Information Technology Investment Decisions by Practitioners Responsible for IT Planning in Namibia / <i>Karna Naidoo</i>	3036
Chapter 6.10. A Case Study on the Selection and Evaluation of Software for an Internet Organisation / <i>Pieter van Staaden</i>	3042
Chapter 6.11. Managing Socio-Technical Integration in Iterative Information System Development Projects / <i>Bendik Bygstad</i>	3057
Chapter 6.12. Several Simple Shared Stable Decision Premises for Technochange / <i>Richard Diamond</i>	3072

Chapter 6.13. Integrating Real Option and Dynamic Capability Theories of Firm Boundaries: The Logic of Early Acquisition in the ICT Industry / <i>Alfred G. Warner and James F. Fairbank</i>	3083
Chapter 6.14. IT Training as a Strategy for Business Productivity in Developing Countries / <i>Shirish C. Srivastava and Thompson S. H. Teo</i>	3101
Chapter 6.15. Action Research Methods / <i>Patrice Braun</i>	3112
Chapter 6.16. The Impact of IT Investment in South African E-Commerce SME Organizations / <i>Sam Lubbe</i>	3119
Chapter 6.17. Organizational Performance and IT Investment Intensity of South African Companies / <i>Johan Nel</i>	3129
Chapter 6.18. Government Procurement ICT's Impact on the Sustainability of SMEs and Regional Communities / <i>Peter Demediuk</i>	3137
Chapter 6.19. Women Entrepreneurs in Finnish ICT Industry / <i>Tarja Pietiläinen, Hanna Lehtimäki, and Heidi Keso</i>	3142
Chapter 6.20. Directing Equal Pay in the UK ICT Labour Market / <i>Claire Keogh, Angela Tattersall, and Helen Richardson</i>	3150
Chapter 6.21. MNE Knowledge Management Across Borders and ICT / <i>Jürgen Kai-Uwe Brock and Yu Josephine Zhou</i>	3158
Chapter 6.22. Is Organizational e-Democracy Inevitable? The Impact of Information Technologies on Communication Effectiveness / <i>Bernadette M. Watson, Gavin M. Schwarz, and Elizabeth Jones</i>	3171
Chapter 6.23. The Role of Information and Communication Technology in Managing Cultural Diversity in the Modern Workforce: Challenges and Issues / <i>Indrawat Nataatmadja and Laurel Evelyn Dyson</i>	3190

Volume VI

Chapter 6.24. Creating an Entrepreneurial Mindset: Getting the Process Right for Information and Communication Technology Students / <i>Briga Hynes and Ita Richardson</i>	3207
Chapter 6.25. Working at Home: Negotiating Space and Place / <i>Tracy L. M. Kennedy</i>	3229
Chapter 6.26. Writing-Across-the-IT/MIS Curriculum / <i>Stephanie J. Etter and Jeffrey W. Merhout</i>	3246

Chapter 6.27. Management of Telecommunications Services: A Vital New Content Area and a Course Model for the College of Business / <i>Faye P. Teer, Young B. Choi, and Harold B. Teer</i>	3259
---	------

Section 7. Critical Issues in Information Communication Technologies

This section addresses conceptual issues related to the field of ICT, such as the existence of a gender barrier and the potential of ICT for realizing social justice. Within these chapters, the reader is presented with an in-depth analysis of the most current and relevant conceptual inquiries within this growing field of study. Particular chapters address attitudes toward ICT in high schools, international ICT spillover, and ICT literacy among members of society. Overall, contributions within this section ask unique and often controversial questions related to ICT study and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1. ICT, Work Organisations, and Society / <i>Gunilla Bradley</i>	3273
Chapter 7.2. A Time Series Analysis of International ICT Spillover / <i>Juan Juan Zhang and Sang-Yong Tom Lee</i>	3285
Chapter 7.3. From Information Society to Global Village of Wisdom? The Role of ICT in Realizing Social Justice in the Developing World / <i>Sirkku Kristina Hellsten</i>	3299
Chapter 7.4. What Kinds of Organisations do We Want to Build in Africa with Information Communication Technology? / <i>Rembrandt Klopper</i>	3322
Chapter 7.5. Computing and ICT Literacy: From Students' Misconceptions and Mental Schemes to the Monitoring of the Teaching-Learning Process / <i>Antonio Cartelli</i>	3338
Chapter 7.6. ICT in Schools: What is of Educational Value? / <i>Aidan Mulkeen</i>	3348
Chapter 7.7. ICT, Knowledge Construction, and Evolution: Subject, Community, and Society / <i>Antonio Cartelli</i>	3368
Chapter 7.8. Attitudes Towards ICT in Australian High Schools / <i>Kaylene Clayton</i>	3384
Chapter 7.9. A Comparative Analysis of Online and Traditional Undergraduate Business Law Classes / <i>Daniel J. Shelley, Louis B. Swartz, and Michele T. Cole</i>	3391
Chapter 7.10. Concerns with "Mutual Constitution": A Critical Realist Commentary / <i>Alistair Mutch</i>	3405
Chapter 7.11. Emotional Digitalization as Technology of the Postmodern: A Reflexive Examination from the View of the Industry / <i>Claus Hohmann</i>	3417
Chapter 7.12. Optimality-Theoretic Lexical Mapping Theory: A Case Study of Locative Inversion / <i>One-Soon Her</i>	3428

Chapter 7.13. Trusting Computers Through Trusting Humans: Software Verification in a Safety-Critical Information System / <i>Alison Adam and Paul Spedding</i>	3460
Chapter 7.14. Propagating the Ideal: The Mobile Communication Paradox / <i>Imar de Vries</i>	3475
Chapter 7.15. A De-Construction of Wireless Device Usage / <i>Mary R. Lind</i>	3489
Chapter 7.16. Virtual Networking without a Backpack? Resource Consumption of Information Technologies / <i>Justus von Geibler, Michael Kuhndt, and Volker Türk</i>	3500
Chapter 7.17. Cultural Factors and Collective Identity of Women in ICT / <i>Phyl Webb and Judy Young</i>	3514
Chapter 7.18. A Cultural Studies Approach to Gender and ICT / <i>Merete Lie</i>	3522
Chapter 7.19. Who's Talking Online? A Descriptive Analysis of Gender & Online Communication / <i>Taralynn Hartsell</i>	3529
Chapter 7.20. Who's Talking Online II: Revisiting Gender and Online Communications / <i>Taralynn Hartsell</i>	3540
Chapter 7.21. Cultivating Greater Acceptance of Women in Technology: A Pilot Study / <i>Mara H. Wasburn</i>	3552
Chapter 7.22. Are Cross-Gender Conversations in Threaded Discussions Reminiscent of Communicating Across Cultural Boundaries? / <i>David Gefen, Nitza Geri, and Narasimha Paravastu</i>	3566
Chapter 7.23. The Paleolithic Stone Age Effect? Gender Differences Performing Specific Computer-Generated Spatial Tasks / <i>Geoffrey S. Hubona and Gregory W. Shirah</i>	3578

Section 8. Emerging Trends in Information Communication Technologies

This section highlights research potential within the field of ICT while exploring uncharted areas of study for the advancement of the discipline. Introducing this section are chapters that set the stage for future research directions and topical suggestions for continued debate. Discussions exploring RFID, virtual religion in the 21st century, and new ICTs for conflict management provide insight into forthcoming issues in ICT study. Authors within this section look past the digital divide to a time when ICT is ubiquitous and divisions no longer exist. These contributions, which conclude this exhaustive, multi-volume set provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Chapter 8.1. Bringing on the Next Billion Online: Cooperative Strategies to Create Internet Demand in Emerging Markets / <i>Karen Coppock</i>	3603
Chapter 8.2. ICT and the Efficient Markets Hypothesis / <i>Andrea J. A. Roofe</i>	3623

Chapter 8.3. Creating Competitive Advantage: The Emergence of a New Business through Collaborative Networks—An Empirical Case Study in the ICT Sector / <i>Arla Juntunen</i>	3634
Chapter 8.4. Enabling the Expansion of Microfinance Using Information and Communication Technologies / <i>Narima Amin</i>	3658
Chapter 8.5. Management of New Genetic Knowledge for Economic and Regional Development of Ethnic Minorities in China / <i>Jan-Eerik Leppanen</i>	3681
Chapter 8.6. Visualizing ICT Change in the Academy / <i>Gale Parchoma</i>	3695
Chapter 8.7. Perspectives on 21st Century E-Learning in Higher Education / <i>Lalita Rajasingham</i>	3716
Chapter 8.8. RFID: New Technology on the Horizon for IT Majors / <i>Eric Puffenbarger, Faye P. Teer, and S. E. Kruck</i>	3730
Chapter 8.9. Games and Advertisement: Beyond Banners and Billboards / <i>David B. Nieborg</i>	3744
Chapter 8.10. Believe It or Not: Virtual Religion in the 21st Century / <i>Susan E. George</i>	3759
Chapter 8.11. Changing Technological Trends in the Travel Behaviour of Older Tourists / <i>Ian Patterson</i>	3768
Chapter 8.12. New ICTs for Conflict Prevention and Management / <i>Ángela-Jo Medina</i>	3784
Chapter 8.13. Crossing the Digital Divide and Putting ICT to Work to Improve People's Lives / <i>Teresa Peters</i>	3804
Chapter 8.14. Creative London? Investigating New Modalities of Work in the Cultural Industries / <i>David Lee</i>	3807
Chapter 8.15. Information-Communications Systems Convergence Paradigm: Invisible E-Culture and E-Technologies / <i>Fjodor Ruzic</i>	3820

Preface

The development, advancement, and implementation of Information Communication Technologies (ICT) within today's ever-changing society profoundly impacts the way we lead our lives. With its rapid growth and continual evolution, this field has provided the impetus for economic innovation, cultural revolution, and social reform. Consequently, the effects of these pervasive technologies present both a challenge and an opportunity for researchers, educators, and students worldwide.

As applications of ICT have grown in both number and popularity, researchers and educators have devised a variety of techniques, methodologies, and measurement tools to develop, deliver, and, at the same time, evaluate the effectiveness of their use. The explosion of these methodologies in this new field of ICT study has created an abundance of new, state-of-the-art literature related to all aspects of this expanding discipline. This body of work allows researchers to learn about the fundamental theories, latest discoveries, and forthcoming trends in the field of ICT.

Constant technological innovation challenges researchers in ICT to stay abreast of and continue to develop and deliver methodologies and techniques utilizing the latest advancements in ICT. In order to provide the most comprehensive, in-depth, and current coverage of all topics related to ICT and its application, as well as to offer a single reference source on all conceptual, methodological, technical, and managerial issues, *Information Science Reference* is pleased to offer a six-volume reference collection on this rapidly growing discipline. This collection aims to empower researchers, students, and practitioners by facilitating their comprehensive understanding of the most critical areas within this field of study.

This collection, entitled ***Information Communication Technologies: Concepts, Methodologies, Tools, and Applications*** is organized in eight distinct sections, which are as follows: (1) Fundamental Concepts and Theories; (2) Development and Design Methodologies; (3) Tools and Technologies; (4) Utilization and Application; (5) Organizational and Social Implications; (6) Managerial Impact; (7) Critical Issues; and (8) Emerging Trends. The following paragraphs provide a summary of what is covered in each section of this multi-volume reference collection.

Section One, ***Fundamental Concepts and Theories***, serves as a foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of ICT. Chapters such as "An Overview on Strategic ICT Implementations Toward Developing Knowledge Societies" by Hakikur Rahman and "ICT and Business in the New Economy: Globalization and Attitudes Towards eCommerce" by John Sagi, Elias Carayannis, and Subhashish Dasgupta, provide an excellent framework for discussing the fundamental relationship between ICT and societal growth. Sadayoshi Takaya's, "The Evolution of ICT, Economic Development, and the Digitally-Divided Society" offers insight into some of the critical issues resulting from ICT development, which include the emergence of a digital divide and the social, political, and economic impact this may have. Another chapter, "Between Tradition and Innovation in ICT and Teaching" by Antonio Cartelli, addresses how ICT has changed the face of modern education. The contributions within this foundational section enable readers to learn from expert research on the elemental theories underscoring the discipline of ICT.

Section Two, *Development and Design Methodologies*, contains in-depth coverage of conceptual architectures and frameworks, providing the reader with a comprehensive understanding of emerging technological developments within the field of ICT. “Connecting the First Mile: A Best Practice Framework for ICT-Based Knowledge Sharing Initiatives” by Surmaya Talyarkhan, David J. Grimshaw, and Lucky Lowe offers a method for introducing knowledge sharing in developing countries through ICT. Rosa Borge’s contribution, “An Explanatory Approach to the Political Uses of ICT Initiatives for Participation,” demonstrates that ICT also extends into the political sphere, since politicians use ICT to bridge the gap between themselves and the voting public. From basic designs to abstract development, chapters such as “Developing Regional Tourism Using Information Communications Technology” by Dean Carson and “Peering into the Black Box: A Holistic Framework for Innovating at the Intersection of ICT & Health” by Ben Bellow, Aman Bhandar, and Mahad Ibrahim serve to expand the reaches of development and design technologies within the field of ICT.

Section Three, *Tools and Technologies*, presents extensive coverage of various tools and technologies available in the field of ICT that researchers, educators, and professionals alike use to streamline and enhance their daily tasks. Chapters such as “Internet: A Right to Use and Access Information, or a Utopia?” by Inban Naicker and “Radio for Social Development” by Patrick Craddock and Peggy Duncan emphasize the widespread impact that particular technologies have upon entire communities. Similarly, contributions such as “Innovations in Wireless Technologies” by Diego Ragazzi and “Satellite Technology in Schools” by Anneleen Cosemans provide overviews of revolutions in ICT while also discussing the potential effects of these technologies. These rigorously researched chapters provide insight into the tools and technologies that ICT has spawned and how these tools and technologies are incorporated into education, business, and society at large.

Section Four, *Utilization and Application*, provides an in-depth investigation into the ways in which ICT has been adopted and implemented in society. This section includes contributions such as “Formation of a Knowledge-Based Society through Utilization of Information Networking” by Hakikur Rahman, which explains how ICT can empower and enable developing communities. Conversely, Kennedy D. Gunawardana’s “Potential Challenges of ICT Implementations in Sri Lanka” reveals possible barriers to ICT utilization and application. ICT’s application to other diverse fields is mentioned in chapters such as “Implementation of a Health Information Systems Programme” by Zubeeda Banu Quraishy and “Virtual Reality Applications in Tourism” by Călin Gurău. Research in this section provides excellent coverage of today’s global community and demonstrates how ICT impacts the social, economic, and political fabric of our present-day global village.

Section Five, *Organizational and Social Implications*, includes a wide range of research pertaining to the cultural and organizational impact of ICT around the world. Introducing this section is Matthew Mitchell’s “Convergence of ICT and Culture,” which analyzes the impact that ICT utilization and development has upon culture. Additional chapters included in this section, such as “Mind the Gap!: New ‘Literacies’ Create New Divides” by Andrew D. Madden, J. Miguel Baptista Nunes, and M. A. McPherson, emphasize one of the most contested issues regarding access to technology—the digital divide. This unique problem, in which a veritable wall between the technology “haves” and “have nots” is constructed, is also examined in “Digital Opportunities, Equity, and Poverty in Latin America” by Simone Cecchini, as well as in Pattarasinee Bhattarakosol’s contribution, “Interactions among Thai Culture, ICT, and IT Ethics.” The discussions presented in this section offer insight into the integration of technology in society regardless of socioeconomic status—arguably the most important social and organizational barrier that this field of study has yet to overcome.

Section Six, *Managerial Impact*, presents contemporary coverage of the social implications of ICT, which are, more specifically, related to the corporate and managerial utilization of ICT within organiza-

tions. Core ideas such as integration, training, and potential strategies for increasing the effectiveness of modern organizations are discussed in this collection. “A Framework for Business Performance Management,” by Marco van der Kooij emphasizes ICT’s role in fostering successful predictions about the future of a business. Equally essential to this examination of managerial impact is evaluating the effectiveness of already-implemented ICT programs, which is examined at length in chapters such as “The Use of IT in Small Business: Efficiency and Effectiveness in South Africa” by Sam Lubbe. A contribution by Indrawat Nataatmadja and Laurel Evelyn Dyson, “The Role of Information and Communication Technology in Managing Cultural Diversity in the Modern Workforce: Challenges and Issues” explores how managers can make the utilization of ICT in a culturally diverse workplace more successful. As a result of their research, the authors of this chapter conclude that since no individual ICT application works best in existing social and cultural contexts, managers must provide flexibility in their ICT integration.

Section Seven, *Critical Issues*, presents readers with an in-depth analysis of the most current and relevant issues within this growing field of study by addressing topics such as the existence of a gender barrier, social justice, and the relationship between technology and humanity. Sirkku Kristina Hellsten’s “From Information Society to Global Village of Wisdom? The Role of ICT in Realizing Social Justice in the Developing World” advocates the theory that ICT can, potentially, allow us to enhance our well-being, realize our capabilities, and, ultimately, promote better standards of living and social justice. Other chapters discuss the role of gender in ICT from a number of distinct angles. Within Taralynn Hartsell’s “Who’s Talking Online? A Descriptive Analysis of Gender & Online Communication” and the successive publication “Who’s Talking Online II: Revisiting Gender and Online Communications,” the difference between men and women’s online communication styles is illustrated and analyzed, while in “Cultivating Greater Acceptance of Women in Technology: A Pilot Study,” author Mara H. Wasburn attempts to account for the shortage of women pursuing careers in ICT, as well as devise strategies for attracting more women to the field.

The concluding section of this authoritative reference tool, *Emerging Trends*, highlights research potential within the field of ICT while exploring uncharted areas of study for the advancement of the discipline. New trends in ICT implementation discussed in this section include virtual religion, which is defined in “Believe It or Not: Virtual Religion in the 21st Century” by Susan E. George, the use of RFID technology, which is considered in “RFID: New Technology on the Horizon for its Majors” by Eric Puffenbarger, Faye P. Teer, and S. E. Kruck and the use of ICT in managing and preventing conflict, which is examined in “New ICTs for Conflict Prevention and Management” by Ángela-Jo Medina. Other topics, such as ICT’s future role in education, are envisioned in selections such as Gale Parchoma’s “Visualizing ICT Change in the Academy” and “Perspectives on 21st Century E-Learning in Higher Education” by Lalita Rajasingham. The future trends and research examined in this final section demonstrate that the always-changing field of ICT promises to transform every aspect of our technological lives.

Although the contents of this multi-volume book are organized within the preceding eight sections, which offer a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore, to ensure that the scholar, researcher, and educator have access to the entire contents of this multi-volume set, as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited, multi-user electronic access to the online aggregated database of this collection for the life of the edition, free of charge when a library purchases a print copy. In addition to providing content not included within the print version, this aggregated database is also continually updated to ensure that the most current research is available to those interested in ICT.

The diverse and comprehensive coverage of ICT in this six-volume, authoritative publication will contribute to a better understanding of all topics, research, and discoveries in this developing, significant field of study. Furthermore, the contributions included in this multi-volume collection series will be instrumental in the expansion of the body of knowledge in this enormous field, resulting in a greater understanding of the fundamentals while also fueling the research initiatives in emerging fields. We at *Information Science Reference*, along with the editor of this collection, hope that this multi-volume collection will become instrumental in the expansion of the discipline and will promote the continued growth of ICT.

Introductory Chapter

A Brief Introduction to the Field of Information Communication Technologies

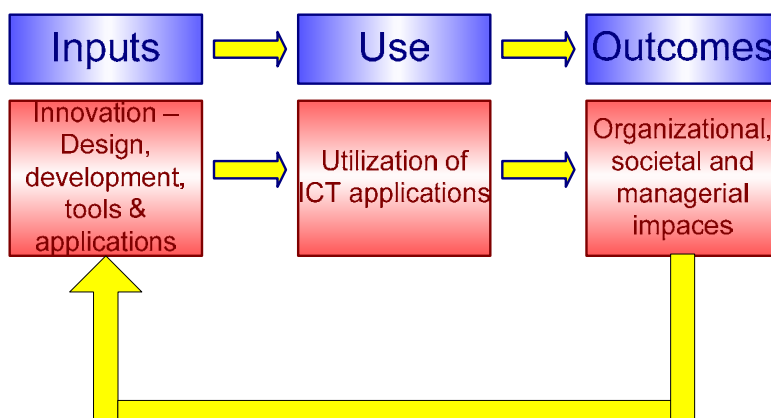

Craig Van Slyke
University of Central Florida, USA

INTRODUCTION

Information and communication technologies (ICT) have evolved from back-office, workhorse devices to become central to our daily work and personal lives. ICT research has evolved along with the technologies. ICT research now involves on personal, organizational, societal and economic topics and utilizes theories from a wide range of research traditions. In this chapter, we try to give a sense of the breadth of ICT research by providing a broad overview of many of the topics covered throughout the six-volume reference set. To do this, we discuss a variety of topics related to the creation, use and impacts of ICT.

This chapter is organized around a concise, yet useful framework, which is shown in Figure 1. After discussing some core concepts and theories, the chapter follows a flow model that originates with activities centered on innovation—the creation of new information technologies and the modification of extant ICTs. These innovations, in essence, provide the “inputs” into the system of ICT concepts. The discussion of innovations or inputs is broken down into two areas. Development and design methods

Figure 1. Organizing framework

pertain to the methods and theories related to the creation of new ICT. This topic is taken rather broadly to include such subjects as end-user development, and community development. The second area under the innovation/inputs area concerns the tools and applications themselves. Applications such as enterprise systems, supply chain management, and social computing are discussed.

After discussing innovations and inputs, we turn attention to the utilization of the innovations discussed previously. The focus here is on issues related to how and why individuals and organizations use ICT. These are fundamental questions for without use, there can be no outcomes, which brings us to the third component of our framework—outcomes of ICT use.

Outcomes are discussed at three levels, societal impacts, organizational impacts, and managerial impacts. Subsumed within the societal impacts are impacts on the individual. ICT have had and continue to have substantial impacts on all levels of society. Topics such as globalization, e-government, and environmental impacts are among the organizational and societal impacts discussed. ICT also impact how leaders manage their organizations and workers. Topics include outsourcing (and the reverse, back-sourcing), and managing a global workforce. After discussing outcomes, we describe a number of critical issues and emerging trends that are important to ICT research.

FUNDAMENTAL CONCEPTS AND THEORIES

ICT research has used a vast array of theories, borrowing from reference disciplines ranging from sociology to computer science. As might be expected, the theory applied relies on the level of analysis and research questions being pursued. Psychology and sociology-based theories seem to dominate individual-level studies, although communication and economic theories are also widely used. In this section, we provide a brief discussion of some of the more widely used theories, and describe their core concepts and how they have been applied to ICT research. This list is not intended to be exhaustive, but rather is meant to provide a sense of the range of theories used in ICT research. Table # lists the theories introduced in this section and provides key references for each.

Table 1. Fundamental theories

Theory	Focus	Key References
Technology acceptance model	Individual behavior	Davis, 1989
Theory of reasoned action	Individual behavior	Fishbein & Ajzen, 1975
Diffusion of innovation	Individual behavior, social interaction	Rogers, 1995
Task-technology fit	Individual behavior	Goodhue & Thompson, 1995
Social cognitive theory	Social interaction	Bandura, 1986
Social exchange theory	Social interaction	Homans, 1958
Social identity theory	Social interaction	Tajfel & Turner, 1986
Social network theory	Social interaction	Granovetter, 1973
Actor-network theory	Social interaction	Latour, 1986
Agency theory	Economic behavior	Eisenhardt, 1989
System theory	General theory	Von Bertalanffy, 1962

The technology acceptance model (TAM) (Davis, 1989) is among the most widely-applied theories in ICT research. This theory posits that two beliefs, perceived usefulness and perceived ease of use, influence use intentions, which impact actual use. Attitude towards use is sometimes included as a mediating variable between the beliefs and intentions (e.g. Davis, Bagozzi & Warshaw, 1989), although most researchers omit attitudes. The theory of reasoned action (TRA) (Fishbein & Ajzen, 1975) is the theoretical foundation of TAM. TRA is a general model of human behavior, while TAM is an adaptation of TRA specifically intended for explaining and predicting use of ICT. TAM has generally enjoyed reasonable empirical support, although the significance of perceived ease of use is sometimes unsupported. TAM-based studies typically take one of two approaches, either applying TAM in a new context (such as electronic commerce), or adding new variables to TAM (such as trust).

Diffusion of innovation theory (Rogers, 1995) is also widely used in ICT research. Broadly speaking there have been two major ways in which this theory has been applied. The first way is similar to TAM in that these studies seek to understand factors that lead to the adoption or rejection of ICT-based innovations. These studies often use perceived innovation characteristics (or the perceived characteristics of innovating) as the main factors that influence adoption. Beliefs regarding these characteristics are expected to impact decisions to adopt or reject an innovation. Widely-studied beliefs include relative advantage, compatibility and complexity. Perceptions of result demonstrability, visibility, and trialability are also included in many studies of ICT adoption (e.g. Van Slyke, Lou & Day, 2002; Ilie, Van Slyke, Green & Lou, 2005; Plouffe, Hulland, & Vandenbosch, 2001). The second manner in which diffusion theory has been applied to ICT research concerns how the use of an innovation spreads throughout a social system (this is the definition of diffusion). These studies are not concerned with an individual user's or organization's adoption, but are instead concerned with how the use of the innovation spreads. Some studies within this category are focused on understanding what leads to adoption at various points along the diffusion curve.

The task-technology fit model is another approach to understanding individual use of ICT, although it is directed at understanding what leads to productive use of an ICT (although utilization is also a dependent variable in the model). Task-technology fit theory proposes that a technology is more likely to positively impact individual productivity if the characteristics of the technology fit the characteristics of the task (Goodhue & Thompson, 1995). In addition, the technology is more likely to be utilized when the task and technology fit well. Important task-technology fit dimensions include quality, locatability, authorization, compatibility, ease of use, timeliness, and reliability.

Theories of social interaction have also been important to ICT use. The use of ICT requires interaction between an individual and the ICT. People are fundamentally social creatures, so a complete understanding of ICT requires understanding the social aspects of ICT use. Researchers who are interested in this area often apply social theories in their studies. Examples include social-cognitive theory, social exchange theory, social identity theory and social network theory. (Other theories, such as diffusion theory, also include social components.) Social-cognitive theory (Bandura, 1986) seeks to explain human behavior through understanding how people, their behaviors, and their environments interact. Further, learning can occur through the process of observing others in the context of social interactions and personal experiences. Social-cognitive theory is closely linked to self-efficacy theory. Social exchange theory views social interactions as exchanges where the parties contribute on the expectation of gaining rewarding reactions from the other party in the exchange. People contribute to the relationship in order to gain through social reciprocity. In contrast, social identity theory posits that people gain "social identities" through their association with various groups. Some propose that social identity theory may be more applicable to the study of group-oriented ICT, such as knowledge management systems (Jarvenpaa & Staples, 2001). Social network theory views relationships in terms individuals and the connections

among them. In the view of social network theory, the connections among individuals are as important as characteristics of an individual (if not more important).

Another network-oriented theory is actor-network theory, which extends the idea of social networks to include non-human elements, such as ICT. Networks, therefore, contain both social and technical elements. Actor-network theory is concerned with how the networks come together (and fall apart), rather than why the network might exist.

Economic theories have also been widely applied to ICT research. For example, agency theory (Eisenhardt, 1989) has been applied to studies of outsourcing (as well as other areas) (e.g. Choudhury & Sabherwal, 2003). Agency theory is concerned with the principal-agent problem, which occurs under conditions of asymmetric and imperfect information when a principal hires an agent to act on the principal's behalf. The problem of asymmetric information is also important to trust-oriented studies because the asymmetric information leads to increased risk, which increases the importance of trust. Resource-oriented theories from economics have also been used in ICT research (e.g. Oh & Pensonneault, 2007).

The final fundamental theory we discuss is perhaps the most fundamental of all, general systems theory (Von Bertalanffy, 1962). The basic idea behind general systems theory is that one cannot understand an entity through the study of each component individually. Understanding an entity requires understanding how the various components fit together; one must understand the arrangements of and connections between the components that make up the whole. This basic concept is at the very core of ICT research, whether or not this is explicitly acknowledged. General systems theory is used to understand ICT and the environments in which they are applied. Further, it has spawned other important theories and approaches to understanding ICT, not the least of which is the concept of systems thinking. It may be time to return to our roots and take the ideas of systems theory more to heart. This is apparent from the growing interest in considering the role of context in ICT studies. Just as the components of a system interact with their environment (for open systems), so do ICT interact with the various elements that make up the context in which the ICT is used. This inescapable fact should be considered more explicitly in ICT research.

Clearly, there are many other important theories and concepts that have been used in ICT research. A complete discussion is beyond the scope of this section. However, we hope that our brief treatment provides some insights as to the breadth of theories that ICT researchers employ. Throughout the remainder of this chapter we will refer to these and other fundamental ICT theories.

INPUTS

In this section, we discuss the innovation or inputs phase of our framework. Here we are concerned with theories and research related to methods for designing and developing ICT, and with the tools and applications that result from design and development efforts. Development and design methods are included in this section because they provide the means by which ICT are created. The actual ICT that are created (the tools and applications) are also inputs in our framework because they are the artifacts that are employed in the next stage of our framework (use).

Development and Design Methods

Development and design methods form the basis for the creation of ICT applications. While a plethora of such methods exist, this section focuses on two fundamental areas, design science and end-user de-

velopment. Design science is a broad area that has been employed since the early days of ICT research. Such core concepts and methods as database design and modeling, the systems development life cycle, and decision support systems have all been profoundly impacted by design science. Further, there has been a recent resurgence in interest in the application of design science in ICT research (Gregor & Jones, 2007). End-user development is the other topic discussed in this section. As development tools become increasingly sophisticated and easy-to-use, it is likely that the prevalence of end-user development will increase. As a result, it becomes increasingly important to understand end-user development and its impacts.

Design Science

While ICT research seems dominated by behaviorally-oriented studies, there is also a need for research and theories related to the design and creation of ICT artifacts. Design science and design theories address take the latter approach to understanding ICT. Fundamentally, design science seeks to understand ICT by designing and building artifacts, which are applied to problems of interest (Hevner, March, Park and Ram, 2004). The newly-created artifact is also evaluated. Theory can be refined on the basis of application and evaluation. The term “artifact” should be taken in a rather broad sense; it does not imply that a computer program is written or new hardware is created. Artifacts may include constructs, models, methods and instantiations (Hevner et al., 2004). Behavioral science and design science are not at odds with one another. Design science may use theories and knowledge generated from behavioral science to inform the design and creation of artifacts. In addition, behavioral science studies may identify the problem space and environment to which the artifacts are applied.

Design science spawns and uses design theories. Design theories focus on how to do something; they are directed at design and action. This is in contrast to other classes of theories, which may be directed at analyzing, explaining and/or predicting (Gregor & Jones, 2007). Design theories may be directed at understanding or creating a methodology or a product. As Hevner et al. (2004) point out, design is both a noun and a verb. Design can refer to the artifact itself, or to a set of activities. Design theories may address three different phenomena: instantiations (physical artifacts or a set of actions with physical existence), (2) theories or artificial artifacts (artifacts without a physical existence, and (3) human understanding of artifacts (Gregor & Jones, 2007). At a minimum specifying a design theory requires addressing five areas, (1) purpose and scope, (2) constructs of interest, (3) principles of form and function, (4) artifact mutability, and (5) testable propositions. Full specification should also include principles of implementation and expository instantiation (Gregor & Jones, 2007).

There seems to be an ongoing debate as to the relevance of design science as an appropriate paradigm for the study of ICT. Recently, strong arguments have been made in favor of design science (e.g. Hevner et al., 2004; Ball, 2001). Ball (2001), using Whetten’s (1989) definition of contributions of theory, demonstrates how design science research can satisfy all of Whetten’s criteria for “contributions of theory.” For example, design science satisfies the “what” requirement of contributions of theory by studying the effects that the artifact has on other elements in the environment in which the artifact is implemented. Using the example of e-commerce research, Ball (2001) provides several example of how design science could be used to build theories related to e-commerce research.

Information systems design science has made contributions to ICT research and practice. One excellent example of such a contribution is the system development life cycle (SDLC) (Gregor & Jones, 2007). While many SDLC variations exist, the concept of an SDLC can be considered the object of a design theory; this is an example of a methods artifact. Other examples of how design science has been applied to ICT research include decision support systems (DSS), research, the entity-relationship model, executive information systems and group support systems (Hevner et al., 2004).

Usability research represents an interesting application of design science. Design science can be used to develop methods for including usability into current design and development methodologies or for developing new methods for evaluating usability. For example, Zhang Cary, Te-eni, Termaine, 2005) propose a method for integrating usability into the modern SDLC. Such an integration may help fill the gap between systems that satisfy organizational needs and systems that are satisfying to individual users. Design science can be used to test the actual ICT developed using these methods. Given the increasingly central nature of ICT in our lives, enhancing usability is of critical importance. Design science holds considerable promise for helping ICT researchers and practitioners better understand how to improve ICT usability.

The further emergence of design science and the development of design theories holds considerable promise for extending our knowledge of development and design methods. Existing methods can be extended, and new methods can be created. Because the world of ICT is constantly changing, we frequently need new methods and tools for creating and applying ICT. Studies that utilize design science methods are particularly useful for addressing these needs.

End-User Development

Over time, application development tools and environments have become increasingly sophisticated. End users have also become increasingly knowledgeable. Software publishers have, at the same time, begun to offer software that allows for increasing amounts of customization (Hansen-Asand & Morch, 2006). The confluence of these events brought about a growing tendency for end users to engage in activities that were once the purview of dedicated application developers. This trend towards end user development raises a number of interesting theoretical and practical issues. Interestingly, some of these same issues were studied in the earlier days of ICT research in the context of spreadsheet development.

There is a continuum of actors in software development and use, ranging from “regular users” who do not engage in any customization or other tailoring of a system, through “local developers” who have more computer and development skills than even super-users, to professional developers (Hansen-Asand & Morch, 2006). This range of actors leads to opportunities to apply a variety of social theories to understand the motivations of the various parties involved. For example, Hansen-Asand and Morch (2006) applied activity theory to the study of end user application development in a Scandinavian accounting firm. Their findings revealed interesting insights into the roles played by the various actors.

A major area of interest concerns the risks associated with end-user development. These risks range from a lack of accuracy (in part, due to a lack of proper testing), to failure to properly back up data (McGill & Klisc, 2006). A particularly interesting aspect of this research concerns the IT auditing implications of end-user development. Verifying that systems analysis and development methodologies are sound and are followed is one aspect of IS assurance. End user development is often undisciplined and ad hoc; in such cases an organization’s prescribed methodologies are unlikely to be followed. Even the existence of end user-developed systems may be difficult for auditors to uncover. Reports of covert end user development projects are not unheard of (Ferneley, 2007). This leads to a number of questions that are interesting from both theoretical and practical perspectives. For example, can methods be developed for uncovering the existence of such systems? It might also be interesting to develop theoretically-sound interventions for helping end users understand the need to follow the organization’s methodologies. In a similar vein, developing methodologies specifically intended for less formal end user development may be in order. An example of such a methodology comes from Costabile Fogli, Lanzilotti & Mussio (2006) who developed a methodology specifically intended for end-user development. In developing this methodology, Constabile et al. (2006) considered the fact that end users are the ones who possess domain knowledge; or as they put it are “owners of the problem.”

TOOLS AND APPLICATIONS

Given the pervasiveness of ICT, it is not surprising that many interesting and important ICT-based tools and applications have emerged. These applications range from enterprise systems to socially-oriented ICT. In this section, we examine a number of these applications and discuss the theories that have been used in related research. Of course there are many tools and applications that could be discussed here. We focus on several that we believe will have a growing impact. Specifically, we discuss knowledge management systems, open source software, health care ICT and education-oriented applications. Admittedly, the choice of these particular tools and applications is based primarily on personal interest, but we believe that they demonstrate the breadth of tools and applications that utilize ICT.

Knowledge Management Systems

Knowledge is a critical organizational and societal resource, so the management of knowledge continues to be an area of interest to researchers and practitioners. While organizations have always been engaged in managing knowledge, the application of ICT to knowledge management brings some interesting issues to light. Technology offers considerable promise in helping organizations manage knowledge. Thus, knowledge management systems have emerged as important applications of ICT.

To be complete, a knowledge management system must not simply be a repository for storing and retrieving knowledge-based resources. At a minimum, a comprehensive approach to knowledge management should include the following processes: knowledge creation, knowledge storage and retrieval, knowledge transfer, and knowledge application (Alavi and Leidner, 2001). ICT can be applied to all of these processes. For example, business intelligence tools, such as data warehouses and data mining applications can be used to uncover information that can be applied, thus becoming knowledge. Collaboration systems, such as groupware, and directories of experts may facilitate the storage and retrieval of knowledge, as can query and search technologies, databases, and other ICT (Alavi and Leidner, 2001; Smith & McKeen, 2003). Communication-oriented ICT, such as groupware, electronic mail and forums, help facilitate knowledge transfer.

Knowledge transfer is a particularly thorny issue that can only be partially addressed by ICT. Two parties must cooperate in order for knowledge transfer to occur. The knowledge creator (or possessor) must be willing and able to share the knowledge. The knowledge consumer must be willing to apply the shared knowledge. Typically, much of an organization's knowledge resides in and is controlled by individuals (Jarvenpaa and Staples, 2001). Because of this, sharing of knowledge is not influenced by organizational norms of ownership, but rather is driven by some sense of personal benefit. Motivating individuals to share knowledge, whether directly with another individual or through an ICT-based knowledge repository, requires understanding the gains and losses that might result from such sharing. These perceptions must then be manipulated so that the individual possessing the knowledge sees the gains of sharing as offsetting the potential losses of sharing. Successful knowledge management requires identifying incentives for and consequences of knowledge sharing (Massey, Montoya-Weiss & O'Driscoll, 2003); these must be considered from the perspective of the individual, not the organization as a whole.

While there are many benefits to knowledge management, potential losses also exist. Consider, for example, the issue of knowledge as a source of power. Possession of knowledge is a source of power within an organization, because knowledge is a scarce resource. Sharing that resource dilutes its scarcity and thus also dilutes the organizational power of the individual. In to induce sharing, the gain from sharing knowledge must be sufficient to offset the loss of power. Otherwise, individuals may hoard knowledge (Jarvenpaa and Staples, 2001). Social theories, such as social exchange theory and social

identity theory have been applied in attempts to gain an understanding of the social aspects of knowledge sharing (Jarvenpaa and Staples, 2001). The use of these theories serve as reminders that knowledge management can be assisted by ICT, but proper ICT alone is not adequate for ensuring the success of a knowledge management system.

OPEN SOURCE SOFTWARE

Although the concept of open source software goes back to the early days of computing, there has been a resurgence of interest in open source software following the success of open source applications such as Apache. In fact, there is so much interest in open source software that there are now references to the open source “movement” and a “sea change” in the migration to open source software on the server and the desktop (Hardaway, 2007). In this section we use the term “open source software” to refer to software that can be freely distributed and modified by anyone.

Open source software differs from commercial software in a number of important ways. First is the obvious difference in the initial cost of the software. Typically, there is some initial cost associated with acquiring commercial software; in contrast there are no acquisition costs for open source software. (It is worth noting that some claim that the total cost of ownership of open source software actually exceeds that of commercial software. While this is a matter of debate, it would be inaccurate to say that open source software has a total cost of ownership of zero.) Open source software also differs in how it is created and maintained. Typically the development of open source software is a community effort, as is the ongoing maintenance. This community is made up of volunteers, rather than paid employees of a software company. Finally, support for open source software often comes from the community of developers and users, rather than from the software publisher. However, in some cases commercial enterprises package (with drivers, etc.) and offer support for open source software. An example of this is Red Hat, which distributes and supports Linux.

There are four components to open source software, the license, the community, the development process and the software itself (AlMarzouq, Zheng & Grover, 2005). The community and the development process are of primary interest here. The community surrounding an open source software package consists of developers and users. Both are critical to the success of the software (Jin, Robey & Boudreau, 2007). These communities have several salient characteristics. First, they are typically made up of volunteers. In addition, the members of the community are dispersed both in terms of time and location. Because of this dispersion, members of the community typically use network-based collaborative tools, such as the Internet, forums and the like to interact.

Community members contribute for a variety of reasons. Some are motivated by a desire to see the open source movement succeed, while others contribute as a way to further their careers by demonstrating expertise. Different motivations may lead to different levels of participation. Those driven by career concerns tend to exhibit low levels of participation, while those motivated by a desire to integrate their own code into the products source code tend to have higher levels of participation (Shah, 2006). Interestingly, enjoyment seeking tends to lead to quite high levels of involvement (Shah, 2006). This is not completely surprising; prior research indicates that both cognitive and affective factors motivate membership and involvement in virtual communities (Gupta & Kim, 2007).

The structure of an open source development community has been compared to an onion; with core developers at the center and passive users at the outermost layer. Core developers contribute most of the code (both in terms of original creation and ongoing maintenance). Co-developers report bugs and request feature. They may also contribute code and bug fixes from time to time. Active users also report

bugs and request new features, but do not contribute code. They may assist other users in community forums. Passive users are the “freeloaders” of the community, making little or no contribution (AlMarzoug et al., 2005).

One interesting area of future research is to apply design theories and design science methods to the context of open source. Extant theories could be tested in open source communities, then modified if necessary. This could lead to interesting insights and enhancements to our current theory base.

HEALTH CARE ICT

The use of ICT in health care represents a critical application area. While diagnostic ICT tools, such as MRI machines represent cutting-edge ICT applications, the use of ICT tools for records management and other administrative uses lags other industries. Some have gone so far as to claim that the use of ICT in the health care industry is a decade behind other industries (Burke & Menachemi, 2004). Applications such as electronic medical records (EMR) and computerized physician order entry (CPOE) hold considerable potential for improving both the efficiency and quality of health care. Unfortunately, relatively few hospitals are taking full advantage of these ICT.

EMR systems have multiple benefits to the practice of health care. These ICT provide an integrated, structured approach to the management of patient data. They also provide ready access to up-to-the-minute data, as opposed to paper charts, which often take hours to update with new lab test results and the like. EMR systems also provide a single point of access for all patient data, which may help reduce medical errors. Potential efficiency gains are also a major benefit of EMR; the United States Department of Health and Human Services estimates that the use of ICT in health care has the potential to cut health care costs by as much as 10%, which is a staggering sum considering the amount of money consumed by health care costs.

There are many ways in which ICT can be applied to health care. Records-oriented systems such as EMR systems are directed at improving the organization of and access to medical records. Taken a step further, COPE systems add decision support and knowledge management functions to help health care professionals with diagnostic decision making. Telemedicine systems are directed at accessing health-related information and expertise at a distance. For example, a Peruvian telemedicine system allows remote access of medical knowledge, and consultation with non-co-located specialists, among other functions (Miscione, 2007). Public health information systems make health-related information available to the general population. These systems target consumers rather than providers; the focus is on prevention, not treatment (LeRouge and Niederman, 2006).

Various theories have been applied to the study of health care-related ICT, which is not surprising given the vast array of health care ICT applications. Health care has been studied at various levels of analysis, including country-level, organizational level, and individual level. Interestingly, the individual-level studies investigate impacts on various health care professionals (such as doctors and nurses) as well as patients.

Theories of behavior seem to dominate individual-level studies. For example, Hennington and Janz (2007) used the Universal Theory of Acceptance and Use of Technology (Venkatesh et al., 2003) to study physician adoption of EMR. More general behavioral theories have also been used. The theory of planned behavior (TPB) was used in an empirical investigation of medical residents' adoption and use of EMR (Ilie et al., 2007). More studies are needed in this area, especially those directed at understanding the use of ICT to support physicians' clinical decision making.

Institutional, economic and diffusion-oriented theories may be more appropriate for the study of organization- and country-level studies. Institutional theory would be helpful in understanding the various

pressures that impact organizational health care ICT adoption. Using this theoretical foundation allows health care ICT researchers to better understand how the nuances of the health care industry impact ICT use by hospitals and other health care institutions.

Country-based studies of health care ICT can take different focuses, depending on whether the interest is on governmental efforts to promote health care ICT or how these ICT impact local health care practices. A good example of the latter comes from Miscione's (2007) study of the introduction of telemedicine in the upper Amazon area of Peru. This study used new institutional theory as the lens through which to examine the interplay between telemedicine and local, traditional health care practices. (New institutional theory focuses on what actors in an arena consider to be normal, and on the various constraints on human activity.)

Although the bulk of the research into health care ICT is performed in the context of developed countries, there is a growing need to better understand these applications in the context of developing countries. Many of these countries face challenges that are not found in the developed world. In many cases, the technological and social infrastructures taken for granted in developed countries are not present in the developing world. Even the stable availability of electricity is not a given in many less developed countries. Interestingly, it may be necessary to alter our theories when doing research in less developed countries. Most of our theories were created and refined in the context of developed countries. It is not clear whether these theories hold when studying ICT in the developing world.

EDUCATION-ORIENTED APPLICATIONS

The application of ICT to education is an area of growing importance. Since the early days of the personal computer, educators and technologists alike have touted the potential of ICT to revolutionize education. There are a number of ways in which ICT can be applied to education. One of the most popular education-oriented ICT applications is in technology-mediated learning. An important subtype of technology-mediated learning, distance education, is an area of particular interest to researchers and practitioners. Distance education is growing at a rapid pace; both educational institutions and non-education organizations are increasingly turning to ICT-based distance learning as a way to improve the efficiency and/or effectiveness of education.

As is the case with electronic commerce, ICT can be applied to education to extend reach. Universities can use Web-based systems to deliver courses to individuals who are outside the immediate geographic vicinity of the institution. ICT can also be used to provide education to individuals who find it inconvenient or impractical to attend traditional class sessions. Distance learning technologies can be used to deliver either synchronous or asynchronous learning. Synchronous distance learning is similar to teleconferencing in that the teacher and learner are not co-located, but are online at the same time. Asynchronous distance learning does not have this requirement, but rather allows the learner to access course materials at any time s/he finds convenient.

Despite the many advantages of distance learning, there are a number of challenges both pedagogically and institutionally. Cost and funding concerns are among the many challenges educational institutions face when implementing distance learning. Other challenges include adapting to market changes and new types of students, and providing an adequate infrastructure (Folkers, 2005). Pedagogical concerns also arise when implementing ICT-based distance learning. Teaching online is very different from teaching face-to-face. The absence of visual cues, loss of control over the learning environment, and learning how to interact with students online are only a few of the challenges faced by instructors who teach distance learning courses. Students also face challenges when learning online. A much higher degree

of self-regulation is required in online courses. Gone is the imposed discipline of a regularly-scheduled class meeting. Some students may have weak ICT skills, which can hinder online learning.

In order for distance learning to be successful, there must be a proper fit among the institution, course, instructor and student. If any one of these elements does not fit, success is unlikely (Van Slyke, Belanger & Kittner, 1998). Theory can help us understand how various elements must come together in order for distance learning to be successful. For example, the task-technology fit model has been applied to distance learning (Van Slyke, et al., 1998). Studies of individual elements may use a variety of theories. For example, studies of student or instructor adoption may appropriately use theories of individual behavior, while organizational-level studies may find institutional and economic theories more applicable.

One particularly interesting area related to distance learning borrows from theories surrounding object-oriented programming languages. The basic concepts and theories from object-oriented programming have been adapted to develop the concept of reusable learning objects. Reusable learning objects are learning modules that are designed so they can be redeployed in different contexts. This is similar to the way in which a C++ object can be reused in multiple applications. These modules are particularly useful when coupled with a learning management system. This allows an entire curriculum to be customized to the learning goals of each individual learner (Dick, Case, Rhulman, Van Slyke & Winston, 2006). These ICT are already being applied to organizational learning contexts, and may soon become more widely used in higher education (Dick et al., 2006).

Use

In order for an ICT to have an impact, it must be used. Understanding the utilization and application of ICT is a topic of enduring interest to ICT researchers. In this section, we discuss some of the more important theories and research directed at understanding issues related to ICT use. We begin by providing an overview of theories related to the adoption, diffusion and acceptance of ICT. Then, we dig deeper by discussing factors that impact ICT use (which we call antecedents to use) and factors that may moderate the influence of these antecedents. This is followed by the discussion of two areas that may be of growing interest in the future, hedonic (non-utilitarian) motivations for use, and the grassroots diffusion of ICT within organizations. The section closes with a brief discussion of institutional theories, which help explain how the use of particular ICT spread across organizations.

UTILIZATION AND APPLICATION

Adoption/Acceptance/Diffusion

Many theories have been applied in attempts to understand ICT use, including the elaboration-likelihood model (Bhattacharjee & Sanford, 2006), the technology acceptance model (Davis, 1989), innovation diffusion theory (Rogers, 1995), the unified theory of acceptance and use of technology (Venkatesh, et al., 2003) among many others. Inherent in these theoretical approaches is the notion of adoption, acceptance or use. However, understanding at a precise level what these constructs mean is a critical hurdle that must be overcome if the research is to move forward. An interesting development related to this issue is the increasingly sophisticated, theoretically-grounded perspectives on what “use” means.

On the surface, this may seem like a trivial issue. However, use is much more complex than it first seems. Does using an ICT once qualify as prior use? Is the frequency of use what is important? Even

what is meant by frequency may vary from study to study. Frequency may be the number of times in a period one uses an ICT, or it may mean the amount of time one is logged into a system. Do we care only about whether or not the ICT is used (or how much it is used), or are we more concerned with *how* the ICT is used?

In the past, most research has used rather cursory methods for measuring the use of an ICT. Self-reported use is often employed by asking users about their frequency of use, either directly (such as number of hours per day), or through Likert-type scales (e.g. never ... daily). Binary views of use (use/don't use) are also common. When actual use is measured, system logs are often used to measure number of log-ins per day, number of hours logged in, and the like. While these measures are expedient, they do not measure the nuances of types of use, quality of use or depth of use. At the least granular end of the spectrum is the binary view (which I must admit to using in my own research). This view makes no distinction between a one-time user and a heavy, several hours per day user, which is an obvious weakness of this particular approach.

A variety of more comprehensive measures of use have also been employed. These range from duration and frequency of use to dependence of use (Burton-Jones and Straub, 2006). Unfortunately, these, more fine-grained self-reported use measures, while preferred to the binary view, also suffer from some weaknesses. Burton-Jones and Straub (2006) delineate some of the weaknesses of traditional use measures. One of the major problems concerns the fact that most of these measures are developed without solid theoretical grounding, and often seem to be chosen simply because they have been used in prior research.

Various approaches to addressing the weaknesses in traditional use measures are emerging. Boudreau & Seligman (2005) approach use from a quality perspective, basing their work on that of Bevan (1995), who views quality of use as the effectiveness, efficiency and satisfaction with which users can achieve specific goals in a specific context. This is an interesting perspective in that it looks at what can be accomplished by using the system rather than looking at quantity of use. If the point of use is to accomplish some task, then considering how well the system helps the user accomplish the task seems to be a reasonable way of viewing use.

Burton-Jones and Straub (2006) offer a detailed two-stage approach for defining system use and selecting (or developing) appropriate use measures. The first stage in this method is to define the characteristics of system use that are appropriate for the study context, and to also state any assumptions that are made with respect to these characteristics. The second stage involves choosing the best measures for the type of use that is of interest.

It is important for ICT research to refine its understanding and measurements of use, whether one is interested in the antecedents or consequences of use. If we want to understand what leads to use, we must understand exactly what we mean by use, and we must be able to measure use. (Of course, this is a positivist view, but even more interpretive research approaches gain from a better understanding of what we mean by use, even if no quantitative measures are employed.) A number of theoretical perspectives of ICT acceptance and use could benefit from refined views and measures of use.

Antecedents to Use

There is considerable continuing interest in antecedents of ICT use/adoption. Briefly, we can divide these efforts into three groups (1) investigations of new antecedents, (2) refined conceptualizations of widely-used antecedents, and (3) studies aimed at "opening the black box" of well-established antecedents such as perceived usefulness.

The first category includes studies that investigate new applications of ICT. For example, there are numerous studies of new antecedents that influence the use of electronic commerce. Among these are studies of trust (e.g. Gefen, Karahanna & Straub, 2003; Van Slyke, Belanger & Comunale, 2004) and information privacy concerns (Kimery & McCord, 2002; Malhotra, Kim & Agarwal, 2004; Van Slyke, Shim, Johnson & Jiang, 2006). Together these works have helped refine our theoretical and practical understanding of consumer-oriented e-commerce. Other examples of emerging use antecedents come from studies of instant messaging. The concept of critical mass was introduced to ICT research by Markus (1987), who proposed that the diffusion of interactive communication innovations that reach a certain level of adoption will seem to explode. In contrast, those innovations that fail to reach this critical mass will fall into disuse. Unfortunately, the exact point at which critical mass is reached is difficult to predict, and is only evident in retrospect. Lou, Luo and Strong, (2000) addressed this limitation by proposing the concept of perceived critical mass, which is the degree to which potential adopters' believe that an innovation has attracted a critical mass of users. The original conceptualization of perceived critical mass investigated the construct in the context of groupware adoption. Subsequent research has refined and further demonstrated the efficacy of this construct in predicting the adoption of instant messaging (Li, Chau & Lou, 2005, Ilie, et al., 2005; Van Slyke, Ilie, Lou & Stafford, 2007). As new ICT and new applications of existing ICT continue to emerge, it is likely that we will continue to see the theoretical development of new constructs that may influence ICT use.

Karahanna, Agarwal & Angst's (2006) study represents a significant effort to refine the conceptualization and measurement of a widely-used construct related to ICT adoption. Perceived compatibility is a core construct in the innovation-decision process of Rogers' (1995) diffusion of innovation theory. Perceived compatibility has received considerable empirical support in studies of innovation adoption. Tornatzky and Klein (1982) found perceptions of compatibility to be among the most consistently supported innovation characteristics impacting adoption. A number of ICT-based adoption studies have found similar results (e.g. Moore & Benbasat, 1991, Eastlick, 1993; Van Slyke, et al., 2002; Ilie et al., 2005). Unfortunately, the most widely-used measure of perceived compatibility in the ICT literature (developed by Moore & Benbasat, 1991), suffers from discriminant validity problems. A number of empirical studies have reported a lack of discriminant validity between Moore and Benbasat's (1991) perceived compatibility and relative advantage scales. Karahanna et al. (2006) addressed this problem by engaging in a careful theoretical analysis of the compatibility construct, and determined that compatibility is actually a multi-dimensional construct consisting of four dimensions, compatibility with prior experience, compatibility with existing work practices, compatibility with preferred work practices and compatibility with values. After drawing these theoretical conclusions, Karahanna et al. (2006) developed and tested scales for each of the compatibility dimensions. Other core concepts of adoption and acceptance theories may also benefit from such theoretical scrutiny.

MODERATION EFFECTS

Another area of considerable theoretical interest is the investigation of more complex relationships, particularly moderating relationships. Studies that examine moderating effects often add one or more moderating variable to existing theoretical models. The typical pattern is to develop a theoretically-based rationale for the moderating variable, then to test the effects empirically. For example, Ilie et al. (2005) investigated whether gender moderates the impact of beliefs about the use of instant messaging on intentions to use the technology. The core theory was Rogers' diffusion of innovation theory (Rogers, 1995). Prior literature on gender, communication and technology was used to propose hypothesis, which were

then empirically tested. Results confirmed that beliefs have differential effects according to gender (Ilie, et al., 2005). Other research has also investigated gender as a moderators in studies of ICT use intentions (Gefen & Straub, 1997; Venkatesh & Morris, 2000; Venkatesh, Morris & Ackerman, 2000).

One of the more significant theoretical and empirical efforts in this area comes from Venkatesh et al. (2003), who included a number of moderating effects in their UTAUT model. Three of these moderating variables were based on characteristics of the individual user, including age, gender, and experience. A fourth moderator, voluntariness of use, is a belief-based construct rather than an individual characteristic. Empirical results indicated general support for these moderating effects.

As research into ICT adoption and use continues to mature, researchers are well advised to further consider moderating effects. A particularly interesting avenue of research would be to investigate whether or not moderating effects can account for inconsistent findings in previous research. For example, the gender or experience profile of a sample of subjects may account for the significance or non-significance of perceived ease of use as a predictor of use intentions.

Grassroots Diffusion (Appropriation from Personal to Organizational Use)

One of the interesting recent phenomena in ICT use is the appropriation of personal technologies for work purposes. For example, instant messaging, which was originally intended primarily for recreational communication found its way into organizations. Surprisingly, much of the communication that occurred over instant messaging was business-oriented rather than personal in nature. Instant messaging is just the latest example of ICTs that have migrated to personal use. As ICTs become increasingly ingrained in our personal, day-to-day lives, it is quite possible that the rate of organizational appropriation of personal ICTs will increase.

The migration of personal ICT into organizations presents a number of interesting theoretical questions. When personal ICT are introduced into the organization, their use often spreads throughout an organization through informal means and without organizational sanction or support. This sort of diffusion has been called grassroots diffusion (Van Slyke, Ilie & Stafford, 2004). One fundamental question concerns how the grassroots diffusion differs from organizationally-sanctioned and sponsored diffusion. Traditional diffusion-assisting practices such as organized training sessions, mandatory use, etc. are absent in grassroots diffusion; other influence practices must substitute for organizational diffusion efforts. For example, rather than formal change agents, proponents of a new ICT must take it upon themselves to build awareness of the existence and advantages of the new ICT. Further, influence processes must be more subtle since the proponents may lack the ability to mandate use (or provide extrinsic rewards for use). Training may be informal as well, with early adopters providing education and perhaps technical support for later users.

Grassroots diffusion is only one interesting area of potential research related to the use of personal-level ICT in organizations. Theories should be developed related to how organizations take advantage of these technologies. Both the providing organization and the user organization should be studied. How user organizations react to control and take advantage of (or restrict the use of) these ICT is an interesting research question. Equally interesting is how the organizations that developed the ICT react to its use in organizations. For example, do such organizations introduce “enterprise-class” versions of the technology?

Hedonic Motivations

Originally ICTs were primarily utilitarian technologies directed at improving the efficiency and/or effectiveness of work. However, with the emergence of lower cost, more ubiquitous ICT, a transformation

occurred as the technologies became part of our non-work lives. Although personal ICT use certainly existed long before the Internet and Web became household words, the emergence of low-cost, readily-available Internet access seems to ignite the transition of ICT from the work world into our personal lives. Hedonic outcomes refer to the pleasure or enjoyment received from using an ICT, as opposed to utilitarian outcomes, which refer to how well an ICT enhances the efficiency or effectiveness of some task (Venkatesh & Brown, 2001).

Hedonic motivations are the desire to achieve enjoyment from using an ICT. In the home, hedonic motivations are partially responsible for ICT adoption in households (along with the desire for social and utilitarian outcomes) (Venkatesh & Brown, 2001). Households acquire ICT not just to accomplish tasks such as paying bills and banking online, but also to have fun by surfing the Web, listening to music and playing games. In terms of theory, these and similar findings mean that we need to expand our theories to consider non-utilitarian factors that may influence ICT adoption and use. Interestingly, theories that have been expanded to include hedonic motivations have been applied in research in a variety of contexts, including ICT adoption in developing countries (Dwivedi, Khoumbati, Williams, Lal, Gharavi, 2007).

On the surface it may seem that hedonic motivations would be of little interest to researchers interested in work-related ICT use. However, this is not the case. As discussed earlier, use is not either/or; different levels and different types of use exist. One perspective theorizes that individuals may use a technology for exploitation or exploration (March, 1991). Exploitation occurs when the ICT is applied to tasks in a routine manner. In contrast, exploratory use of ICT involves seeking out new ways in which to use the ICT. Such use may be driven primarily by the desire for utilitarian outcomes, but there is an undercurrent of enjoyment as well. When users derive more pleasure from ICT use, they may be more likely to “play” with the technology and discover new uses. The beneficial aspect of “playing” with an ICT has been noted. Webster & Martocchio (1991) pioneered this avenue of thought by developing the concept of microcomputer playfulness, which they define as the “degree of cognitive spontaneity in microcomputer interactions.” More recently, Belanger and Van Slyke (2000; 2002) posit that playful (non-work-related) use of ICT applications may result in learning that is beneficial for more utilitarian applications. They use an example of email implementation in a small business to demonstrate how hedonic and social motivations for email use lead to email communication becoming ingrained in work practices. While there is still much work to be done in this area, it seems that examining the interplay between hedonic motivations and utilitarian outcomes may be a fruitful and interesting avenue of inquiry.

INSTITUTIONAL THEORIES

There continues to be considerable interest in what motivates organizations to innovate through the adoption of ICT. A variety of theories have been applied to the study of organizational ICT adoption. One of the more enduring of these is institutional theory (DiMaggio & Powell, 1983). Institutional theory posits that three forms of influence facilitate the spread of an innovation through the companies within an industry through the pressure to conform to organizational forms and practices that are viewed as “legitimate.” Mimetic pressures concern the pressure to conform to the ways in which other organizations practice. Coercive pressures are exerted by governments or other regulatory agencies to bring about the adoption of practices and technologies that are seen as desirable. Finally, normative pressures result from attempts to professionalize an industry.

A number of studies have used institutional theory to examine ICT diffusion and adoption at an organizational level (e.g. Orlikowski & Barley, 2001; Chatterjee, Grewal & Sambamurthy, 2002). A

recent application of institutional theory to the study of ICT comes from Liang, Saaf, Hu & Xue (2007). This study investigates the influence of normative, mimetic and coercive pressures on the assimilation of enterprise systems. The authors posit that top management beliefs and top management participation mediate the impacts of institutional pressures. Interestingly, institutional pressures influence enterprise system assimilation when there is a prolonged integration process and outcomes are dynamic and uncertain. Liang et al.'s (2007) results indicate that mimetic and normative pressures also exert a direct influence on enterprise system assimilation. Accordingly, the authors suggest that there may be additional mediating influences. This may well be an interesting avenue for future research.

OUTCOMES

Having discussed the first two components of our framework, we now turn attention to the third, the outcomes of ICT use. As ICT become increasingly ubiquitous in our work and personal lives, an interesting phenomenon occurs. To an extent, the more ubiquitous something becomes, the less noticeable it is. However, this does not mean that its impacts are lessened; they simply become less apparent. In turn, this sometimes makes teasing out the exact impacts of a particular technology a bit more difficult. Fortunately, we have at our disposal a variety of useful theories that can be applied to investigations of the outcomes of ICT use.

In this section, we discuss how ICT impact four broad areas. First, we discuss impacts on the individual. Next, we examine organizational impacts. This is followed by a discussion of managerial impacts. We close the section with an overview of the broad social impacts of ICT.

ORGANIZATIONAL IMPACTS

The degree to which ICT impacts organizational operations and outcomes continues to be of considerable interest to ICT researchers and practitioners alike. One area of particular and enduring interest concerns how ICT can be employed strategically to gain competitive advantage. A more fundamental question is whether gaining sustained competitive advantage is even possible. Although studies of the value of ICT are hardly new, there seems to be a renewed interest that was touched off by Carr's (2003) controversial article "IT Doesn't Matter." It is possible that the commoditization of ICT has progressed to the point that long-term, strategic advantage can no longer be gained from ICT. Of course, this position is not universally held, and much research energy has gone into refuting this thesis, either directly or indirectly.

Because ICT are so pervasive in organizations, exactly how ICT impact organizations becomes a knotty question. One way to untangle this knot is to consider the intent of the ICT application. A deeper understanding of this helps researchers choose the appropriate theoretical perspectives from which to investigate the value of ICT investments. To this end, Oh et al., (2007) compare two approaches to assessing the strategic value of ICT. Their work reveals that a contingency-based view is more appropriate for explaining the impact of ICT applications that are directed at cost reduction. In contrast, a resource-centered view does a better job of explaining ICT investments that are directed at increasing revenue and profitability. Further, their results indicate that investments in growth-oriented ICT applications have a direct impact on improving an organization's revenue.

There is also research being done to refine theories related to organizational impacts by developing new constructs. An interesting work in this area introduces the construct of IT leveraging competence

(Pavlou & El Sawy, 2006). IT leveraging competence is the ability to effectively use the functionality offered by IT to support IT-related activities. These authors also propose that two capabilities mediate the impact of IT leveraging competence on competitive advantage. The first of these is functional competence, which is the ability to execute operational activities effectively. The second is dynamic capability, which is the ability to “integrate, build, and reconfigure existing functional competencies to address turbulent environments” (p. 199). Empirical results show support for the notion that IT leveraging competence can be used for competitive advantage, but that this impact is fully mediated by functional and dynamic competencies. The Pavlou and El Sawy (2006) study used the context of new product development to develop the theory surrounding their new constructs and to test their empirical efficacy. Other researchers may further test and possibly refine the new theory in other contexts.

A number of recent studies have investigated the impact of specific ICT applications. Some of these studies are directed at more micro-level impacts (which we discuss later), and others examine more macro-level impacts. In one example of a broader-based study, Ranganathan & Brown (2006) used an organizational integration theoretical lens to investigate how different types of ERP projects impact shareholder values. ERP projects that are broader in functional scope (involving modules that impact two or more value-chain components) or physical scope (involving multiple sites) lead to higher shareholder returns than do lesser-scope projects. Projects that have broad functional and physical scopes bring about the highest returns.

Some studies take an indirect approach at demonstrating the value of ICT. These works show the value of ICT by investigating how particular applications impact operations. By extension, one may conclude that if operations are improved, then there is an overall improvement in firm performance. (Whether this improvement gains the company a sustainable competitive advantage is another question.) For example, Mishra et al. (2007) used a resource-based theoretical view to investigate antecedents and consequences of the use of the Internet to support procurement activities. These authors took a holistic perspective by considering the firm, the technology, the organization, and the environment. Their results indicate that some resources impact Internet use in only one stage of the procurement process, while others impact multiple stages. In addition, their work indicates that Internet use in the order initiation and completion stage of the procurement process has the strongest positive influence on performance. Using the Internet in the search stage has a lesser impact.

Other studies have also examined the ability of ICT to improve supply-chain operations. For example, Grant’s (1996) theory of higher-order capabilities serves as the foundation for arguing that organizations that use supply-chain management systems to create higher-order supply-chain integration capabilities generate significant and sustainable performance improvements (Rai & Patnayakuni & Seth, 2006). Providing the infrastructure integration necessary to support supply-chain management allows firms to integrate supply-chain-related information flows with their trading partners. This, in turn, leads to performance gains in both operations and revenue growth. Rai et al.’s (2006) study formalizes a number of theoretical constructs and relationships related to integration capabilities that might be applicable to studying the impacts of other ICT applications.

Enterprise systems are also the subject of numerous studies concerned with understanding how ICT impact operational performance. Cotteleer and Bendoly (2006) used a case study approach to investigate how enterprise systems impact operational performance. In this study, not only did enterprise systems impact order fulfillment lead time, it also brought about performance improvement on an ongoing basis.

Given the amount of interest in the organizational impacts of ICT, it is not surprising that attempts have been made to synthesize the literature in this area. One example of this comes from Piccoli and Ives (2006), who provide a comprehensive review of the literature on sustained competitive advantage. They use a theoretically-derived framework to organize their review, which is focused on understanding

factors that create barriers to the erosion of ICT-enabled competitive advantage. These factors are further organized into four groups. IT resource barriers include IT assets, such as the IT infrastructure, and IT capabilities, including technical skills and IT management skills. Complementary non-ICT resources create the second barrier. Examples of complementary resources include distribution channels, slack resources, and brand image. The third group of factors comprises the IT project barrier. These factors include technology characteristics (such as complexity and uniqueness) and the implementation process (such as the complexity of the implementation process, and the extent of change required in an organization's processes to fully utilize the ICT). The final barrier is the preemption barrier, which concerns whether the leader's competitive advantage can be threatened, even after successful implementation has taken place. Switching costs and value-system structural characteristics (such as relationship exclusivity) form the preemption barrier. Taken together, the studies reviewed by Piccoli and Ives (2006) offer support for the belief that ICT can, in fact, lead to sustainable competitive advantage.

SOCIETAL IMPACTS

ICT have also had considerable impacts at the societal level. The increasingly pervasive presence of ICT make these impacts almost inescapable. From automated check-out aisles at the grocery store, to personal entertainment devices such as MP3 players and digital video recorders, ICT seem to touch most aspects of day-to-day life.

DIGITAL DIVIDES

While there are many benefits to ICT use by individuals, not all are able to fully participate in the information society. As a result, there is much interest in studying various digital divides. A digital divide exists when there is a separation between "haves" and "have nots" with respect to access to digital information and ICT (Dewan & Riggins, 2005). Identifying divides, their underlying causes and potential solutions are all topics of interest to researchers and policy makers.

There are actually a number of digital divides, including those based on age, gender, socio-economic status, and location. In addition to understanding digital divides at the individual level, there is also a need to understand community- and nationality-based divides.

Developing and less-developed countries may benefit greatly from ICT. Unfortunately, in many cases, these nations suffer from a digital divide in that they lack the necessary infrastructure to provide ICT access to their citizens. Even in rapidly developing countries such as India, there may be significant infrastructure issues, especially in poorer or rural areas. These conditions may have a detrimental impact on ICT applications, such as e-commerce. For example, there is evidence that perceptions of e-commerce are more negative among Indian consumers than American consumers (Van Slyke, Belanger & Sridhar, 2005). These differences may be due to less favorable local conditions in India. The digital divide is even more pronounced in less developed areas, such as sub-Saharan Africa.

Some claim that an age-based digital divide exists, even within developed countries. The elderly face a number of challenges when attempting to use ICT. A number of studies in this area use human-computer interaction studies to examine how various aspects of common ICT interfaces impact older users. For example, Wu and Van Slyke (2005) use a synthesis of the technology acceptance model and cognitive theories to posit that the increasing functionality of modern software applications may be more detrimental than beneficial to older computer users.

Location may lead to variations in access to digital resources, even within a given country. For example, there may be considerable differences in Internet access quality between urban and rural areas. High-speed cable and DSL connections may not be available in rural areas, which significantly limits the utility of accessing multimedia content.

One of the more interesting areas of digital divide research concerns second-order digital divides. A second-order divide exists when an individual or organization has access to the requisite ICT, but lacks the necessary expertise to make use of the ICT (Dewan & Riggins, 2005). Some individuals may lack early-life exposure to ICT, and thus may fail to develop ICT skills. Lack of skills may further lead to a lack of confidence in using ICT, which may hinder use.

Reducing the digital divides becomes especially important when governments pursue electronic government (e-government) initiatives. When e-government is implemented, ICT access inequities may lead to inequitable access to governmental services and representation. Even something as basic as renewing a driver's license is much more difficult when one does not have access to online resources. Governments may need to pay particular attention to this matter if online voting is seriously considered. This brings us to our next topic, electronic government.

ELECTRONIC GOVERNMENT

The use of ICT by governmental entities goes back to the very beginning of computing. In fact, ENIAC I was developed for the government (specifically for the United States military). However, the term "electronic government" seems to have emerged towards the end of the 1990s. In contrast to earlier governmental ICT applications, which were primarily internal applications, e-government applications are directed at making information more accessible to stakeholders and at making stakeholder interactions more efficient and effective. Applications range from simple directories of governmental offices and representatives, to tax-roll databases, and license applications and renewals. Such diverse ICT applications in a critically-important area lead to many interesting research issues. These run the gamut from appropriate research methods and instruments, to trust and privacy issues (Gronlund & Horan, 2004). Some believe that the emergence of e-government is not simply a matter of automation, but is a fundamental change in the way governments operate (Tan, Pan & Lin, 2007).

E-government applications bring many potential benefits. Operations may be made more efficient through automation and process transformation. This may lead to financial benefits through the reduction of staff and infrastructure necessary to carry out basic operations. In addition, making representatives and governmental services more available bring about obvious benefits to constituents. However, there are also a number of challenges, including redesigning processes, change management, and coordination among stakeholders. It is also possible that e-government transformation may shift some transaction costs to citizens, which may be burdensome to some (Tan et al., 2007).

Given the range of individuals and organizations who are affected by e-government, it is not surprising that stakeholder analysis has been applied to the study of e-government (Flak & Rose, 2005; Tan et al., 2007). As Tan et al. (2007) point out, a stakeholder perspective allows addressing several critical aspects of e-government, including identifying stakeholders, recognizing differences in stakeholder interests, and how governments can address these differences. As ICT continue to become more ubiquitous and universally available, it is likely that the scope of e-government applications will increase. Because of this it is critically important that ICT researchers continue work in this area.

MANAGERIAL IMPACTS

ICT have considerable impact on management. These impacts run the gamut from individual issues, such as managing technical workers, to strategic issues, such as gaining strategic advantage from ICT. In this section, we discuss a number of the more interesting theoretical developments related to the managerial impacts of ICT.

Sourcing Arrangements

Since the early 1990s, ICT researchers have been interested in gaining a better understanding of sourcing ICT functions (e.g. Loh & Venkatraman, 1992). A number of theory-based models of the outsourcing decision process have been proposed, including Chaudhury, Nam & Rao (1995) and Lacity and Willcocks' (2000), both of whom proposed six-stage processes to explain the outsourcing decision. (It should be noted that the stages differ across the two models.)

Outsourcing is a complex phenomenon, which leads to corresponding complexity when attempting to understand the totality of prior outsourcing research. Thus, alternative approaches have been used to review the outsourcing literature. Ilie and Parikh (2004) offer an interesting synthesis of the outsourcing literature using a process model of outsourcing. Their model consists of seven phases, (1) decision to outsource, (2) vendor selection, (3) outsourcing contract, (4) implementation, (5) operations/relationship, (6) evaluation, and (7) decision to renew (or not renew). Research can investigate single phases, multiple phases or links between phases.

Dibbern et al. (2004) also offer a stage model in their extensive review of the outsourcing literature. They begin with Simon's four-stage model of decision making (intelligence gathering, decision design, choice, and implementation). This is adapted to be more specific to the outsourcing decision. The first three stages (why, what and which) make up the decision process phase. In the "why" stage, organizations consider the arguments for and against outsourcing. The "what" stage is directed at determining which specific sourcing arrangements are to be considered. In the "which" stage, the organization makes the choice among the alternatives considered earlier. The last two stages (how and outcome) together form the implementation phase. The "how" stage includes activities such as selecting the specific vendor, contract negotiation, and relationship management. Finally, the "outcome" stage reflects the consequences of the chosen sourcing arrangement.

Quite an array of theoretical perspectives has been used to study sourcing arrangements, ranging from economic theories to social theories. Some studies have used multiple disparate theories in attempts to understand the range of processes and factors that are important to outsourcing. Whitten and Leidner (2006), for example, used transaction cost theory (an economic theory) and social exchange theory in a study of backsourcing (returning previously outsourced operations to the organization). Others have also studied the backsourcing phenomenon (e.g. Veltri & Saunders, (2006), which seems to be an area of increasing interest.

Theories from economics are often used in studies of outsourcing (even when financial factors are not the focus of the work). Dibbern et al. (2004) offer an excellent discussion of the theories that have been applied to the study of outsourcing. (The remainder of this paragraph is derived from their discussion.) Agency theory, game theory, transaction cost theory and resource-based theories have all been applied to outsourcing. Agency theory considers the divergent interests of principals (e.g. the client company) and agents (vendor). Contracts and other mechanisms are required to ensure that the information asymmetries and different risk perceptions do not lead to opportunistic behavior on the part of the agent. Game theory tries to explain the different actions a party will take, based on its understanding of what

actions the other party might take. The parties (players in game theory) interact to produce outcomes based on the players' preferences. Players attempt to anticipate the actions and preferences of the other player and act accordingly. Transaction cost theory attempts to explain the transaction conditions that lead to certain governance arrangements. Resource-based theories consider the resources an organization possesses (or does not possess) form the basis for the organization's strategy. Basically an organization is seen as a collection of resources that can be used to produce outputs. Other theories that have been applied to outsourcing include strategic management theories, social exchange theories, diffusion theories, political theories and relationship theories.

Outsourcing arrangements involve interactions among parties with differing interests and motivations. In essence, these arrangements are relationships between the client and vendor organizations. It seems appropriate, then, to consider relationship factors as being worthy of additional study. Although most outsourcing studies seem to use cost-oriented economic theories (Ilie & Parikh, 2004), there are notable exceptions. Choudhury and Sabherwal (2004) used both agency and organizational theories to study control mechanisms in outsourced software development projects. Based on these theories, Choudhury and Sabherwal (2004) proposed that organizations used a portfolio of different control modes and mechanisms to bring about desired behaviors from the outsourcing vendors. These portfolios might include both formal and informal controls. Formal controls use performance evaluation and rewards/sanctions to bring about the desired behavior. Formal controls can be divided into two types. Behavior controls focus on the process by which desired outcomes can be achieved. Outcome controls specify desired outcomes and the rewards for achieving those outcomes (or sanctions for failing to achieve them); the means by which the outcomes are achieved are not considered.

In contrast to formal, informal controls use social and relationship strategies to control the vendor's behavior. Choudhury and Sabherwal (2004) also divide informal controls into two types, clan controls and self-controls. Clan controls seek to close the gap between the client's and vendor's preferences through promoting common beliefs and philosophies. Self controls involve the vendor establishing standards for its own behaviors; these standards are hopefully in line with the client's interests. In their empirical work, Choudhury and Sabherwal (2004) found that outcome controls dominated outsourcing arrangements, particularly in the earlier stages of the outsourcing relationships. Later in the project, behavior controls are added. This work illustrates how theories from reference disciplines can be used to study a specific aspect of outsourcing.

There has also been considerable research into factors affecting the outsourcing decision (as opposed to the process by which the decision is made). Most of these studies are based on economic theories, which has led to a corresponding focus on economic drivers of outsourcing, including cost savings and other financial drivers. However, technological and strategic drivers have also been investigated. Technological drivers include lack of internal technical capabilities, access to new technologies, increasing flexibility and reducing technology-related risk. Focusing on an organization's core business, restructuring and improving the management of the ICT operation are among the strategic outsourcing drivers (Ilie & Parikh, 2004).

Despite the amount of research on outsourcing, as Ilie and Parikh (2004) point out, there are a number of gaps in outsourcing research. Unfortunately, there seems to be a lack of research using institutional and political theories. The vendor side of the outsourcing equation needs to be better understood. Examining how vendor practices, reputation and other characteristics influence vendor selection may help us better understand the totality of outsourcing. Other gaps identified by Ilie and Parikh (2004) include:

- How the complexity of the outsourcing contract influences the outsourcing relationship and its ultimate success or failure.

- What conditions facilitate or hinder the implementation process.
- How the outsourcing arrangement evolves from an “arms-length” relationship to a strategic partnership.
- Development of comprehensive measures and methods for assessing outsourcing performance.
- The impact of client lock-ins such as asset specificity on the decision to continue or terminate the outsourcing arrangement.

MANAGING A GLOBAL WORKFORCE

The increasing globalization of ICT has led to a more global workforce. In today’s environment, teams may be distributed around the world, spanning national boundaries, time zones and cultures. Managing in such an environment is challenging; managers must understand how to manage workers that are not collocated and who may not be influenced by the same cultural norms.

Managing workers from different cultures can be particularly challenging. This challenge is not reduced by the fact that ICT may mediate much of the communication among geographically dispersed workers. Beyond the obvious logistical challenges, there are also difficulties brought about by different norms and practices in the various cultures. These differences potentially lead to unproductive conflict in culturally diverse teams. We know from the literature on teams and teamwork that certain types of team conflict are productive, while others are not. Substantive (or task-related) conflict often improves the work output of a team. Such conflict comes about from different perspectives on the task at hand. This conflict is a positive byproduct of one of the main strengths of teamwork, diversity of perspectives. Affective conflict also results from diversity, but does not result in positive outcomes. Affective conflict is typically thought to be caused by visible demographic diversity, such as differences in age, race, and gender. Affective conflict hinders team processes; teams must spend time and energy resolving the conflict. However, unlike substantive conflict, there is no offsetting improvement in output quality (Pelled, 1996; Pelled & Alder, 1994.)

An interesting related theoretical and practical question is how the notion of visible demographic diversity translates into the context of virtual teams (teams that interact using ICT rather than face-to-face). Since visible differences are not apparent when teams do not meet face-to-face, it is possible that other cues to differences lead to affective conflict. For example, differences in language usage, interaction norms and the like may substitute for visible cues. One particularly interesting cultural difference that may lead to affective conflict is the notion of culturally-based time visions (Saunders, Van Slyke & Vogel, 2004). A time vision is how an individual or culture perceives the nature of time. Time is an extremely complex concept, and different cultures have differing views of time. Time visions vary across a number of dimensions, including subjectivity, continuity, linearity and homogeneity, among others (Saunders et al., 2004). Americans, for example, tend to view time as linear, unidirectional, and homogenous. Time is viewed as a scarce resource that must be managed wisely. In contrast, individuals from regions where Hinduism or Buddhism predominate may view time as being without a discrete beginning or end. The concept of “wasting” time, which is common in many western cultures, has little or no meaning to those with a timeless view of the nature of time. One can easily see how these differences might lead to conflict in a team. Deadlines have very different levels of importance to those with different culturally-based notions of time. As workforces become increasingly global, managers will have to deal with this and many other cultural differences.

CRITICAL ISSUES AND EMERGING TRENDS

A number of critical issues face the ICT research community. In this section we discuss a number of these, starting with the importance of more explicitly considering the context in which our studies are conducted.

Context

As ICT research matures, it becomes important to more explicitly consider the role of context. The context of a study may influence the findings and/or the proper application of theory. For example, it may be inappropriate to apply individual-level theories to group- or organizational-level studies. Because research is cumulative, lack of consideration of context may lead to misconceptions that carry through to later studies. Explicitly and carefully considering the impact of context not only avoids this issue, it may also help explain equivocal results. Four aspects of context should be considered and explicitly described in ICT studies; the users, the environment, the task, and the technology. Doing so may bring about a number of benefits to ICT research. More thorough consideration of context encourages researchers to dig more deeply into the theories that they employ. Thinking about how context may alter or impact the suppositions of a theory may lead to better understanding of the nuances of our core theories. Deeper consideration of context may also lead to more cohesive research streams. In addition, better integration of context may help researchers avoid inappropriately adopting findings of prior research. Finally, research that better integrates context will provide a more solid foundation for future research.

Globalization

Globalization brings about opportunities and challenges for ICT researchers. As we just discussed, context is important to well-done ICT research. One aspect of context is the country or culture in which a study takes place. Most of our theories were developed and tested in the context of western countries, particularly North America. It is not clear whether our extant theories will hold in non-western contexts. Theoretical relationships that are found in individualistic western countries may not hold in more collective societies. For example, perceived relative advantage (and the similar concept of perceived usefulness) has enjoyed wide support as a predictor of use intentions. However, this construct did not have a significant relationship with e-commerce use intentions among Indian consumers (Van Slyke, et al., 2005). Theories may need to be modified or extended as we look beyond western countries. There is an increasing amount of research being conducted in Asian countries. This is a good opportunity to more completely understand our fundamental theories.

We must also carefully examine our measurement instruments to see if they are valid outside the countries in which they were developed. Simple translation-back-translation strategies are helpful, but they do not go far enough. We should perform more rigorous tests of the content validity and factor invariance of our widely-used instruments when applying them globally.

Social Software

The emergence of social software may be a fruitful area for ICT researchers. Although an exact definition of social software seems to be missing from the literature, the basic idea is that individuals jointly contribute to an effort, such as a wiki. The end product is not the output of any single individual, but

rather is a community effort. (Interestingly, in some cases, no “end product” exists; the product is under ongoing evolution as more and more individuals add their contributions.)

In the absence of a widely accepted definition of social software, it is useful to examine common characteristics of such applications. Parameswaran & Whinston (2007a) offer a list of traits of social computing (which is analogous to social software). Social computing has a decentralized organization, a transient membership, and a loosely defined structure. Further, the scope of the system is rather fluid. Content is dynamic and quality control is unstructured, occurring primarily through peer feedback.

Social computing applications/platforms are quite varied. Blogs (Web logs), which are basically public online journals are an example. Typically, authors allow others to comment on blog entries, which increases the social nature of the platform. Wikis are another example of social computing. A wiki is an online information compendium, such as Wikipedia, which is an online, open source, user-created encyclopedia. Social bookmarking services, which enable different users to share their Web bookmarks, are another example, as are YouTube, Flickr, MySpace, and the like (Parameswaran & Whinston, 2007b). These applications may be directed at both personal and work-related uses. For example, it may be that social networking systems are an important new element in knowledge management systems (Smith & McKeen, 2007).

There are many interesting theoretical questions related to social software. Understanding what motivates individuals to contribute may lead to systems that lead to even greater levels of participation. (As noted earlier, this same question is of interest to open source software researchers.) Individual-level motivational theories are the most applicable to this question; theories from sociology and anthropology may also be appropriate. Social capital and social learning theories may be interesting to apply to the study of reputation mechanisms, which are key to some social computing platforms. Organizational theories may be applied to understanding the governance structures and organizational forms that social computing communities take. For example, Ouchi's (1980) theory of the clan organizational form may be an appropriate lens through which to study social computing (Parameswaran & Whinston, 2007a).

An interesting question related to social computing is what role critical mass plays in the development of a particular social computing platform or application. Markus (1983) contends that interactive communication technologies must either reach a critical mass of users, or its diffusion will stall, and the technology will fall into disuse. It would be interesting to see if the same rule applies to social computing communities. If a community fails to reach a critical mass, does it die out, or is a small core of dedicated contributors sufficient to ensure the communities survival? Similarly, it would be interesting to determine if perceptions of critical mass are important to individuals' decisions to join a community.

CONCLUSION

As the evolution of ICT continues, so must our research. New theories must be developed to fit new circumstances, existing theories must be re-tested and, if found lacking, must be revised. None of us know what the future of ICT will be, what we do know is that new technologies will emerge, new uses will be found for existing technologies, and new classes of users will take advantage of ICT. Our research must keep pace if we are to continue to build our understanding of ICT and how they affect our world.

Section 1

Fundamental Concepts and Theories in Information Communication Technologies

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of information communication technology (ICT). Chapters found within these pages provide an excellent framework in which to position ICT within the field of information science and technology. Individual contributions provide insight into the critical incorporation of ICT into the global community and explore crucial stumbling blocks of the field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of ICT.

Chapter 1.1

An Overview on Strategic ICT Implementations Toward Developing Knowledge Societies

Hakikur Rahman

Sustainable Development Networking Programme (SDNP), Bangladesh

ABSTRACT

As nations continue to conceptualize, adopt, implement, and monitor their respective information and communications technologies (ICTs) policies and e-strategies, it is vital that a critical assessment is undertaken on their effective progress. This includes analysis of strategies, methodologies, and best practices while weighing the impact, effectiveness, and efficiency of these policies and strategies. However, the demands, motivations, and incentives of various governments for adopting, adapting, and initiating ICTs varies from country to country, with diverse economic, social, cultural, and political environments. Researches in this aspect recognized the necessity of a cohesive ICT policy and strategic framework in each country for socio-economic development at their grass roots. The execution of these policies and strategies should include concrete national commitment and strong political will at

the highest levels of government, and an enabling environment that promotes stakeholder involvement in setting agendas and implementing plans and programs. This chapter provides insights into various national implementations in promoting related activities, tries to establish an analytical approach that would assist in formulating ICT policies and strategies by identifying different ICT indicators. Furthermore, this chapter focuses on critical aspects of different strategic national level policies with short-medium-long term visions that targeted both the immediate needs of the populace and long-term needs of nations by integrating ICTs. Finally, this chapter has recommended that via coherent and complimentary policies that engage both the private sector and civil society organizations, nations can move forward towards creating a knowledge society and at the same time by leveraging capabilities of ICT can address the social, economic and political issues on the ground.

INTRODUCTION

During 1970 to 2000, the largest users of foreign direct investment (FDI) flows were generally in Asia (China alone had 33.2%), while portfolio flows were more concentrated in Latin America (Brazil, Mexico, and Argentina added up to 26.9%, Singapore and Malaysia obtained 10%, and rest of the developing world had 29.9%). An important point can be noted that, despite low FDI, Singapore and Malaysia have successes in economic development due to the implementation of successful ICT strategies in their countries.

In essence in many countries, ICTs provide the means to accelerate their progress or even leapfrog into the new phase of development and to enable their integration into the global economy. Particularly, in developed countries the knowledge-based economy allows further specialization, improvements in productivity, and the achievement of sustainable growth. By virtue knowledge capital is the only asset that can grow without limits; and new knowledge increases the efficient use of resources that are in finite supply

(Léautier, 2005). Figure 1 gives a global view on how knowledge-based economy has been adopted in many countries, since 1995. It also shows that a few countries have been achieved almost highest ranking in terms of knowledge economy index (KEI) in recent years¹.

With an estimated span of about 50 years of Information Age (1950-2010)², the world has been passing through revolution of changes and witnessing astounding development in ICTs. Today, the Second World³ has about 30% of the world's population and about 20% of its wealth. The Third World⁴ accounts for some 60% of the population but enjoys less than 10% of its wealth. These classifications relate primarily to economic indicators such as GDP, but they can also be equated to the differing rates of adoption of industrial technologies. In this context, information technology presents an opportunity to the Second and Third World countries to improve their economies. However, the First World⁵ countries were among the leading developers and early adopters of Information Age technologies. Therefore, Second and Third World countries

Figure 1. Global view: Knowledge economy index by countries and regions (Adapted from Dahlman, Routti, & Ylä-Anttila, 2005)

have an opportunity by embracing ICT to equal these information economies (UN, 2003).

This chapter has analytically observed some of the ICT indicators in a few countries of the world, synthesized their approaches of overall development, tried to find out any synergy among them that can be replicated elsewhere, and endeavored on critical assessment of potential ICT parameters that are being used to represent a nation's digital presence, including status of their economic development. It has been observed that a few countries in Europe and Asia have reached an acceptable level of development through implementation of strategic ICT policies. Keeping this in mind, brief review on transformation of digital governance in Finland and Ireland have been incorporated, while Turkey has been discussed due to its transitional nature in the European Union that may be treated as a success case among many nations. In Asia, Japan, Singapore, and Thailand are leading in many parameters of digital access index (DAI)⁶, and at the same time, a few countries of Africa have been included in the synthesis with specific focus to Kenya.

BACKGROUND

Technology planning is the process of strategically deciding what technologically should be implemented to best poise a nation's vision, mission, strategy, activities, outputs, and outcome. It involves a candid assessment of the current scenario and an analysis of what can be improved upon with technology tools to enhance their effectiveness. It is also useful in identifying innovative program delivery opportunities that could be available through technology. Where most nations employ technology in a reactive fashion, responding to current short-term measures, strategic technology planning encourages a more long-term focus, making a realistic assessment of both the economic value and the cost of implementing technology. Although technology planning is a process, at

the same time it also results in a document—the Strategic Technology Plan, which serves as a snapshot of current technology adoption and a roadmap for integrating technology more effectively (Uganda-Africa, 2005).

Strategy is to be defined as a plan to reach the goals in terms of systematic actions to be taken by different actors at all levels. In addition, an action plan goes beyond by clarifying measures to be taken—what should be accomplished, by whom, and when?⁷ Currently, all strategic planning on ICTs emphasizes on building knowledge societies apart from establishing networks, contents, and learning. Knowledge is fueling economic growth and social development in all regions of the world. Along the way, the forces of globalization such as migration, travel, trade, foreign investment, and communications are speeding the dissemination and utilization of information across boundaries. Novel ideas and innovation are spreading faster than ever. Furthermore, knowledge-based growth and development offer opportunities for both developed and developing economies, and advancement in ICTs has been a necessary precondition for these new developments in the global economy (Léautier, 2005).

The world has seen remarkable achievement in terms of Internet penetration and broadband penetration as many countries have adopted successful ICT strategies in their policies and economies. Table 1 shows the top five countries of the world with highest Internet penetration⁸ in 2005, Table 2 shows the top five countries with highest broadband penetration in 2005, Table 3 shows the top five countries with highest technology achievement index (TAI) in 2001⁹ (UNDP, 2001), and Table 4 shows the top five countries with highest ICT diffusion index (ICTDI) in 2004.

From Table 1 it can be noted that top 30 countries (with 13.74% of world population) have 66.2% penetration in terms of their percentage of population, while the rest of the world has a penetration rate of 8.8%. At the same time from Tables 1, 2, 3, and 4 it has been found that Hong

An Overview on Strategic ICT Implementations Toward Developing Knowledge Societies

Finland	0.744
USA	0.733
Sweden	0.703
Japan	0.698
Korea (R.)	0.666

Table 4. Top 5 countries with ICT diffusion index (ICTDI) in 2004 (Source: UN, 2006)

Rank	Country	Access Index	Connectivity Index	ICT Diffusion Index ¹⁰
1	Luxembourg	0.928	0.703	0.815
2	USA	0.833	0.754	0.794
3	Iceland	0.854	0.706	0.780
4	Sweden	0.836	0.700	0.768
5	Denmark	0.828	0.667	0.748

Kong, Korea (R.), Iceland, Sweden, and USA have accomplished as such in developing their ICT sector to remain at the top in terms of Internet penetration, broadband penetration, TAI, or ICTDI.

In terms of Internet penetration, the European Union is leading the world with 49.8% of penetration rate, comprising 230,396,996 users with a growth rate of 147% between 2000 and 2005. Though growth rate in Africa rises to 424% between 2000 and 2005, the Internet penetration rate is only 2.6% of its population. Similarly, Asia has shown a growth rate of 219% with 9.9% penetration and America has a growth rate of 143%, but Internet penetration rate is much higher at 34.7%. Tables 5, 6, 7, and 8 show other parameters in Europe, Africa, Asia, and America.

To show the trend on settling down of Internet penetration in the developed world, a survey conducted by the Oxford Internet Institution (OII) can be highlighted. OII has been found that Internet penetration is growing slowly in UK with 3% between 2003 and 2005. However, Internet users are skeptical about the Internet's ability to help develop social relations. Sixty-five percent disagree ('disagree strongly' and 'disagree') that it is easier to meet people online than in person, while 73% agree ('agree' and 'agree strongly') that the Internet is a toll of benefit in a time-starved world that saves time; and 63% agree ('agree and 'agree strongly') that technology is making things better for people (OII, 2005).

Subsequently, case of a small country, Macedonia is being highlighted that is thriving for ICT development. ICT Assessment Report of Municipalities in FYR Macedonia 2004 and Recommendations and E-model of Municipalities summarizes that the 6.75% of budget spent on ICT and its development is graded very low, with 1.73% of the total budget being spent on IT infrastructure and 5.02% on communications. It follows that municipalities do not assign sufficient importance to ICT usage and do not recognize the work-related benefits of the new

technologies. The existing municipality profile is without a strategy for development of ICT usage. Nearly all municipality decision-making persons know little of ICT and no ICT initiatives are implemented, with the exception of a few sponsored projects and donations. The level of computer literacy of employees and members of the municipality council is graded very low, with a quality measure of 0.75 on a scale from 0 to 4, where value 1 signifies basic IT skills and value 2 moderate IT skills, which scores very low in comparison to the surprisingly high educational level (UNDP, 2004).

More importantly, in recent years many researchers, including world reputed agencies have been showing particular interest in ICTs. According to the Committee on Science and Technology at the Service of Development, ICTs "will become crucially important for sustainable development in developing countries." (Credé & Mansell 1998: ix) For the past two decades, most developed countries have witnessed significant changes that can be traced to ICTs. These multidimensional changes (technical, financial and economic, cultural, social, and political) have been observed in almost all facets of life: economics; education; health; communications; leisure; and travel (Thioune, 2003). The World Summit on Sustainable Development in 2002 and subsequent sessions of the Commission of Sustainable Development (CSD) encouraged further work on indicators for sustainable development by countries in line with national conditions and priorities and invited the international community to support these efforts (UN, 2005). Therefore, a number of areas, including sustainable tourism, marine environment, national strategies for sustainable development, and good governance, require further work to identify appropriate indicators. In the next section, various ICT indicators have been critically analyzed and appropriate measures at national levels have been closely followed, that have created positive environment in formulating successful ICT strategies.

An Overview on Strategic ICT Implementations Toward Developing Knowledge Societies

Table 5. Internet usage in Europe (Source: <http://www.internetworldstats.com/stats4.htm>)

EUROPE	Population (2006 Est.)	% Pop. of World	Internet Users, Latest Data	Penetration (% Population)	% Usage of World	Use Growth (2000-2005)

TOTAL AMERICAS	885,381,908	100.0 %	307,266,489	34.7 %	100.0 %	143.5 %

Furthermore, the changes observed in these countries have led to what is now referred to as “the knowledge society.” ICTs have made it possible to find fast access to, and distribution of, information as well as new ways of communication in real time at a cheaper cost. However, still a considerable gap exists between developing countries and developed ones in terms of the contribution of ICTs to the creation of wealth. The gap has tended to widen among developed countries, the technology suppliers, and the receiving developing countries. At the same time, the gap between the privileged and the grassroots communities within these developing countries is also expanding in terms of their access to ICTs. If measures are not taken to make ICTs both affordable and usable, mere access to them will be insignificant (Thioune, 2003).

Finally, technologies can play a crucial role in determining how networks can be used, whether they will be centralized or decentralized, who can own them, who can set them up, and whether they can be adapted to specific needs of individuals and communities. Certain technological developments and choices can decentralize networks and offer local communities a role in shaping the services and applications that are achievable. Conversely, any restricted choices and configurations may leave entire communities completely outside of the networks (Siochru & Girard, 2005).

MAIN THRUST: ANALYSIS OF ICT INDICATORS

This section has tried to identify some leading countries across the globe that have developed in terms of ICTs indicators, successful implementations of their ICT strategies in achieving human development, and have transformed into knowledge societies. Firstly, a few of ICT indicators have been discussed with specific focus on their developments, and consequently some of the parameters have been critically analyzed to build some form of inference. Secondly, a few of ICT parameters have been highlighted to observe their follow up in different economies, and finally ICT strategies in a few countries have been closely monitored, focusing their regional contribution.

For this purpose, one of the ICT indicators, the penetration of main telephone lines in top five countries during 2002 to 2005 have been highlighted in Tables 9 to 12. Penetration of main telephone lines per 100 inhabitants has been considered and it has been found that Bermuda remains at the top. This gives the indication of Bermuda’s growth of basic information infrastructure and dependency on communication media.

In 2005, Vietnam had the highest CAGR¹¹ of 42.5% per 100 inhabitants from 2000-2005 (ITU, 2006). The lowest CAGR was -16.6 in D.R. Congo. In 2004 Somalia had the highest CAGR of 46.6%

Table 9. Penetration of main telephone lines in order of per 100 inhabitants – 2005

Country	CAGR (%) 2000-2005	Per 100 inhabitants	CAGR (%) per 100 inhabitants
Bermuda	-1.4	86.15	-0.5
Luxembourg	2.8	79.75	1.8
Sweden	-1.1	71.54	-1.4
Switzerland	-0.4	68.66	-1.1
Germany	1.9	66.57	1.7

Table 10. Penetration of main telephone lines in order of per 100 inhabitants – 2004

Country	CAGR (%) 1999-2004	Per 100 inhabitants	CAGR (%) per 100 inhabitants
Bermuda	0.6	86.15	0.2
Luxembourg	3.7	79.75	2.6
Sweden	-0.2	71.54	0.1
Switzerland	0.8	70.97	0.1
Germany	2.5	66.15	2.4

Table 11. Penetration of main telephone lines in order of per 100 inhabitants – 2003

Country	CAGR (%) 1998-2003	Per 100 inhabitants	CAGR (%) per 100 inhabitants
Bermuda	1.0	86.15 (2002)	0.6
Luxembourg	-5.8	79.75	-4.5
Sweden	0.5	72.89	0.2
Switzerland	1.7	72.74	1.2
Germany	3.1	65.71	3.0

Table 12. Penetration of main telephone lines in order of per 100 inhabitants – 2002 (Source: ITU statistics)

Country	CAGR (%) 1997-2002	Per 100 inhabitants	CAGR (%) per 100 inhabitants
Bermuda	1.6	86.15	1.2
Luxembourg	4.9	79.68	3.7
Switzerland	2.8	73.99	2.3
Sweden	1.0	73.57	0.8
Denmark	2.1	68.86	1.7

per 100 inhabitants from 1999-2004, and the lowest CAGR was -14.0 in D.R. Congo, while Vietnam maintained CAGR of 35.6. In 2003 Sudan had the highest CAGR of 38.5% per 100 inhabitants from 1998-2003, with the lowest CAGR of -24.0 in D.R. Congo, and Vietnam kept the CAGR at 19.2. In 2002 Sudan had the highest CAGR of 39.0% per 100 inhabitants from 1997-2002, while the lowest CAGR was -5.7 in Solomon Island, but Vietnam had a CAGR of 22.7.

Main Telephone Lines

Due to non-availability of continuous data, two small countries in Europe, Guernsey, and Jersey could not be put in the table, but Guernsey had over 90 main telephone lines per 100 inhabitants in 2002 and 2003, while Jersey had over 80 main telephone lines per 100 inhabitants in 2002 and 2003. At the same time, a country can be put into focus, which is Vietnam. That country has been consistently increasing its number of land telephone per 100 inhabitants throughout the period. This has been possible due to Vietnam's

An Overview on Strategic ICT Implementations Toward Developing Knowledge Societies

recent ICT reformations. Table 13 shows various stages of ICT strategies that have been taken in Vietnam.

Vietnam will boost its digital content industry through streamlining its legal environment and upgrading its broadband network by 2006. In this context, a master plan on digital content industry drafted by MPT will be submitted to the government later in 2006. The country hopes that this industry will generate USD400 million by 2010 with an annual growth rate of 50%. Meanwhile, Vietnam will provide skills development training to around 300,000 digital content industry experts. Digital content industry will include e-learning, games for computer, online game, interactive game, game for mobile handset, Internet e-content (online newspaper, Web sites, searching, library), and value-added services for mobile (logo, ring tones, digital movies, television, and cartoon). Furthermore, Vietnam's ICT develop-

ment strategy aims to reach annual ICT revenue of USD6-7 billion by 2010 including USD3 billion in the computer hardware industry, USD2 billion in electronics production, and USD1.2 billion in the software/outsourcing¹².

Next, compound annual growth rate of cellular phones have been considered in Tables 14 to 17 and found that Hong Kong, Italy, Luxembourg, and Sweden remain at the top, though Lithuania had the highest CAGR of with 127.10 per 100 inhabitants and highest percent of total telephone subscriber in 2005. It has also been found that Nigeria had the highest CAGR of 261.8% between 2000 and 2005. Furthermore, D.R. Congo had the highest percent of total cell phone subscribers as indicated in Table 18. Previously it was observed that D.R. Congo had the lowest CAGR in main telephone lines (Tables 9 to 12) and this reflect their dependency on the cellular phone, in lack of any robust information infrastructure. It is also

Table 13. Actions taken by the Vietnam's Government for the improvement of ICT (Source: Thanh, 2003; Soan, 2006; ThuHue, 2005; MPT, 2003; World Bank, 2005)

Action Taken	Year	Remarks
National Program on IT (NPIT) initiated	1996-2000	Implementing major application projects in state management and in some socio-economic areas
Directive No. 58-CT/TW	2000	Articulated the national strategy plan and policies for ICT development, and pushed IT towards the forefront of the country's industrialization drive for the period 2000-2010
Decision No. 81/2001/QD-TTg	May 2001	Approval of the Action Program to implement Directive No. 58-CT/TW
Internet Policies initiated	2001	Amended in 2003-2004
	February 2002	Ordinance on Posts and Telecommunications adopted
Decision No. 95/2002/QD-TTg	July 2002	Approval of the IT Application and Development Master Plan in Vietnam by 2005
Decree No. 90/2002/ND-CP	November 2002	A new Ministry of Posts and Telematics (MPT) created to develop ICT Strategy along with other ministries
ICT Strategy initiated	January 2003	The Vietnam ICT development strategy to 2010 and forward to 2020 approved
ICT Strategy approved	2005	
e-transaction law drafted	2005	
ICT Law	2006	Drafted by MPT and to be approved by end of 2006

Table 14. Compound annual growth rate of cellular phone 2002-2005 in order of per 100 inhabitants

Country	CAGR (%) 2000-2005	Per 100 inhabitants	As % of total telephone subscribers
Lithuania	52.7	127.10	84.5
Italy	11.1	123.14	74.1
Hong Kong, China	9.7	122.65	69.5
Macao, China	30.4	115.82	75.3
Czech Republic	22.1	115.22	78.5

Table 15. Compound annual growth rate of cellular phone 1999-2004 in order of per 100 inhabitants

Country	CAGR (%) 1999-2004	Per 100 inhabitants	As % of total telephone subscribers
Luxembourg	24.8	138.17	63.8
Hong Kong, China	14.0	118.77	68.6
Sweden	13.8	108.47	60.3
Italy	15.7	108.19	70.7
Czech Republic	40.9	105.64	75.9

Table 16. Compound annual growth rate of cellular phone 1998-2003 in order of per 100 inhabitants

Country	CAGR (%) 1998-2003	Per 100 inhabitants	As % of total telephone subscribers
Luxembourg	32.8	119.38	60.0
Taiwan, China	40.4	114.14	65.9
Hong Kong, China	18.3	107.92	65.9
Italy	22.6	98.07	68.1
Sweden	16.5	98.05	57.4

to be noted that Nigeria had the highest CAGR of 261.8% from 2000-2005 in terms of cellular phone subscribers.

Cellular Subscriber

Afterwards, Internet penetration has been considered and found that USA remains at the top consequently in 2002, 2003, and 2004 (see Tables 17 to 19), with the highest Internet hosts per 10,000 inhabitants. But, Iceland and Korea (R.) took the lead in terms of Internet users per 100 inhabitants. This supports towards their efforts in implement-

ing successful ICT strategies in those countries for creating enabling environments.

Information Technology

Lastly, before performing a critical analysis of an ICT indicator, basic indicators of ICT during 2002 to 2005 have been portrayed in Tables 22 to 25. It has been found that, despite high population density of over 6,500 per Km² Hong Kong has maintained to keep higher number of total telephone subscriber per 100 inhabitants, with over 23,000 USD per capita. This reflects the

national commitment in implementing successful ICT strategies for their economy.

Basic Indicators

All these indicators are providing with facts that countries/communities will emerge as successful if and only if, successful ICT strategies can be implemented properly through longer-term strate-

gies. Else, the ultimate result will not be visible in terms of their outcomes. Table 26 shows a critical analysis on one of ICT indicators (number of Internet users per 100 populations):

In this context, to make pragmatic steps, indicators on national sustainable development strategy and implementation of ratified global agreements have been modified to establish good global governance. At the same time, indicator

Table 26. A critical analysis on one of ICT indicators (Adapted from UN, 2005)

<p>Parameter: Number of Internet users per 100 populations</p> <p>Purpose: The number of Internet users is a measure of Internet access and its use</p> <p>Relevance to building knowledge society: As an information distribution system, the Internet and its usage provide opportunities for bringing education and information within the reach of all. It can significantly shorten time lags as well as opening up a new range of information resources and creating a knowledge society by enabling them to take informed decisions.</p> <p>Relevance to Sustainable/Unsustainable Development: Telecommunications and social, economic, and institutional development are closely linked. Modern communications is considered to be relatively favorable to the development processes. There is unlikely to be sustainable development without a well-developed communications infrastructure. Communication is critical to support sustainable development.</p> <p>International conventions and agreements: The four-year strategic Istanbul Action Plan adopted by the ITU World Telecommunication Development Conference in 2002 provides a six-point action plan that address the key elements needed to bridge the digital divide. Similarly G8 Okinawa charter on Global Information Society in 2000; two phases of World Summit on the Information Society (WSIS), first phase in Geneva from December 10-12, 2003 and second phase in Tunis from November 16-18, 2005 endorsed by the UN General Assembly Resolution 56/183 ¹³ (December 21, 2001); and WSSD in Johannesburg August 26-September 4, 2002, including many follow up meetings are providing dynamic guidance to the global communities.</p> <p>International targets/ Recommended standards: The benefits of new technologies, especially ICTs should be available to all, UN Millennium Declaration #55/2.</p> <p>Linkages to Other Indicators: There are also other variables (e.g., Internet hosts and subscribers), which provide a measure of how many people are accessing the Internet. This indicator is also related to other telecommunication indicators (e.g., main telephone lines, mobile cellular subscribers), as well as income and education indicators.</p>

#47¹⁴ and 48¹⁵ of MDGs have been made less dense by extending to 1000 inhabitants, instead of 100 (Table 27). They seem realistic in sense, that many countries will not be able to achieve MDGs by 2015, unless they keep forcing on improving indicators on knowledge building and increase expenditures on research and development as a percent of their GDP.

Before proceeding further, ICT strategies of a few countries in regional aspect have been highlighted. They are Finland, Ireland, and Turkey from European Union; Japan, Singapore, and Thailand from Asia Pacific and Kenya from Africa.

European Union

An international cooperation dimension integrated with the activities of each of the thematic priority fields of these specific programmes, “Integrating and strengthening the European Research Area,” “Specific activities covering a wider field of research,” and “Structuring the European Research Area” allowed the European research community to benefit from the knowledge and expertise of third countries and institutions through the participation of researchers, teams, and institutions from those countries. The general objective under the 6th Framework programme

is to help open up the European research area to the world focusing mutual benefits of the community. The overall objective is, therefore, for the European Union to develop strong scientific partnerships with developing countries in order to contribute to their sustainable development (EC, 2004), by means of human capital development, mobility, and institution-building (EC, 2005, 2006). It is thus important that the ownership of the knowledge and technology developed in partnership under this activity be equitably shared. The results will be used to contribute to improved regional cooperation strategies, the elaborations of concepts aimed at sustainable development, and societal innovation.

It has been observed that, over a quarter of EU GDP growth and around 50% of productivity growth is due to improvement in ICT. In recent years ICT services, skills development, media and content services, and their usage in other economic sectors, are growing fast within the economy and society. However, many Europeans are yet to reap a few benefits from ICT. As such, 57% of individuals living in the EU did not regularly use the Internet in 2005; only 10% of persons over 65 used Internet against 68% of those with age between 16 and 24; only 24% of persons with low education used the Internet against 73% of those with high education; and only 32% of unemployed

Table 27. Modified MDG indicators (Adapted from UN, 2005)

CSD ¹⁶ Indicators	MDG Indicators	New Indicators
National Sustainable Development Strategy		
Implementation of Ratified Global Agreements		Good governance indicators
Number of Internet Subscribers per 1000 inhabitants	48. Personal computers in use per 100 population and Internet users per 100 population	
Main Telephone Lines per 1000 inhabitants	47. Telephone lines and cellular subscribers per 100 population	
Expenditure on R&D as a percent of GDP		

persons used the Internet against 54% of those with employment (ICT Riga, 2006).

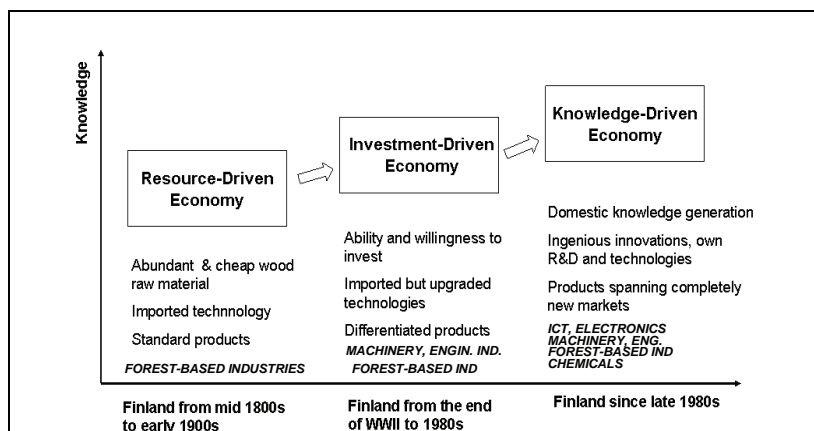

Finland

Finland is a unique example of how a country can rapidly transform itself from a resource-based economy into one based on innovative and intellectual technologies. In Finland, the specialization of production, trade, and R&D in more knowledge-intensive products and services coincided with the gradual opening of the economy and deregulation of capital flows. A peculiarity of the Finnish case is the atypical pattern of industrial renewal from essentially natural-resource-based industries toward machinery, engineering, electronics, and ICT. However, there are a few other examples of natural-resource-abundant countries that have managed to transform their industrial structures toward higher knowledge intensity and value added so rapidly and successfully as Finland. The origins of the Finnish knowledge economy can be traced back to user-producer linkages between the forest-based industries as early users of high technology, and the emerging

engineering, electronics, and ICT industries in the 1960s and 1970s (see Figure 2).

The Finnish experience in the 1990s is an example of how knowledge becomes the driving force in economic transformation and growth. Although as recently as in the 1970s Finland was relying mainly on resource-intensive industries, it has transformed to be the most ICT specialized economy in the world. In this aspect, rapid structural transformation beginning in the mid nineties coincided with equally rapid improvements in macro balances, and by the end of the decade the country's macroeconomic implementation was one of the strongest in Europe. Although Finland has many characteristics that cannot easily be replicated by other countries, much of its experience in designing knowledge-based economic and social strategies are highly relevant. However, a key lesson is the importance of flexibility in responding to change and the critical role of a responsive education system. Finland's experience also highlights the importance of developing a vision, a process for consensus building and accomplishment (Léautier, 2005).

Figure 2. Finland's stages of industrial and economic development (Adapted from Dahlman, Routti, & Ylä-Anttila, 2005)

Ireland

ICTs lead a transition in the Irish economy to get away from low-end manufacturing to hardware manufacturer and software developer. Over the past decade, Ireland has become one of the strongest growing partners in the EU and ranked nineteenth in the Networked Readiness Index¹⁷. Heavy government spending on technical and tertiary institutions

in the early 1980s gave the country to provide steady supply of highly skilled manpower and at the same time creation of tax and trade regulators gave it a better environment for ICT investors.

The Irish economy escalated during the 1990s, with GDP per capita growing by an annual average of 7.1% between 1990 and 2000, compared to an OECD average of 2.6%¹⁸. A few of the strategies are being illustrated in Table 28.

Table 28. Various steps taken by the Irish government to promote ICT for knowledge development^{19;20;21}

Turkey

Since the founding by Mustafa Ataturk in 1923, the government of the Republic of Turkey has been moving to integrate the country into Europe. To achieve this long term aim the country in recent years has been investing aggressively in networked readiness. Turkey ranks forty-first in overall Networked Readiness²³. Digital access index (DAI) of Turkey in 2002 was 0.48, that falls under medium access (under a category of high access, upper access, medium access, and low access, respectively)²⁴. Table 29 shows the broadband subscribers per 100 inhabitants, by technology in December 2005.

Asia Pacific

The world economy is in the midst of a profound transformation spurred by globalization and sustained by the rapid development of ICT that is

accelerating the transmission of information and knowledge in every part of the globe, including the countries and regions in the Asia Pacific. ICT has a great potential to facilitate the achievement of the UN Millennium Development Goals, particularly to combat poverty, hunger, disease, illiteracy, environmental degradation, and gender inequality (Hak-Su, 2003).

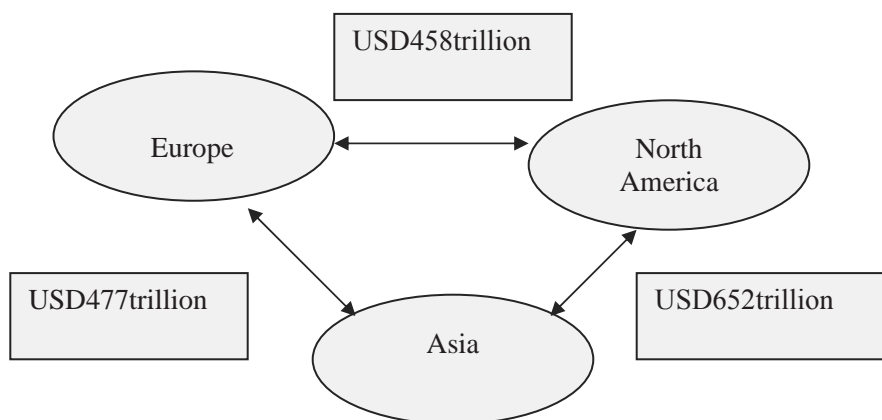

At the same time, the Asia Pacific region is also the most dynamic and fastest growing region of the world and it is expected to account for more than half of the world trade in the twenty-first century. Current trade estimates among the three continents is given in Figure 3, and it has been observed that it is highest between Asia and North America.

Particularly, the economic and technological levels in East Asian countries are not uniform, and the bases and environments for network economic development are also diverse. However, the growth tendency for the network economy in East Asia as

Table 29. Broadband subscribers per 100 inhabitants of Turkey (Source: www.oecd.org/ict/broadband accessed on August 16, 2006)

DSL	Cable	Other	Total	Rank	Total subscribers
2.1	0.0	0.0	2.1	29	1,530,000

Figure 3. Amount of trade estimates in three continents (Adapted from UN, 2003)

a whole is very noticeable. For the average growth rate of Internet users, in 2000, it was 150% in the East Asia region, higher than 130% in Europe and 51% in North America. Similarly, network economy is becoming the new motive force for the development of Asian economy²⁵.

Asia Pacific homes more than 60% of the world's population, among them more than 75% are below the poverty line, despite being the most dynamic and fastest growing region of the world. However, due to its diverse nature of characteristics comprising the world's richest and the poorest nations, it represents more than half of the world trade. At the same time, it establishes a unique feature in this region to promote growth of ICT, as the region dwells orient cultures that have been centers of learning and have created huge intellectual property in several languages. GDP per capita grew from USD120 in the 1900s to USD1600+ in the 2000s (Japan has the highest GDP per capita of US \$37890 in 2005)²⁶ despite the fact that only 11 economies in this region has over 25% of teledensity and Internet penetration rate ranges between 10 and 50 (UN, 2003; ITU, 2005)²⁷. Currently, Japan has 21,304,292 (2005) Internet hosts and 86.3 million (2005) Internet users²⁸ that shows their ICT development, and at the same time, Japan's KDDI has launched an unlimited access mobile Internet tariff at a price equivalent to entry-level digital subscriber line (DSL) that gives their competency in establishing local knowledge repository²⁹. Another country, with more than 95% of internal content, Korea (R.) is currently ranked highest in the world in terms of the development of information infrastructure³⁰. Korea (R.) also enjoys the highest penetration of broadband Internet with over 70% of total households and all schools of that country have broadband Internet. Korea (R.) ranked fourth in DAI 2002 with high access of 0.82³¹.

Japan

Initially, at the first meeting of the IT Strategic Headquarters in January 2001 "e-Japan Strategy" was launched to establish the goal for Japan 'to become the world's most advanced IT nation within 5 years (by the end of 2005). To achieve this goal the public and private sectors together have been expending great efforts in implementing various measures, such as the development of communications infrastructure, promotion of e-government, and e-commerce. As a result, stunning achievements have been made in the area of ICT. For example, Internet service in Japan is the fastest and cheapest in the world, e-government instrument is expanding (online procedures operate 24 hours a day for 365 days and handle more than 100,000 applications annually) and its e-commerce market is growing in scale to become the second largest in the world after the United States (the United States ranked at the top with 9.0%, followed by Japan with 7.1%) (ECOM, 2003). At the 29th meeting of the IT Strategic Headquarters, the "IT Policy Package 2005: Towards the Realization of the World's Most Advanced IT Nation" was announced. It is desired that the "IT Policy Package 2005" will further enhance measures mainly in the areas closely related to the peoples' daily lives, including administrative service, medical care, and education. The IT Strategic Headquarters will work to realize a knowledge society in which people can experience the change and enjoy the benefits brought upon by ICT (Government of Japan, 2005).

If observed closely, one will comment that these have been achieved not just in a few days or months, but years of relentless efforts and endeavors to fulfill the mission of a nation. Table 30 shows a chronological overview of various steps taken by the Japan government along this prospect.

Table 31 provides a comparison on e-strategies of Singapore and emerging Thailand who may

take a leading role in South East Asia within a few years.

Africa

Africa is confronted with numerous challenges. But, one of the most important of these challenges is to integrate the continent into the information

society. Furthermore, reducing the digital divide and facilitating the continent's absorption into the global information society could overcome Africa's isolation. In an avant-garde approach, concerned authorities have been convinced that research through the production of learning and applicable knowledge could contribute significantly to a better development. For this purpose, the International

Development Research Centre (IDRC) launched a program known as Acacia to contribute to the production of an essentially African body of knowledge on the role of ICTs in the economic and social development process. This focus on learning and the production and sharing of knowledge is reflected in the systematic documentation and evaluation of Acacia's experiences in sub-Saharan Africa (Olu-koshi & O'Neil, 2003).

For the past few decades, the international community has noted a growing digital gap between developed countries and Africa, on the one hand, and within African countries, between the elites and the poorer and underprivileged populations, on the other hand. New information and communication technologies can serve as a development lever to speed up the economic development of Africa and its poor communities. However, the details of these transformations and the degree and pace of such changes in poor communities have yet to be fully grasped. Equally, the ways in which ICTs might best serve development are still relatively unknown.

Therefore, it is critical to determine the implications that these changes will have on the poor

communities that ICTs are supposed to transform. Studies and investigations are needed to generate new hypotheses that can be tested. The results of such research must also be shared rapidly and effectively to keep up with the pace at which ICTs evolve (Adera & Camara, 2003). To illustrate on how ICT strategies have been implemented in Africa and how indicators of ICT are being developed, Tables 32-35 are showing the basic ICT indicators for the five top countries, in terms of total telephone subscribers. From these tables, it has been observed that Reunion, Seychelles, and Mauritius are at the top with robust information infrastructure, while South Africa and Botswana have been driving towards the achievement with increased GDP per capita.

Basic Indicators

Kenya

Despite advances in private sector initiatives, the government has been found to be reluctant to embrace ICTs for social and economic development for some time³². However, Kenya's e-strategies

Table 32. Basic ICT indicators in 2005

Country	Total telephone subscribers per 100 inhabitants	Per capita USD (2004)	Population density (per Km ²)
Reunion	98.65	-	313
Seychelles	96.80	8,348	200
Mauritius	86.13	5,146	668
Tunisia	69.06	2,821	61
Botswana	54.11	4,957	3

South Africa	46.76	2,293	38

Table 34. Basic ICT indicators in 2003

Country	Total telephone subscribers per 100 inhabitants	Per capita USD (2002)	Population density (per Km ²)
Reunion	98.65	1,893	301
Seychelles	85.07	8,348	205
Mauritius	55.22	3,957	655
South Africa	46.76	2,293	39
Botswana	37.19	2,939	3

Table 35. Basic ICT indicators in 2002 (Source: ITU statistics (www.itu.int/ITU-D/ict/statistics.htm))

Country	Total telephone subscribers per 100 inhabitants	Per capita USD (2001)	Population density (per Km ²)
Reunion	98.65	1,893	296
Seychelles	78.81	7,603	207
Mauritius	55.79	3,771	649
South Africa	40.80	2,562	38
Botswana	33.57	2,921	3

have been best poised through the approval of its national ICT policy by the Ministry of Information and Communication in January 2006. Table 36 shows the steps of the Kenyan government towards establishment of a knowledge society through initiating relevant ICT strategies:

The next section puts forward a few recommendations for successful implementation of ICT strategies by upholding the concept of creating knowledge societies.

RECOMMENDATIONS

Creation of knowledge societies demand high initial investment in sectors that are seemingly looked as unproductive at the beginning, commitment at all levels of the policy initiations, and mass awareness at the end users level. Furthermore, increasing investments in R&D during these periods of high unemployment demand great political wisdom and courage, when an easier

path may seem to generate immediate employment rather than build up longer-term strengths. At the same time, increasing R&D must be supported by national industrial and innovation strategies, which should be properly communicated by governments. These national strategies should focus on consensus building; such as, by organizing economic policy programs attended by practically all members of the Parliament and other decision makers from the public and private sectors, media, and labor market organizations (Dahlman, Routti & Ylä-Anttila, 2005).

There should be a triangular incorporation of partnerships, as shown in Figure 4³³.

Consequently, it is almost impossible to identify the embedded ICT component due to non-availability of the financial data, and for that reason the aggregate figure cannot be calculated. However, figures for ICT-specific projects/programmes are easier to produce and some reported figures (including some non-ODA) have been highlighted, and it also shows various approaches taken by governments across the globe through

Table 36. Various steps taken by the Kenyan government to promote ICT

Country	Policies taken	Period of implementation	DAI Ranking in 2002
Kenya	The Kenya Information and Communications Bill 2006	February 2006	0.19 (low access)
	National ICT Policy	January 2006	
	Freedom of Information Act 2005	2005	
	The Kenya Communication Act, 1998	October 1998	
	The Science and Technology Act	1980	

Figure 4. Transformation to knowledge society demands tri-partite involvements

their direct commitments in establishing knowledge societies:

- Canada estimates a minimum expenditure of \$33 million per annum
- European Commission has a commitment of €250 million for multi-year ICT-specific programmes in addition to €110 million from the European Development Fund and €750 million from the European Investment Bank (1999–2003)
- France committed about €40 million (2002–2005) to global programmes over and above its country programmes and other facilities
- Germany supports at present ICT applications with approximately €180 million;
- Japan launched its Comprehensive Cooperation Package for bridging the “digital divide”

—Japan’s commitment for ICT support, announced at the G8 Kyushyu-Okinawa Summit in 2000—which consists of non-ODA and ODA funding with a total of \$15 billion over 5 years (2000–2005)

- Sweden spent approximately \$18 million in 2003
- the United Kingdom currently has multi-year ICT-specific programmes and projects, mounting to approximately a total of \$83 million
- the United States estimates its spending of ICTs for development at more than \$200 million in 2003, and through leveraged or matching outside resources a further \$240 million was mobilized (OECD, 2005).

Taking all these facts into consideration, the following recommendations may be adopted for

successful implementation of ICT strategies in each country:

- Formulation of appropriate policies for promoting investment in ICT sector and establishing a transparent and consistent legal and regulatory framework to foster ICT development
- Ensure investment to improve access and network infrastructure, establish investment friendly climate by setting up policy, regulatory, and legal framework and by providing fiscal incentives, induction of new less expensive and cost-effective broadband wireless technology, and optical fiber communication transport backbone infrastructure (UN, 2003)
- Provide a framework for establishing national, regional, and international partnerships and help in coordinating programmes and activities aimed at specific ICT application areas with well defined objectives, milestones, and outcomes
- Formulate action plan for implementation at national and regional levels aimed at achieving the MDGs by mainstreaming ICTs
- Supporting national actions aimed at harnessing the potential of ICT for development through providing necessary assistance
- Serving as a common global forum to accelerate and promote universal access to knowledge and information, contribute to the development of norms and standards in a transparent, meaningful, and participatory way, taking into account development priorities and incentives for innovations and contribute to addressing issues like cultural diversity, information ethics, information rights, intellectual property rights, privacy, security, and cyber crime
- Contributing to a more systematic approach, review, and dissemination of ICT expertise, distance learning programmes, information and reliable data on ICT, case studies,

best practices and successful models, thus becoming an important 'knowledge bank' in this field

- Emphasizing universal access to knowledge and information for promoting grass roots development
- Taking actions in bridging the digital divide and promoting digital opportunities and adopting a coherent ICT strategy that would ensure cooperation and synergy among programmes and activities of the involved organizations or agencies so as to transform into a knowledge based society (UN, 2003)

The author feels that many nations are yet to cross the boundaries of implanting ICTs for fostering their economic outgrowths, despite substantive themes were addressed by various agencies including the Commission of Sustainable Development (CSD) since 1995. The box shows the themes of CSD with years as a ready reference and it can be observed that, including 2001 (focus was on biotechnology), all the themes were on capacity development or related to it.

- Technology for small-scale economic activities to address the basic needs of low-income populations; the gender implications of science and technology; and the contributions of science and technology to an integrated approach to land management (1995)
- Information and communication technologies for development (1997)
- Science and technology partnerships and networking for national capacity building (1999)
- National capacity-building in biotechnology (2001)
- Technology development and capacity building for competitiveness in a digital society (2003)
- Promoting the application of science and technology to meet the development goals

- contained in the United Nations Millennium Declaration (2004)
- Science and technology promotion, advice and application for the achievement of the internationally agreed development goals contained in the United Nations Millennium Declaration (2005)
- Bridging the technology gap between and within nations (2006)

Furthermore, nations can endorse a two-prong approach to promote successful ICT strategies. One may be in the technology context and the other one in the management perspective. The box (Figure 5) shows different action plans; a nation can take in these aspects.

An integrated approach is desirable in the implementation process along with the design and development phases, including critical assessment of the implementation strategies. Notwithstanding technologies are dynamically adjustable and varied in nature, but countries with success cases can easily be adopted without much duplication. This would save time, effort, and resources for many economies. Rather, efforts can be concen-

trated to localize the technology, content, and the change management processes through recursive simplifications. A circular modality can be followed as shown in Figure 6.

Finally, a context diagram is being developed that may be adopted in implementing national ICT strategies (see Figure 7).

WAY AHEAD AND CONCLUSION

National regulators, financial institutions, and market participants have shown that the global financial system can continue to function smoothly even under a difficult and totally unanticipated form of extreme constraints. Globalization of the world economy has been driven by a variety of forces: rising trade in goods, increasing international capital flows, enhanced technological spillovers, and emergent labor mobility.

A second channel has evolved in recent years through which capital account liberalization can have a positive impact is technology spillovers. These spillovers are most noticeable in the case of foreign direct investment (FDI), especially

through foreign firms incorporating new technologies in their subsidiaries. As novel technologies are generally developed and adapted by firms in industrial countries, FDI may be the most efficient way for developing economies to gain access to them. In addition, this knowledge may become more widely available in the country over a longer time, as employees with experience in the techniques used in foreign companies switch to other firms. Furthermore, foreign investment could increase competition in the host-country industry, and hence force local firms to become more productive by adopting more efficient methods or by investing in human and or physical resources (IMF, 2001).

Many countries have already released various strategic plans over the last decade. The worldwide technology revolution makes such strategies much more imperative. However, unlike the industrial revolution, the knowledge revolution encompasses all aspects of society, so e-strategies must go beyond technical goals in addressing the challenge of universal access to, and the usage of ICTs. The responsibility for adopting appropriate e-strategies rests not just with government, but also with civil society and the private sector. Moreover, much depends on how open governments want to be with their people in formulating and implementing such policies (Ulrich, Chacko & Says, 2004).

Along this aspect, the UN regional roadmap adopts the common vision and the key principles consistent with the WSIS Inter-sessional meeting recommendations that envisage the Information Society as a new and higher form of social organization, where highly-developed ICT networks, equitable and ubiquitous access to information, appropriate content in accessible formats, and effective communication must enable all the people to achieve their full potential, promote sustainable economic and social development, improve quality of life and therefore, alleviate poverty and hunger (UN, 2003).

Similarly, the UNESCO declaration urged the governments, parliaments, and other agencies to establish the legislative and political framework for reform and further development of higher education, taking into account of the fact that education and research are two closely related elements in establishing knowledge economy. Innovation schemes of collaboration among education institutions and different sectors of society might ensure that education and research programs effectively contribute to local, national, regional, and global development (Rossman, 2005).

Furthermore, the World Summit on the Information Society (WSIS) held in Tunis in November 2005 requested ECOSOC³⁴ to oversee the system-wide follow-up of its Geneva and Tunis outcomes. To this end, it requested ECOSOC, at its substantive session of 2006, to appraise the mandate, agenda, and composition of the Commission on Science and Technology for Development (CSTD), including considering the strengthening of the Commission, taking into account the multi-stakeholder approach. This mandate was immediately endorsed by the General Assembly in its resolution (A/60/252) adopted by consensus on March 27, 2006 (ECOSOC, 2006).

In these contexts, if the Internet penetration rate were taken as an indicator of successful implementation of ICT strategies, then it has been observed that during 1994-2000 it reaches to about 7%, while till 2003 the rate has increased to about 11%. However, mobile penetration rate was around 13% in 2000 and in 2003 it was about 23%. Hence, it can be seen that during 2000-2003 Internet penetration rate has increased by 4%, while mobile penetration rate has increased by 10%. If Internet growth is to recover, it is important to reach out to the growing number of users who have a mobile phone but no fixed-line telephone. Handheld Internet enabled devices could open up the information gateway in a new and exciting manner—through that one could help further the goals of universal access while challenging manufactures and service providers

to meet different users' need across the globe. Table 37 synthesizes the growth rate of Internet penetration and mobile penetration across the globe during 1994 to 2003.

Technologies, such as Bluetooth, ZigBee, and RFID allow low-power—short-distance connectivity within a range of 30 meters. Medium-range technologies can communicate at least 150 meters from a hotspot (e.g., Wi-Fi or IEEE 802.11b) and up to several kilometers, depending on environmental, geographical, and regulatory factors. Similarly, long-range technologies such as WiMAX (IEEE 802.16) and IMT-2000 (3G) have ranges that may extend up to 50 kilometers from a base station, and to near-nationwide coverage through a networked service. Furthermore, in this category fit solutions based on high or low-altitude platform stations (HAPS/LAPS), LMDS, and MMDS that can serve a whole town or city, and finally satellite that can serve a whole region (ITU, 2004).

Academic institutions can play greater role in helping design and evaluate ICT projects that may involve technically challenging research. In addition, their corporate research counterparts could become active in developing standards that are revolutionizing the spread and use of ICT: from open source software and the next-generation Internet IPv6, to wireless LAN (IEEE 802.11b or 'Wi-Fi'), the longer-reaching standard of IEEE802.16 (or Wi-Max'), and the IEEE802.20

(or 'Wi-Mobile'). At the one end of the academic spectrum are scholars involved in cutting-edge innovations designed at leading research institutions and higher education institutions (HEIs); at the other are those toiling on the front lines of basic education. Each stage of the continuum has a stake in national e-strategies and input to provide into their own design.

Developing a cadre of digitally literate workers is necessary for a country to participate in the ICT revolution. However, such a process takes time—in fact, education and the investment in human capital can have a longer horizon for payback than almost any other investments. In 1980, when Singapore first began looking at computerization, the island city-state had just 850 computer professionals among its three million people. In 2004 it reaches to over 100,000. Similarly, India's policy of putting resources into tertiary ICT education took over two decades to bear fruit in creating global centers for outsourcing software development and business processes for multinational firms (call centers, etc.).

North American Companies' outsourcing of software development, processing of health-insurance claims, and maintenance of customer databases has generated 3000 jobs long back in 1998 in the Barbados, which was the same number of people employed in sugar cane farming³⁵. After about 8 years in the age of ICT, still those sectors deserve the same attention from many

Table 37. Internet and mobile penetration rates (Source: ITU World Telecommunication Indicator Database)

Year	Internet penetration rate	Mobile penetration rate
1994	0	0
1996	3	5
1998	4	7
2000	7	13
2002	9	19
2003	11	23

nations who need to adopt ICT in their knowledge economy.

Mexico's GDP per capita in 1960 was about 2.5 times higher than that of Korea (R.), but by 2003 Korea (R.)'s GDP per capita was more than double than Mexico's. Without the contribution of knowledge, Korea (R.)'s actual GDP per capita would have been lower than Mexico (World Bank, 2006).

No matter how undeveloped they are, virtually all countries recognize that ICT development is the key to future prosperity, and ICT has to be embedded into the daily life with an enabling environment (Capacity dot org, 2004). Furthermore, without knowledge workers, nations cannot move up to higher rank of GDP, and more remunerative links in the global value chain. Hence, in a few countries (some indicated in this chapter) and elsewhere, digital literacy has become the highest priority, emphasizing math, basic science, technical skills, and for better or worse, English, as the prevailing lingua franca of international business and the Internet (Ulrich, Chacko & Says, 2004).

FUTURE ICT STRATEGIES

National development strategies calls for the creation of a high-skill, high-value added economy to increase the GDP and help bridge the wealth gap among cities and between country and the rest of the world. Skills development can be seen as moving a country eventually into the knowledge-based economy. Hence, the vision of the strategy should be dynamic, inclusive, and sustainable depending on world-class competitive business and skilled motivated people (National Assembly for Wales, 2001). From these aspects, national ICT strategies of a country should act as catalytic agents in reinforcing the overall development through innovative application of technologies and promotion of ubiquitous access to information.

Development of ICT needs assessment and strategic planning; policy development and implementation; information management; project development and implementation for e-services in health, education, environment, and other economic sectors; private sector entrepreneurship; awareness, education, and capacity building; e-government strategic planning; information infrastructure improvement; enterprise information resources integration; information systems design and deployment; business process reengineering and optimization; grass-roots and national institutional reforms and change management; and foremost improved regulatory environment.

For successful strategic ICT development, the following steps may be initiated at national level:

- Formulation and realization of ICT-enabling policy, institutional and regulatory framework and its incorporation into the overall strategy of the national social and economic development
- Formulation and implementation of sectoral ICT strategies and policies in health, education, environment, SMEs, and other economic sectors
- Advisory services to central and local governments on policies to raise awareness and encourage application of ICT to strengthen the economic and social position of the poor masses and ensure their enhanced participation in decision-making processes
- Advisory services on e-governance including strengthening of e-government road-map, strategies and policies, and implementation framework, e-government systems architecture improvement, strategic planning for information integration, e-service planning and research, information security strategies, knowledge, and content management
- Advisory services on ICT infrastructure advancement, ICT manpower development,

- institutional restructuring, change management and business process re-engineering
- Sponsor training courses, capacity building and awareness creation workshops on ICT policy, institutional and legislative issues, e-government, ICT standards, information security, and data protection (UNESCAP, 2006)

Figure 8 shows the various steps needed to develop strategic ICT implementations in a country.

As described earlier, in recent years many governments have undertaken, as part of the Millennium Declaration, to develop and put into effect strategies to give common people a real change to find decent and productive work. The Heads of State and governments have also resolved to 'ensure that the benefits of new technologies, especially information and communication technologies are available to all' (UN General Assembly, 2000). Furthermore, as developing countries join the global information infrastructure, each country will need to find competent ways of maximizing the benefits and reducing the risks from ICTs. This will involve synchronized action

through national ICT strategies encompassing the technologies and services as well as many aspects of the institutional settings. Strategies are needed to build the necessary scientific, technical, and engineering knowledge as well as the management techniques so that the social and economic institutions that are consistent with creativity using ICTs may reap the potential social and economic benefits. Eventually, effective national ICT strategies are most likely to materialize through creatively combining competencies in scientific, technological, and management fields related to ICTs in each country and recombining these strengths with externally available technologies, information, and knowledge resources (Mansell, R. & When, U., 1998).

Figure 9 illustrates an ideal environment to develop successful ICT strategies. The core parameters are hardware, software and access to ICT services, and the basic preconditions are to improve appropriate infrastructure, enhance human capacity, incorporate supportive public policy, establish supportive framework for enterprises, and strengthen local content and applications.

In terms of hardware, ICT refers to a wide range of products and service activities. These include

Figure 8. Steps towards successful ICT strategy implementation

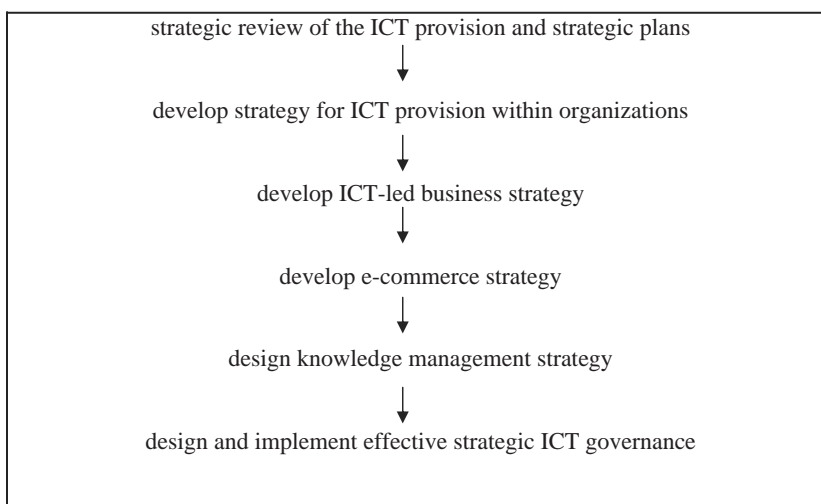

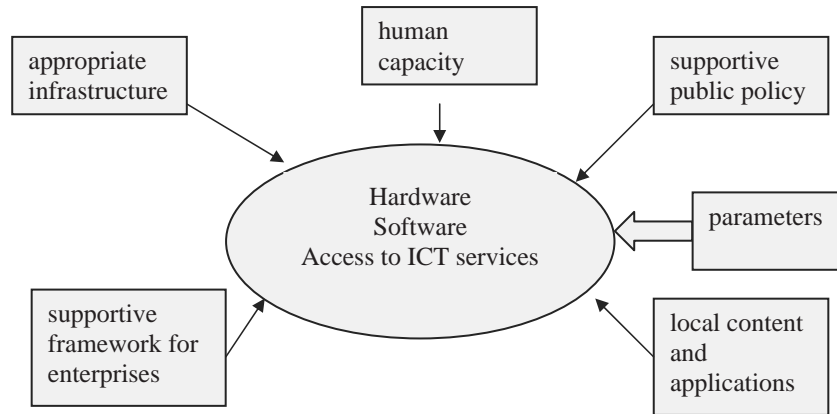

Figure 9. Preconditions for a successful ICT strategy

computers, related equipment, and accessories. In recent years, it also includes the fiber optics, satellites, sub-marine cables, voice over internet protocol, cellular phones (3Gs, 4Gs), high speed communication equipment, high definition television, and wifi/wimax equipment. ICT strategy should also encompass the software and related services industries, as such computer programming services, pre-packaged software, wholesale trade of software, retail trade of software, computer-integrated system design, computer processing, data generation, data security and information retrieval services, computer application and services management, computer rental and leasing, as well as computer maintenance and repair (Curtin, 2001).

Chapter 1.2

The Role of Information and Communication Technologies in Knowledge Management: A Classification of Knowledge Management Systems¹

Irma Becerra-Fernandez

Florida International University, USA

Rajiv Sabherwal

University of Missouri-St. Louis, USA

INTRODUCTION

Rapid changes in the field of knowledge management (KM) have to a great extent resulted from the dramatic progress we have witnessed in the field of information and communication technology. ICT allows the movement of information at increasing speeds and efficiencies, and thus facilitates sharing as well as accelerated growth of knowledge. For example, computers capture data from measurements of natural phenomena, and then quickly manipulate the data to better understand the phenomena they represent. Increased computer power at lower prices enables the measurement of increasingly complex processes, which we possibly could only imagine

before. Thus, ICT has provided a major impetus for enabling the implementation of KM applications. Moreover, as learning has accrued over time in the area of social and structural mechanisms, such as through mentoring and retreats that enable effective knowledge sharing, it has made it possible to develop KM applications that best leverage these improved mechanisms by deploying sophisticated technologies.

In this article we focus on the applications that result from the use of the latest technologies used to support KM mechanisms. Knowledge management mechanisms are organizational or structural means used to promote KM (Becerra-Fernandez, Gonzalez, & Sabherwal, 2004). The use of leading-edge ICT (e.g., Web-based conferencing)

to support KM mechanisms in ways not earlier possible (e.g., interactive conversations along with the instantaneous exchange of voluminous documents among individuals located at remote locations) enables dramatic improvement in KM. We call the applications resulting from such synergy between the latest technologies and social or structural mechanisms knowledge management systems. We discuss the topic of KM systems in detail in the next sections.

BACKGROUND

We describe the variety of possible activities involved in KM as broadly intending to (a) discover new knowledge, (b) capture existing knowledge, (c) share knowledge with others, or (d) apply knowledge. Thus, KM relies on four kinds of KM processes as depicted in Figure 1 (Becerra-Fernandez et al., 2004). These include the processes through which knowledge is discovered or captured, and the processes through which this knowledge is shared and applied. These four KM processes are supported by a set of seven KM subprocesses as shown in Figure 1, with one subprocess, socialization, supporting two KM processes (discovery and sharing).

Polyani's (1967) distinction between explicit and tacit is at the heart of most KM papers. These constructs follow in that explicit knowledge is knowledge about things, and tacit knowledge is associated with experience. Nonaka (1994) identified four ways of managing knowledge: combination, socialization, externalization, and internalization. Of the seven KM subprocesses presented in Figure 1, four are based on Nonaka, focusing on the ways in which knowledge is shared through the interaction between tacit and explicit knowledge. New explicit knowledge is discovered through combination, wherein the multiple bodies of explicit knowledge (and/or data and/or information) are synthesized to create new, more complex sets of explicit knowledge. Therefore, by

combining, reconfiguring, recategorizing, and recontextualizing existing explicit knowledge, data, and information, new explicit knowledge is produced. In the case of tacit knowledge, the integration of multiple streams for the creation of new knowledge occurs through the mechanism of socialization. Socialization is the synthesis of tacit knowledge across individuals, usually through joint activities rather than written or verbal instructions. Externalization involves converting tacit knowledge into explicit forms such as words, concepts, visuals, or figurative language (e.g., metaphors, analogies, and narratives; Nonaka & Takeuchi, 1995). It helps translate individuals' tacit knowledge into explicit forms that can be more easily understood by the rest of their group. Finally, internalization is the conversion of explicit knowledge into tacit knowledge. It represents the traditional notion of learning.

The other three KM subprocesses—exchange, direction, and routines—are largely based on Grant (1996a, 1996b) and Nahapiet and Ghoshal (1998). Exchange focuses on the sharing of explicit knowledge and it is used to communicate or transfer explicit knowledge between individuals, groups, and organizations (Grant, 1996b). Direction refers to the process through which the individual possessing the knowledge directs the action of another individual without transferring to him or her the knowledge underlying the direction. This preserves the advantages of specialization and avoids the difficulties inherent in the transfer of tacit knowledge. Finally, routines involve the utilization of knowledge embedded in procedures, rules, and norms that guide future behavior. Routines economize on communication more than direction as they are embedded in procedures or technologies. However, they take time to develop, relying on constant repetition (Grant, 1996a).

Other KM system characterizations present similar models to describe KM systems. For example, the acquire, organize, and distribute (AOD) model (Schwartz, Divitini, & Brasethvik, 2000)

uses a similar characterization to describe organizational memories. Comparing the two models, the acquisition process relates to how we collect knowledge from members of the organization or other resources, and it is related to the processes of knowledge discovery and knowledge capture. The organizing process refers to structuring, indexing, and formatting the acquired knowledge, and it is related to the process of knowledge sharing. Finally, the process of distribution relates to the ability to get the relevant knowledge to the person who needs it at the right time, and it is related to the process of knowledge application.

Knowledge management systems utilize a variety of KM mechanisms and technologies to support the knowledge management processes. Depending on the KM process most directly supported, KM systems can be classified into four types: knowledge-discovery systems, knowledge-capture systems, knowledge-sharing systems, and knowledge-application systems (Becerra-Fernandez et al., 2004). In the next sections, we provide a brief overview of these four kinds of

systems and examine how they benefit from KM mechanisms and technologies.

Types of Knowledge Management Systems

Knowledge-discovery systems support the process of developing new tacit or explicit knowledge from data and information or from the synthesis of prior knowledge. These systems support two KM subprocesses associated with knowledge discovery: combination, enabling the discovery of new explicit knowledge, and socialization, enabling the discovery of new tacit knowledge. Thus, mechanisms and technologies can support knowledge-discovery systems by facilitating a combination and/or socialization.

KM mechanisms that facilitate combination include collaborative problem solving, joint decision making, and the collaborative creation of documents. For example, at the senior-management level, new explicit knowledge is created by sharing documents and information related

Figure 1. KM processes

to mid-range concepts (e.g., product concepts) augmented with grand concepts (e.g., corporate vision) to produce new knowledge about both areas. This newly created knowledge could be, for example, a better understanding of the products and corporate vision (Nonaka & Takeuchi, 1995). Mechanisms that facilitate socialization include apprenticeships, employee rotation across areas, conferences, brainstorming retreats, cooperative projects across departments, and initiation processes for new employees. For example, Honda “set up ‘brainstorming camps’ (*tama dashi kai*)—informal meetings for detailed discussions to solve difficult problems in development projects” (Nonaka & Takeuchi, p. 63).

Technologies facilitating combination include knowledge-discovery or data-mining systems, databases, and Web-based access to data. According to Nonaka and Takeuchi (1995, p. 67), the “reconfiguration of existing information through sorting, adding, combining, and categorizing of explicit knowledge (as conducted in computer databases) can lead to new knowledge.” Repositories of information, best practices, and lessons learned also facilitate combination. Technologies can also facilitate socialization, albeit to less extent than they can facilitate combination. Some of the technologies for facilitating socialization include videoconferencing, electronic discussion groups, and e-mail.

Knowledge-capture systems support the process of retrieving either explicit or tacit knowledge that resides within people, artifacts, or organizational entities. These systems can help capture knowledge that resides within or outside organizational boundaries, including within consultants, competitors, customers, suppliers, and prior employers of the organization’s new employees. Knowledge-capture systems rely on mechanisms and technologies that support externalization and internalization.

KM mechanisms can enable knowledge capture by facilitating externalization, that is, the conversion of tacit knowledge into explicit form,

or internalization, that is, the conversion of explicit knowledge into tacit form. The development of models or prototypes and the articulation of best practices or lessons learned are some examples of mechanisms that enable externalization.

Learning by doing, on-the-job training, learning by observation, and face-to-face meetings are some of the mechanisms that facilitate internalization. For example, at one firm, “the product divisions also frequently send their new-product development people to the Answer Center to chat with the telephone operators or the 12 specialists, thereby ‘re-experiencing’ their experiences” (Nonaka & Takeuchi, 1995, p. 69).

Technologies can also support knowledge-capture systems by facilitating externalization and internalization. Externalization through knowledge engineering is necessary for the implementation of intelligent technologies such as expert systems, case-based reasoning systems, and knowledge-acquisition systems. Technologies that facilitate internalization include computer-based communication. Using such communication facilities, an individual can internalize knowledge from a message or attachment thereof sent by another expert, from an AI- (artificial intelligence) based knowledge-acquisition system, or from computer-based simulations.

Knowledge-sharing systems support the process through which explicit or implicit knowledge is communicated to other individuals. They do so by supporting exchange (i.e., the sharing of explicit knowledge) and socialization (which promotes the sharing of tacit knowledge). Mechanisms and technologies supporting socialization also play an important role in knowledge-sharing systems. Discussion groups or chat groups facilitate knowledge sharing by enabling an individual to explain his or her knowledge to the rest of the group. In addition, knowledge-sharing systems also utilize mechanisms and technologies that facilitate exchange. Some of the mechanisms that facilitate exchange are memos, manuals, progress reports, letters, and presentations. Technologies facilitat-

ing exchange include groupware and other team collaboration mechanisms, Web-based access to data, databases, and repositories of information, including best-practice databases, lessons-learned systems, and expertise-locator systems.

Knowledge-application systems support the process through which some individuals utilize knowledge possessed by other individuals without actually acquiring or learning that knowledge. Mechanisms and technologies support knowledge-application systems by facilitating routines and direction.

Mechanisms facilitating direction include traditional hierarchical relationships in organizations, help desks, and support centers. On the other hand, mechanisms supporting routines include organi-

zational policies, work practices, and standards. In the case of both direction and routines, these mechanisms may be either within an organization (e.g., organizational hierarchies) or across organizations (e.g., software-support help desks).

Technologies supporting direction include experts' knowledge embedded in expert systems and decision-support systems, as well as troubleshooting systems based on the use of technologies like case-based reasoning. On the other hand, some of the technologies that facilitate routines are expert systems, enterprise resource-planning systems (ERPs), and traditional management-information systems. As mentioned for KM mechanisms, these technologies can also facilitate directions and routines within or across organizations.

Table 1. KM systems, subprocesses, mechanisms, and technologies

KM Processes	KM Systems	KM Subprocesses	Illustrative KM Mechanisms	Illustrative KM Technologies
Knowledge Discovery	Knowledge-Discovery Systems	Combination	Meetings, telephone conversations, and documents, collaborative creation of documents	Databases, Web-based access to data, data mining, repositories of information, Web portals, best practices, and lessons learned
		Socialization	Employee rotation across departments, conferences, brainstorming retreats, cooperative projects, initiation	Videoconferencing, electronic discussion groups, e-mail
Knowledge Capture	Knowledge-Capture Systems	Externalization	Models, prototypes, best practices, lessons learned	Expert systems, chat groups, best practices, and lessons-learned databases.
		Internalization	Learning by doing, on-the-job training, learning by observation, and face-to-face meetings	Computer-based communication, AI-based knowledge acquisition, computer-based simulations
Knowledge Sharing	Knowledge-Sharing Systems	Socialization	See above	See above
		Exchange	Memos, manuals, letters, presentations	Team collaboration tools, Web-based access to data, databases, and repositories of information, best-practices databases, lessons-learned systems, and expertise-locator systems
Knowledge Application	Knowledge-Application Systems	Direction	Traditional hierarchical relationships in organizations, help desks, and support centers	Capture and transfer of experts' knowledge, troubleshooting systems, and case-based reasoning systems, decision-support systems
		Routines	Organizational policies, work practices, and standards	Expert systems, enterprise resource-planning systems, management-information systems

Table 1 summarizes the above discussion of KM processes and KM systems, and also indicates some of the mechanisms and technologies that might facilitate them. As may be seen from this table, the same tool or technology can be used to support more than one KM process.

Information and Communication Technology Infrastructure in Knowledge Management Systems

The knowledge management infrastructure is the foundation on which knowledge management resides. It includes five main components: organization culture, organization structure, communities of practice, information technology infrastructure, and common knowledge. In this section, we concentrate on the role of ICT infrastructure on KM systems.

Knowledge management is facilitated by the organization's ICT infrastructure. While certain information technologies and systems are directly developed to pursue knowledge management, the organization's overall ICT, developed to support the organization's information-processing needs, also facilitates knowledge management. The ICT infrastructure includes data processing, storage, and communication technologies and systems. It comprises the entire spectrum of the organization's information systems, including transaction-processing systems and management-information systems. It consists of databases and data warehouses, as well as enterprise resource-planning systems. One possible way of systematically viewing the IT infrastructure is to consider the capabilities it provides in four important aspects: reach, depth, richness, and aggregation (Daft & Lengel, 1986; Evans & Wurster, 1999).

Reach pertains to access and connection, and the efficiency of such access. Within the context of a network, reach reflects the number and geographical locations of the nodes that can be efficiently accessed. Keen (1991) also uses the term reach to refer to the locations an ICT plat-

form is capable of linking, with the ideal being able to connect to anyone, anywhere. Much of the power of the Internet is attributed to its reach and the fact that most people can access it quite inexpensively (Evans & Wurster, 1999). Reach is enhanced not just by advances in hardware, but also by progress in software. For instance, the standardization of cross-firm communication standards and languages such as XML (extensible markup language) make it easier for firms to communicate with a wider array of trading partners, including those with whom they do not have long-term relationships.

Depth, in contrast, focuses on the detail and amount of information that can be effectively communicated over a medium. This dimension closely corresponds to the aspects of bandwidth and customization included by Evans and Wurster (1999) in their definition of richness. Communicating deep and detailed information requires high bandwidth. At the same time, it is the availability of deep and detailed information about customers that enables customization. Recent technological progress, for instance, in channel bandwidth, has enabled considerable improvement in depth.

Communication channels can be arranged along a continuum representing their relative richness (Carlson & Zmud, 1999). The richness of a medium is based on its ability to (a) provide multiple cues (e.g., body language, facial expression, tone of voice) simultaneously, (b) provide quick feedback, (c) personalize messages, and (d) use natural language to convey subtleties (Daft & Lengel, 1984). ICT has traditionally been viewed as a lean communication medium. However, given the progress in information technology, we are witnessing a significant increase in its ability to support rich communication.

Finally, rapid advances in ICT have significantly enhanced the ability to store and quickly process information (Evans & Wurster, 1999). This enables the aggregation of large volumes of information drawn from multiple sources. For instance, data mining and data warehousing to-

gether enable the synthesis of diverse information from multiple sources, potentially to produce new insights. Enterprise resource-planning systems also present a natural platform for aggregating knowledge across different parts of an organization. A senior IS executive at Price Waterhouse Coopers, for example, remarks, “We’re moving quite quickly on to an intranet platform, and that’s giving us a greater chance to integrate everything instead of saying to people, ‘use this database and that database and another database.’ Now it all looks—and is—much more coordinated” (Thomson, 2000, p. 24).

To summarize, the above four ICT capabilities enable knowledge management by enhancing common knowledge or by facilitating the four KM processes. For example, an expertise-locator system (also called knowledge yellow pages or a people-finder system) is a special type of knowledge repository that pinpoints individuals having specific knowledge within the organization (Becerra-Fernandez, 2000, 2001). These systems rely on the reach and depth capabilities of ICT by enabling individuals to contact remotely located experts and seek detailed solutions to complicated problems. Another KM solution attempts to capture as much of the knowledge in an individual’s head as possible and archive it in a searchable database (Armbrecht et al., 2001). This is primarily the aim of projects in artificial intelligence, which capture the expert’s knowledge in systems based on various technologies, including rule-based systems and case-based reasoning, among others (Wong & Radcliffe, 2000). But the most sophisticated systems for eliciting and cataloging experts’ knowledge in models that can easily be understood and applied by others in the organization (see, for example, Ford, Coffey, Cañas, Andrews, & Turner, 1996) require strong knowledge-engineering processes to develop. Such sophisticated KM systems are typically not advocated for use in mainstream business environments primarily because of the

high cost involved in the knowledge-engineering effort.

FUTURE TRENDS

The future of knowledge management will be highlighted by three continuing trends: (a) KM will benefit from progress in ICT, (b) KM will continue the shift toward integrating knowledge from a variety of different perspectives, and (c) KM will continue to make trade-offs in numerous important areas.

First, in the future, KM will benefit from continual, and even more dynamic, progress in ICT. Improvements in cost and performance ratios of ICT have caused the cost of digitizing information to approach zero, and the cost of coordinating across individuals, organizational subunits, and organizations to approach zero as well (Grover & Segars, 1996). ICT progress also includes developments in autonomous software-based agents. Thus, the future of KM will be dramatically different due to the inevitable and unpredictable over any long period of time, and quantum changes in ICT and underpinning technologies such as artificial intelligence.

Second, in the future, KM will continue the shift toward bringing together, and effectively integrating, knowledge from a variety of different perspectives. Knowledge management originated at the individual level, focusing on the training and learning of individuals. Over time, the emphasis of knowledge management shifted to groups and entire organizations, and now examples of interorganizational impacts of knowledge management are becoming increasingly common. This trend in the impact of KM is expected to continue with its use across networks of organizations and across governments, enabling collaborations across historical adversaries and integrating knowledge across highly diverse perspectives and disciplines.

Finally, in the future, knowledge management will continue to make trade-offs in numerous important areas. One such trade-off pertains to the use of ICT for sharing. The same communication technologies that support the sharing of knowledge within an organization also enable the knowledge to leak outside the organization to its competing firms. Another trade-off concerns the balance between technology and people. It is essential to maintain a balance between using technology as substitutes for people (e.g., software agents) and using technology to enable collaboration from a wider range of people within and across organizations.

In conclusion, the future of knowledge management is one where people and advanced technologies will continue to work together, enabling knowledge integration across diverse domains with considerably higher payoffs. However, the new opportunities and greater benefits will require the careful management of people and technologies, a synthesis of multiple perspectives, and effectively dealing with a variety of trade-offs. The future of knowledge management will clearly be exciting due to the new opportunities and options, but interesting challenges definitely lay ahead for knowledge managers.

CONCLUSION

We have described the key aspects of knowledge management in this article. We have provided a working definition of knowledge management systems and presented the four types of KM systems: knowledge-discovery systems, knowledge-capture systems, knowledge-sharing systems, and knowledge-application systems. We also discussed how KM systems serve to support KM processes based on the integration of KM mechanisms, technologies, and infrastructure.

KEY TERMS

Artificial Intelligence: The branch of computer science concerned with making computers behave like humans. John McCarthy coined the term in 1956 while at the Massachusetts Institute of Technology. It refers to the science that provides computers with the ability to solve problems not easily solved through algorithmic models.

Common Knowledge: An organization's cumulative experiences in comprehending a category of knowledge and activities, and the organizing principles that support communication and coordination.

Knowledge Capture: The process of eliciting knowledge (either explicit or tacit) that resides within people, artifacts, or organizational entities, and representing it in an electronic form such as a knowledge-based system for later reuse or retrieval.

Knowledge Discovery: The development of new tacit or explicit knowledge from data and information or from the synthesis of prior knowledge.

Knowledge Engineering: The process of eliciting an expert's knowledge in order to construct a knowledge-based system or organizational memory.

Knowledge Management: They perform the activities involved in discovering, capturing, sharing, and applying knowledge in terms of resources, documents, and people skills so as to enhance, in a cost-effective fashion, the impact of knowledge on the unit's goal achievement.

Knowledge Management Infrastructure: The long-term foundation on which knowledge management resides. It includes five main components: organization culture, organization structure, communities of practice, information technology infrastructure, and common knowledge.

Knowledge Management Mechanisms:

Organizational or structural means used to promote knowledge management. They may (or may not) utilize technology, but they do involve some kind of organizational arrangement or social or structural means of facilitating KM.

Knowledge Management Processes:

The broad processes that help in discovering, capturing, sharing, and applying knowledge.

Knowledge Management Systems:

They integrate technologies and mechanisms to support KM processes.

Knowledge Sharing:

The process through which explicit or tacit knowledge is communicated and appropriated to other individuals.

This work was previously published in Encyclopedia of Knowledge Management, edited by D. Schwartz, pp. 230-236, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 1.3

Postcolonial ICT Challenges

Birgitta Rydhagen

Blekinge Institute of Technology, Sweden

Lena Trojer

Blekinge Institute of Technology, Sweden

INTRODUCTION

This article has a particular interest in the introduction of ICT in the postcolonial parts of the world. The fundamental arguments for investing in ICT all over the world rest on the view of ICT as a necessity for successful integration into the world economy. ICTs are regarded as having great potential to promote development in key social and economic areas where a shortage of capital, knowledge and local capacity obstructs progress. However, “information itself does not feed, clothe or house the world” (Main, 2001, p. 96), and it remains to be seen whether ICTs in developing countries will create wealth among the poor in those countries or among the already wealthy.

In the promotion of ICTs for development, the introduction of these technologies is mainly discussed in technical terms, considering the problems of electricity, telephone access, and expensive computers. The argument for introduction is also rather instrumental, expecting income generation and economic improvement.

At the same time, ICTs are sometimes referred to as revolutionary, but they will travel on existing technologies, modes of communication and (post) colonial relationships.

The introduction of new technologies will not only be regarded as a technical issue. It may also be politically sensitive, if the technology shows signs of disrespect for the local culture, if it promotes only specific groups and ways of life in the local society, or if it bypasses the local society when reaching out for a specific target like a company (see e.g., Redfield, 2002). As for example Weckert and Adeney (1997) argue, the spread of ICTs in diverse cultural settings might very well be regarded as cultural imperialism, given the unequal access to resources for alternative technologies or content. The directions that ICTs lead towards, for example distant communication, may be interpreted as unifying and networking on a global scale between interest groups to their own and society’s benefit. ICTs may also lead to an increased spread of (androcentric) American and western ideals and commercial products,

increasing the global dominance of the U.S. and other western nations. These examples show the impossibility in treating technologies as neutral tools.

The aim of this article is to develop postcolonial and feminist technoscience requests for context sensitive and distributed ICT processes in relation to the development of ICTs for Tanzania at the University of Dar es Salaam.

BACKGROUND

The position of “having never as much” (Redfield, 2002, p. 810) will for a long time be the position from which people in the Third World will receive ICTs. In his study, Redfield showed what reactions and tensions this position may create. Are ICTs yet another way of imposing control, of deciding what is important to know and to have, of showing who is in charge of globalisation? Are they yet another demand on transfer from national to private and commercialisation of common goods? A tool “to make the poor dream the same dreams as the rich” (Martín-Barbero, 1993, p. 165)?

Mörtberg (2000) raises the issue of equal access to ICT in a time when we see less of arguments for “technology in a democratic society” and more of arguments for “democracy in an information society”. Equal access, referring to gender, class, race, religion, language etc. is by no means inherent in the ICTs. The gender dimension in the case of ICT in the postcolonial context relates to a double burden of men’s supposed supremacy in technological matters, and women’s specific barriers in the developing world, including illiteracy, unfamiliarity with English (that dominates the Internet), domestic work load, lack of valuable information on the Internet, and lack of connectivity in rural areas where women primarily live (Gurumurthy, 2004).

The links between equal-level¹ participation and ICT development or ICT policy development are created by means of hard work and tedious

dialogues, multidimensional partnership co-evolution with developed and working sensitivity and awareness of diverse interests, gender dimensions and cultural—ethnic pluralism, among other components in an increasingly complex world.

Suchman (2002) argues that the *design from nowhere* is a result of the idea that technical systems could be constructed with a minimal cultural connection “as commodities that can be stabilized and cut loose from the sites of their production long enough to be exported en masse to the sites of their use” (p. 140). Suchman also points out that the distinction between designer and user is not straight forward. The designers are users of their own products, and that invisible design-in-use often takes place without rigorous documentation. “Even to keep things going on ‘in the same way’ in practice requires continuous, mundane forms of active appropriation and adaptation of available resources” (p. 143).

Requests for access to communication (not only information; Colby, 2001), relevant material (e.g., Morley & Robins, 1995) and appropriate modes of communication practices (oral/literal, face-to-face or over distance; Mejias, 2001) highlights the borderline between ICTs supporting imperialism or pluralism. “Our challenge lies in theorizing exactly this interstitial space between agency and the lack thereof, between being constructed within structures of domination and finding spaces of exerting agency” (Shome & Hegde, 2002, p. 266).

These issues make it necessary to investigate and de-naturalise the discussion of former colonies as nations in need of ICT *transfer*. As Rwandan ICT expert Albert Nsengiyumva has stated², all electronic technologies have been brought into the African countries from outside. The new ICTs are often referred to as a sign of the jump from the modern into a postmodern age. Hess (1995) is very critical of the reference to a global postmodern age,

before claiming that “we” are living in a post-modern age, it is worth remembering that not everyone is included in that we. Cyberspace is an elite space ... There is a glass ceiling, and for many in the world a large part of postmodern technoculture lies well above it. (p. 116)

THE ROLE OF THE UNIVERSITY IN TANZANIAN ICT DEVELOPMENT

Feminist technoscience with emphasis on ICT is certainly motivated by transformation goals. The needs for transformation are not only seen in the ongoing difficulties of achieving appropriate ICT system solutions especially in low income countries, but also in a more general process of knowledge and technology development (Gibbons et al., 1994; Nowotny, Scott, & Gibbons, 2001). The latter urge for transformation not the least within academy and technical faculties (Etzkowitz & Leydesdorff, 1997). Feminist technoscience within technical faculties is a driving force for the transformation processes required (Trojer, 2002). The transformation on a deeper level is vital to address appropriateness, access and utilisation not only for women within the academia, but for the majority of women in the local society (Gurumurthy, 2004).

In order to be able to understand and learn about distributed knowledge and technology production you have to be situated in a very concrete, day to day practice as well as achieve broad contextual knowledges. The postcolonial situation carries the potential for distributed knowledge production that are of particular interest in this sense. Experiences from Tanzania and the role of the main university of the country will be used to elaborate on these negotiation processes.

Relevance and Transformation

The University of Dar es Salaam (UDSM) is the main university out of five in the country and the

only university holding a technical faculty. The challenge for the university as an actor in societal development is huge. High expectations are placed on the implementation of ICT, which can be recognised in strategic documents of UDSM:

As part of the ongoing transformation programme, the UDSM has initiated a number of reforms aimed at improving its main outputs (teaching, research and services to the society) through ICT. The improvement of ICT aims to suit the needs of the students and staff, the working environment and establish linkages with both industry and government. The new ICT developments are also expected to contribute to income generation in order to complement government and other funding sources to ensure sustainable academic programmes. (University of Dar es Salaam, n.d., para. 1)

The vice chancellor emphasizes that within the larger transformation activities of the university the issue of *relevance* becomes central. As far as possible a public university in a very poor country must aim to be relevant to the developmental aspiration of the people in all knowledge areas.

The transformation should go deeper in the academic organisation culture, the vice chancellor argues.

I must say it is not easy. If you want to bend a fish you bend it while it is still alive, before it is dry. If dry you crack it. We have come to learn that it is a bit difficult. We are still struggling with it. (vice chancellor, interview September 12, 2003)

Resource for Society and Government

The experience of approving ICT at the university started in 1993. Responsible people at UDSM put in a 2 MBite wireless line to the university main campus. UDSM even brought Internet to the Tanzania telephone company (TTCL) and

not the other way around. Now, twelve years later, Tanzania has Internet backbone in every region. In order to reduce the costs and ensure connection for the ministries, the university also connected eight government ministries to the wireless internet line at UDSM. As a result of this process, expert people from UDSM are now managers at TTCL.

Today, when the university competes with several other Internet service providers (ISP), a number of governmental bodies are still connected through the university link. The impact of the initiative coming from the university was an increased motivation for the university staff to keep on with ICT development, as the university staff members were the only ICT experts within Tanzania at that time. For the content development for the government (eGov) the process is both ways. The government as well as the university are looking to find the easiest way to implement the government's own processes and demands, which are monitoring, evaluation and easy communication. UDSM is trying to provide that kind of solutions.

ICT Politics and Borders in Question

The University of Dar es Salaam (UDSM) played a key role in the national ICT policy process. The policy draft was developed in a very broad and open process to reduce the dominance of the academy. The role of UDSM in the policy process can be viewed as part of a sensitive technopolitical agreement between the university and the government. We have to keep in mind that the knowledge experts of ICT in Tanzania were and are mostly located at UDSM or trained at the same place as the only institution having a technical faculty in the country.

The national ICT policy gives a substantial understanding of the status of ICT in Tanzania as well as strategic areas for ICT and development. One of the central statements concerns the needs for Tanzania to move from being mere

consumers of technology to being the designers and manufacturers of ICT.

At UDSM, the issue of how to achieve the dreams like poverty reduction, more education, gender equality and so forth is on the agenda. ICT can provide tools for this, but how much is really Tanzanian? The academic staff regards ICT as more promising than other technological fields in this sense:

We have a kind of technology where we can provide significant content of products, more than 60% as equal partners in the provision of products and services. This is mainly knowledge based. We have an opportunity to do that (provision) much more than in for example nuclear physics. (interview with academic staff, September 2003)

A department director at Tanzania Commission for Science and Technology (COSTECH) stressed that,

it is very unfortunate that computers came to Africa as prestigious tools, as elite, sophisticated tools and not as non rocket signs. This is a myth that came with them. Computers are just ordinary technology, much easier than automobile and more powerful than automobiles, because they are all knowledge based. Knowledge based technologies transform individuals. Many have a lot of interest in them. The West pushed computers as tools for private sector. That this is not true was not understood by the government ... It all depends on how you look at things within your own country ... This element of articulation is what we need to do.

FUTURE TRENDS

Experiences from international feminist research closely linked to dominant areas of technology (information technology, biotechnology, and material engineering) imply recognition of techno- and

research politics deeply rooted in understandings of knowledge and technology production as processes which occur in distributed systems. In other words, knowledge creation today takes place on the boundaries between universities, private sector, public sector and the political spheres.

We can recognize ICT as one of the technological science fields most evidently challenging the borders between academic research and politics/society (Gulbrandsen, 2000) and experience how the negotiations (Aas, 2000) about the character of academic research take place in society. Academic ICT and its applications in society and every day life force our attention towards the relation between dominating actors, of which the university is one. It stresses relevant knowledge about its prerequisites, which in turn results in transformation challenges within the traditional universities. One model explored for these processes has been the *triple helix model* stating that the three institutional bodies university, industry and government are increasingly working together (Uhlin & Johansen, 2001). The triple helix model focuses more on the outer frame for the processes. The actual knowledge and development processes are more explicitly discussed within the concept sphere of *mode 2* (Nowotny, Scott, & Gibbons, 2001). Mode 2 knowledge is created in a broad and transdisciplinary social and economic context involving varying actors and participants in the research process. This is seen in contrast with the traditional scientific knowledge, produced in separate, academic institutions with efforts to *reduce* influence from the society.

In a developing country like Tanzania in particular, the process of mode 2 knowledge production in a triple helix formation will present an example for the traditional academic institutions in the industrialised parts of the world. We see that the ICT development in Tanzania and other postcolonial countries will have an advantage in this sense of intensive interaction between different actors in society.

However, as already stated, equal access for people in rural areas, women in particular, and disadvantaged groups, will require active participation also from local organisations and NGOs with feminist agendas (see Gurumurthy, 2004, p. 42ff).

CONCLUSION

From our perspective, the situation at UDSM carries potentials of a contextual awareness that opens for a benign triple helix knowledge and technology production. A more broadly defined group of stakeholders in the early phases of ICT development may increase the robustness of the choices that are made along the road.

At UDSM in Tanzania, the priority of collaboration with institutions outside the university shows a potential for an ICT development drawing from a more conscious technopolitical work in a postcolonial situation. The recognition of the necessary efforts to enter into technology *development* has a potential to bring about a more domestic and context aware ICT development process. Feminist technoscience perspectives are supporting these processes.

If the ICT priorities of African nations shall become directed towards the population, internal expertise needs to develop the technologies and to utilise them. As the quotation from the department director at COSTECH indicates, the way ICT was introduced by foreign companies and nations can be criticised for attempting to retain an unnecessary control, carrying colonial marks, over the use of technology in the postcolonial context. The people at UDSM and COSTECH, however, have made conscious efforts to change the situation of “having never as much” into a situation where the control over the ICTs lies with the domestic expertise. As the interviewed academic staff member acknowledged, this is easier to achieve with ICT, which is knowledge

based, than in other technological fields which are more technology based.

The issues of software and content have not been addressed as thoroughly as the technical infrastructure. What we here regard as knowledge production within a triple helix or mode 2 system involves the technical expertise at the Tanzanian universities and in the Tanzanian society. Continuous efforts to address equality issues and access to ICT for diverse user groups, including women and men, rural and urban and so forth are needed.

KEY TERMS

Cyberspace: A world-wide computer network that allows people to communicate with each other.

eGov: The government's information and communication with citizens via the use of the Internet.

Internet Backbone: A larger transmission line that carries data gathered from smaller lines that interconnect with it. On the Internet or other wide area network, a backbone is a set of paths

that local or regional networks connect to for long-distance interconnection. The connection points are known as network *nodes* or telecommunication data switching exchanges (DSEs).

Mode 2 Knowledge Production: Some characteristics of mode 2 knowledge productions are situated in the context of application; distributed knowledge processes; development of robust knowledge; subject to multiple accountabilities.

Postcolonial: The period after the independence for colonized states in Africa, Latin America and Asia. Postcolonial also refers to a discursive space that has opened up for diverse positionings, discussions and practices after independence.

Technoscience: In the new fields of ICT, biotechnology and material sciences in particular, science and technology are so intimately related that they have merged into one. The concept of technoscience signals that the boundaries between science, technology, politics and society are about to weaken.

Triple Helix: Knowledge production taking place in the collaboration between the university, the government and the industry.

Wireless Technology: Wireless is a term used to describe telecommunications in which electromagnetic waves (rather than some form of wire) carry the signal over part or the entire communication path. Wireless technology is rapidly evolving, and is playing an increasing role in the lives of people throughout the world. In addition, ever-larger numbers of people are relying on the technology directly or indirectly.

Chapter 1.4

Holistic Evaluation of the Roles of ICTs in Regional Development

Chris Keen

University of Tasmania, Australia

Dean Steer

University of Tasmania, Australia

Paul Turner

University of Tasmania, Australia

ABSTRACT

Regional Australia continues to be the recipient of public programs premised on assumptions about the benefits of Information and Communications Technologies (ICTs) related development, at the same time as it is experiencing a reduction in basic services and problems associated with the digital divide. From a research perspective, these circumstances pose challenges on how to evaluate meaningfully the impacts of ICTs on regional development. These challenges are compounded by the considerable confusion that exists over what is meant by regional development, how it can be achieved, and how to measure and evalu-

ate the role ICTs play in reviving and sustaining regional communities. The exploratory research reported in this chapter examines the issues surrounding what is meant by ICT-related development in a regional context. It also explores the usefulness of multiple measures, as opposed to single measures, to describe what in reality is a very complex process. In this context, the chapter outlines the preliminary development of, and the rationale behind, a holistic approach for evaluating the role of ICTs in regional development, based on insights generated from ongoing research in Tasmania.

INTRODUCTION

The role of ICT ... in economic growth and social change has received considerable attention in recent years [but] ... reliable and comprehensive indicators are needed to track developments in new information technologies and understand their impacts on our economies and societies. (OECD, 2002, p. 3)

Community informatics researchers are well aware of the huge volume of literature on the impact of ICTs on economic (particularly urban) development. This discourse often relies on a simplistic assumption that “what is good for the economy is good for the community.” Too frequently their attempts to assess the impact of technology adoption on the social fabric of communities have been marginalized by the prevalence of this “dominant discourse.” While it is clearly problematic to marginalize questions relating to the influence of ICTs on the social framework of communities, particularly in regional areas, it does highlight the challenges that need to be overcome if more effective ICT-related interventions are to be designed, initiated and implemented.

In examining the role of ICTs on regional areas it is easy to be in support of the need for a recalibration from purely economic indicators to an aggregation of indicators encapsulating social and community dimensions. It is however, considerably more difficult to identify those indicators and the mechanisms for their meaningful aggregation. This is the case in regional Australia, where even obtaining an official and consistent definition of “regional” is fraught with difficulties. Indeed, while linking economic, social, and community factors together is an important and worthy step, it has not led to the identification of mechanisms for achieving such a meaningful aggregation (Steer & Turner, 2004).

The exploratory research reported in this chapter aims to contribute to an understanding of the issues surrounding what is meant by ICT-related

development in a regional context. It outlines the development of a holistic approach for evaluating the role of ICTs in regional development, based on insights generated from ongoing research into the impact of ICT-based projects in Tasmania.

ICTs and Regional Development

Despite the difficulties of defining “regional” that have been considered elsewhere (Steer & Turner, 2004), it is evident that the overall trends of slower industrial growth, decreasing rural populations, and the emergence of issues associated with the adequacy and/or affordability of telecommunications are very much a part of the everyday experience of the information economy for many Australians in regional areas, outside of the main metro area (DCITA, 2002).

In this context, it is not surprising that there has been considerable support for the deployment of ICTs as a mechanism to revitalise regional Australia. However, while ICTs clearly have the potential to connect regional Australia to the world, their impacts have been far from uniform and not always beneficial. ICTs and in particular e-commerce “raises the possible outcome of increased market share and dominance of large urban based companies in regional areas rather than the promised expansion of regionally based companies outside their regions” (Coulthard, 2001, p. 420).

The lack of uniformity of benefits is indicative of the fact that the implementation of ICTs are highly differential, depending on existing local regulatory, economic, and social infrastructure context, and that in turn re-emphasizes the importance of an assessment of the unique characteristics and circumstances of individual regional areas (Hearn, Kimber, Linnie & Simpson, 2005). From a different but complementary perspective, Lloyd and Hellwig (2000) have highlighted how socio-demographic factors are also extremely influential in relation to determining the extent to which Australians use ICTs and participate

in the information economy. Both perspectives highlight how both regional and individual differences are central to determining the outcomes of the development of ICTs infrastructure.

More broadly, it is interesting to consider the perspective of Hicks and Nivin (2000) who, in examining the huge U.S. investment in ICTs during the 1980s, researched the difficulty of finding consistent evidence of measurable impacts of these investments on overall U.S. economic performance. Hicks and Nivin found that when this ICT investment was assessed in isolation there was “no evidence of IT-induced income gains” (2000, p. 115), rather there was significant evidence to suggest that a “marked geographical concentration of IT investment” underscored the existence of the strong localization effects of ICT impacts. Simpson (2001) also noted that the majority of ICT-related economic growth in the U.S. was centralized in the relatively small locations of Silicon Valley and Seattle (Microsoft’s and Amazon.com’s headquarters).

The ICT-related investment and the deployment of ICTs has, and is having an impact on regional development. While ICTs can connect a region to the global economy, they also expose the region to global competition and the associated socioeconomic uncertainties of globalisation. What remains unclear is the extent to which this net impact will be positive (Coulthard, 2001; Wilde, Swatman & Castleman, 2000). More seriously, within the current conceptualization of the issues there is no way of meaningfully assessing whether the introduction of ICTs will mitigate, exacerbate, or simply replicate the pre-existing urban/regional divide (Steer & Turner, 2004).

EFFORTS AND INSIGHTS TO DATE

In recent years the provision of telecommunications, and especially broadband services, to rural and remote Australia has become a hot political topic. Not surprisingly this has resulted in a

large number of ICT-related policies, projects and schemes aimed at issues such as maintaining equity of access to ICT services, bridging the digital divide, providing regional economic growth, and empowering local communities. It has also given rise to an increasing number of theories and models on best practice. Unfortunately, what is often missing from these endeavors is a clear articulation of the specific goals of the projects in relation to how their impact will be measured, what outcomes are anticipated, and over what time frame.

At the Australian national level this can be seen in the HealthConnect project, estimated to cost \$AU300 million (Dearne, 2005), which is the Australian National, State and Territories Governments’ planned nationwide electronic health record system “to improve the flow of information across the healthcare system through the electronic collection, storage and exchange of consumer health information” (Productivity Commission, 2005, p. 260).

A report by the Australian Government’s Productivity Commission notes, “Overall, the approach taken in assessing the costs and benefits of HealthConnect has been disjointed” and that “the fact that so many unresolved issues remain after seven years of research and development suggests that there have been gaps in the planning and evaluation of the project and/or how these have been acted upon” (Productivity Commission, 2005, p. 260).

In Tasmania, expectations were high for significant change in economic and social terms, based on the promises of several multi-million dollar ICT-based development projects. One of these projects, the AU\$30 million Telstra Broadband-eLab, setup in the State’s north, is a test and development site for broadband and multimedia applications (Mitchell, 2003). However, according to industry groups in Tasmania the Telstra Broadband-eLab had “not delivered on its promises to either Launceston or the Tasmanian IT industry” (Mitchell, 2006, p. 33).

At the broadest level, this highlights the problem that if the goals of ICT-related regional development are vague, it remains very difficult to be able to assess whether they have been achieved. Indeed, without clarity any project is open to interpretation of success and/or failure depending on an evaluator's perspective and priorities.

This is more than just of academic interest; there can be serious consequences if effective evaluations of such projects are not conducted. If the impact of ICTs is identified overall as positive when in fact it has been negative, this may lead to either a continuation of the same policies that are in reality having a negative effect, or the scaling down or the withdrawal of the initiatives due to the perception that they have accomplished their aim. Conversely, if the impact of ICTs is identified overall as negative when in fact it has been positive again this may lead to undesirable policy changes where successful programmes are reduced or stopped to the detriment of the region (Chester, 2003).

Meaningless Measurement

It is easy to argue that single measures seldom present a meaningful indicator of the state and focus of any individual project, community, or regional economy. For example, the Federal Government's advisory body on broadband development in Australia, the Broadband Advisory Group (BAG) recently called on the Federal Government to "encourage the OECD to introduce mechanisms that measure the effective use of broadband and not merely take-up" (NOIE, 2003, p. 4), without offering any substantial suggestions as to how this would be achieved and how it would be used.

By using multiple, disparate measures the complexity of interpretation of any situation is dramatically increased. This is particularly the case, if there is no consensus amongst researchers on what multiple measures to use or how best to integrate/aggregate the results (Henderson-Montero, Julian, & Yen, 2003). Of course, the

accuracy of the measures themselves is also an essential element and relies on tailoring them to the specific situation under examination.

Moreover, despite the vast amount of data collected, Papadakis (2001) implies that in the main, most of the measures used to date have missed the point – the true significance of ICTs is not in the technology itself, but rather in its use and the consequences of its use.

Similarly, Sorensen (2000) questions the use of a "single picture" representation of regional Australia, insisting that this flawed depiction masks a diverse and complex range of economic and social conditions which are multifaceted, complex, interrelated and dynamic. Further, Sorensen (2000, p. 17) concludes that there is a "need to understand better how Australia's regional economies operate and are evolving," and that "the measurement and analysis of regional economic and social well-being in Australia requires in-depth clarification, focusing especially on the more intangible lifestyle, wealth, taxation, demographic and cost of living aspects."

It can be seen in the literature that scholars have been debating for almost 20 years about the return on investment from large scale ICT projects, without coming to a consensus as to whether the economy as a whole has benefited for this expenditure (Peslak, 2003). A study of data by Peslak (2003) that related to the ten year period from 1989 through to 1999, using both financial and market based productivity measures in the U.S. at the firm level, rather than at the industry or national level, concluded that despite popular rhetoric "the overall results do not show clear consistent positive results for the relationship between information technology spending and firm level productivity" (Peslak, 2003, p. 80).

These discussions reveal the difficulty in developing and utilizing individual measures and aggregating multiple measures. The dependent variables have not been identified, let alone characterisation of the independent variables in the evaluation of these programs. They also point to

the difficulty of being able to accurately compare results across regions.

The more geographically specific and sophisticated the tailoring of measurements is to a specific ICT or region, the more difficult it becomes to compare it with other regions. More than this, the outcomes of any regional development initiatives can carry different values in different regions, for example, creating 10 new jobs in a large regional city is always welcomed, but those same jobs created in smaller, struggling regional centers may have a much greater significant impact on the local economy and community.

New Alternatives

From an international perspective, recent work in the United Nations (UN) provides some insights that might assist in refining tools and techniques for measuring the impact of ICTs on regional Australia. The United Nations Development Program's Human Development Index (HDI) and the Genuine Progress Indicator (GPI) are two emerging major alternative measurement processes that are gaining some international support and credibility (ABS, 2002).

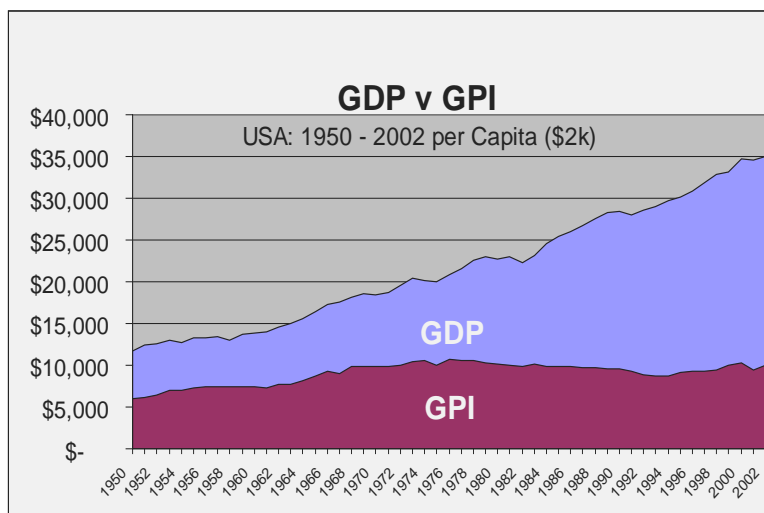

The Human Development Index (HDI) "was created to re-emphasize that people and their lives should be the ultimate criteria for assessing the development of a country, not economic growth" (UNDP, 2003). The HDI summarises three basic dimensions of human development: "living a long and healthy life, being educated and having a decent standard of living" (UNDP, 2003, p. 2). This is achieved by combining measures of life expectancy, school enrolments, adult literacy rates, and per-capita income rates. However, the United Nations Development Program (UNDP) acknowledges that the HDI is only a "useful starting point" as it "omits several vital aspects of human development, notably the ability to participate in the decisions that affect one's life" (UNDP, 2003, p. 60). Further, the UNDP recognizes that more complete pictures of human

development require the analysis of "other human development indicators and information" (UNDP, 2003, p. 60).

According to Colman (2001, p. 70), growth in Gross Domestic Product (GDP) "is simply a quantitative increase in the physical scale of the economy, and tells us nothing about our actual well-being." Colman's solution is to use an alternative measuring system, the Genuine Progress Indicator (GPI), which was developed by redefining progress to measure "the real state of our economy, our environment, and social justice" and to "indicate genuine progress in people's quality of life" (RP, 2000, p. 1). The GPI builds upon the personal consumption component of the GDP, and includes capital investment, government spending, and net exports. However it also includes quality of life measures that are not typically measured in monetary terms; for example, the contributions of volunteer work in the community, crime, and family breakdown (Colman, 2001; RP, 2000). When GDP and GPI are compared for the period 1950 to 2002 in the U.S., the distinction is marked. During this period the GDP rose at a relatively steadily rate, while at the same time the GPI, after a peak in the late 1970s, has remained relatively flat (Figure 1).

Yet another model for aggregating multiple measures is the Wealth of Nations Triangle Index for emerging economies, developed by the Money Matters Institute, Inc. This model uses economic environment, social environment, and information exchange variables to comprise legs of an equilateral triangle, and is built on the premise that sustainable growth is dependent on balance between these three areas (Sullivan, 2002). "Each leg contains 21 variables, chosen for both their relevancy and consistency over the years. Each variable is given equal weighting, based on a desire for simplicity, transparency, and balance among the three legs" (Sullivan, 2002, p. 4). The Index includes 70 nations that are considered to be "emerging economies" by the international investment community, and "measures the sustainable

Figure 1. Gross production vs. genuine progress for USA, 1950 to 2002 (Adapted from RP, 2004)

economic and social development potential of a nation and related risks, against those of other nations” (Sullivan, 2002, p. 4).

The Australian Bureau of Statistics also recognises that “public interest in the interrelationships between economic, social and environmental aspects of life” is growing (ABS, 2004, p. v), and that their statistical publications have tended to treat these issues as discontinuous. In recognising the current debate, the ABS is periodically publishing a series of discussion chapters called “Australia Now: Measures of Australia’s Progress.”

It is evident, even from this brief overview of just a few of the many attempts to capture and aggregate multiple measures of development of social progress that accurately measuring the impact and role of ICTs in regional development is likely to be fraught with difficulty. Nonetheless, it is also clear that if meaningful interventions have to be shaped by using ICTs in regional areas, meaningful measures must be obtained that present a more holistic picture of what is occurring.

DEVELOPING A HOLISTIC APPROACH

While numerous measures for economic, social, and community dimensions exist, it is a very difficult in any individual measure to clearly isolate the role of ICTs from other factors that may be at play and to develop a meaningful aggregation of these different measures. This is due to the fact that they often rely on different conceptual and methodological bases. However, despite these difficulties, the development of sophisticated holistic measures is not just of research significance but critical in accurately evaluating ICT-related regional development.

Purposeful Measurement

Ryan and Hess (1999, p. 3) assert that the “the choice of the measurement instruments to be employed is the most important step in the entire [assessment] process.” Winter (2001, p. 7) suggests that there are six sets of critical questions that should be considered when deciding what measures to use:

- What are the primary purposes for collecting information about ICT-related development in regions? What information is needed to fulfil the purposes?
- How will the information be used? What decisions will be made based on the assessment of ICT-related regional development?
- Do the measures adequately reflect the breadth and depth of ICT-related regional development? Do they provide information at each potential area of impact? That is, do they align with expectations?
- Do the measures provide reliable information about the ICT-related regional development process?
- Are there differences between the information needed from the key regional policy stakeholders and what the measures provide?
- Do the various measures, as a whole, serve their intended purpose? (Adapted from Winter, 2001, p. 7)

Winter also suggests that “some of the questions can be answered during the development or selection of the measures.” However, “some can be answered only by trying out various techniques for combining data and analysing the characteristics of the measures and how they contribute” to the assessment process (Winter, 2001, p. 7).

Chester (2003) cautions that multiple measures do not necessarily provide a clearer understanding of the underlying issues, but rather it is the reasoning behind the choosing and combining of the measures that determine their accuracy and appropriateness. Further, he states that the way multiple measures are combined is as “important as the measures themselves” (Chester, 2003, p. 9).

Disparate Measurement

However, from ongoing research in Launceston, a regional city in Tasmania, Australia, it is pos-

sible to outline the beginnings of an approach to accommodate a diverse range of measures. Launceston, with a population of around 70,000 people, is 200 km north of the State’s capital city of Hobart (with a population of 200,000), and is the second largest city in Tasmania.

In his work, which in part assessed the use and implications of ICTs in the household sector, Papadakis’ (2001) uses three areas of assessment: the socio-demographics of access and adoption, patterns of IT use, and research on impacts. A preliminary structured approach to evaluate the different measures based on Papadakis’ work has been developed. This preliminary structured approach will allow the development of a holistic picture to emerge of the impact of ICT-based projects on regional development in Launceston.

So far within this preliminary structured framework two major types of data are being collected: quantitative data from multiple statistical sources, such as the Australian Bureau of Statistics and the Tasmanian Department of Economic Development (see Table 1); and qualitative data obtained using a combination of semi-structured interviews and surveys of approximately 40 key regional policy stakeholders. The aim of the qualitative data collection is to interpret the assumptions, attitudes, and understandings of issues with regard to ICT-related regional development and associated economic sustainability (see Table 2).

Multiple Measurement

As has been discussed above, the principal difficulty in using diverse measures is how to aggregate these data. The approach being developed in this research program draws on the work of Henderson-Montero, Julian, and Yen (2003, p. 9), who list four possible approaches for meaningfully combining multiple and diverse measures: conjunctive, compensatory, mixed conjunctive-compensatory, and confirmatory:

Holistic Evaluation of the Roles of ICTs in Regional Development

Table 1. Quantitative data

Sources:	Data sought: (current and changes over past 5 years)
<ul style="list-style-type: none"> ▪ Australian Bureau of Statistics (ABS) ▪ Major Australian banks ▪ Tasmanian Department of Economic Development. ▪ Tasmanian Department of Education. ▪ Tasmanian Chamber of Commerce and Industry ▪ Launceston City Council ▪ Service Tasmania (A Tasmanian Government agency) ▪ Tasmania Business Online ▪ Tasmanian Communities Online ▪ Tasmanian Electronic Commerce Centre 	<p>Home PC ownership / Internet connection and use</p> <ul style="list-style-type: none"> • Number of people with home PCs • Hours of home PC / Internet use per user • Primary areas of use? • Hours connected to the Internet per user • Type of connection (Dialup, ISDN, ADSL) <p>Business PC ownership / Internet connection and use</p> <ul style="list-style-type: none"> • Number of Businesses connected • Type of connection (Dialup, ISDN, ADSL) • Primary areas of use • Percent / value of business using ICTs <p>Educational PC access and Internet use</p> <ul style="list-style-type: none"> • Number of Students per computer in Schools • Number of Students per Internet enabled computer in Schools <p>Online Government Services</p> <ul style="list-style-type: none"> • Number and percentage of Local, State, and Federal Government services online • Number and percentage of people using online Government services

Table 2. Qualitative information: Semi-structured interviews

Sources:	Information sought:
<ul style="list-style-type: none"> ▪ General Businesses – local, state wide, national and international ▪ ICT-related businesses ▪ Recipients of ICT-related development funding ▪ Community Groups ▪ Schools – Teachers, students, and parents ▪ Home PC and Internet users and non-users ▪ Online Access Centre staff and users ▪ Politicians and Community leaders ▪ Telecommunications providers ▪ IT Industry representative groups 	<p>Businesses</p> <ul style="list-style-type: none"> • How have ICTs impacted on the business? • What are the barriers to the adoption or further utilisation of ICTs? <p>Educational Institutions</p> <ul style="list-style-type: none"> • How are ICTs used in education? • What are the barriers to the adoption or further utilisation of ICTs in the education process? <p>Politicians and Community leaders</p> <ul style="list-style-type: none"> • Have the actual impacts matched original goals? <p>Home PC and Internet users and non-users</p> <ul style="list-style-type: none"> • What are (would be) the benefits of home PC / Internet use? • Who is (would) using the PC / Internet? • How did (would) you do previously spend your time now spent using the PC / Internet? • What are the barriers to the adoption / further adoption of ICTs?

- Conjunctive approach requires the demonstration of a minimum level of performance across all measures;
- Compensatory approach allows for the poor performance in one or more measures to be counterbalanced by higher performance in another measure;
- Mixed conjunctive-compensatory approach requires a minimum level of performance across the different measures; however, poorer performances measures can be counterbalanced by better performing measures;
- Confirmatory approach uses information from one measure to confirm or evaluate information from another independent measure. (Henderson-Montero, Julian & Yen, 2003, p. 9)

Preliminary research to date indicates that the mixed conjunctive-compensatory approach is providing the best holistic assessment in the Launceston region. However, mixed conjunctive-compensatory is not new and has been used for many years and in many different settings. What is new is its adaptation to the area of assessing ICT-related regional development.

Mixed conjunctive-compensatory techniques have been applied in diverse areas, such as marketing, teamwork evaluation and surveys of community cohesion. A potential application of this technique in the area of ICT adoption may be the development of a longitudinal analysis of the uptake of broadband communication technology. A survey of distinct technologies, such as high bandwidth cable connection, low to medium ADSL connections, and a variety of satellite connections can employ compensatory techniques to accommodate the differential uptake, degree of uptake, and extent of satisfaction with such a range of technologies. The conjunctive element of the analysis arises through the combination of data on different providers, technologies and pricing strategies, both geographically and over

time, so that the combination of several factors, including speed of access, price of service provision, download limits, and availability of distinct technologies can be accommodated in the one study.

ANALYSIS AND FINDINGS

Return on investment has been identified as the dependent variable for ICT development in regional areas, where this return encompasses both economic outcomes and social outcomes. A complete triple bottom line approach was not considered appropriate since the projects under consideration had negligible relationship to environmental outcomes. Preliminary analysis of the data collected, using the mixed conjunctive-compensatory approach, has identified the following independent variables as being relevant to the determination of the return on investment in large scale ICT development for the region of Tasmania under consideration:

- Clarity of formulation of project objectives.
- Extent of effective communication of these project objectives to stakeholders and participants.
- Extent of alignment with declared project objectives that is evident in the decision making by the project management team during the project planning and administration phases.
- Extent of communication of project outcomes to stakeholders, especially key interested parties in local government and the community, during and after the project.
- Extent of linkage of these project outcomes with other regional activities, projects and infrastructure.

In comparison with ICT projects, other infrastructure works, such as the construction of new

roads and highways, have clearly defined and communicable objectives of providing transport linkages between two or more points. The decision making during such a project is focused on civil construction and engineering. The key interested parties can relatively comprehend the outcomes that will eventuate when the road or highway is completed, and the linkages with economic and social development, and with other regional activities, projects and infrastructure become readily apparent once the road or highway is completed. Despite the widespread adoption of the metaphor of the information superhighway, ICT projects lack transparency of objectives and outcomes, and are far more difficult to comprehend. In particular, the strategic outcomes of a large scale ICT project are very difficult for many communities to envisage and to realize.

The determination of the dependent variable that characterises success in ICT projects has been identified as problematic (Milis, Meulders, & Mercken, 2003). The lack of comparable and statistically consistent data over a long time periods is also exacerbated by the rate of change of the underlying technologies and factors influencing its adoption, such as government policies and competitive pricing structures. Much more research in this field is needed to develop reliable, generalisable statistical frameworks to strengthen and support future investigation.

CONCLUSION

Evaluating the impact of ICTs on regional development is a complex process. It has been seen from the above discussion that much has been promised of ICT-focused developments, in terms of delivering benefits to regional areas including economic sustainability and connectivity to the global community. Clearly, if community informatics researchers are to assist in ensuring that the ICTs do impact positively on regional areas it is essential that more adequate measures are

introduced so that a better picture of the diverse range of impacts (positive and negative) are considered in shaping future interventions.

This chapter has promoted a more holistic view of ICT-related development that includes assessments specifically designed to capture the value of ICTs for social and community development as well as economic, and has outlined an initial approach to doing this based on insights generated from ongoing research in Tasmania.

Chapter 1.5

ICT in Regional Development

Saundarjya Borbora
IIT Guwahati, India

Mrinal Kanti Dutta
IIT Guwahati, India

INTRODUCTION

Economic development and information and communication technology (ICT) are found to move together in the present day era of globalization. ICT can contribute significantly in economic development of a region by providing adequate information at the minimum of time and cost, thereby enhancing productivity in different sectors of an economy. This fact is substantiated by several studies (Kraemer & Dedrick, 2001; Pohjola, 2001). Some country specific studies like that of Singapore (Wong, 2001) also highlighted similar results. ICT diffusion in the world has been quite rapid since the mid 1990s. While the developed countries have benefited substantially from the ICT growth, the developing countries could not reap similar benefits out of it which has resulted in emergence of a digital divide across the countries (Economist, 2000; Nkrumah, 2000; Norris, 2001). This divide is noticed not only across countries but also within a country and this is more prominent in developing economies

like India. ICT diffusion is another area which needs more attention in India as it will lead to ICT access and application of ICT in real sectors to increase productivity and output. During the past one decade India has made rapid advances in ICT growth as reflected in the increase in the number of Internet connections and users. The growth of Internet connections and users in the country is shown in Table 1.

Thus, Internet growth in India during the second half of 1990s has been phenomenal. However, the country is lagging behind other countries in ICT diffusion. The comparative position of India with some selected Asian countries in terms of Internet growth and usage is shown in Table 2.

The table clearly indicates that there is appreciable growth in Internet use in India over the period 2000-2004, but the penetration is abysmally low at 1.7% of the population whereas in China it is 6.0%. Some other small Asian countries like Japan, South Korea, Singapore, Taiwan have made substantial progress in terms of penetration which is evident from the table. Digital divide is glaringly

Table 1. Internet growth in India (Source: Adopted from Globalization, Inequality and the internet in India by Elizabeth C. Hansen [<http://www.isanet.org/archive/hanson.html>])

Date	Number of Internet Connections	Number of Internet Users
1	2	3
August 15, 1995	2000	10,000
March 31, 1996	50,000	250,000
March 31, 1997	90,000	450,000
March 31, 1998	140,000	700,000
March 31, 1999	280,000	1,400,000
March 31, 2000	900,000	2,800,000
August 31, 2000	1,600,000	4,800,000
January, 2001	1,800,000	5,500,000

obvious across different regions of the country. For example, while many states in Western and Southern region of India have witnessed rapid ICT growth and diffusion, states in regions like East and North East are found to lag behind. Out of 28 states and six union territories in India, only five states namely, Karnataka, Delhi, Tamil Nadu, Andhra Pradesh and Maharashtra accounted for

1.4 million Internet connections out of a total of 1.5 million connections in the country in 2000 (Prabhakaran, 2003). Increasing participation of non-governmental organizations (NGO) and private sector is important for bridging the digital divide. Efforts are already going on to achieve this objective by involving private sector companies in many parts of the country¹. However, infrastructural bottlenecks in the backward regions of the country are found to be a major obstacle in effective participation of the private sector in providing benefits of ICT diffusion to different sections of the society. Hence, the government sector has a crucial role to play in this area. In view of this, the Government of India has initiated efforts to provide the benefits of the ICT revolution to the rural masses through disseminating information and to enhance productive capacity of the rural sector. In line with the stated objectives of ICT diffusion, the Community Information Centres (CICs) Project was conceived and implemented by the Ministry of Communications and Information Technology, Government of India in the North Eastern Region of the country. In terms of providing benefits of ICT, CICs is the first initiative by the government to provide ICT access to

Table 2. Internet growth and usage in selected Asian countries (Source: www.internetworldstats.com)

Countries	Internet users (2000)	Internet users (2004)	Use growth (%) (2000-04)	% population penetration
1	2	3	4	5
China	22,500,000	79,500,000	253.3	6.0
India	5,000,000	18,481,000	269.6	1.7
Japan	47,080,000	64,537,437	37.1	50.4
South Korea	19,040,000	29,220,000	53.5	62.0
Malaysia	3,700,000	8,692,100	134.9	35.3
Pakistan	133,900	1,500,000	1,020.2	1.0
Singapore	1,200,000	2,100,000	75.0	60.0
Sri Lanka	121,500	200,000	64.6	1.0
Taiwan	6,260,000	11,602,523	85.3	50.3
Thailand	2,300,000	6,031,300	162.2	9.4
Vietnam	200,000	3,500,000	1,650.0	4.2

the people living in remote areas. Such an initiative may have an impact on the socio-economic development of the region and bring the region closer to the national mainstream.

North Eastern Region of India consists of the eight states of Arunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram, Nagaland, Sikkim and Tripura with a total population of 39,125,582 in 2001 (Government of India, 2002). The CICs project was launched with a pilot project covering 30 blocks in the region including 15 in Assam and was inaugurated in August 2000. By August 2002, CICs were established in all the blocks in the region, including 219 CICs in Assam covering all the 23 districts. These CICs were expected to help the region avail the benefits of global connectivity through the Internet as well as other local benefits.

A year after the establishment of CICs in North Eastern India, including Assam, it was felt necessary to assess the functioning of the CICs in Assam and its role on regional economic development. It was also necessary at this point to find out the expectations of the rural people from these centers. Keeping these twin objectives in mind, the present study was undertaken to examine the achievements of the CICs in Assam taking into account the aspirations of the rural people of the state. An attempt was also made to record the expectations of the users from the CICs in terms of information dissemination and its catalytic role in increasing productivity in the rural sector. This type of study offered promise to provide valuable guidelines to the government and as a result provide different services to the society through diffusion of ICT. It also provided the opportunity for the users to communicate their requirements/local content to the service providers. Such studies also bring out information on the stages of ICT infrastructure and acceptance of ICT as a tool of development by the users which may act as a guide to the private sector, NGOs, etc. in the process of ICT diffusion.

The following were the specific objectives of the study:

- To examine the functioning of CICs in relation to their stated objectives.
- To find out the socio-economic aspirations of the people at the block level and how CICs could help fulfill their expectations.
- To put forward recommendations for better functioning of the CICs in order to generate ICT awareness among rural people, to narrow the digital divide and achieve regional development.

CICS IN ASSAM AS A TOOL TO BRIDGE THE DIGITAL DIVIDE

Assam is the gateway to the North Eastern region of India. Because of its prominence in economic activities, contribution of a larger share to the national income and a larger population in the region it was felt to provide a good base for a sample case in relation to ICT diffusion and impact of ICT in regional development.

The case was considered to be reflective to the region as a whole. CICs in the state were set up in order to establish ICT infrastructure, to create ICT awareness amongst the local populace, to provide computer education and training, to provide government to community (G2C) services and to use ICT for sustainable regional development.

To achieve these objectives, each CICs was well equipped with infrastructure including one server machine, five client systems, VSAT, Laser Printer, Dot Matrix Printer, Modem, LAN, TV, Web cam, UPS, generator, telephone, air conditioner etc. The project was jointly implemented by Department of Information Technology under the Ministry of Communications and Information Technology, National Informatics Centre (NIC) and state governments.

The present study was based on primary data, which were collected through field work with the

help of structured questionnaires. For collection of data, a procedure of multi-stage sampling was adopted.

In the first stage, nine out of 23 districts belonging to different climatic, geographical conditions and socio-economic groups of people were selected. The districts selected for the study were Kamrup, Nagaon, Jorhat, Dibrugarh, Lakhimpur, Sonitpur, Goalpara, Bongaigaon and Cachar.

In the second stage, two CICs from each of the districts were chosen keeping in mind the intra-district variations in socio-economic conditions. The CICs covered under the study were: Rani and Kamalpur from Kamrup; Raha and Kaliabor from Nagaon; Dhekergorah and Titabor from Jorhat; Khowang and Barbaruah from Dibrugarh; Lakhimpur and Bihpuria from Lakhimpur; Dhekiajuli and Biswanath Chariali from Sonitpur; Balijana and Rongjuli from Goalpara; Dangtol and Borobazar from Bongaigaon and Borjalenga and Silchar from Cachar.

This was followed by selection of five villages from each CICs using simple random sampling procedure. Finally, about 10% of the beneficiaries were selected at random from each of these villages. Thus, total number of samples for the present study was 900. This included both users and non-users of the facilities provided by the CICs. Effort was made to include at least 75% users among the beneficiaries.

Further information were collected from the CICs operators of the CICs used in the samples with the help of structured questionnaires to elicit their opinions about the functioning of the CICs.

The data thus collected were tabulated and analysed using appropriate statistical tools.

SUMMARY OF THE FINDINGS

Some of the findings from the study are summarized below.

Participation of women in accessing information through CICs was very low. Only about 9% of users were found to be women, which clearly shows that gender participation of the sample was skewed towards male.

Students were found to be the dominant group among the users. While about 67% of the users were students, farmers and housewives constituted only 6% and 1.2% of the sample respectively. Again, about 85.11% of the sample, which comprises mostly the youth, were found to be aware about the CICs. Awareness about the facilities provided by CICs among the farming community, businessmen and other sections of the society was not spreading in desired manner. However, about 76.4% of the users were found to use the services provided by the CICs.

Some of the services provided by the CICs in Assam are:

- Training on computer application and advanced training in computers
- Word processing and printing
- Internet browsing and e-mail
- Examination results
- Health/Medical information
- Information on career opportunities
- Information on government schemes
- Information on banks' schemes
- Information on Public Distribution System (PDS)
- Downloading of application form for different government certificates
- Agricultural commodity prices
- Entertainment facility

Of all these services provided by CICs, the computer training programme was the most used (72.40%) by the users.

Providing G2C services was one of the prime objectives of establishing the CICs in the state. However, the spread of G2C services through the CICs was not very impressive. Only about 33% of the beneficiaries were found to avail themselves

of these services. The G2C services currently provided by the CICs were limited to providing information only. However, some of the information provided was found to be not current and not relevant to the rural people. Moreover, the rural people were not getting further benefits, such as getting birth certificates, death certificates, records of rights etc. at the village as was initially intended by establishing the CICs.

Among the users of other services, 49.39% were accessing information on employment opportunities followed by information on banks' schemes (37.29%) and downloading of various application forms (13.32%). The severity of unemployment problem in the state especially among the educated youth was reflected in the type of information sought by the users. In addition to these, the entertainment facility was also used by the participants in the CICs. It was found that about 51% of the sample were using the entertainment facility which was provided mostly through television broadcasting.

All the users were found to pay a user fee for various services used by them. Variation in user fee was observed depending on the type of facility used.

Location of the CICs was found to be an important parameter in accessing the services of CICs. About 82.70% of the users were found to reside within 5 kilometers from CICs. 33.28% of the users resided within 2 kilometers of the CICs. Only 0.73% of the users were found to travel a distance of more than 10 kilometres. This reflects an inverse relationship between distance from residence and the number of users.

About 36% of the users reported facing difficulties in accessing the facilities of the CICs. Most of these problems were related to the infrastructure of the CICs. Irregular supply of electricity, lack of sufficient space and furniture, non-availability of sufficient computers, delay in providing maintenance services, etc. were found to be the hindrances in exploiting the facilities of CICs. However, all the users found the services provided

by the CICs in the present form useful.

Some of the specific expectations of the beneficiaries about the services that should be provided by CICs are as follows:

- Distance education
- Information on banks' schemes
- List of beneficiaries of government schemes
- Information on career opportunities
- Redressing Public grievances online
- Information on government holidays
- Land patta and records of rights
- Matrimonial issues
- Tender notice
- Government certificates
- Information on agricultural commodity prices in neighbouring markets
- Information on health and medical services
- Information on Public Distribution System
- Downloading of application forms

Some of these expected services are being currently provided by some of the CICs in Assam, but in a low key.

SUGGESTIONS

The following suggestions are offered as easy ways of improving the effectiveness of CICs in the state.

Generating awareness among the rural people about the services that can be provided by the CICs needs to be taken up rigorously. At present, awareness about the services provided by CICs is found to be mostly among the educated youth. It should be extended to the rural masses in order to achieve the objectives for which CICs were established. Emphasis should be given to make females more aware about the services provided by the CICs. This is required as women can play

an active role in enhancing productivity in rural sector.

The limited spread of G2C services is mainly because of non-computerization of information and data at the district level, poor connectivity as well as lack of initiative from the state government. Initiative on the part of state government is necessary to make the CICs more vibrant and useful.

Some interactive services like online public grievances, providing records of rights of land, issuing of different certificates, residence certificates, caste certificates, birth and death certificates etc. will be taken up immediately in coordination with district administration. These types of services should be able to attract more rural people to use the services of CICs.

Efforts should be made to provide innovative services that cater for specific needs of the people. As for example, farmers could be provided with information on latest technology and specific problems such as raising alternative crops in the event of natural calamities like flood, etc. and agricultural experts may be involved online to provide advice. This has to be done within an acceptable time frame. These types of services may also be extended to school children, youth and other sections of the rural people.

Updated and relevant information should be provided by the CICs. As for example, in case of agricultural commodity prices, the figures may be updated at least weekly and the prices should be relevant to the area that a CICs serves.

Distance education programmes can be popularized through the CICs. Different universities and educational institutions providing specialized courses should be involved in this endeavour. Such programmes may be region specific and rural need based.

In order to bring transparency in government functioning, additional services may be brought under the purview of CICs. As for example, official information could be posted at different health centres in the villages and official information

on rural development etc. should also be made available.

The location of the CICs needs to be reviewed. Presently, most of the CICs are found to be located either in block development offices or schools. It was observed that some of the CICs located at block development offices were too far away from the centres of the villages they serve. This affects the use and the popularity of the CICs.

In order to make the CICs sustainable in the long run, it is necessary to provide their services effectively and efficiently. The role of CICs operators in this respect is most important. They have to keep abreast of the village environment and the requirements and expectations of the rural people under changing circumstances.

CONCLUSION

Establishment of CICs was an innovative step by the Government of India to minimize the digital divide. It has been found that CICs in Assam are providing various services to rural people in a limited way both in terms of providing relevant information and G2C services. The CICs have been able to achieve some of the stated objectives such as providing ICT infrastructure at the block level, providing e-mail and internet services and conducting computer based training programmes. But they have only been partially successful in facilitating distance education and G2C services. The objective of using CICs as a tool for sustainable regional development has not been satisfactorily achieved as they are providing mostly limited information and services which are not directly augmenting the rural productivity in a desired manner. To achieve some of the stated objectives of the CICs, a stronger coordination between the state government and the CICs is required. In order to make the CICs more viable and effective in achieving regional economic development there is a necessity for wider coverage of G2C services, a better awareness campaign and

region-specific innovative services. Involvement of the private sector for economic sustainability of the CICs in future may also be a necessity. Further research is needed to verify the scope and viability of involvement of NGOs, the private sector and corporate bodies. Such an effort has already taken place in some states of India. Evaluative studies incorporating the requirements in changing circumstances in the rural areas may need to be undertaken. Such an effort should provide future guidance to the service providers so that relevant ICT services can be provided to the rural population.

NOTE

The case study of CICs in Assam is based on a consultancy project by the authors funded by the National Informatics Centre, Ministry of Communications and Information Technology, Government of India, March 2004.

KEY TERMS

Block: An administrative unit in India which occupies fourth place after centre, state and district.

CICs (Community Information Centres): Information Centres set up by the Government of India in the north eastern region of the country to provide IT related services with internet access to the rural population.

Digital Divide: The gap in accessibility of ICT and its related services.

G2C (Government to Citizen) Services: Different citizen centric services provided by the government for the benefits of the citizen. These include providing birth and death certificates, records of rights of land, information on govt. schemes and so on.

ICT Diffusion: Spread of ICT benefits to the majority of the population for using ICT to increase productivity and regional development.

NGOs (Non-Governmental Organizations): Associations of like-minded people serving the society specially the downtrodden and vulnerable sections on their own or supplementing the organized effort.

Sustainability: A situation in which a particular mechanism is viable for a longer period.

Transparency in Government Services: A mechanism by which citizens know and understand the different activities of the government. Information on functioning of different government machineries is made available to the citizens.

UPS (Uninterrupted Power Supply): A mechanical/electronic device used to provide power supply without any disruption at the time

of power failure. This is mainly used in computers as a power back up.

VSAT (Very Small Aperture Terminal): An earthbound station used in satellite communications of data, voice and video signals, excluding broadcast television.

ABSTRACT

In this chapter the authors introduce the digital-divide concept to the reader, bring its different definitions, and describe the short history of the problem. The basic figures and facts, which characterize the information and communication technologies' usage in different countries and regions, are given as well. Also, basic indicators that allow the monitoring of the country's advancement on the way to bridging the digital divide are stated.

The main purpose for the authors was to show that the digital divide is not only (and not as much) a technical problem, but rather a social and political one. Hence, the approaches to this problem decision, both in the world community as a whole and in separate countries, are described.

INTRODUCTION

“The future belongs not so much to those peoples who have achieved today a high standard of well-being, as to those ones which can induce new ideas

in the field of high technologies and in their relations with the Nature. The erudition is necessary for this purpose, and not of separate people, but of the nation as a whole. And this circumstance imposes the special responsibility on a governing body of the state and on the intelligentsia.” (N. N. Moiseev, “Universum. Information. Society.” Moscow, 2001)

“It is not the gap that divides, but the difference of levels.” (Stanislaw J. Lec, “Unkempt Thoughts”)

The problem of the digital divide has probably only now begun to be perceived as it deserves. Practically any society can face it. Its manifestations are so various in different countries that it is actually impossible to offer common recipes for its solution. As the problem is basically social rather than technological, the ways of its overcoming depend on the degree of the democratization of a society, on the standard of living of a population, on the level of population erudition, and on cultural and ethnic features of the specific community of people. Certainly, the presence of an ICT infrastructure is necessary, but this is only the necessary condition. This chapter contains a brief history of the problem and various relevant definitions. On the basis of statistical data, the state of the art in the world is shown, the various countries are compared, and some basic ideas of the Genoa action plan are stated.

The necessary steps, without which the solution of the digital-divide problem is impossible, are brought. Positive experiences of the European Union (EU) and other countries are confirmed by examples. Basic indicators of the digital divide that allow the monitoring of the problem solution are brought as well.

A SHORT HISTORY OF THE PROBLEM

The end of the 20th century and the beginning of the 21st were marked by the rapid development of information and communication technologies, which has led to the avalanche growth of digital information. However, any progressive phenomenon, as a rule, is accompanied also by negative by-products. In this case, alongside the overcoming of existing temporal, spatial, and social borders when using information, society has also received a new problem, the so-called digital divide. There are a lot of definitions of this term, which as a matter of fact are reduced to the following: “the term ‘digital divide’ describes the fact that the world can be divided into people who do and people who don’t have access to—and the capability to use—modern information and communication technology” (*Digital Divide*, 1999).

The world community started talking about the problem of the digital divide and the “have-nots” at the end of the last century (Brown, Barram, & Irving, 1995). The *Oxford English Dictionary Online* (2004) considers that the term digital divide was used for the first time in 1995 in an article of Ohio’s daily newspaper *Columbus Dispatch* and gives the following explanation as the commonly accepted meaning of this term: “the gulf between those who have ready access to current digital technology (esp. computers and the Internet) and those who do not; (also) the perceived social or educational inequality resulting from this.” At that time, many people refused to take this problem seriously and even spoke about it as a far-fetched problem that promoted further enrichment of computer and telecommunication corporations. By the end of the ’90s, the stable concept of the digital divide appeared as the serious, recognized problem that is regularly being studied and periodically being discussed by people all over the world today.

In 1999, in its third survey *Falling Through the Net: Defining the Digital Divide*, the USA

National Telecommunications and Information Administration (NTIA) noted that the digital divide became “one of America’s leading economic and civil rights issues” (1999, p. xiii).

With time, many international organizations and agencies (United Nations [UN], European Union, World Bank, United Nations Development Program [UNDP], Organization for Economic Cooperation and Development [OECD], International Telecommunications Union [ITU], United Nations Educational, Scientific, and Cultural Organization [UNESCO], Economic and Social Council [ECOSOC]) began to express growing concern that the deepening of the digital divide problem may leave many nations far behind, producing growing disparities between advanced, industrialized countries and developing societies. Therefore, they give a lot of attention, force, and means for studying decisions regarding this problem. The international community carries out international conferences and summits (the Digital Divide Summit by the United States Department of Commerce in 1999, and the World Summit on the Information Society [WSIS] in Geneva in 2003 to Tunis in 2005), organizes various forums, creates specialized sites on the digital-divide problem (<http://www.pbs.org/digitaldivide/>, <http://www.digitaldivide.net>, <http://cbdd.wsu.edu/>, http://europa.eu.int/information_society/europe/i2010/digital_divide/index_en.htm), and launches various programs and initiatives. They study the experiences of various countries in overcoming this problem. Their discussions have come to a level of development on which practical recommendations are giving for bridging digital inequality both within an international scope and between separate states as well.

DEFINING THE CONCEPT OF DIGITAL DIVIDE

There are a lot of terms to describe the concept of digital divide—digital gap, digital inequality,

and rarely, information inequality—but all of them reflect the inequality of access to digital or information technologies.

However, before speaking about the problem of digital inequality, and for easier understanding of its essence and origin, it is necessary to pay attention to inequality in general. The following discussion is widespread and absolutely true. Inequality takes place in all spheres of social life from the moment of the beginning of a society. This is the inequality in access to vital resources (food, raw power, and now to information as well), workplaces, education, medical services, and cultural heritage. The distinctions of people regarding social status, the amount of available money resources, level of education, age, residence, and so forth lay in the basis of inequality. Inequality is the reason for conflicts and social cataclysms of various scales. Therefore, the world community, first of all the advanced countries, makes efforts for the neutralization of threats to global and local stability caused by various sorts of inequality.

In this way, the ensuring of equal access to social, economic, cultural, educational, and technological opportunities is offered for all people and for all states. Thus, they get the potential opportunity to reach an equal social status. However, it is an opportunity only, not the solution of the problem. In fact, certain limited resources (financial and especially human resources), even in the presence of political will, cannot be the sole determining factor as they do not allow the removal of inequality. If the opportunities exist already, then it is the will and efforts of people that will determine whether the actual inequality will proceed or will be eliminated. The consciousness of the person influences his or her will. The comprehension of inequality is already a powerful stimulus for social transformations, and for the development of separate people, social groups, and states as a whole. Therefore, discussion of the problem and the popularization of the necessity of overcoming inequality at all levels—internation-

Digital Divide

ally, nationally, and in governmental circles and various social groups—are very important.

Now let us turn to the digital-inequality problem, or as it is put more often, the digital-divide problem.

The attention of researchers of the problem at first was usually focused on the inequality in access to technical equipment. Even the definition given in the UN review (UN, 2003) fixes this position: The digital divide is “the fact that poor people in the industrialized world and almost all in the developing world are excluded from modern (information and communication) technologies” (p. 25).

However, this definition is too elementary to characterize the problem, which, actually, is much deeper and extensive. For today, we may consider, among others, the following aspects of the digital divide as basic ones:

- Property
- Age
- Education
- Territory
- Gender
- Culture

In addition, all these aspects are manifested differently in various countries, irrespective of their well-being and ICT infrastructure development level. From practical experience it becomes obvious that the idea “the more computers, the less digital divide” is narrow.

Irvine M. Warschauer (2002), a professor at California University, analyzed three examples of projects concerning ICT promotion. The conclusion was that providing access to ICT is not enough for bridging the digital divide. Analogously, taking into account each of the factors of the digital division (social factors, age, etc.) separately does not determine the problem. The problem needs to be considered in a complex way, taking into account all relevant factors.

For an illustration, let us examine these projects.

- **Example 1. (Warschauer, 2002, “A Slum ‘Hole in the Wall’”):** This project was established in 2000 by the New Delhi government in collaboration with an information-technology corporation. A computer kiosk was set up in one of New Delhi’s poorest slums. Five computers were inside a booth, and monitors were placed in holes in the walls. Specially designed joysticks and buttons were provided instead of computer mice and keyboards. Dial-up, 24-hour Internet access was available. There were no teachers in accordance to the concept of minimally invasive education. The idea was to allow children to learn by their own desire and capabilities.

Researchers and government officials appreciated this project as it was one that offered a model for how to bring India’s and the world’s urban poor into the computer age. However, as M. Warschauer (2002) noted, visits to the computer kiosk indicated a rather different reality. Internet access was of little use since it seldom functioned. There were no special educational programs and no special content in Hindi, the only language the children knew. Children did learn to manipulate the joystick and buttons, but almost all their time was spent drawing with paint programs or playing computer games.

Parents had ambivalent feelings. Some saw the kiosk as a welcome initiative, but most expressed concern that the lack of organized instruction took away from its value. In short, the community came to realize that minimally invasive education was, in practice, minimally effective education.

- **Example 2. (Warschauer, 2002, “An Information Age Town”):** In 1997, Ireland’s national telecommunications company held a national competition “Information Age

Town.” Towns of 5,000 people and more across Ireland were invited to compete by submitting proposals detailing their vision of an information-age town and how they could become one. Four towns were chosen as finalists, and then Ennis, a small, remote town of 15,000 people, was selected as the winner. The prize consisted of over \$1,200 per resident, a huge sum for a struggling Irish town.

The proposal planned for the following:

- An Internet-ready personal computer (PC) for every family
- An ISDN (integrated services digital network) line for every business
- A Web site for every business that wanted one
- Smart-card readers for every business, and smart cards for every family

Ennis was strongly encouraged to implement these plans as quickly as possible.

Meanwhile, each of three other towns received consolation prizes of about \$1.5 million. These towns were not limited by time.

Three years later, Ennis had little to show for its money. Training programs had been run, but they were not sufficiently accompanied by awareness programs. People were not prepared to use advanced technology. In some cases, well-functioning social systems were broken.

The unemployed had received computers and Internet connections at home so that they could sign in and receive electronic payments via the Internet, thus the necessity to visit the labor registry office fell away. However, these people lost the important social function to overcome isolation. More over, they could not use the equipment, and most others saw no reason to do so. Thus, a good number of those computers were sold.

Meanwhile, the other three towns with far fewer resources were forced to carefully plan

the usage of their funds rather than spend them for massive amounts of equipment. Community groups, small businesses, and labor unions participated in the planning process. Much greater effort and money were spent on developing awareness, planning and implementing effective training, and setting up processes for sustainable change. The towns built on already existing networks among workers, educators, and businesspeople to support basic uses of technology. As a result, these three towns actually achieved more success than the winner.

- **Example 3. (Warschauer, 2002, “A Model Computer Lab”):** An international donor project funded by the United States Agency for International Development decided to donate a computer laboratory to the College of Education at a major Egyptian university. The purpose was to establish a model teacher-training program using computer-assisted learning in one of the departments of the college. State-of-the-art equipment was selected, including more than 40 computers, an expensive video projection system, several printers and scanners, and expensive educational software. To guarantee that the project would be sustainable, the Egyptian university would be required to manage all the ongoing expenses and operations, including paying for Internet access, maintaining the local area network (LAN), and operating the computer laboratory.

Before the equipment was installed, it became clear that the college would have difficulty in making use of such a huge and expensive donation. Other departments within the college became envious because of the fact that a single department would have such modern and expensive equipment. The college and university could not easily justify spending the money. No money was available to engage an outside LAN manager or provide Internet access at the proper level. Due to

Digital Divide

all these difficulties, the expensive state-of-the-art computers sat in boxes in a locked room for more than a year before they were even installed, thus losing about one third of their economic value.

These experiences confirm the idea expressed by Bridges.org that states:

providing access to technology is critical, but it must be about more than just physical access. Computers and connections are insufficient if the technology is not used effectively because it is not affordable; people do not understand how to put it to use, or they are discouraged from using it; or the local economy cannot sustain its use. (“Spanning the Digital Divide,” 2001, p. 5)

Thus, we come to the wider definition: “digital inequality is a going deep inequality in access to social, economic, educational, cultural and other opportunities owing to unequal access to information and communication technologies” (Baranov, 2003).

FIGURES AND FACTS

A lot of analysis and research was carried out to compare the state of the art in the world. The results allow for the assessment of disparities existing in the access to and use of ICT between different countries (international digital divide) and groups within countries (domestic digital divide).

The existence of the digital-divide problem is recognized already by one and all. However, to compare the problem in different countries and at various times, it is necessary to measure it somehow. There are three basic parameters that are frequently used for measuring the digital divide: the number of ICT users, number of computer users, and number of Internet users.

According to data from the Digital Opportunity Task Force (DOT Force, 2001), 70% of the world’s poor live in rural and remote areas, and very often they have scarce access even to

a telephone, not speaking about ICT in general. Thus, one third of the world population has never made a telephone call.

In its *Human Development Report* of 1998, the UNDP drew attention to the fact that 109 million primary-school-age children (22% of those in the world) were out of school, 885 million adults (age 15 and above) were illiterate, and 4 copies of daily newspapers were circulated per 100 people in developing countries, in contrast to 26 in industrial countries.

Other impressive comparative statistics include the following:

- On the entire continent of Africa, there are only 14 million phone lines—less than the number in either Manhattan or Tokyo (Nkrumah, 2000).
- Wealthy nations make up only 16% of the world population but possess 90% of Internet host computers (Nkrumah, 2000).
- Sixty percent of world Internet users reside in North America, but only 5% of the world population reside there (Nkrumah, 2000).
- One in two Americans is online as opposed to 1 in 250 Africans (“Falling through the Net?” 2000).

In digital-divide studies, Internet-usage numbers are most often cited to describe the divide. Nua Internet Surveys (“How Many Online?,” 2002) offers an estimate of the global Internet-user population based on an extensive examination of surveys and reports from around the world. Nua’s data on how many people have used the Internet show a clear division. In 2001 in the world as a whole, there were 407.1 million Internet users; by 2002, the online users numbered 605.6 million. The leading regions were Europe (190.91 million), Asia and the Pacific (187.24 million), and Canada and the USA (182.67 million). A comparison with similar data on Latin America (33.35 million), Africa (6.31 million), and the Middle East (5.12 million) impresses.

Internet World Stats (2005), an International Web site, shows up-to-date 2005 worldwide Internet-usage and population statistics for over 233 countries and world regions. See Table 1 for world-regions data. These data as well as Nua's ("How Many Online?," 2002) show the identical world tendency: Asia, Europe, and North America remain leaders in Internet usage.

However, one can notice that in 2002, Europe was the leader by the absolute amount of Internet users (though its population makes up only 11.4% of the world's population); in 2005, Asia was the leader in the world (see Figure 1). Nevertheless, speaking about the percent of the country's population using the Internet (see Internet penetration in Figure 1), Asia, the population of which makes up 56.4% of the world's population, is still far behind (8.9%), and Northern America is the absolute leader (68%), though its population makes up only 5.1% of the world's population. By examining the dynamics of Internet users' growth inside each region for 2000 to 2005, one can see that the largest progress during these 5 years was made by the nonmembers of the EU (377.6%);

the Middle East follows with 311.9%. However, penetration inside these regions remains at only 17.5% and 8.3%, accordingly. The tendency is characteristic for countries of Latin America and the Caribbean (277.1%), Africa (258.3%), and Asia (183.2%) as well, where the penetration parameter is equal to 12.5%, 1.8%, and 8.9%, respectively. Let us compare the same parameters for North America, with a penetration rate of 68%. In this region for the same period, Internet users' growth was only 106.7%.

That is, during the last several years, less developed countries of the Middle East, East Europe, the Asian-Pacific region, and Latin America showed a constant increase in the active Internet audience, but not the USA, Japan, and countries of Western Europe. Insignificant growth of the number of Internet users in countries where penetration is already high is quite clear. Additionally, it is not only saturation, but probably an insuperable part of the digital divide that will remain in each society, at least in the near future.

According to the statistics in Table 1, on July 23, 2005, only 14.6% of the world population

Table 1. World Internet usage and population statistics for July 23, 2005 (Source: The table is made according to the data taken from Internet World Stats, 2005).

World regions	Population (million; 2005 est.)	Population % of world	Internet usage (million; latest data)	Usage growth 2000-2005	% population (penetration)	% world users
Africa	896.72	14.0	16.17	258.3	1.8	1.7
Asia	3622.99	56.4	323.76	183.2	8.9	34.5
Europe	731.02	11.4	269.04	161.0	36.8	28.7
European Union	460.27	7.2	221.60	137.9	48.1	23.6
Rest of Europe	270.75	4.2	47.44	377.6	17.5	5.1
Middle East	260.81	4.1	21.77	311.9	8.3	2.3
North America	328.39	5.1	223.39	106.7	68	23.8
Latin America/ Caribbean	546.72	8.5	68.13	277.1	12.5	7.3
Oceania/ Australia	33.44	0.5	16.45	115.9	49.2	1.8
World total	6420.10	100	938.71	160	14.6	100

Figure 1. Comparison of population and Internet usage for different world regions (Source: Diagram is made by the authors of this chapter using data taken from Internet World Stats, 2005)

used the Internet. The reasons for which the other 85.4% are nonusers are interesting. Numerous reviews specify the following reasons: poverty, a badly advanced ICT infrastructure, a lack of education, a misunderstanding of the benefits of ICT usage, bad content, the absence of interesting e-services, and so forth. However, the factor of motivation in using or not using ICT, the Internet in particular, is not less important. The report (Kalkun & Kalvet, 2002) prepared at the order of the Estonia state chancellery contains an analysis of motivation regarding Internet nonuse. Some ideas of this analysis are appropriate for the discussion below.

This report indicates that Internet nonusers constitute about 58% of the Estonian population in the age group of 15 to 74 (February 2002). Every second nonuser acknowledges one or many

benefits of computers or the Internet, while one half of the nonusers cannot point out any benefits of Internet.

One third of Internet nonusers are motivated to use the Internet. They have access to the Internet due to ongoing projects. This is because they have a more open attitude to learning new skills on the one hand, and an ability to overcome any barriers to Internet use that may arise on the other hand.

New projects should pay special attention to those two thirds of Internet nonusers who do not associate the possibilities of Internet use with their lives. There are two distinct categories in this group: retired persons and workers, or, as they are called in this report, “passive people” and “blue collars.”

- **Passive people** (28% of nonusers)
 - About 60% of people in this group are of 50 or older.
 - They have relatively little interest in matters outside their daily life.
 - They have a very weak relation to the Internet or computers; they see no benefits in the Internet and have no need to use it.
 - They prefer to use traditional media (even if the Internet were cheaper and more convenient); besides a lack of interest, they have a language barrier and are incapable of handling the user interfaces of computers. They are also relatively less able to learn and memorize new things, and are unwilling to change their habits.
- **Blue collars** (27% of nonusers)
 - They are mainly unskilled and skilled workers who do not use computers in their work.
 - About half of people in this group see no benefits in the Internet and would not very willingly change their daily routines as the Internet is unattractive for them.
 - A personal monetary gain would make the Internet attractive for them.
 - There are social and psychological barriers (fear of new technologies, no perception of the need for lifelong learning, a fear of demonstrating their lack of skills to others), skill barriers (lack of computer and ignorance of foreign languages), and economic barriers (income per family member is low).

These groups have not realized a relation between their lives and the Internet yet. That is why the important task is to motivate them, to introduce Internet services adjusted to the habits of these target groups, and to develop suitable Internet services where necessary. It is also important to

pay attention to the Internet-skills and Internet-access problems of the passive people and blue collars groups. The rest of the nonusers already have the motivation to use the Internet.

It may be said with fair certainty that the sociodemographic characteristics of the population segments that do not use information technologies are similar to those of other countries. The problem of motivation regarding ICT use arises in many countries, both in the developing and advanced. For example, in Scotland, where the technical base exists and is at a high-enough level, the question about the necessity of projects for the motivation to use ICT arises for those who do not use them (nonusers). Viviane Reding, member of the European Commission, states the same idea. She notes that governments need to encourage the use of new technologies, saying that the public will find new technologies “beneficial but guidance will be needed. The infrastructure exists but is underused: broadband is available on 80% of the European network but has been taken up by only 7% of users” (Raven, 2004).

The authors of the Estonian review fairly remark that if the problems of nonusers are ignored, a part of the population would effectively be excluded from actively participating in economic activities. This implies a decrease in the number of consumers, lower labor quality for the private sector, and, in the worst case scenario, the generation of an army of unemployed for the public sector, which in turn may cause extensive social problems (Kalkun & Kalvet, 2002).

SOLUTIONS FOR THE DIGITAL DIVIDE PROBLEM

In July 2000, the summit of the Great 8 (G8) was held in Kyushu-Okinawa, Japan. At this summit, the leaders from G8 countries adopted the *Okinawa Charter on Global Information Society* (2000). This charter established the DOT Force to integrate “efforts into a broader international

Digital Divide

approach” (p. 5). The DOT Force presented the report *Digital Opportunities for All: Meeting the Challenge* (2001) at the G8 summit held in Genoa in 2001. In that report, a nine-point action plan (Genoa Plan of Action) was proposed as well as a theory of ICT utilization to activate social and economic development.

Since then, the recipes for overcoming the digital inequality in and among countries have found reflection also in a lot of other world community documents (“Spanning the Digital Divide,” 2001; UNECOSOC, 2000). Today, the European Union is aimed to become the most dynamic knowledge-based economy and considers closing the digital divide as a key goal. This idea is reflected in such fundamental EU documents as the conclusion of the European Council in Lisbon 2000 (Lisbon European Council, 2000), the *eEurope 2002 Action Plan* (Council of the European Union & Commission of the European Communities [CEU & CEC], 2000), the *eEurope Benchmarking Report* (CEC, 2002b), and the *eEurope 2005 Action Plan* (CEC, 2002a).

There are many initiatives in the world directed to the digital-divide reduction.

However, it is necessary to understand the idea (“Spanning the Digital Divide,” 2001) that solutions that are successful in developed countries cannot simply be copied in the environments of developing countries. The solutions must take into consideration the local needs and conditions. As UN review (UN, 2003) stated, “The UN Millennium Declaration mentions the digital divide issue as one of the symbols of deepening developmental inequality in the world and indeed, finding a comprehensive solution to it belongs to world-making efforts” (p. 26).

Also, the analysis of relevant documents allows drawing a conclusion that the solution to the digital-inequality problem demands a balanced, nationwide-system approach that concentrates on the following basic directions: (a) policy, (b) access, (c) services, (d) content, (e) knowledge and skills, and (f) motivation.

In the Genoa Plan of Action (DOT Force, 2001), special attention is given to the coordination of strategies produced by less developed countries, as well as to involving in the work representatives of both private and state sectors. The states should produce these strategies by themselves, and the strategies’ presence in itself is already important for less developed countries. With that, it is necessary to formulate the strategy in strict conformity with national interests.

The many areas of human activity where ICTs can be applied and the many reasons for the digital divide assume many directions to operate and many various forces to involve for its overcoming. In what proportion, when, and what should be preferred depends on features of the specific country. The problem should be solved in a complex way, taking into account and coordinating the actions directed on the elimination of the separate reasons and overcoming any separate barrier. To embrace the basic aspects of the digital divide and to take into account the fact that each society has its own economical, political, social, and historical peculiarities, the following level of reality is necessary to be achieved.

- Physical access (infrastructure, computers, availability of necessary information in the language required on the Net)
- Comprehension of necessity and desire for ICT advantages
- Sufficient degree of society democratization
- Certain literacy level and opportunity for training
- Legislative base (electronic signatures, electronic documents, rights of access to information and protection of confidential information)
- Commercial-structures participation
- Sufficient financing
- State support (political will)

Having in view the objective of achieving this level, experts emphasize the following steps for overcoming the digital divide that are necessary to undertake in the directions listed previously.

1. Formation of national strategy, international and internal policy, and a favorable legislative, public, and economic atmosphere in the fields of informatisation and of ICT use
2. Maintenance of the potential opportunity for the population to access ICT everywhere due to the association of efforts of the state and private sectors of the economy on the development of an information infrastructure
3. Assistance to increase the variety and amount of services for the population and business by means of ICT
4. Concentration of efforts of the state and society for the creation of public electronic information resources (content) on the basis of national, world, political, economic, cultural, religious, and other types of aspects of development
5. Ensuring the possibility to get knowledge and skills in ICT use while getting basic special and higher education, and also the creation of conditions for obtaining initial knowledge and skills in this area for all layers of the population
6. Creation of a system of motivations for ICT application and use, aimed at the formation of wide demand for the use of such technologies in all spheres of society life

In these directions, a variety of avenues have been taken to bridge the digital divide in the world in general and in the EU particularly. Primarily, there have been efforts to promote e-government, encourage technological innovation and the use of existing technologies, guarantee more people Internet access, and advocate media pluralism and creativity. Many of these plans are interest-

ing and noteworthy, but it will take a great deal of political will to accomplish them.

Lately, many high-ranking officials in the EU in their statements express their readiness to undertake the necessary actions to bridge the digital divide. British prime minister Tony Blair, in his speech to the Labour Party Conference in Brighton (Blair, 2004), promised a broadband Britain by 2008. Also, member of European parliament and former French minister of culture and communication Catherine Trautman stated, "Europe must allocate resources for equity of access but also in equipment and in education" (as cited in Raven, 2004). These intentions of high-ranking officials agree with the *eEurope 2005 Action Plan* (CEC, 2002a), which is based on two complementary groups of actions: "On the one hand, it aims to stimulate services, applications and content, covering both online public services and e-business; on the other hand it addresses the underlying broadband infrastructure and security matters" (p. 3).

According to information presented in *People's Daily Online* ("280 Mln U.S Dollars Spent to Eliminate Digital Divide in HK," 2001), the Hong Kong secretary for information technology and broadcasting, Carrie Yau, emphasized that in spite of the fact that the digital-divide problem is not so sharp for Hong Kong as for other countries, the government had formulated clear policies in tackling the issue. She outlined a series of measures taken to bridge the gap or avoid the emergence of a potential gap between various sectors of the community. These include providing education and training, creating a favorable environment for technology diffusion in the community, enhancing knowledge and awareness, and developing e-government. By 2001, the Hong Kong government already expended \$282 million to strengthen the community for the exploitation of opportunities in the digital world. Yau noted that a substantial proportion of the local population already had the opportunity to access ICT and the Internet. Half of the households have installed computers.

Digital Divide

One third of the population are Internet users. The mobile-phone penetration rate has reached nearly 80%.

The new-coming technologies of information transmission are currently applied to bridge the technology and media clusters of the digital divide. The EU's action plan for 2005 includes a thesis for carrying out a cost-benefit analysis of various technological options including space-based ones (CEC, 2002a). In the summer of 2004, the eEurope Advisory Group published *Work Group No.1: Digital Divide and Broadband Territorial Coverage*. The main idea of this paper is that fast data exchange can supply citizens with e-services and help in bridging technological and other clusters of the digital divide. The paper presents recommendations to public authorities for selecting proper and effective technologies that correspond to local conditions. Satellite technologies are proposed for low-density rural areas because of "service costs dependent on the average bit rate usage, and investment costs dependent on peak bit rates" (p. 7). WiFi (wireless fidelity), DSL (digital subscriber line), and fibre technologies are recommended in the case of a medium-density village. High-density rural and urban areas are supposed to be covered by ADSL/VDSL and fibre or cable. The eEurope Advisory Group has examined other alternative technologies such as third-generation mobile/UMTS, power-line communications, broadband wireless access, and digital terrestrial TV, but found out that these technologies are more expensive or offer insufficient bit rates and interactivity as compared with other solutions.

According to these recommendations, "public authorities could also encourage the creation of Public Access Points (libraries, community centres, schools) in order to extend broadband access as much as possible into rural areas" (p. 10).

In particular, WiFi is currently widespread. Several projects based on this technology started during the last 3 years. Both inter-European projects, for example, TWISTER (Terrestrial

Wireless Infrastructure Integrated with Satellite Telecommunications for E-Rural; European Space Policy, 2004), and national projects, for example, the Spanish program Rural Public Access Points (Diputacion de Badajoz, 2005), have begun.

Included in the framework of the EU action plan of 2005 was the forum on the digital divide (<http://www.techsoup.org/fb>). Through this forum, any concerned person can exchange opinions, ask about possible solutions to a problem, or share a solution.

Although the digital-divide problem has become apparent all over the world, it has its own manifestations in each country because of different experiences according to the situation in the respective country.

ABOUT BASIC INDICATORS CHARACTERIZING THE DIGITAL DIVIDE PROBLEM

The sets of indicators for digital-divide assessment differ when mentioned by different organizations. These sets sometimes have some common elements, and sometimes they differ in their composition; however, they are not contradicting in essence, but supplement each other. Even in the evolution of these sets, we can track some consecution and regularity. Thus, at the first stages of studying the digital-divide problem, more attention was paid to the technological aspects. In the course of time, the world community became conscious that this problem is also of human and social character, and that is why the indicators characterizing this problem began to reflect these parts of human activity as well.

Thus, inasmuch as the digital divide was in the first place directly connected with ICT penetration into society life, for digital-divide monitoring and assessment it will be efficient to evaluate ICT development using a range of indicators to benchmark connectivity, access, ICT policy, and overall ICT diffusion. In the Geneva *Plan of Ac-*

tion (WSIS, 2003), in the section “Action Lines,” it is stated, “In the context of national e-strategies, devise appropriate universal access policies and strategies, and their means of implementation, in line with the indicative targets, and develop ICT connectivity indicators.” In the section “Follow-Up and Evaluation,” the following is stipulated:

Appropriate indicators and benchmarking, including community connectivity indicators, should clarify the magnitude of the digital divide, in both its domestic and international dimensions, and keep it under regular assessment, and tracking global progress in the use of ICTs to achieve internationally agreed development goals, including those of the Millennium Declaration...

All countries and regions should develop tools so as to provide statistical information on the Information Society, with basic indicators and analysis of its key dimensions. Priority should be given to setting up coherent and internationally comparable indicator systems, taking into account different levels of development.

So, each country should develop its own basic indicators to characterize the state of the art of ICT development in it, and to be able to evaluate the development or reduction of the digital divide. Nevertheless, there is a core list of ICT indicators that was developed and is adopted by international organs; it is recommended to be followed, not excluding the indicators elaborated to stress the specific country’s peculiarities. Thus, the WSIS Thematic Meeting on “Measuring the Information Society,” held in Geneva in February 2005, published the recommended core list of ICT indicators and its broad evolution (“Final Conclusions,” 2005). So, not to overload the space in this chapter but to give an idea of their details, we give the core list of ICT indicators and only some of its subindicators given in the document.

Core List of ICT indicators:

- Infrastructure and access core indicators (CIs)
- CI on access and ICT use by households and individuals
- CI on access and ICT use by businesses

Infrastructure and access CIs (basic core):

- Fixed telephone lines per 100 inhabitants
- Mobile cellular subscribers per 100 inhabitants
- Computers per 100 inhabitants
- Internet subscribers per 100 inhabitants
- Broadband Internet subscribers per 100 inhabitants (fixed and mobile)
- International Internet bandwidth per inhabitant
- Population percentage covered by mobile cellular telephony
- Internet-access tariffs
- Mobile-cellular tariffs
- Percentage of localities with public Internet-access centres by number of inhabitants (rural/urban)

Certainly, the problem of digital-divide evolution is a rather specific one. This problem differs to some extent from the problems of ICT evolution and of information-society evolution. Perhaps it should take into account some specific trends, but these basic trends are useful for assessment, too. Therefore, the indicators mentioned above are taken as the components for the calculation of more complex indicators that take into account the human factor as well. These are e-readiness, e-government, and e-ranking. They were calculated in analytical UN reports during last decade to estimate the level of society informatisation.

For example, we show the structure of the e-government indicator according to its explanation presented in the UN report (American Society for Public Administration & United Nations Division for Public Economics and Public Administration [ASPA & UNDPEPA], 2002).

Digital Divide

- a. **Presence on the Internet**
- b. **Infrastructure of telecommunications**
 - Number of PCs per 100 persons
 - Number of Internet hosts per 10,000 persons
 - Percentage of population using Internet
 - Number of telephone lines per 100 persons
 - Number of mobile telephones per 100 persons
 - Number of TV sets per 1,000 persons
- c. **Human resources**
 - Human-development index
 - Index of access to information
 - Ratio between urban and rural population

Tracking all of these indicators is useful for digital-divide monitoring and comparative analysis. These indicators' are indicative for every country, too.

The mentioned indicators for any range of countries or population groups allow carrying out comparative analysis, but do not allow expressing numerically the unevenness of the researched resource distribution between these groups. In the UN report *The Digital Divide: ICT Development Indices 2004* (2005), the authors propose to use Gini coefficients and Lorenz curves in the fields of telephone main lines, mobile subscribers, Internet hosts, PCs, and Internet users for the measurement of digital-divide unevenness.

The Gini coefficient is a measure of inequality. It is usually used to measure income inequality, but can be used to measure any form of uneven distribution. The Lorenz curve was developed as a graphical representation of income distribution and is used to calculate the Gini coefficient. These tools are very visual and can be calculated simply enough, having the values of the researched indicators for the chosen set of countries or groups of population.

In the same report, the calculated Gini coefficients are presented (UN, 2005). These data show changes that occurred during the period from 1995 until 2002 in the fields of telephone main lines, mobile subscribers, Internet hosts, PCs, and Internet users. For example, for telephone main lines, the value of the Gini coefficient in 1995 was equal to 0.688 for 200 measured countries, and it became equal to 0.551 in 2002 for 188 measured countries. For mobile subscribers, these values were 0.822 (195 countries) and 0.609 (194 countries), correspondingly. In other words, the inequality of these resources' distribution between countries had decreased. The same tendency was seen for PCs and Internet users. However, for Internet hosts, the picture is different: In 1995, the value was 0.910 (199 countries), and in 2002, it was 0.913 (204 countries). In this field, the inequality had increased instead of decreased. Perhaps this can be explained by the fact that this resource is the most expensive and requires a strategic approach.

Summarizing all discussed above about digital-divide estimation, we can recommend the use of the simple and complex (e-readiness, e-government) indicators as well as Gini coefficients for digital-divide monitoring and assessment.

In this chapter, the authors described the history of the problem, showed the situation in the world and the large-scale and magnitude of the problem, and set out the traditional, generally accepted views and trends for its solution. Every time, before giving a thesis, the authors endeavored to choose demonstrative examples from the world practice and then, on their basis, to make generalizations and conclusions.

Now, when benchmarking is made, it would be logical and useful to show the application of these judgments and recommendations for specific situations in the example of a typical, average country that is not distinguished by anything. The authors examine the application of these judgments for a specific country in the next chapter of this book. Being an agrarian country with a transition

economy (from planned to market), in which the digital-divide problem is especially manifested, Moldova was chosen as such a country.

CONCLUSION

The analysis of the situations in some countries, made in this chapter, shows that the digital-divide problem has a set of common aspects irrespective of country's development level or other (geographical, demographical, etc.) characteristics. Moreover, this problem is not so much technological as it is even more social and political. Therefore, its solution needs not only technological measures, but social and political ones as well.

- Creation of a system of motivation for ICT usage in everyday life
- Creation by the state and society of national electronic, informational resources, available for the population
- Elaboration of national strategy for information-society development, supported by a system of laws that provide (ensure) the creation of a favorable climate for nondiscriminated access to information for all citizens, for economic activity, and for social progress

ENDNOTE

- ¹ Here and further on, the most recent data available at the moment of this chapter's writing are presented. For example, the data for year 2004 for Moldova are taken when possible from a preliminary report issued in 2005 by the National Bureau for Statistics. If the table or diagram lacks some data for year 2004 for Moldova, it means that the data were not presented in 2004's report and in the preliminary 2005 report. Also, it may be that corresponding data from the preliminary 2005 report were calculated by a different method and disagree with similar data for previous years from the 2004 report.

This work was previously published in Information Communication Technologies and Human Development: Opportunities and Challenges, edited by M. Gascó-Hernández, F. Equiza-López, and M. Acevedo-Ruiz, pp. 57-76, copyright 2007 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 1.7

The Evolution of ICT, Economic Development, and the Digitally–Divided Society

Sadayoshi Takaya
Kansai University, Japan

ABSTRACT

In this chapter, we mention that a digital divide could bring about an income divide both within a country and between countries. The more the uses of the Internet diffuse, the more the divide may introduce serious concerns. From a macroeconomic point of view, the increase in the digital divide diminishes ICT investments and delays the innovation of ICT. As a result, we propose that the public policies of each government provide the devices of ICT as social capital and infrastructure. On the global stage, the digital divide exists between developed and developing countries. Therefore, international provision of the digital devices should be achieved through a cooperative effort between developed countries and international organizations.

INTRODUCTION

Currently, the global information society achieves progress by the development of information and communication technology. ICT offers the global society several conveniences, such as communication measures among countries and/or local areas, Web systems for businesses, online trading of securities, and distance learning.

ICT has the characteristics of a general-purpose technology (GPT); that is, it has the two qualities of compatibility and applicable innovation as identified by Helpman and Trajtenberg (1994). A GPT has broad compatibility across many industrial fields, for example, the steam engines of the 18th century. Furthermore, a GPT encourages the creation of new technologies based on its own core technology. Through such movements, the core technology diffuses across many

industries. Presently, in what is known as the IT revolution, ICTs are widely used by citizens, firms, and governments across the world. At the same time, ICTs create applied technologies in many fields. Looking back at this age from the future, one might well regard the ICT as being a GPT.

Figure 1 presents the contributions of ICT investment to gross domestic product (GDP) growth in Organization for Economic Cooperation and Development (OECD) countries during 1990 to 1995 and 1995 to 2003. From this figure, we can observe that ICT could contribute to increasing the growth rate in developed countries. Because ICT investment includes two aspects—increase in demand and technological change in the supply side—this contribution may not stem solely from innovations by ICT. Nevertheless, ICT may be one of the factors in growth engines.

We would like to suggest that there are two perspectives on ICT. One is the perspective of ICT as development infrastructure; the other is that of ICTs as communication measures. From the first perspective, networks provide the production factor and nurture human capital. This perspective is based on the view that ICT is an infrastructure

of economic development that is related to the supply side of economies, not the demand side. Developments of ICT provide new information, knowledge, and education to nurture highly qualified human capital. This argument is based on the endogenous growth theory,¹ which suggests that economic growth is driven by the accumulation of knowledge. Since this theory regards knowledge as capital, economic development progresses if the development of ICT contributes to the diffusion and deepening of knowledge.

On the other hand, the perspective of ICTs as communication measures is related to the demand side of the economy. Horrigan (2002) suggests that the notion of social capital is linked to the concept of measures as reducing transactions costs by access to ICT. ICT is, then, proposed to be social capital. The Internet provides facilities of the network of information exchange that can promote businesses and consumptions.

When, however, people use tools innovated by ICT, a burden is imposed on them. Their ability to use the devices, therefore, depends on whether or not they can bear the burden. Furthermore, their ability to use the devices depends on where

Figure 1. Contribution of ICT investment to GDP growth 1990-1995 and 1995-2003. Source: OECD Productivity Database, September 2005 (www.oecd.org/statistics/productivity)

Note: (1) 1995-2002 for Australia, France, Japan, New Zealand, and Spain.

they reside because regional differences exist with regard to the uses of the devices, such as the Internet. Due to these reasons, the uses of digital devices depend on incomes and areas of residence. As a result, the digital divide, which causes the difference with regard to the uses of digital devices, may become an issue in both the global and local society.

The concept of the digital divide was first used in a 1999 report entitled *Falling through the Net: Defining the Digital Divide* by the Department of Commerce in the United States. This concept includes the difference in the availability of the Internet and/or broadband Internet as well as the disparity of information literacy by region, country, and/or individual.

For our purposes, we use the concept of the digital divide to imply the disparity of information literacy and availability. Furthermore, a person under a digitally divided society faces some challenges in accessing the private and public services supplied through the Internet.²

In former studies of economic effect by ICT, Jorgenson and Stiroh (2000) estimated that average labor productivity in the United States grew at 2.4% annually during 1995 to 1998. They concluded that there was little evidence of ICT's effect on production. Gordon (2000) found that ICT led to price-induced substitution and rapid investment in ICT devices. He concluded, therefore, that ICT capital was deepening in the 1990s. Bailey and Lawrence (2001) found empirical evidence for the effect of ICT development on higher productivity in service industries. These empirical works implicate that access to ICT products is important for development, and ICTs also reduce the real costs of ICT equipment to increase the economic welfare of persons who can easily access ICT devices.

Casselli and Coleman (2001) found that computer skill is positively related to the level of human capital. Openness of trade, high rates of investment, and low share of agriculture in GDP had a positive relationship to computer use. Their

findings are important because human capital is complementary to computers

On the other hand, there are only a few effects of the digital divide on economic growth or development. Sidorenko and Findlay (2001) discussed the concept of digital divide in a global economic context, related to the economic growth theory and the evolution of technology in East Asia. They suggested that an appropriate policy for bridging the digital divide could bring about considerable gain in East Asia through openness in trading ICT products and through policy cooperation.

Wong (2002) estimated the scope of the economic effect of the divide in East Asia, despite the region having captured a high share of the global production of ICT goods. He found that a significant digital divide exists between the five leading countries in East Asia and the other seven developing countries.

Antonelli (2003) examined the composition effects stemming from the interaction between the direction of technological change and relative factor prices. He also suggested that these effects are necessary in order to understand the economics of new ICT in the global economy because of the significance of the digital divide.

Mariscal (2005) investigated the appropriate policy to address the digital divide. He classified different policy trajectories recommended by the literature on telecommunications development. He investigated the case of a developing country to use it as an analytical framework.

Most of these previous studies are empirical, not theoretical. Our work involves a mathematically theoretical approach through the construction of a simple economic growth model. The purpose of this chapter is to clarify the macroeconomic effects of the digital divide. If the digital divide in a digital economy progresses, the divide may result in a decrease in the aggregate economic demand. If this is the case, the divide should be resolved using political initiatives.

The remainder of this chapter is divided as follows. First, ICT diffusion and division in the

global economy is explained. Then we illustrate a static economic model to clarify the macro-economic effects of digital divides. Next, the implementation of public policies is suggested. Finally we conclude the chapter.

ICT DIFFUSION AND DIVISION IN THE GLOBAL ECONOMY

Since the late 1990s, the Internet has come to be widely used, particularly in the industrialized societies. The Internet has provided not only useful services of communication among individuals, but also new business opportunities for many private companies. For instance, a worker who gains access to a personal computer (PC) and the Internet will find it easy to secure a higher paying job. Moreover, many companies can get opportunities to tackle new businesses in ICT fields.

Table 1 charts the current aspects of ICT diffusion in leading ICT countries. With regard to the number of computers per 100 persons, the United States is the highest, followed by Korea. However, with regard to the diffusion rate of the Internet, Korea ranks first, with the United States being second. With regard to the number of contracts for broadband Internet, the country with the highest diffusion is the United States with Japan being second. Diffusions of the PC, the Internet, and broadband Internet vary even among the leading countries.

Furthermore, Table 2 indicates the regional differences in the diffusion of the Internet and PC; it displays the Internet usage indicator by the International Telecommunication Union (ITU).

This table indicates the disparity in Internet usage among country groups categorized according to income level. People in low-income countries do not have easy access to PCs, the Internet, and/or broadband. This condition creates a divide between people in the high- and low-income groups with regard to their current income and their potential to earn higher incomes in the future.

For example, the highest average number of hosts for Internet networks is in North America; this is followed by the industrial economies in Asia, including Malaysia, Korea, Hong Kong, Japan, Singapore, and Taiwan. The number of network hosts is an important indicator because the data indicate the degree of ICT as well as the degree of dependence on hosts in the home country that is needed in order to connect to the Internet. In the case of the average number of PC users, North America ranks the highest, followed by the industrial countries in Asia and subsequently by the EU (European Union) countries. The average numbers of Internet hosts and users, and PC users in developing Asian and African countries are very low; this is in conjunction with the fact that the per capita GDP of these countries is also low.

These data imply that the digital divide exists in the global society and it is caused by the disparity in income. Since the infrastructure of the Internet—that is, the hosts and the network of the Internet—and personal computers place an enormous expense on individuals, companies, and even governments, low-income countries are unable to afford the costs and shoulder the burden. For this reason, the diffusion of the Internet in low-income countries is low, which may make it difficult to boost the growth of these economies.

If the digital divide exists, it may create an income divide on a global scale.

Table 3 shows the aspects of the digital divide in Japan, which has local differences with regard to the use and the diffusion of the Internet. Although Japan is one of the leading countries in ICT fields, the disparity of the Internet environment exists in this country. From this example, we infer similar conditions in other countries. In developing countries, these conditions may be cause for more serious concern.

In order to clearly highlight the digital divide, we estimated a cross-country relationship between the diffusion of PC use and per capita income in 2004. The sample consists of 160 countries and the method used is the ordinary least squares method. The estimated equation is as follows:

$$\log(PC_i) = c_1 + \alpha_1 \log(GDP2004_i) + u_1, \quad (1)$$

where i country's PC_i denotes PC users per 100 inhabitants, $GDP2004_i$ is i country's per capita GDP in 2004, and u_1 is the error term. Furthermore, we estimated the cross-country relationship between the diffusion of the use of the Internet and per capita GDP. The estimated equation is as follows:

$$\log(Internet_i) = c_2 + \alpha_2 \log(GDP2004_i) + u_2, \quad (2)$$

where $Internet_i$ denotes i country's Internet users per 100 inhabitants and u_2 stands for the error term. Tables 4-1 and 4-2 display the results. The per capita GDP significantly affects the use of the PC and the Internet in 160 countries. Therefore,

unit: percentage

the higher the income, the greater the diffusion of the PC and the Internet. Such results show that the diffusion of ICT implies the burden of a large amount of expense because people should pay more in order to catch up in using the new digital devices. In addition, we chart the graphs of the relationship between per capita GDP and the diffusion of the PC, as well as between per capita

GDP and the diffusion of the Internet. From these figures, we can easily infer that these diffusions are positively correlated with per capita GDP.

However, if the diffusion divide is transitory, the so-called digital divide poses no problem. For instance, advanced technologies such as ICT have a tendency to be more developed in a few industrial countries. Thereafter, other developed

Table 4-1. Estimation results of diffusion of the PC

and developing countries obtain those advanced technologies, which subsequently results in high levels of growth in those countries, similar to the leading industrial countries. This is known as the flying-geese pattern of development. If the pattern is applied at the current stage, the digital divide will be merely a transitory problem. Therefore, there is no need for governments or industrial organizations to reach a solution to the divide problem.

Until now, the trend was unclear; however, we estimated the relationship between the diffusion of the PC and the Internet and income disparity from the average value. The estimated equations are as follows:

$$\log(std_GDP2004_i) = c_3 + \alpha_3 \log(PC_i) + u_3 \tag{3}$$

$$\log(std_GDP2004_i) = c_4 + \alpha_4 \log(Internet_i) + u_4 \tag{4}$$

where $std_GDP2004_i$ denotes i country's deviation of GDP from the average of 160 countries in 2004. Equation (3) suggests that the diffusion of the PC may cause deviation of GDP from the global average value, and equation (4) suggests that the diffusion of the Internet may bring about the deviation. Therefore, coefficients c_3 and c_4 are supposed to be positive.

Table 5-1 presents an estimation result of equation (3). According to Table 5-1, the diffusion of the PC may contribute to the disparity of GDP in the global society. Table 5-2 also presents an estimation result of equation (4). According to Table 5-2, the diffusion of the Internet may also lead to gaps in GDP.

Since we can easily anticipate the progress of PC and Internet uses, the gaps of GDP may also expand further. However, simple market mechanisms, which remain unaccounted for in the global economy, are not the panacea for the digital divide. Consequently, should the divide be narrowed regardless of the efforts involved?

If not, should it be permitted to exist even if it may be serious? Our response is that the divide should be resolved because GDP gaps by the divide may cause a decrease in the aggregate demands in the global economy. Because ICT has the distinct feature of progressing rapidly, some persons, companies, or countries will be unable to keep pace with the progress pertaining to the usage and the developments. As a result, the rapid progress may bring about an impoverishment in the case of a majority of people or countries. If this scenario actualizes, the global economy will shrink. The next section illustrates this scenario more clearly using a simple static model.

THEORETICAL MODEL

In this section, we theoretically examine the effects of ICT diffusion and divisions on economic development as this chapter represents effects of economic activity by evolution of technology because there could be a positive relationship between technological developments and economic progress. For the purpose of the investigation, we construct a simple static economic model.

Our model is composed of the demand and supply sides. The demand side consists of two strata: well-trained persons who easily access ICT, and less-trained persons who rarely access ICT.

$$m + n = 1 \quad (5)$$

In equation (5), m denotes the population of less-trained persons and n that of well-trained persons. The total population is assumed to be fixed as one. The population of well-trained persons is assumed to be a decreasing function of technology. The development of technology leads users to obtain advanced training for new digital devices and computer applications, and higher information literacy. Consequently, in accordance with the development of technology, well-trained persons n are assumed to decrease:

$$n = \theta(T), \quad (6)$$

$$\theta'_T < 0, \theta''_{TT} < 0$$

Equation 11.

$$\frac{\partial D}{\partial T} = n(\alpha_n - \alpha_m) + \alpha_m - \{(1-n)l_m + nl_n\}T + \theta'_T \{(\alpha_n - \alpha_m)T - (l_n - l_m)\} \equiv D_T \geq 0$$

Equation 12.

$$\frac{\partial^2 D}{\partial T^2} = -\{(1-n)l_m + nl_n\} + \theta'_T(\alpha_n - \alpha_m) + \theta''_{TT} \{(\alpha_n - \alpha_m)T - (l_n - l_m)\} \equiv D_{TT} \sim 0$$

where T is the accumulation of technology. Aggregate demand D is the sum of the incomes of less-trained and well-trained persons.

$$D = mY_m + nY_n \quad (7)$$

In equation (7), Y_m denotes the income of less-trained persons and Y_n that of well-trained persons. Furthermore, both incomes depend on the accumulation of technology as follows:

$$Y_m = \alpha_m T - l_m T^2 \quad (8)$$

and

$$Y_n = \alpha_n T - l_n T^2. \quad (9)$$

Equation (8) represents the income function of less-trained persons, which is a positive coefficient function α_m of T and a negative square function with coefficient l_m . The former term represents the contribution of T to income. In other words, α_m is the income multiplier of technology. The latter term denotes the marginal cost of training or education, which we assume to be the square function of T .

Equation (9) is the income function of well-trained persons, whose components are similar to those in equation (8), with the exception of the coefficient. In addition, we assume the magnitude of coefficient α_n, α_m as follows:

$$\alpha_n > \alpha_m. \quad (10)$$

Equation (10) implies that the contribution of T to well-trained persons' income is higher than that of the less-trained persons. Since a well-trained person can achieve a higher income, he or she has an incentive to obtain training for ICT by paying its marginal cost.

We do not assume the magnitude of marginal cost,

$$l_n - l_m \sim 0.$$

Here, we show effects of technology on aggregate demand as follows, see equations (11) and (12).

Next, we present the supply side of our model. A representative firm infinitely maximizes its profit by investment, subject to technology innovation dynamics; that is:

$$\text{Max } \pi \quad (13)$$

$$\text{s.t. } \pi = D - \frac{cI^2}{2} \quad (14)$$

Here, π denotes the profit function in equation (13). The profit function is defined in equation (14), in which the second term represents the adjustment function of investment, which is supposed to be a quadratic form function. In addition, we assume the innovation function caused by investments I as follows:

$$T = \beta I. \quad (15)$$

Equation (15) indicates that increases of private investments induce developments in information and communication technology; therefore, it is assumed that $\beta > 0$.

From equations (13), (14), and (15), we can easily obtain the FOC as follows:

$$\frac{\partial \pi}{\partial I} = D_T \beta - cI = 0. \quad (16)$$

We can rewrite equation (16) as the following:

$$I^* = \frac{\beta}{c} D_T, \quad (17)$$

where the asterisk denotes the equilibrium value. By using equation (17), we can obtain equilibrium technology and equilibrium aggregate demand as follows:

$$T^* = \frac{\beta^2}{c} D_T \quad (18)$$

and

$$D^* = \left[m \left(\alpha_m - \frac{l_m \beta^2}{c} D_T \right) + n \left(\alpha_n - \frac{l_n \beta^2}{c} D_T \right) \right] \frac{\beta^2}{c} D_T \quad (19)$$

From the above equations, the equilibrium investments, equilibrium technology, and equilibrium aggregate demand depend on the marginal demand of change of technology. If D_T is zero, due to an enlargement of the disparity between less-trained and well-trained persons, the development of technology is zero; therefore, the aggregate demand is also zero.

The implications of our economic model are that the regional digital divide causes decreases of aggregate demands in the domestic dimension, and the international digital divide causes decreases of global demands in the international dimension. If ICT develops further, it is possible to diminish local and global demands, which in turn would bring about stagnancy to ICT innovation itself.

IMPLICATIONS FOR GLOBAL ECONOMY AND DOMESTIC SOCIAL DYNAMICS

In the previous sections, we mentioned that the digital divide exists in the global economy, and it may induce a blockage in the development of technologies. Consequently, in this chapter, we

argue for a policy analysis that would address this digital divide. From the perspective of the market economy, the digital divide is resolved through market mechanisms. That is to say, the market forces should drive the deployment of ICT. A competitive force will encourage technological innovation, and the prices of information and communication will decrease for many people (Moschella & Atkinson, 1998). Therefore, public policy should be used to promote competition in the fields of Internet and communication, for example, in order to promote universal access services and to liberalize the regulations of the Internet and communications. Active competition causes redistribution between digitally divided people.

However, ICT is a GPT whose versatility is considerably high among many industries. This technology has externality in economies. From the perspective of economic theory, the market mechanism does not function effectively to bring about sufficient redistribution. Furthermore, the externality of ICT has two aspects, namely, economic developments and communication measures. The former indicates that ICT contributes directly to economic development by the creation of new businesses and a decrease of transaction costs. The latter indicates that ICT promotes individual and corporate communications at less cost to promote economic growth. With regard to the former aspect, ICT is the infrastructure for development. On the other hand, with regard to the latter aspect, ICT is a social capital for communication.

From the perspective of ICT as infrastructure for development, public policies promote ICT by, for example, supporting the consumption of information and communication services, and/or investing in ICT infrastructure such as LAN (local area network) and public access points. From this perspective, public policies are needed to promote the growth of the entire spectrum of ICT networks, equipment, and infrastructure.

On the other hand, the perspective of ICT as communication measures and social capital is related to the demand side of the economy. From this perspective, public policies must provide the networks in order to activate communication in the community.³ These promote the consumption of digital devices such as mobile phones and PCs, and create investments in digital equipment for offices and factories, such as LANs, mobile PCs, and online systems of orders via the Internet. ICT as social capital, therefore, contributes to economic growth through the enlargement of aggregate demands.

Although the supply side is an important factor for growth in the long run, the demand side is a crucial factor for economic stability in the short run. Both sides interact in each time definitively. Public policies should promote the diffusion of communication methods of ICT in order to provide easy access to them by many users, regardless of their income and/or regional differences. Thus, not only will each government cope with digital divides as a local problem, but international cooperation by the governments and international organizations will also tackle digital divides as a global problem. All governments can support the public provision of information and communication infrastructures by their respective public budgets. While cooperating internationally, developed countries should act as leaders to finance the ICT infrastructures in developing countries in order to bridge the gap in the uses of digital devices. These policies may improve digital circumstances not only in developing countries, but also in developed countries through a global increase in the demand for digital devices.⁴

CONCLUSION

In this chapter, we stated that a digital divide could cause an income divide within a country and between countries. The more the uses of the Internet diffuse, the more serious concerns the divide may

introduce. From a macroeconomic point of view, the increase in the digital divide diminishes ICT investments and delays the innovation of ICT. As a result, we propose that the public policies of each government provide the devices of ICT as social capital and infrastructure. On the global stage, the digital divide exists between developed and developing countries. Therefore, international provision of the digital devices must be achieved through a cooperative effort between developed countries and international organizations.

ENDNOTES

¹ This theory was mainly proposed by Romer (1986).

² The divide includes two phases: an international divide between developed and developing countries, and a domestic phase where the divide exists between highly diffused areas and lesser ones. As we discuss, our investigation sheds light on these phases through the simple economic model.

³ Collier (1998) conducted an empirical study on telephone networks that would activate the requisite social interaction in the community.

⁴ This was pointed out in our model.

Chapter 1.8

Information Dynamics in Developing Countries

Hakikur Rahman

Sustainable Development Networking Programme (SDNP), Bangladesh

ABSTRACT

Revolutionary advancement in information and communication technology (ICT) with strengthening of economic and social aspects is transforming the global communities. A new kind of dynamism—the information dynamics—is emerging where communities are not restricted within boundaries and becoming competent with information, knowledge, networking, and versatility on a global basis. A new society is emerging with pervasive information capabilities, creativity other than the conventional learning system, substantially different from an industrial society; more competitive, better able to address individual needs, and steady to the ever-changing environment. The information revolution creates both the challenge and the means for the developing world to adjust to the newly developed strategic issues and action plans of the New World by accommodating the needful infrastructure of telecommunications and information systems. The information revolution has also opened up opportunities to tackle the problems of poverty,

inequality, illiteracy, and environmental degradation.

INTRODUCTION

Information is the lifeblood of every economy. In more traditional economies, information may be less codified, more often conveyed in personal interaction, but it is vital nonetheless. The ways people get information, and the incentives they have to gather and provide it, are affected by the way society is organized: legal rules and social conventions, institutions and governments, all determine how much information people have and the quality (that is, the accuracy and completeness) of that information (World Bank, 1998).

Information technology is changing throughout the world. Information and communication technologies (ICTs) are generating a new industrial revolution already as significant and far-reaching as those of the past century. This revolution is based on information dynamics, and within itself the human knowledge content.

Recent years have seen rapid progress in science and technology related to the generation, processing, transmission, accumulation, storage, and utilization of information—a field known collectively as information science and technology (Council for Science & Technology, 1999). Advancement in ICT offers unprecedented promise for social and economic development on a global perspective. As the primary means of communication and performance in the networked society, ICT has become a fundamental instrument for both the developed and developing countries.

ICT can contribute to fostering empowerment and participation and making government processes more efficient and transparent by encouraging communication and information sharing among people and organizations, and within government. ICT connects individuals and local communities with information and resources beyond their geographic boundaries, encouraging information dissemination, information exchange, and communication (DOI, 2001).

Wolfensohn (1998) stated in his forwarding for the World Bank WRD1998 report, that the information revolution makes understanding knowledge and development more urgent than ever before. New communications technologies and plummeting computing costs are shrinking distance and eroding borders and time. The remotest village has the possibility of tapping a global store of knowledge beyond the dreams of anyone living a century ago, and more quickly and cheaply than anyone imagined possible only a few decades ago.

Information infrastructure comprised of the cross-country telecommunications network, the user-friendly computing tools, and easy-access information warehouses. Information backbone has the characteristics of easier transportation, manipulation, storage, and dissemination by creating the “knowledge tank” an essential element for the management of the new economy. And because the new economic development is about knowledge networking, the information revolu-

tion holds inestimable promise for downtrodden population in the developing countries.

BACKGROUND

Information can be seen as any communication or representation of knowledge, such as facts, data, or opinions in any medium or form, including textual, numerical, graphic, cartographic, narrative, or audiovisual forms. It is the knowledge acquired through study or experience or instruction. Information is data and facts that have been organized and communicated in a coherent and meaningful manner (Google definition search). Dynamics is that part of the field of mechanics that studies objects in motion, and here it is taken as a representation of movement of entities (human, society, or community). By developing countries, it meant a country that is poor by world standards in terms of real GDP per capita. They are the countries with low- and medium-income in which most of the population have a lower standard of living with access to fewer goods and services.

Then information dynamics can be treated as an integrated knowledge movement of the society or community. Depending on the penetration of various applications on information and communication technologies, information dynamics in low-income countries have potential impact on the community development processes.

Information technology revolution should not be treated as innovation and just advancement, but as “general purpose technology” (Bresnahan & Trajtenberg, 1995) to adopt and improve the livelihood of the general people. This general-purpose technology has surpassed the rapidity and mobilization in many perspectives, and substantially improved the quality of life in the marginal community by simply multiplying the state of applications in everyday usage.

The striving forces behind the so-called information revolution are the sharp decline in the

prices of information processing, the convergence in communication and computing technologies, and the rapid growth in network computing. Communication networks and interactive multimedia applications are providing the foundation for the transformation of existing social and economic relations into an “information society” (OECD, 1997). It is, indeed, widely believed that modern information technology will change the world, but how can such a change be measured and its impacts assessed (Pohjola, 1998)? A question that needs to be addressed properly for successful implementation of the processes before launching it.

Information technology presents the attractive possibility of bypassing older technologies (“leapfrogging”). For example, countries with old-fashioned mechanical telephone systems can skip the analog electronic era and go straight to advanced digital technologies, and that certainly is happening. Leapfrogging is also made possible in a more radical developmental sense (IMF, 2001).

An information system provides a societal capability based on the use of information that encompasses its full context of people, institutions, policies, processes, incentives, data, information technology, and infrastructure. A strategic information system provides a fundamental capability of such importance that it can enhance the scope and efficiency of an entire sector and economy (Talero & Gandette, 1996).

Radical advancement in ICT information technology reinforced economic and social changes by transforming community and society. From this advancement emerges a new kind of economy, the information economy, where information is the critical essence. Traditional ways of doing business has been drastically modified and sometimes, the old ways have been replaced by new means and methods. Technological progress now enables us to process, store, retrieve, and communicate information in whatever form it may take, unconstrained by distance, time, and volume. This revolution adds huge new capacities

to human intelligence and constitutes a resource, which changes the way we work together and the way we live together (Bangemann et al., 1994).

Developing countries and especially the least developed countries (LDCs), have yet to attain measurable socio-economic benefits out of ICT. Development of this sector has often been hindered by a combination of outdated infrastructure, relatively high telecommunication costs, inappropriate technology policies, absence of skilled professionals, and the intricate culture of information interchange. With these views and practices, many of these nations could not able to be the forerunner in the global market and compete with their more fortunate neighbors (Rahman, 2004).

In developing countries, access to information infrastructure always remains inadequate, and progress on telecommunications policy reforms are lagging behind. Yet there is an opportunity for leapfrogging the new technology can provide better, cheaper links to the grass root level stakeholders, while competing global operators can provide low-cost long distance communications. Adopting new technologies, developing countries can deploy telecommunications for lower costs per capita than the industrial world and rapidify poverty alleviation processes.

To create appropriate information dynamics in developing countries, the following issues need to be resolved with greater context; issues of accessibility, intellectual property protection, fair competition, content regulation, and cultural preservation. However, due to many unintended factors, the access to the global information infrastructure by developing countries remains inadequate and dependent on major telecommunications policy reforms yet to be implemented.

KEY FACTORS TO UPHOLD THE INFORMATION DYNAMICS: ISSUES AND PROBLEMS

Information technology has become a potent force in transforming social, economic, and political life globally. There is little chance for countries or regions to develop without their incorporation into the information age. More and more, development strategies see the need for developing countries to embrace information technology both as a way to avoid further economic and social mobilization as well as to offer opportunities for both growth and diversification of their economies (Hafkin & Taggart, 2001).

Communication is no longer focusing on a single issue, but on a range of livelihoods issues and using several channels. Communication theory has not quite come to grips yet with the complexities of participatory communication. What is certain is that implies a change in roles for the main stakeholders, some of whom may be more willing to change than in roles for the main stakeholders, some of whom may be more willing to change than others (Lowe, 2001).

Poor men and women living in urban informal settlements do need knowledge and information to cope with risks and improve their livelihoods, but the urban poor obtain information hard to access (Schilderman, 2002a). Science and technology development is the fundamental driving force in pushing forward the entire process of social evolution while the creation of more advanced tools is the kernel engine of the development (Zhong, 2003).

Therefore, to harness information and communication technology for its mission of poverty alleviation and sustainable economic development, the following objectives to be set at the national level:

- Easy access to communication and information services through accelerated deployment of national information infrastructure

and integration into international communication and information backbone.

- Systemic improvements in the functioning and competitiveness of key sectors of the national economy through strategic policies and implementation plans.
- New ways to use ICT to assist in solving the most prevailing problems of human and economic development—education, health, poverty alleviation, rural development, and reinforced environmental awareness.
- Increased motivation at the national level for economic development through inclusion of information contexts in each level of administration hierarchy.

EVOLVING PARAMETERS: SOLUTIONS AND RECOMMENDATIONS

Information technology can offer significant opportunities in developing countries for virtually all societies, including marginalized communities in rural areas. In considering diversified entrepreneurial ventures associated with information technology, the following parameters need in-depth study to ensure equitable participation of all societies in the information age.

- **Concept of society needs to be re-thinked:** Societal control based on closely-held information is no longer possible when information is ubiquitous and inexpensive. Uncontrolled and easy flows of information increase create opportunities for social manipulation.
- **Environmental awareness to be raised:** Due to faster information dissemination and knowledge development, the preservation of the environment has become a prime concern of a well-informed public society. Economic growth cannot be pursued at the expense of the environment, lest such growth become

unsustainable and threaten the environment of the entire globe, though environment has significantly different connotations in developed and developing countries.

- **Definition of developing countries needs to be adjusted:** With the rapid advancement of the developed world, and unbalanced participation of the developing world in the global economy, developing world is in the competitiveness of their goods and services. They are threatened with a new form of information poverty that could further extend the “digital divide” and widen the gap in economic status and competitive issues. Necessary fine-tuning is essential, though extremely complex, for total diffusion of information technology, which may result in social fragmentation.
- **Information revolution:** In real sense, to keep up with the developed world, the term “information revolution” needs to be retorted. This will assist to create new paradigm to encounter problems of poverty, inequality, and environmental degradation with the potential to achieve unprecedented gains in social and human development.
- **Developing world need rapid transformation:** Information and communication technology in developing countries need transformation to overcome the dynamic challenges and create unprecedented possibilities for sustainable economic development.
- **Strategies for information dynamics to be recapitulated:** Strategic information systems for developing countries should primarily include sector-wise information systems for education, health, governance, and communication at the first phase. E-commerce, knowledge networks, e-business, environmental awareness, disaster prevention and management, and national statistical databank may be treated as the next phase strategic systems.
- **Sectoral information networks need to be developed:** Social networks based on computer-based communications are needed to improvise to connect institutions working in diversified sectors, like, agriculture, education, health, banking, industry, and others. Interconnected networks offer multi-dimensional opportunities in technical cooperation, research, coordination, information, and resource sharing.
- **Social and technical aspects are needed to be simplified:** Design, development, and deployment of information systems and telecommunications capabilities are socially and technically complicated, even in the face of technological advancement and sometime not completely understandable to developing communities. Countries need to depend on the substantial resources, often from abroad, to accomplish this task. They need to establish means and management schemes to facilitate adoption and effective utilization of new systems through adaptive methodologies.
- **State patronization:** Government action is a pre-requisite, but epoch making adjustments are required at the state level in the developing countries to participate in the newly emerged global economy. Governments should establish broad partnerships with the private and corporate sectors, local communities, small and medium enterprises, non-governmental agencies, international and development partners. Government intervention to harness information for development is necessary on several fronts: as policy makers, as major users of information technology, and as compensating influences against market failures. Also, governments must supervise and coordinate education—the key to human and economic development (Talero & Gandette, 1996).
- **Telecommunications reformation is a**

- must:** Reformation in the telecommunications sector are a primary requisite to increase the efficiency and availability of services. Policies and regulations are needed to create the conditions for faster private sector entry, for national integration into global information infrastructure, and for efficient use of the existent infrastructure.
- **ICT policies need to be revisited:** National information strategies and action plans need to be deployed by identifying the parameters leading to based an information-based economy. The policy, institutional, legal, and regulatory changes need to be utilized to create an information-friendly environment. Performance, competitiveness, and governance of all sectors of the economy can be improved through de-regulated information policies and systems.
 - **Priorities needed to be identified:** Information systems with important and catalytic capacity to national economic activity should be considered strategic and put forward as part of national information infrastructure. Sector-wise information systems for education, health, financial management, communication, and transportation fall in this category. Similarly, some other generic value-added information facilities, like e-commerce, environmental awareness, disaster prevention, and poverty alleviation can be added to the priority categories. Each country should define its own set of guideline as part of the national information strategy.

Nation-wide networks can also accommodate:

- Network of the financial institutions, and the information industries
- Cross-country studies on ICTs and e-readiness

- Accumulation and dissemination of best practices
- Establishment of a national databank

Similarly, strategies need to be taken to mobilize financial sector for development:

- Of national information infrastructure projects
- In project financing guarantees
- With technical cooperation

To implement these strategies in actions, nations need to form information dynamics as depicted in Figure 1. From this figure, it is evident that IT revolution is the core of social uplift through proper resource mobilization. Similarly, Figure 2 illustrates how information and content creates dynamics in the society for its uplift and skill development, creating demand at the local level. The entire information process can create a global knowledge network in a three tires context, as shown in Figure 3. Fed with balanced content in repositories and connected through information links community knowledge networks can form a knowledge pyramid.

Derived from these perspectives, the concept of creating an information dynamics at the national level is shown in Figure 4. Proper policy initiation, partnership, and recognition of key players would lead to the development and implementation of information dynamics by bridging the digital divide inside a country. This information dynamics can grow top-down-top fashion according to the information hierarchy as depicted in Figure 5. By pushing forward a balanced information policy to be implemented in modular form at strategic locations, and utilizing the existing infrastructure, in addition to the newly built one can create demands at the local level. Thorough understanding of local level demand and accommodation of content will enhance incremental expansion of the dynamics at the national level. Eventually, these

Figure 1. Information dynamics in social uplift

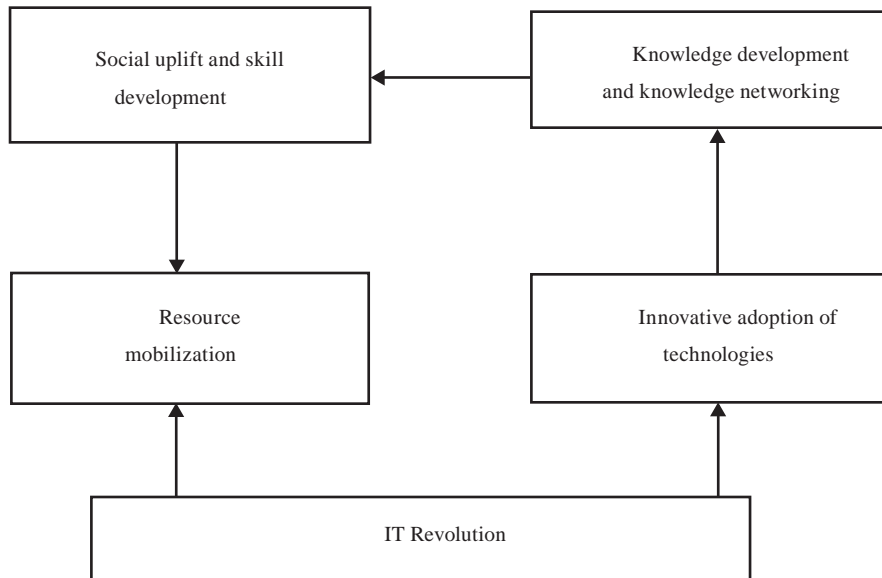

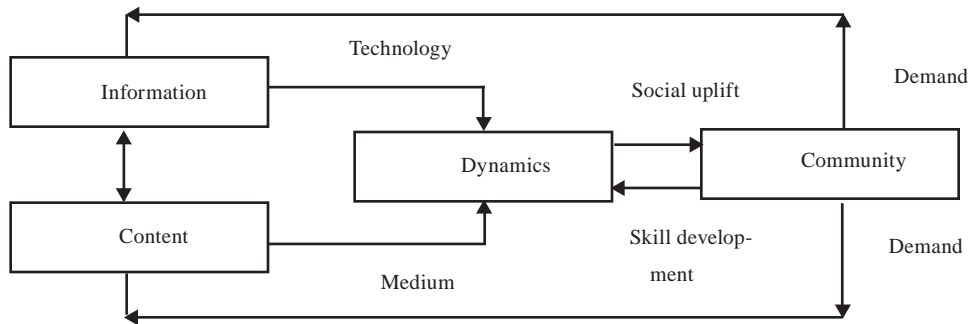

Figure 2. Information dynamics creates demand at the local level

national networks can be interlinked to form a global information backbone.

GLOBAL CHALLENGES AND FUTURE DIMENSIONS

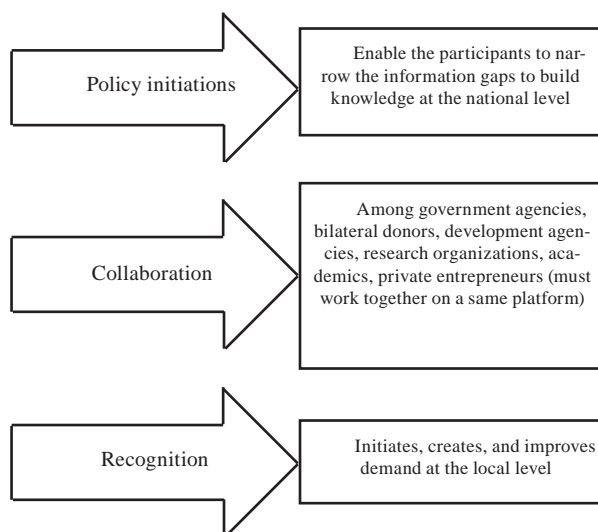

The challenge of communication technologies is not only to transmit pure information but, above all, to enable a real communication between people and communities. The transmission of information is certainly important, but it is far from sufficient. Real, effective, interpersonal

communication is, first of all, based upon the exchange of different kinds of messages, postures, gestures, and intonations that physical co-presence can transmit. It is also important to focus on the fact that communication follows different rhythms of interaction (Casalegno & McWilliam, 2004). To implement a successful ICT application for the development of a society, the ideologies of ICTs in social change, empirical research studies on ICTs and organizational change, changes in everyday life, or larger scale societal changes must be understood. Furthermore, relationships between conceptions of ICTs (tools, media, envi-

Figure 3. Global knowledge pyramid

Figure 4. Concept of information dynamics at the national level

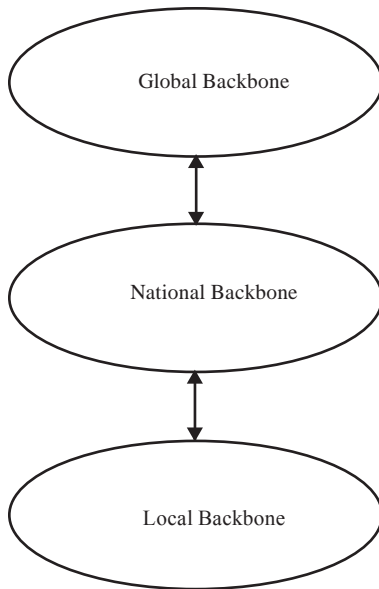

ronments, socio-technical networks), theories of social change, workable evidence, and research methods need to be examined in depth (Kling, 2001). The future of information dynamics in developing countries needs to understand principles of information infrastructure, technologies, architecture, and scaleable use of the information (MIT Report, 1995-96).

The development of new media and the progressive spreading of the emerging and rapidly

growing phenomenon of remote collaboration pave the way for interesting research in several fields, from teaching to communication, from design to architecture, from ergonomics to studying interfaces. Remote collaborative environments represent a very good opportunity to design communication spaces that allow for social interaction between people and between distant communities, supporting different forms of communication, work, and creativity in various domains. Further-

Figure 5. Information hierarchy backbone

more, technological progress makes interactive media progressively more efficient, easier to use and destined to a wider public (Casalegno et al., 2004), through participatory communication.

Participatory communication not only helps to empower communities, it also does allow them to influence development. Impact assessment should therefore also consider whether two-way communication has been established, and whether local knowledge and demands have been taken into account, for instance, in policies and programmes targeted at the urban poor (Schilderman, 2002b). Therefore, understanding of principles of information technologies, pursuing these technologies to create acceptable information architecture, and using these infrastructures on highly scaleable state (MIT Report, 1995-96) at marginal to organizational to national to global level are important.

Nowadays, concept of sustainable development has arisen in the emerging societies. It is the process of achieving a standard of living and a quality of life with a degree of dignity and a measure

of control over their lives, including respect for the environment and the natural resources. This process demands investment, in infrastructure, in human capital, and in productive capacity. In this context, achieving the Millennium Development Goals remains another challenge in reducing poverty and improving livelihoods that world leaders have agreed on at the Millennium Summit in 2000 (<http://www.undp.org/mdg/>).

CONCLUSION

The tremendous opportunities offered by the emerging information technology often come in packages with remarkably high payoff potential and at the same time impart high risk. However, these sort of projects should not divert resources from efforts to address the basic needs of common communities and should be driven to be well-established, low-risk, and easily adaptable.

Poor countries and poor people differ from rich ones not only because they have less capital but because they have less knowledge. Knowledge is often costly to create, and that is why much of it is created in industrial countries. But developing countries can acquire knowledge overseas as well as create their own at home (World Bank, 1998).

The urban poor are often deprived by a lack of knowledge and information. The public sector often discriminates against the poor when they seek access to information, or is simply inefficient. To overcome these problems, development agencies should seek to improve their communication with the poor, reduce exclusion, support communities in building their knowledge and information assets, improve the attitudes and performance of information suppliers and invest in sustainable ICTs that are of use to the poor (ITDG, 2002).

As a starter, community information centers are a good fit. This multisectoral concept can help common citizens, non-governmental organizations, and businesses in poor rural and urban

areas with economical, easy, and ready access to needed information. The centers could be a powerful engine of rural development and a preferred instrument in the fight against poverty. They could be the hub, at the community level, through which a large number of information services can be dispensed--telephone and fax, local bulletins, document searches on demand, video libraries for entertainment, and knowledge development, health and nutrition training, government utility services, market prices, self-paced learning, and more. The centers would be multisectoral facilities and eventually self-sustaining through fees and contracts (VITA, 1995).

At the social context, a new society is emerging with pervasive information capabilities, thus making it substantially different from an industrial society. It is more competitive, able to address individual needs, and environment friendly, dictating a major agenda of structural adjustment. The adjustment, therefore, is needed within the information arena to tackle uncontrolled information flows, global competition, trade unbalance, and investment opportunities.

Chapter 1.9

Role of ICT in Development Process: A Review of Issues and Prospects in South Asia

Dilip Dutta

University of Sydney, Australia

ABSTRACT

Empirical studies that focus on impact of ICT for development usually make a distinction between ICT as a production sector and ICT as an enabler of socioeconomic development. Although the developed countries are reaping very high benefits from the ICT, its diffusion in developing countries has been limited. It is often argued that for developing countries benefits from ICTs are more likely to accrue from consumption rather than production. In the context of the selected five South Asian countries, the ICT penetration is relatively very low, although there have been some success stories in software production sector and IT-enabled service sector in the region. Generally speaking, the author argues that the developing countries need to integrate ICT policies more closely into economic strategies, which can be done by strengthening the links between

development and technology agencies via the organizational structure of policy-making bodies.

INTRODUCTION

Capacity to use conventional technologies varies from country to country and often tends to be location or industry specific. This limitation has been more prominent in developing countries due to a number of reasons. First, imported technologies may not always be appropriate to their endowments of labor or technical skills, or to their scales of operation. Second, limited scope for diffusion of knowledge and imperfect market competition restrict assimilation of these technologies in these countries. Third, inability to upgrade the technologies they utilize into new technologies to suit in new conditions. Finally, many other circumstantial situations play important role in hindering the transition that may

or may not be visible. Technological capabilities (technical, managerial, and institutional) in the industrial sector, therefore, become more often enterprise specific accumulated skills with a tendency for their technical efficiency to lag behind world technological frontiers. As a result, many developing countries may have stayed at, what Lall (1993, p. 20) calls, “low value added end of the industrial spectrum, falling behind world technological frontiers as others forge ahead.”

Over the past two decades or so, the application of new technologies especially, information and communication technology (ICT),¹ has been credited for its positive role in economic growth and development. Although the developed countries are reaping very high benefits from the ICT, its diffusion in developing countries is still very limited. The role of ICT as a means for accelerating development in underdeveloped and developing societies has been lately questioned especially in terms of their social capacity to process and use the growing volume of information for the society as a whole. While assessing the potential development impacts of ICT many pertinent issues are often raised that include (Morales-Gomez & Melesse, 1998, p. 2):

- who benefits and who loses from the introduction of these technologies;
- how can ICT be made useful and meaningful to the developing countries’ poor majority who are struggling to meet their basic needs;
- what are the social and cultural opportunities and risks they present;
- how can developing countries meaningfully adopt these technologies while lessening their undesirable social and cultural consequences?

ICT AND ECONOMIC GLOBALIZATION: EMERGING TRENDS

The new technologies such as information and communication technology (ICT), biotechnology, nanotechnology, and so forth, have been contributing to the rapid transformation particularly of the developed societies. The ICT is, however, singled out as the most pervasive technical innovation of the post Second World War era in the sense that it gives rise to a wide range of new products and services, its applications affect almost all sectors of an economy, it generates strong industrial interest as a means for profitability and competitive advantage, and it gains widespread social acceptance (Avgerou, 1998). ICT is classified as a “general purpose technology” and, therefore, it is a form of drastic technological innovation that can be applied to a wide range of sectors with dramatic change in their existing modes of operations (Helpman, 1998). As Prakash (2002) further elaborates, ICT has wide applicability in various manufacturing and services sectors. It has strong spread effects and extensive linkages with the rest of the economy. However, its potential forward linkages extend to custom made configuration while its backward linkages extend to material sciences.

ICT includes a heterogeneous series of products and services including semiconductors, voice telephony technologies, and technologies supporting high speed data and audio visual systems, as well as computers and packaged and customized software (Mansell, 1999). Starting from the birth of the Internet in the late 1960s, advents of e-mail in the late 1970s, domain name system in the 1980s, the World Wide Web in the 1990s, and repository/portal concepts in the 2000s are the popular applications of ICT, which have emerged as powerful tools for business and development. Afterwards, ICT has integrated computing, communications, and graphics through digitalization. It has thrived on Web sites with the use of broad-

Role of ICT in Development Process

band optical-fiber lines and made headway into wireless mode. It is becoming more and more personalized with greater use of personal digital aids (PDAs) (Prakash, 2002).

Although there are differences in the definitions of ICT, there is general consensus that the main ICT components (already in existence and expected to be added in the near future) such as sensors and detectors, control and display systems, and so forth, are all interconnected with computers and knowledge-based systems, and do function interdependently and, thereby, form an intelligent communication network. This network becomes the main force behind a national information infrastructure and is linked to its global counterpart. Along with globalizing forces of the world economy, today's progress in ICT has been creating a new paradigm of network age with clear advantage over the industrial age. The implication of this historic shift, as has been summarized in *Human Development Report* (2001), is as follows:

Structures of production and other activities have been reorganized into networks that span the world. In the industrial age—with its high costs of information access, communications and transportation—businesses and organizations were vertically integrated. In the network age, with the costs of communications and information down to almost zero, horizontal networks make sense. Production is increasingly organized among separate players—subcontractors, suppliers, laboratories, management consultants, education and research institutes, marketing research firms, distributors. Their complex interactions, with each playing a niche role, create the value chains that drive the technology-based global economy. (p. 31)

Since the early 1980s, there have been two major trends visible in the globalizing world:

- A strong interaction between market & technology related factors.

- Shifting of the determining factors of competitiveness towards social and economic institutional characteristics of a country.

Technology related factors, such as componentization of production, facilitated by advancement in both manufacturing technologies and ICT have led to lowering costs and making geographical distances irrelevant (ESCAP, 1999). Market related factors such as increased competition for resources in the production of the same products, greater engagement in international trade, enhanced effort to attract foreign direct investments, etc., have been greatly influenced by technological as well as information-related innovations. Along this process, the multi-national corporations (MNCs) in both production and service sectors have been exerting competitive pressures on domestic firms and, thereby, leading to some pattern of technological specialization in their favor. For instance, the multi-national retail giants such as Wal-Mart, Metro, Target, and Tesco have recently issued directives to the Indian suppliers to replace bar codes with radio frequency identification (RFID) technology. To the retail giants, RFID is fast emerging as the best option for keeping costs low. Embedded in plastic product tags, RFID chips can track goods, signal the need for restocking, and thus boost supply efficiency. This has caused domestic companies' sleepless nights simply because the cost of RFID labels will squeeze their profit margins. In fact, the cost of one RFID tag results in a loss of about 30 U.S. cents (Jayeswal & Verma, 2005).

Regarding other major trends in the globalizing world, the physical infrastructure, the rules and regulations (applied to business and individuals), the degree of transparency, perception of fairness (or lack of corruption), the investment climate and functioning of the legal system, and so forth, have lately become important elements for inducing investments in the production of goods and services. Technology and skilled labor can move easily as usual, but ability of a country to

be competitive in the contemporary globalizing world depends more and more on the above infrastructural, as well as social, legal and various institutional factors.

ICT and its impact on Economic Growth

OECD (1989) and ESCAP (1999) reiterate at least four dimensions of the positive contribution of ICT to economic growth in the globalizing world:

- **ICT allows process innovation (new ways of doing old things).** Smaller, faster, and cheaper ICT helps to reduce the cost-to-performance (output) ratio of its application and, thereby increases productivity level. Use of ICT could also promote more efficient utilization of inputs such as raw materials, energy and land. Some new applications of ICT may not only make products economical, but also help to customize them. Drawing closer attention to customer's tastes and preferences with the help of ICT, producers could increase the value added (usefulness and appeal) to their products and, thereby improve their quality. The adoption and dissemination of ICT could also contribute to the formation of networks which, in turn, likely to lead to innovation.
- **ICT helps to generate innovative economic activities (new ways of doing new things).** Various new applications of ICT do now allow some small scale production and service activities to be carried out efficiently both within a country and across borders. These have assisted the creation of new opportunities for regional and global subcontracting, and the decentralization and globalization forces have greatly enhanced the speed of this process. Through organizational changes made possible by ICT, developing countries may plan for better spatial distribution of economic activities, especially those industrial and service operations centralized in large cities.
- **ICT can lead to economic restructuring through being a new factor of production (in addition to the conventional factors of land, labor and capital).** With the help of new and varied applications of ICT, a rapid integration of markets across countries has been taking place through the transmission of market signals and consumer/producer responses. As a result, market horizons are becoming broader, with more information available on the nature of various markets, retail outlets, electronic linkages to clients and distributors, and so forth. More and more producers with computer-assisted design are now capable of responding to market signals with greater flexibility and speed. Their capability to provide consumers with tailor-made products and services and to create market niches has, therefore, been increasing. Built-in software and "intelligence" in many products, automatic diagnosis of malfunctions, and electronically assisted after-sales service help to increase their adaptability and substitutability, which, in turn, increases competition. The resulting competition and the pressures of market integration in the globalizing world have compelled most large-scale manufacturers to go global in terms of sources of inputs, markets and competitors.
- **ICT adds a new means of organizing various activities through its synergies with other technologies.** ICT has revolutionized the marketing systems for commodities on international markets due to producers' instantaneous access to the prices of their products on a real time basis through mobile phones, the Internet, facsimile machine, and so on. The nature and structure of the services sector have also undergone drastic changes as a result of various ICT enabled improvements made in the speed, reliability

and cost of processing vast quantities of information related to financial, inventory and sales. Generally speaking, flexible automation technologies and organizational innovations are being combined into new best practice manufacturing systems and service providers. All the above potential contributions of ICT could directly increase a nation's economic growth and indirectly influence (through multiplier effect) its price and income structures.

ICT as a Tool for Socioeconomic Development of the Developing Countries

Several studies including reports by the United Nations Development Program (*Human Development Report*, 2001), the United Nations Educational, Scientific and Cultural Organisation (UNESCO, 2004), the World Bank (*World Development Report*, 1998/99), the Organisation for Economic Cooperation and Development (OECD, 2004) have identified specific socioeconomic areas within developing countries where ICT can have potential impact. Among these, poverty alleviation, empowerment of socially and economically disadvantaged, agricultural and rural development, population and human resource development, and infrastructural development are important. Lopez and Vilaseca (1996) and Mansell (1999), among others, have listed several sector specific impact of ICT application in developing countries:

- **Industrial sector:** Creation of new industries (in the form of microelectronics and software-based products) or the integration of IT with other technologies (biotechnology) has enabled some developing countries to modernize traditionally "low tech" and labor intensive industries by taking significant steps towards closing the technology gap. Many Asian and Pacific developing economies have been successful in this direction in the areas of ICT industry's hardware production, particularly personal computer (PC), as well as software development and services. The success of South Korea and Taiwan lies in their supply of ICT products and components to the world market, while that of Hong Kong and Singapore is in ICT related trading and manufacturing. Subsequently, Malaysia, Thailand and recently China have all followed suit in ICT related manufacturing and packaging. India has emerged as a world leader in software development since the mid 1990s.
- **Service sector:** Adoption of technologies and changes in service sector technologies has major implications for developing countries. This is due to their impact on fundamental process and organizational changes in different areas including product distribution, financial services, engineering, insurance, marketing, transports, and so forth. This impact is, however, not restricted only on economies, it has certainly spillover effects on education, consumer behavior, and quality of life. Many developing countries which have relatively large pool of skilled or semiskilled labour force with some knowledge of English language are found to excel in the IT enabled service activities. These activities include various types of services such as handling of large volumes of marketing and post sale service related telephone communications with existing or potential customers (call centers); data entry, transcription or digitalization, insurance claim processing, compilation of abstracts, and typesetting for publishing companies, design and maintenance of Web sites (business process centers); preparation and collation of research materials (technical support centers), and so forth.
- **Public sector:** Because this sector is highly information dependent, ICT has a very far

reaching impact on it. ICT is being increasingly applied to different processes used by governments in developing countries. These processes include policy making, planning and budgeting, debt management, macro-economic analysis, community participation, monitoring the quality of provided services, implementing new services, and overall, financial accountability and control. "Given the developmental potential of ICTs, there is," as Morales-Gomez and Melesse (1998, p. 2) argue, "a growing trend among industrialized countries, governments, large transnational corporations, donor agencies, and international organizations to see these technologies as a panacea to underdevelopment."

Avgerou (1998) warned that, the developing countries may face several problems in introducing ICTs in different sectors with the adoption of economic and organizational forms that have been transferred from the industrialized countries. There is no unique proven "best practice" or best policy that could be locally effective for achieving socioeconomic benefits from ICT diffusion. Here comes the notion of "appropriate technology" that is also relevant in this context.² Among many of its comparative advantages, availability of local managerial and technical skills, cultural proximity of producers to intended customers, existence of institutionalized user producer networks, and accumulated tacit knowledge are notable. However, adoption of economic mechanisms and organizational practices from the "postindustrial" world may connect organizations of developing countries to the global business, but it may not guarantee them a competitive position in the global economy.

In the following section on impact of ICT in South Asia, the author will draw some attention to how the policy makers are making efforts to ensure the co-ordination of ICT policies could maximize the spillover effects across the society.

ICT RELATED POLICY INITIATIVES AND THEIR DEVELOPMENTAL IMPACT IN SOUTH ASIA

Empirical studies that focus on impact of ICT for development usually make a distinction between ICT as a *production sector* and ICT as an *enabler of socioeconomic development*. ICT as a production element (including ICT enabled production services) for commercial use requires huge capital (physical and human) investments in information infrastructures (including telecommunications), hardware and software. At the same time, ICT as an *enabler of socioeconomic development* requires increased ICT consumption (public and private). However, as preconditions private consumption in developing countries depends largely on public investment in ICT infrastructure, and type of ICT strategy adopted for harnessing wider development objectives. For these reasons, Pigato (2001) argued that "for developing countries benefits from ICTs are more likely to accrue from consumption rather than production" (p. 4).

This section focuses on ICT policy initiatives in the developing nations. To make it more realistic and reach out the largest base of low-income communities, the region of South Asia has been selected. Though in terms of ICT development, a few Asian countries emerge as giants, but South Asia is yet to remain as one of the two poorest regions (with very high incidence of absolute poverty) of the world, the other one being Sub-Saharan Africa. To compare the ICT development in South Asian region, several indicators have been chosen. As shown in Table 1 below, this region has very low intensity of ICT consumption per 1000 inhabitants. Sri Lanka leads ahead in its overall ICT consumption intensity among the five selected South Asian countries, although recently India and Pakistan tend to move ahead of others in Internet users per 1,000 inhabitants and Internet hosts per 1,000 inhabitants, respectively.

On the production front of the information technology (IT) industry,³ India has early success

Table 1. ICT at a glance in selected South Asian countries

	Bangladesh			India			Nepal			Pakistan			Sri Lanka		
	1997	2001	2004	1997	2001	2004	1997	2001	2004	1997	2001	2004	1997	2001	2004

in software sector since the mid 1990s, and then in IT enabled service sector since the beginning of the new millennium. Some of the other South Asian countries have either made similar attempt or have been following the transition. However, before analyzing India’s success story, a brief information on recent ICT profile for each of the other four selected South Asian countries (Bangladesh, Nepal, Pakistan, and Sri Lanka) will be given first.

Bangladesh

Although sales of ICT related consumer products such as mobile phones, desktop computers, modems, networking equipment, and so forth, have been increasing fast, the use of ICT has remained confined mainly to entertainment, voice commu-

nication, and basic Internet access for browsing and e-mail. The Bangladesh Telecommunications Regulatory Commission (BTRC) has reported that there were 150 registered Internet Service Provider (ISP) licence holders (not necessarily operational) at the end of 2003. Among these licensees, 14 were registered as “nationwide service providers.” Apart from ISPs, four registered Very Small Aperture Terminal (VSAT) hub operators had planned to provide satellite terminal and gateway services in December 2003, but a year later only one of them was open for business providing services to financial institutions (Haque, 2005/2006).

As Islam (2005) writes, Bangladesh seems to be waiting for a take off in ICT. Bangladesh’s skilled labor force with expertise in ICT is growing. Training centers, computer institutes, and

both private and public universities are all increasingly contributing to this pool of technical labor force. The present government had approved the National ICT policy in October 2002 with the objective of building an ICT driven knowledge based society. An ICT Task Force with the Prime Minister as its chairperson has also been created for making policy decisions related to various ICT activities. It is expected that the recently established Incubation Center at Kawranbazar in the capital, Dhaka, with data transmission facility and uninterrupted electric supply, will attract companies involved in software and IT enabled services. Establishment of a planned high-tech park with all modern infrastructural facilities at Kaliakair near Dhaka will certainly boost ICT industry and ICT related developmental impacts in Bangladesh.

There seems to have a general feeling that the overall growth of the ICT industry in Bangladesh had been hampered during 2003-2004 due to lack of coordination and cooperation between private and public sector agencies (Haque, 2005/2006). However a recent Springboard Research study⁴ on the Bangladesh IT market finds that its domestic IT spending amounted to US\$235 million, an increase of 9% over the previous year, despite various obstacles such as natural disasters, economic setbacks, political instability, and social unrest. The IT market in Bangladesh is largely dependent on hardware, which represents more than 75% of total IT spending. The software market is stifled by the early state of market development and prevalent piracy, which exceeds 90% in the consumer market. The government sector accounts for over 40% of total spending, and the investment by non governmental organizations (NGOs) such as World Bank, Asian Development Bank, and so forth, is a major driver for market expansion. Apart from these two key market segments, the finance and telecommunications industries also play vital role. These four segments together represent over 70% of total ICT spending in the country.

Nepal

After the launching of IT Policy 2000, Nepal's progress in its implementation has been slow. "However, some of the key national initiatives to develop the ICT infrastructure, such as the construction of the first IT park and the information superhighway, are," as Pandey and Shrestha (2005/2006, p. 1) note, "on the verge of completion." Among the recent efforts taken by the government include establishment of telecenters, licensing of private rural telecommunications operators, liberalization of the telecommunications market, enactment of the long-awaited Electronic Transactions Act in 2004, and so forth. One of the important initiatives taken by the Ministry of Science and Technology in line with the IT Policy 2000 was on human resource development (HRD). Accordingly, the ministry was determined to make sure that sufficient number of people trained at the semiskilled, skilled, and advanced levels could be made available for employment in ICT sector. A long term ambitious program with the slogan "Computer education to all by 2010 A.D." has also been formulated. Five Nepalese universities are offering IT related courses. The total number of private firms engaged in IT sector exceeds 1,000. The majority of these firms are concentrated in Kathmandu Valley and more than half provide various types of training in ICTs. There are about 15 software development companies. Five or six of these companies are export oriented, while the rest cater to the limited demand of the local market (APDIP, 2005).

The number of Internet users has increased sharply in the recent years (see Table 1), due to the private sector's leading role in introducing Internet services. The private sector first connected Nepal to the Internet in 1995. Since then, 12 ISPs have begun their operations in the country, 5 of them are VSAT providers. Although all of the 12 municipalities in Nepal are served by ISPs, but most of the subscribers and users are concentrated in capital Kathmandu. The state

Role of ICT in Development Process

owned Nepal Telecommunications Corporation had been attempting to set up 1,000 VSAT connections for rural telephony with the aim of providing at least two telephones to each Village Development Committee by 2004. The United Nations Development Program (UNDP) and the Nepalese government have recently signed an agreement to run a US\$625,000 two-year pilot project in ICTs (APDIP, 2005).

Pakistan

As a continuation of the IT Policy 2000, the new government of Pakistan which took office in November 2002 has taken a number of initiatives for ICT development. Masood (2005/2006) notes that the current government has been supporting ICT development with a two-pronged strategy. The first part of the strategy aims at generating work for the local ICT industry which is still reeling from the 2001-2002 economic downturn. The second part is designed to assist the small and medium enterprises (SMEs) so that they can embrace ICT to enhance their performance and competitiveness. The Telecom Deregulation Policy approved in 2003 has been taking effect in recent years in terms of the opening up of the telecommunication sector to major investors. Two new cellular licenses have been awarded in April 2004 resulting in an accelerating growth of cellular networks (Table 1).

Pakistan Telecommunication Company Limited (PTCL), the exclusive provider of telecommunication services, is the major Internet backbone in the country. National Telecommunication Corporation (NTC) is the organization entrusted with the responsibility of providing telecommunication services to government agencies and designated users. NTC is deploying a countrywide automatic teller machine (ATM) based multiservices data network capable of carrying voice, video, and multimedia traffic. In addition to public sector operators, there are 80 private sector ISPs and nationwide data communication network opera-

tors who provide Internet access in all major cities of Pakistan. Already, more than 1,800 cities and towns have been connected to the Internet and plans to expand this service are progressing. The use of broadband services has also started to grow in households and offices mainly located in major cities (APDIP, 2005).

Following Masood (2005/2006), an overall state of Pakistan's ICT development and related issues in the recent past has been summarized here. As he mentioned, the ICT sector appeared to have shrunk during the first half of 2004 when a number of ICT companies had closed their operation. This seemed to be partly due to the spillover effect of the global dotcom crash and partly due to geopolitical insecurity. Also, the *e-commerce* and *e-government* initiatives, which were the core of the ICT industry development strategy during 2000-2001, could not achieve much success apparently due to low inertia in government's own system. Meanwhile, the human resource development (HRD) initiative has achieved mixed results. Universities and other educational institutions have been upgraded, and a critical mass of people has been trained in various facets of ICT. However, the pilot programs adopted in these critical areas started to act as agents of change during the second half of 2004 and saw some revival of the ICT industry, especially the outsourcing segment. The companies that survived the downturn during 2001-2002 have emerged to be more focused in terms of their strategies. New firms have also sprouted to capitalize the new opportunities of outsourcing. A number of companies have set up call center operations to provide back office services to foreign-based companies. It is expected that this segment of the ICT services market will grow in the years to come because of favorable business climate.

Sri Lanka

As could be seen from Table 1, Sri Lanka has the highest tele-density (both land line and mobile)

and ownership of personal computers in the region. About 70% of the country's communication infrastructure is, however, concentrated in the Western Province where the country's capital, Colombo, is located. ICT proliferation outside Greater Colombo is still limited. In the case of Internet density, India seems to have overtaken Sri Lanka in 2004 (Table 1). Sri Lanka, which ranks first in South Asia on the Human Development Index (HDI), has a large pool of skilled labor force, as well as an open business culture to global partners and investors. Low cost offshore data entry operations have thrived in Sri Lanka since the early 1980s. The Sri Lankan Government has actively encouraged the spread of computer literacy by providing custom duty concessions on hardware imports and introducing appropriate data transmission systems. Also, in many cases, a large Sri Lankan Diaspora has brought in their knowledge, contacts, and capital back to help integrate companies into the global market of software and tele-services (SLICTA, 2004).

Seven universities in Sri Lanka produce graduates in engineering, electronics, and computer science. In addition, four institutes provide training in electronics. Sri Lanka has recently gained recognition as a competitive choice for top quality ICT outsourcing and call centers in the region of South Asia. Currently, Sri Lanka's ICT industry has an estimated export earning of U.S. \$100 million and has a potential for growth in both ICT and ICT-enabled service industry. About 80 software development companies are in operation. Most of them started their operation since 1996, when the Board of Investment (BOI) offered special incentives in the form of tax holidays and duty free imports for software exporters. Sri Lanka also acts as an offshore development center for companies in USA, UK, Ireland, Australia, and so forth, and joint venture development center for those in Sweden, Norway, USA, Japan, and so forth.

As noted in MAIT (2005), "Open Source" software⁵ presents an opportunity to revolutionize

the ICT industry of Sri-Lanka. Among the 800 committed participators involved in open source projects worldwide, 30 are based in Sri Lanka. The Lanka Software Foundation, a nonprofit organization, has been formed to assist Sri Lanka utilize the opportunities offered by the open source projects. These participators currently operate open source related development laboratories at the Universities of Colombo and Moratuwa, and the Sri Lanka Institute of Information Technology. Among the other significant ICT related initiatives taken in Sri Lanka is the Government's launching of an ICT program in 2003 for the societywide development widely known as *e-Sri Lanka*. Its principal objectives are to foster the local ICT industry, transform the way Government works, improve the quality of life and create opportunities for all Sri Lankans. The first phase of the program focuses on rural connectivity and re-engineering the government. The priority projects for the latter include e-Monitoring, e-Pensions, e-HRM (Human Resource Management), and e-Foreign Employment (MAIT, 2005). As Sri Lanka seems to be gradually recovering from a prolonged civil war, the strategic use of ICT can play a key role to rebuild the country.

India

Significant progress in electronics and computer technology and, therefore, the growth of IT industry has been a major success story in India's economy since the mid 1990s.⁶ From 1996-1997 to 2001-2002 the industry's production grew substantially from Rs. 26,640 crore (US\$7,504 million) to Rs. 80,884 crore (US\$17,324 million).⁷ While the share of hardware products and nonsoftware services (such as system integration including packaged application implementation and custom application development) in the IT sector has declined in the recent past, the share of software services in electronics and IT sector has gone up from 38.7% in 1998-99 to 61.8% in 2003-04. Recently, however, there has been some

Role of ICT in Development Process

acceleration in the growth of hardware sector. Output of computers in value terms has, for example, increased by 36.0%, 19.7%, and 57.6% in 2000-2001, 2002-2003, and 2003-2004, respectively (Economic Survey 2004-2005, p. 147).

During 1990s, the software sector of India's information technology services (ITS) industry has developed as one of the fastest growing sectors in its economy at the compound annual growth rate (CAGR) of 50%, although India's share in the global IT software and services markets was only 2.4% during 2003-2004. A unique feature of India's IT software industry has been its export orientation. Exports of computer software and IT enabled services⁸ have become important sources of India's export earnings in the recent period. The value of India's IT software and services export is estimated to have increased by 30% to US\$12.5 billion in 2003-04 (Economic Survey 2004-2005, pp. 147-148). The general thrusts behind the success of the ICT industry have been highly competitive private sector, public investment in human capital, government's support in IT policies in general, and recent telecommunication policy in particular.

Since the beginning of 2001, India's traditional ITS companies have been focusing more on the IT enabled services (ITeS) including business process outsourcing (BPO) components. The ITeS segment provides people-intensive services that are delivered over telecom networks or Internet to a range of business works and verticals. Services included in this segment are telemarketing, help-desk support, medical transcription, back-office accounting, payroll management, legal database maintenance, insurance claim, and credit card processing. ITeS businesses are operating in India under two categories: *outlocation* services and *outsourcing* services. While the former services are for captive use mainly by foreign companies, the latter ones are through a third-party service provider (Dataquest, 2002). Multinational companies such as *General Electric* (GE) that invested in remote services as captive facilities for world-

wide group operations have adopted a primarily outlocation focus. But Wipro's *Spectramind*, for example, operates as a pure outsourcing service provider, which is funded by banks and venture capital finance, and operates as a niche of contact centre services for Fortune 200 companies. In fact, the ITeS-BPO segment has quickly emerged as a key source of export growth for India's ITS industry.

Following Karnik (2004), major specific factors (external and internal), responsible for high growth rate of India's ITeS-BPO market can be summarized as follows:

External

- Worldwide advancement in technology and infrastructure maturity, which has allowed more complex processes to be off-shored.
- Rapidly improving communications infrastructure for data and voice has enabled this trend to gain pace.
- Competitive pressures faced by global organizations which have been forced to cut costs by outsourcing their non-critical processes.
- Success stories of the BPO route have encouraged other global organizations to opt for the same.

Internal

- Efficiency and productivity improvements achieved by the major Indian outsourcing companies have helped them speed up operations and provide 24x7 customer services.
- Indian IT companies' access to skilled manpower with specific domain knowledge including English-language ability at relatively lower costs is also another advantage.
- Indian IT industry's accelerated pace of consolidation and service convergence has helped stabilize the ITeS-BPO market.
- Success stories of Indian IT companies that have been able to focus on their core business and optimize existing processes by taking

the BPO route have been an inspiration to other Indian organizations to follow suit as well.

However, at the same time, the success of the Indian ITeS-BPO sector due to above factors is also creating challenges in order to maintain its current momentum. Again, following Karnik (2004), some of the major challenges can be noted as follows:

- Because of inadequate ICT infrastructure support, a number of small and medium sized BPO companies have not yet achieved the world class status in terms of communication and other physical infrastructure, which could create shortfalls in this sector's overall service level.
- Performance gap between the top-of-the-line and mediocre suppliers needs to be closely looked into, especially when the lower-rung vendors are also achieving scales, quality levels and portfolio of services by matching to those of the more reputed providers.
- A significant challenge facing Indian BPO vendors today is to cope and successfully combat the backlash against outsourcing, which is creating a negative sentiment for the activity, particularly in the U.S.
- Human resource issues are arising especially in the case of high attrition level, lack of relevant manpower availability and also maintaining the satisfactory level of work environment.
- The Indian ITeS-BPO sector's profit margin seems to be shrinking due to the emergence of competitors especially from China, the Philippines, Vietnam, Ghana, Czechoslovakia, Poland, Romania, Bulgaria, Slovakia, and others.

The increasing importance and growth of ITeS-BPO activities in India have led to specific policy initiatives for this particular segment. These

include measures, to name a few, for adjusting the regulatory and legal framework, rationalizing tax provisions, and improving communication infrastructure. The government is also actively involved in a proper settlement of the backlash against outsourcing through General Agreement of Trade in Services (GATS) negotiations at the World Trade Organization (WTO) level.

In order to meet the challenge of zero custom duty regime in 2005 under the Information Technology Agreement (ITA-1), a number of initiatives have recently been taken by the Indian government. Tariffs on raw materials, parts, other inputs and capital goods have been rationalized to make domestic hardware manufacturing viable and competitive. For example, customs duty on computer parts, static converters for automatic data processing machines and parts thereof has been fully exempted during 2004-2005. Also, computers have been exempted from excise duty (Economic Survey: 2004-2005, pp. 148-49).

Regarding initiatives on ICT as an *enabler* of socioeconomic development, the Department of Information Technology has taken up the following steps:

- An ambitious program of PC and Internet penetration to the rural and underserved urban areas has been launched.
- A program to establish State Wide Area Network (SWAN) up to the block level to provide connectivity for e-governance has been announced.
- Community Information Centers (CICs) have been set up in hilly, far-flung areas of the North-East and Jammu and Kashmir to facilitate the spread of ICT related benefits.
- setting up of CICs in other hilly, far-flung areas of Uttaranchal, Andaman, and Nicobar and Lakshadweep has also been proposed (Indian Economic Survey: 2004-2005, pp. 148-49).

ROLE OF NETWORKING PROCESS⁹

Like most of the developed countries, the developing countries need to integrate ICT policies more closely into societal development strategies. This can be done by strengthening the links between, for example, economic development and technology agencies via the organizational structure of policy-making bodies. Here comes the importance of appropriate networking process at national, regional, and international levels. In the context of South Asia, the countries belonging to the *South Asian Association for Regional Cooperation* (SAARC), a regional institution called the SAARC Agricultural Information Centre (SAIC), has been functioning in Dhaka since January 1989. Because the problems and prospects of agriculture and ecology of the SAARC countries are more or less the same, its main objective is sharing information mutually for the advancement of agriculture, livestock, fisheries, forestry, and allied disciplines. Recently, the SAARC Governing Board has prioritized a program called “SAICNet” with its following specific objectives (SAIC, 2004):

1. Develop Web-based information network that will bring in the synergy of the potential collaborators of SAIC.
2. Establish a gateway mechanism to improve access to agricultural information, which is relevant for researchers, extensionists, policy makers, educationists, students and agribusiness entrepreneurs and through them to the end user, the farmers in the SAARC region.
3. Capture, organize, and disseminate information, wherever it is available, that is relevant for agricultural development in SAARC region.
4. Design and introduce value added services that are based on the ever-changing information needs of the users.
5. Improve use-friendly access to SAIC’s

information services on the Web site that will lead to increased relevance and use of information.

6. Expose and train SAIC staff on the tools and technologies related to Web development and networking.
7. Enhance network activities with the participation of collaborative institutions in sharing information and knowledge resources.

Effectiveness of similar objectives as the above also depends on appropriate networking process among various country specific governmental and non-governmental institutions on the one hand, and the national and regional ICT networks on the other hand. Many non-governmental institutions which have been engaged in introducing ICT for the benefit of rural/urban masses include, among others, *Sustainable Development Networking Program* (SDNP) in Bangladesh, *M.S. Swaminathan Research Foundation* in India, *International Centre for Integrated Mountain Development* (ICIMOD) in Nepal, *All Pakistan Women Association* (APWA) in Pakistan and *Sarvodaya Shramadana Movement* in Sri Lanka. Similarly, various national/regional ICT network agencies have helped different institutions in the South Asian countries to adopt ICT as a means to address their developmental activities. The national ICT networks in the South Asian region include *Bangladesh Advanced Education Research & Information Network* (BAERIN), *Bangladesh Research and Educational Network* (BERNET), *ERNET-India*—India’s education and research network, *Pakistan Educational Research Network* (PERN), *Lanka Educational And Research Network* (LEARN) of Sri Lanka. Among the regional ICT network agencies, important ones are *South Asian Network Operators Group* (SANOG)—a regional forum, *Pan Asia Networking* (PAN)—a program initiative of the International Development Research Center of Canada, *Asia-Pacific Advanced Networks* (APAN)—a non-profit high-performance network for research and develop-

ment on advanced next generation applications and services, *Asia Pacific Network Information Centre* (APNIC)—responsible for addressing the challenges of Internet resource distribution in the Asia Pacific region.

Because of a variety of country specific socioeconomic needs and challenges, namely in the areas of health, education, livelihoods, and governance of the South Asian countries in particular or developing countries in general, it is very crucial that the economic development and technological policy making agencies must not only make sure to select the most appropriate ICT available (of course subject to financial constraint), but also try to gather information on the recent technological changes, especially in the area of ICT networks.

CONCLUSION

Developing countries have different levels of socioeconomic development depending on the structural, institutional and infrastructural constraints at their economic, political, and social levels. In fact, efforts undertaken in a coordinated way with systemic approach seem to have a greater chance for faster socioeconomic development than otherwise. In most cases, level of socioeconomic development has a direct bearing on a country's level of technological development. The recently published UNCTAD's *Information Economy Report 2005* illustrates that many developing countries are undertaking vigorous efforts to catch up with their more developed partners in the dissemination and use of ICT; it also shows that the gaps are still far too wide and the catching-up far too uneven.

It is true that the ICT as a *production sector* or as an *enabler of socio-economic development* has potential for economic growth and development. Because of the availability of surplus skilled labor force in many developing countries

including those in South Asia, there is some prospect for them to participate in the production of the IT services related to ITeS-BPO segment. However, unless the fundamentals as required by the globalizing world are made favorable for this segment, there is little hope for this to happen. Similarly, to take advantage of the ICT as an *enabler of socio-economic development*, the country's strategies and actions must make sure that its marginalized social and economic groups are not left out, otherwise the *digital divide* within the country will choke its overall socio-economic development.

The ICT penetration in five countries selected from the poverty stricken South Asian region can easily be seen to be very low in comparison to the newly industrializing countries (NICs) in other part of Asia. This low ICT penetration also indicates the existence of *digital divide* within each of these countries. What is needed to combat with digital divide that exists both across various developing regions and within developing countries is "the sustained engagement of national governments, the business sector, and civil society, and the tangible solidarity of the international community" (UNCTAD, 2005, p. xv).

ENDNOTES

¹ Following OECD (2004, p. 63), the term “information and communication technology” (ICT) is broadly used to refer the family of related technologies that process, store, and transmit information by electronic means. The term “information technology” (IT) is narrower and is used to denote computer, software, and related technologies not including communications and network technologies. The boundary between the two is, however, getting increasingly blurred.

² The author (Dutta, 2005, pp. 15-16) has

recently summarized the “appropriate technology” movement in the context of earlier industrial technology.

³ The term “information technology (IT) industry” generally covers development, production, and services related to IT products. Hence, it contains three basic sub sectors: hardware, software, and services. IT services include those services which result from the use of any IT software over a system of IT products for realizing value addition. There are three broad categories of the entire IT services (ITS) industry: (1) system integration, which includes packaged application implementation, custom application development and integration; (2) application outsourcing, which includes support and maintenance services; and (3) IT consulting, which includes strategic consulting, business process consulting and change management (Retrieved June 26, 2006, from www.expressindia.com/full-story.php?newsid=29232&spf=true).

⁴ <http://economictimes.indiatimes.com/articleshow/1214281.cms> (Retrieved June 26, 2006)

⁵ “Open Source” software is a method of software creation, distribution, and licensing, which permits accessibility of its source code. In contrast, for the proprietary companies such as Microsoft, IBM, Oracle, and so forth, the source code is a closely guarded secret.

⁶ Some detailed analysis of India’s software industry and major Indian ICT firms’ quality achievement process can be found, respectively, in Chakraborty and Dutta (2003), and Dutta and Sekhar (2005).

⁷ Note that 1 crore = 10 million. The rupee figures are from Economic Survey: 2002-2003, p. 143. Exchange rates used are: US\$1.00 = Rs 35.50 in 1996-1997 and US\$1.00 = Rs. 46.69 in 2001-2002.

Role of ICT in Development Process

⁸ The IT enabled service industry in India began to evolve in the early 1990s, when companies such as American Express, British Airways, General Electric and Swissair set up their offshore operations in India. A large number of foreign affiliates now

operate IT-enabled services in India (Ibid., p. 148).

⁹ The author is grateful to Dr. H. Rahman who has provided the names of most of the national and regional ICT networks included in this section.

This work was previously published in Information and Communication Technologies for Economic and Regional Developments, edited by H. Rahman, pp. 240-258, copyright 2007 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 1.10

Information and Communication Technology and Good Governance in Africa

Godwin Onu

Nnamdi Azikiwe University, Nigeria

INTRODUCTION

The 20th and 21st centuries have witnessed major paradigm shifts in the conceptualization of development and governance. These phenomena are aided and propelled by a new “network intelligence” consummated in the introduction of information and communication technology (ICT). The world has also witnessed a reinvention of the whole process of governance that has impacted society in various ways. Through the Internet and digital connectivity, today’s world has come to be closer than ever before. Efficiency and processes of governance have been improved through faster information flow in the governance chain. Bottlenecks and cost of labor have been reduced across the world. Furthermore, ICT has opened new possibilities, improved transparency and access to information as well as partnership and collaboration, leading to improved relationships between the citizen and state. While Europe and North America, as well as some countries of Asia and the Pacific, have taken advantage of

this development to improve their economies and governance process, Ningo (1999) observes that sub-Saharan Africa has remained either passive or in the periphery, often reduced to a consumer for reasons related to its history or its system of governance—or lack of one. This has led to a yawning digital divide (especially between Africa and developed states of the world).

What led to this divide and how can Africa, then, benefit from this revolution? What are the obstacles?

BACKGROUND

Such historical factors as colonialism and associated exploitative orientations and, more recently, military dictatorship and neo-liberalism have dominated the literature of Africa’s political economy as explanatory framework for underdevelopment. Little has been blamed on the problems of state interventionism that characterized the post-independence period and that appear to

have exposed the weakness of the state in Africa to manage its resources and deliver services, thereby leading to underdevelopment and poverty. Even at that, the prognosis and taxonomy of the post-cold war developments in Africa still lean on such templates. In fact, African scholarship has continued to heap blames for underdevelopment on doors of liberalism, mercantilism and their “center-peripheral” characters. According to Bathily (Nnoli, Ed., 2000, p.49), “It appears clearly that the crisis of the post-colonial state is not directly caused by state intervention in the economy.” To that extent, Bathily contends that the solution to this crisis cannot be generated by the mere restoration of the so-called macro-economic equilibrium.

The current Africa’s problems have also been traced to corruption and bad governance (World Bank, 1989). Identification of these problems and their impediments to political and economic development have led experts, scholars, organizations and agencies to show concerted interests towards paradigm shift and reinventing governance. The move is borne out of the genuine conviction that there is a correlation between bad governance as witnessed in Africa and other parts of the world and over-centralization. This correlation also extends to governance and problems of war, poverty, corruption and human security. Consequently, these have led to various dimensions of inequality and growth below the world’s minimum standards for economic development. According to Adedeji (2002), African performance in 1960-1975 was substantially below all the targets set by the United Nations (UN) Second Development Decade. Its GDP annual growth was 4.5% instead of the 6.0%; its export was 2.8% instead of 7.00%; its agricultural growth rate was 1.6% instead of 4.00%; while manufacturing grew at 6.0% instead of 8.00%. Import was 10.0% instead of 7.0%. This, according to Adedeji, reveals that Africa was faced with development crisis. Unfortunately, performance during the one-quarter of the 20th century (1975-2000) was more abysmal than that

achieved during the first 15 years of independent Africa (1960-1975). It is postulated that if Africa has to exit from poverty and develop, it needs a growth rate of 7.0% per annum (Adedeji, 2002). The following data demonstrate Africa’s growth rate and prospects from 2002 to 2006.

It is the contention of scholarship also that this bad governance could be averted if there is culture of accountability, transparency, as well as commitment of political leadership to deliver services to the governed.

STEPS TAKEN TO ACHIEVE GOOD GOVERNANCE

Various steps have been taken at the national, regional and global levels to address the problems of bad governance in Africa. At the global level, there is a general call for democratization and economic reforms that could entrench a regime of accountability, transparency and culture of trust. Institutions, such as the World Bank, International Monetary Fund (IMF) and donor nations, have not minced words on these virtues as conditions for granting any form of aid to Africa. They have even extended their definition of governance to include a redefinition of the state, the de-politization of public administration and involvement of non-governmental organizations.

At the regional level, there have been concerted efforts at political and economic integration as well as such programs as the New Partnership for Africa’s Development (NEPAD), which is designed to use its Peer Review Mechanism and ICT as tracking tools against bad governance. Through this process, NEPAD will help eradicate poverty and empower African states to develop.

At national levels, states of Africa have various provisions in their constitutions and have introduced various institutional measures and anti-corruption agencies to check bad governance. In spite of these efforts, corruption and bad governance continue to ravage the continent,

Table 1. Real GDP growth rate of developing countries (International Development Economic Associates, 2005)

	2002	2003	2004	2005	2006
East Asia and Pacific	6.7	7.9	7.8	7.1	6.6

Total	40.4	32.8	28.4	27.9	26.3	22.8	21.8	21.1

leading to abject poverty. The main thrust of this article, therefore, is to establish how ICT can help achieve good governance in Africa and bridge the divide in overall development (but also the digital divide) between the advanced industrial countries and Africa.

ICT AS A ROAD MAP TO GOOD GOVERNANCE IN AFRICA

While good governance could be achieved through efficient management of the nation's resources,

entrenching a culture of trust, accountability and transparency, we argue that ICT could be a veritable tool of making the above factors possible. ICT in governance has been defined as "the use of Information and Communication Technology to support the act and process of governance through the provision of improved administrative systems within and without government" (Duncobe, 1999) in Emadoye (2002, p. 1). On the other hand, governance is an exercise of political, economic and administrative authority to manage a nation's affairs (UNDP, 1997). It is the complex mechanisms, processes, relationships and institutions

through which citizens and groups articulate their interests, exercise their rights and obligations, and mediate their differences. This poses the concept of governance in two dimensions (good and bad). But we are concerned with good governance. This, the United Nations Development Program (UNDP) argues, has to do with effective management of public resources in response to the critical needs of the society. According to Cloete (2001, p. 4), good governance is “the achievement by a democratic government of the most appropriate developmental policy objectives to sustainably develop its society, by mobilizing, applying and coordinating all available resources in the public, private and voluntary sectors, domestically and internationally, in the most effective, efficient and democratic way”. According to Cloete, this latter definition contains both empirical and normative utilitarian approach. It is also a reflection of the current academic state of public administration/management.

Having said this, it is important to note that no matter how defined, good governance must take care of the principles of responsibility, accountability, transparency, trust and efficient service delivery – all channeled towards the improvement of the welfare of the governed. It is being emphasized, because good governance provides an enabling environment for economic development, political participation, social inclusion, equity and quality of life of citizens. These issues generate broad consensus in society and reduce the problems of war and violence; it reduces poverty by creating employment opportunities through investment and guarantees human security. It creates an atmosphere of freedom, develops talent and ingenuity, reduces fear and throws open windows of opportunity to both domestic and foreign investors.

The above background suggests one basic question. In what ways can ICT be used to achieve this good governance? In other words, what is the instrumental utility of ICT to improve peoples’

welfare, hold government accountable and achieve a responsible, efficient and transparent public administration that could deliver services?

Backus (2001) writes that ICT can be involved in governance in two major dimensions: internally and externally. Internally, it facilitates speedy, transparent, accountable, efficient and effective process for performing government administration activities. Externally, it facilitates speedy, transparent, accountable, efficient and effective interaction with the public, citizens, business and other agencies.

Duivenboden (2002) agrees that ICT could create new ways of service delivery through multi-challenging information supplies. It could equally influence the behavior of governments in their relations with citizens to a certain extent. Duivenboden admits that electronic governance (e-governance) could lead to increased access of citizens to government information and increase the process of transparency. E-governance also saves time and money for both citizens and the state.

Cloete (2001) emphasized the importance of electronic management assessment tools and their use to improve policy outcomes and service delivery. He observed that the poor state of these tools have led to policy failures and poor policy implementation in most developing states. ICT, according to Uma (2004), enables the government to reinvent itself, get closer to the citizenry and forge closer alliances and partnerships with diverse communities of interest, practice, expertise, conviction and inter-dependence within the context of national agendas. Backus (2001) writes further that the objective of e-governance is similar to the objectives of good governance: Good governance is the exercise of economic, political and administrative authority to better manage affairs of a country at all levels, national and local. Many other ways have also been identified as roadmaps to good governance via ICT:

Citizen Participation

The introduction of ICT (including the widespread use of the Internet across the world and its increasing use in Africa) has proven to be a major way of increasing public participation in the governance process. E-governance through ICT is a major roadmap towards defining a society's vision and priorities for e-government. ICT facilitates electronic democracy—voting; public opinion polls; policy inputs; campaigns; payment of taxes; political contacts, especially with elected leaders; networking; as well as advocacy. According to the Pacific Council on International Policy (2002), participation requires collaboration, especially between the private sector and civil society groups that may possess the much-needed expertise and resources. Participation makes it possible for citizens to evaluate government services openly. This enables the government to make improvements in its services and policy process. Good governance in Africa could be facilitated through this process of participation, as it would enable the average African to make input into policy process and generate confidence and trust in the political system. The overall consequence may be political stability and economic development. Experiences from across the world reveal that ICT can be instrumental to community development, improved access to information and public-private partnership, and all of these can also be of tremendous benefit to Africa.

Community Development

ICT in Africa could lead to information sharing, local administration, healthcare service delivery, and accessing information needed at localities without traveling to the state or nation's capitals. In Africa also, ICT could be used by civil society organizations to inform people in the localities about their rights and privileges, and so forth. The effect of this is the empowerment of the civil societies to checkmate their governments and hold

them accountable for their responsibilities. This is a major way of guaranteeing transparency and good governance.

Access

ICT in Africa can create access to information about the entire political process, services and choices available. Government agencies can equally use ICT facilities to advertise their activities, programs and plans, as well as achievements. It can also be used to announce jobs and opportunities on Web sites. Citizens can submit applications online and fill out forms. Though this access still follows the digital divide between developed and developing states, among African states as well as in their urban and rural centers, its benefits are numerous if made possible. The divide also has its gender dimension, since speculations are that women have less access to ICT worldwide.

Partnership

Through ICT in Africa, a feeling of ownership of policy process, legitimacy, and sense of efficacy and patriotism will be generated. As states in transition, it can help in forging a closer and stronger partnership between public and private sectors.

It can also be possible to transact business and send messages faster than ever before in Africa. Though connectivity is still abysmal, such facilities as e-mail, fax and cellular telephones, digital television and radio have been of immense benefits. Cost-effective administration (through microelectronics, fiber optics, video compression, fast-packet switching and high-density storage technology, reduction in the volume of files and of the cost of labor) has been enhanced.

Finally, ICT in Africa, like in other parts of the world, has led to information gathering for intelligence, national security and ecological monitoring, not only to manage natural disasters but also for improvement of agriculture.

Having outlined how ICT can benefit Africa and improve governance, it is noteworthy to state that ICT is like the theory of the hammer, which the carpenter can use for good, bad and ugly. This understanding informs part of its special constraints. Ningo (1999) suggests that Africa should take advantage of the development of ICT, since it offers a dramatic opportunity to leap-frog into the future and break out of decades of stagnation and decline. In this regard, Hegener (1996) warned that if Africa cannot take advantage of the information revolution and surf this great wave of technological change, it may be crushed by it. This, he argues, will lead to greater marginalized and economic stagnancy in the future. Ronfeldt (1992) also suggested that governments that succeed in using the information revolution and its associated technologies to develop advanced information and communication infrastructures may leap ahead of others in terms of their capacity to deal with current issues, assert their presence, build cooperative networks and partnerships, and cope with competition and conflict at home and abroad.

THE FUTURE OF ICT IN AFRICA: PROBLEMS AND CONSTRAINTS

The introduction of ICT at least brings the hope that if adopted and properly implemented, African states can transform from a culture of distrust, dishonesty and mismanagement to that of transparency and accountability that will encourage an efficient and cost-effective public administration and good governance. It will also enable the continent benefit from the present UN Millennium Development Goals.

While this is admissible, it is important to note that peculiar environmental factors may constrain the extent ICT will determine the roadmap to good governance in Africa. Though these factors are not peculiar to Africa, their presence is widely engrossed and their effect severe. The following factors could

hinder Africa's dream and disrupt this roadmap to political and economic development.

Problems

Lack of Infrastructure

Infrastructure is essential to successful ICT procurement and sustenance. These include legal recognition and acknowledgement of electronic data as legal documents, electronic signatures, issues of piracy and intellectual property rights, and procurement policies. These require legal reforms and broad policy frameworks that are yet to be developed in most African states.

Telecommunication

Most African states are still below the world minimum in accessibility to telecommunications. It was found out that Africa has only a 13% share of the world population. Out of this number, only 1% has total global telephone lines, 1% Internet users, 1.2% of total world Internet sites, and almost 0% of global ICT production. With an estimated 274,742 hosts in 2001, Africa has 0.19% of the total global Internet hosts, while its share of personal computers stood at 7,558,000, representing 1.53% of the world total (United States Internet Council, 2001). There is no gainsaying that without this facility, electronic governance, democracy and commerce will be hampered. While in many African states the telecommunication industry has been liberalized, still, the cost of access to these facilities are yet to be within the reach of majority, especially when telecommunication companies are constituting themselves into new monopolies, thereby defeating the essence of liberalization. Even at that, the distribution of the telephone is not only skewed in favor of urban residents, especially the urban elites, but the digital divide continues to increase between the urban and rural dwellers. This divide has also proven to be generational. While African youths appear to be

more ICT literate, a greater percentage of elders appear to be behind this new technology.

Lack of Knowledge Jobs

There is still a gross lack of technical manpower in the field of information technology (IT). This affects not only software maintenance, but also development of new ones and manufacturing of accompanying hardware. IT facilities need to be properly set up, computers repaired and serviced. To a large extent, trained manpower for these services are in short supply. In some offices, where computers are available, they serve the purpose of decoration. Even at homes, generational gaps also exist in their use. Older people feel it is not their business. Younger ones get more interested. Unfortunately, it is the older people that occupy most sensitive positions in the public and private offices.

Poverty/Cost

Poverty is still a major handicap in access to ICT. Most Africans cannot access the Internet or own telephones or other digital receivers, because they are unaffordable. Because of this lack of access, most cannot benefit from various online facilities, such as information, education, e-commerce and so forth. This could endanger the future of ICT benefits for good governance in Africa. Computers are very expensive and, in many cases, unaffordable to the average person.

Another major effect of this poverty in Africa is the use of IT to achieve an inter-generational shift in corruption. The few cyber-cafes that are available are owned by private persons and are often filled with young men and women scamming to defraud – a technique unknown to the older generation and a more sophisticated form of corruption. Employing such people in government offices will offer opportunity for new forms of fraud in the future.

Civil Wars

Available statistics show that many states in Africa are deeply engrossed in civil wars and political instability. The report of the UN Secretary General (April, 1998) shows that since 1970, more than 30 wars have been fought in Africa, most of them intra-state in origin. In 1996, 14 out of 53 countries in Africa were experiencing armed conflicts that accounted for more than half of all war-related deaths globally. This creates environmental problems that are hardly ideal for the development of ICT. Mostly, these states are more committed to basic survival, containing insurgency and fundamentalism than development of ICT infrastructure.

Electricity

In such countries as Nigeria, electricity supply is grossly irregular. In many cases, electricity supply is erratic. It comes on and off. This not only slows progress and development, but also inflicts serious damage to computers and their software. The future of IT development in Africa could be endangered by the poor energy sector existent in many states of Africa, coupled with the fact that many rural communities have no electricity.

Then, there is the lack of most governments' willingness to set up public information centers for cheaper and easy access to information and business transaction. This is not because the government policy makers do not acknowledge the benefits of these; but, lack of patriotism and corruption stand in their way, disposing them to be unwilling to invest where there are no direct cash rewards.

Lack of Space for Open Comments

This might look minor or ignorable, but it is very important. In designing Web sites, most agencies and organizations hardly create open space for exchange of information and comments on

government policies. What government and its agencies do is tell people what they want them to know. This channel is closed for the fear of criticisms arising from the public as well as challenge of policy options. The future of ICT in Africa faces an uphill task in the challenge of the above constraints.

Policy Dichotomization

In some African countries, ministries of communications are separated from those of technology. This keeps IT and communication technologies as separate issues. In Nigeria, for instance, ICT understanding is narrowed down generally to just computers and Internet. There are three separate policies on IT. IT and Broadcasting have different regulatory bodies (Ya'u, 2001). According to Ya'u, this not only creates problems in terms of coordination between the various agencies and resulting duplication of efforts, but also does not allow the countries to tackle the issues of convergence that ICT represents. This dichotomous stance was exemplified when ministers responsible for economic planning were meeting with the Economic Commission for Africa (ECA) in May 1996 to conceptualize the African Information Society Initiative (AISI). That same month, the Ministers responsible for telecommunications were meeting in Abidjan to agree on the green paper outlining the Telecommunication Policies for Africa (Apeworkin, 2001). Again in Nigeria, while the Minister for African Integration was representing Nigeria in the African Development Forum (ADF'99), the Minister for Telecommunications was releasing the National Policy on Telecommunication in Abuja with no reference to what was going on in Addis Ababa (Ya'u, 2002).

PROSPECTS OF ICT IN AFRICA

Leaderships have at least demonstrated some

desires to embrace ICT. For instance, there have been numerous initiatives to embrace ICT and bridge the yawing gap at both international and domestic levels. The World Bank, UNDP and even the Group of Eight initiate some. These have led to modest improvement in connectivity in most African states. By 1995, only six African states had the Internet, but by 2002, virtually all had access to the Internet (Ya'u, 2002).

In spite of these modest improvements, the reports of the Organization for Economic Cooperation and Development (OECD, 2001) and the US Internet Council (UIC, 2000) showed that the divide between Africa and other developed parts of the world is still on the increase. This position leaves us with one major, disturbing question. Will Africa ever catch up and bridge the divide in IT? Mansell and Wehn (1998:25) said it will take at least a century. Cogburn and Adeya (1999, p. 12) sounded even more pessimistic. According to them, "it is an illusion to think that ICT-poor countries can 'catch up' or keep pace with advances in the most technologically advanced countries." Even the efforts through NEPAD did not seem to win the confidence of some scholars. According to Ya'u (2005, p. 8), "NEPAD is symptomatic. There is nowhere in the document in which the ways ICTs are reinforcing existing global inequalities or how the challenges e-commerce is posing to developing countries are factored in the discussion on bridging the development gap." He blamed Africa for taking the matter on its surface level without taking into consideration its historical roots and for thinking that the gap can be bridged just by promoting access for foreign investors in ICT industry by removing for them import duties, taxes and breaks as well as holidays, and reducing itself to consumerist status. The extent to which Africa can catch up therefore, will depend on the level of its leadership commitment to achieving good governance that will enshrine principles of transparency, accountability and service delivery. It is in realization of these virtues that words could be matched by action that could bring Africa

nearer to actualization of digital technology and bridge its consequent divide.

CONCLUSION

The World Bank (1994) had noted that the future of economic development and good governance are hinged on ICT. Africa needs to translate this prediction from mere expression of interest to concrete efforts at bridging the digital divide, not only between the continent and the rest of the world, but within Africa itself, between rural and urban dwellers. For instance, while 29 members of the OECD share 97% of Internet hosts, 92% of the market in production and consumption of computer hardware and software services and 86% of all Internet users, the whole of Africa contain only 2.5% Internet users, or less than 1% of the world's online community (Norris, 2000). This calls for indigenous investment in the ICT sector, with the hope that it will positively impact on governance process. This is a major way of getting through the center-periphery model of development that has beset Africa since the period of colonization. It is equally important to note that the problem of governance does not solely lie in lack of technology. Effective use of technology calls for improvement in various governance infrastructures that will not only enable this technological acquisition but its productive usage. This, therefore, calls for the ICT knowledge society. It is observed that one of the fundamental reasons for the absence of good governance in post-colonial Africa is the sheer incapacity of its bureaucracy to discharge its duties (Chabal, 1992). With creation of a knowledge society and the positive use of IT, the bureaucracy may be better positioned to discharge its roles and deliver services. If Africans can see ICT as an innovation for the common good and adjust from the current culture of greed to that of using the new technology to track bad governance, then the benefits will be tremendous and the future bright. The problem

of ownership of ICT may not even constitute an impediment.

KEY TERMS

Bureaucracy: This refers to the personnel and administrative structure of an organization. Business, labor, religious, educational and governmental systems depend on a large workforce arranged in a hierarchy to carry out specialized tasks based on internal rules and procedures. The term is used mostly in referring to government administration, especially regarding officials in government and civil services. It is often used pejoratively to suggest waste, inefficiency and red tape (Encarta, 2003). In sociological theories, bureaucracy is an organizational structure characterized by regularized procedure, division of responsibility, hierarchy and impersonal relationships. The term can characterize either governmental or nongovernmental organizations.

Cyber Café: “Cyber” is anything related computers or networking. Cyber Café, though, used in exchange with Internet café, is expected to be a coffee shop that offers computer terminals for customers to browse the Internet while sipping coffee. It is a colloquial concept that is fast becoming an accepted formal language.

Globalization: The process by which markets and production in different countries are becoming increasingly independent due to the dynamics of trade in goods and services and flows of capital and technology (European Commission, 1997). Globalization involves much more than economic transaction and spans into political, social and cultural issues. Economic globalization has to do with a borderless global economy, in which the principal agents are the multi-nationals, which are disembodied from any national base. Political globalization refers to the withering away of the state. Cultural globalizing refers to the present global village that watches more or less the same television serials and videos, consumes or aspires to consume the same products. Social globalization refers to the homogenization of today's mode of life, which is based on an individualist and consumerist culture. As a result of globalization, social geography gains a planetary dimension. "Place" comes to involve more than local, provincial, country, regional and continental realms. With globalization, the world as a whole also becomes a social space in its own right (Encarta, 2003).

Governance: The term governance has not received any universal fit-all definition. The best we have are working definitions by international organizations, which in most cases lack underlying theories. The UNDP defines governance as "the exercise of political authority to manage a nation's affairs. It is the complex mechanisms, processes, relationships and institutions through which citizens and groups articulate their interests, exercise their rights and obligations and mediate their differences." In keeping with this, it defines sound governance as effective and efficient management of public resources and an adequate response to critical societal needs. It also denotes democratic forms of relationships between the governed and the governors, relationships that have in-built mechanisms for public participation, accountability and transparency.

It is contended that systems that incorporate the above elements have been better able to satisfy broad societal needs, including sustainable human development (Economic Commission for Africa, 1988). It can also represent decision-making processes in the administration of an organization. Governance also refers to the process whereby elements in society wield power and authority, and influence and enact policies and decisions concerning public life, as well as economic and social development.

Human Security: Human security has been looked at from two primary perspectives. From the narrow perspective, it has to do with protection of individuals and communities from violent threats and internal conflicts. The broad perspective defines it to include threats of hunger, poverty, exclusion and natural disasters.

Internet: Internet is a collection of computer networks that operate to common standards and enable the computers and the programs they run to communicate directly. There are many small-scale, controlled-access "enterprise Internets," but the term is usually applied to the global, publicly accessible network, called simply the Internet or Net. By the end of 2002, more than 100,000 networks and around 120 million users were connected via the Internet. According to Encarta Encyclopedia (2003), Internet connection is usually accomplished using international standards collectively called Transmission Control Protocol/Internet Protocol (TCP/IP), which are issued by an organization called the Internet Engineering Task Force, combined with a network registration process and with the aid of public providers of Internet access services, known as Internet service providers (ISPs). This global communications network consisting of thousands of networks typically interconnected by fiber-optic cabling had two parent networks whose joining began the ongoing evolution.

- U.S. Military (tactical communication in the event of telephone downtime during war-time)
- Academics (shared information between researchers).

Poverty: Poverty is an economic condition in which people lack sufficient income to obtain certain minimal levels of health services, food, housing, clothing and education, generally recognized as necessary to ensure an adequate standard of living. What is considered adequate, however,

depends on the average standard of living in a particular society. Poverty could be relative or absolute. Relative poverty is that experienced by those whose income falls considerably below the average for their particular society. Absolute poverty is that experienced by those who do not have enough food to remain healthy. However, estimating poverty on an income basis may not measure essential elements that also contribute to a healthy life. People without access to education or health services should be considered poor even if they have adequate food (Encarta, 2003).

Chapter 1.11

Telecommunications Sector and Internet Access in Africa

Vanessa Phala

LINK Centre, Research ICT Africa, and University of the Witwatersrand, South Africa

INTRODUCTION

The “information revolution” has not only transformed the world as we know it, but also its future potential. Information and Communication Technologies (ICT), with their major technological advances, have affected the lives and lifestyles of people across the globe, as well as the way institutions and organizations do business. However, not all outcomes of the spread of information technologies have been positive. A majority of the world’s population, especially those who live in poverty, have been largely bypassed by this revolution. The gap between them and the rest of the world has expanded precisely as a result of the facilitation capacity of these technologies for those who have access to them (Figueres, 2003). The majority of these people are situated in the African continent and other developing countries.

According to Jensen,³ from the study he conducted on the current status of information and communication technologies in Africa, the use of ICT has grown relatively rapidly in most urban areas in Africa. Five years ago, only a few countries had local Internet access, and now it is

available in every capital city. In the same five-year period, more mobile cell phones were deployed on the continent than the number of fixed lines laid in the entire previous century. Hundreds of new local and community radio stations have been licensed, and satellite TV is now also widely available. However, the digital divide is still at its most extreme in Africa, where the use of ICT is still at a very early stage of development compared to other regions of the world (Okpaku, 2003).

The history of the development and spread of computers in Africa can be traced back to the 1960’s when Ethiopia first introduced computers. This was followed in 1961 in Zimbabwe and Zambia and 1962 in Kenya and Nigeria. The spread of computers and related technologies raised broad a wave of fear about important social and economical issues concerning the loss of jobs. Regardless of this fear, computers became and are the vital tool for economic development of all countries. The spread of these technologies demanded effective legislations which to govern their usage and contributed to the formulation of national information and informatics polices in the 1970’ and 80’s (Adam, 2004).

In addition to this, during 1992-1996 Africans were introduced to the Internet and this further highlighted the importance of regulation. Most countries adopted policies which favored the promotion of privatization and competition. The period between 1996-2000 saw the birth of broad-based policy formulation around health, education and business. Many African countries adopted policies which allowed people to make use of the ICT to better their economic standard and increase their social status. The incorporation of Communications into Information Technology reinforced the importance of using Information and Communications Technology for development (i.e., e-education, e-health, e-commerce, e-democracy and so forth).

Currently, many African countries are racing towards achieving the Millennium Development Goals by using ICT as part of their development strategy. In addition, the spread of ICT has increased digital opportunities for some and a “digital divide” for the rest, especially in developing countries. It has also given rise to other important development challenges such as achieving real access to telecommunications, incorporating gender equity into ICT programmes, the importance and relevance of Intellectual Property Rights, the need to license VoIP (Voice over Internet Protocol) and VSAT, especially in poor nations, the need for Internet governance, and the right to communicate. Most of these issues were discussed during the first phase of the World Summit on Information Society in Geneva December 2003 and will be further discussed during the second phase in Tunis 2005.

According to the Fair Access to Internet Report (FAIR) produced by the Research ICT Africa (RIA) network⁴ concludes that Africa is the continent with the lowest diffusion of the Internet in the world. It has an average of only 111 users per 10,000 people and only three Internet hosts per 10,000 inhabitants (RIA, 2004). This is attributed primarily to the limited penetration, unreliable connections and high costs of usage of typical

of the communications infrastructure across the continent. The limited network roll-out and high prices are often attributed to the restrictive policy and regulatory environment and monopoly market structures that persist in many African communications sectors, which have contributed to low levels of competition.

The Research ICT Africa network has recently produced two research reports. The first was the FAIR analysis of Internet access that covered 13 African countries (i.e., Algeria, Cameroon, Ethiopia, Ghana, Cote D’Ivoire, Kenya, Mozambique, Namibia, Nigeria, Rwanda, South Africa, Uganda and Zambia). The second research report (Sector Performance Review) reviewed the performance of seven African countries’ (Cameroon, Ethiopia, Kenya, Rwanda, South Africa, Uganda and Zambia) telecommunications sector at the national level against their stated policy objectives and strategies. The main thrust was to determine which reform strategies are contributing positively to the realization and achievement of development objectives, and which ones are failing.

FINDINGS

Sector Performance Reviews

Though only seven case studies are reviewed in this paper, they reveal that development of the ICT sector continues to be highly uneven within countries and across the continent. What these studies also demonstrate is the lack of availability of statistical data, even from the major government departments and international reporting archives such as the International Telecommunication Union World Development Report Indicators. Further, where indicators did exist, they were often not appropriate to a developing-country context (Gillwald, 2004).

In addition, the report revealed that the primary objective of all countries reviewed was the improvement of access to telephony services, with

added commitment not only to network extension but also to modernization of the network in order to meet the needs of the modern economy.

Ironically, at least one of the regulatory regimes that has proven to be effective, has achieved its success as a result of a policy and regulatory vacuum that left the regulator neglected or ignored by central government. Uganda's regulator has emerged as a well-resourced, autonomous body, at least partially because mechanisms were not put in place to provide for its funding or accountability. The regulator set about resourcing itself through levies on the sector, which allowed it to attract and train personnel who could competently deliver on the regulator's legislated mandate (RIA, 2004).

In other cases, regulatory weakness has been a key dynamic. The weak Zambian regulatory regime has been identified as one of the factors contributing to the government's inability to privatize the incumbent PSTN. This, together with high license fees, has impacted on the emergence and sustainability of ISPs (Internet Service Providers) and the penetration of the Internet. Like other jurisdictions that have to date protected the rights and revenue streams of current incumbents (such as Cameroon, Ethiopia, Rwanda and South Africa), Zambia does not permit the deployment of cost-effective technologies such as Voice over IP (VoIP) outside of the existing incumbent.

In Ethiopia, which has seen some institutional reform since the 1996, legislation separated operations from regulation—through the creation of the Ethiopian Telecommunications Company and Ethiopian Telecommunications Agency. This provides one of the purest examples of state-provisioning, with a strict monopoly on fixed, cellular, Internet services and international gateways. With a regulatory agency that lacks political independence and human and financial resources, the likelihood of Ethiopia's monopoly PSTN being regulated to more effectively meet national needs seems remote. Unlike Uganda, where the loss-earning incumbent provider was

viewed as “a yoke around the government's neck” that had to be gotten rid of, the provider in Ethiopia is one of the few revenue streams for the government. As a result, by 2004 the government remained unconvinced that privatization would sufficiently compensate it for any loss of income. For the same reason, the Ethiopian government, like many other governments that have pursued monopolistic models, remained unconvinced of the benefits of liberalization in 2004.

A key area of difficulty in regulating incumbent PSTNs is interconnection. Generally, the problems around interconnection are caused by incumbent providers not being used to operating in a competitive environment or from them being regulated. In South Africa, despite a relatively sophisticated interconnection and facilities-leasing frameworks, the principle (drawn from international best practice) that new entrants or competitors are required by law to acquire their facilities from the incumbent provider and to enter into commercial agreements prior to regulatory intervention, have resulted in protracted negotiations, competition disputes and lengthy legal reviews. Generally, the incumbent monopoly providers have the financial resources to draw out negotiations so that new entrants are forced into agreement or forced out of business. Or incumbent monopoly providers can use their superior resources to tie up the regulator in the courts for years on end, challenging what they regard as unfavourable regulatory intervention. This has been the case in South Africa. In fact, in South Africa, it was a complaint brought by the VANS providers—including Internet Service Providers—to the Competition Commission that resulted in the commission recommending to the Competition Tribunal that the incumbent provider be fined 10 percent of total annual earnings for competition breaches.

The issue of interconnection highlights the need for appropriate regulatory models for developing countries, where regulators often have restricted human and financial resources. An

“access regulation” paradigm has developed globally in response to the emergence of a competitive environment. But under the highly imperfect market conditions that exist in many developing nations—where there are legacies of the “natural monopoly”—this form of regulation is overly resource-intensive and complex. Often the incumbent monopoly provider’s position is inherently anti-competitive, either because of the vertically-integrated market structure that inevitably exists or because of formal protection of certain of its activities.

What emerges starkly from the different country studies is the pattern of political, social and economic legacies that determine the ability of a country to respond to the challenges of globalization and, in particular, the so called “digital divide.” Each study unveils the impact of a country’s unique history. So that, whilst facing the already-stark global challenges of new technologies and liberalization, each country has, in addition, to confront the impact of its own history. This includes such events as apartheid in South Africa and Namibia, genocide in Rwanda, years of civil war in Ethiopia, ongoing violent dissent in Uganda, strong neo-colonial tendencies in Cameroon, and the collapse of the “mono-crop” copper economy in Zambia (www.researchICTafrica.net/homepage).

Fair Access to Internet Report (FAIR)

The purpose of this study was to understand the relationship between the market structure and regulatory frameworks, the cost of Internet connectivity and the levels of Internet penetration. The survey strategy was pragmatic rather than exhaustive, aiming to answer the minimum number of questions needed to derive simple yet reliable indexes—of market structure, associated regulatory frameworks and usage prices—which would then allow countries to be compared and ranked. To achieve this, survey tools were developed which aimed to place a value on the regula-

tory environment and the market structure and to determine the local prices for access Internet services.

The study aimed to develop indicators that would allow for comparison of market structures and costs of connectivity in different African countries. It also aimed to compare various strategies to reduce cost of access, and to understand the relationship between these measures and other development indicators, some of which have the potential to override ICT data (e.g., per capita GDP).

The ICT market structure and policy framework of the entire 13 countries studied were assessed by assigning points on a scale from one to five for a series of seven variables: fixed-line competition; state ownership of fixed-line operators; regulatory strength; technology openness; VSAT; WiFi/unlicensed spectrum; and interconnectivity. These variables were used to generate a comparison of the success of various strategies in reducing the cost of access to communications infrastructure. Equally important was the need to understand the relationships between these measures and other development indicators as indicated above.

The results from the study revealed that the impact of market structure and regulatory framework differs from one country to another, depending on the existing policy, market openness and the wealth of the country. Furthermore, the impacts differ for varying levels of Internet penetration. In South Africa, for example, there were more than 680 Internet users for every 10,000 inhabitants in 2002. This was due primarily to a high per capita income of US \$2,542 in 2001 compared to the continental average of US \$705 and to some extent due to the openness of the market and the effectiveness of the regulator. In comparison, Algeria, with a per capita income that was two-thirds that of South Africa’s, had fewer than 160 users per 10,000 inhabitants. But Nigeria, with a relatively high GDP per capita, had among the lowest number of Internet users,

while Kenya had a high number of users with a low GDP per capita. Generally, what emerged from the analysis was that cost of access has a dramatic impact on usage patterns. In terms of telecom prices, the report revealed that the costs of telecom facilities were high in Africa, and they impacted negatively on the usage levels (www.researchICTafrica.net/research).

However, the report acknowledged that other factors including privatization, competition and independent regulation could, and have, impacted on the provision of telecommunications services in Africa.

The report concludes by arguing that Internet growth in Africa was constrained by the low penetration rates for fixed-line telecom services, which set the geographical bounds for Internet participation. Other important factors were: basic access charges for telephone service; the start date of Internet provision, as that determined the number of months/years that Internet services had a chance to grow; access and usage charges for Internet service; disposable income; the extent to which countries had completed their telecom reform processes, prices charged by fixed-network operators to ISPs; the extent of competition in the supply of Internet services to the public; and the effectiveness of telecom regulation in providing a framework conducive to the development and growth of Internet services (www.researchICTafrica.net/research).

CONCLUSION

Though there has been some impressive growth and development in ICT adoption in some countries—particularly South Africa and Uganda—there were no cases of entirely open markets, with monopolistic or partially competitive markets not being regulated in an effective manner. Some markets had slightly more providers than others, and there was no market on the continent that provided a developed model by which to assess

competitive efficiency, price reductions and increased penetration rates.

In addition, the report acknowledged that available baseline data in African countries was often inaccurate and did not include the informal sector, which could be highly developed and yet was seldom reflected. The report recommended the development of methodologies and indicators that could reliably draw these activities into assessment.

KEY TERMS

ICT: Information and Communications Technology generally used in relation to any computer-based processes in which information and content are developed, shared and transmitted over local, regional or international boundaries.

Internet: A world wide interconnection of individual networks operated by government, industry, academia, and private parties.

ISPS: Internet Service Providers provide access to the Internet via different communications channels such as traditional telephone lines or high-speed fiber-optic channels.

PSTN: Public-Switched Telephone Network, consist of analog local loops that connect subscribers to the local central office, and digital facilities that link central offices together via various regional, long- distance, and international backbone.

VOIP: Voice over Internet Protocol applications send telephone voice calls over the Internet inexpensively, by transforming people’s voices into packet-based data.

WIFI: Wireless Fidelity networks use small, low-power antennas to carry voice and data communications between a backbone and users at schools, businesses, households and public places, all without laying a single wire, thus greatly reducing the cost of “traveling the last mile.”

ENDNOTES

- ¹ Vanessa Phala is the knowledge manager at the LINK Center and a Ph.D. student at Wits University, P&DM.
- ² The Learning Information Networking Knowledge (LINK) Centre is the leading public policy, regulation and management education body in the area of information and communication in Southern Africa. The mission of the Centre is to enhance capacity-building in the public sector and development arenas through quality training, applied research and consultancy services necessary to maximize the benefits of the information society and economy.
- ³ Mike Jensen is a research consultant on ICT in Africa.

- ⁴ Research ICT Africa is an ICT policy and regulatory resource base and research “collaboratory” for decision-makers in the public and private sectors and civil society, developing public-interest research findings through the networking of researchers at African universities. Built through the development of collaborative relationships among African institutions in Botswana, Cameroon, Ethiopia, Kenya, Mozambique, Namibia, Nigeria, Rwanda, Tanzania, Uganda, Zambia and South Africa, the network has linked with prestigious international research networks, such as LIRNE.NET, to create rigorous and independent research in the public domain.

Chapter 1.12

The Arab World, Culture, and Information Technology

Mohamed El Louadi
University of Tunis, Tunisia

INTRODUCTION

In 801, Harun Rashid offered Charlemagne a water clock, the like of which was inexistent in all of Europe at that time; the King's court thought that a little devil was hidden inside the clock. In the 1930s, King Abdulaziz of Saudi Arabia had to convince his people that the radio was not the making of the devil and that it could in fact be used to broadcast and spread the Quran. In 2003, the Arab region is found to be still lagging in modern technologies adoption (UNDP, 2003). Thus, in a little more than 11 centuries, the Arabs were transformed from leaders to adopters, then to late adopters as far as technologies are concerned.

The Arab world is taken to mean the 22 members of the Arab League, accounting for more than 300 million people with an economy of 700 billion dollars. Although most Arabs practice Islam, they represent less than one third of all Muslims. The Arab world is often thought of as economically prosperous due to its oil resources; yet its total GDP is lower than that of Spain (UNDP, 2003).

Arab countries share language and culture but differ in size, geography, demographics, govern-

ment type, etc. In terms of spending in and use of IT, statistics portray the Arab world as far from being up-to-date (UNDP, 2003).

This article raises the question of whether existing research models are appropriate to explain this delay. If certain characteristics proper to the Arab culture play an important role in explaining the delay in IT adoption, then we anticipate the answer to be that no existing model is able to adequately study the IT adoption phenomena in the Arab world.

THE ARAB WORLD AND IT

It is a recognized fact that the Arab world lags behind in terms of IT (Aberdeen, 2001; UNDP, 2003). (See Figure 1.) In 2001, Ajeeb reported that the number of Arab Web sites reached 1.24% of the Arab population (Ajeeb, 2001), it predicted that the number of Internet users would equal 5 million by 2001, and reiterated DITnet's March 2000 prediction that Internet users would number ten to twelve million by the end of 2002. In fact,

Figure 1. The MENA region is under-performing in terms of IT spending even when compared with other developing regions (Source: Aberdeen, 2001)

there were a reported 8.2 million users by the end of 2002.

To date, no Arab country has been able to develop its electronic commerce capabilities to the extent seen in the West.

REASONS FOR THE LAG

The lag can partly be explained by the delay with which technologies have traditionally reached Arab countries¹. Davison et al. (2000) suggested several other reasons: a perceived incompatibility between local cultures and imported technologies, a preference for autonomy and independence with respect to technology, and a lack of economic resources to acquire technology.

The first two of are plausible as is it often the case that IT stumbling blocks occur not because of technical reasons but rather because of human and social obstructions. The third reason can be excluded for the six Gulf countries which claim per capita revenues of nearly five times the average of the rest of the Arab countries. The rate of adoption of the Internet for these countries is up to fifteen times that of the rest of the Arab world.

Other factors also explain the low rate of Internet penetration in Arab nations as compared to the rest of the world. In these nations, the rate of penetration is essentially measured based on only one part of society: men.

The Arab Woman

Two thirds of the 65 million illiterate Arabs are women. Women make up only 4% of all Arab Internet users while in Europe women make up 42% on average². The UNDP states that the condition of women is one of the three main factors explaining the current state of economic development in the Arab world.

In that more than 40% of women in Arab countries are denied participation to the technological revolution, Arab nations are failing to integrate a considerable part of their human resources in their future economies.

Information and IT

When Arab countries invest in IT, they do so mainly in hardware. While this may be a characteristic of developing countries, it may also be

Figure 2a. While hardware is projected to represent less than 35% of all IT investments in the world...

Figure 2b. ...it will continue to represent more than 70% of all IT investments in the MENA region (Source: Aberdeen, 2001)

viewed as Arabs’ distrust of anything immaterial. Software on the other hand is associated with innovation, creativity, and the free flow of information and knowledge, qualities that the Arabs have been found lacking (UNDP, 2003). Thus, not only Arabs are increasing their dependence to the West being consumers of hardware, they seem to be passive users of the software and intelligence produced elsewhere.

This issue leads to the tight relationship between information (and not IT, let alone hardware) and democracy and freedom. If Arab countries are truly “information shy” (Henry, 1998), then what information is to be shared and circulated by IT? Therefore, the Arab does not see what use he could make of IT and would therefore not consider it an instrument of development.

Culture

Culture is “[the] collective programming of the mind that distinguishes the members of one group of people from those of another” (Hofstede, 1991). For Ibn Khaldun, 14th century Arab sociologist, man is son to his habits and his environment, not to his nature and his moods³.

Hill et al. (1998) claim that the Arab culture is one of the most complex of the world. It is complex

for several reasons. Though the majority of Arabs are Muslim, many are Jewish or Christian while others are agnostic and even atheists. Many actions and symbols assume a particular significance. Often in traditional Arab cultures a handshake or the spoken word are seen as more legally binding than a signed contract and the written word has less significance than in other cultures⁴.

For Arabs bartering is very different from what the West calls negotiating. The numerous steps involved in bartering hold social meanings, the least of which is to learn about and get more acquainted with the other so as to build trust in terms of the product quality. Selling and buying are social acts not replicated by technology.

In his study of Qatari and Emirati cultures, Solberg (2002) found that “wasta” (social connections and string-pulling) could be used to lower the level of uncertainty during business transactions. Even when more direct means are available, Arabs prefer wasta because of the human contact it offers. Wasta is a way of life that builds upon human interactions, a major part of an Arab’s life, which she or he may not be willing to sacrifice to technology.

Arabs tend to be more talkative than Westerners; they are fond of sentences with several adjectives, the number of which, combined with

the length of sentences and the tone of the voice, make up an integral part of the message. For example, when a guest is offered a cookie, it is customary to not accept too keenly or quickly. It is up to the host to insist (invoking God) to convert the initial refusal into a yes⁵. Arabs rarely say yes or no, rather, they are inclined to answer using less committed terms such as “usually” and “Inshallah”. The design of computer interfaces with only the “yes”, “no” and “cancel” options is clearly rooted in other cultural norms.

THEORIES AND RESEARCH MODELS

Many research models are available to study IT adoption. Flowers et al. (1975), for example, built upon the framework of Graves (1970) in which people would evolve through levels of “psychological existence” reflecting their personal values and lifestyles, which vary with their cultural programming.

Research using this framework suggests that dominant value systems of Middle-Eastern managers are conformist, sociocentric and existential and their dominant decision-making style is consultative (Amirshahi, 1997).

Another important stream is represented by Hofstede’s work (1991) which considers culture a national trait. The results of Hofstede’s research is a typology of cultures based on five cultural dimensions: power distance, individualism, masculinity, uncertainty avoidance, and long-term orientation⁶.

In research pertaining to IT, some dimensions have been invoked more than others: individualism (Jarvenpaa et al., 1999), power distance (Simon, 2001) and masculinity (Hofstede, 2001b). Findings from Hofstede (2001b) show a relationship between masculinity and fax machines, and femininity and cellular phones. Like authority, a masculine trait, a fax is not interactive; and like

exchange and dialogue, which are feminine traits, a cellular phone is interactive.

Certain Arab values could be mapped onto Hofstede’s cultural dimensions⁷. What one calls “*maslaha el amma*” (public interest) happens to mean the exact opposite of individualism. In the Arab culture, public interest could even be extended to the notion of Umma (nation). Family commitments and responsibility towards authority figures and political leaders are often held as priorities over other matters. Arabs from the Gulf swear allegiance to the family, clan, tribe, religion, and nation⁸ (Abbas, 1987). Usunier (1993) suggests that Arab cultures tend to resemble cultures that are focused on the present and for whom the future (destiny) is inevitably predestined (Mektoub) by God (Inshallah: God willing). For Patai (1973), fatalism is a predominant trait of the Arab culture. If past-oriented cultures are more passive than future-oriented cultures, the Arabs should have an attitude that can be summarized as “if it is written then it will happen” henceforth they will not feel the urge to go toward the technology and will expect it to come to them⁹.

LIMITATIONS OF EXISTING MODELS

The Absence of Arab Dimensions

If in Hofstede’s model, the first four dimensions are applicable to other cultures, it would be useful to more closely study Arab values in order to include them in existing models.

Cultures are likely to diverge rather than come together as we would assume on the basis of globalization and the democratization of media. Hofstede (2001b) has shown that cultures are diverging rather than converging. More specifically, current world events do not lend support to the hypothesis that Arab and Western cultures are closing in.

Current research models would therefore benefit from including Arab dimensions; otherwise they would risk being applicable only to those cultures for which they were developed or for the Arab culture to continue being perceived through the lens of another culture. This could be done following the example of the Far East cultures. These cultures were really only taken into account into Hofstede's model with the addition of the fifth dimension, Confucian dynamism, thereafter called long-term orientation. It was added in order to complete Hofstede's model since it was the dimension that distinguished western and far-eastern cultures.

The Implicit Cultural Homogeneity

Differences exist among Arab countries (Solberg, 2002), and even between different regions of a same country. This is even more noticeable as the borders between Arab countries were often drawn arbitrarily during colonization.

Fundamental cultural differences exist between Sunnis and Shiites, among them masculinity (Noland, 2003). Sunnis are considered more "triumphant" (sic.) while Shiites focus more on suffering. The two strains of Islam could therefore be considered at the extremes of the masculinity dimension although scores for this dimension place the Arab world at the midpoint of the scale. However, even Sunnis bear certain feminine traits such as seeking good relationships with leaders and cooperating with colleagues in order to foster equally good relationships with them (Weir, 2001).

Differences can also be found between the cultures of the Gulf and other nations of the Arab world. The discovery of oil in the 1930s resulted in an odd mix of traditional and tribal cultures with modern cultures. This mix did not manifest itself in North Africa resulting in the Arab world composed of countries generally having either people or oil¹⁰. Furthermore, North African countries have not always had Arab identity.

Unlike the Gulf countries, they became Arabs at the same time as Muslims.

The Cultural Barrier

Arabs, Arab culture, and Arab religion have always been a black box for the Westerner. For instance, some westerners have a near-Manichean tendency to dichotomize (Good vs. Evil, Them vs. Us, etc.) and are fond of clash-of-civilizations theories (see Huntington, 1996). El-Solh and Mabro (1994, p. 14) show how the application of over-simplistic dichotomies to the study of gender relations in the Middle East have left out much of the flexibility women might have in actual terms. The simple idea that the sexes have a complementary role in Arab society has often been misunderstood in Western studies as a binary opposition with a tacit hierarchy.

Furthermore, if by fatalism it is understood that humans have no say in their destiny, then the concept of time orientation of Patai (1973) originates from a fundamentally inaccurate understanding of a large part of the Arab world. Islam is founded on the promise of salvation (Jenna) or the threat of damnation (Jehenna). Debates on the "kadha and kadar"¹¹ (destiny and predestination) continue to fuel the controversy that divides theologians on the issue. Suffice it to mention that Arab societies do not necessarily neatly fit within cultures anchored in either the past or the present.

CONCLUSION

Significant contradictions may exist between how Arabs perceive themselves and how they are perceived by others. For example, Hill et al. (1998) argue that the adoption of technologies is rarely in quest of imitating the West. But Ibn Khaldun maintains that imitation is characteristic of Arabs. Abbas and Al-Shakti, (1985) even suggested that Arab executives are the product of cultural values that tend to produce more followers than

leaders. Yet, imitation is sometimes suspicious in the Muslim's eye as some believe that imitation of the non-Muslims is "haram" (sinful) While it is also believed that imitating non-Muslims is permissible, the average Arab Muslim sometimes wonders when imitation stops being haram and starts being hallal (allowed)¹². How to reconcile these points of view?

Two theories seem promising in that they may complement the research models we reviewed here. Social Identity Theory recognizes that cultural layers exist that describe different levels of programming (social, national, regional, religious, contextual, organizational, etc.).

Abdul-Gader and Kozar (1995) borrowed the construct of technological alienation from psychosociology to explain certain purchase and use decisions of IT. They showed that alienated individuals resist any kind of technology adoption. More generally, Value-Expectancy Theory (Feather, 1995) promises to enrich the debate on IT adoption by Arabs since it addresses the issue of the value attributed to things by individuals and their expectations, founded or not, such as their resistance to the possible danger of technological and cultural dependence. This is all the more valid that Arabs view IT as a technology, not as a medium of knowledge and of accessing knowledge, something they need direly as evidenced by the conclusions of the UNDP (2003).

KEY TERMS

Arab World: The Arab world is taken to include all 22 countries members of the Arab League.

Culture: According to Hofstede (1991), it is “[the] collective programming of the mind that distinguishes the members of one group of people from those of another”. For the 14th century Arab scholar, Ibn Khaldun, man is son to his habits and his environment, not to his nature and his moods. In all the literature about culture, there is a common understanding that culture is an abstraction from concrete behaviour but is not behaviour itself. Hofstede’s typology includes five cultural dimensions:

- **Individualism:** as opposed to collectivism, describes the degree to which a culture relies on and has allegiance to the self or the group.
- **Power Distance:** reflects the degree to which a culture believes how institutional and organizational power should be distributed.
- **Masculinity:** indicates the degree to which a culture values such behaviours as assertiveness, achievement, acquisition of wealth, social supports and the quality of life.
- **Uncertainty Avoidance:** refers to the extent to which a culture feels threatened by ambiguous, uncertain situations and tries to avoid them.
- **Long-Term Orientation:** reflects the degree to which a culture is oriented toward the search for virtuous behaviour rather than being oriented towards the search for truth.

Information Technology: Hardware, software, network and services related to the use and operation of equipment with the aim of processing and communication of analogue and digital data, information, and knowledge. These include computers and computer applications such as the Internet, Intranets, Extranets, Electronic Data Interchange, electronic commerce, mobile and fixed lines, etc.

ENDNOTES

¹ Most technological innovations are adopted by the Arabs with some delay. For example, if the printing press was invented around 1450, the first Arab book to have been printed was the Quran, in 1537 in Venice. Arabic character-based printing reached the Arabs only in 1728 under the reign of Ahmed III (1703-1730) when the Arabs were occupied by the Ottoman Empire. Bukhara (today's

Uzbekistan) delayed the introduction of printing until 1917 (See Khalid, 1994). It is as though in the Muslim world, the advent of printing broke the ulama's long-established control of knowledge. Similarly to the Bible and the printing press, no longer could knowledge be obtained through someone "more knowledgeable". It could be read and understood - or misunderstood—in libraries, schools, and even homes. Later, while e-mail was invented in 1971, the first Arabic Web-based mail solution was released in December 1998 (see <http://web1.maktoob.com/maktoob/press1998/press1998-1.html>). See more on Kaitlin Duck Sherwood's site, <http://www.webfoot.com/advice/WrittenArabic.html>.

² Nielsen//NetRatings (May 2003), www.journal_dunet.com/cc/01_internautes/inter_profil_eu.shtml, accessed August 31, 2003.

³ Ibn Khaldun, *The Muqaddimah, An Introduction to History*, Translated from French by F. Rosenthal, Princeton, 1958; 1967.

⁴ For Muslim Arabs, this may be explained historically and religiously by the fact that when the Divine message was delivered, the Angel Gabriel dictated the Quranic verses to the Prophet Muhammad. In all pre-modern times, documents were not copied; they were memorized, where there was no other way to preserve them.

⁵ In his book, "The Saddam Years" (Fayard, 2003), Saman Abdul Majid, personal interpreter to the deposed dictator, explains how, in 1993, President Clinton sent a secret agent to Iraq to suggest that a new leaf be turned over and that discussions be resumed. Saddam did not immediately answer, an act that Clinton took as a refusal. That file was then closed. In fact, Saddam was expecting a more solid and thought-out proposition to be put forward, and was surprised that Clinton did not come through with one. This mis-

communication between two men of very different cultures has had the now all-too known consequences.

⁶ It is assumed that most readers are familiar with Hofstede's work. Due to space limitations, details of his work will not be elaborated here. For more information, the reader is referred to Hofstede (2001b).

⁷ Also of interest is the GLOBE (Global Leader and Organizational Behavior Effectiveness) project which seeks to determine the relationship between leadership and societal culture (House et al., 2002). GLOBE uses nine dimensions, six of which are the same as Hofstede's: uncertainty avoidance, power distance, institutional collectivism, in-group collectivism, gender egalitarianism, assertiveness, future orientation, performance orientation, and humane orientation. Using these dimensions, Gupta et al. (2002) identified 10 "cultural clusters": Asia, Anglo, Arab, Germanic Europe, Latin Europe, Eastern Europe, Confucian Asia, Latin America, Sub-Sahara Africa and Nordic Europe. Unfortunately, often in GLOBE papers, the Arab cluster is composed of very few countries (see Abdalla and Al-Homoud, 2001). Other countries, such as Turkey, have disconcertingly been found in such "Arab clusters" (see Kabasakal & Bodur, 2002) ignoring the fact that Turkey is not a member of the Arab League and overlooking its claim to European Union membership.

⁸ Perhaps even in this order, especially if one takes into account the famous proverb in which an Arab states: "Me, against my

brother; my brother and I against our cousin; my brother, my cousin and I against all others." Was it not written of Ishmael (and by extension of all Arab children) in the Bible that "And he will be a wild man; his hand will be against every man, and every man's hand against him; and he shall dwell in the presence of all his brethren" (Genesis 16:12). This, however, does not seem to hold any longer given the events that took place between Iraq and Kuwait in 1990-1991 as well as since then.

⁹ Judging by the lack of cultural sensitivity of today's graphical user interfaces and icons, that technology is all but coming to the Arab culture.

¹⁰ The only exception being Iraq.

¹¹ This highly philosophical issue revolves around the overly simplified question that if God had already decided on much of what we humans will do on Earth even before we were created, what is the Last Judgment about?

¹² One has to remember that the digging of the trenches around Madina in the battle of Al-Ahzab, which was led by the prophet Mohamed (Peace Be Upon Him) and his companions as a defense system, and the application of Omar Ibn Al-Khattab, the second khalif after the prophet, of the filing system in the Islamic State, for organizing taxes on cultivated land and payroll of the soldiers are examples of imitation as they were borrowed from Non-Muslim Persians (see more on this subject on www.islam1.org/khutub/Imitation_of_None-Muslims.htm, accessed April 13, 2004).

Chapter 1.13

ICT Growth and Diffusion: Concepts, Impacts, and Policy Issues in the Indian Experience with Reference to the International Digital Divide

Saundarjya Borbora
IIT Guwahati, India

ABSTRACT

This chapter examines the role of technology in economic and social development in developing countries, with a particular emphasis on India as an example. The concepts of ICT growth and ICT diffusion are examined. From this the chapter reviews the Indian government's successful policies encouraging ICT Growth through the support of the export-oriented service industry. This industry has witnessed long-term growth primarily as the result of the increasing tradability and consequent internationalisation made possible by changes in ICTs. However, the export focus policy has created enclaves within the Indian economy without significant forward and backward linkages. Evidence suggests that the International Digital Divide may be increasing. This chapter suggests that in order to maintain its relative technological position and to increase its comparative advantage in the IT sector, government policy should focus on domestic

ICT Diffusion. The chapter reviews several local public, private, and public-private initiatives to spread the use of ICT throughout Indian regions that have been successful and may serve to offer examples for future development. We conclude that ICT-driven development may be achieved with supportive central government policies, lessening the International Digital Divide.

INTRODUCTION

Today Information and Communication Technologies (ICTs) pervade almost all human activities. In both developed and developing countries there is an intense debate concerning the contribution of these technologies towards economic development and, consequently, human welfare. In relation to the economic benefits, several cross-country studies in recent years have indicated that the return on investment in information technology created by

increasing productivity and growth is substantial (Kraemer and Dedrick, 2001; Pohjola, 2001). According to Pohjola's study, the output elasticity of IT capital was found to be 0.31 for a sample of 39 countries, which is quite high, and a figure of 0.23 in the OECD sub-sample. Another cross-country study by the IMF (2001) also provides a similar conclusion. Country-specific studies, of Singapore for example, have concluded that the net return to IT capital is 37.9 percent compared to 14.6 percent for non-IT capital, which is about two and a half times higher (Wong, 2001). These studies also highlight that IT-induced productivity, and thereby economic development, is still concentrated in developed countries and the developing countries are yet to gain the same order of benefits as their counterparts in developed economies.

This leads us to the ongoing debate over the International Digital Divide. Examining the present unequal access to ICT, it may be stated that new technologies reinforce the disparities between developed societies and developing societies. Several studies supplement this view. OECD (2000) stated that affluent states at the cutting edge of technological advantage have reinforced their lead in the knowledge economy. The benefits enjoyed by the most technologically advanced economies have not yet trickled down to their neighbors. Many European countries are still behind the most advanced countries, not to speak of poor countries in the Sub-Saharan Africa, Latin America or South East Asia that are much further behind. Similarly, UNDP (1999) argues that productivity gains from ICT may actually widen the gulf between the developed economies and those that lack the skills, resources, and infrastructure to invest in ICT.

The impact of ICT can be seen from the perspective of two inter-related issues: ICT growth and ICT diffusion. ICT growth refers to the growth of IT-related industries and services and their effect on employment, export earnings,

and the outsourcing of activities. ICT diffusion refers to IT-induced development, which increases productivity, competitiveness, economic growth, and human welfare from the use of the technology by different sectors of the economy. Until now, India has mainly benefited from ICT growth through a series of institutional innovations and policy measures, although it would not be correct to say that the importance of ICT diffusion has not been recognized. For example, the software policy of 1986 explicitly recognized the importance of the balanced development of the software industry both for export and domestic use. But of late emphasis has been given to the diffusion of new technology and ICT-induced development. Therefore, in the Indian context, the often-cited success of the IT sector has not been achieved by the harnessing of new technology to increase efficiency and productivity, but mainly derived from earning foreign exchange by exporting IT-enabled goods and services. India's export performance in this sector is noteworthy in comparison with other producers of exports, not only in terms of its growth rates but also in terms of its stability.

The current chapter will focus on the direct benefits of ICT growth, paying special attention to the service sector. We argue that the role of IT in economic development has not received adequate attention. The purpose of the chapter is to highlight the contemporary economic realities and to suggest that the ICT development should be the focus of research and policymaking in India. We propose to undertake this both on the basis of empirical facts and on the basis of the arguments regarding the International Digital Divide. The central message of this chapter is that although ICT growth is important for developing countries such as India, it is time to shift the focus towards ICT-induced development. The following section subjects these issues to analytical and empirical scrutiny within the limits of data availability.

THE DIGITAL DIVIDE

The concept of the Digital Divide is a complex one that manifests itself in different ways in different countries. This leads us to accept that there is no single definition of the Digital Divide, although it is clear that there are growing disparities between the “haves” and “have-nots,” and to conclude that the potential impact on society will be exacerbated by technology. This divide poses both practical and policy challenges. It is also evident that solutions that work in developed countries cannot simply be transplanted to a developing country’s environment. Solutions must be based on an understanding of local needs and conditions.

Broadly, we can examine both International and Domestic Digital Divides. Real disparities exist both in the access to and the use of information and communication technology between countries (the International Digital Divide) and between groups within countries (the Domestic Digital Divide). The concept of the Digital Divide is grounded in substantial empirical research (Norris, 2001) and the extent of the Divide can be suggested with some statistics: “In the entire continent of Africa, there are a mere 14 million phone lines – fewer than in either Manhattan or Tokyo. Wealthy nations comprise some 16 percent of the world’s population, but command 90 percent of Internet host computers. Of all the Internet users worldwide, 60 percent reside in North America, where a mere five percent of world’s population reside” (Nkrumah, 2000). In addition to this, even the positive outlook adopted by the Economist (2000) accepted that “One in two Americans is online, compared with only one in 250 Africans. In Bangladesh a computer costs the equivalent of eight years’ average pay.” From such studies and statistics, the following patterns emerge:

There is a trend of growing ICT disparities between and within countries:

- All countries are increasing their access to and use of ICT. But those countries that are

the “information haves” are increasing their access and use at such an exponential rate that, in effect, the divide between countries is actually growing.

- Within countries, all groups are increasing access to ICT. But the “information haves” are increasing access and use at such an exponential rate that the division within countries is actually growing.

ICT DIFFUSION

The Digital Divide is not a simple phenomenon, but a complicated overlapping set of issues created by varying levels of ICT access, basic ICT usage, and the patterns of ICT applications among countries and peoples. Developing countries may have to achieve higher levels of *per capita* income in order to support the level of IT dissemination throughout society that is a precondition for ICT-induced development. However, due to the characteristics of ICTs, the leapfrogging of stages of development is possible as long as supportive government policies are in place. In fact it can be argued that there is an advantage in not having the problems associated with obsolete IT infrastructures and legacy systems typical in early investing countries for late entrants. Investment made in new technologies also complements investments already made in communication technologies such as satellites, telephone, and cable networks. Again newly developed technologies like the “wireless in local loop” (WILL) can significantly reduce the cost of last-mile connectivity, making it possible to connect remote villages cost-effectively (Planning Commission, 2001). Many new computer technologies are essentially multi-user by nature and there is scope for Internet kiosks, community Internet centers and hubs to provide access for many users. As previously indicated, late entrants such as India have the advantage of access to frontline technologies and cost-effective infrastructure development without the sunk costs in extant systems carried by many more developed

countries (Planning Commission, 2001). There exists real opportunities for promoting ICT diffusion through the involvement of both the public and private sectors, NGOs and other stakeholders (Mansell, 1999).

The new technologies are mostly supply-driven and provide a greater scope for diffusion agents to influence the technology diffusion process. There are a large number of organizations involved in developing country's ICT development and adoption. This multi-institutional stakeholder network should be in the forefront of diffusion of ICT in developing countries. In India recently there have been a number of ICT diffusion initiatives undertaken by the government, the private sector, and NGOs for economic development and to provide services to citizens. Some of the initiatives are in the initial stages, but acceptance by local communities has the potential to transform technological usage in rural areas of the country.

Bridging the Digital Divide: Selected Experiments from Indian States

The following section details some of the government initiatives that are underpinning technological change in Indian regions. This does not seek to be a comprehensive survey, but rather to present a selection of initiatives to give a feel for the type of development plans currently being undertaken. The first example examines an initiative in the state of Andhra Pradesh, which includes 23 districts, 1,125 mandals, 295 assembly constituencies and 28,245 revenue villages. This area has been digitized to a certain extent by a state-wide area network (SWAN) called APSWAN. With this SWAN the state is in a position to provide government-to-citizen services. Agricultural market yards have been computerized and connected with state headquarters, providing the prices of commodities and arrival times to markets and other important information to agriculturists. This process has the aim of eliminating middlemen and, in policy terms, the exploitation of farmers.

This digital connectivity also brings transparency and efficiency to the functioning of government. Other states are also trying to undertake similar projects.

The second example considers the Gyandoot Dotcom project in Madhya Pradesh, which has demonstrated the feasibility of universal access to information. The Dhar district has been connected by 21 centers situated in 30 villages using locally made servers and multimedia kits in a cost-effective way. Villagers are required to pay a nominal charge for services such as accessing land records and for regular market updates. Each of these centers has a potential clientele of around half a million inhabitants in the Dhar district. The success has emphasized the social and economic benefits of mass empowerment. The potential of this project has been recognized internationally for introducing a new paradigm in the use of IT in bringing about social transformation.

In addition, the region of Uttar Pradesh provides more examples of central and state government-initiated ICT service-based projects. Initiatives such as Internet kiosks providing e-mail and access to computer education programmes are common. In eastern UP, for example, Kashika Telecom has established a presence in low-cost dhabas (computer kiosks) financed through bank loans. Such initiatives can be seen in Karnataka, Tamil Nadu as well in the North Eastern States of India.

The private sector also has been responsible for developing new IT initiatives. The Zee Interactive Learning System Project, for example, provides interactive multimedia learning using satellite, video, Internet, and a cable network for delivery at several "ZED point" kiosks. This is directed towards educating rural children by constructing "knowledge building communities" at an affordable cost even to the rural population. With a continuing focus on education, the Intel Corporation has taken the initiative to set up teacher training laboratories to train 100,000 schoolteachers in India. At the time of this writing,

Table 1. Indicators of IT use in India's industrial sector, 1997

Industries	Total no. of Factories	Percent of Factories with:			
		Computers in office	Network	Internet	Robots or computer in production
Food products	14,695	13.01	0.84	1.39	0.29

Intel also envisages operating a “cyber school on wheels” project also targeted toward educating rural masses.

Despite the initiatives outlined above, there is no specific central government policy for ICT diffusion in India. However, the current evidence

suggests that there has been some degree of ICT diffusion created by both the activities of industry and discrete public and private initiatives. Within India, computers for accounting and management functions are widespread, especially in private enterprises (as in Table 1). With regard to Internet

use, some industries are ahead of others. Evidence shows, in this time of liberalization and globalization, that some firms are using technology to increase their productivity and competitiveness. Some degree of ICT diffusion has been taking place, although it may be mostly confined to the manufacturing sectors of the economy, even though this has been a low central government political priority.

ICT AND THE SERVICE SECTOR

Economic globalization has facilitated the internationalization of the service sector and the advances in ICTs have made it possible for firms to provide novel services that are creating new forms of international trade. Service industries provide links between geographically dispersed economic activities and play an important role in the growing interdependence of markets and production activities across nations. As technology develops, it further reduces communication costs, stimulating the faster growth of the international trade in services.

For developing countries such as India, the internationalization of services and the development of the ICT sector have provided an opportunity as well as a challenge. The opportunity has been in terms of the potential exports of services and of service-related foreign investments and trade. The challenges are for designing appropriate regulatory environments for the service sector as it is an important factor influencing productivity and competitiveness, providing the necessary investments in the ICT sector and adapting the education system in line with the requirements of the Information Age.

Until recently economists characterized the service sector as generally non-tradable activities whose growth was perceived to be a by-product of expansion of the primary and secondary sectors. The changes in the service sector driven by development in ICTs have changed this concep-

tion and today service industries are regarded as a pre-condition of economic growth. The main growth in this area has been the rapid expansion of knowledge-intensive services (KIS), such as professional and technical services, advanced health care, education, banking, and insurance. The growing tradability of services has been a direct outcome of these changes, and many developing countries have benefited from the outsourcing of services by multi-national companies (MNCs) made possible by ICTs. Today service industries are important investors in IT throughout the world, and KISs that have high income elasticity are growing in both developed and developing economies. Technological innovation has expanded the opportunities for the provision of services, and electronic networks such as the Internet are a dynamic force for creating new possibilities for trade between distant areas. Technological developments in ICTs are driving not only the internationalization of services but also of manufacturing and primary industries, as technology blurs the boundaries between products and services. In the United States, for example, as much as 65 to 75 percent of employment in manufacturing may be associated with service-based activities (Braga, 1996). With falling communication costs the potential for international outsourcing in both the service and manufacturing industries has grown.

Service activities such as data entry, the analysis of income statements, the development of computer software and financial products are mostly exportable services. The impact of ICTs on the tradability of services is not only limited to international markets, but has facilitated the expansion of services within and between regions, from firms to final consumers. Even services in which consumer-provider interaction has been very high, such as education and health services, are today offered using high technology in ICT. Advances in computer-mediated technology make it possible to effectively gain the benefits in distance education and tele-medicine without

relocating to provider locations. Trade in commercial services has been growing exponentially, and with the internationalization of services the flow of FDI to developing countries has increased faster than global trade and output. Services now represent a much higher share of FDI. The prospect for the continuing internationalization of services through FDI is bright as the demand for services is still in the growth phase. Developing countries are attracted to FDI in services as a means of obtaining the transfer of technical and professional skills and know-how.

As modern service industries are highly ICT-dependent they require human and financial capital input. Developing countries such as India are carving out areas of comparative advantage in IT-based services, and one of their key strengths is the ability to offer access to large numbers of highly trained and lower-cost IT professionals. This phenomenon not only acts to expand exports, but also helps domestic producers gain access to more efficient and diversified services in world markets. Efficient producer services are increasingly important in this outward-oriented development strategy.

Developing countries have much scope for the expansion of traditional service export areas. Data entry was one of the first services to be the subject of international outsourcing. Software programming is another activity that is increasingly traded internationally. India has taken a big lead in these areas and one estimate suggests that India has captured roughly 12 percent of the international market for customized software. Yet another area of strong comparative advantage is in “back office” service activities. For example, several US and UK-based insurance and accounting companies now send claims overseas for processing. In manufacturing, service activities such as logistics management, design, and customer services are being outsourced internationally. It may be difficult to estimate precisely the size of these markets, but from the perspective of developing

countries the potential impact in terms of higher exports over the long term is significant. These important developments reveal that developing countries with large workforces and a modern technology infrastructure can successfully exploit the changing patterns of international production made possible by ICTs.

THE INDIAN IT EXPORT SCENARIO

The growth of IT exports from India over the last decade has been the subject of considerable interest to developed as well as developing economies. This attention has been stimulated by studies demonstrating that the spillover benefits and linkages with the rest of the economy from the IT sector are extensive (Joseph, 2002). The contribution made by Software Exports to India’s Economy is shown in Table 2.

Table 2 illustrates the sustained growth of foreign exchange earnings represented by Software Exports to the Indian economy, and highlights the rapid increase made after the liberalization of the Indian economy to the international services sector began in 1991.

Whether the IT sector with its export-oriented growth strategy will generate significant spillovers and linkage effects with the rest of the economy is not the focus of this chapter, but on the basis of available data this seems unlikely. The Indian IT industry appears to be locked into activities such as low-level design, coding and maintenance with negligible linkages to rest of the economy (D’Costa, 2001). As these activities are primarily driven by the export market, the growth of this sector remains an enclave of the general economy without many forward or backward linkages. In terms of the spatial location of the industry, approximately 90 percent of software development and export is confined to the four major metropolitan areas of Bangalore, Mumbai, Delhi and Chennai (as shown in Table 3), leading

ICT Growth and Diffusion

Table 2. India's software exports (gross foreign exchange earnings)

Year	Software Exports(US\$m)	Export Growth (%)
1980	4.0	-
1981	6.8	70%
1982	13.5	99%
1983	18.2	35%
1984	25.3	39%
1985	27.7	9%
1986	38.9	40%

Mansell (1999) to perceive that export-oriented IT growth would seem to have generated marginal spillover benefits.

The IT sector export-based strategy has been successful in India primarily as a result of the outsourcing of services by the firms based in the developed economies. India has been the focus for many Western firms as its competitive advantage is based on technological agility, flexibility, cost control, time-to-market and quality. These advantages are rooted in the established education sector, and Indian technology institutes are acknowledged as world-leading institutions that

select and train IT professionals. 115,000 Indian IT professionals graduate annually in a country with an English speaking population of around 1 billion people. There is expansion in the IT market with more than 3,000 Indian software exporting companies currently having export relationships with over 100 countries. Some of the leading Indian companies are registered with the NYSE or Nasdaq.

It should be noted here that the IT sector is highly labour intensive, and one that employs mostly skilled labour, although the level of this varies with the nature of a firm's activities. Avail-

Table 3. Distribution of software sales and exports across major locations in India

Location	Sales %		Exports %	
	1997	1998	1997	1998

Source: Heeks (1999), adapted from Rubin (1996)

able empirical evidence suggests that the IT export boom of the last decade should be considered in the context of India's labour cost advantage (as shown in Table 4). The IT sector upswing has led to increases in the demand for labour and also wage rates.

Table 4 reflects India's cost advantage in relation to skilled employable labour in the IT sector.

More than this, off-shore IT work is also cheaper for MNCs than employing Indian IT labour onsite. For example, using data invoice processing as an example, onsite work at the client's site would cost US \$8,000 (plus local taxes) as opposed to US \$4,600 offsite in India (Heeks, 1999).

POLICY MEASURES SUPPORTIVE OF IT GROWTH IN THE INDIAN EXPERIENCE

The importance of promoting the software development industry has long been recognized in India by the Department of Electronics (DoE), and suitable supportive policies were in place as far back as in 1972 (Parthasarathi and Joseph, 2002). By 1982 the DoE had begun concentrating on software export promotion policies, and the Computer Policy of 1984 gave further thrust to the industry by underlining the need for institutional and policy support in key areas. The accelerated growth of the computer industry after 1984 created calls for the rationalization of the import policies and for additional export promotion. As a result of this, a new policy was announced in 1986 that identified software specifically as one of the key areas for export promotion and underlined the importance of an integrated approach to the development of software for both domestic and export markets. This policy had the following major objectives:

- To promote software exports to take a quantum leap and capture a sizeable share in international software markets;
- To promote the integrated development of the national software industry for both domestic and export markets;
- To simplify existing procedures allowing the software industry to grow faster;
- To establish a strong base for the national software industry in India;
- To promote the use of the computer as a decision-making tool, to increase work efficiency, and to promote appropriate applications in order to gain long-term benefits of computerization for the economy.

To achieve these objectives various commercial incentives were provided to software firms. These measures included tax holidays, income-tax

exemption on software exports, and the subsidized and duty-free import of hardware and software used for export industries.

In 1991 the Indian government began to open the economy with a programme of market liberalization and economic reform. At that time the Indian government's assessment of the IT industry was that India had a comparative advantage in the software export market but not the hardware sector. Following this evaluation, the government consciously prioritized software exports and new policy measures were initiated to support this strategy, including the removal of entry barriers for foreign companies, the lifting of restrictions on foreign technology transfers, the participation of the private sector in policymaking, the provision of finance through equity and venture capital, reforms for faster and cheaper data communication facilities, and the rationalization of taxes and tariffs (Narayanmurthy, 2000).

In addition to these measures the Indian government also undertook a series of institutional reforms including the establishment of an integrated Ministry of Communications and Information Technology. One key development stemming from these reform was the establishment of Software Technology Parks (STP) to provide the necessary infrastructure for software exports. At the time of this writing, there are 18 STPs in India throughout the country and these play a significant role in exports. The total number of units registered with the STPs increased from 164 in 1991 to 5,582 in 1999, accounting for about 68 percent of all Indian IT Exports (Table 5). The facilities in these STPs include, amongst others, modern computers and communication networks that are beyond the reach of individual firms. In June 2000 a new STP consisting of a business support center and an India Infotech Center was set up in Silicon Valley to facilitate software exports by small and medium Indian firms to the US (Economic Times, 2000). The center also fosters business relationships by providing access to US financial institutions, venture capitalists and

Table 5. Trends in IT exports from units registered with software technology parks

Year	No. of units registered With STPs	Total exports from India (US\$million)	Share of STP units in total exports
1991-92	164	164	na
1992-93	227	225	8
1993-94	269	330	12
1994-95	364	485	16
1995-96	521	734	29

1999-2000	5582	3900	68

Source: Joseph, 2002

specialized trade bodies to promote partnership between the US and Indian ICT software and service companies.

The success of the aforementioned policies and of the STPs led to an appreciable growth of investment in ICT exports (Venkitesh, 1995). The growth of the sector outstripped that of the workforce, leading to eventual labour constraints (Schware, 1987; Sen, 1995). Traditionally the main source of ICT and software professionals was from Indian public-sector educational institutes such as the Indian Institutes of Technology (IITs), Industrial Training Institutes (ITIs) and engineering colleges, as well as additional public-sector institutions such as C-DAC and CMC, Ltd. engaged in training computer personnel. With the demand for skilled IT-sector labour increasing in the early 1980s, the Government permitted private investment in IT training. Today, there are private companies running training centers throughout the country through franchise networks offering many courses. These institutes primarily cater to the middle and lower-skill-level labour demand. In addition to this, seven Indian Institutes of Information Technologies (IIITs) were established to provide excellence in IT with the input of academics. Available estimates indicate that in 1999 there

were over 1,832 educational institutions providing training in IT to 67,785 professionals (Nasscom, 1999). The breakdown of the current labour pool indicates that holders of the three main awards relevant to the sector, B.Techs, diplomas and ITI certificates, account for some 70 percent of the total IT workforce in India.

Besides development of the infrastructure and labour pool for the IT sector, the Indian government has taken measures to address the problem of software piracy by including the protection of the computer software copyright within the established Indian Copyright Act of 1957, reinforcing active role of the state in promoting the industry. Other factors which have added to India's comparative advantage in this sector have been the availability of a highly skilled English speaking workforce and also the time difference between India and major export markets such as the USA.

It is clear that over the last decade the Indian IT sector has benefited enormously from a national system of innovation comprised of many actors working effectively together in order to develop international competitive advantage and credibility. This successful strategy has been the result of a focused state development strategy

toward the promotion of the ICT software and service sector for foreign exchange earnings. This export-oriented strategy has so far overlooked the importance of ICT diffusion to the economy in general, such as improved efficiency, productivity, and competitiveness to domestic industries and services.

CONCLUDING REMARKS

Today there is an increasing realization that the benefits offered by IT for improvements to human welfare, economic productivity, and growth are mainly limited to the developed economies. Even though this International Digital Divide is a feature of the current global environment, there is potential to reducing the gap between the leading and developing countries with appropriate government policies. The development of such policies requires an integrated approach with the involvement of actors in counties across the public and private sectors. Sustained development requires both revenues from ICT-growth strategies and from improvements to the economy obtained through ICT diffusion. With reference to the Indian experience, we can observe that an export-oriented IT-growth strategy has deflected attention away from ICT diffusion at a time when a recent study by the IMF (2001) has reported that IT-using countries tend to benefit more than IT-producing countries. The disappointing welfare gains for IT producers have been attributed to the deterioration in the terms of trade between the producers and users. Despite the growth of the software industry, India is also among the losers. These finding underline the importance of the complementary roles of the domestic market in promoting innovation and exports and export-orientated, IT-induced productivity and growth. The policy implication for developing countries, and for India in particular, would suggest that ICT diffusion should be prioritized for economic development and growth.

The growth of the service sector has been one of the key drivers of economic development in both the developed and developing world in the last decades, underlining the fact that international competitive advantage will in the future be determined more by trade in intangibles rather than goods. Developing countries such as India can obtain the benefits resulting from the internationalization of services with the adoption of liberal trade and investment policies designed to support IT growth. However, in order to maximize the wider economic and social benefits, complimentary policies supporting national ICT diffusion cannot be overlooked, and should be the focus of future policy development.

ACKNOWLEDGMENTS

I would like to express our gratitude to Professor K. J. Joseph (Jawaharlal Nehru University, India), Dr. Richard Heeks (University of Manchester, UK), and the information officer of Bridges.org for allowing the use of the duly acknowledged sources in the development of this chapter.

Chapter 1.14

ICT, Education, and Regional Development in Swiss Peripheral Areas

Chiara Giorgi

Università della Svizzera Italiana (USI), Switzerland

Dieter Schürch

Università della Svizzera Italiana (USI), Switzerland

INTRODUCTION

Since the end of 20th Century, the introduction of Information and Communication Technologies (ICT) has deeply influenced many aspects of everyday life, leading to the creation of new meanings for the traditional concepts of identity, culture, economy and, above all, communication (Mantovani, 1995; Perriault, 1989; Rullani, 2002). Trends about technological development show how, in the next years, the change will gradually concern all elementary daily actions, due to spreading of the electronic devices in the environment (OCDE, 2002; Saracco, 2003). If ICT will be ever more deeply-rooted in our reality, how fast will they consequently influence our socio-cultural identity? What sort of consequences do we have to imagine at economic level? What variety of scenarios can we draw about our future?

And, above all, how will the concept of development change?

If on the one hand the global trend seems to lead towards a reality without any kind of borders, on the other one the political and cultural centres are privileged in taking advantage of the opportunities opened by ICT. Therefore, peripheral areas¹ run the risk of becoming more and more isolated and excluded from the innovation process. Is it possible to reverse this tendency by using ICT as developmental devices? Can we re-direct the attention on those areas that seem to be “dead” regions? And in what way?

BACKGROUND

The relationship between communication and regional development has deeply influenced the fate of a great number of geographical areas;

examples are the building of railways, of roads and fluvial connections. If and in what way can the CmC² be considered a factor, parallel to those we have mentioned, to open new opportunities for peripheral regions?

The rapid spread of communication networks—ignoring the presence of natural and political boundaries—is changing the economic and social scenarios. In this context, new kinds of “regions” are emerging, the so-called “learning regions” (Florida, 1995). They are characterized by a system in which communication networks and data processing work give both shape and substance to connections between public institutions (such as schools and universities) and private institutions (firms), this leading to generate new knowledge and productiveness.

In Switzerland, a country characterized by a strong multicultural and multilingual tradition (above all in valleys of alpine regions), the creation of a new idea of “region” meets several kinds of dissensions. There are a lot of questions about the way to get over mental and cultural borders (see Arnaud & Perriault, 2002; Bressaud & Dirlter, 2003; Calvo, Ciotti, Roncaglia & Zela, 1998).

The behavioural changes always continue in daily action, and the action always places itself in a human, social, geographical, cultural and economic territory (Brown, Collins & Duguid, 1989). The use of communication devices can't escape this rule, because they've got a sense if they can be interpreted and situated by the people who live in that particular area (Galimberti & Riva, 1997). The process of interpretation of these devices had to consider, on the one hand, the starting of forms of “unlearning” (Grabher, 1993), and on the other one the building of a different nature of the concept of territory that has to be identified and tested (Delai & Marcantoni, 1992).

REGIONAL DEVELOPMENT IN SWISS PERIPHERAL AREAS

Situation in Peripheral Sub-Alpine Regions

Swiss reality is characterized by fragmentation at several levels. From a geographical perspective, the mountainous territorial morphology creates several natural partitions, causing the isolation of some areas and particularly those distributed along the Alpine chain. Besides, the Swiss Confederation is a set of 26 political Cantons, each of these having its own administrative independence even if partial, and with four official languages³. At a deeper level, the fragmentation is perceived as socio-cultural complexity: geographical and political configurations, in fact, don't correspond to an unequivocal identity; very often different cultural and language realities—including dialects - are present on the same territory, giving it a cross cultural profile⁴.

The process of globalisation over the last decade has led to the trend of concentrating the power in the centres, namely those places having infrastructures and accessibility to innovation, and so to choose a developmental way. These centres become the reference point for all the relevant activities. These are the “places of the knowledge,” the places where people decide the future trends of development, definitely the places that the peripheral regions “gravitate around.” From this perspective, the break between central and peripheral areas becomes even more perceivable. Peripheral regions seem to have neither any kind of power about their future development, nor interesting elements making them recognizable as “cultural regions.” If this trend is observed at a general level, now it has repercussions also

on Swiss Confederation, European symbol of a perfect integration between different cultures and ethnic groups.

What is actually going on in these regions, often coincident with valleys? First of all, it is important to point out the trend of native people moving out from the territory, frequently youth, to find a better working perspective just in the centres. This leads, obviously, to a progressive death of the local economy and working activities. The economic sphere, anyway, can't be separate by the question regarding education, in which the working world is deeply-rooted. If this movement from the regions begins in the young age, it's necessary to understand the reason underlying that.

During the period of education, the young decide to abandon his/her own place of origin to look for better education and training opportunities. In some cases, the young have no other choice. This problem is strongly felt about vocational training, that represents a relevant portion of educational system: more than 60% of young people, in the age of secondary education, choose the way of apprenticeship. Swiss apprenticeship is based on the dual vocational system coming from the German tradition. Apprentices work in a company or small firm and at the same time attend Vocational School. The dual system spans over the whole training period, up to four years, thus insuring the connection between school and education and the working world. What happens in remote regions? Vocational Schools collect different professional trainings and are often dislocated far away. The apprentice is forced to leave his native territory during the week to move to the place where he can study and carry on his/her apprenticeship in a firm. This situation of eradication from the native territory leads the young to a progressive loss of his/her own socio-cultural identity, to get hold of the place he/she will study or work.

Finally, we have to face a sociological problem: the development of a negative mentality. If valleys are characterized by the elements mentioned before, the young person—but not only our youth—is

led to relate his/her native region with lack of real opportunities for the future, and definitely not to recognize any chance of development.

What long-term consequences can we imagine for the increasingly isolated valleys? How is it possible to intervene, so as to change this vision about the future? Can the introduction of ICT change this situation?

Swiss Regional Development

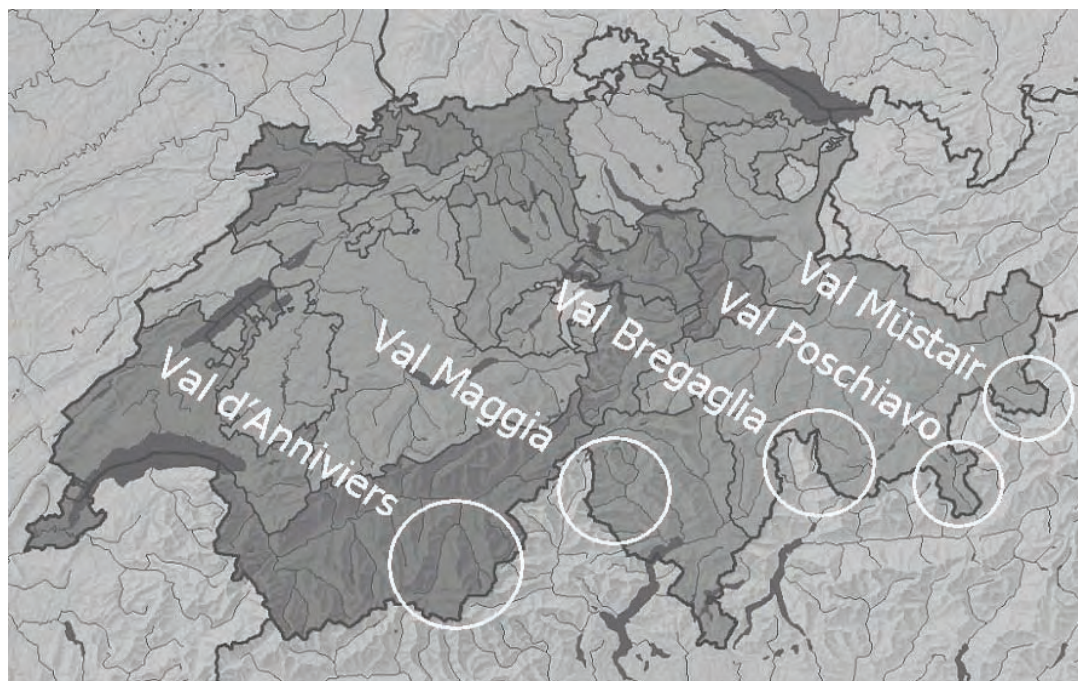

Since 1995, Swiss peripheral zones of sub-alpine arch (see Figure 1) are involved in projects of regional development, based on the conviction that changes take place not simply by giving direct financial support, but by setting up educational and training devices, to achieve a revaluation of these regions as characterized by their own specific social, cultural and economic values and so to allow them to survive both on the identity level and the economic one.

Poschiavo Project: A Pilot Project

The pilot project, Progetto Poschiavo⁵, started in 1995 involving the area of Poschiavo Valley, a region of the Grisons Canton at the boundaries with Italy, speaking Italian, German and Romansh. The aims of the project were both the revaluation of the cultural and linguistic reality by a human ecology approach⁶, and the realization of a communication network that allows a cultural exchange not only within Poschiavo region, but also between this territory and the centres, to promote a reversal of the tendency towards isolation.

From a practical point of view, the project followed a regional development strategy founded on the direct involvement of the local people. After an initial contact with local institutions, a group of people was trained to take the role of Practice Assistant in Distance-Education (APFD)⁷, to accompany the local population in project of territorial development. In this sense, it was important that APFD were native people,

Figure 1. Swiss peripheral territories involved in projects of regional development

to avoid any hindrance to the developmental process itself. The second step was the setting up of project groups (composed of local people and accompanied by an APFD) and the introduction of Information and Communication Technologies. During this period, participants acquired both the means to “read” the territory through a human ecology approach and the necessary know-how to use ICT. The project groups took the role of connection between the valley and the centres. Finally, in a consolidation phase, project groups began a more operative and practical work, involving in their activities the whole population and local Institutions.

Nowadays, we can observe a new trend for Poschiavo Valley, characterized by a consciousness about the value of its own cultural identity, a new esteem of the role of education in processes of regional development, a consolidated trend to self-entrepreneurship and a resumption of economic vitality. A simple example is represented by Polo Poschiavo: a body born from the pilot

project, now institutionally recognized as a reference point for the development of the region, that is the promoter and responsible for some training projects in the valley.

The progress of the Poschiavo Project and the relapses of the project itself (Rieder, Giuliani & Schürch, 2000; Schürch, 1999, 2000), show how it is possible to achieve concrete regional development, without betraying the region’s historical and geographical roots, to satisfy the demands of the present time and create innovative scenarios for future years.

movingAlps Project

In 2000, these outcomes lead to the birth of the movingAlps Project⁸, based on Progetto Poschiavo experience and representing its natural consequence. If the old Poschiavo Project focused on a limited area, movingAlps extends its action field to all the peripheral regions of the sub-alpine arch at the boundaries with Italy.

movingAlps tries to work out and to practice a regional development model that may represent both a rediscovery of the peripheral areas as characterized by specific elements and a chance to increase the values of these areas themselves. To allow the isolated regions to identify and develop opportunities that may be synonymous of social and cultural identity survival⁹, movingAlps chooses to start moving from local people project ideas. This implies an analysis of the ground and of people expectations and representations about their future. Financial support is given only in a second time. By this strategy, the developing process not only fits the demands of the region, but it's shared by the involved people. This also allows the creation, step by step, of a new vision about the opportunity to act on and modify the current situation going towards a better one. The process of development is then characterized by a steady and progressive adaptation of the project to consider and to include the unexpected elements rising up from the territory and people living in.

In conclusion, movingAlps aims to:

1. Perform a change of social perceptions, allowing a gradual and progressive re-appropriation of entrepreneurial, working and formative culture that finds its origins and nourishment in the region itself;
2. Overturn the relationship between centres and peripheral areas, to reverse a process of progressive isolation of the peripheral zones as regards to the centres, and to reach a joint and mutual exchange of knowledge and culture.

The Role of ICT

How to achieve this reversal of relationship between centres and peripheral regions? In this developmental approach, the introduction of Information and Communication Technologies (ICT) can play a central role, both by making

easier the involvement of the isolated zones in the intercultural exchange typical of the global village and by supporting a push towards innovation and development.

To overcome temporal and spatial barriers by ICT means the establishment of continuity and interchange relationships between centres and peripheral areas. ICT enables the onset of a process of de-centralization of knowledge, by offering the opportunity of training "in situ" that may emphasize the value of the cultural traditions of the territory which people belong to.

From another perspective, this process leads to a renewal and updates the knowledge and skills acquired over the formative itinerary (Schürch, 2004). Education and its links with the economic and working spheres have obviously to be considered as the key-points from which development becomes possible. ICT, in this sense, provide access to a kind of knowledge that is typical of the information age and that's becoming the base enabling participants to act and work in the future daily life.

Education and ICT in movingAlps Project: A Concrete Micro-Example

A concrete example of regional development with the help of ICT is represented by a project¹⁰ involving the vocational school of Samaden, in Bregaglia Valley, and in particular a class of bricklayer apprentices living in various dispersed locations in the valley.

As mentioned previously, apprentices are forced to leave their villages to reach the place of study and carry on their apprenticeship. Often this situation leads to migration to these centres and consequently to an abandonment of the native valley. On the other hand, a series of studies in Bregaglia Valley¹¹ have pointed out how it is characterized by the presence of multiple diversified sectors of production, covering the entire outline of traditional regional activities. This means a working reality that is still alive,

at least at a potential level. The question is: how to meet young people's demands and to rebirth the local economy?

The way chosen by moving Alps-Bregaglia was to develop a net of collaborations between educational bodies and private firms by using ICT, to allow the apprentices to study without leaving their locations in the valley. This should lead, on one hand, to creating the necessary conditions to encourage the introduction of young people in the local working activities, but also lead to a renewal of the professions based on the new approaches brought in by the apprentice who has learnt to use ICT.

The experience of Progetto Muratori, started in May 2002 and stopped in June 2003, has given the opportunity to a group of 12 bricklayer apprentices to attend courses in General Studies and in Professional Knowledge in a blended-learning form¹². The course ran from December 2002 to May 2003, and took the form of three three-week distance sessions alternated with periods of classroom-based learning. Over the distance-learning phase, communication and interaction between apprentices, teachers and the other people involved in the project has been secured by a virtual learning environment (Giorgi & Schürch, 2004).

This experience shows, at several levels, what are the opportunities arising from a territorial intervention. Briefly, it has led to:

1. Overcoming the problem of spatial and temporal distances—by the use of technology—leading to apprentices having wider accessibility to training and to knowledge in general;
2. Moving from a vocational training based on the culture of the “places of knowledge” towards an education founded on the values and on the identity characteristics of the native region;
3. The development of a training system preparing young people to face changes due to the introduction of ICT in professional world, by integrating them within the formative itinerary; and
4. The development of the necessary basis for a reevaluation of vocational training and of professional activities within Bregaglia Valley, and an input towards innovation.

CONCLUSION

Regional development goes through both the revaluation of the culture and of the regional identity, and education and training in a large sense. To be effective, this process has to occur at different levels; some can be considered at micro-levels (as in the case of Progetto Muratori, focused on a limited target), others regard wider spheres such as the projects of territorial development considered as a whole. Sharing of future sceneries and collaboration between institutions and local people are central elements for development that becomes possible.

Information and Communication Technologies offer interesting tools for the revaluation of peripheral areas own identity, introducing at the same time a wave of innovation. It's not a question of assimilating a particular territory to defined standards but instead to make the innovation a means to give a new value to the culture, economy and local identity.

However a question still remains open: Is it possible to define a model of regional development, integrating ICT, that is flexible enough to be adapted and transferable to every territory? Furthermore, can such a model be characterized by a defined structure of functioning?

KEY TERMS

Developing Project: Creation of a small group of people that work on an existing problematic theme and design solutions where Information and Communication Technologies make sense.

Human Ecology: In a holistic vision of the environment, human ecology is an approach to read changes and transformation in action; a way of integration of history, culture and work in peripheral regions in a communicative and distance-exchange perspective; a tool for creating conditions for sustainable development.

Information and Communication Technologies: Technology referring to IDP systems; examples include the Internet, videoconferencing, videostreaming, text-editing, robotics, productive processes automation, etc.

Peripheral Regions: Geographical areas characterized by a particular territorial morphology that causes the isolation from bordering zones inhabited by a linguistic and cultural identity minority. Areas cut off from economic and cultural development.

Regional Development: The notion of development that has been recently better defined with the concept of “learning region” (“regionalità apprendente”) that suggests the existence of a dynamic net of relationships among different activity sectors (economic, administrative, educational and cultural) of a region. It is thought that education and training represent the central device of such development.

Regional Identity: Is a linguistic and cultural concept linked to the feeling of belonging shown by the inhabitants.

ENDNOTES

- ¹ For example, mountainous zones.
- ² Computer-mediated-Communication.
- ³ These are: French, German, Italian and Romansh.
- ⁴ For instance, in some areas of the Grison Canton, which is open to Italy and where Italian is spoken, we can perceive that, although politically belonging to Switzerland cultural traditions are strongly rooted in Italian culture.
- ⁵ Progetto Poschiavo is born from the collaboration of Istituto Svizzero di Pedagogia per la Formazione Professionale (ISPFP) of Lugano, Cantons Ticino and Grisons, Jacobs Foundation, Progetto Poschiavo Foundation, Ufficio Federale per la Formazione e la Tecnologia (UFFT), Swisscom, University of Svizzera Italiana of Lugano, University of Ginevra, University of Neuchâtel and University of Bologna; web site: <http://www.progetto-poschiavo.ch>.
- ⁶ The concept of “human ecology” refers to the environment in a global sense, originated by the consideration of all its components and where the human being has an important role.
- ⁷ The APFD, or Assistente di Pratica in Formazione a Distanza was a new professional category created within the ISPFP of Lugano; their role is to accompany groups of

development projects, offering both technical and pedagogical assistance, sometimes at a distance but mainly face-to-face. The particular characteristic of the APFD, however, is that they originate in the same regions as the people themselves, and so share the same socio-cultural background as the people they are working with.

⁸ As Progetto Poschiavo, movingAlps derives from the collaboration of Istituto Svizzero di Pedagogia per la Formazione Professionale (ISFPF) of Lugano, Cantons Ticino and Grisons, Jacobs Foundation, Progetto

Poschiavo Foundation, Ufficio Federale per la Formazione e la Tecnologia (UFFT), Swisscom, University of Svizzera Italiana of Lugano, University of Ginevra, University of Neuchâtel and University of Bologna; Web site: <http://www.movingalps.ch>.

⁹ Obviously, in a sense of multi-culture and multilingualism survival.

¹⁰ That is Progetto Muratori.

¹¹ The studies were carried out by ISFPF-Lugano and Politecnico Federale of Zurigo.

¹² Either face-to-face or through ICT-based distance learning.

Chapter 1.15

Applying for Government Grants for ICT in Australia

Lynne H. De Weaver

Southern Cross University, Australia

BACKGROUND

The legend on the CTC@NSW Web site, <http://www.ctc.nsw.gov.au/about/>, defines Community Technology Centres (CTCs) as “computer enabled multi-purpose facilities based in the Main Street or main centre of a town. They provide access to Internet-connected computers as well as provide printers, video and teleconferencing facilities, business equipment, and e-commerce incubator facilities. CTCs are owned and managed by a non-profit group, such as an incorporated association, co-operative, or local government committee. There are a number of titles that have been used to date to describe CTCs including Telecentres and Telecottages.”

The CTC@NSW program was established to build capacity and deliver a range of nominated services to communities with populations of less than 3,000 through the use of information and communications technologies (ICTs). Each applicant community had to develop its own business plan to meet the identified needs of their community. Successful applicants received grants

of between \$150,000 and \$200,000. These funds were to be used as seed money to establish a community owned and operated business.

The NSW State Government and Commonwealth Government jointly funded this program to run from early 2000 to June 30, 2004. During this period, over 60 new Community Technology Centres (CTCs) were funded in small, regional communities throughout NSW. Unfortunately, towards the conclusion of the funding period, those communities who had been funded in later rounds had to do without the support, resources and assistance provided by the CTC@NSW Support Unit because the funding for this part of the program concluded on June 30th. Only the CTCs that had been funded in earlier rounds would be the full beneficiaries of this aspect of the program.

In order to be eligible for funding under the CTC@NSW program, interested communities had to first complete an Expression of Interest and demonstrate that they met the program’s specific eligibility criteria. If they made it through this “hoop,” they then had to complete a complex application form, which required them to develop

a comprehensive business plan, which included technology and marketing plans in addition to annual cash-flow projections for the first three years of operation. Applicant communities had to demonstrate how they could establish and maintain viable businesses within their communities during the three-year period of funding as well as how they planned to make their CTC viable after all grant funding had been expended.

However, it was through working on the CTC@NSW program, as well as several other ICT programs, that the author came to grips with many of the issues that make economic development in regional Australia so problematic. Her findings were, in many ways, similar to those of Wolstenhome's (1995) who stated, "The continued application of inappropriate models may arise out of difficulties in communication between government representatives and members of community groups during the consultation and planning process. Such difficulties may be due to a lack of understanding about the ways in which rural communities work" (p.1). In particular, some of the difficulties with communications were often exacerbated by the bureaucratic language used in the information packs supplied by the funding bodies as well as in the actual applications themselves.

While it is perhaps easier to have a relatively esoteric discussion about regional economic development, perhaps the single most important asset that is often overlooked or marginalized in these discussions, is the people who actually live and work in regional communities *and* apply for grant funding. It is important to note that while the levels of formal education of these people may not be as high as those living in major urban centres, this does not mean they are not as capable of successfully administering grant funds, but rather they are not familiar, or comfortable with, the phraseology and business-oriented buzzwords that proliferate in the documentation of government funding programs.

Shepherd (1998) noted that, "Rural development, like other creatures of the 'development

industry'...is prone to jargon and the extensive use of buzzwords. Sustainable development, sustainable agriculture, participation, women's involvement, indigenous knowledge, integration, are all examples of phrases which are uttered ritualistically when the need arises" (p. 19).

It is also worth noting that during the period of time the author worked with small communities in the Northern Rivers to help them gain access to a range of ICT services, she drew many of the same conclusions about the nature of the people who lived in regional communities as did Plowman, Ashkanasy, Gardner, and Letts (2003). They stated, "Innovative towns were perceived to have these characteristics in greater abundance: administrative and managerial capacity to run and promote the town...availability of a variety of experts to provide the breadth of services that the residents expected...managerial attitude towards change...a higher proportion of residents who had lived elsewhere, a higher proportion of residents working in the so-called creative-class" (p. 2).

Over the course of her work with regional communities, the author developed a methodology for the process of applying for grant funding which helped to increase the "success rate" for applicant communities. This is not to say that all of the communities and grant applications she worked with were successful, but rather the communities that used this methodology, and had more of the characteristics mentioned earlier, tended to be more successful with their applications for funding.

A STAGED APPROACH TO THE TASK

Stage 1: Getting Started

In order to better understand the nature of the grant for which they were applying, communities first had to determine:

Applying for Government Grants for ICT in Australia

- Who is offering the grant, e.g., the State or the Federal Government?
- What does the government expect to achieve through offering the grant?
- What is the grant expected to achieve for the applicant communities, e.g., what are the expected outcomes?
- Which region(s) is the grant supposed to benefit?
- Is there a time span involved? (Many government grants have specific periods of availability, e.g., funding rounds as well as closing dates.)
- A list of the criteria against which the application will be assessed;
- Information regarding the supporting documentation that might be required;
- The contact details of the people who may be able to assist communities with their applications;
- Information regarding any other resources that might be available;
- Any specifics that pertain to a particular program; and
- Information as to the number of funding rounds and their closing dates or, if it's a one off program, the actual closing date.

Communities also had to consider that there may be political implications or other issues regarding the particular program for which they were applying. They also needed to look at it from the government's perspective because in their eyes, a successful grant program is expected to generate a high level of interest from potential applicants. This means that government agencies actively seek to encourage as many applications as possible in the belief that this will help them direct their funds to the most promising projects. (It is worth noting, that the most deserving communities might not be the ones most able to prepare and submit the "best" application.) Additionally, applicant communities must make sure that their funding objectives match those of the grant program's so that the collective time and energy of the people involved in the process isn't wasted.

However, the first step in the process is to acquire the program's information pack and read it carefully. Much of this information is also available on the relevant agencies' Web site, <http://www.grantslink.gov.au>, is an excellent reference site for communities to explore as it takes a whole-of-government approach to funding.

Good "grant information packs" should be comprehensive and include such things as:

- A clear statement of the funding program's objectives;

Applicant communities also need to be aware that government-funding programs are usually created in response to policy decisions and often focus on a particular issue or range of issues that the government of the day has decided to address. Applicant communities must determine, at the very onset of the process, whether some of the funding program's objectives or criteria have greater weight than others. This is often the case in regional Australia, and that's why it is a good idea to establish a good working relationship with the program's administrators.

Jargon and three letter acronyms (TLAs) are often the hallmark of grant programs and applicant communities need to familiarize themselves with the "language of the grant" before proceeding. They also need to understand all of the requirements at each step in the process, e.g., an initial Expression of Interest (EOI) to determine eligibility, the application itself, regular progress reports, Memorandums of Understanding (MOUs) from potential partners, and so forth.

While applicant communities must also build and maintain ongoing community support for their funding project, they must also determine who will be on the Grant Planning Committee. Having the right mix of skills on that committee plays a crucial role in achieving a positive outcome, and the importance of strategic partner-

ships cannot be under-estimated in achieving a successful outcome. If training is to be one of the services provided, then strategic alliances with like-minded organizations such as Adult & Community Education (ACE) programs, University of the Third Age (U3A) groups, local libraries, and so forth, cannot be under-estimated in terms of the skills and experience they can provide. The planning committee also needs to include representatives from all the key stakeholder groups in the community and have a chairperson who is well-respected and networked in the community.

Finally, members of this committee must possess the range of skills required to successfully complete the application. The capacity of the committee to prepare marketing plans, spread sheets and understand accounting or bookkeeping procedures and software applications is essential for achieving a successful outcome. Last but not least, a good planning committee needs to maintain community interest and support through ongoing public relations activities.

Stage 2: Meetings and the Application Process

All successful communities had strong committees that held regular and productive meetings. These meetings were productive because the committees were committed to the proposition that good meetings led to good outcomes. These committees would:

- Set agendas and stick to them;
- Use the application as their reference point;
- Determine priorities, e.g., what needed to be done and in what order;
- Determine which tasks could be done concurrently;
- Appoint sub-committees as required BUT make sure they reported back to the entire committee;
- Assign tasks or set homework;

- Set timelines and met deadlines;
- Establish a communications procedure, e.g., who is going to keep the minutes at meetings and who will distribute them; and
- Set times, dates and venues for subsequent meetings as far in advance as possible.

Stage 3: Finding Out How to Find Out

Grant applications include a range of questions that need to be addressed so that the funding body can determine need and eligibility. The committee must therefore address all of the criteria for the grant for which they are applying and complete all sections as comprehensively as possible. This means they have to:

1. Identify their critical reference group and understand its needs;
2. Determine what they really need to find out;
3. Test/challenge assumptions they may have about their communities;
4. Identify the questions on the application that need substantive, well-researched answers;
5. Develop a strategy for getting the answers, e.g., written surveys, public meetings, focus groups, services audit, telephone surveys, traffic counts, interviews, etc.;
6. Determine other factors that might be impacting on their community, e.g., conflicts, service overlaps, other issues on the front burner;
7. Analyze and discuss their “research” findings at meetings and prepare concise reports supported by facts and figures;
8. Build ongoing community support for the project; and
9. Communicate—keep everyone in the loop.

While point three might seem unnecessary, one of the communities that planned to apply for a CTC@NSW grant wasted a considerable amount of time due to lack of knowledge about their community. They had originally decided that their primary target population would be seniors. But when they finally conducted their research, they were surprised to find out that this group was particularly well served in the community as there was a Seniors' Computer Club, free Internet access at the Public Library and the U3A had recently established a branch and were planning to offer a computer and Internet training program.

While there are many ways to gather information, each community must devise the strategies they need to employ in order to gather the type of information required for the particular grant for which they are applying. If surveys are undertaken, then the questions need to be as unambiguous as possible and key demographic information captured. Short surveys are much easier to prepare, undertake and analyze.

Conducting a community survey can be a discrete task undertaken over a designated period of time. However, in order to be effective, the preparation work required for that survey must be thorough and comprehensive, as it requires solid intellectual and physical input in order to provide convincing evidence or data, to support the community's application, e.g., all projected user groups for the proposed CTC facility must be included in the survey. The planning committee must decide who needs to be surveyed, what type of questions need to be asked and how many responses are required to yield a statistically relevant level of response, e.g., their sample size. It is also important to ensure that the questions in the survey are written to support an application rather than as promises of things to come.

It is both practical as well as advisable, to approach other people in the community to assist in conducting a survey, as they may be very interested in the project, but don't have the time to be on a planning committee. Assisting with

the application process in this way also helps to generate greater community "buy-in".

Often the results of a community survey make an interesting story for the local newspaper and this is another good way to keep the community informed. Once the survey information has been collected and analyzed, it's time to actually start completing the application, which leads to Stage 4 of the process.

Stage 4: Preparing and Submitting the Grant Application

In order to complete and submit an application, the planning committee will need to:

- Allow sufficient time for the task because applying for a grant *does* take time;
- Include as much supporting documentation as possible, e.g., if you state in the application that public transport is limited, include evidence, bus schedules, ABS statistics on car ownership, etc.;
- Answer all questions in each section carefully and accurately;
- Pay attention to detail;
- Make sure the application demonstrates that the community has the management capability to take on the project;
- Comply with all presentation and submission requirements, e.g., soft copy on disk and two bound hard copies, etc.;
- See if someone from the grant program can "preview" the application before it is officially lodged as they might be able to make some additional suggestions to strengthen it;
- Make a copy of the completed application, including all attachments, for the committee's records; and
- Meet all deadlines.

Once the application has been submitted, it is important to continue to manage the community's

expectation. The planning committee, as well as the community, must remember that just because they have put in the time and effort, there is no guarantee of a favorable outcome.

CONCLUSION

A great deal of community consultation and business planning is required in the application process. The skills of the people on the planning committee are crucial to achieving a favourable outcome. Some of the other key factors that emerged as determinants to the success of a community's application were:

- The capacity of the organizing committee to understand *all* of the requirements of the application;
- Their ability to articulate community needs;
- The business skills and financial acumen of the members of the planning committee;
- The community's commitment to the project for which they are seeking funds; and
- Their understanding of how ICTs could serve as a means of promoting economic development and building capacity in their communities.

Further research is being conducted to determine whether or not the communities that received CTC@NSW Grants have been able to achieve their goals.

KEY TERMS

Australian Bureau of Statistics (ABS): ABS provides information to assist governments and communities with their research, planning and policy formulation. It houses Australia's largest statistical database, covering a wide range of economic, social and demographic information. The ABS Web site can be found at <http://www.abs.gov.au>.

Broadband: "Broadband" refers to a telecommunication service in which a "wide band" of frequencies is available to transmit information. When a wide band of frequencies is available to subscribers, information can be multiplexed and sent on many different frequencies or channels within the band concurrently. This means more information can be transmitted in a given amount of time, just as more lanes on a highway allow more cars to travel on it at the same time. As a general rule, the greater the bandwidth, the faster the service.

Demographics: Involves the statistical study of characteristics within any populations such as age, gender, marital status, address, occupation, mobility, health or disease rate, etc.

Grant, Tied Grant: A grant is generally a sum of money that is either paid in full or installments over the life of a particular project, while a tied grant stipulates particular conditions.

Target Population: A particular group within a larger group, about which the researchers are trying to generalise their study or research findings, e.g., seniors. Sometimes referred to as the Reference Group.

U3A: An educational organization with charitable status, where retired people from all walks of life, meet like-minded members to expand their knowledge, share interests or acquire new skills. Members usually offer a lifetime of experience, expertise or know-how in professions, occupations or hobbies and form study or activity groups to share their knowledge with fellow members. Although called a University, no academic qualifications are required or given. Those who teach are also those who learn.

Wireless Local Loop (WLL): A system that connects subscribers to the public switched telephone network (PSTN) using radio signals as a substitute for the usual copper phone lines for all, or part, of the connection between the telephone subscriber and the switch. This includes cordless access systems, proprietary fixed radio access, and fixed cellular systems. WLL technology is an efficient-as well as cost-effective-way to deploy telephony services to subscribers in remote and regional areas without the expense of burying tons of copper wire. WLL services enable newer telecommunications companies such as Norlink to bypass Telstra's wireline networks to deliver more affordable telephony and data access services.

Chapter 1.16

Role of ICTs in Socioeconomic Development and Poverty Reduction

Hakikur Rahman

Sustainable Development Networking Programme (SDNP), Bangladesh

ABSTRACT

Information and Communication Technologies (ICTs) are often promoted as central to reviving and sustaining regional communities. Apart from these, the revolutionary feature of modern ICTs—mainly the Internet and mobile telephony—facilitate low cost and speedy interaction among network participants. In this context, knowledge and information are fundamental for facilitating rural development and bringing about social and economic escalation. Nowadays, ICTs are universally acknowledged as powerful tools for development. At the same time, ICTs are seemingly essential to social development and economic growth. In recent years, the process of ICTs has been influencing the socioeconomic context in many countries. Despite that, in many countries a significant proportion of the population does not have access to clean water, sanitation, basic health services and proper education; ICTs provide novel opportunities for information

interchange and technology transfer. This chapter looks into critical aspects of ICTs in raising socioeconomic development in underdeveloped countries and tries to illustrate success cases in developed countries that can be replicated in developing countries to reduce poverty. Emphasis has been given to analyze the role of ICTs in poverty reduction processes upholding regional developments. Enactment of ICTs has been elaborately discussed for the uplift of community and it has been observed that solving common causes for common citizens needs strategic implementation of policies at the central core and pragmatic implementation of actions at the grass roots. Simultaneously, this chapter discusses various critical aspects of the development processes to achieve good governance that is vital for sustainable development. However, as ingredients for uplift through ICTs, institutional approaches in various forms have been found to be extremely effective for socioeconomic development and at the same time for regional developments.

HARNESSING ICTS FOR DEVELOPMENT

Information and Communication Technologies (ICTs) are frequently promoted as central to reviving and sustaining regional communities (Simpson & Hunter, 2001). In this context, knowledge and information are fundamental for facilitating rural development and bringing about social and economic escalation. The position that ICTs have a role in enhancing sustainability in regional communities has various threads and can be seen from the three spheres; community, government, and business (Kasigwa, Williams & Baryamureeba, 2005).

Many pre-Marchallian classical economists and their immediate post World War II followers like Lewis, Rodan and others viewed “economic development as a growth process that requires the systematic reallocation of factors of production from a low-productivity, traditional technology, decreasing returns, and mostly primary sector to a high-productivity, modern technology, increasing returns, and mostly industrial sector” (Adelman, 1999, p. 1).

In recent years, the process of ICTs has been influencing the socioeconomic environment in many countries. While ICTs provide novel opportunities for information exchange and technology transfer, they have increased deprivation for those nations that have not been able to update with these neoteric adjustments. In many countries, a significant proportion of the population does not have access to clean water, sanitation, basic health services and proper education (Ghaus-Pasha, 2005). To overcome these, ICT procedures can be utilized in bridging the digital divide and harnessing the potential of ICTs as a development tool (European Commission, 2005). Each country needs to find the proper determinants on the use of ICTs for development in the context of acculturation processes of socioeconomic development and poverty reduction (Graham, 2005).

The connection of economic development to ICTs is based both on the communication and the information elements. Communication includes both affective and cognitive analysis, while the information element includes only the cognitive portion (Pigg & Crank, 2004). However, the information function is rather complex due to its variety of features within the network along the Internet-based information transfer. Hence, the information transfer can be treated as *active* (interactive information interchange), or *passive* (repositories or knowledge management features), and can be transmitted in many forms.

The content side of ICTs has often been neglected when dealing with ICTs and development. The creation and strengthening of a content repository in different countries represent significant advantages on the usage of ICTs and their development aspect. First, socially it provides contents for society by operators in close contact with it, its needs, expectations and demands. Second, culturally it helps to keep local cultures alive and allows them to be presented to the rest of the world, thus safeguarding and enriching cultural diversity. Third, economically it generates local employment based on its own sustainable resources, and even constitutes a source of income when exported (European Commission, 2005).

The revolutionary feature of modern ICTs—mainly the Internet and mobile telephony—is their ability to facilitate low cost and speedy interaction among network participants (Proenza, 2002). It makes the economic aspects of people’s lives more efficient, as they keep in touch with personal networks, learn about markets, refine production techniques, eliminate time spent on travel to meet people to get information (Hudson, 1984), and able to take knowledgeable decisions. It also helps to build social capital (Woolcock & Narayan, 2000).

Connectivity to the Internet can help overcome some of the most significant obstacles undermining the development of remote rural areas. It can enable low-cost access to governmental services,

agricultural product and market information, local investment opportunities, financial services, distance education, online health services, and job vacancies to uplift community development processes (Proenza, 2002).

The vast majority of donors recognize the potential of ICTs as a catalyst for socioeconomic development but not all of them have reached the same consensus in using ICTs to assist development activities. While some are planning to develop new ICT strategies, others have already used ICTs for years and have drawn lessons from their success stories. In all cases, donors put ICTs to the service of the achievement of their broader strategic objectives in a number of development sectors (health, education, e-commerce, e-government, etc.). However, the overall focus is on meeting specific objectives, not on technology, *per se*.

Achieving the Millennium Development Goals (MDGs), particularly poverty reduction, is a frequently cited objective reinforcing most donor ICT strategies. These strategies aim at creating an inclusive information society with special attention paid to underserved regions, that is, the least developed countries (LDCs) and marginal communities. In this endeavor most of the donors prefer to build ICTs for development strategy on a partnership basis involving a number of actors from other bilateral and multilateral agencies, ministries, civil society, the private sector, universities and research institutions in both developed and developing countries (OECD, 2003). This has created reinforcement of institutional development approach for socio-economic development in many regions, and in reality immensely increased credibility of institutional partnership at grass roots.

It has been found that regional policies increasingly derive their parameters from a global horizon of different development paths, technological options, product life cycles, and so forth, and must also do justice to regional policy objectives such as employment, income,

taxation, and welfare development (Braczyk & Heidenreich, 1996). Thus, global development logics, dynamism (Harvey, 1989), and creation of fluidity vs. regionality (Laepplé, 1999) deserves immense dialogues at each and every stakeholders' stake conforming its proper implementation through information networking and upgrading technological knowledge.

Technological knowledge is not only organized in large-scale technical systems (Hughes, 1987), in branches or in professions but frequently also in regional economic areas. And this knowledge incorporated in regional production clusters, cooperative relations, institutions and policy patterns does not usually develop in great leaps and bounds, but incrementally, step by step. Regional economies can be understood from the accumulation of collective technological learning (Braczyk & Heidenreich, 1996). Technological knowledge and technological learning are, therefore, bound to context, community and region; and "technological capabilities reflect local, regional and national contexts and environments" (Storper, 1995, p. 897).

"Despite the growing importance, civil society organizations in the developing world remain only partially understood" (Ghaus-Pasha, 2005, p. 2), they are the important contributors in raising awareness, creating enable environment and promoting ICTs for potential development of the society. At the same time, the government has a critical role to play in promoting technological dynamism, policy, and in increasing productivity in related sectors, including industry and agriculture. Technological dynamism was the essence of the Industrial Revolution (Adelman, 1999), but, nowadays information dynamism is the core of all development perspectives.

However, rapid technological change and global connectivity has generated an information and knowledge gap between countries, the so-called "digital divide." About half of the world's population has never made a phone call, or Africa has only 2% of the world's telephone

mainlines (World Bank, 2000). Only 2.4% of the world populations are users of the Internet (internetworldstats.com, 2005a) and almost all of whom are concentrated in the Organization for Economic Cooperation and Development (OECD) countries. Roughly, 90% of Internet host computers are located in high-income countries that account for only 16% of world population (Global Reach, 2005; World Bank, 2000). Overcoming this dynamically changing digital divide is going to be a potential challenge for many developing countries in the coming years.

This chapter looks into critical aspects of ICTs in raising socioeconomic development in under-developed countries and will try to illustrate success cases in developed countries that can be replicated in developing countries to reduce poverty. Furthermore, emphasis has been given to analyze the role of ICTs in poverty reduction processes upholding regional development.

BACKGROUND

ICTs are universally acknowledged as powerful tools for development. ICTs are seemingly essential to social development and economic growth. Simultaneously, they are critical to the development of good governance, can be effective vehicles for the maintenance of security, and are vital for sustainable development (Pacific Plan, 2005). As discussed earlier, enactment of ICTs in the uplift of community and common causes for common citizens needs strategic implementation policies at the central core and pragmatic implementation at the grass roots. However, as ingredients for uplift through ICTs, institutional approaches in various forms have been found to be extremely effective for socioeconomic development and at the same time for regional development.

Before starting with the arguments on the context of socioeconomical development and relating it to the reduction of poverty utilizing ICTs, the author feels it is important to elaborate on defi-

nitions of a few related terms. The first term is development. Development refers to improvement of the economic and social conditions of poorer countries,¹ and can be treated as the process of improving the quality of all people living in a country.² Then comes poverty. Poverty can be seen as the state of being deprived of basic essentials of well-being such as food, shelter, income, employment, access to social services, and social status.³ Naturally, another question arises. What has been understood by ICTs in this chapter? Generally, it is the acronym for Information and Communication Technologies and used to handle information and assist communication.⁴ ICTs are the fusion of computers and telecommunications.⁵ But ICTs incorporate innovative ways to provide their users with global access to information, learning, and support.⁶ Information technology comprises the knowledge, skills and understanding needed to use ICTs appropriately and effectively⁷ to process, transmit, and store data and information⁸ for appropriate use.

These background definitions of ICTs can lead the researchers to think ICTs as a catalytic agent of development. Now comes the reasoning. What is social development, what is meant by economic development, and how can institutional development be defined?

Social development encompasses a commitment to individual well-being and the opportunity for citizens to determine their own needs, and to influence decisions that affect them. It incorporates public concerns in developing social policy and economic initiatives.⁹

Economic development can be related to the institutional changes made to promote economic betterment. It is the social organizational changes made to promote growth in an economy.¹⁰ Economic development strengthens an area's economy and employment base¹¹ with sustained increase in the economic standard of living of a country's population by increasing its stocks of physical and human capital through improved technology.¹² Economic development is the process of

improving the quality of human life through increasing per capita income, reducing poverty, and enhancing individual economic opportunities, including better education, improved health and nutrition, conservation of natural resources, a cleaner environment, and a richer cultural life.¹³ In other words, economic development is a sustainable wealth creation process that works within the framework of community parameters to maximize the efficient and effective utilization of community resources for economic gain for the local community.¹⁴

Regional development refers to the improvement in the capability of regions to conduct development programs such as agriculture, education, skill development, research, health, and other public issues, including physical infrastructure, information infrastructure, and institutional infrastructure but primarily aimed to the development of human capital.¹⁵ Regional development is the process of enabling and facilitating a region to develop and increase its capacities and capabilities to meet its desired objectives.¹⁶

The synthesis above has tried to define all parameters related to ICTs and regional development. Before proceeding towards the main thrust of the chapter, it is important to emphasize on a few intimate contexts of ICTs in poverty reduction phenomenon through several implicit manifestations.

ICTs are cross-cutting technologies with a fundamental impact on the various sectors of society, culture, and the economy. A decade ago, ICTs were considered marginal to the issues of economic growth and poverty reduction. Since then, skepticism has given way to more open cognizant and attitudes. ICTs are now seen as powerful enablers of development goals. In many developing countries, policy attention has begun to turn towards the convergence of industrial policies that emphasize manufacturing capabilities and science, technology. At the same time, innovative policies are increasingly seen as important tools

for development because of their power to generate and utilize knowledge (UN, 2005).

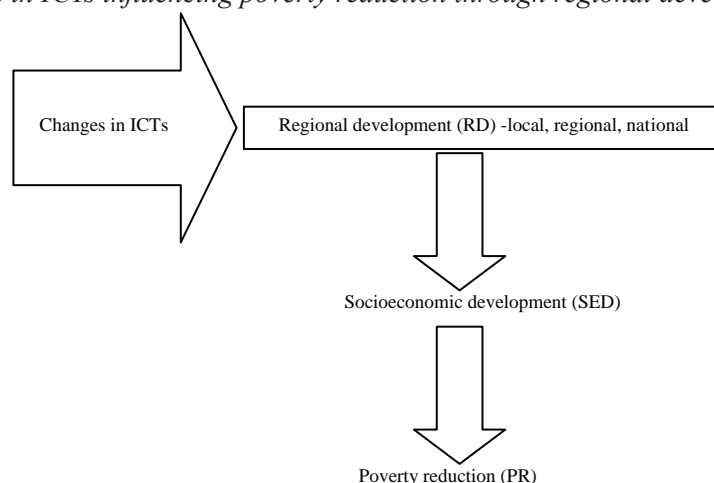

More precisely, ICTs are increasingly being seen by global analysts, the governments of many countries (especially developing ones), and development agencies as stimulating catalysts of collective learning. They enhance social development; improve individual people's lives by allowing them to acquire the knowledge and skills that empower them to be productive in innovative ways; and strengthen overall economic growth and income by raising productivity. Policies designed to enhance the role of ICTs in development have created new avenues for reducing poverty, especially through the beneficial effects they have on mainstream development objectives like, health, education, capacity-building, knowledge management and improving overall living conditions (UN, 2005).

RELATIONSHIPS OF ICTS WITH REGIONAL DEVELOPMENT

For having clear understanding of relationship between methods of ICTs and factors of socioeconomic development (SED) and poverty reduction (PR) in effect regional development (RD), as depicted in *Figure 1*, a mathematical model was established in this research that was formulated as shown in *Formula 1*. In a broader context, ICTs can be directly related to RD (see *Figure 2*), or in a more specific context (see *Figure 3*), a three tier RD perspective can be portrayed. However, for realistic propagation of ICT effects, a five tier RD can be more effective as shown in *Table 1*. Furthermore, a direct relationship between ICTs and RD can effect SED (see *Figure 4*) and between ICTs and RD can effect PR (see *Figure 5*) can be transformed into another mathematical model as formulated in *Formula 2*.

Factors₁ of *Formula 2* are related to socioeconomic development, but encompass ICT methods

Figure 1. Changes in ICTs influencing poverty reduction through regional development

Formula 1. Relationships among factors of socio-economic development and poverty reduction for regional development

$$\int (\text{factors of SED} \pm \text{factors of PR}) \Big|_{\text{ICTs}} \infty \text{ RD}$$

in their implementation. Similarly, factors₂ are related to poverty reduction processes. With clear understanding of the factors related to SED and PR, and adequate nourishment at each stake during the formulation, formation, and implementation phases can eventually lead to incremental institutional development. Moreover, for having better strategic implementation, a transparent understanding of the input and out determinants specified in Table 2 and 3 would be helpful.

To implement ICT based proponents in consolidating socioeconomic development and poverty reduction processes and make ICTs more meaningful to those who need information and knowledge the most (Adam, 2005), various approaches have been discussed in this section. However, before that, a few objectives have been described that seem essential for strategic planning. An ICT-based system for SED and PR, should:

- Clearly focus on identifying role of ICTs in generating opportunities that have more of a pro-poor focus.
- Find ways to link e-government, public sector and institutes reform and enhance public service delivery.
- Create opportunities to involve a variety of partners, including local business and telecom operators by linking the development of ICT infrastructure and access the development uses and strategies (UNDP, 2004).

At the same time, the strategies should have:

- a more strategic regional focus and an agreed economic development directive;
- improved knowledge of a region’s strengths and advantages that the future projects can be attuned along the success cases;

^c Amin & Thrift, 1994; Flora, 1998; Lallana, 2004; Onyx Bullen, 2000; Putman, 1993; Roure, Jennings & Shadbolt, 2002; Wall, Ferazzi & Schryer, 1998; UNDP, 2003c, 2004; Woolcock & Narayan, 2000, Giddens, 1990

- extended economic development networks with increased partnership approaches;
- Improved cooperation and trust among groups with better understanding of other stakeholders' goals and processes.
- Better cooperation and alignment between central and local government resources (Government of New Zealand, 2004a).
- A better working environment conducive to improved partnership among various local development agents and stakeholders (representing government, private sector and civil society) (Demeksa, 2001).

Formula 2. A mathematical model for regional development ^a

$$RD \approx \int_{k=0}^n \text{ICTs + SED factors}_1 + \int \text{ICTs PR factors}_2, \quad i=0$$

= factors of SED, ICTs and
 = factors of PR, ICTs

- updating information (policy, planning), ^b
- education (basic literacy), ^b
- social protection system, ^b
- information infrastructure, ^b
- technological development, ^b
- regional cooperation, ^b

Furthermore, to implement these strategies, the institutions should be:

- Decentralized and team-based with strong lateral communication and coordination that crosses functional boundaries within and among organizations.
- Acting to empower stakeholders and facilitate cooperation among them.
- Able to analyze regional development structures and strategies needed to justify the aims, objectives and effectiveness.
- Able to supplant more conventional institutional features of governance (Ansell, 2000).

Table 3. Output determinants of institutional development

Regional development through utilization of information and communication technologies	Output Determinants^d
	Knowledge base society
	Improved decision support
	Transparency in system
	Industrial districts and their distinctiveness
	Organizational flexibility
	Regional economic planning
	Human capital formation
	Technology parks
	University expansions
	Access to market prices
	Access to information for improved decision-making, technology options and improved family links
	Improved policy environment to attract Foreign Direct Investment
	Equitable universal service policies and provisions
	Establish financial mechanisms to promote cost effective access and connectivity
	Governance (at all levels of the decision making processes)
	Poverty diagnostics, monitoring and evaluation
	Institutional arrangements
	Development of ICT infrastructure
	Creation of a secured cyberspace environment
	Creation and management of local content
	Establishment of effective regulatory policies and agencies
	Launching of education policies that utilize and encourage the expansion of ICT capacities
	Improving economic governance
	Developing human resources, including education and health
	Developing infrastructure, with particular attention paid to ICTs
	Improving market access and trade
	Improving financial flows and managing debt

FORMULATING A MATHEMATICAL MODEL LEADING TO ICT DEVELOPMENT MATRIX

Tichy and Fombrum (1979) and Shrader, Lincoln, and Hoffman (1989) argued that the organic form of organization can be reinterpreted in the terms

of mathematical network theory. They also argued that Burns and Stalker’s (1994) mechanistic organization corresponds to “sparse” internal networks, low degrees of connectivity, and the predominance of asymmetrical relationships, while organic organizations have “dense” networks, high degrees of connectivity, and a predominance

Figure 6. Global Information backbone hierarchy

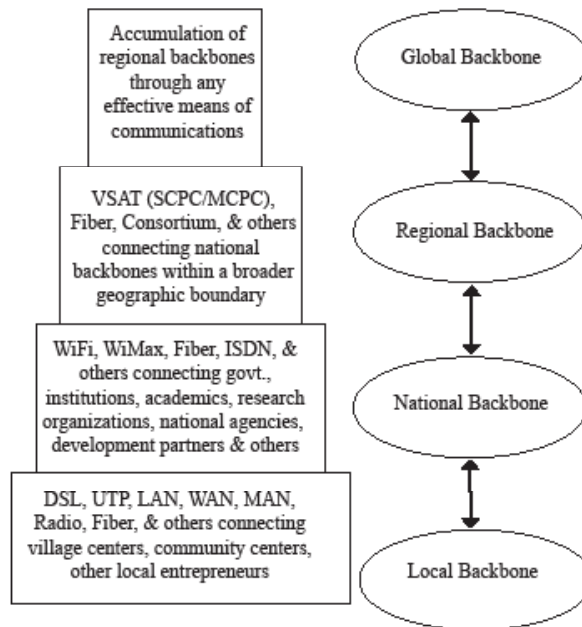

Figure 7. “One-to-one,” “one-to-many,” and “many-to-many” network relations

of symmetrical relationships. Structurally, the network organization can be characterized as heterarchical rather than hierarchical (Ansell, 2000). On the other hand, for a N-Form Organization (a symmetrical network) Hedlund argued that in a heterarchy “several strategic apexes emerge, that

these shift over time” (Hedlund, 1994, p. 87). What distinguishes a heterarchy from a hierarchy is the capacity of lower-level units to have relationships with multiple higher-level centers as well as lateral links with units at the same organizational level. Figure 6 shows a possible formation of global

Figure 8. Networking hierarchy within a country (Adapted from Rahman, 2004b)

Formula 3. Degree of connectivity of a network

$$d = \frac{\sum_{i=1}^n d(n_i)}{n}$$

where $d(n_i)$ = number of edges incident on node i
 i = node as depicted in figure 8 (Rahman, 2004b).

Figure 9. Person a is virtually linked to persons b, c, d, and e (Adapted from Rahman, 2004b)

information backbone through institutional build up (Rahman, 2004a), while Figure 7 illustrates the various network relationships.

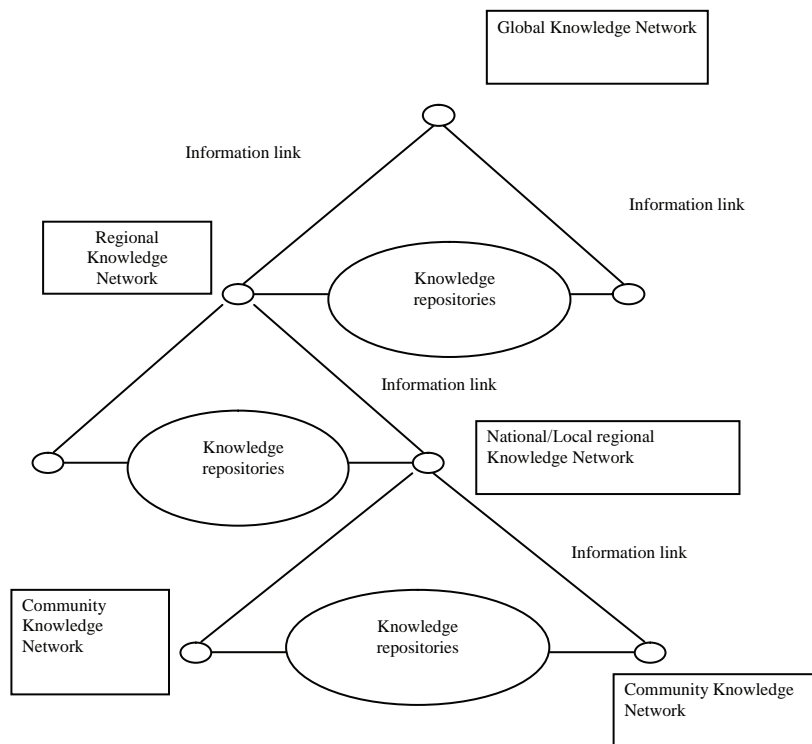

Kontopoulos (1993) suggests that while hierarchy entails a “many-to-one” form of structural aggregation, heterarchy entails a “many-to-many” relationship between different nodes in a social structure. The parallel to the mathematical network language is clear: many-to-many relations imply dense networks and high degrees of connectivity (Ansell, 2000). However, an exchange of information is characterized by the ability to be easily transferred, carefully measured and can be specified as valuable content, and at the same time it has to be reciprocally exchanged to become a value-added product. Figure 7 represents one-to-one, one-to-many, and many-to-many connectivity relationships within network hierarchies. N11 and N12 designate level 1 (national backbone); N21, N22, N23, N24, N25 designate

level 2 (state/division/local region); N31, N32, N33, N34, N35 designate level 3 (city/town/district backbone); and N41, N42, N43 designate level 4 (village centre/call centre/local centre/telecentre/knowledge centre) junctions/terminations.

The degree of a network gives an indication of how many entities a user interacts with. The average degree is calculated by.

Research works indicate that degree of around unity in a typically medium network is acceptable, while degree of around 1.5 can be taken as medium interaction, and greater than 1.5 can be referred as heavy interactions. Figure 8 illustrates acceptable information infrastructure hierarchies and it can be saturated by both hierarchies (top-down, or bottom-up). However, the author proposes establishment of bottom-up networking hierarchy in weaker economies. This way network establishment may be made more easily adaptable to the society and may be made more versatile by using

Figure 10. Global knowledge pyramid

Matrix 1. ICT Development matrix for uniform network distribution

<i>a</i>		-	1	1	1	1	
<i>b</i>		1	-	0	0	0	
<i>c</i>		1	0	-	0	0	
<i>d</i>		1	0	0	-	0	
<i>e</i>		1	0	0	0	-	

indigenous methods. Afterwards, by aggregating in dynamic fashion these hierarchical networks as shown in Figure 8 may be integrated with the next upper layer of aggregation.

Another indicator about the relationship among the member of a network can be derived, if the edges of the network (Figure 9) can be set in a symmetrical matrix, as in Matrix 1. while in Figure 9, a knows b, c, d and e. But, the relationship between b, c, d and e may not be known (Rahman, 2004b). These relationships will establish the ICT matrix and with point-to-point relationships among the network entities, the ideal relationship value may be given to unity. The ICT development matrix evolves from this unity relationship. Even if the network entity may follow point-to-multipoint, or multipoint-to-point paths, for a development matrix it must be upgraded to provide unity relationship value (either a zero communication, or unity communication). However, alternate to ICT development matrix, a global knowledge pyramid (see Figure 10) may be formed following illustrated hierarchies. In Figure 10, establishment of a global knowledge pyramid has been shown incorporating community, national, and regional networks.

Approaches to Strengthen Socioeconomic Development

Approaches in different forms that have been taken varying from Keynesian to neo-liberal

approaches on economic and regional developments are being indicated in Table 4. However, the author proposes an approach that may be enacted in distributed network driven system to make it sustainable.

As indicated in columns two and three of Table 4, the approaches have been described as “imperative” by Hausner (1995) and referred to be modest in terms of stimulating sustained improvements in the economic competitiveness of the Least Focused Regions (LFRs). Though Keynesian approaches have assisted in increased employment and income in the LFRs, they have failed in securing increased productivity compared to those in more prosperous regions, and importantly, also failed to achieve sustaining growth in terms of mobilizing resources and becoming less dependent on externally driven growth factors. The market therapy has revealed a far more threatening outcome that by removing barriers on financial and income transferring processes (though vital for social survival), have exposed lower spectrum LFRs to become more deprived of basic social elements, creating by far more divide (digital, economic, social, and others).

Recent global trend has enlarged the free market zones and seemingly failed to balance the flow of relevant input-output parameters. It may be improved through an incentive-based, open-economy approach for quite a few years more, until regional specialization attains at an appropriate state. Each of the LFR governing

Table 4. Different approaches for socio-economic development

Level of intervention	Keynesian Approach (Amin, 1998)	Neo-Liberal Approach (Amin, 1998; Hausner, 1995)	Proposed Approach
Financial	Income Redistribution	Market Mechanism	Clustered through distributed networks (uniform distribution)
National Policy	Welfare Policy	Firm Policies	Emphasize SMEs, CBOs, CSOs
Regional Level	Focus Less Favored Regions	Market Deregulation	Integration into a common platform
Local Level	Direct/indirect incentives	Free Market	Transform towards sustainability (long term transparent policy)
All Approaches	Top-Down	Top-Down	Bottom-Up

Table 5. Transformation of approaches for socio-economic development

Conventional approaches	Transformed approaches
Firm centered	Demand driven
Incentive-based	Incentive-based, but with focus on sustainability
State-driven	State-entrepreneurs partnership
Standardized	Dynamically adjusted
Top-down	Bottom-up
National-specific	Region-specific (more meaningful if, local specific)
Short and medium-term	Short, Medium and Longer-term
Single-sectored	Multi-sectored

entities must act through a common achievable platform (MDGs, WSIS¹⁷, WSSD¹⁸, etc. are a few). ICTs, a plethora here can assist in migrating from older to newer approaches.

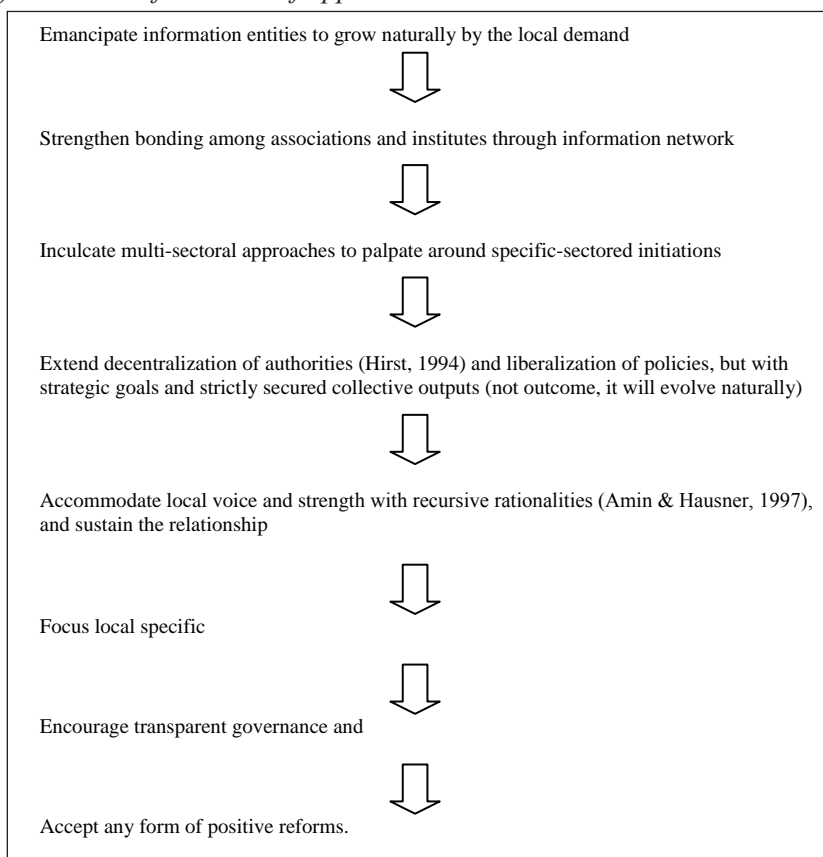

The local supply side infrastructure (the author prefers information infrastructure) need to be upgraded eventually to accommodate this transformation processes and ultimately compete with the upcoming, seemingly unknown (may be more uneven), distribution of resources. Resources may be propagated from concentrated supply to thinner supply depending on the acceptability,

capability, and transformation successes (never be trapped within any nontransparent consequences). For achievable transformation process, a proper information infrastructure is a must.

A bottom-up, local-specific, longer-term and multisectored approach has to be initiated at the early stage within all the developing economies. The author has tried to compile the transformation of approaches in Table 5.

The author describes a workflow on approaches to transform a conventional economy towards networked information driven economy as shown in Figure 11.

Figure 11. Workflow on transformation of approaches

Many of the so called learning regions (Morgan, 1997) such as Silicon Valley in the U.S., Baden Wurttemberg in Denmark, Indian IT Parks, and the Italian industrial districts have gained comparative advantages over others along these years in forming information networks with specialization (Amin, 1998) have found to adopt similar transformation in their approaches.

Effort has been made here to incorporate the determinants related to the institutional development on effect of ICTs with a few successful approaches. Firstly, the author would like to relate the potential of community enhancement that leads to institutional development.

Community Development Approach

Community informatics represents an emerging subset informatics that addresses the commu-

nity-based institutional dimensions (Gurstein, 2001; Loader, Hague & Eagle, 2000). Sometimes, community informatics tends to concentrate on communities of place rather than communities of interest. Hence, this field has to focus on social capital as well as studies related to community development (Doheny-Farina, 1996; Kavanaugh & Patterson, 2001; Pigg, 2001), rural economic development (Pigg & Crank, 2004), health care, and education. This approach and its work plan should address issues on sustainability of technology development, community networking, digital divide factors (Civille, Gurstein & Pigg, 2001), design issues, and effective usage (Gurstein, 2004; Pigg & Crank, 2004) of ICTs.

Rhetoric abounds regarding the importance of social capital in considerations of community sustainability. Considerable rhetoric also exists regarding the potential of modern ICTs to affect

the development of social capital in positive ways (Pigg & Crank, 2004). Furthermore, integrating low income or hard-to-employ workers and targeting disadvantaged groups are also important cornerstones of poverty alleviation strategies at the grass roots (Ghaus-Pasha, 2005). ICTs in this context can act as the facilitator of local content and information interchange and can enhance the process of development and create bonds of relationship among the stakeholders.

Social content is a second dimension of exchange relationships. Communication among parties and their respective knowledge of one another can complete the exchange. Common normative commitments are unimportant, and the value of the relationship is limited to the value of the exchange. They share common normative commitments and these relationships produce value-added products at the end. Together these two independent but often closely correlated dimensions—discreetness and social content—allow in drawing a relative (but not absolute) distinction between demands, markets, and networks (Ansell, 2000). ICTs can transform this discreetness towards togetherness and thus leading to empowerment of the community.

So, empowerment of societal actors and the creation of networks among them is an essential characteristic of the networked society for reasons identified both by work on the embeddedness of states in society (local demand) and work on constitutional order (state demand) (Ansell, 2000; Sabel, 1989, 1994). It is not difficult to imagine a community-based system that would act primarily on information function and then support the networking component of social capital building. Following Kretzman and McKnight's (1993) "asset model" of community building, the development of a searchable database that contains a brief description of community members' interests and skills (assets) could be useful in creating new networks among community members based on those interests or on skill building (Pigg & Crank, 2004).

However, economic behavior is embedded in networks of interpersonal relations, and therefore, crucially influenced by aspects such as mutuality, trust, and cooperation (Amin, 1998; Ingham, 1996; Smelser & Swedberg, 1994) and economy is shaped by enduring these forces collectively (Amin, 1998; Hodgson, 1994; Samuels, 1995), especially their role in disseminating information, knowledge, and learning for economic adaptability (Amin, 1998). These call for collective approaches through networked institutes of similar nature or of associations linking markets and states in participatory form. Institutional building in various natures has been evolved in many countries that have contributed positively in their development processes. Establishment of various civil societies across the globe can be cited here.

Civil Society Approach

Civil society is comprised of autonomous associations to develop a dense, diverse and pluralistic network. As it extends, civil society may consist of a range of local groups, specialized organizations and linkages among them to amplify the corrective voices of civil society as a partner in governance and in economy (Connor, 1999). Civil society should not be commensurate to non-government organizations (NGOs). NGOs are a part of civil society though they play an important and sometimes leading role in activating citizen participation in socioeconomic development and in shaping or influencing policy. Civil society is a broader concept, encompassing all organizations and associations that exist at the outer periphery of the state and the economy (Ghaus-Pasha, 2005).

"Civil society" is a relatively loose concept. Customarily used in reference to civil society organizations (CSOs), civil society includes a wide spectrum of community-based organizations (CBOs), trade unions, local communities, advocacy groups, policy research institutions,

private entrepreneurs, and social movements (Gabriel, 2003).

Through the free flow of information, which is clear and accessible, civil society groups with a vibrant media, can serve as a monitoring mechanism to ensure that government policies are carried out in a manner intended and thereby significantly contribute to good governance. Social mobilization (organizational strengthening) of CBOs at grassroot/sectoral levels is another major contribution of CSOs. It has been found that many civil society groups are constituted around specific issues of social concern such as the environment, labor rights, gender equity, and public health (Ghaus-Pasha, 2005). Encouraging new technologies including policy advice, technical support, information sharing, and resource optimization to establish their own businesses in the form of entrepreneurship, partnership, cooperative, or community enterprises in various agricultural, trade, or consumer commodities can promote RD. Simultaneously, integrating low income or hard-to-employ workers and targeting the marginal communities can form an important cornerstone of poverty alleviation strategies at local level.

Telecenter Approach

The deployment of ICTs in developing countries has become a key tactics of the international development community to support poverty reduction strategies. In this context, telecenters are seen as a tool to bring the benefits and potential of ICTs to locations that have so far been suffering from their remoteness and lacking connectivity to the world's information alliance. Very often telecenters are established to target communities in their entirety, providing Internet access, e-mail services, telephone services, educational services, and also library services or even postal services to large parts of the community. Consequently, these "Multipurpose Community Telecenters (MCT)" take an approach to improve the access to ICTs

on a broad range, in order to narrow the "digital divide" (UNIDO, 2003). Globally, telecenters is not a new concept anymore. However, Murray and Comford (1998) found that more than 60% of them in the UK and Ireland have been operating on a sustainable basis, though they may or may not be profitable.

UNIDO has clear finding on the success of MCT in Sri Lanka and Uganda which contribute to their national economic development. The Uganda Business Information Network (UBIN) in its capital, Kampala, is acting as an "infomediary," a One-Stop-Shop (OSS) in the form of a physical location operated by a private entrepreneurship that provides information services, ICT support services, and enterprise Internet solutions to SMEs on a commercial and demand driven basis (UNIDO, 2003).

INCLUSION IN PRSPS

At this moment, Poverty Reduction Strategy articles (PRSPs) are being treated as the driving force behind the overall development strategy of many developing countries. It is, therefore, essential to consider the role of information infrastructure in poverty reduction process (Murooka, 2004). In this context, private sector development comprising support for Small- and Medium-scale Enterprises (SMEs) also forms one of the contemporary strategies in PRSPs that may lead to socioeconomic development.

Like other developing countries of this region, in 2004 the Government of Lao PDR completed its National Growth and Poverty Eradication Strategy (NGPES) as the country's poverty reduction strategy article (PRSP). The NGPES identifies agriculture, education, health, and transport as priorities for public investments, and sets the country's medium-term development objectives. As an instrument to implement the NGPES, the Government has launched preparation of its Five-Year Socioeconomic Development Plan (SEDP)

for 2006-2010, and is keen to incorporate the management for development results (MfDR) approach in its formulation that undoubtedly involves ICT applications (Government of Lao PDR, 2005). However, countries of similar context must launch even longer-term initiatives to stabilize the economy and social sustainability.

They can establish programs enhancing the three-tier effect of ICTs:

- By enhancing access to information and creating and sharing of knowledge.
- By effectively speeding up the production processes and facilitating financial transactions throughout the economy with reduced costing.
- By connecting individuals, groups, enterprises, communities, and governments faster and more cost-effectively. (Lallana, 2004)

ARGUMENTS

Pervasive poverty and inequality are the major threat to prosperity, stability, and peace at the dawn of the 21st century. Notwithstanding extensive anecdotes about the digital divide, most ICT initiatives start by encouraging nations to become e-ready: to boost economic growth and increase e-commerce. These initiatives may assist countries to grow and contribute to poverty alleviation. However, globalization and ICT development tend to increase the inequality. Countries that seek widespread prosperity and sustainability may focus on e-ForAll; that is, on making the opportunities of ICTs open up for individual and social improvement accessible to all its citizens; and on applying ICTs to empower common folk and engage their participation in national and local development initiatives (Proenza, 2002).

There has been much experimentation, and much discussion, in recent years on the contributions that ICTs can make in combating poverty and promoting broad-based economic and social

development. Yet, there is still much needed to know about the actual impact of ICTs relative to other tools and resources; about the most effective strategies for mainstreaming ICTs as strategic tools of development and poverty reduction; about the necessary enabling factors for assuring maximum effective access to and sustained impact of ICTs in poor communities; and about how developing countries can use ICTs for growth and competitiveness in a global economy (infoDev, 2005). The question that always remains is how to effectively mainstream ICTs as tools of development and poverty reduction. Poverty reduction should be considered the entry point and not ICTs per se (UNDP, 2004).

By its very nature, ICT development tends to increase income inequality within the country for several reasons: (1) it requires relatively good education and special skills to make full use of ICTs for socioeconomic gains, (2) ICT infrastructure is more profitable and therefore easier to develop in urban areas, thus further broadening the gap between urban and rural access to ICTs, (3) those who developed widely used ICT applications are mainly from urban areas who could reap benefits from being first in tapping the ICT market in the country. However, despite the inequality bias, ICTs have the potential to improve the livelihoods of low-income earners by enhancing delivery of socioeconomic services, offering them opportunities to increase income and empowering them through participation in decision making processes.

CASE STUDIES

This section puts forward several case studies from different countries ranging from developed to developing with varying nature of ICT implementations, but mainly related to regional development through socioeconomic development and poverty reduction. Many of them are successful cases in their own localities, countries, and regions, and

Table 6. Countries and programs under APPEAL

Country	Program(s)
Lao PDR	Non Formal Education (NFE) to strengthen Community Learning Centres (CLCs)
Sri Lanka	Sarvodaya
Thailand	NFE with inter-village connectivity
Uzbekistan	Community empowerment
Indonesia	NFE through CLCs

may be replicated elsewhere, while a few had some difficulties that have been discussed here. Activities of a few organizations with tangible output have also been noted in this section.

Despite the poor growth of the overwhelming majority of developing countries, that of East Asian and some South Asian countries, in which governments continued to play an active role, had been remarkably good in managing ICT for development (Adelman, 1999). The use of ICTs in non-formal education programs to foster participation of marginal community in literacy, basic education, and continuing education activities in Indonesia, Lao PDR, Sri Lanka, Thailand, and Uzbekistan has launched with funds from Japan as UNESCO’s Asia-Pacific Program of Education for All (APPEAL) (UNESCO, 2004). Table 6 shows the program that has been started in those countries. This program mainly aims at PR through ICTs, which ultimately improves SED.

In 2002-2003, New Zealand’s Ministry of Economic Development (MED) undertook a review of the Regional Partnership Program (RPP). That review included an assessment of regional development policy in building local economic development capability and governance, development of partnerships and networks, and building of institutional linkages (Government of New Zealand, 2004a).

The review reveals that the RPP was performing against policy objectives, and the indicators of success that were selected to measure impact on outcomes. The indicators were mainly focused

on changed economic development partnership behaviors (Government of New Zealand, 2004b). After the review, two sets of changes were recommended, including those associated with the program itself, a few changes in the RPP, and changes in policies. Among many, one is “building better information into the next stage of strategy development (where there are regional data and information needs and gaps), to strengthen existing strategies, and in particular, identified regional specializations” (Government of New Zealand, 2003, p. 4).

In 1992, Estonia had just lost its major trading partner and was experiencing hyperinflation and a 15% fall in GDP (Darling, 2001). The country was turned around with sound economic policies and a thrust to modernization in which equitable ICT development played a key role. In similar context, building on a traditional policy of equitable growth, South Korea’s informatization program has raised the number of Internet users from 2% in 1995 (Park, 2001) to 55% in 2001 (ITU, 2003) to 63% in 2004 (Internetworldstats.com, 2005b). Primarily both countries have a substantial educational base that developed through sustained effort over the years. Furthermore, their action programs include cost-effective comprehensive measures to ensure that all citizens have access to and partake in the benefits of ICT development (Proenza, 2002).

In the U.K., Scotland and Wales have been adopting a “network strategy” for creating regional interfirm networks. In Belgium, creation

of smaller “impulse regions” has encouraged the formation of a social network and network among municipal bodies to provide comprehensive ways of thinking about the region (Ansell, 2000; Scottish Enterprise Network Strategy, 2005). This process of “regional networking and comprehensive thinking can be considered an important innovation in regional development practice” (Houthaave, 1998, p. 172).

In 1973, Ireland’s membership in the EEC enhanced its economic development. From 1973 to 1981, foreign direct investment increased by more than 27% per year. However, at the same time, traditional businesses were impacted by severe competition and from 1973 to 1988, 75% of domestic textile and apparel firms and 50% of domestic metal and engineering organizations collapsed. By 1987, Ireland took some measures through the Program for National Recovery and these actions helped restore confidence in the management of the public finances, break a cycle of inflationary wage expectations, improve relationships with the commercial sector, and establish an ongoing focus on economic development reform through partnership. During the 1990s, Ireland was ranked high for growth and development among many “rapid technological advances in industries” and “competitive telecoms and e-commerce infrastructure” (Dravis Group, 2004, p. 4) that could encourage foreign direct investments.

Malaysia, a high middle-income country is leading among many Asian counterparts in terms of telephone (fixed and mobile) and Internet penetration. Malaysia is also well known for its Multimedia Super Corridor (MSC) initiative. The Philippines is emerging as one of the key players in ICT enabled services like call centers and Business Process Outsourcing (BPO). Similarly, Sri Lanka has boldly declared that by 2007 it will be better known as the “e-SriLankan Miracle,” a model achieving global recognition in the deployment of ICTs towards the achievement of Social and Economic Development (Lallana, 2004).

On March 29, 2001, the “e-Japan Priority Policy Program” was adopted to realize the e-Japan Strategy and taken all measures that the government should rapidly implement it by 2006. The roles of the private and public sectors are detailed in the program with the private sector playing the leading role in the area of IT. The Program also identifies five areas for action:

1. Formation of the world’s most advanced information and telecommunications networks.
2. Promotion of education and learning as well as development of human resources;
3. Facilitation of electronic commerce.
4. Digitization of the administration and application of IT in other public areas.
5. Ensure security and reliability of advanced information and telecommunications networks. Further to this, in July 2003, “e-Japan strategy II” was launched aiming to create a “vibrant, safe, impressive and convenient” society with the active use of IT (Lallana, 2004, p. 5).

The South Korean government unveiled its fourth ICT master plan in December 2003, named “Broadband IT Korea Vision 2007.” This new master plan focuses on improving national productivity and individual quality of life through informatization (Lallana, 2004). Among its objectives, “e-Korea Vision 2006” aimed to facilitate continued economic growth by promoting the IT industry and advancing the information infrastructure.

By far the biggest contribution to Vietnam’s development process and poverty reduction over the past fifteen years has come from the *doi moi* reform process aimed at transforming the economy towards being more market oriented. ODA and UNDP have key roles in providing research based policy advice and analysis to facilitate the reform process (UNDP, 1999). Among four of the socioeconomic development strategies 2001-

2010, “science and technology for modernization” with practical implications in education and information technology has accelerated the increasingly knowledge-based economy in Vietnam. The Socioeconomic Development Strategy (2001-2010) aims to accelerate economic growth and poverty reduction through macroeconomic and structural policies designed to protect macroeconomic stability. It has been observed that, in the absence of a long-term strategic framework to guide and coordinate microfinance activities, the response to emergency challenges would be ad hoc. At the same time, the technical assistance program financed by the Japan special fund has emphasized enhancing the institutional capacity of various organizations within the economy. In this program, a microfinance library including a Web site and data center has been targeted (ADB, 2001) for ICT facilitation.

In accordance with the International Monetary Fund (IMF) and World Bank framework, the Royal Government of Cambodia (RGC) prepared an interim Poverty Reduction Strategy Article (IPRSP) in October 2000 based on a broad consultative process launched with active participation from inter-ministerial setup, development partners, and NGOs. The RGC has identified a number of priority public actions to reduce poverty. Among many, agriculture, rural development, trade, infrastructure, education, and health validates the potential areas where ICTs can be utilized for strategic implementation (Royal Government of Cambodia, 2001).

The Jamaican national poverty eradication program may have contributed, tangentially, towards the reduction of absolute poverty levels over the last half-decade, as claimed by the government, but a close examination of program management revealed deep-seated problems. These included a weak political analysis, poor coordination at the national and local levels (weak information backbone), and a lack of adequate institutional support (Osei, 2001).

The Government of Guyana and UNDP have agreed that the main thrust of UNDP’s assistance to Guyana should be directed towards supporting policies and programs for the eradication of poverty in the country. It was consistent with the strategies laid out in the two key Government policy documents, namely the National Development Strategy (NDS) and the Interim Poverty reduction Strategy chapter (IPRSP). Both of these documents recognize that no individual factor can be singled out as the cause of poverty in Guyana (IPRSP Guyana, 2000). However, a project support document (UNDP, 2005) suggests the involvement of ICTs by creating a modern and cost-effective management information system to facilitate aid coordination and management, including strengthening institutional capacity within central government agencies and increased ability to interface with donors and line ministries.

On June 7, 2004 the Government of Albania publicly presented its second Annual Progress Report (APR-2) of the National Strategy for Socio-economic Development (NSSED). Among several recommendations, strengthening the monitoring and evaluation functions within key line ministries and monitoring indicators for each line ministry were emphasized. In addition, a department of the NSSED (DoNESSED) has been established for coordination of all NSSED-related activities (IMF, 2004). These entail articulation of ICT applications within the Government systems. UNDP Albania has been supporting projects fostering capacity building and deployment of ICTs or the facilitation of their use within other development activities for many years. In 2001, the Country Office, with assistance of the regional SURF/BDP, formulated an ICTs for Development Framework document designed to focus ICTs for Development (ICTD) activities to have maximum impact and effectively mainstream ICTD tools within all UNDP programme areas. In June 2003, the document was updated to reflect the efforts of UNDP to support national efforts on the MDGs

and create a comprehensive MDG Umbrella Support Program (UNDP, 2003a).

Over the years, the Government of Malawi has taken a number of steps within specific socioeconomic development frameworks and programs to address some of the social and economic challenges facing the country. The Vision 2020 recognized the important role that ICTs can play in national development. Malawi has acknowledged the need to emphasize on ICT usage to solve its multifarious socioeconomic problems that include widespread poverty, rising urban unemployment and rural under-employment, deteriorating terms of trade and balance of payments, low growth in output, and environmental degradation (SDNP Malawi, 2003).

Philanthropy Australia is a peak national body in Australia in the philanthropic sector, representing individuals, families, communities, and corporate grant making trusts and foundations. Since 2001, Philanthropy Australia's ICT environment has improved significantly. The successful redevelopment of its ICT base has contributed to the development of more positive attitudes to the use of ICTs in the philanthropy sector and created more operational transparency (Government of Australia, 2005a). Barnardos Australia, another leading children's charity organization in Australia has developed an innovative ICT application, the Looking After Children Electronic System (LACES) to create a streamlined case management system and ultimately assists in improving children's community in Australia (Government of Australia, 2005b).

Between two of the very small organizations, SIDSNet (<http://www.sidsnet.org>) the Small Island Developing States Network, is a communication medium to discuss and share information on biodiversity, climate change, coastal and marine management, energy sources and trade. It promotes sharing experiences and developing a global SIDS agenda through information networking (World Bank, 2002). The other one, Fantsuam Foundation of Nigeria uses Microfinance and ICTs

as complementary tools for poverty alleviation. The ICT program started with only two rooms provided by the community. One of the rooms was the Community Library and the second was the IT training room (Comfort, Goje & Funmilola, 2003).

The New partnership for Africa's Development (NEPAD) strongly advocates private sector development for increased trade and investment as a key component to Africa's growth for poverty reduction (DBSA, 2003). However, Africa is already too dependent on the rest of the world. Sub-Saharan Africa's trade in goods with the rest of the world accounted for 56% of GDP in 2001 while the same ratio for North America was only 13.2%, 12.8% for Western Europe, 23.7% for Latin America, and 15.2% for Asia (World Bank, 2003). This does not translate into more effective poverty reduction processes. Increased trade could guarantee foreign debt service capacity but will not guarantee progress towards poverty reduction targets. Partnerships across social sectors and spheres of governance and policy development are, therefore, emphasized. These demand more effective civil society formation with better communication strategies (Gabriel, 2003).

On the other hand, recognizing the role of science and technology in socioeconomic development, many countries of Sub-Saharan Africa established science and technology policy-making bodies and research and development institutions. The United Nations Education and Scientific and Cultural Organization (UNESCO) acted as a catalyst by organizing the CASTAFRICA conferences for African ministers responsible for science in 1974 and 1987. The 1979 Vienna global conference on science and technology for development organized by the United Nations further sensitized and spurred African countries towards action. Along this path, Science and Technology policy making bodies and research and development institutions that were formed during the decade of independence are the National Council for Scientific Research (NCSR) in

Zambia, the Council for Scientific and Industrial Research (CSIR) in Ghana, the National Council for Science and Technology (NCST) in Kenya, and the Commission for Science and Technology (COSTECH) together with its many other research institutes and centers in Tanzania. The recognition of the role of ICTs in development by governments continues till today by putting in place national policies on science and technology, by the enactment of science and technology legislation and by the establishment of ministries of science and technology (Siamwiza, 2002).

The Organization for Economic Cooperation and Development (OECD) defines an international non-governmental organization (INGO) as “an organization established and governed by a group of private citizens for a stated philanthropic purpose, and supported by voluntary individual contributions” (Wheeler, 1988, p. 2). Throughout the 1980s, INGOs from around the world had been learning to use a computer network for socio-economic development. In 1984, a few INGOs agreed to establish a computer network, Interdoc, with member institutions from four continents. Interdoc formalized its mandate with an international accord called the Vallettri Agreement, and aimed to manage the system from a social perspective. Mainly, the network was used to inform and empower organizations, and disseminate information on sustainable development. Later on, Interdoc and its members assisted in forming the Association for Progressive Communications (APC). APC is one of the world’s largest computer networking institution at this moment, and serving NGOs dedicated to human rights, social, economic, and environmental aspects (Murphy, 2005).

ICTs was one of the major subjects that were discussed at G8 Kyushu-Okinawa Summit in July 2000, which adopted the “Okinawa Charter on Global Information Society.” In the Charter, ICTs were defined as one of the most potent forces in shaping the twenty-first century as well as an important means for communities to fulfill their potential demand. The Charter urged all stake-

holders concerned, including the private sector, to participate in constructing a global information society in which everyone, no matter where they live, can benefit from ICTs (JICA, 2001).

UNESCO recognizes the importance of using ICTs to achieve broad development goals. It has also given importance in the learning processes in understanding how ICTs can play an effective role in economic development, social transformation, political empowerment, and cultural enrichment.

The Global Village Energy Partnership (GVEP) was launched at the World Summit on Sustainable Development (WSSD) in Johannesburg in 2002. As a “partnership of partnerships,” it brings together a wide variety and number of partners. By accelerating the pace and scope of energy activities in a more coordinated fashion to reach the target of improving access to energy services for an additional 300 million people, mainly living in rural areas, by 2015. GVEP mainly rely on a multi-sectoral partnership approach (UNDP, 2003b).

InfoDev is an international consortium of official bilateral and multilateral development agencies and other key partners, facilitated by an expert Secretariat housed at the World Bank. Its mission is to assist developing countries and their partners in the international community to use ICTs effectively and strategically as tools to combat poverty, promote sustainable economic growth, and empower individuals and communities to participate more effectively and creatively in their societies and economies. It is an ongoing effort to develop innovative forms of partnership for knowledge-sharing and joint action bringing together government, the private sector and civil society in developing countries with the international donor community, the international private sector and other key partners (InfoDev, 2005).

There is a growing stake in using ICTs to support poverty reduction efforts and strategies to achieve the Millennium Development Goals (MDGs). However, many development initiatives

are increasingly incorporating an “ICT component” in their activities, but mostly as mere projects without a focus on policy variables that could enhance longer term impact and sustainability. UNDP is supporting this initiative in many countries by integrating ICTs appropriately into poverty reduction processes and other development strategies with linkages between ICT development strategies and policies, with a view to identifying opportunities, constraints, and priority areas of focus (UNDP, 2004).

FUTURE OF ICTS IN THE CONTEXT OF SOCIOECONOMIC DEVELOPMENT

ICTs, as enabling technologies are being used in almost all sectors of economy and facets of human life. However, how they impact on the development of the ICT sector remains always critical. Subsequently, it is equally important to assess the wider ramifications of ICTs on society at large. Delving more deeply, there is consensus in many researches that ICTs will shape the future of the world through growing reliance on the technology itself, in all aspects of life and in all sectors—at work, at home, in medicine, in communications, in transport, and so forth. The Internet is seen as the lynchpin, ushering in a world that is more “connected” than ever before. Nevertheless, concerns are raised in some studies that access may become increasingly restricted to those who can afford the technology by creating the information rich and information poor. There has been a paradigm shift in innovation of ICTs with convergence between ubiquitous computing, ubiquitous communication, near-zero telecommunications costs and intelligent user interfaces providing seamless interoperability of devices across networks (EMCC, 2003a, 2003b).

ICTs can play a variety of roles in sustainable development in many countries, acting as monitoring tools, assisting improved production

techniques, enhancing resource optimization, assisting environmental management, improving lifelong learning, and so forth. At the same time, ICTs should not be allowed to create negative impact through channeling any obsolete technology (EMCC, 2003a). The technology gap may grow (DotCom, 2005). However, ICTs should not just be treated as tools for development; rather, they should be treated as tools for empowerment.

At the end of 2000, the U.S. had about 135 million Internet users. Between 1990 and 1995, the compound annual growth rate of U.S. Internet users was over 73%, and from 2000 to 2007, the growth rate is expected to be less than 8% per year, while, the Asia Pacific region became the largest with 178 million Internet users in 2001 and it is expected to grow to over 615 million in 2007. At the same time, the wireless Internet users are expected to grow at a very rapid pace. Wireless Internet users in 2001 were about 102 million, and it is expected that in 2007 it will be more than 800 million (about 41% rise per year). Thus, the wireless Internet will take off rapidly as an always on service, readily available and a useful content provider with small displayable wireless devices (eTForecasts, 2005).

Enterprise development at the marginal end requires adoption of ICTs by SMEs. Duncombe and Heeks (2001) conducted a study for DFID and found that the most direct benefit (employment, growth and local capacity) within the ICT sector itself goes to the institutes that are working at the grass roots. Raising local ICT sector capacity was identified as a key enabler for other sectors—government, private, and NGOs—particularly those concerned with implementing ICTs within wider poverty alleviation programs—in health, education, environment, and governance (ICT4D Social Enterprise Toolkit, 2005).

Many policies, initiatives and measures concerning ICTs exist, impacting at the national, regional, as well as at global level. In the global context, there are international agreements, treaties (concerning international trades, protection

of intellectual property, Internet domain name system coordination, telecommunication standards, etc.) enhancing parameters of development at all levels. Activities of the World Trade Organization, the World Intellectual Property Organization, the Internet Corporation for Assigned Names and Numbers, and the International Telecommunication Union are there to name a few (EMCC, 2003c).

Despite all the massive obstacles that stand between small and medium sized enterprises (SMEs) in developing countries and state-of-the-art entrepreneurs in developed countries, there are opportunities to create demand, provided that the establishment has something of quality to offer and deliver it reliably (Southwood, 2004). ICTs can assist there to bridge the gap and able to make them easily achieve the target. Ranging from controlling internal cash flow, to zero-time-delayed order placing via Internet, to secured financial transaction, to management of entire operation can be effectively controlled by ICT applications.

ICTs allow a reduction in transaction costs, improved communications with different marketing interfaces, and improved information about new opportunities. They can remove the constraints in obtaining and communicating information through empowerment of Micro and SMEs. Evidence suggests that service based enterprises (business, financial, technical) and value-added entrepreneurs (tourist sector, manufacturing—ready made garments, and so forth—utility, call centers, offshore software houses, etc.) will reap most benefit from ICTs and will be in a better position to transmit benefits to the wider community (ITDG approaches, n.d.).

Emphasizing on increased engagement of community groups and development NGOs in the design of regulatory frameworks for public-private-partnership-based ICT access in remote areas might result in more balance in the competitive bidding of operators between achieving least cost (and/or subsidy) and livelihood-driven

performance. The design parameters of partnership projects should be formulated for ICT entrepreneurs to test the financial viability of marketing or products/service development targeted to low-income consumers. And, successful partnership business models should be replicated into low-income consumer market in developing countries (UNICT Task Force Report, 2004a).

However, to take full advantage of these relative strengths demands vision and leadership in different segments of the society with a clear and renewed definition of roles and responsibilities among government, business, civil society, academia and international organizations. Active leadership is needed in regulatory support for the breakthrough of wireless solutions and delicensing of frequency spectrum. Sustained funding for digital divide research and development projects and pilots is another prerequisite. Leadership is also essential in areas that can employ ICTs by reengineering the public sector such as e-government (UNICT Task Force Report, 2004a draft).

For business, leadership is needed for the allocation of investment in financial, human and organizational resources in ICTs. For civil society, leadership is needed for leveraging the process of transforming ICT technology into tools for transparency emphasizing the benefits of the poor. For multilateral institutions and international agencies, leadership in the form of funding is needed for continued and renewed support in mobilizing resources for roll-out of ICT infrastructure, and continued support for applications of ICTs in all sectors (UNICT Task Force Report, 2004a draft).

Strategic alliances amid government, business, civil society and international organizations are a growing feature of both developed and emerging economies. Such multi-stakeholder partnerships (MSPs) are essential because it is evidently clear that no other sector in society can deliver the complexities of sustainable human development alone. MSPs are alliances of parties drawn from government, business, civil society, and

international organizations that strategically aggregate the resources and competencies of each to resolve the key challenges of ICTs as enablers of empowerment that are founded on principles of shared risk, cost, and mutual benefit (UNICT Task Force Report, 2004b).

CONCLUSION

Despite the huge potential of ICTs in assisting communities to increase their overall well-being through community development, there are relatively a few examples of sustained community networks built around ICTs when compared to commercial applications, even in the developed countries where the technologies have been increasingly available for more than 20 years (Marshal and Taylor, 2005). Koanantakool (2002) stated that though the burgeoning use of ICTs is widely acknowledged and discussed today in the global economy, it remains largely undefined and unrecognized in official ICT statistics. This is mainly because various data on ICTs are not readily available or differ widely or varied in nature, depending on the definition and methodology used by each entity collecting them. Therefore, the ICT measurement is becoming a universal issue in many countries and international organizations, comprised of agreed definitions, methodologies, and guidelines.

It demands combined and complementary efforts by international agencies, national governments, local authorities, private sector, and civil society organizations (CSOs). In this aspect, civil society can make a larger contribution both directly and indirectly to the process of poverty reduction and attainment of other MDG targets (Ghaus-Pasha, 2005). The question remains how to effectively mainstream ICTs as tools of socioeconomic development and poverty reduction (InfoDev, 2005). Given the ability to accept and control the situation at local level, the local infrastructure is not always a barrier to use but skill,

resources, and funds remain always susceptible to sustained operation.

It is important to distinguish between the incidence of poverty as a percentage of the total population and the absolute number of the poor. The share of the population in poverty has declined for many developing countries as a whole (28.3% in 1987 to 24% in 1998 based on \$1/day and from 61% in 1987 to 56% in 1998 based on \$2/day), and in all developing regions except Sub-Saharan Africa and Eastern Europe and Central Asia. Declines have been pronounced and sustained over a longer period for the most populous developing countries (World Bank, 2000).

When choosing the appropriate technology for any poverty intervention project, particular attention should be paid to infrastructure requirements, local availability, training requirements, and technical challenges. Innovative technology solutions can be used to take advantage in development projects when they respond to user requirements at the grassroots. Existing technologies, particularly the telephone, radio, and television, can often convey information at less expense, in local languages, and to larger numbers of people than can newer technologies. In some cases, the former can enhance the capacity of the latter (InfoDev, 2003). However, financial sustainability remains as the most important challenge for ICTD initiatives.

The impact of ICTs in rural areas and particularly on rural poverty is very limited despite its penetration into every corner of society. Although, experiences abound demonstrating that ICTs can make a significant contribution to reduce poverty, the list of failed initiatives appears even longer. One of the major reasons for this mixed performance in rural areas is that its adaptation to the local needs was left either to the private sector or to non-governmental organizations. These organizations seldom operate without an official framework of policies and guidelines and a clear definition of tasks and responsibilities for the different “players.”

Development of national ICT strategies for poverty alleviation is a relatively complex matter. There is no single solution or best ICT project to fit all situations, but a variety of approaches would be needed, particularly in the early stage of ICT insemination. Understanding how ICTs can service specific development goals requires both knowledge of appropriate technologies and how these technologies could be operationalized to address socioeconomic goals. Key policymakers need to make informed decisions to enact “enabling” policy frameworks appropriate for their contexts and demands (Expert Group Meeting, 2003). It has to be understood that:

- ICTs alone are insufficient for making significant benefits to emerge in a near future.
- ICTs will not transform bad development into good development in a nightfall but can make good development better in a few years.
- Effective applications of ICTs comprise both a technological infrastructure and an information infrastructure.
- In rural settings in developing countries (where the vast majority of poor people live), it is always a challenge to install the technological infrastructure, but the task is relatively simple in establishing the information infrastructure.
- The application of ICTs in the absence of a national development strategy will inevitably result in sub-optimal outcomes.
- Though ICTs provide opportunities for development, desirable outcomes always arise from the actions of people at large (Lallana, 2004).

There is no clear-cut measurement for the value and significance of institutional consistency or their partnerships in regional context. Firstly, the resource functions are associated with the limitation to trusted and tried development paths, the concentration on certain contents, the exclu-

sions of other possibilities—up to institutional lock-ins (Grabher, 1993). Secondly, regions are neither autonomous nor sovereign in the relations to the national state or supranational organizations (Braczyk & Heidenreich, 1996). Thirdly, regional innovation capacity depends mostly on the individual elements of local order (Friedberg, 1995) and their inherent governance elements (Braczyk & Heidenreich, 1996). Finally, attention should be paid to the process of how poverty is perceived and defined vis-à-vis ICTs at both ends of the pipeline.

If all agreed that poverty is the sum of all hungers then ICTs can play a definite role as tools to provide information. Furthermore, links to other seemingly unrelated areas such as energy provision services, disaster prevention and management, and education and learning should become more self-reliant (UNDP, 2005). For optimal partnership effectiveness among development actors, there is a need to patronize coordination and cross sectoral fertilization within and among the regions (World Bank, 2003b).

Chapter 1.17

Evolution of the Euro and Currency Competition in the Global ICT Age

Sadayoshi Takaya
Kansai University, Japan

ABSTRACT

This chapter focuses on the function of international currencies as foreign exchange vehicles, which has a character of the network externality. On January 1999, the euro was introduced in Europe where the functions of the euro are limited as a currency. After January 2002, the euro had perfect functions, while the competition between the euro and the U.S. dollar was keen as the dominant international currency. We present the currency competition model with a decreasing transaction cost that reflects the character of the network externality, to investigate the competition between the euro and the dollar. We suggest the impact of introduction of the euro is the determinant for competition winner between the euro and the dollar.

KEY CURRENCY AND INTERNATIONAL MONETARY REGIMES

International monetary regimes are arrangements that are made for agents to carry out foreign official and private settlements. These regimes include provisions pertaining to the use of international currencies as settlement currencies, exchange rates regimes and degree of capital mobility in order to decide the availability of foreign settlements. In particular, the international currency that is used primarily in international settlements is referred to as a key currency. Furthermore, there exists an inherent asymmetry in international monetary regimes between the key-currency country and the non-key currency countries. In other words, although the country providing the key currency can make foreign settlements using its home currency, the country providing a non-key currency cannot. Therefore, the key-currency country does not face exchange rate risks.

Since the key-currency country is secure in the independence of its own policy objectives, it has the option of altering the exchange rates regime and the degree of capital mobility depending on the global economic situation. The degree of flexibility of the fiscal policy is also a criterion for the choice of an international monetary system. If a government intends to expand its fiscal deficits, it would be inclined to opt for a system wherein it is easier to raise finance from foreign agents. In brief, if liberalization is faced with a difficulty in sustaining a fixed exchange rate regime, the government will be able to liberalize capital controls in order to alter the flexible exchange rate regime.

Non-key currency countries use the key currency because of its easy availability and for international settlements. Under this circumstance, non-key currency countries choose an exchange rates regime and the degree of capital mobility taking into consideration the effects that exchange rates and capital mobility have on their economies. The choice of an international monetary system depends on the preference of the country or the government. For example, if a government prefers to stabilize exchange rates, it will not hesitate to restrain capital mobility. If a government prefers to import foreign capital, it will opt to liberalize capital controls and adopt a fixed exchange rates regime. However, such countries will face a difficulty in maintaining a consistency between free capital mobility and fixed exchange rates regime.

Historically, the international gold standard persisted before World War I with free capital mobility and fixed exchange rates. The pound sterling of Great Britain was the key currency at that time. The gold exchange standard survived through the interval period with unstable exchange rates and capital controls. Although the pound sterling continued to be the key currency during this period, its significance was diminished. Post World War II saw the emergence of the Bretton Woods regime with fixed exchange rates and

capital controls. The U.S. dollar has since been the key currency. Since the 1970s, most major countries have experienced the flexible exchange rates regime. Although international capital movements were formerly restrained, these have gradually been liberalized in developed countries since the 1980s. This liberalization led to the emergence of a global financial economy and intensified capital mobility by hedge funds, mutual funds, pension funds and so forth.

The evolution of the euro in the 1990s is considered to be a prominent characteristic of the globalized economy. The emergence of a single currency area accelerated the further integration of money and financial markets in the European Union (EU) to promote the possibility of the euro emerging as not only an international currency but also the key currency. As a non-national but common currency, the euro is currently not used in most countries in the EU, but only in the periphery countries of the EU. It is possible that the euro will compete with the U.S. dollar, which has been the key currency globally since World War II. This chapter investigates the possibility and conditions for the euro to emerge as the key currency by presenting the dynamic currency competition model.

The primary functions of an international currency are described in terms of its three roles. It acts as (1) a unit of exchange, (2) a means of payment, and (3) a store of value. These three functions of the international currency are not independent of each other. Any currency or medium of exchange has the function of being a store of value, which implies purchasing power. Money cannot work as a medium if currency does not play the role of a unit of account. Therefore, any currency must perform these perfect functions.

On the other hand, the functions of the international currency include six roles, which are classified by users, the private sector, the official sector, and traders in foreign exchange markets. In the private sector, the international currency is used as denomination currency, vehicle currency,

payments currency and investment currency for portfolio allocation. The denomination currency is used when private agents write an invoice to denominate prices in trading goods and services with foreign countries. In addition, agents use this currency for domestic trading in high-inflation countries. This case is referred to as currency substitution. Vehicle currency is used for trading with foreign agents, and payments currency is used for trading settlements. Private agents also use the international currency when they prefer global portfolio allocation. If capital movements are liberalized, it will be possible for private agents to invest in foreign assets or currencies. The international currency for portfolio allocation is the currency that these assets or moneys are denominated in.

As mentioned above, in foreign exchange markets, traders use the international currency as a foreign exchange vehicle. In the foreign exchange markets, official agents use international currencies to intervene in the markets to restore the stability of exchange rates. Hereafter, we will refer to the international currency as “intervention currency” in the context of this function.

International currencies do not always perform all six functions. At present, only the key currency, such as the U.S. dollar, has these perfect roles. However, the U.S. dollar does not always play a dominant role as an international currency. Private agents in industrialized countries prefer to use their home currency for exchange risks or transaction costs. This results in a decline in the private use of the U.S. dollar as the denomination and the vehicle currency.

The determinants of international currencies are transaction costs, security issues, policy incentives, policy instruments and risk¹. From among these determinants, this chapter will focus on transaction costs because they are related to the settlement system, which is dependent on Information and Communication Technology (ICT). The transaction cost of international currencies implies a bid-ask spread, which becomes low if

the market for the foreign exchange vehicle is large and deep. Further, as pointed out by Hartman (1997), high exchange volatility increases the transaction cost. Monetary authorities tend to use the same currency for intervention.

One of the determinants of international use for a currency is safety, which depends on the settlement system between cross-border banks. This is because global risk and more importantly, systemic risk that arises from currency crisis and contagion, result in a cross-border bank failing to run other banks not only in the same country but in other countries as well. Since cross-border banking is always faced with systemic risk, banks with cross-border operations pay particular attention to safety settlement networks. Further, risk-averse investors tend to select the currency without systemic risk, resulting in the use of banks participating in safety settlement networks or RTGS.

The Economic Monetary Union (EMU) in Europe now has a settlement system between banks in EMU and non-EMU member countries-Trans-European Automated Real-time Gross settlement Express Transfer (TARGET). TARGET is a pan-European system interlinking EU real-time gross settlement systems. It allows large euro payments to be made in real time across EU countries. Although private banks in EMU member countries have deposits in each central bank for settlement purposes, the central banks of member countries share information on settlements through the EMU in order to connect to a common information platform, or TARGET, which is a decentralized system, not through the European Central Bank (ECB) but through interlinking or bilateral linking. EMU member countries can connect with each other through this system with low risk. The real-time gross settlements system (RTGS) is sustained by ICT, which provides the potential to conduct massive settlement procedures between banks in EMU and non-EMU member countries.

In addition to TARGET, private foreign settlement systems such as EURO1 by the Euro Banking Association (EBA), RTGS^{Plus} in Germany, and Paris Integrated Settlement (PIS) in France provide payments services.

EURO1 is not a gross settlement but a net settlement system operated by EBA, which was a former ECU clearing system. The use of TARGET incurs a high transaction fee because it employs RTGS; however, the transaction fee incurred for EURO1 is lower because it employs a netting payment system for large transactions. In addition, the STEP1 system connected to EURO1 is a netting payment system for small transactions.

The Euro Access Frankfurt (EAF), a net settlement system operated by Landesbank Hessen, has been substituted by RTGS^{Plus} following its declining usage since the introduction of the euro. RTGS^{Plus} has two payments systems, express payments and limit payments. The former is for emergent settlements and the latter for regular settlements. RTGS^{Plus} is open to banking institutions not only in Germany but also in other European countries.

PIS is a liquidity bridge between two net settlement systems: the Paris Net Settlement (PNS) and RTGS in France and Transfers Banque de France (TBF). PNS carries out continuous daily bilateral settlements. Meanwhile, the system makes multi-lateral netting unsettled volume. PNS is connected to TBF, which is operated by Banque de France and is also interlinked with TARGET.

On the other hand, the Clearing House Interbank Payment System (CHIPS) sustains international settlements by using the U.S. dollar. CHIPS is installed in the New York Clearinghouse, where net settlement amounts are calculated. Finally, the amounts are cleared through Fed Wire in the Federal Reserve Bank of New York, where 21 member banks make settlements through deposits in the Reserve Bank. Non-member banks can use deposits in member banks for domestic and international settlements. In addition, information can be obtained regarding agreements and

confirmations of international settlements, such as trade payments, international investments, loans and deposits, and transmits through the Society for Worldwide Interbank Financial Telecommunication (SWIFT), which is a computerized system for information transfer.

TARGET, like RTGS, differs from CHIPS as a net settlement system in real-time risk management. Worldwide users of international settlements would make a choice between the euro and the U.S. dollar for risk management. In other words, because the development of ICT sustains the safety of the settlement system, ICT would be one of the determinants of the international currency.

If the role of the U.S. dollar as a foreign exchange vehicle declines, an alternate international currency has the potential to emerge as a dominant currency in foreign exchange markets. We attempt to investigate the conditions for the shift of the key currency from the U.S. dollar to the euro. In the next section, we develop a model with decreasing cost function.

The remainder of this chapter is organized as follows. In Section 2, the model is introduced in order to explain the characteristics of the foreign exchange vehicle function of the international currency and discuss the competition between the euro and the U.S. dollar. Section 3 is a summary that discusses the future role of the euro.

THE MODEL OF THE CURRENCY COMPETITION

Framework of Our Model

We focus on constructing the model of exchange vehicle currency among foreign exchange traders. This is done for following reasons. First, the use of international currency as exchange vehicle currency is dominated in foreign exchange markets, while the share of trade vehicle currency is small in the markets. This situation is resulted

by a series of exchange control liberalization in developed and developing countries. Second, Krugman (1980) suggests the exchange vehicle currencies are the most important factor of the character of international currency, which has a network effect including increasing return. However, Krugman doesn't indicate the dynamic model of international currency. So, his suggestion is not sufficient to explain why a currency becomes the international currency. We assume a dynamic model in this chapter, which basically has same structure in Takaya (2005).

The increasing return model is applied to explain the characteristic of the network effect of exchange vehicle role of international currency in the foreign exchange markets. The network effect means that the more of an international currency trader of foreign exchange use, the smaller the transaction fee for the international currency becomes. To explain this, the decreasing cost model that applies the increasing return model is introduced. Recent studies by Krugman (1991), Matsuyama (1992) and Murphy, Shleifer and Vishny (1989) have attempted to derive multiple equilibrium to mention economic development when the paths both to good development and to bad development. Their studies suggest roles of expectation for future return and historically initial equilibrium. In this chapter, the increasing return model is applied to our non-linear decreasing transaction model to describe the network effect of the international currency. Krugman (1991) constructs the linear model with increasing return to investigate the characteristic of local equilibrium. Krugman's model is expanded to non-linear model in our model.

We assume two relevant currencies. These are international currencies traded in the foreign exchange markets, for example, the euro and the U.S. dollar. Here, we introduce currency speculators in the third country, who maximize their returns in each period. 1 denotes the currency or assets denominated in the euro, 2 ones denominated in the U.S. dollar. The third countries' currencies are

not international currency, therefore, traders in the countries trade the euro or the U.S. dollar for international transactions. They decide on which currency they investment inter-temporally without considering interest rate differentials. Here, δ_j denotes interest differentials between interest rate in j country and home country.

Since traders face the volatility of exchange rates between international currencies and home's, they make expectations on exchange rates. ε_j represents expected fluctuation of exchange rates. While ε_j generally depends on volume of trade in foreign exchange markets, we assume ε_j is constant at first. We relax this assumption later².

All of trade are assumed to be charged the ratio of transaction fee c_j ($j=1, 2$) which is decreasing function of the total assets balances, B_j ($j=1, 2$) denominated by each currency. In the practical markets, there are differentials between bid rate and ask rate, so called bid-ask spreads, which are though to be reflected in the search cost of each currency trade. Since the search cost assumed to be depend on convenience of meeting currency which trader intend to buy and sell it, the more the volume of transaction increase, the smaller the transaction fee decrease. That is, the transaction cost has the character of economy of scale. Form the other view, difference of ICT innovation related with settlement system results in different structure of transaction cost. We assume z as the ICT innovation parameter by the euro. z represents TARGET system, which is superior to CHIPS. The flows not only of transactions in the foreign exchange markets but also of potential transactions affect the cost, which are the asset positions. Then, we assume c_j decreasing function³. However, each trader deals with c_j exogenously because economy of scale is externality. The cost function is as follows;

$$C_1 = zc_1(B_1) \tag{1}$$

$$c'_j = \frac{\partial c_j}{\partial B_j} > 0, c''_j = \frac{\partial^2 c_j}{\partial B_j^2} < 0$$

where α is assumed to be the parameter representing technology for transaction by using the euro.

We assume each trader also faces the adjustment cost φ , depending on investment volume N . Adjustments of asset position assume to be expense increasingly. The function φ is a following increasing function;

$$\varphi = \varphi(N) \quad (2)$$

Here, we assume $\varphi' = \frac{\partial \varphi}{\partial N} > 0, \varphi'' = \frac{\partial^2 \varphi}{\partial N^2} > 0$.

The number of traders in the third countries is assumed constant. For simplicity, trader's investment volumes are supposed to be constrained constant instantaneously. When each trader determines whether they invest in assets denominated in the euro or the U.S. dollar, she or he faces the constraint:

$$n_t = n_{1,t} + n_{2,t} \quad (3)$$

where n_t denotes constraint of each speculator's total investment in period t , n_1 investment to assets denominated in the euro, n_2 investment to assets in the U.S. dollar. Total investments in this whole economy are defined as N in each period, which is assumed to be constant for simplicity. In other words, we assume accumulation rate of total assets is given. Investment constraint in this whole economy is as follows:

$$N = N_1 + N_2, \quad (4)$$

where N_1 denotes investments in the euro assets, N_2 investments in the U.S. dollar assets. Stock constraint of each trader is as follows:

$$b = b_1 + b_2,$$

where b denotes total holding assets of each speculator, b_1 holding euro assets, b_2 holding

U.S. dollar assets. Aggregated stock constraint in whole economy is as follows:

$$B = B_1 + B_2, \quad (5)$$

where B denotes aggregate assets in this economy, B_1 aggregate the euro assets, B_2 aggregate the U.S. dollar assets.

Let an individual speculator's profit function be represented by π as follows:

$$\pi = (\varepsilon_1 + \delta_1)b_1 + (\varepsilon_2 + \delta_2)b_2 - zc_1(B_1)n_1 - c_2(B_2)n_2 - \varphi(N_1 + N_2)$$

We can aggregate each speculator's profit function to get a profit function in this whole economy:

$$\Pi = (\varepsilon_1 + \delta_1)B_1 + (\varepsilon_2 + \delta_2)B_2 - zc_1(B_1)N_1 - c_2(B_2)N_2 - \varphi(N_1 + N_2) \quad (6)$$

Π denotes an aggregate profit function. The change of asset denominated by the 1 currency is as follows:

$$\dot{B}_1 = N_1 \quad (7)$$

Each trader maximizes inter-temporal profit subject to the change of asset denominated by the euro. Trader's maximization problem is as follows:

$$\max \int_t^\infty \Pi_t e^{-\rho(s-t)} ds \quad (8)$$

$$\text{s.t. } \dot{B}_1 = N_1.$$

Each speculator in each period determines the volume of investment in euro assets or U.S. dollar assets, while she or he regards transaction cost function as given.

We can define the current value Hamiltonian as follows:

$$H = (\varepsilon_1 + \delta_1)B_1 + (\varepsilon_2 + \delta_2)B_2 - zc_1(B_1)N_1 - c_2(B_2)N_2 - \varphi(N_1) + \lambda N_1 \quad (9)$$

where γ denotes co-state variable. Necessary condition is as follows;

$$\frac{\partial H}{\partial N} = 0, \quad (10)$$

$$\dot{\lambda} = \rho - \lambda \frac{\partial H}{\partial B_1}. \quad (11)$$

Transversality condition is as follows:

$$\lim_{t \rightarrow \infty} \lambda_t B_{1,t} \exp(-\rho t) = 0. \quad (12)$$

From (10),

$$-\alpha c_1(B_1)N_1 - c_2(B_2)N_2 - \phi'_{N_1} + \lambda = 0,$$

which can be written by a form of inverse function as follows:

$$N = N(\lambda, B_1), \quad (13)$$

where we note $\frac{dN}{d\lambda} = \phi'' > 0$, $\frac{dN}{dB_1} = -\frac{zc'_1 + c'_2}{\phi''}$ for our assumptions.

From (13), Equation (11) yields:

$$\dot{\lambda} = \rho - \lambda \left(\Omega - zc'_1(B_1)N_1 + c'_2(B_2)N_2 \right), \quad (14)$$

where we note $\Omega = (\varepsilon_1 - \varepsilon_2) + (\delta_1 - \delta_2) = const.$ from our assumption. With attention to (12), equation (14) can be solved as follows:

$$\lambda = \int_0^{\infty} \left(\Omega + \alpha c'_1(B_1)N_1 - c'_2(B_2)N_2 \right) \exp((- \rho)(s - t)) ds, \quad (15)$$

where γ represents a current value of a series of difference of expected gains and transaction cost between both two currencies. This suggests determinants of investment are current and future gains from both assets and transaction costs. In other words, difference of future transaction costs depends on other speculator's expecta-

tion for future transaction costs for a reason of externality.

A simple way of exploring how speculations to the assets denominated in the euro determine is to take a linear approximation to the two-equation system in a neighborhood of the steady state. The result is:

$$\begin{pmatrix} \dot{B}_1 \\ \dot{\lambda} \end{pmatrix} = \begin{pmatrix} A_1 & \phi''_{\lambda} \\ A_2 & \rho \end{pmatrix} \begin{pmatrix} B_1 - \bar{B} \\ \lambda - \bar{\lambda} \end{pmatrix}, \quad (16)$$

where we define $A_1 = \frac{\partial N}{\partial B_1} < 0$,

$A_2 = \alpha c''_1 N_1 + c''(\bar{N} - N_1) + zc'_1 N'_{B_1} + c_2 N'_{B_1}$. The sign of A_1 is negative, but that of A_2 is ambiguous.

The transaction cost c assumed to be a decreasing function of B . Then, the sign of A_2 is negative, which is shown above. Trace (tr.) and determinant (det) of matrix (16) are as follows:

$$tr. = A_1 + \rho = -\phi''^{-1}(zc'_1 + c'_2) + \rho, \quad (17)$$

$$\begin{aligned} \det &= A_1 \rho - A_2 \phi''^{-1} \\ &= -\left(\phi''^{-1}(zc'_1 + c'_2) \right) \left(\rho - \phi''^{-1}(\alpha c'_1 + c'_2) \right) - \phi''^{-1} \\ &\quad \left(\alpha c''_1 N + c''(\bar{N} - N_1) \right). \end{aligned} \quad (18)$$

Both of signs of trace and determinant are ambiguous a priori. Here, we suppose *trace* is positive. That is:

$$\rho - \phi''^{-1}(\alpha c'_1 + c'_2) > 0, \quad (19)$$

is assumed⁴. This inequality implies that the size of ρ and ϕ is sufficient large, or the technological innovation z is large. z means ICT innovation speed in the euro might be higher than that in the U.S. if the innovation causes the cost decrease through the construction of rigid sage and convenience system. Now, we can make a distinction between some cases below, according

Figure 1. The phase diagram in the case of decreasing function of transaction cost (1)

to parameters of the determinant because the sign of determinant is ambiguous a priori.

Case 1

We assume the following inequality:

$$\begin{aligned} & \left| -(zc'_1 + c'_2)(\rho - \phi^{-1}(zc'_1 + c'_2)) \right| \\ & > \left| (zc''_1 N_1 + c''_2 (\bar{N} - N_1)) \right|. \end{aligned} \quad (20)$$

This inequality (20) means that the degree of decreasing cost of transaction is smaller. In case 1, the network effect of an international currency as the foreign exchange vehicle is not strong.

In case 1, two equilibriums E_1 and E_2 are saddle because the determinant of each equilibrium is negative. Because det is negative in this case, the equilibrium is saddle point with unique stable arm, which we have explored in the previous section. The phase diagram is shown as Figure 1.

Case 2

In case 2 of the parameters of the determinant, the following inequality is assumed:

$$\begin{aligned} & \left| -(\alpha c'_1 + c'_2)(\rho - \phi^{-1}(\alpha c'_1 + c'_2)) \right| \\ & < \left| (\alpha c''_1 N_1 + c''_2 (\bar{N} - N_1)) \right|. \end{aligned} \quad (21)$$

This inequality (20) means that the degree of decreasing cost of transaction is larger. In case 1, the network effect of an international currency as the foreign exchange vehicle is strong.

Figure 2 shows the phase diagram of λ and B . The lines of $\dot{\lambda} = 0$ and $\dot{B} = 0$ are right upper slope with two equilibrium E_L and E_H . E_H is equilibrium where share of the euro is highest in the equilibrium. Also, E_H is saddle point. The reason is that determinant of matrix of coefficients of (16) is negative since B_1 is smaller for the bigger B_1 from our assumptions. The share in E_L is lower than one in E_H . The determinant of matrix of coefficients in E_L is positive since B_1 is bigger for the reason of relatively smaller B_1 . Thus, this point is source. The point 0 is also equilibrium, where the share is zero. The determinant of matrix of coefficients in zero point is positive as we mentioned above.

Thus, smaller uses of the euro can move to high uses in case 3 by speculator's expectations. At the beginning of introduction of the euro, frequency of use is lower than that of the U.S. dollar. However, the share of the euro could be higher if expectation of use of the euro is evolved in the near future, to higher frequency than the U.S. dollar.

Figure 2. The phase diagram in the case of decreasing function of transaction cost (2)

IMPLICATIONS FOR THE FUTURE OF THE EURO

This chapter investigated the conditions for the euro to dominate the U.S. dollar as the key currency in foreign exchange markets. When the euro was first introduced, technical innovations in dealing in the euro significantly decreased the transaction costs due to network effects. We focus only on the foreign exchange vehicle function of the international currency because this is more important a factor than the other factors. Even if there were no technical innovations in dealing in the euro, the large increase in the transaction volumes in the euro could still be regarded as technical progress.

Table 1 lists recent statistics on the current use of major currencies. As evident from this table, the U.S. dollar has the largest share in terms of international use, but not a dominant share, except in the case of foreign exchange turnover. Therefore, today, the U.S. dollar as the key currency is sustained by its role as a foreign exchange vehicle. In this chapter, we focus on this role. We attach importance to the foreign exchange vehicle function since it is the dominant function in foreign

exchange markets. In particular, the currency that function as a vehicle of trade between small volume currencies in foreign exchange markets emerges as an international currency. The logic that applies here is the same as that applicable to the evolution of money. Alogoskoufis, Portes and Rey (1997) use Hartman's estimates to compute the bid-ask spreads with zero volatility, which are shown in Table 2 as spot foreign exchange transaction costs. Although the difference in transaction costs due to difference in liquidity is very small for a ten thousand dollar transaction, the actual amount of the difference is very large because the number of daily transactions in foreign exchange markets is very high. Therefore, these differences are very important for traders dealing in currencies.

The U.S. dollar is likely to retain its current status for some period of time even after the introduction of the euro. The hysteresis effect or the history of the use of the U.S. dollar causes traders to deal in the dollar. However, if the areas using the euro expand — if Central and Eastern Europe accept the euro as their currency — it will result in the euro being used more frequently as the denomination or vehicle currency. If Asian or

other countries prefer to hold assets denominated in the euro, its importance as portfolio currency will increase. This will result in a decline in transaction costs for the euro, making it more convenient to use. Once the use of the euro becomes more frequent, the transaction costs will dramatically decrease, and its share will increase correspondingly as it will be able to compete with the present key currency — the U.S. dollar. Therefore, the euro has the potential to emerge as the key currency of the world.

With regard to a bipolar key currency regime, we have historical experience of the sterling-dollar regime during the interwar period, when massive capital flow resulted in instability in the sterling/dollar exchange rates. Furthermore, the international monetary regime became unstable

due to the competition in devaluation in order to take advantage of lower prices in foreign trade. Theoretically, exchange rates are indeterminate if capital mobility is deregulated to become perfect between symmetric countries. If capital mobility became perfect between the areas using the euro and the U.S. dollar, and the network effect diminished, the bipolar regime would become unstable through speculative capital flows between these areas.

As a method of preventing these instabilities, the following points may be considered: (1) implementation of capital controls, (2) introduction of a fixed exchange rates regime, and (3) promotion of discretionary economic policy coordination. The first proposal — implementation of capital controls — is expected to be resisted under cur-

rent globalizing capital flows and the ICT age. Although controls by different governments may succeed in restraining globalizing capital, profit-seeking entities such as hedge funds, mutual funds, pension funds, and individual investors object to the implementation of capital controls. Second, if a fixed exchange rates regime is introduced, macroeconomic policies will be restrained in the concerned country. Therefore, the government may hesitate to introduce the fixed regime. The areas using the euro have decided upon a macroeconomic policy mix of price stability by the European Central Bank and fiscal deficit by the Stability and Growth Pact, leaving no scope to commit to exchange rates stability. Third, policy coordination is the only way to prevent instability; however, in some ways, this constrains room for discretion in macroeconomic policies. Agreement on policy coordination is a comparatively easier option because it does not require strict rules. Thus, policy coordination is the only realistic solution to prevent an unstable international monetary regime. To be more precise, the current key-currency country, the United States, should control its twin deficits, namely, its current account deficits and fiscal deficits. On the other hand, the areas using the euro should pay attention not only to price stability but also to economic growth in order to have an impact on world business cycles.

Although policy coordination among these areas may enable the realization of a stable situation, this coordination has the potential to become a moral hazard for the U.S. government. The government may have an incentive to suffer fiscal deficits as a consequence of the facility to finance these deficits. Therefore, the U.S. government should commit to policy coordination in order to decrease its current account and fiscal deficits. If traders in foreign exchange markets realize the U.S. government's reluctance to coordinate its policies with the areas using the euro, they may shift the massive funds they own from the United States to other countries, thereby resulting in unstable exchange rates and real economy. As

suggested by our model in the previous section, a small change in the expectations of traders, arising from mistrust regarding policy coordination, can cause massive capital flows and a switch in the key currency.

In the global ICT age with globalizing capital, the stability of the international monetary system may depend on appropriate policy coordination between the U.S., which provides the existing key currency, and the areas using the euro, which have the potential to provide the next key currency.

Chapter 1.18

The Genesis, Political, and Economic Sides of the Internet

Andrew Targowski

Western Michigan University, USA

ABSTRACT

The purpose of this chapter is to show that the Cold War is behind the invention of the Internet. This is one of very few positive results of this war, which had tremendous influence on the further development of civilization. The research on the universality of info-communication processes was conducted on both sides of the Iron Curtain, which indicates the similarities in engineering thinking, regardless of geographic locations. The political meaning of the Internet does not only result from its history but also stands for the support of democratic development and the obstruction of dictatorships. The history of the Internet is also an example of the development of great engineering talents and research and development centers, which rise to the occasion on such ambitious projects. All of these aspects of the Internet will be investigated in this chapter, as well as its impact on the emergence of the global civilization.

INTRODUCTION

The purpose of this chapter is to show that the Cold War is behind the invention of the Internet. This is one of very few positive results of this war, which had tremendous influence on the further development of civilization. Research on the universality of info-communication processes was conducted on both sides of the Iron Curtain, which indicates the similarities in engineering thinking, regardless of the geographic locations.

The political meaning of the Internet does not only result from its history but also stands for the support of democratic development and the obstruction of dictatorships. The history of the Internet is also an example of the development of great engineering talents and research and development centers, which rise to the occasion on such ambitious projects. All of these aspects of the Internet will be investigated in this chapter, as well as its impact on the emergence of the Global Civilization.

CHALLENGES OF THE COLD WAR

The Cold War began to take shape just before the end of the World War II in April 1945 when President Harry Truman reprimanded Vyacheslav Molotov, the Soviet Foreign Minister and Stalin's confidant for sabotaging the Yalta Agreement in Poland, where a free election was postponed. Formally speaking, the Cold War began after Winston Churchill's speech on the Iron Curtain in Fulton, Missouri, on March 5, 1946. He said that an "Iron Curtain had fallen from Stettin in the Baltic to Trieste in the Adriatic. The Soviets had installed pro-communist governments in every country which had been occupied by the Red Army as well in the Soviet zone of Germany" (Kissinger, 1994).

The Cold War lasted 46 years, from 1946 to 1991, when the Soviet Union collapsed. This war relied on the symmetry of military power between the United States (U.S.) and the USSR, who both kept their respective military forces in balance to avoid unwanted military confrontations. The U.S. treated this war as a means of promoting democracy and containing communism (Kennan, 1947), while the USSR used the war to conduct the double standard, officially promoting world peace and unofficially looking for the opportunity to defeat capitalism (Targowski, 2000).

The politics of communist containment was implemented by the strategy of circling the USSR by friendly states, which hosted American bases (Spykman, 1942, 1944). In Europe, NATO was organized to counter the Warsaw Pact armies (Moczulski, 1999). The architecture of the Cold War is shown in Figure 1.

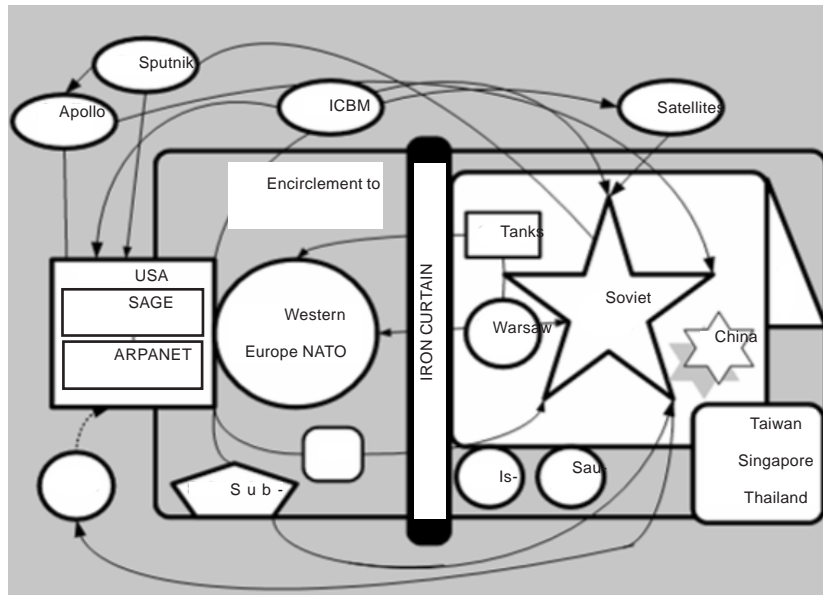

The Cold War was a good pretext for the development of different kinds of weapons, which pushed scientific and technological progress forward both in military and civilian areas. In this respect, the Soviets surprised the Americans when they sent Sputnik 1 into space in 1957. This was a message that the Soviets were transforming from the aircraft to the rocket-oriented strategy to

reach the American homeland. In the U.S., there took place a short-lived consternation, which led towards the growth of funding for universities and research.

The development of American weaponry in the period of the Cold War was oriented around systems of communications, information, transportation and efficient destruction armaments as follows:

1. Offensive systems:
 - 1.1. Fusion bombs to enhance the striking power of the Air Force
 - 1.2. Long-range bombers, such as the B29 and B52
 - 1.3. "Polaris" atomic submarines
 - 1.4. Project Atlas: the development of Intercontinental Ballistic Missiles (ICBMs) during the 1950s
 - 1.5. Satellite technology for gathering intelligence in the 1950s
 - 1.6. Space technology for ruling space – the Apollo Project in the 1960s
 - 1.7. Other
2. Defensive systems:
 - 2.1. Semiautomatic Ground Environment Project (SAGE) – a real-time computer-and-radar-based air defense system, created in the 1950s under the Atlas project, to collect and process information for commanding the Air Force in defending the country
 - 2.2. A reliable telecommunication network ARPANET, later transformed into the Internet to assure governing the country "the day after" an atomic assault
 - 2.3. Other
3. Management and problem-solving systems:
 - 3.1. System analysis in the 1950s
 - 3.2. PERT in the 1960s
 - 3.3. Intelligence, Command, Control and Communication (I/C³) in the 1960s
 - 3.4. Other

Figure 1. The architecture of the Cold War and its major weapons

In the 1950s-70s, military-funded projects dominated the technological and management landscape. These projects were developed in the so-called military-industrial-university complex. Many young engineers and scientists had chosen to work in this complex, since they believed that they were responding to the threats of the Soviet Union. The commitment of these professionals, however, began to erode in the 1960s during the Vietnam War, and with the rise of counterculture values, were strongly present in the San Francisco Bay area.

Among the then-leading research centers was the RAND Corporation, created in 1948 in Santa Monica, Calif., and later transformed into the Air Force's Think Tank. Other leading centers were the MITRE Corporation, Western Development Division (WDD) of the Air Force Research and Development Command, the Ramo-Wooldridge Corporation, the Advanced Research Project Agency (ARPA), Betchel/Persons Brinckerhoff and the National Aeronautic and Space Administration (NASA).

At the beginning of its existence, RAND was involved in the development of the U.S. atomic strategy and later undertook projects on research operations and system analysis to optimize the complexity of large-scale weapons. For RAND, it was just one step in moving from system analysis to systems of info-communications in the military.

THE POLITICAL GENESIS OF THE INTERNET

In 1959-60s, the Cold War was dominated by the strong personalities of Soviet Premier Nikita Khrushchev and the American President John F. Kennedy. After sending Sputnik to space in October 1957, on November 10, 1958, Khrushchev delivered a speech demanding an end to Berlin's four-power status and warning that the Soviet Union intended to turn control of its access over to its German satellite. In May, 1960 an American U-2 spy plane was shot down over the Soviet

Union. The summit in Paris was cancelled by the Russian Prime Minister. By the time John F. Kennedy entered office, one of his first projects was the attempt to send Cuban exiles to overthrow Fidel Castro at the Bay of Pigs in April 1961.

In the summer of 1961, the U.S. confronted the Soviet Union over the divided city of Berlin. Opposing Khrushchev's effort to break the long-standing impasse over Berlin on Soviet terms, Kennedy announced a new military buildup and employed martial rhetoric to summon U.S. citizens to a new test of their resolve. In response, the Soviets constructed the Berlin Wall in 1961, the hardware of the Iron Curtain. The following year, in 1962, the Soviet Union began building missile bases in Cuba, which threatened the U.S.. President Kennedy ordered a naval blockade of Cuba and demanded that the Russians remove the missiles. Faced with the threat of war, Khrushchev agreed to dismantle the bases if the U.S. secretly agreed to withdraw nuclear-tipped missiles from nearby Turkey.

THE TECHNICAL GENESIS OF THE INTERNET

After the Cuban crisis, the Americans became aware of how close to catastrophe they were if Soviet rockets could be launched from Cuba, just about 90 miles away from American soil. In such a political climate, the U.S. government initiated work on communication systems that could function the "day after." These systems brought the Internet to our civilization practice.

The official birth of the Internet is associated with the development of ARPANET in 1969-'72 by ARPA (located at the DoD (DoD) since 1958). At the beginning of its existence, ARPA was involved in researching how to detect attacking rockets and the enemy's atomic tests. In 1959, ARPA began sponsoring a research project on interactions between an operator and computer within a system of control-command. This project

was done by the System Development Corporation (SDC), which trained hundreds of future computer programmers. It is worth mentioning that at that time, the education of computer specialists was in its infancy.

Prior to ARPA's involvement in the development of ARPANET, one must take into account RAND's work on telecommunication systems in the late 1950s. This was the post-Sputnik period, when both sides of the Cold War were developing intercontinental ballistic missiles targeted at the enemy's communication systems to stop the country's activities. Without an efficient communication system, the U.S. could not function. In 1959, Paul Baran began to work at RAND, and his first major project was to define the feasibility of a survivable communication system.

At RAND, Baran spent 2 years creating a workable design and another 3 years trying to prove it could work. In other words, his initial research lasted 5 years (1959-1964) until he could write an 11-volume outline of a decentralized network where the nodes have a redundancy level of three, thus making it extremely resistant to destruction. His ideas were published in open literature in 1964. "We felt," Baran said, "that it properly belonged in the public domain." Not only did RAND create it, they sent it to laboratories around the world. Therefore, RAND did not apply for a patent. These ideas have become the basis for the modern Internet.

In 1959-1964, years of the Berlin and Cuban crises, Baran was asking the question, "What is the minimum requirement for a survivable communication system?" He calculated that the U.S. network of AM radio stations could be used to relay messages by attaching a little digital logic at each of the broadcast "nodes." With this design, it would be possible to send a message under almost any circumstance, because once a message was sent, it would continue transmitting itself until copies of it bounced back. However, the idea was scoffed at by military leaders for lack of enough bandwidth.

Figure 2. Three topologies of a network

To develop more communication capacity and efficiency, Baran devised five guidelines:

1. The network cannot be centralized
2. The network of nodes must have distribution, each node connected to more than one neighbor (Figure 2)
3. The network must have redundancy, which is where each node must be connected to more nodes than necessary for normal communications
4. Messages should be divided into small blocks, called “packets”
5. Message blocks should be digital rather than analog

Baran’s inspiration for a non-centralized system is based on human brain functioning. He knew that the most reliable network is the human brain. His question was: How does the brain work? Does it have any centralized points? With such questions, Baran contacted a brain surgeon, Warren McCulloch of the Massachusetts Institute of Technology. He said that if “you cut a piece of the brain or damaged a part, its functions will move over to the undamaged part.” “So that is a distributed network—neurons connected to one another” (Baran, 2003).

A distributed network was only a part of the plan. Baran’s “decisive invention” was packet switching. This invention has changed the world. Baran’s solution breaks a message into small blocks; hence, its transmission is more efficient. These small blocks can take a variety of routes and be rebuilt at the destination’s node. It is how data travels online today.

To achieve the best transmission quality, message blocks must be digital, not analog, according to Baran’s solution. Digital signals, unlike analog ones, do not degrade every time they are transmitted. Furthermore, if the signal is damaged, several error-correcting procedures can be used to correct distortions.

Moreover, Baran divided the signal into what he calls “message blocks.” The message is broken into several data streams, and each is independently routed, using packet switching, for a destination. The network would relay each segment without any centralized control. He developed a rapid store-and-forward algorithm that indicates the best possible route to the destination. In addition, the table is constantly being updated by information on neighboring nodes.

The centralized network has all its nodes connected to a central switching node to allow simple switching, giving it a single point of high vulner-

ability; for example, a single explosion could destroy the point of control. The decentralized network, representative of the AT&T long-distance network at the time, is better. Instead of a single central switching node, the network comprises small-centralized clusters, with most traffic going to nearby neighbors, and only the longer-distance traffic routed to the longer links.

The distributed network is a network without any hierarchical structure; thus, there is no single point of vulnerability to bring down much of the network. Manhattan has streets organized in a semi-distributed network, while Paris is organized into a decentralized streets network.

The latter had been built by a police chef (Haussman) to stop revolutionary crowds. However, in today's environment, this network slows traffic, while it's still manageable in downtown New York City, due to its streets network.

The DoD wanted AT&T to develop Baran's network. AT&T replied that, "it's not going to work, and furthermore, we're not going into competition with ourselves." A few years later, Baran said: "The 'Net's biggest threat wasn't the USSR, it was the phone company" (Baran, 2003). Because of the roadblocks at AT&T and the Pentagon, it wasn't until the 1970s that the technology was finally adapted as the foundation architecture of ARPANET, the precursor of the Internet.

Baran's Vision of the Web and Projects

Around December 1966—when IBM had just introduced its famous IBM 360 series with disks and online capability of processing transactions and queries, the first mature solutions in the industry—Baran presented a paper at the American Marketing Association called "Marketing in the Year 2000." He described push-and-pull communication and how we are going to do our shopping via television set and virtual department store. This is pretty much what Web TV is today. Some in the audience were furious. They said, "People

don't go shopping to buy things. They go there because of the enjoyment." Today, online shopping has not replaced traditional shopping, but it remains very popular.

The architect of the Internet, Baran, quit RAND and moved to the private industry as an entrepreneur. He and Millard started a string of companies specializing from consulting to satellites. In 1972, the two men founded CableData Associates, with an initial contract to study the divestiture of ARPANET into MILINET and INTERNET. The next set of companies is rich: The latest one is Com21 Inc., founded by him in 1992, which is a major supplier of cable modems and head ends for cable systems. Baran also works to preserve the history of technology as a member of RAND President's Council, as a trustee of the IEEE History Center, a trustee of the Charles Babbage Foundation and a trustee of the Marconi Foundation at Columbia University. He is recipient of many honors and awards. To mention a few: Armstrong Award (1987); Alexander Graham Bell Medal (1990); Electronic Frontier Foundation Pioneer Award (1993); IEEE's Life Fellow (1993); Franklin Institute Bower Award and Prize for Achievements in Science (2001; he received \$250,000, later donated by Baran to education); and more.

THE NEXT MILESTONES OF THE INTERNET'S DEVELOPMENT

The Information Processing Techniques Office (IPTO) at ARPA was supported by Congress generously. IPTO initiated the ARPANET project in 1966 to interconnect time-sharing computers at the 17 ARPA-founded academic, industrial and government computer centers around the country. This project had in mind the electric-generating station analogy to optimize capacity utilization through sharing of computer resources to meet demand. This was a time when the cost of large-scale computing could be in the tens of millions

of dollars.

The future designers of ARPANET were supposedly more familiar with Leonard Kleinrock's dissertation (published in 1964) on "time slicing," which anticipated packet switching and distributed control in data networks, than with Baran's concept (Hughes, 1998). On the other hand, "time slicing" as a concept of time-sharing was implemented by General Electric (GE) in its "225" computer in 1962, which applied John Kemeny's interactive BASIC language. It is hard to accept the view that RAND's major project developed by Baran for the DoD was not known by the DoD's ARPA researchers.

The next milestones of future Internet solutions are as follows:

- **1967:** Interface Message Processors (IMP) are defined by Lawrence Roberts at ARPA.
- **1969:** IMP hardware and software are developed by Bolt Beranek and Newman (BBN) company, where the project was led by Frank Heart and Robert Khan. Also, Honeywell's crew adapted Honeywell 516 computer as an IMP.
- **1972:** Network Control Program (NCP), including host-to-host and host-to-IMP protocols, was defined and implemented by the Network Working Group at UCLA, led by Kleinrock.
- **1972, August:** 15 host-computer sites connected to the network were using the NCP protocol; however, the network ran at only 2% capacity.
- **1973:** E-mail constituted 75% of ARPANET traffic, giving the greatest stimulus for the growth of the 'Net.
- **1974:** Transmission Control Protocol/Internet Protocol (TCP/IP) was defined by Vinton Cerf and Robert Kahn.
- **1983:** The DoD decided that all ARPANET computers must apply TCP/IP and not the OSI standard.
- **1983:** The DoD divides ARPANET (with hundreds of host computers) into MILINET and a public net, after advice from Baran and Millard.
- **1984:** Internet is named and the TCP/IP protocol adapted.
- **1989:** World Wide Web (WWW) was created by Tim Berners-Lee at CERN in Geneva, Switzerland.
- **1990:** Information Superhighway – Al Gore.
- **1992:** The Internet Society, a private non-profit group, supports the Internet Activity Board (IAB), which handles much of the Internet's behind-the-scenes and architectural issues.
- **1993:** Mosaic, the first user-friendly software-oriented browser, was developed by Marc Andreessen at the University of Illinois.
- **1994:** Netscape, the first commercial-friendly software-oriented browser was developed by Andreessen at the Mosaic Communications Group (later renamed to Netscape), which was bought by America onLine (AoL) in 1998.
- **1995:** First version of Microsoft's Internet Explorer was launched, which in the 1990s has about 70+ percent of the browsers' market.
- **1997:** E-commerce takes off, Amazon.com – Jeff Bezos.
- **1998:** Growth of the New Economy (Global Economy based on the Net).
- **1999:** Internet2 created. It is a project led by 200+ universities working with corporations to develop a leading-edge network for the national research community.
- **2000:** Dot.Com crisis.
- **2001:** The rise of an e-republic.
- **2003:** The rise of an e-enterprise.
- **2004:** About 1 billion users of the Internet in Global Economy.
- **2005:** Emergence of Global Civilization and "flattened" world.

POLITICAL CONSEQUENCES OF THE INTERNET

The development of a universal telecommunication network is of great importance for politics and civilization. As indicated, the Internet is a product of the Cold War, when at its peak in 1972 it reached the first phase of development, connecting 15 centers within the pilot system of ARPANET. It is necessary to mention that behind the Iron Curtain, a concept of the INFOSTRADA was launched in the same year, 1972. *La strada* means “highway” in Italian; hence, with an exception in Germany, all European highways are called “*autostrada*.” The Polish INFOSTRADA was planned to transform Poland from an uninformed to informed society within the communist regime. Already in 1973, three nodes, Gdańsk – Warsaw – Katowice, had been interconnected via Singer 10 computers (IMP) within a “packet switching” network. Targowski learned about the technical solutions of ARPANET from Dr.

L. Roberts during the Diebold Research Program Conference in Madrid in June 1971. The project, in addition to the Polish funds, was also sponsored by \$1 million from the Singer Corporation, which wanted to apply tested solutions in its business in the U.S. However, ARPANET was designed to interconnect super-computers of scientific centers, while INFOSTRADA (Figure 3) was planned to support a flow of economic-social information among main organizations and citizens within the National Information System. Very soon, the communist authority found that INFOSTRADA led to the uncontrollable flow of information, and immediately the project was closed and its leaders, including the author, were put out of the job market (Targowski, 1991, 2001).

Of course, the INFOSTRADA project was not foreign to the Central Intelligence Agency (CIA), since it was widely publicized in the Polish press. At that time, a young Congressman—Albert Gore—was member of the Intelligence Committee and had to know all about the Polish project. When he became vice president of the U.S., he

Figure 3. National Information System and INFOSTRADA (Targowski model, 1972)

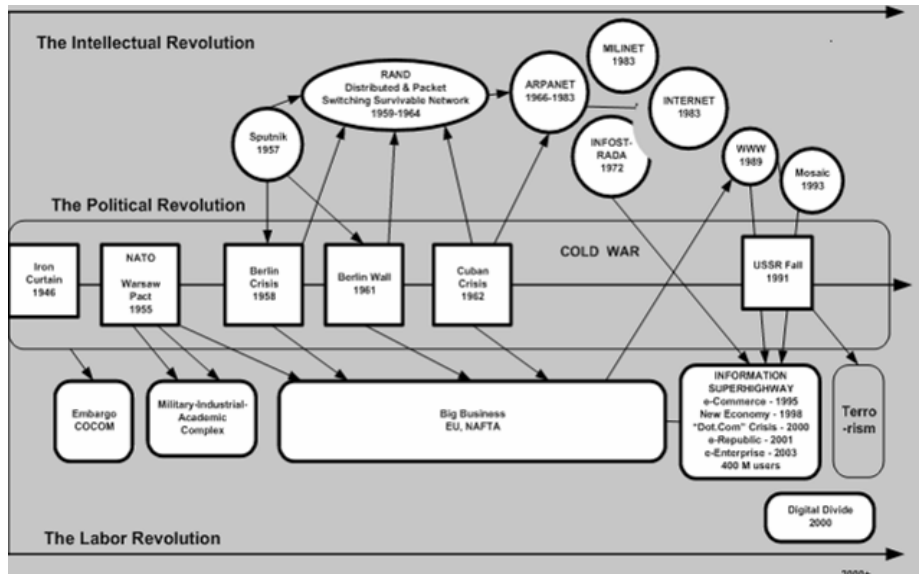

Figure 4. Relations among civilization revolutions

translated “INFOSTRADA” into “Information Superhighway” and admitted as much in the December 1995 issue of *Wired* magazine (Hellman, 1995). This idea soon became the leading concept for the development of all sorts of information infrastructures, triggering the emergence of the so-called New Economy in the U.S. as well as in the “new” Global World.

The Internet on the global scale supports the free-flow of info-communication and is positive for the expansion of democracy and negative for political or theocratic dictatorships. These types of dictatorships censor the info-communication flow on their servers. These attempts are reminiscent of the Pony Express strategy, where faster horses were introduced when the telegraph was introduced for the first time in America. Of course, the Internet enables the dissemination of criminal info-communications, including those among terrorists. The issue of practically applying ethics to the Internet is a hot topic among many societies. For example, in Russia, e-commerce cannot be applied due to dishonest practice of all involved parties, including gangsters.

Figure 4 illustrates the relationships among intellectual, political and labor revolutions. This model proves how these relationships are important for each type of revolution development.

THE SOCIAL CONSEQUENCES OF THE INTERNET

The use of the Internet requires access to a computer and an Internet service provider (ISP), which can be afforded by people with some resources. Hence, the digital divide issue takes place not only in underdeveloped countries but in developed ones, too. Nowadays, in the world there are 1 billion people with a password to a computer net and 5 billion without such a password. This leads towards the bifurcation of civilization and all of the negative consequences of it. One can say that the Internet accelerates the development of developed nations and relatively slows the development of underdeveloped nations. However, many civilization positives, such as education, training, and information and knowledge dissemination, can be accelerated by the Internet in those less-fortunate nations.

THE ECONOMIC SIDE OF THE INTERNET

The Emergence of Global Economy and Civilization

These transportation and info-communication technologies provide the infrastructure for global operations. Table 1 illustrates the decreased costs of transportation in the last 160 years (1830-1990), and Table 2 shows how the costs of communication and computers declined in the last 40 years (1960-2000). During the first and second waves of globalization, technology provided incredible productivity in making and moving things. In the third wave, technology is driving the productivity of information itself.

Information and communication technology (ICT) triggers a shift in the post-industrial society's *modus operandi*, which is based on new key features (Bell, 1981):

1. The shift from a goods-producing to a service economy
2. The increasing reliance on theoretical knowledge

3. Creation of a new “intellectual technology” based on computers and other smart machines

Manuel Castells (1996) observes that, “what has changed is not the kind of activities humankind is engaged in, but its technological ability to use as a direct productive force what distinguishes our species as a biological oddity: its superior capacity to process symbols.” ICT technology does not replace agriculture and industry, but optimizes them. It leads towards the “informatization” of the Global Society, which by connecting all of us makes us the Global Open Society (Anderson, 2004). The emerging Global Digital Consciousness (GDC) as the symbiosis of humans and machines provides cognition and external memory systems that support Global Civilization and vice versa. Hence, the GDC is composed of:

- *infosphere* (computerized info-communication systems composed of databases, applications and networks),
- *cyberspace* (the Internet and Web applications),
- *mediasphere* (radio, TV, cable), and
- *mindsphere* (global ideas generated by previous global spheres).

Table 1. Transport costs, 1830-1990 (Sources: Baldwin and Martin, 1999, World Economic Outlook, May 1997, Table 11)

Year	Ocean Transport		Average Air Transportation Revenue per Passenger Mile (in 1990 US \$)
	Wheat, Percent of Production Cost	Ocean Freight	
1830	79		
1850	76		
1880	41		
1910	27.5		
1920		100	
1930		65	0.68
1940		67	0.46
1950		38	0.30
1960		28	0.24
1970		29	0.16
1980		25	0.10
1990		30	0.11

Table 2. Communication and computer costs, 1960-2000 (Sources: World Economic Outlook, May 1997, Table 11, updated to 2000; U.S. Commerce Department, Bureau of Economic Analysis and Mason [2001])

Year	Cost of a 3-Minute Telephone Call, New York to London (in 2000 US \$)	Price of Computers and Peripheral Equipment Relative to GDP Deflator
1960	60.42	1,869,004
1970	41.61	199,983
1980	6.32	27,938
1990	4.37	7,275
2000	0.40	1,000

The Globalization Index, which breaks down globalization into its most important component parts, indicates that the “most wired” countries in the world are beneficiaries of globalization. The Globalization Index tracks the movements of money in terms of investments and business transactions in the era of “electronic capitalism” (Bledsoe, 2001).

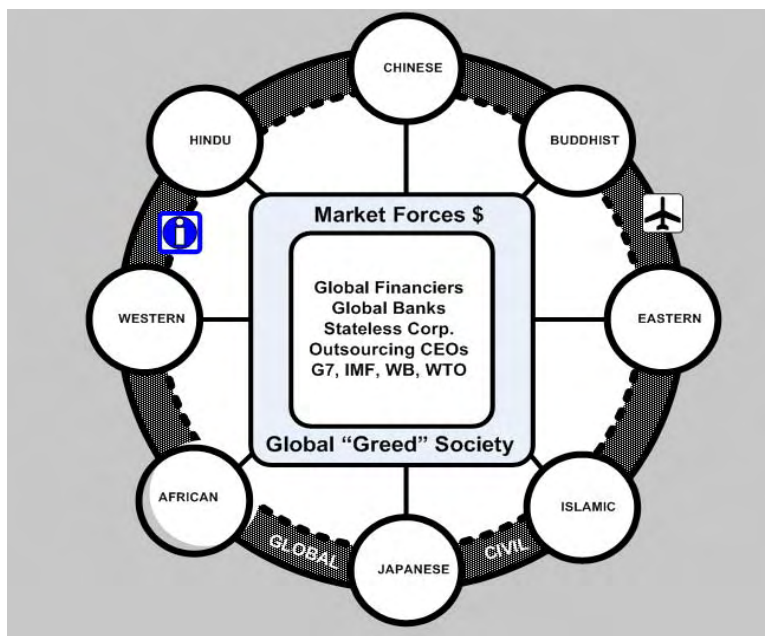

The fourth wave of modern globalization at the beginning of the 21st century leads towards the emergence of Global Civilization, because this civilization meets the general criteria of civilization (Targowski, 2004). For example:

- Human entity as the global society is composed of certain segments of the societies of eight autonomous civilizations (Western, Eastern, Islamic, Japanese, Chinese, Buddhist, Hindu and African), which apply global culture and infrastructures
- Culture has global character, which means that similar patterns of behavior are practiced (*de facto* by certain segments of those societies only) in those autonomous civilizations; for example, such ones as “English,” professional and student dress code, music, movies, food, drinks and so forth
- Global Infrastructure of Information (1) (the Internet and global area networks) and of material (2) (transportation, finance, and business) are reaching every autonomous civilization and integrating them into an

emerging global society and global economy. Furthermore, there are many international organizations (for-profit and non-profit, official and unofficial), such as United Nations (UN), UNESCO, GATT, World Trade Organization (WTO), World Bank (WB), IMF, NATO and others, which create the Global Infrastructure of Regulations (3). The last kind of infrastructure plays a paradoxical role, promoting justice and enhancing inequality, triggering world conflicts and instability. For example; globalization triggers the anti-globalization movement, putting emphasis on local forces and potential, which *de facto* can be called “glocal” (GLObal-lo-CAL), since their uniqueness is a product of global forces. Among anti-global forces, one that is becoming very violent is global terrorism, which can destroy huge parts of any civilization. In response, civilization develops security systems that protect global order against global chaos. Hence, the Global Infrastructure at the same time creates order and chaos!

The global economy is only possible because it is supported by global infrastructures, supporting; global communication (the Internet, global area networks); global transportation; global finance activities; global scientific knowledge creation and dissemination; global management practices; even global peace keeping (with less success).

Figure 5. The solar model of global civilization in the 21st century (Driven by info-communication and transportation technologies)

The solar model of global civilization is shown in Figure 5. The global civilization is controlled by an invisible power, composed of global financiers and banks, stateless corporations, outsourcing CEOs (receiving fat bonuses for better performing stocks), G7, IMF, WB, WTO. The evolution of this civilization is driven by the following process of wealth formation with the help of technology: The dynamics of global civilization is not limited to economic rivalries and financial operations only. This dynamics is more complex: Religious and sectarian forces for global harmony and conflict have become pervasive, and they are intensified on the Web. The accelerated migration of peoples and the speeding of e-communications, especially by means of the Internet, have led to the globalization of religion. This process has generated contradictory responses: Some communities are confrontational, insisting on their monopoly of truth and access to salvation, whereas others

are more adaptive (Fred W. Riggs, webdata.soc.hawaii.edu/fredr/faith.htm).

Global culture develops to support a global flow of ideas, capital, goods, services and people. It interconnects different national cultures by common patterns of behavior. For example, English becomes the main language and the Western dress code, and international food is applied in global activities of business, politics, science, entertainment and art. Global communication culture is based mostly on the Internet and “CNN” culture. Global business transactions and political dialogs are supported by Western Culture’s patterns of behavior, encoded in policies of the WTO, IMF, WB, UN and UE. In general, global culture interconnects national cultures to conduct Global Civilization’s activities. However, because of the lack of the global society (or pseudo “global government”), global culture is very weak in regulating global economy and infrastructures.

THE “FLATTENED” WORLD

According to Friedman (2005), the world has been flattened by convergence of 10 major political events, innovations and companies:

1. The victory of Solidarity in Poland on August 1, 1989 and the fall of the Berlin Wall on November 9, 1989 unleashed forces that ultimately liberated all the captive people of the Soviet Empire. It was caused by the impact of the underground press (information), which exceeded the readership of the official press.
2. The world has not been same since Netscape went public on August 9, 1995, since everybody could easily navigate the Internet to any location in the world, connecting millions of personal computers.
3. Work flow software (based on such standards as SOAP, XML and others) enabled the collaboration of many contributors dispersed throughout the world—a supply chain of making movies, publishing books, organizing big events and so forth.
4. Open sourcing, leading to self-collaborating communities producing competing software (like Linux, Open Office, and so forth), mostly for free, which looks at the post-capitalistic model of production.
5. Out-sourcing—making software components, mostly programming them by specialized workers from other companies and delivering their solutions via global networks, either private or public (the Internet).
6. Off-shoring—outsourcing to foreign countries, with well-educated workers “enjoying” low wages and delivering their solutions via global networks, either private or public (the Internet).
7. Supply-chaining—the computers and their networks allow for brand companies such as Wal-Mart to sell 1 million products through highly automated and computerized distribution centers. The high volume of business puts special pressure on subcontractors, who have to trim costs and keep good quality. In order to get “always” low prices, Wal-Mart is outsourcing and off-shoring its orders, mostly to China and other low-wage countries.
8. In-sourcing—based on asking world-oriented companies such as UPS or FedEx to carry the transportation processes inside of a company to speed up the delivery of goods and semi-products among units of a company or to its customers throughout the world.
9. Informing via Web search engines, such as Google, Yahoo and others, to speed up information-seeking users.
10. Mobile communication—a growing number of wireless gadgets (cell phone, iPaq, etc.), which can beam information to/from any location in the world, making people connected and informed with bullet train speed.

The Convergence I of all mentioned flatteners allows (according to Friedman, 2005) for multiple forms of collaboration at the level of knowledge production or project implementations in real time, without regard to geography and language. The Convergence II allows for the connection of all computers and involved workers/specialists into one virtual organization, which works productively and at low cost as one, but is spread out through the world. Convergence III allows for inclusion into the global economy/civilization people from developing or undeveloped countries, who without info-communication technology could be left behind the fast-progressing world. Of course, not everybody welcomes this working world, which takes advantage of weak partners, their discontent expressed under the form of anti-global activities.

Figure 6. The Internet cathedral

CONCLUSION

1. Development of the Internet is the result of the Cold War, which has strong influence on the growth of the global economy and civilization.
2. Systems like the Internet are the results of many coincidences, where the most important one is the presence of exceptional research talent, such as Baran and others mentioned in this investigation.
3. Systems of the Internet's type are outcomes of many peoples' effort, similar to that which takes place when a cathedral is under construction for many centuries. Every new builder adds a new brick and says: "I built the cathedral." (Baran's statement in Hughes, 1998, p. 274). The Internet cathedral is shown in Figure 6.
4. The wide acceptance of info-communication systems depends on its "user friendliness." Therefore, the discovery of the WWW and Mosaic/Netscape browsers accelerated the acceptance of the Internet at the end of the 20th century and its influence on the further development of civilization.
5. The most unexpected influence of the Internet is on the conduct of war. For example, both sides of the battle can communicate via e-mail, as happened during the war in Iraq in 2003.
6. New capabilities of the Internet are con-

stantly being discovered, and it seems that this process has not yet reached the point of saturation.

7. The close of INFOSTRADA/NIS in Poland in 1974 stopped the development of advanced info-communication systems for at least 25 years. In 2003, Poland created a Ministry of Science and Infomatization and launched the project to develop e-Poland.
8. Because global civilization at the same time creates order and chaos, it means that it becomes more “closed” and “undemocratic” than it looks at first glance, as can be explained by the II Law of Thermodynamics (closed systems generate more entropy, which is a measure of chaos-disorder). What does it mean? It means that global civilization should be more open, accepting not only one view (“Western View”), but many views, perhaps by development of another layer of world civilization, a universal-complementary civilization, which exchanges and accepts main and complementary values from all civilizations, as shown in Figure 7 (Targowski, 2004b).

Chapter 1.19

The Transformation of the Distribution Process in the Airline Industry Empowered by Information and Communication Technology

Patrick S. Merten

International Institute of Management in Technology, Switzerland

ABSTRACT

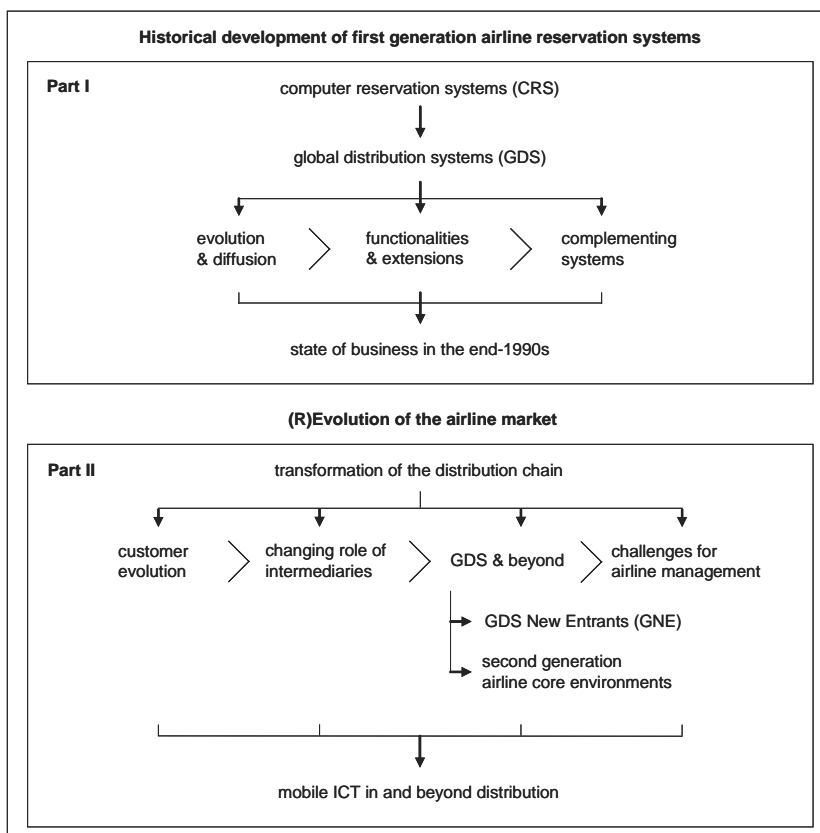

This chapter reviews the historical evolution of the airline market and its first-generation airline reservation and distribution systems. The development and diffusion of computer reservation systems (CRS) and global distribution systems (GDS) is discussed extensively in order to provide a comprehensive overview of the state of business in the 2000s. Based on this evaluation, the influence of modern information and communication technology (ICT) on the airline distribution system environment is discussed. The traditional distribution chain has been transformed into an electronic multi-channel distribution environment. This (r)evolution of the airline market is analysed for the different market participant groups, as the competitive and cooperative situation increases in this cross-influence network industry.

INTRODUCTION

The information revolution has dramatically reshaped global society and is pushing the world ever more towards an information-based economy. Tourism is one of the industries which is able to generate enormous synergy effects from the use of the Internet. This technology is a potential instrument to implement change in the structure and processes of the entire sector. In particular, the airline market environment has experienced significant changes in the recent decades, induced by the different generations of information and communication technology (ICT). Consequently, this chapter deals with the fundamental transformation of the airline industry—with a focus on the technologies in the distribution process.

Since its emergence, the tourism industry has experienced continuous and sustainable growth,

Figure 1. Overview of chapter structure

not only in terms of increasing customer numbers, but also in the acquisition of new markets. These developments have been coupled with the expansion of travel intermediaries in response to an increasing demand for travel. While airlines first sold their products separately and on their own, they soon became an integral part of the tourism industry, which in turn gained complexity in terms of distribution. Therefore, and not surprisingly, the airline industry is one of the first business sectors that introduced and relied on information and communication technology to cope with the challenges of rising complexity, notably in distribution. Accordingly, the first main part of this chapter reviews the historical evolution of the airline market and its first-generation airline reservation and distribution systems. This

provides a comprehensive overview of the state of business in the latter part of the 1990s.

The following and key part of this chapter focuses in particular on the current reshaping of distribution processes, caused by and based on the development of new information and communication technology. The exponential growth of online platforms and Internet usage has led to the appearance of numerous alternative distribution channels and new intermediaries. Having already established their positions on the market, the new electronic distribution channels now co-exist alongside traditional channels. As a result, the market structure and balance of power between airlines, distributors and customers is rapidly changing. To understand this multi-channel distribution environment, an in-depth analysis of

today's airline market is required. Therefore, in the second part of this chapter, the (r)evolution of the airline market is examined from diverse perspectives, that is, those of the different market participants. Furthermore, the evolution towards second-generation airline core environments is investigated, in order to understand the forces behind the emerging paradigm shift.

Figure 1 gives an introductory overview of this chapter's structure.

FIRST-GENERATION AIRLINE RESERVATION SYSTEMS

Today's airline industry is a product of post-World War II prosperity. Civil aviation took off in the second half of the 20th century with the introduction of many new technologies including jet engines, new lightweight metals, radar systems, and computers—making air transportation faster, more comfortable, and above all safer (Prideaux, 2001). In the early years of commercial air flights, bookings were made via telex, telephone, and postal services. These methods were labour intensive, relatively slow, and expensive. However, there were no options to paper-based storage and retrieval systems. Usually, a “request and reply” system was used, collecting all the information and inquiries at a central location. Other airlines used wall-sized availability boards, which had to be updated manually (Sheldon, 1997). This situation changed radically with the emergence of information technology and the diffusion of modern telecommunication networks. The ensuing evolution of first-generation airline reservation systems is discussed in the following sections. For a more detailed description of the historical development leading to computer reservation systems see Copeland and McKenney (1988).

The Emergence of Computer Reservation Systems (CRS)

Since the 1950s, when air travel became a mass phenomenon, airlines have had to deal with large amounts of diverse information (Sheldon, 1997). The enormous increase in demand (passenger numbers) in the 1950s and 1960s brought management and operational challenges for airlines and airports. In particular, the complexity of all passenger related processes increased dramatically (Buhalis, 2003). Sheldon (1997) stated, that “it is a daunting task to keep track of thousands of flights, fares, seat inventories, crew, passengers, cargo and baggage without automation” (p. 15). Hence it is not surprising that from the outset the airline industry has been one of the most technologically advanced sectors in the field of tourism. The need to formalise the exchange of booking related information led to the introduction of computerized reservation systems (Werthner & Klein, 1999). A harbinger of such systems in the 1950s was a mechanical system called Reservisor used by American Airlines. It performed arithmetic algorithms with the aid of random access memory drums (Sheldon, 1997).

The concurrent computing revolution paved the way for the following first technology driven reservation and distribution systems. However, as no standard platforms and solutions were available at that time, first *computer reservation systems* (CRS) had to be developed in a “hand coded” manner (Werthner & Klein, 1999). For this reason, American Airlines initiated cooperation with IBM in 1953, finally developing the first computer reservation system after years of research and investments of over US\$40 million (Sheldon, 1997). This significant breakthrough system was initially called SABER (Semi-Automated Business Environment Research) and has been trailblazing ever since.

The immense technological requirements for the introduction of automated reservation systems ranged from real time and simultane-

The Transformation of the Distribution Process in the Airline Industry

Figure 2. Configuration of an airline reservation system environment (Source: Sheldon, 1997)

ous transaction processing to an airline specific message code for transmitting information. In addition, the system had to be designed for permanent operation with high reliability (Werthner & Klein, 1999). This necessity resulted in the advancement of new technological concepts such as hardware redundancy, backup generators and uninterrupted power supplies (UPSs). The fully functional SABER was launched by American Airlines and IBM in 1963/64, consisting of two IBM 7080 mainframes for real time and batch processing, an online storage of six magnetic drums and terminal connections at 2,400 baud (Copeland & McKenney, 1988) and met the demanding requirements.

The first requirement for real time and simultaneous transaction processing was fulfilled by the introduction of a new operating system, the Transaction Processing Facility (TPF). Originally this real time inquiry-response system had a response time of less than three seconds and is still the core of most of today's airline reservation systems. But as the TPF is a 6-bit processing first-generation computer language, it requires large investments

in human resources to keep the system running and updated; for example, in the 1990s an airline employed an average of 1,200 programmers, each paid approximately US\$100,000 to keep the system up to speed (Feldman, 1994).

The second requirement for an airline specific message code for transmitting information led to the introduction of the Airline Line Control (ALC), a full-duplex, synchronous communication protocol, which is still used today (Sheldon, 1997). However, the real challenge at the time was the design of an extensive data communication network across the U.S. and "eventually" across the world (initially offering a 2,400 bits per second transmission rate). This pioneering goal was reached in cooperation with telecommunication companies, in particular the ARINC network (Aeronautical Radio Incorporated) and the SITA network (Société Internationale Télécommunications Aéronautique).

After SABER's completion, IBM used its know-how to create the Programmed Airline Reservation System (PARS) which incorporated application software into the TPF operating system

(Sheldon, 1997). Capitalising on their experience with state-of-the-art mainframes, IBM offered PARS to other airlines such as Delta, Continental, Northwest, PanAm, and United Airlines, enabling them to create their own systems similar in function to SABER. In response to IBM's move, American Airlines renamed the original system as SABRE. While the evolution of CRS described so far mainly refers to developments in the U.S., in Europe and Asia airlines also computerised their reservation systems, but did so using videotext technology to perform queries and bookings.

Figure 2 shows the typical configuration of an airline reservation system environment, keeping the mainframes, storage devices, and front-end communication processors (FECs) on a central site, under high security because of its immense value to the airline, and designed to withstand natural disasters such as fire, flood or earthquake in addition to bomb attacks (Sheldon, 1997).

Implemented as illustrated in Figure 2, the first terminals were installed at airports and airline offices in the late 1960s. These terminals enabled agents to check airline schedules, seat availability and prices from their desktop, allowing them to make confirmed bookings at the time of first inquiry. Until the mid-1970s, computer reservation systems were used only for proprietary airline information, that is, every airline had to have its own system running (Sheldon, 1997). To conclude, CRS can be “regarded as a critical initiator of the electronic age, as they formulated a new travel marketing and distribution system” (Buhalis, 1998, p. 412).

The Development of Global Distribution Systems (GDS)

The distribution of products and services—available through the CRS—became the next unique challenge for the industry in the 1970s. At an early stage, the distribution of flights was handed over from the airlines (at airports and offices) to travel intermediaries (Werthner & Klein, 1999).

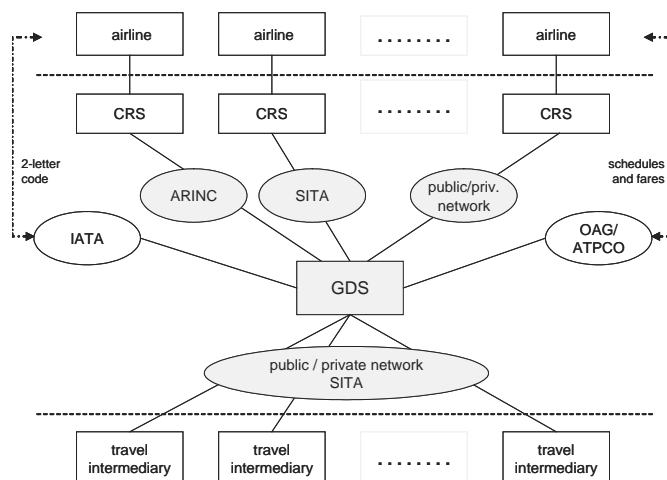

As travel intermediaries needed access to more than one CRS, but more than one terminal on an agent's desk did not make sense, an initiative was started in 1975 to create a single industry reservation system. In the same year, the Joint Industry Computer Reservation System project took place, bringing together the major carriers to plan a system which could enable travel intermediaries access to all major airline information. However, despite intense discussions, the effort failed and no agreement was reached (Sheldon, 1997). The situation remained unchanged: the different CRS were each in the possession of single airlines and used exclusively by them.

However, due to the increasing number of airlines and respective CRS, vice versa, combining the different CRS became mandatory in the 1970s. Consequently, some of the CRS, such as SABRE, opened their systems to other airlines. As a result of a continuous concentration process, different CRS were combined and became known as global distribution systems (GDS) (Inkpen, 1994). From this point on, airlines were able to store their information either directly in a GDS or in their own CRS and link it to one or more GDS. This choice basically depended on whether an airline was affiliated with a GDS company or not (Sheldon, 1997). Despite the affiliations, GDS suppliers became generally independent market participants. Therefore the term GDS denotes both the systems as well as the companies operating these systems. Their shareholders are mainly airlines, since the management of airline inventories and their distribution constitute their origin (Werthner & Klein, 1999).

Despite the systems' evolutionary differences, the two terms CRS and GDS are often used synonymously in the literature. This can be legitimated by the overlapping functionalities and complexity of the systems. Henceforth, in this chapter, the systems also are referred to as first-generation airline reservation systems. In general, the CRS/GDS:

- Contain and handle flight schedules, seat inventories, availability and prices

Figure 3. Distribution structure of first-generation airline reservation systems (Source: Werthner & Klein, 1999)

- Enable airline reservations and ticketing
- Store passenger name records (PNRs)

Thus, CRS/GDS have provided airlines with a powerful database that enabled new efficiencies in inventory control and other fields, for example through the introduction of yield management methods (Prideaux, 2001). As GDS contained all necessary distribution information of a growing number of airlines, the GDS suppliers have leased their systems to travel intermediaries. This move led the GDS providers to become the key link between the airlines and travel intermediaries (Prideaux, 2001). The consequential basic distribution structure is shown in Figure 3.

The complex structure of first-generation airline reservation systems can be justified by “the huge number of interconnected companies, both on supply as well as the demand side” (Werthner & Klein, 1999, p. 186) and the existence of numerous different communication channels. Although the underlying architecture can be simply displayed as a star, as illustrated in Figure 3, over time the network has expanded due to new business needs, technological progress and also legal interventions. Companies or institutions such as the

Official Airline Guide (OAG) and Airline Tariff Publishing Company (ATPCO) have maintained databases of flight schedules and fares (Werthner & Klein, 1999). For instance, a new airline must be first certified and assigned a two-letter code by the International Air Transport Association (IATA). Subsequently, the airline has to deposit its fares at the ATPCO and its schedules in the OAG, or appropriate institutions (if not based in the U.S.). The transfer of all these files, containing approximately 40 million fares and schedules, over private or public networks is handled by the Aeronautical Radio Incorporated (ARINC) or Société Internationale Télécommunications Aéronautique (SITA). Founded in 1949, SITA is owned by over 600 airlines and air transport related companies and offers support connections in over 220 countries worldwide (SITA, 2006).

The GDS Worldwide Evolution and Diffusion

A cause and effect of the emergence of global distribution systems were the travel intermediaries, by taking over the business of distribution of airline products to the end customer. For this

Figure 4. History of CRS/GDS (Source: Kärcher, 1997)

reason, travel intermediaries, also often referred to as travel agents, though not including tour operators and speciality providers, were equipped with CRS/GDS terminals in the mid-1970s. Not taking telephone, fax and telex into account, these originally “dumb” terminals were the first kind of information technology in travel offices, providing a connection to the host mainframes and an interface to the airlines. For instance, they replaced the printed Official Airline Guide (OAG) for schedule and fare information. Over time, more and more computer terminals were installed to facilitate airline bookings.

Due to the deregulation of the U.S. airline market in 1978, the number of terminals installed increased tremendously, reaching a penetration of over 85% in the early 1980s (Werthner & Klein, 1999). As prices, schedules and routes were liberated, airlines were able to change them indefinitely, that is, they could be flexible in adjusting pricing, and in setting the medium range schedules and adapting routes to the actual demand. This led to increasing complexity as well as a lack of transparency in fares, which again increased the computing and communication needs for airlines as well as travel intermediaries (Boberg & Collison, 1985). In addition, “until the late 1970s, airlines relied

on the International Air Transport Association (IATA) to negotiate international fares on behalf of airlines. IATA mediated between airlines and regulators on the determination of bilateral air service agreements and operation of distribution systems. Domestic fares were often subject to government regulation” (Prideaux, 2001, p. 215). However, with the deregulation and the challenge to IATA’s fare regime by non-IATA airlines in South East Asia (Singapore Airlines, Thai and MAS) the importance of IATA as a price regulator subsequently declined.

As a further consequence of deregulation, the American Civil Aeronautics Board issued the first regulation on CRS/GDS in 1984. This directive forced the CRS/GDS providers to display all airline offers in a neutral order, sorted by flight numbers. Until then, SABRE for example always listed American Airlines flights on top (so-called biased listing). This was a lucrative approach for their owner, as it generated as much as 40% extra income (Werthner & Klein, 1999). Following Boberg and Collison (1985) flights of the first screen were booked in 90% of the time, in 50% even of the first line of the first screen. According to Williams (1994), airline-owned GDS allowed a small number of carriers to achieve positions of

The Transformation of the Distribution Process in the Airline Industry

market dominance through the airline's ability to control the sale of their products via travel agencies. Despite the U.S. Department of Transportation regulations, in 1984, sorting algorithms for flights were often still not fully unbiased, as other variables such as displacement time, non-stop, direct, or connecting flights and elapsed time of the journey were "legal" variables to be used.

Looking at the GDS providers themselves again, SABRE remained affiliated with American Airlines during this period, while Apollo belonged to United Airlines. Other airlines such as Delta Airlines, Eastern Airlines and TWA followed with GDS called DATAS II, SystemOne and PARS respectively. By the 1980s travel intermediaries wishing to automate had a choice of these five systems. A merger between DATAS II and PARS created a new system called Worldspan and reduced the number to four by the early 1990s. Figure 4 shows the start-ups and merges within the CRS/GDS market, leading to four main systems, holding over 98% of the total market in 1992.

Having reviewed the historical evolution and diffusion of GDS in terms of the systems them-

selves, the terminals for travel intermediaries and the merges of suppliers in the U.S. market, the following sub-sections reflect on the development of airline reservation systems in other parts of the world.

The European and Asian Markets

The European idea of nationally developed systems and the subsequent goal of later on dominant GDS was the creation of systems representing multiple carriers—learning from problems in the U.S., where systems were originally affiliated with only one airline. Overall, the European market developed differently from the U.S. market. In the beginning, airline reservations could be made through videotext terminals of the national airline's computer systems (Sheldon, 1997). In the UK, for example, TRAVICOM, a multi-access reservation system owned by the national carrier British Airways, was used primarily; another videotext system was called Prestel (Bennett, 1988). However, in Germany a system called START was designed and implemented jointly by

Table 1. Airline affiliations with GDS in the 1990s (Source: Sheldon, 1997)

GDS	Airline	Affiliation
Amadeus	Lufthansa	29.2%
	Air France	29.2%
	Iberia	29.2%
	Continental Airlines	12.4%
Galileo	United Airlines	38%
	British Airlines	15%
	Swiss Air	13%
	KLM Royal Dutch Airlines	12%
	US Air	11%
	Alitalia	8.7%
	Olympic, Air Canada, TAP Air Portugal,	2.3%
	Austrian Airlines Aer Lingus	
Sabre	American Airlines	100%
Worldspan	Delta Airlines	38%
	Northwest Airlines	32%
	TransWorld Airlines	25%
	Abacus	5%

Table 2. Estimated market value of major GDS in the 1990s (Source: Green, 1996)

GDS	Million US\$
Abacus	650
Amadeus (System One)	600 (500)
Galileo (Apollo)	400 (1100)
Sabre	1500-2000
Worldspan	500

Table 3. GDS scope and penetration (Source: Original by the author)

GDS	Scope	Major markets
Abacus	Southeast Asia	Southeast Asia
Amadeus	Worldwide	Europe, South America, USA
Apollo	USA, Canada	USA and Canada
Galileo	Worldwide	Australia, Europe, New Zealand
Sabre	Worldwide	Canada, Europe, USA
Worldspan	Worldwide	Europe, Middle East, USA

travel agencies, the national carrier Lufthansa as well as German Rail and a tour operator. START subsequently merged with Amadeus (Sheldon, 1997). Finally, in Europe two systems: Amadeus and Galileo appeared and dominated the market. Merging with SystemOne (Amadeus) and Apollo (Galileo) respectively, these GDS expanded the global reach of the systems (Sheldon, 1997). But unlike in the U.S., the Europeans and Asians designed their systems to be unbiased from the beginning. This choice was made by the European Commission and the management of Abacus after seeing the controversy created by biased systems in the U.S. (Sheldon, 1997).

In the Asian market (the next most automated area after the U.S. and Europe), a system called Abacus was established by an independent company; however, it has not operated its own GDS. It initially used the system Worldspan, but in March 1998 signed a cooperation agreement with SABRE and switched its operations to this platform (Werthner & Klein, 1999). In addition

to Abacus other GDS vendors, represented by so-called national marketing companies (NMC), have established a 40% market share of GDS in Asian travel agencies.

Tables 1 and 2 give an overview of the airline affiliations and the huge market value of the major GDS Amadeus (including SystemOne), Galileo (including Apollo), SABRE and Worldspan in the 1990s.

Other Regions Worldwide

In Australia NMC again took over the promotion of the GDS: Sabre is distributed by Fantasia and Southern Cross has the marketing rights to the Galileo system, which hold 53% of the Australian market. The distribution of the GDS in Australia is carried out under the auspices of TIAS (Travel Industries Automated Systems, Ltd.). In New Zealand, all four major GDS are represented but Galileo and SABRE cover 80% of the agencies and 95% of the bookings (Sheldon, 1997).

Finally, in some lesser developed countries, the GDS vendors are aggressively trying to capture the market. In India, for example, the SABRE system is being marketed under the name SITAR and in Latin America, SystemOne from Amadeus is well represented with two national airlines (Varig and Aerolineas Argentinas) being part of the Amadeus consortium. Still, due to the lack of telecommunication infrastructure, numerous countries do not have GDS access (Sheldon, 1997).

Although GDS act on a worldwide basis, they have regionally dominant positions in specific markets (see Table 3), for example the nearly exclusive position of Amadeus in Germany. Overall, however, the four GDS providers Sabre, Amadeus, Galileo and Worldspan hold a worldwide dominant market position as distribution partners of airlines, and intermediaries between airlines and travel intermediaries (Sheldon, 1997).

A comprehensive overview of the historical GDS development and their role in distribution is given by Sloane (1990) and Truitt, Teye, and Farris (1991).

GDS Functionalities and Extensions

Having discussed the appearance, evolution and diffusion of global distribution systems, this section concentrates on their functionalities and extensions, again focusing on the travel intermediaries, as their agents are the main end users of the systems. "Even though all GDS have much in common, there are variations in the product and in the contract that must be considered" (Sheldon, 1997, p. 45). A travel agents' choice of GDS involves the consideration of many factors. In general, the system of choice should provide easy access to the most relevant and updated information on the one hand, and a most flexible contract with low costs and excellent service on the other hand.

GDS Product and Contracts

The first aspect mentioned above refers to direct access links, quicker communication, faster confirmations, and access to last seat availability, as well as an unbiased display of data. Then again the aspects of the contract itself are much more complicated. Historically, contracts issued by the GDS supplier were very restrictive and were often referred to as a "golden handcuff." However, very tight contractual clauses became more flexible over time as, prior to the deregulation, contracts had an infinite length with no option to discontinue or switch systems without paying damage costs. In addition, the GDS had to be used exclusively and required a certain minimum usage level. Finally, productivity pricing was part of the contract, meaning that travel agencies with larger volumes of transactions were charged less by the GDS supplier (Sheldon, 1997). The latter point is still part of most contracts while the other aspects have undergone some change over time. For example, in 1984 the maximum length of contracts was limited to five years, and again reduced to three years in 1992. The U.S. Department of Transportation also decided that exclusivity was illegal (Sheldon, 1997).

It is thus clear that the complexity of GDS contracts is a huge challenge for travel agency managers, and the need for careful analysis of contractual clauses cannot be overemphasized. More room for negotiation lies in the level of service and training provided by the GDS suppliers. For a long time, this aspect has been of some importance, as the GDS have traditionally been command-driven, requiring the use of formats and codes to process inquiries and perform transactions. Compared with menu-driven systems, they are often faster for expert users and are still widely used (Sheldon, 1997). Nevertheless, the dominant Microsoft Windows environment forced

the GDS to offer a graphical user interface, this in turn reducing the need for expert training. In addition, as most systems today have computer-aided instruction modules, training issues have become less critical. Finally, the service aspect or rather the repair or replacement of hardware as well as software problems are mostly solved on-site (often by a national service company) or online.

As the handling of information is critical to business for the travel intermediaries, not only the contract and service level agreements, but also the range of functions of the GDS product is of fundamental importance. Sheldon (1997) stated that “indeed, information on travel products, destinations, schedules, fares, rates, and availabilities is their most important product and defines their existence. The more information the travel intermediary can access electronically, the more timely, accurate and efficient service can be provided to the client” (p. 42). Consequently, the entire airline distribution process should be supported by the system. Starting with the request of flight information (schedules, availability and prices) and followed by reservations and bookings, the system also should include a payment and ticketing engine as well as diverse management functionalities (Sabathil, 2002).

GDS Extensions

As GDS became the first and most important interface and database to be used widely, other industries from the fields of tourism became interconnected with the GDS. Hence the systems contain or connect to various sets of other information, for example concerning transport and accommodation as well as tour operator products. This information is integrated by links to the respective reservation system. For instance, the hotel industry established a system called THISCO (The Hotel Industry Switch Company) in 1989 to link major hotel chains. It is owned by 70 major hotel chains and provides common electronic booking interfaces for hotel reservation systems worldwide. The core of this system is called the UltraSwitch, which performs the switching and translation of data formats necessary for the communication of different systems; see Figure 5 for illustration (Werthner & Klein, 1999). In fact, it has been recognised and obviously accepted that GDS networks represent the main distribution channel.

Following Hart (1997), THISCO processed 600 million messages and made 18 million net reservations per year in the mid-1990s. It covered 60% of the worldwide market share and generated US\$3.2 billion in room revenue. THISCO also has subsequently adjusted its strategy to the Internet and launched an Internet system travelWeb.

Figure 5. THISCO system basic structure (Source: Hart, 1997)

Wizdom, owned by Avis Rent-a-car, is a similar system with access to the GDS world (Sheldon, 1997). It serves a client base of car rental companies and other travel businesses.

GDS Widespread Functionalities

Having discussed aspects of the GDS products and contracts, as well as their extensions, the overall functionalities can now be recapitulated. In general, Buhalis (1998) described the role of GDS as horizontally integrating airlines and vertically integrating all other tourism suppliers in a system that can be described as the circulation system of the tourism industry. By 1995 the coverage of GDS had expanded to such an extent that they could be termed 'global travel and tourism information and reservation systems' (O'Conner, 1999). Therefore, the widespread functionalities of GDS systems and terminals can be summarised according to Sheldon (1997):

- Flight information: schedules, inventories, availability, fares, fare rules, bookings
- Passenger information: create, modify and store passenger name records (PNRs), itineraries, frequent flyer information, and special requests
- Document printing: facilities to print tickets, boarding passes, and itineraries
- Car rental, hotels, cruises, rail, and tour packages booking*
- Theatre & event ticket and foreign currency ordering*
- Accessing Department of State travel advisories*
- GDS subsection TIMATIC provides information on visas and passports, health, customs, currency controls, and departure taxes*
- Communication service: fax & e-mail*

** Non-airline functions mostly available through today's GDS*

In general, business applications such as word processing and spreadsheets but also data communication programs (e.g., e-mail clients) represent the standard of today's computer infrastructure of travel agents—independently from the GDS.

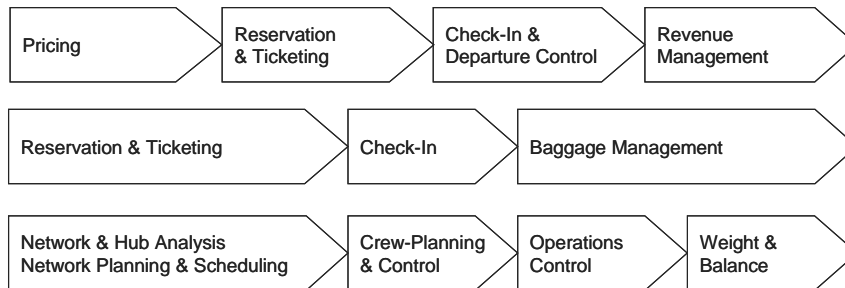

GDS Complementing Airline and Airport Systems

Due to their historical evolution, their functionalities and extensions as well as their worldwide spread and dominance, the GDS have become the core systems of operational and strategic airline management. In general, a wide range of business functions of tactical and strategic management are supported: revenue analysis and forecasting, yield management, competition monitoring, maintenance of historical data to predict demand or to design desirable products, and finally management of business models. In addition, numerous information management and decision support systems are used to support core business processes. The operational management requirements for airlines include check-in procedures, allocation of seats, generation of reports and orders, such as flight paths, weather forecasts, load and balance calculations, manifests for airports, in-flight catering orders, and crew rotas (Buhalis, 2003).

However, as management needs and processes have increased in complexity, different distribution and distribution related tasks had to be supported or executed by additional systems. So far in this paper, distribution has been equated with the GDS, but as Figure 6 shows, the understanding of the term "distribution" has to be expanded to cover enlarged management and process challenges. Figure 6 shows different views on distribution, taking airline, airport, intermediary and customer aspects into account.

To deepen the view of Figure 6, the following paragraphs briefly consider some special systems; as described extensively in Buhalis (2003). For example, special flight schedule management

Figure 6. Different views on the distribution process (Source: LufthansaSystems, 2006)

systems have been introduced to optimise network performance, taking technical and operational characteristics into consideration, including, for example, equipment, human resources, availability of seats, regulations, demand for traffic, or air traffic control rules. Following the flight scheduling, station control systems monitor all kinds of connections on a hub in an airline's network, including passenger and crew connections. The handling of crew planning processes is supported by crew management systems. These assist in the creation and maintenance of duty rotas, ensuring that they are efficient, complete, legal, economical, and fair.

Due to the multiplicity and complexity of all these systems, a separate operations control system is often included to generate alert messages and update all other operational systems, such as flight scheduling, reservation, maintenance, and crew control systems.

In addition, all airlines need airport infrastructure for their operations. Different systems cope with the challenges of requesting landing slots and docking gates, informing about arrivals and departures, altering slots in case of delays, declaring flight paths and coordinating their operations. Other activities at the airport, such as maintenance, refuelling, catering and cleaning as well as the loading and dispatch of aircraft are carried out by different cooperating organisations. The latter interacts closely with

the baggage handling and monitoring systems, ensuring that baggage is distributed correctly and no baggage is transported without its owner, as per the International Civil Aviation Organisation (ICAO) regulations.

The GDS and Airlines State of Business in the 1990s

To round off the historical analysis of first-generation airline reservation systems the airline distribution situation in the 1990s is more closely examined in this section. Economically, the 1990s were challenging for the airlines. Even though the overall passenger numbers increased, ticket prices had to be lowered constantly and profits deteriorated due to growing competition. The challenge of keeping up or even improving current market shares led to different worldwide operations and marketing alliances. Competition between alliances replaced the rivalry between single airlines—introducing an intra-alliance-cooperation, a mix of cooperation and competition. A good example of this new strategy seems to be the combination of different frequent flyer programmes (FFP), which were introduced by airlines earlier, due to the new possibilities of the digitalisation of all reservation based information. These kinds of new marketing strategies represent one possible instrument of cooperation. However, in the beginning, alliances were initiated in terms

The Transformation of the Distribution Process in the Airline Industry

Figure 7. Fees and commissions in the airline distribution chain (Source: GAO, 2003)

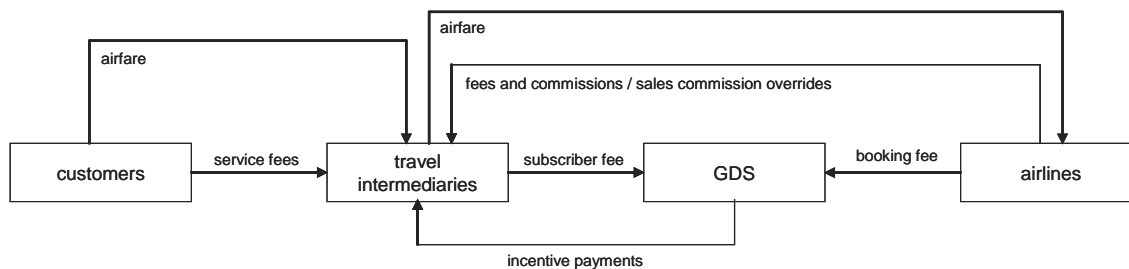

Figure 8. Traditional distribution chain (Source: Original by the author)

of code sharing agreements to overcome air traffic regulations, for example concerning departure and touch down slots restrictions. Another key aspect of strategic cooperation has been the stabilisation of the market environment, as competitors became partners and gained bargaining power within a network. These network effects could not only be identified in back office activities but, above all, have been clearly visible and advantageous to the customers. In contrast to today's three large strategic airline alliances (StarAlliance, OneWorld, and SkyTeam) the emergence of low-cost airlines evoked a serious competitive challenge to traditional airlines, even forcing them to retreat from some markets, especially on short distance routes. It is worth noting that most of these developments would not have been possible without the emergence of modern information and communication technology (ICT), especially the diffusion of the Internet and online platforms.

In fact, traditional airlines suffered from their dependency on the GDS supplier throughout the decade. The cost of GDS representation and distribution increased considerably in the 1990s, when it was estimated that average airline expen-

diture on distribution represented 25-30% of their turnover. Basically, the GDS income rested upon usage based fees, which were rather high compared to the respective costs. In addition, suppliers and intermediaries also had to pay to link their systems to a GDS. Furthermore, airlines relied on travel agencies to distribute their products in exchange for a commission payment, which was usually between 5 to 10% or more. During this era, distribution costs were regarded as a fixed cost (Prideaux, 2001). Doganis (1991) estimated ticketing, including commission and promotion costs, comprised 18% of the total operating cost. The different fees and commissions are represented in detail in Figure 7.

Thus it becomes clear that the fees and commissions (illustrated in Figure 7) in the traditional airlines' distribution chain represented a growing threat to the existence of many airlines. The rising costs of distribution were additionally accompanied by stagnating market segments. Still, until the end of the decade, GDS suppliers represented major players in the tourism value chain, since they provided the main (electronic) link between a huge supplier group and the travel intermediary

community. As illustrated throughout this first main part of this chapter, Figure 8 summarises the traditional distribution chain on the airline market.

By the mid-1990, this traditional distribution chain had already existed for almost three decades, being a constant in an ever-changing environment. Although the basic structure remained the same, the underlying processes altered over time, concerning all market participants. But, due to the emergence of new information and communication technology the entire distribution process is now almost turned upside down. With the rapid growth of the Internet in the late 1990s, the second stage of information and communication technology (ICT) evolution in the airlines industry ended. The third phase of growth of airline distribution systems is discussed in the following part.

(R)EVOLUTION OF THE AIRLINE MARKET

In the early years of the new millennium the airline industry is facing major challenges subsequent to the privatisation of many national airlines and the establishment of partnerships and global alliances. The airline free market economy has become highly volatile in recent years, especially after facing an economic and psychological crisis in the light of the terror attacks using passenger aircrafts in the United States on September 11, 2001. Furthermore, economic factors such as deteriorating revenues, the fluctuating health of several major national economies, and new competitors such as low-cost carriers have further exacerbated the situation. Thus, deregulation and globalisation forces have brought both new challenges and threats to airline management. These include, for example, over-capacity, high investment pressure, and rising cerosin prices. Consequently, the influence of such wide-ranging factors on the airline business frequently demands

rapid adaptations or even a change of business models (Merten & Teufel, 2006).

Above all, the emergence of modern information and communication technology (ICT) has led to a fundamental transformation of the airline market environment. In particular, the appearance of the Internet and the diffusion of the World Wide Web have radically reshaped the distribution environment. This alteration of the distribution structure and processes is examined in the following sections. For this analysis the impact on each market participant group will be considered separately, using the relationships outlined in Figure 8 and starting with the customer. After looking at customer evolution, the changing role of travel intermediaries will be studied. Subsequently, the main section of this chapter analyses the transition from first-generation airline reservation systems (CRS/GDS) to the introduction of second-generation airline core environments. To round off the discussion, the consequences of modern information and communication technology are reviewed from an airlines perspective, including future scenarios, even beyond the distribution systems themselves.

Customer Evolution

The rapidly increasing popularity of the Internet in the 1990s and its penetration into private households as well as business environments pushed airlines to launch their first Web sites in the mid-1990s. By 1998 most airlines already offered Web sites, which primarily informed visitors about schedules, prices and itineraries as well as other flight and airline-related information. Over time the interaction potential of these platforms grew and the adoption of modern technologies brought new opportunities. Indeed, the Internet provided airlines with the potential to open direct channels to their customers, offering their whole range of services, from flight information (schedules, availability and prices) to reservations and ticketing

The Transformation of the Distribution Process in the Airline Industry

Figure 9. Trends of online distribution on the airline market (Source: von Götz, 2005)

(including payment options), as well as further value-adding services. As a rapidly increasing number of flights are booked over the Internet, more and more information is being made available to the end consumer. By bringing all necessary booking information right to the customer, online booking engines have enlarged product availability and price transparency.

In this newly created online distribution environment, customers are increasingly using the Internet to obtain travel information and book online. Thus, their behaviour has become more individual, heterogenic, mobile, sovereign, and time-sensitive, as they can take advantage of a far wider range of options than it was previously the case. Furthermore, a broad shift of bookings from classical distribution channels back to the airlines themselves can be observed, while customers seem to swap between channels during the buying process. Therefore, in future, a multi-channel distribution environment will be the most likely scenario (Schmidt, 2004). Figure 9 underlines these trends.

So far, the discussion focused on the customer as an individual. However, customers as a category also can be subdivided into leisure customers as well as unmanaged and managed business travel

customers. The business analyst PhoCusWright Market Research forecasts that the online part of leisure and unmanaged business travel bookings would double in size in the period from 2003 to 2006, being worth some US\$78 billion in the U.S. In addition US\$36 billion is predicted to be spent online on the managed corporate market (N.N., 2005). On closer examination of the latter point, it can be noted that in particular large-scale businesses hold strong framework agreements with single airlines. However, in the corporate market, companies more and more allow their employees to make their own bookings online, but within the rules set by their employer. These online booking services are thus proving extremely popular. Moreover, low-cost airlines encourage, and in most cases require, customers to buy their tickets online. In addition, America's and Europe's market-shaking shift to online travel services and bookings is yet to take off in the huge Asian market, for which an enormous potential also is forecast. These trends, along with ever-changing customer behaviour and new airline strategies represent a threat to travel intermediaries, to be considered in the next section.

The Changing Role of Travel Intermediaries

Obviously, the establishment of direct channels to customers also marked a turning point in the relationship between airlines and travel intermediaries. As the Internet allowed airlines to bypass travel agencies, commission payments from airlines were lowered or even cancelled. Indeed, tensions peaked when airline management embarked on its policy of reducing or eliminating the existing commission structure. In turn, this zero commission forced travel agencies to move to charging customers a fee for products and services offered (Prideaux, 2001).

Since electronic connectivity brings air travel products directly into the hands of the consumer, this poses a potential threat to the existence of travel intermediaries. But in the same way, information and communication technology is threatening the agencies; they also mitigate the threat by creating value-added products and services, and by integrating ICT into their strategic planning and operational processes. For instance, the World Wide Web can not only be used by them to access more information about transportation and destination products, which is in turn passed on to the customer. Offering their services online also can widen their geographical range when receiving requests and booking orders through the Internet.

These trends can be exemplified by looking at the “.travel” initiative. The Tralliance Corporation is the registry for these “.travel” sponsored top level domain names. Its major aim is to improve the Internet identity of travel-related companies and to increase the level of trust between the tourism industry and its customers. For this, the initiative features an authentication of a registrant’s industry credentials and name(s) eligibility by an independent third party. With this confirmed identity, a registrant lifts its business out of anonymity of today’s Internet. Beyond this, a first of its kind

central online directory has been established, based on a unique vocabulary to match providers travel products and services precisely with consumers needs worldwide (www.directory.travel). The success of this initiative is however yet to be confirmed as the whole system was only launched on January 2, 2006 (Tralliance, 2006).

Beyond the external opportunities offered by the Internet, modern ICT also can be used to optimise, simplify and extend current internal business processes, for example, by sending tickets or booking information via e-mail. Finally, online platforms from airlines, which enable the bypass of travel intermediaries from an airlines point of view, of course also can be used by the travel agents themselves. In doing so, they in turn bypass GDS, no longer relying on a terminal infrastructure and tight contracts with the GDS.

GDS and Beyond

Due to their historical development, the GDS providers have established supremacy in the airline industry and its traditional distribution chain. They have proven to be reliable, they succeeded in standardising the products included and still hold a dominant market position (see Figure 10) (Merten & Teufel, 2006).

Although the GDS provide airline managers with powerful management tools, for example to identify new market segments and maximize yields, the use of GDS adds to the overall distribution costs (Prideaux, 2001). On the one hand, the systems themselves have become more and more expensive in terms of maintenance and upgrades, with respect to finance and personnel (Werthner & Klein, 1999). On the other hand, fees and commissions increased over time as already shown in Figure 7. As Graham Atkinson, a United Airlines Senior Vice-President, noted, “The company spends about US\$250 million on GDS fees annually” (Tedeschi, 2005). In fact, the margin of airline market participants correlates

The Transformation of the Distribution Process in the Airline Industry

Figure 10. GDS air bookings year-on-year percent growth at month end (Source: Sattel, 2005)

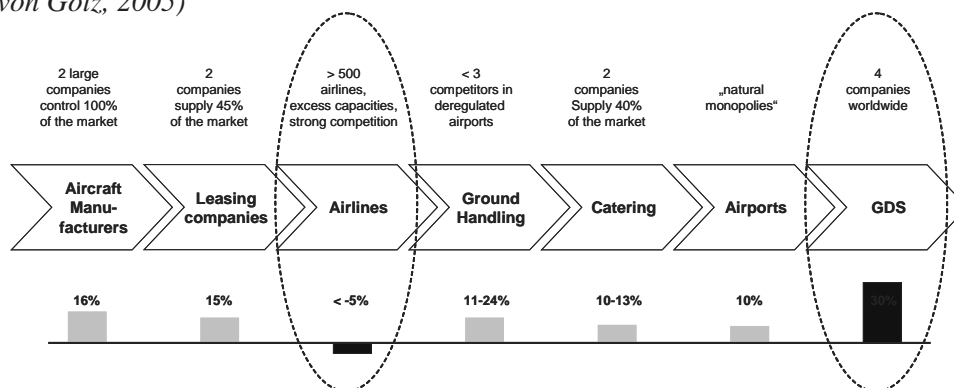

Figure 11. Margins of air travel participants in correlation with their relative dominant market position (Source: von Götz, 2005)

with their relative dominant market position and is especially high for the GDS companies, as shown in Figure 11.

Similarly, Atkinson (ibid.) remarked, that “there has been awareness in the industry for some time that the price-value relationship there is out of sync. Anytime that happens, you will ultimately find someone with a better solution to the business problem. That is what has happened” (Tedeschi, 2005).

In consequence, airlines and travel agencies have sought for possibilities to bypass the GDS as distribution intermediaries, not least because

GDS fees amount to approximately \$12 per ticket (LufthansaSystems, 2006). Parallel to this development and due to rapid technological progress, alternative distribution platforms have achieved maturity and market penetration in recent years, which has enabled airlines to compete directly with the traditional distribution channels. Still the airlines’ backend systems are the GDS, but new technologies opened up new opportunities with alternative front ends for new distribution channels, which therefore not directly involve the GDS companies any more. This competition has placed increasing pressure on the GDS suppliers.

To give an example, in 2004, Northwest Airlines cancelled, with immediate effect, a new fee charged to travel agencies for a round-trip domestic ticket booked through global distribution systems. Northwest hoped the move would drive customers and travel agents to its Web site to buy tickets, which did not include ticketing fees. In response, Sabre said they would no longer prominently display Northwest fares on the schedules they provided to travel intermediaries. In consequence, Northwest sued Sabre for changing the way it displayed fares on its reservation system and Sabre sued the carrier for alleged violation of contract (von Götzt, 2005)

This example shows that the Internet enables airlines to regain control over the distribution of their products by bypassing the travel intermediaries and enforcing a zero-commission. Likewise, travel agencies use these online platforms to become more independent from the GDS suppliers. These distribution platforms were first set up by airlines by adapting the front end of their distribution systems. As airlines are not only trying to bypass the GDS in the distribution chain, but also search for opportunities to replace the existing GDS as backend systems themselves, the GDS suppliers have to reflect on their own strategy. The first step for GDS suppliers has been, not surprisingly, to counter with their own online booking engines like amadeus.net. However, having to deal with the problem of brand (non)recognition, they also have started to offer their complete range of services under new brand names, as they have developed or bought special alternative Internet platforms such as opodo.com (Amadeus) or last-minute.com (Sabre). Further, GDS providers have reacted by expanding the functionality of their old platforms using modern technologies—but still having old legacy technology in the centre of their systems. Consequently, and in addition to the adoption of front ends of GDS, also the backend systems were due for redesign.

In addition, in July, 2004, the U.S. Department of Transportation formally phased out all GDS

regulations. This deregulation empowered suppliers to re-evaluate their participation in the four major global distribution systems. Finally, GDS became fully independent and no longer airline owned. Airlines were thus able to selectively distribute inventory at different levels in the four systems. Therefore, with the deregulation of GDS, it was no longer possible to rely upon a single GDS as the sole source of all air travel information. As a single source information distribution model, the GDS were no longer sufficient to ensure total content availability. Therefore new platforms were needed to aggregate disparate content and enable comparative shopping from multiple sources of fares and inventory. These platforms should seamlessly provide content from traditional distribution sources (GDS), direct connections to emerging suppliers and Web-based inventories as well as private fares and Internet fare sources.

These developments clearly show that the GDS suppliers have to fear for their traditional core business. As Holger Taubmann, CEO of Amadeus Germany, admitted in 2005, due to growing online bookings the whole classical GDS market will stagnate or even decrease in the long run as increasing cost pressure and declining margins are foreseeable (Genger, 2005). Therefore GDS providers today have to re-evaluate their business strategy. Nevertheless, airlines will still rely on the traditional distribution system at least for some years.

In the light of these challenges and threats, GDS companies turn their business strategy from travel distribution system and content providers to travel IT solution providers with new technologies (Merten & Teufel, 2006). For example Amadeus changed its name to Amadeus IT Group SA and identified three future business fields (Amadeus, 2006): the travel distribution business area covers all aspects related to the traditional GDS (more and more building on modern technologies), including additional tools and services. Second, Amadeus e-travel provides online travel technology and corporate travel management solutions for airlines,

corporations, travel agencies and other online travel businesses. Next to this e-commerce division, the airline IT services business area offers a new second generation IT platform: Amadeus Altéa Customer Management Solution (CMS). It is built on open system technology and consists of three different modules: Amadeus Altéa Reservation (sell), Amadeus Altéa Inventory (plan) and Amadeus Altéa Departure Control (fly). This CMS platform has been designed scalable for airlines, low cost carriers and as well as airline networks or alliances (Amadeus, 2006).

Despite all these developments, decisions and improvements, GDS suppliers have been struggling for some years, as new companies appeared on the market and offered simpler and cheaper solutions—so called GDS new entrants (GNE). Although, as start-up companies, GNE could not effectively compete the GDS in all fields, they increased the competition and enabled airlines and travel agencies cheaper access to the market and new opportunities.

GDS New Entrants (GNE)

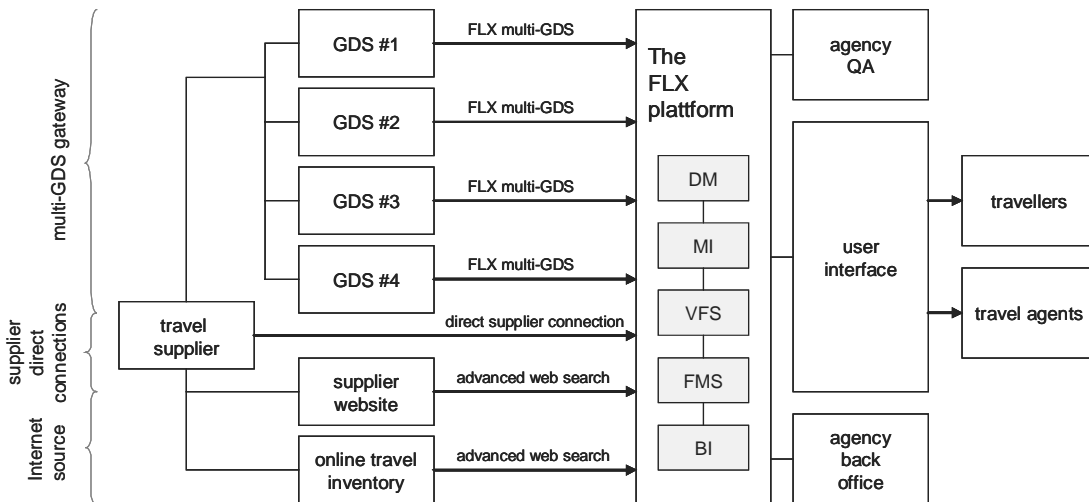

Due to the GDS deregulation and the emergence of alternative platforms for direct sales, the limits of the original GDS and their underlying technologies became more and more obvious in the last years. Additionally, as the number of alternative platforms for direct sales grew, GDS became unable to cover the full range of services on the market. Consequently, different kinds of work around systems, combining the “legacy” GDS with new technology appeared on the market and called themselves GDS new entrants (GNE; also known as global new entrants). GNE providers used modern technologies to allow airlines to close this gap and pool the offers from GDS and other distribution platforms. Table 4 gives a short overview of the leading GNE players on the market, listing some highlights of the different companies.

All of these companies target low cost distribution with their systems, while recognizing the need to aggregate content from all kinds of

Table 4. GDS new entrants (GNE) credible players (Source: Lewitton, 2005)

GNE Company	Highlights
ITA Software	Founder: Jeremy Wertheimer, PhD (MIT) Established in 1996, privately held. Built industry-leading shopping engine. Supplied code for Orbitz launch. Clients include agencies, suppliers and GDS.
G2SwitchWorks	Founder: Alex Zoghlin, built 3 successful tech. companies, including Orbitz. Privately held start-up (2004). Employing existing direct connects to AA, CO, NW, UA and others.
FareLogix INC.	Founder: Rick Gossage CEO: Jim Davidson, ex-CEO Amadeus US Established in 1998, privately held. Built industry leading contract management system and call centre travel booking applications. Clients include major agencies and consolidators.

Figure 12. Components of the FareLogix FLX platform solution (Source: FareLogix, 2006)

different sources. FareLogix is exemplarily in its approach and will therefore be examined more closely. The company currently provides solutions with multiple source content to some of the largest travel companies in Canada and the United States, including Navigant International, American Express, and Carlson Leisure Group Services. The centrepiece of the FareLogix system environment is the FareLogix FLX platform, as illustrated in Figure 12. Following FareLogix (2006), it represents a multi-GDS gateway that connects to all four GDS, using structured data streams that normalize the communication in a common application programming interface (API). The multi-GDS gateway provides independence from the single-source GDS model and allows the integration of multiple GDS inventories at an individual-itinerary level. In addition, direct connections to supplier systems can be established for real-time availability. And finally, as new Web-based direct distribution platforms have diffused, content from low-cost carriers and online travel sites is integrated via appropriate interfaces. Consequently, FareLogix banks on advanced Web search technology to capture and aggregate content from different online portals to provide travel agents and travellers with a comprehensive integrated inventory solution.

As illustrated in Figure 12, the FareLogix FLX platform consists of a set of different systems. First of all, the Distribution Manager (DM) is a business rules engine, which controls the supply and handling of source information. The sources are the different GDS, direct supplier connections and Web inventories. The Master Itinerary (MI) integrates the supplied source information into a so called super-PNR (passenger name record), which acts as a single record repository for all travel itinerary information. Furthermore, the Virtual Fare Store (VFS) incorporates fares from the Airline Tariff Publishing Company (ATPCO) and private fares from the Fare Management System (FMS) to calculate the lowest fare for each itinerary. The FMS itself provides a new flexible platform to store private fares from airlines, no longer requiring the cumbersome reliance on traditional ATPCO fare filing. This independent faring and pricing engine allows airlines a new level of distribution channel management that did not exist in the ATPCO-driven, GDS-centric environment. Finally, the business intelligence (BI) module primarily serves reporting purposes on operational performance and vendor analysis. For a more comprehensive description of the FLX platform, see FareLogix (2006).

Going one step further, travel intermediaries and customers can either access the FLX platform by a standard certified user interface or use an existing neutral agent point-of-sale (POS) application. Based on an API technology, it also allows simple interfaces to agency quality assurance (QA) and back office accounting systems. Obviously, the FLX platform is built on open standards using Web technologies such as “the Extensible Markup Language (XML), simple object access protocol (SOAP), Web Services Description Language (WSDL), and the universal description, discovery, and integration (UDDI) open standards over an Internet protocol (IP) backbone. This robust open architecture enables seamless integration of disparate inventory sources. Furthermore, the platform uses standard Open Travel Alliance (OTA) XML schemas and traditional EDIFACT communication protocols to provide suppliers with familiar communication methodologies” (FareLogix, 2006).

In conclusion, referring to the CRS/GDS as first-generation airline distribution systems, the GNE platforms can be seen as a transitional solution, which will presumably have a growing importance in the airline distribution market in forthcoming years. The GNE platforms provide airlines with a sophisticated and cheaper solution and the possibility to circumvent the GDS companies as distribution intermediaries; still the GDS remain the systems in which airlines store all their business critical data. But, as airlines are offering more and more information and functionalities via direct connections (for example the FLX platform), they increasingly have to develop their own systems, often with the aim of becoming totally independent from the GDS. With regard to the growing complexity of airline systems, not only in terms of distribution, but also with regard to internal and external processes and management, it can be foreseen that second-generation airline core environments will emerge (also including new systems of the GDS providers). Of course, airline distribution will remain their central fo-

cus. As system development is generally not part of the airlines’ core competences, the need for airline IT providers has risen. These providers can either position themselves as a full service provider of airline systems and supporting IT solutions, the latter going beyond airline core processes (so-called value added services), or they can be a specialised supplier of only these value adding systems.

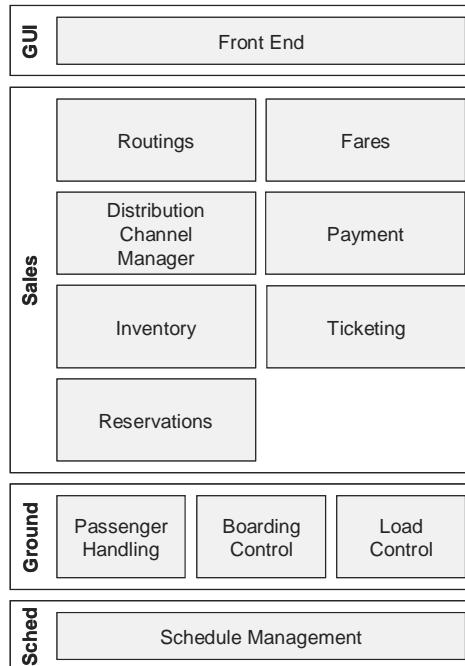

Second-Generation Airline Core Environments

In the current changing market environment, airlines are offering their products through a wide range of distribution channels. Nevertheless, although circumventing the GDS in the distribution chain through direct channels (for example online platforms), the airline system environment still relies on the GDS. Therefore, if airlines are to regain total control over the whole distribution process they will be forced to undertake a radical shift towards completely new airline core system environments. Regaining control means not only cutting costs and eliminating commissions. The new systems also can provide new kinds of management information, while supporting a much broader range of operational and management processes.

In addition to new IT platforms of traditional GDS companies, new airline IT full service providers offer these new systems and promise flexible solutions for quick reactions in a fast paced market environment. In general, the requirements for a second-generation core environment range from multi-channel distribution and distribution cost control to immediate adjustment possibilities of core processes to keep the system in line with the business strategy.

Different new airline full service IT providers have emerged on the market recently and have developed completely new information system environments. An example of such a system in terms of the fundamental change from first to second-

Figure 13. FACE—Future Airline Core Environment by Lufthansa Systems (Source: LufthansaSystems, 2006)

generation systems is that of Lufthansa Systems, whose new system is called FACE: Future Airline Core Environment. The struggle of global distribution systems will inevitably “be an opportunity for flexible and cost-effective solutions to move into spotlight”, predicted Wolfgang F.W. Gohde, CEO of Lufthansa Systems, at a press conference in Frankfurt/Germany on June 24, 2005 (LufthansaSystems, 2006). Lufthansa Systems is currently investing 40 million euros in the future development of its airline systems—regarding FACE as the cornerstone of the new information based landscape (LufthansaSystems, 2006).

The FACE platform uses a modular approach, enabling a suitable fit for different business models: from classic network carriers with global route networks, to low-cost airlines with point-to-point transportation. Furthermore all business models can be used simultaneously within a single airline or airline group. FACE supports the classic core

processes of passenger airlines, from inventory, schedule distribution, reservations, ticketing and departure control, to passenger service processes as classified in Figure 13.

“FACE enables airlines to freely choose their favourite distribution channels,” stated Gohde (ibid.). “This makes airlines more flexible and allows them to respond faster to market changes. FACE provides open interfaces, thus ensuring seamless data communication between different technology platforms—including airlines using different systems” (LufthansaSystems, 2006). The modular approach further enables airlines to adopt different parts of the system over time and adapt them to their business processes and requirements. The different parts or functional areas introduced in Figure 13 support the following business processes (LufthansaSystems, 2006):

- All schedule management processes support the creation of schedules and the conversion

into marketable offers, thus allowing the distribution to all relevant partners.

- Passenger ground handling processes maintain the passenger handling from check-in to boarding, including additional customer care activities. The management of flight-related processes involved in loading an aircraft and preparing it for departure also is included.
- Sales processes range from the management of the inventory via reservation and sale to the issuing of and payment for a ticket. Special emphasis is placed on enabling airlines to actively manage and effectively control sales through the various traditional and upcoming distribution channels in a deregulated, competitive, and agile market environment.
- Finally, the FACE front-end graphical user interface (GUI) provides the business process logic with workflow orientation and a high degree of automation.

Beside the fact that FACE is GDS neutral, it operates under the IATA code L1 so that it can be run as a computer reservation system by Lufthansa Systems, and therefore represents a potentially fully equivalent system to replace the GDS backend. Of course, connections to GDS, GNE, and Internet sources will still be possible; to keep the backdoors open for all intermediaries and customers still relying on these kinds of information sources. Enabling airlines to combine different distribution channels, FACE also is designed for use in airlines alliances, and will therefore be marketed both inside and outside of the StarAlliance.

New Management Challenges for Airlines

At the beginning of this part of the chapter, general airline management challenges relating to economic factors were already discussed. This section therefore concentrates on the opportunities

and threats for airlines with regard to distribution. In fact, distribution is increasingly regarded as one of the most critical managerial aspects, as it can determine the competitiveness and profitability of organisations.

In the airline business, distribution has always been ICT driven, in the past heavily relying on the first-generation of airline reservation systems (CRS/GDS). However, modern information and communication technology has provided airlines with a completely new set of diverse opportunities. Today, airlines can take advantage of such opportunities by using the Internet as a distribution channel, starting with airline-owned Web sites, alliance booking engines, electronic intermediaries and other kinds of sales tools, including electronic auctioning of unsold seats. Airlines have managed to bypass intermediaries and to enforce zero commission, and also regained control over distribution. All of these different options represent a potential threat to travel intermediaries and GDS suppliers, as examined throughout the previous sections. As a result, the airlines' distribution chain has undergone a fundamental transformation. An overview of these transformations is given in Figure 14.

In this highly competitive market environment, airlines of all sizes have to react swiftly to market trends and constantly cut costs. In fact, increased cost pressure seems to have become a constant. In the past, management often concentrated on cost cutting while improving efficiency and effectiveness—traditionally targeting fields such as engineering, engine efficiency, air traffic control systems, administration, wage costs, and improvement in the design of aircrafts and related systems. With the emergence of the Internet, however, airline managers were enabled to shift the emphasis from these previous fields to a focus on reducing distribution costs. To round off the analysis of today's distribution environment from the different perspectives throughout the previous section, Figure 15 reflects on the different stages of distribution technologies and providers.

Figure 14. Transformation of the distribution chain (Source: Original by the author)

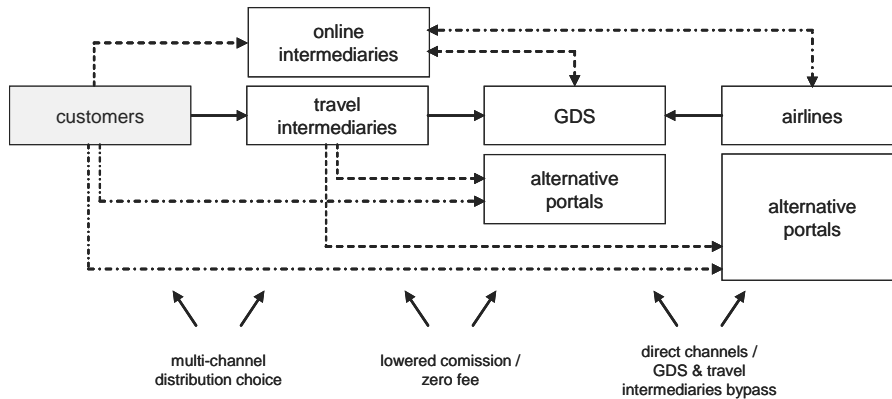

Figure 15. Stages of evolution in distribution technologies and providers (Source: LufthansaSystems, 2006)

Overall, modern information and communication technology has led to a fundamental reshaping of the airlines’ distribution, internal processes as well as the market structure and balance of power. As the ICT induced opportunities for airlines become obvious in terms of distribution processes, the possible use of modern information and communication technology beyond the distribution rises. The following section concentrates on these

new efforts and future developments, going one step further beyond distribution.

Mobile ICT in and Beyond Distribution

In recent years, not only “traditional” information and communication technology have developed rapidly. Increasingly, also the impact of mobile

The Transformation of the Distribution Process in the Airline Industry

Figure 16. Network architecture of in-flight entertainment and communication systems (Sources: Jahn, Holzbock, & Werner, 2002a; Jahn, Holzbock, Diaz, & Werner 2002b)

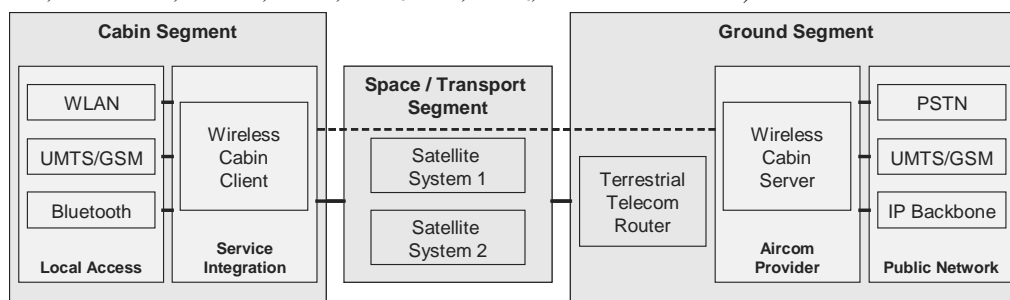

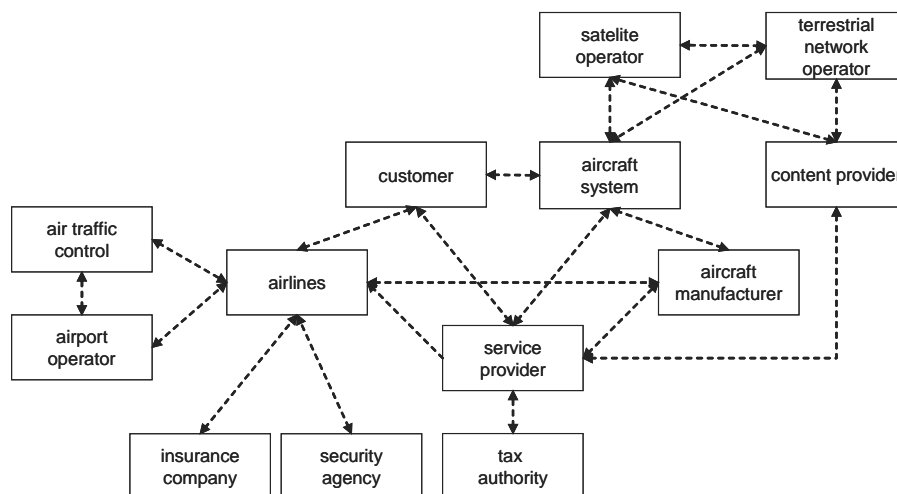

Figure 17. Parties and relationships involved in the new business model (Source: WirelessCabin, 2006)

technologies has to be considered when planning and developing business solutions and system environments. For companies as well as private and business customers, mobile networks and end devices represent new opportunities and are becoming widely used standards. Clearly both airlines and other distribution channel providers are thinking about means of transferring and integrating existing online booking engines to mobile platforms. As successful general mobile platforms (for example, i-mode or Vodafone live!) vary markedly depending on providers and countries/continents, it seems difficult to identify a representative solution among those available. Except for some information services, so far mobile

ticketing is the only available mobile distribution service going beyond the booking process itself. Principally, it is based on a similar assumption to electronic ticketing, that is, clients who book online also possess an e-mail address and a mobile end device respectively, to receive their booking confirmation. This mobile ticket could replace not only the printed invoice and booking confirmation, but also the whole paper-based ticket. In addition, the electronic ticket is the basic precondition for most available self-check-in procedures at airports. Again, the check-in procedure marks today's end of a seamless electronic distribution process, due to the necessity of passport control and registration of baggage.

To return to the discussion on the use of mobile end devices, it can be observed that a growing number of passengers are carrying their notebooks, organisers or mobile phones on to the aircraft. On the ground, that is, at airports, these devices can be widely used, encouraging airports to ensure good network coverage or even install wireless access points, so far often been restricted to business and first class lounges. Furthermore, a survey from WirelessCabin (2006) shows that business customers in particular, increasingly demand on-flight connectivity. The survey identified 30% of these customers as potential frequent users. The demand for services on-board ranges from news (84%), e-mail (78%), Internet (73%) and virtual private network (VPN) access to the company's intranet (66%) to mobile telephony (60%) and video conferencing (16%).

For these reasons different interest groups of industrial and scientific background work on new technological and business solutions for a new generation of in-flight entertainment and communication systems (IECS). For example, as part of the European initiative (European Union contract no IST 2001 37466) the WirelessCabin project has been launched with the aim to clarify a possible system and business structure. Based on these elaborations and different scientific publications on numerous mobile technology conferences the basic network architecture can be displayed as shown in Figure 16.

Following Jahn et al. (2002a, 2002b), a future IECS will consist of three different parts: the cabin segment, space or transport segment, and the ground segment. Passengers are offered mobile access with their own notebooks, PDAs, or mobile phones via different wireless technologies, which are combined in a so called collectively mobile heterogenous network (CMHN). After the service integration, the wireless cabin client establishes a satellite connection to the terrestrial server, which in is handled by the aircom provider. As part of the ground segment, this server also provides links to fix-line and mobile networks as well as

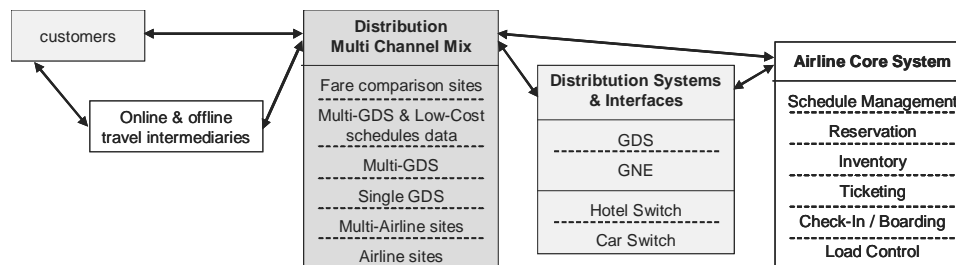

the Internet and other networks as for example corporate intranets or virtual private networks (VPN). The complexity of establishing such new systems can be generally underlined by showing an abstract diagram of the parties involved as well as their relations in Figure 17.

Due to customer expectance and the complexity of these new systems, it is not surprising that Boeing and Airbus as the major aircraft companies are investing in the development of innovative new on-board systems. The current communication and entertainment infrastructure in airplanes is planned to be completely replaced within this decade by new systems called "Connexion by Boeing" or "OnAir", the latter being a joint venture system of Airbus, SITA, and Tenzing. In both cases, the business model involves a large number of parties as pointed out in Figure 17 and represents a major challenge to all participating players. This shows on a more general level that the entire distribution process, including all related processes, is a complex phenomenon—inter alia caused and affected by information and communication technology.

CONCLUSION

Throughout this chapter, it has been shown that information and communication technology (ICT) has always been a driver of change in the airline industry. For over four decades, ICT has repeatedly affected and determined the way of airline business. In turn, the airline industry also has been a driver of evolution for the ICT sector. First, ICT helped the airline industry to lift-off in the 1950s and 1960s, by providing new methods of handling the rising flood of passenger related information. Indeed, ICT soon became critical to business in the distribution process. As a result of ongoing system enhancements and due to the influence of deregulation on the airline market, original computer reservation systems (CRS) slipped into a concentrating process, which led to

Figure 18. The airline industry's electronic multi-channel distribution environment (Source: Merten & Teufel, 2006)

an interconnected network of different systems, calling themselves global distribution systems (GDS). Over several decades, the GDS suppliers grew to be major players on the airline market, handling the distribution of products for the airlines, with the aid of travel intermediaries as main access to the end consumer. Finally, modern information and communication technology has led to a fundamental reshaping of the airlines' internal processes as well as the market structure and balance of power, resulting in a need for completely new airline core system environments. In this process the traditional distribution chain has been transformed into a form of multi-channel distribution environment as illustrated in Figure 18.

In this, all different market players form an interconnected network, where every action directly influences the entire network and vice versa. Due to this cross-linking the complexity of management decisions increases, and enforces a much stronger competitive situation. As a result, a duality of competitive and cooperative relationships coexists. Therefore future research ought to examine the network effects and challenges of the so-called co-competition in the airlines industry's cross-influenced network. A particular focus should be on the different market players in this multi-channel distribution environment. For further details see Merten and Teufel (2006).

This chapter aimed to provide a comprehensive overview of the transformation of the distribution process in the airline industry empowered by information and communication technology. Today, airlines, old and new intermediaries as well as the customers are all affected by changes made possible through the Internet. While airlines are successfully using the opportunities provided by the Internet, travel agents quarrel with lowered commissions and are forced to charge customer fees as they have not yet identified the potential of the World Wide Web for their sector. Customers, on the other hand, drift off to online services using the new diversity of distribution channels, exploring and exploiting the possibilities of their newly gained independence.

ABSTRACT

This chapter tests empirically to what extent technological innovation influences international trade and studies its effect on different groups of countries according to their level of economic development. Different measures used in the literature to proxy for technological capabilities are reviewed and two of them are selected. The estimation results show that technological innovation has a considerably high explanatory power on trade compared with other traditional determinants. Countries tend to trade more when they have similar technological capabilities and the development of technological innovation has lowered the effect of geographical distance on trade. According to the obtained results, investing in technological innovation leads to

the improvement and maintenance of the level of competitiveness, therefore a good economic policy in developing countries is to invest in technological innovation.

INTRODUCTION

In the last decades there have been important changes in the international environment, with an increasing number of countries that are closely linked to one another through international trade and foreign direct investment. Globalization, new technologies, and information flows play an important role in this worldwide interdependence. In this framework, trade theory highlights the importance of technological change in explaining the competitiveness of a country.

The main purpose of this chapter is to test empirically to what extent technological innovation influences international trade and to study its effect on different groups of countries according to their level of economic development.

In the next section, different measures used in the literature to proxy technological capabilities are presented. In a knowledge-based economy with high and increasing dependence on technology, information and human capital, the development of relevant indicators to measure the level of technological innovation across countries is a matter of great importance. For this purpose, three components of technological innovation are considered: creation of technology, diffusion of recent innovations and diffusion of old innovations (as measures of information technology), and development of human skills (as a measure of human capital).

The third section presents the estimated model and the empirical results. Empirical results show that technological innovation has a considerably high explanatory power on trade in comparison to other traditional determinants. Moreover, the view that countries tend to trade more when they have similar technological capabilities is supported. Results also show that the development of technological innovation has lowered the effect of geographical distance on trade, since long distances are less important nowadays than in the past. Therefore, investing in technological innovation could help to improve and maintain the level of competitiveness and this will increase the participation of the poorest countries in the world economy.

The fourth section includes a sensibility analysis where groups of countries with different levels of income are considered in order to test for the pooling assumption. Since the magnitude and sign of the explanatory variables depend on certain characteristics of the trading partners, the estimation results support the existence of important differences concerning the goodness of fit, and the significance and magnitude of the variable coefficients.

The fifth section includes three future perspectives for this research, related to the variables included in the model (distance as proxy of transport costs) and the improvement of the estimation methodology (division of countries in different groups and panel estimation). Finally, some conclusions of this research are presented in the last section.

BACKGROUND

The interest in the study on the relationship between technological innovation and competitiveness dates back to the so-called “neo-technological trade theories” of the sixties (technology gap, product-cycle). Most of the research in this field was based on Schumpeter’s analysis of innovation and diffusion as the driving forces behind the competitiveness of firms. This author placed technological change and innovation at the core of economics.

The development of relevant indicators to measure the level of technological innovation across countries is a matter of great interest in a knowledge-based economy that is driven by high and increasing dependence on information technology and human capital. In recent years, important attempts have been taken to measure technology creation and diffusion, and human skills across countries. For example, Wakelin (1997) classifies different proxies for technological innovation used in the literature and points out that the main choice of technological innovation proxies has been between using an input to the innovation process, such as R&D expenditure or the number of scientists and engineers employed in research departments, and an output, such as number of patents. In a more recent study, Keller (2004) states that technology is an intangible parameter that is difficult to measure directly and he proposes that three indirect approaches can be used to measure it. This can be done through the measurement of inputs (research and

Table 1. Measurement of technological innovation with composite indices

Variable	Description	Source
ArCo	This index takes into account three dimensions: Creation of technology (number of patents, number of scientific papers), diffusion of technology (Internet penetration, telephone penetration, electricity consumption) and development of human skills (gross tertiary science and engineering enrolment, mean years of schooling, adult literacy rate).	Archibugi and Coco (2004)
European Innovation Scoreboard	This index takes 17 indicators into account. The aspects of the innovation process measured by the scoreboard are: Availability and use of people with the right skills, creation of new ideas, innovation by firms, and a range of issues. From these indicators a so-called “tentative summary innovation index” (SII) is constructed. The index is normalised to the interval [-10, 10]. An index of zero represents the European Union average (Grupp and Moguee, 2004).	European Commission (2005)
ITR	The “Internet Traffic Report” monitors the flow of data around the world. The index takes values between zero and 100. Higher values indicate faster and more reliable connections.	ITR ¹ (2004)
ICT	The Index of Information and Communication Technology (ICT) diffusion consists of two dimensions: Connectivity (Internet hosts, PCs, telephone mainline,s and cellular subscribers) and access (Internet users, literacy, GDP per capita, and cost of a local call). Moreover, a third dimension (policy) is presented separately.	Biggs, UNCTAD (2003)
TAI	The “Technology Achievement Index” is built up of four dimensions: Creation of technology (number of patents granted to residents, receipts of royalty, and license fees from abroad), diffusion of recent innovations (Internet hosts, exports of high technology and medium technology products), diffusion of old innovations (number of telephones, electricity consumption) and human skills (mean years of schooling, gross tertiary science enrolment ratio).	UNDP (2001)
NRI	The “Network Readiness Index” measures the degree of preparation of a nation or community to participate in and benefit from Information and Communication Technology (ICT) developments. It is built up of three dimensions: Environment offered by a country or community, the readiness of the community’s key stakeholders, and the usage of ICT.	WEF, World Bank, and INSEAD (2004)

development), outputs (patents) and the effect of technology (higher productivity). From a different point of view, Archibugi and Coco (2005) review several synthetic indexes that are used to assess the impact of technological capabilities on economic and social indicators. These authors also recommend considering individual indicators and sub indexes to understand how and why countries differ. The use of composite indices is criticised by Grupp and Moguee (2004), since composite scores and country rank positions can vary considerably depending on the selection process and alternative methods of calculation.

Table 1 shows six different composite indices that measure countries’ endowment of technological innovation and that have been recently developed by some institutions and individuals. Most of the indices take into account several dimensions (3 or 4) that include variables related to the creation, the diffusion and the use of new technologies and the development of human skills and new ideas. However, the correlation coefficient among these indices is high and the availability of the data varies considerably.

Table 2 shows a selection of 20 papers that have used single variables to proxy technological

Technological Innovation, Trade, and Development

Table 2. Proxies for technological innovation

Variable	Description	Source
Proportion of non-managers using computers	Measures the impact of computers on productivity	Black and Lynch (2004)
R&D expenditure Workers in R&D and innovation sectors Number of researchers	Indicators of R&D and innovation	Caballero, Coca, and Escribano (2002)
Expenditure on innovation per worker	Indicators of innovation	Calvo (2002)
Imports of computer equipment	Proxy for technological adoption	Caselli and Coleman (2001)
Foreign R&D capital stock	R&D <i>spillovers</i>	Coe, Helpman, and Hoffmaister (1997)
Variable related to the stock of past research effort and the stock of human capital in countries	Level of technology	Eaton and Kortum (1997)
R&D expenditure	Input measure of investments in new technologies	Fagerberg (1997)
Absolute difference between the ArCo of the two trade partners	Proxy for technological distance	Filippini and Molini (2003)
Internet <i>hosts</i>	Measures the Internet development in a country	Freund and Weinhold (2004)
International patents	National innovative output	Furman and Hayes (2004)
Telecommunications and Internet consumption	Indicators of Information and Communication Technology (ICT)	García Castillejo (2002)
Total factor productivity (TFP)	Output measure of investments in new technologies	Gustavsson, Hansson, and Lundberg (1997)
Firms introducing an innovation (preceding year) Innovation expenditure	Indicators of innovation in firms	Lachenmaier and Woessmann (2004)
Average number of patents <i>per capita</i>	Proxy of innovative output	Moreno, Paci, and Usai (2004)
R&D expenditure Inputs assigned for basic research Information and Communication Technology (ICT) expenditure	Indicators of R&D and ICT	SánchezUsaz, López, Cervantes and Cañibano (2000)
R&D expenditure	Identifies industries where countries tend to have relatively efficient technology	Torstensson (1996)
R&D expenditure Number of patents	Input measure of investments in new technologies Output measure of investments in new technologies	Verspagen and Wakelin (1997)
Total factor productivity (TFP)	Output measure of investments in new technologies	Wolff (1997)
Equipment investment per person engaged in production	Proxy for technological change	Wolff (2002)
Telephone call traffic	Proxy for “disembodied” idea flows	Wong (2004)

innovation. More than half of them have selected the innovation process as an input and only a few have chosen it as an output measure.

Among all the indices available in the literature, the technology achievement index (TAI), developed by the United Nations Development Program (UNDP, 2001), and the ArCo technology index, introduced by Archibugi and Coco (2004), have been selected to be used in this study. The selection has been made in order to analyse as many countries as possible. The TAI is available for 72 countries, but it is not comparable across time because the maximum and the minimum observed values used to calculate the index can change over time. The ArCo technology index is available for 162 countries. The authors fix an identical time period for a maximum and a minimum value (1987-1990 and 1997-2000) to allow symmetrical time-series comparisons. These indicators are also more complete compared to others, as they take into account a wider array of variables related to technological innovation.

The effect of the technological innovation dimensions on international trade is analysed, and each of the components of the TAI was included separately in the regression analysis. A detailed description of the components of the selected indices is presented in Martínez-Zarzoso and Márquez-Ramos (2005).

ESTIMATED EQUATION AND EMPIRICAL RESULTS

To evaluate the empirical effects of technological innovation on international trade, a gravity model, augmented with technological variables and a transport infrastructure index is estimated. The theoretical framework is taken from Suárez-Burguet, Martínez-Zarzoso, and Márquez-Ramos (2005). These authors analyse the role played by cross-country differences in both relative factor endowments and relative country size when determining the volume of trade. They developed a

model based on Helpman and Krugman (1996) and introduced trade barriers, and “hard” and “soft” investment in infrastructure as determinants of the volume of trade. The model supports the notion that comparative advantage determines international trade, adding factors with a positive influence on production factors: “hard” (transport infrastructure) and “soft” (technological innovation) investment in infrastructure. Although the gains of increasing trade are attenuated by the resistance imposed by geographical barriers, infrastructure endowment also determines countries’ specialisation and trade flows.

Based on this theoretical framework, an empirical model is derived to test the influence of technological innovation on trade. Integration dummies are included to take into account the impact of trade agreements on international trade. A number of dummies representing geographical and cultural characteristics are also added. The model is expressed in additive form using a logarithmic transformation.

The estimated equation is shown in equation 1, where \ln denotes natural logarithms.

The model is estimated with data from 62 countries available in 1999 and a total of 3782 (62*61) bilateral trade flows are obtained (see Figure 1). The presence of missing/zero values in the bilateral trade flows data reduces the sample to 3126 observations. An Ordinary Least Squares (OLS) estimation on the double log specification is performed as given in Equation (1).

X_{ij} denotes the value of exports from country i to j ; Y_i and P_i are income and population in the exporter’s country; Y_j and P_j are income and population in the destination market; Adj_{ij} is a dummy that takes a value of 1 when countries share the same border and zero otherwise; Isl takes a value of 1 when the exporter or the importer are an island; $Land$ is a dummy for landlocked countries; $CACM$ is a dummy that takes a value of 1 when both countries belong to the Central American Common Market; $CARIC$ is a dummy that takes a value of 1 when both countries belong

Equation 1.

$$\ln X_{ij} = \alpha_0 + \alpha_1 \cdot \ln Y_i + \alpha_2 \cdot \ln Y_j + \alpha_3 \cdot \ln P_i + \alpha_4 \cdot \ln P_j + \alpha_5 \cdot Adj_{ij} + \alpha_6 \cdot Isl + \alpha_7 \cdot Land + \alpha_8 \cdot CACM + \alpha_9 \cdot CARIC + \alpha_{10} \cdot MERC + \alpha_{11} \cdot NAFTA + \alpha_{12} \cdot CAN + \alpha_{13} \cdot UE + \alpha_{14} \cdot \ln Dist_{ij} + \alpha_{15} \cdot Lang_{ij} + \alpha_{16} \cdot TAI_i + \alpha_{17} \cdot TAI_j + \alpha_{18} \cdot Inf_i + \alpha_{19} \cdot Inf_j + u_{ij}$$

to the Caribbean Community; MERC is a dummy that takes a value of 1 when both countries belong to Mercosur; NAFTA takes a value of 1 when countries are members of the North American Free Trade Area; CAN is a dummy representing Andean Nations Community members; and UE takes a value of 1 when countries are members of the European Union. Since direct measures of trade costs are unavailable, geographical distance between countries is often used as a proxy for transport costs in gravity equations, so $Dist_{ij}$ is the geographical great circle distance in kilometres between the capitals of country i and j . $Lang_{ij}$ is a dummy for countries sharing the same language, and TAI_i and TAI_j are technological variables measuring technological innovation in the exporter and the importer countries. Inf_i and Inf_j are infrastructure variables measuring the level of transport infrastructures in the exporter and the importer countries. Finally, u_{ij} is independently and identically distributed among countries.

Table 3 shows the results for the baseline model and the contribution of the dimensions considered in the TAI (creation of technology, diffusion of recent innovations, diffusion of old innovations, and human skills) to trade flows. Model 1 presents the OLS results, excluding technological and transport infrastructure variables. The coefficients on income are both positive, as expected, and the income elasticities are below one for the exporter and the importer. The coefficients on population are positive and significant – a higher market fosters trade, thus indicating the presence of economies of scale. However, since countries with different levels of development are included, the sample should be divided according to the

specialisation patterns in order to analyse the effect of demographic variables on trade². Developed countries can be considered as manufacturing exporters and developing countries can be seen as non-manufacturing exporters. The elasticity of demographic variables might have a different sign and dimension across the two groups of countries (Filippini and Molini, 2003). The coefficient of distance has a negative sign, as expected, because lower distances imply lower transport costs and a higher amount of goods traded.

Models 2, 3, 4, and 5 consider the gravity model augmented with technological variables: creation of technology, diffusion of recent innovations, diffusion of old innovations, and human skills. These variables are significant and have the expected sign, although some differences in the magnitudes of the coefficients and in the significance of variables can be observed, depending on the dimension included in the gravity equation. For example, adjacency is not significant when human skills are considered and some coefficients and signs on integration dummies are also different. Moreover, income coefficients are lower when technological diffusion or human skills are added than when the creation of technology index is added. The reason could be that the two former variables are capturing part of the positive effect of income on trade. Results show a higher explanatory power when including technological variables for exporter countries than when including them for importer countries. Then a higher technological innovation in the exporter country leads to greater exports. When the diffusion of old innovations index is included as a proxy for technological innovation, a higher variability of the bilateral export flows is experienced.

Notes: ***, **, *, indicate significance at 1%, 5%, and 10%, respectively. T-statistics are in brackets. The dependent variable is the natural logarithm of exports in value (current U.S. dollars). Income, population, and distance are also in natural logarithms. The estimation uses White's heteroscedasticity-consistent standard errors.

Model 1: Baseline model; **Model 2:** Augmented gravity model. Contribution of the creation of technology dimension on trade; **Model 3:** Augmented gravity model. Contribution of the diffusion of recent innovations dimension on trade; **Model 4:** Augmented gravity model. Contribution of the diffusion of old innovations dimension on trade; **Model 5:** Augmented gravity model. Contribution of the human skills dimension on trade.

In the quest of the differential effect of investing on each one of the four dimensions, the variability between the maximum and the minimum values of the indices is analysed. It has been found that the variability in the indices is 61.9% for creation of technology, 79.35% for diffusion of recent innovations, 87.86% for diffusion of old innovations and 89.72% for human skills. Therefore, those countries that do not reach a basic level of technological innovation should invest in old innovations and education for fostering international trade.

Table 4 shows estimation results when the technological variables included are the TAI index (Models 6, 7, and 10) and the ArCo index (Models 8, 9, and 11). Technological variables are found to be significant and positive, as expected. A higher technological innovation endowment fosters international trade, although the magnitude of the estimated coefficient for TAI is higher than the estimated coefficient for ArCo.

In Models 7 and 9, a different way to add technology in the trade equation is considered: the variable included is the technological distance between trading partners (Filippini and Molini, 2003). This is defined as the absolute difference between technological indicators in the exporter and the importer countries. This variable indicates that two countries can be far away from each other not only geographically, but also from a technological perspective. Technological gaps can deter trade since similar countries trade more. Therefore, a negative correlation between this new variable and the export flows is expected. In Models 7 and 9, the TAI and the ArCo indices, respectively, have been used to construct the technological distance variable. Technological distance has been found to be significant in both models and it increases the explanatory power of the regressions. Therefore, results support the view that countries tend to trade more when they are “closer” from a technological point of view.

In order to determine the relative importance of the different variables included in the aug-

mented gravity model, the beta coefficients are calculated (see Table A.2). They are used by some researchers to compare the relative strength of the various predictors within the model. Since the beta coefficients are all measured in standard deviations they are comparable when the explanatory variables are expressed in different units. The estimates of Model 6 imply that the highest beta coefficients are, in absolute value, for technological variables (0.504 for TAI in the exporter and 0.359 for TAI in the importer country). This means that a standard deviation increase in the endowment of technological innovation in the exporter country would lead to a 0.504 standard deviation increase in the logarithm of exports, whereas a standard deviation increase in the endowment of technological innovation in the importer country would enhance a 0.359 standard deviation in the logarithm of exports. Clearly, this indicates that technological variables are important determinants of international trade flows. Beta coefficients for technological innovation are also the highest in Model 7 (0.506 for TAI in the exporter country and 0.357 for TAI in the importer country). However, when beta coefficients for geographical and technological distance are compared, geographical distance appears to be a more important determinant of international trade flows since this variable may be capturing the effects of trade barriers that is different than transport costs such as cultural proximity, a shared history and information costs.

Freund and Weinhold (2004) fail to show evidence of the role played by the Internet in altering the effect of geographical distance in trade patterns. They use a dummy variable (LONGDIST), which equals one if the distance between trade partners exceeds the average distance between all countries. Then, they interact it with the growth in the number of Internet hosts in each country. In the process of comparing the results in this research with those obtained by these authors, the same interaction variable is added in the estimated equation. As in Freund and Weinhold

Notes: ***, **, * indicate significance at 1%, 5%, and 10%, respectively. T-statistics are in brackets. The dependent variable is the natural logarithm of exports in value (current U.S. dollars). Income, population, and distance are also in natural logarithms. The estimation uses White's heteroscedasticity-consistent standard errors.

Model 6: Augmented gravity model (technological innovation measured by TAI); **Model 7:** Augmented gravity model and estimation of the effect of technological distance on trade (technological innovation measured by TAI); **Model 8:** Augmented gravity model (technological innovation measured by ArCo); **Model 9:** Augmented gravity model and estimation of the effect of technological distance on trade (technological innovation measured by ArCo); **Model 10 and Model 11:** Augmented gravity model and estimation of the effect of technological innovation on geographical distance and, therefore, on trade.

(2004), the coefficient of this variable is not significant. It could be that a more general proxy for technological innovation would be better to measure this effect. In Model 10, the technological variable TAI is interacted with the dummy LONGDIST, instead of using Internet hosts, obtaining LONGDIST_i (LONGDIST*TAI_i) and LONGDIST_j (LONGDIST*TAI_j). If technology and the advance of information and knowledge have reduced (increased) the impact of geographical distance on trade, then the coefficient on the interaction term should be positive (negative). However, though these coefficients have been found to be positive but they seem to be non-significant.

Finally, ArCo is used instead of TAI in Model 11 to analyse the effect of the knowledge-based economies on trade (LONGDIST_i and LONGDIST_j are interacted with TAI_i and TAI_j). Since the coefficient of LONGDIST_i and LONGDIST_j are both positive and significant, results in this research offer partial evidence showing that the information and knowledge advances have reduced the effect of geographical distance on trade. This result supports the inference to take into account different dimensions of technology, such as creation and human capabilities, and not only diffusion.

MODEL EXTENSIONS

Sensibility Analysis

To understand whether there exists a differential behaviour concerning the determinants of trade flows for developed (high-income) and developing (low-income) countries, the 62-country sample is divided into three groups according to their level of economic development: countries with high GDP per capita, medium GDP per capita, and low GDP per capita. Countries are ordered from higher to lower income levels, and then an upper level of GDP is composed by calculating

the average of the first half of the sample, and an inferior level is set by calculating the average of the second half (see Martínez-Zarzoso & Márquez-Ramos, 2005).

Table 5 shows the main results of the augmented gravity model for developed and developing countries. Results are only presented for two groups instead of three in a way to have a higher contrast between them³.

Model 12 presents the OLS results for the augmented gravity equation in the richest countries. Results show that income variables, adjacency, island and landlocked dummies, geographical distance, exporter's TAI, and exporter's transport infrastructure are significant. These variables have the expected sign, although island dummy presents a positive coefficient indicating that, when the richest economies are islands, they export more. Demographic variables (population of the countries) are not included since they are highly correlated with income in this group. The language dummy is not significant in this group of countries, proving that to share an official language with other high-income countries is not an important determinant of bilateral exports. However, it is positive signed and significant when trade among medium-income countries is analysed (see Table A.3)⁴. Variables in this model explain 87.8% of the variability in exports.

In Model 13, the augmented gravity model is estimated for low income countries. Exporter's and importer's population, being landlocked, geographical distance, the language dummy, and the exporter's and importer's TAI are significant and have the expected sign. Demographic variables for exporters have a positive relation with trade, indicating that greater availability of cheap labour force for industries in developing countries fosters trade. This model has a lower explanatory power (66.8%) than the model for the richest economies, which could be due, in part, to the data for developed countries' being of higher quality.

In Model 14 and 15, the technological differences variable is included. Results show that,

when trade is among countries with a similar level of development, technological endowments are more important for trade than the technological gap existing among these countries. Integration dummies are considered for the richest and the poorest countries, although they are only significant for the latter group.

In relation to the income coefficients, Garman, Petersen, and Gilliard (1998) analyse economic integration in a number of developing countries and support the notion that the costs and benefits of integration are unevenly distributed among members of an integration agreement in favour of the richest countries. They found that the income coefficients for Latin American countries have a smaller magnitude than those reported in other studies of European trade. Table 5 shows that income coefficients are negative signed and low in magnitude for the poorest economies; however, as income coefficients are not significant for these economies, the obtained results do not show clear evidence about this issue.

Technological and transport infrastructure variables are expected to have a positive influence on trade. Results show that they are non-significant for importers when trade is among high-income countries, and transport infrastructure variables are not significant for low-income economies. One explanation could be the non-arrival at a minimum level of infrastructure in developing countries.

Testing the Pooling Assumption

To improve the understanding of the differential behaviour concerning the determinants of trade flows for developed and developing countries, equation (1) is estimated by interacting the exogenous variables (except integration dummies) with a dummy (DP)⁵ that takes the value of one when trading partners are richer than the simple average in the 62-country sample. DP takes the value zero when trading partners are poorer than the simple average in the sample. In Model 16,

an OLS estimation is performed on the double log specification.

The Wald test is used in order to check whether both the exogenous variable and its interaction with the dummy representing developed countries present a different coefficient. The null hypothesis on equality of the coefficients in the two sub-samples (developed and developing countries) cannot be accepted. Table 6 shows the estimation results.

Model 16 presents the results for low-income and high-income countries, with the inclusion of interaction dummies. Results in this model can be compared to those obtained in Model 9. The results from the Wald test show that the poolability assumption is indeed rejected for bilateral exports and that the estimated parameters are not identical across bilateral relationships. In this research, the DP dummy has also been included as independent variable, to analyse whether the different behaviour of the determinants of trade in groups of countries can be found in the constant term and not only in the slope coefficients. Estimation results show that this dummy is not significant.

The income variable is more relevant for developed countries. A 1% increase in own GDP increases exports from developed countries by 0.52% (0.04+0.48), and by only 0.04% when exports are from developing countries. Very similar coefficients are obtained for foreign GDP. Since the gravity equation is an accepted methodology to analyse the effects of economic integration on trade flows, a lower magnitude obtained in the elasticities of income may indicate that the costs and benefits of integration and globalisation are unevenly distributed among different economies depending on their level of development and it goes in favour of the richest countries (see Garman et al., 1998).

The coefficients for population variables present positive signs, but with a very low magnitude for developed countries and a magnitude close to unity for developing countries. As developing

Notes: ***, **, * indicate significance at 1%, 5%, and 10%, respectively. T-statistics are in brackets. The dependent variable is the natural logarithm of exports in value (current U.S. dollars). Income, population, and distance are also in natural logarithms. The estimation uses White's heteroscedasticity-consistent standard errors. For the richest countries, income and population variables are highly correlated; only income variables are included in the gravity equation for this group of countries.

Model 12: Determinants of trade in developed countries; **Model 13:** Determinants of trade in developing countries; **Model 14:** Determinants of trade in developed countries and estimation of the effect of technological distance on trade (integration dummies are included); **Model 15:** Determinants of trade in developing countries and estimation of the effect of technological distance on trade (integration dummies are included).

countries are more specialised in labour intensive exports, the results indicate that greater availability of cheap labour force in developing countries fosters trade, whereas in developed countries the trend of population growth is stable and almost close to zero (see Filippini and Molini, 2003).

The magnitude of the distance coefficient is lower for developed, -0.72 (-0.97+0.25), than

for developing countries (-0.97). The adjacency dummy coefficient falls 68% (-0.45/0.66) for developed countries, and also the language dummy is reduced 50% (-0.53/1.04) when countries are developed. Therefore, the responsiveness of trade to adjacency falls by about 36% $\{\exp(-0.45)-1\} \times 100\}$ and to language by 41% $\{\exp(-0.53)-1\} \times 100\}$.

Summarizing, results show that trade flows are more sensitive to geographical and cultural variables (adjacency, geographical distance, and language) for developing than for developed economies. Since developing countries face higher transport costs, higher institutional and informal barriers, and more limited access to market information they tend to trade more with neighbouring countries. The result that language links have an impact on international trade has also been found by other authors, such as Guo (2004) who shows that language influences on trade are more significant in China (a developing country) than in the U.S. (a developed country).

The estimated coefficients for technological innovation and transport infrastructure variables are significant and higher in magnitude for developing countries. Moreover, results show that trade flows are more sensitive to technological distance in developing than in developed economies and suggest that technological innovation investments are a good economic policy for developing economies.

FUTURE TRENDS

Future developments for this research are related to the variables included in the model and to the improvement of the estimation methodology.

Concerning the first issue, distance between country capital cities has been used in this chapter as a proxy for transport costs, assuming that $t_{ij} = t_{ji}$. Better transport costs measures could be investigated and included in gravity models instead of distances. Since transport costs tend to be fixed according to the supply and demand conditions applying in the market, the endogeneity of the transport cost variable in the gravity equation could also be investigated.

Concerning the second issue, a further extension of the current research could be not to impose *a priori* by dividing countries into developed and developing economies, but to estimate both the number of “regimes” and their positioning.

Finally, the sample could be extended to more countries and years and a panel data analysis could be undertaken, in order to investigate whether trade is beneficial for all countries in a dynamic environment. Nowadays, information flows, new technologies, regionalisation and globalisation are strengthening the interconnection and dependence among all countries.

CONCLUSION

The recent changes attended in international trade patterns and the growing interest in technological innovation claim for a better understanding of the relationship between both variables.

In this chapter, a gravity equation augmented with technological innovation and transport infrastructure variables is estimated in order to analyse their impact on trade. Geographical (distance, adjacency, being an island, and being landlocked) and social variables (integration agreements among countries and sharing a language) are also considered.

When the 62-country sample is considered, variables included have the expected sign and are significant, excluding some integration variables. Distance has a considerably low explanatory power on trade compared with transport infrastructure and technological innovation. Importers' technology has a lower effect on trade than exporters' technology and a higher technology endowment in the exporter country leads to greater exports. Moreover, results support the hypothesis that countries tend to trade more when they are “closer” from a technological point of view.

In a further step, it is analysed whether technology has any effect on geographical distance in a more globalised and integrated world. The results partially support that the development of technological innovation has lowered the effect of distance on trade, since its development means that long distances are less important nowadays than in the past.

To infer whether there is a differential behavior among countries, the components of the 62-country sample are divided according to their level of economic development. For the high-income countries, the model has a higher explanatory power than for the low-income countries. Geographical factors are always relevant, but geographical distance and being landlocked have higher elasticities for poorer countries than for richer ones. Technological and social factors also seem to be more important for developing economies. Furthermore, technological endowment in each group of countries seems to be more important for trade flows than technological differences among the countries in the same group.

Finally, the pooling assumption has been tested. This chapter shows that the coefficients of the explanatory variables are not the same for all the trading patterns and that the magnitude and sign of the explanatory variables depend on certain characteristics of the trading partners.

A common result is obtained in all regressions. Technological innovation and transport infrastructure can be considered as barriers to trade for those countries with lower endowment levels; thus, investing in these variables could foster international trade and increase the participation of developing economies in a more globalised and integrated world. Results obtained in this chapter advise authorities of developing economies to promote investments in traditional information technologies and human capital, since these variables are a good starting point to improve technological innovation and international competitiveness.

Australia, 7 routers in Asia, 25 in Europe and fifty in North America. A lower number of routers has an adverse effect on Internet data flows.

² This is carried out in the next section.

³ Results for medium GDP per capita countries are presented in the Table A.3 (Appendix).
⁴ Two trading countries that speak a same language trade a 197% [$\exp(1.09)-1$]*100 more than the rest of country pairs in this group of countries.

⁵ **Developed countries:** Belgium-Luxembourg, United States, Norway, Iceland, Switzerland, Canada, Ireland, Denmark, Austria, Japan, Australia, Netherlands, Germany, Finland, France, Sweden, Italy, United Kingdom, Hong Kong, Singapore, Cyprus, Israel, Spain, Portugal, Republic of Korea, Greece, Czech Republic, Argentina, and Slovak Republic.

Developing countries: South Africa, Uruguay, Costa Rica, Chile, Poland, Mexico, Trinidad and Tobago, Croatia, Brazil, Turkey, Panama, Colombia, Dominican Republic, Bulgaria, Algeria, Peru, Syrian Arab Republic, Paraguay, El Salvador, China, Jamaica, Egypt, Honduras, Nicaragua, India, Ghana, Pakistan, Sudan, Senegal, Nepal, Kenya, Mozambique, and Tanzania.

ENDNOTES

¹ In 2004, this measure only considers three routers in South America. However, 4 routers measure ITR in Australia, there are 13 routers in Asia, 22 in Europe and 58 in North America. In 2006, the ITR considers 6 routers in South America, 7 routers in

APPENDIX

Data, Sources, and Variables

Table A.1 shows a summary of the data used in the analysis. With respect to technological and infrastructure variables, some additional explanations are needed. Values for TAI have been calculated using the same criteria followed by the United Nations Development Program. The classification obtained is slightly different from the Human Development Report classification for 2001 because the arithmetic averages are calculated for Organisation for Economic Cooperation and Development (OECD) member country indicators and then they are used to fill the gaps of missing data for some OECD countries, thus increasing the sample size. Results are able to be summarised in a ranking (see UNDP, 2001; also see Martínez-Zarzoso & Márquez-Ramos, 2005).

Transport infrastructure variables are calculated with data on kilometres of paved roads and kilometres of motorways per square kilometre, taking into account the quality of the roads. Equation (A.1) is used to calculate the index.

$$\text{Infrastructure variable} = \frac{((0.75 \cdot \text{paved roads (km)}) + \text{motorways (km)})}{\text{Land area (km}^2\text{)}} \quad (\text{A.1})$$

The dependent variable is the natural logarithm of exports in value (current U.S. dollars). Income, population, and distance are also in natural logarithms. The estimation uses White's heteroscedasticity-consistent standard errors. For the medium income countries, income and population variables are highly correlated; only income variables are included in the gravity equation for this group of countries.

Figure A.1. Selected countries

Table A.1. Variable descriptions and sources of data

Variable	Description	Source
X_{ij} : Exports from i to j	Nominal value of bilateral exports	Statistics Canada (2001)
Y_i : Exporter's income	Exporter's GDP, PPP (current international \$)	World Bank (2001)
Y_j : Importer's income	Importer's GDP, PPP (current international \$)	World Bank (2001)
P_i : Exporter's population	Total population in the exporter's market	World Bank (2001)
P_j : Importer's population	Total population in the importer's market	World Bank (2001)
Adj_{ij} : Adjacency dummy	Dummy variable = 1 if the trading partners share a border, 0 otherwise	CIA (2003)
Isl : Island dummy	Dummy variable = 1 if the country is an island, 0 otherwise	CIA (2003)
$Land$: Landlocked dummy	Dummy variable = 1 if the country is landlocked, 0 otherwise	CIA (2003)
CACM dummy	Dummy variable = 1 if the trading partners are members of CACM, 0 otherwise	
CARICOM dummy	Dummy variable = 1 if the trading partners are members of CARICOM, 0 otherwise	
MERCOSUR dummy	Dummy variable = 1 if the trading partners are members of MERCOSUR, 0 otherwise	
NAFTA dummy	Dummy variable = 1 if the trading partners are members of NAFTA, 0 otherwise	
CAN dummy	Dummy variable = 1 if the trading partners are members of CAN, 0 otherwise	
UE dummy	Dummy variable = 1 if the trading partners are members of European Union, 0 otherwise	
$Dist_{ij}$: Distance	Great circle distances between country capitals of trading partners (km)	Great circle distances between cities (2003)
$Lang_{ij}$: Language dummy	Dummy variable = 1 if the trading partners share the same official language, 0 otherwise.	CIA (2003)
TAI_i : Exporter's TAI	Technological variable	UNDP (2001), author's calculations
TAI_j : Importer's TAI	Technological variable	UNDP (2001), author's calculations
$ArCo_i$: Exporter's ArCo	Technological variable	Archibugi and Coco (2004)
$ArCo_j$: Importer's ArCo	Technological variable	Archibugi and Coco (2004)
Inf_i : Exporter's infrastructure	Transport infrastructure variable	CIA (2003), authors' calculations
Inf_j : Importer's infrastructure	Transport infrastructure variable	CIA (2003), authors' calculations

Note 1: The first column lists the variables used for empirical analysis, the second column outlines a description of the variables, and the third column shows the data sources.

ABSTRACT

Many authors argue that information and communications technology (ICT) in this New Economy is causing a globalized, unified society. Others take the opposite stand, viewing local factors such as national culture as very important to the success of information technology (IT). Research indicates that related factors such as gender may also play important roles in the use and accep-

tance of IT. This paper uniquely examines these perspectives by using electronic commerce as the common technology. Business students from the U.S., Greece and England expressed opinions on the important issues of national control, privacy cost, property rights and consumer preferences. The authors find evidence that concludes that there are statistically significant differences in attitude about e-commerce among cultural groups, but not with gender.

INTRODUCTION

In this age of information, researchers postulate that information technology (IT) is providing a new medium to finally unite society. According to the futurist Francis Fukuyama (1992), the end of the Cold War signals a shift towards a “normative integration of principles and institutions”. Todd (1986) states that technology provides ever-narrowing approaches to social problems, and these approaches are reducing social options. He notes that an “unnatural” selection process caused by technology results in a loss of diversity in human society. Volti (1992) discusses a “convergence theory” where opportunities and demands presented by modern technology promote the convergence of all societies towards a single set of social patterns and individual behaviors, due in part to the requirements of technology for a common set of development and implementation steps, and for common organization constraints. Rosabeth Moss Kanter (1995), in her classic *World Class*, predicts that internationalism will prevail over “nativism”. That is, for future corporate profitability, the boundaries of national identity must be subsumed to the need for quality products and global goodwill.

Greider (1997) writes of *One World, Ready or Not*, with mobile phones as the “universal artifact of the revolution”. He predicts that there will be four major competitive factors: labor, national governments, multinational corporations and financial investors. Hope and Hope (1997) discuss the “third wave” leading to more homogeneous global marketing patterns. Cairncross (1997) observes that time zones and language groups will soon define distance, rather than mileage. She further notes that the credit card is the certain symbol of a unified world currency. Kevin Kelly (1998), editor of *Wired* magazine, in his *New Rules for the New Economy*, writes that technology has “been able to infiltrate into our lives to the degree it has become more like us...Technology has become our culture” (p. 33).

On the other hand, however, some argue that a globalization of society has not, and perhaps will not occur. Ferkiss, in *Technological Man* (1969), claims that the existence of technology change presupposes cultural acceptance, and that a single culture, “embracing both the famine-stricken world and the well-fed nations is obviously impossible...cultural variation is likely to be the rule” (p. 171). Volti (1992) observes that technologies developed and implemented in one culture or society may fail when taken to a different setting. Nelson and Clark (1994) note that European firms commonly develop differing computer systems for different nations. Hamel and Prahalad (1994), in their classic *Competing for the Future*, warn firms to address and work with global differences; that global markets emerge at differing speeds; and that global differences will continue to be a challenge. Doremus et al. (1998) note that corporate governance is closely linked to national culture, and boldly claim that the global corporation is a myth. Fine (1998) cautions managers to be more sensitive to the effects of national business mores, values, standards, laws and cultures. Bowers (2000) claims that the most dominant characteristic of computers is their culturally mediating and transforming effect, but that computers are viewed as a destructive form of Western colonization. “Members of other cultures are aware that when they use computers, they must adapt themselves to radically different patterns of thought and deep culturally-bound ways of knowing” (p. 22).

Castells (2001) observes that “core economic, social, political and cultural activities throughout the planet are being structured by and around the Internet...(yet) its logic, its landscape and its constraints are not well understood beyond the realm of strictly technological matters” (p.3). He further writes of a large digital divide within a globalized Internet between developed and developing nations; and of a resulting number of challenges, including ownership and control of data, and the exclusion of groups by virtue of edu-

cation, technology, and national culture. Albrow (2000) discusses several facets of globalization, including values related to daily behavior of many groups (also called “globalism”), universally available information and commodities (“globality”), communications technologies used to maintain relationships (“time-space compression”), and worldwide institutional arrangements permitting personal mobility and local lifestyles (“disembedding”) (p. 199). This research was concerned with personal values, information and technologies, using globalization under those contexts.

The late Michael Dertouzos (1997) predicted that the “homogenizing forces” of information technologies can “only go so far, because of the overwhelming power of ethnicity... Most likely, the Information Marketplace will superimpose a cultural veneer of shared experiences on top of the individual cultures of the world” (p. 283). Berger and Huntington (2002) write about differing and separate globalization processes. “The emerging global culture is defined through both elite and popular vehicles,” including a business-oriented “Davos culture” and an academic-oriented “faculty club culture”.

Further, globalization encompasses ideologies other than culture, such as environmentalism and feminism. The International Telecommunications Union (ITU) identified gender differences as important to global technology policies. In a recent paper, they observe that technology is not gender neutral, and that there is a statistically significant correlation between the gender of Web users and the global UN Development Program (UNDP) Technology Achievement Index (Hafkin, 2003). Several Internet statistical monitors also claim that the number of female Internet users in the U.S. now equal males.

Thus there are conflicting theories about globalization, with issues often embracing a broader group of ideologies than national culture. The purpose of this research is to investigate and understand the extent of globalization by studying attitudes about electronic commerce. It will show

whether the world is truly coming together as prophesized by Fukuyama, Volti, Greider, Kelly and others. It will also identify certain global differences about e-commerce, in spite of the common technology. Also, given the recent increases in female Internet users, this research investigates the effects of gender on these attitudes.

LITERATURE REVIEW

E-commerce relies heavily upon information and communications technology (ICT). The Internet, and specifically the World Wide Web, is being used by businesses worldwide to manage day-to-day transactions and as an integral part of their marketing strategy. E-commerce, as a global transaction system, must fall under the same multi-cultural scrutiny and research as previous ICT projects. The success of e-commerce across national borders is a function of several variables, including the national economy, national literacy, national culture, telecommunications availability, and Internet technology penetration and acceptance (Tillquist, 1997; Pitkow and Kehoe, 1996). Still, little research has been conducted that examines the extent of globalization on Web usage and the associated social implications.

From a comparative analysis of cross-cultural studies, Ein-Dor et al. (1993) observe that economic, demographic and socio-psychological factors affect information systems. They integrate these into a framework of research and write that “perhaps the most important immediate finding to emerge is...that cultural differences have greater impact on the technical and procedural aspects of IS.” Deans and Ricks (1993) provide an agenda for research linking IS and International Business. They write that, from an IB perspective, the role of IS “may be viewed as a facilitator of information flows across national borders”, and that IB offers “theoretical underpinnings that may be relevant for international IS research.”

National Culture

Straub (1994) studies the globalization of IT using email and fax in the U.S. and Japan. He concludes that while U.S. companies exploit the advantages of IT, the Japanese do not, and that a strong sense of uncertainty avoidance and the use of complex language symbols make the fax a more useful tool in the Japanese culture. Straub et al. (1997) test the Technology Acceptance Model (TAM) on email use with airline employees in Japan, Switzerland and the US. They find that the cultural works of Geert Hofstede (1983, 1997) are not strong predictors of technology use across all cultures. They write that cultural differences alone may not explain differing results. In Japan cultural tendencies towards uncertainty avoidance (UAI), greater power distance (PDI) and collectivist sentiments may limit email use and disassociate the TAM concept of perceived usefulness (PU) from actual technology use. Hasan and Ditsa (1999) interviewed managers in Australia, West Africa and the Middle East to study the impact of culture on the global adoption of IT. They question the belief that technology is culturally neutral, and also use Hofstede (1997) to explain differences in attitudes. They confirm that many aspects of IT are not culturally neutral and conclude that IT products should “accommodate the cultural, economic, social and other characteristics of a particular group.” Markus and Soh (2002), in studying the structural influences on global e-commerce activity, find that cultural differences alone do not provide a satisfactory explanation. Research by McLeod et al. (1997), Rose and Straub (1998), Dasgupta et al. (1999), Al-Khaldi and Wallace (1999), Cheung and Lee (2001) and Carayannis and Sagi (2001) also find differences across the nations in IT use and attitudes.

Gender

Several of the aforementioned studies note that cultural differences do not provide sufficient

explanation for differences in attitudes and use of IT. One of these other factors is gender. Harris and Davison (1999) research global anxiety and technology involvement, and their influence upon attitudes towards computers in developing societies. Using computer students in China, Hong Kong, Malaysia, New Zealand, Tanzania and Thailand, they find that many differences are attributable to gender and computer experience. Hoxmeier et al. (2000) study the impact of culture, gender and other variables on user confidence in email. They report gender differences that “appear to diminish through technical education and experience.” In a study of national level culture and global Internet diffusion, Maitland and Bauer (2001) write that economic factors were strong predictors of IT adoption, that cultural variables are slightly less powerful predictors and that gender plays a significant role. Simon (2001) studies Web site perceptions, and finds that there are both cultural and gender factors involved. Zhang et al. (2002) study the characteristics of Internet users and privacy concerns, surveying U.S. undergraduate students and Chinese graduate students, university professors and managerial professionals. They observe that female respondents are “more concerned with the Internal Unauthorized Use of personal information and the possible misuse of credit card information than male respondents.”

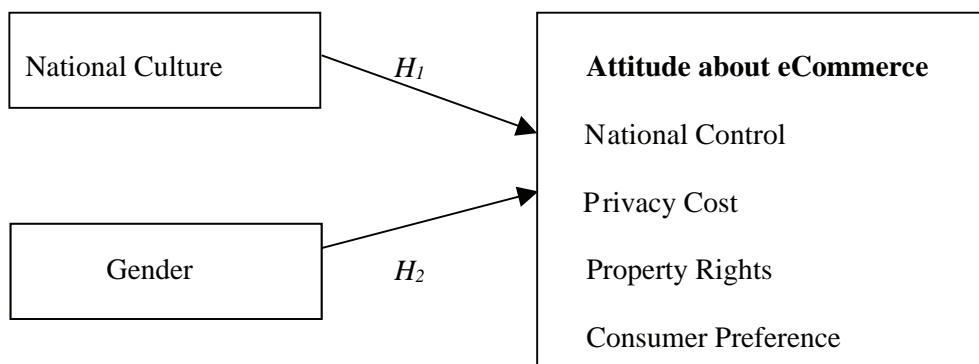

RESEARCH MODEL AND HYPOTHESES

From the literature it is clear that there are aspects of e-commerce which can be explored to understand globalization. Straub et al. (1994, 1997), Hasan and Ditsa (1999), Markus & Soh (2002) and others find cultural differences in IT use. Harris and Davison (1999), Hoxmeier et al. (2000), Maitland & Bauer (2001), Simon (2001) and Zhang et al. (2002) also report gender differences in cross-cultural studies. Thus, this study chose cultural groups and gender, and their influence

Figure 1. Research model

upon attitudes about a globalized e-commerce, with the following research questions:

1. What aspects of e-commerce may be influenced by national culture?
2. What aspects of e-commerce may be influenced by gender?

The independent variables were national culture and gender, while the dependent variables were attitudes about e-commerce. These are shown in Figure 1.

To test the extent of globalization based upon differences in attitude among the independent variables of culture and gender, given the previously discussed research, several hypotheses were created. These hypotheses were developed from

issues about electronic commerce described in Turban et al. (2000). These issues include national control of data across borders, the individual cost of privacy, property rights and consumer preferences.

RESEARCH METHODOLOGY

Instrument Creation, Validity and Reliability

This research developed an instrument that measured the attitudes about e-commerce. Students were chosen as a convenience sample, and they provide a uniform group of educated samples, with common technology access and education representing the future leadership in technology

(Harris and Davison, 1999). Zmud and Boynton (1991) state that Likert-scale self-reporting questionnaires are very important to information systems research. The design of this research was a cross-sectional study to probe attitudes about major issues of e-commerce. The questions were opinion questions asking the subjects what they think about an event. Opinions are the verbal expressions of attitude (O'Sullivan and Rassel, 1999). This study built upon previously unpublished research conducted in October 2000 at Anne Arundel Community College (AACC), Arnold, Maryland (Sagi, 2000). In that study, business students in an electronic commerce course identified major issues and developed a list of 43 Likert-scale questions related to these issues. The students were directed to develop questions on both the

national and macro-economic levels, as well as including personal issues such as Napster and commercial trust. Demographic and behavioral questions about age, gender, prior Web purchases and number of hours online were added to the instrument. The researchers and several faculty edited the questions for content validity.

Validity was further improved by a literature scan for similar questions, techniques and issues. The research of Doll and Torkzadeh (1988) was helpful in understanding the measurement of end user attitude. The works of Harris and Davison (1999) and Hoxmeier et al. (2000) were used as excellent examples of the cross-cultural survey instrument development and use, and of Analysis of Variance (ANOVA) methodology. The revised questions were then given to a pilot group of busi-

a. Rotation converged in 14 iterations.

b. Only cases for which class = Pilot are used in the analysis phase.

c. class = Pilot

ness students (N=17). Cronbach's alpha was an acceptable .7281 for this pilot group. According to Harris and Davison (1999), who develop a similar instrument, an alpha above .7 is satisfactory. Factor analysis was used to reduce the questions to express one or more concepts. All of the variables (43 questions) were originally considered, and a correlation matrix constructed. Several stronger correlations appeared to express similar attitudes about similar issues. These correlations were rotated using Varimax rotation. According to George and Mallery (1999), the process is highly subjective. The results are shown in Table 2.

Component 1 (Eigenvalue = 21.6) represents two e-commerce issues, national control and privacy. Hofstede's (1983, 1997) research identifies both of these with the index Individualism (IDV). However, these are differing and unique aspects of e-commerce. Thus in this study Component 1 represents two variables, National Control (national control, control) and Privacy Cost (give up privacy, privacy cost). Component 3 (Eigenvalue = 14.6) also contains two questions and represents the construct Property Rights (right to resell, copy ok). Finally, Component 7 (Eigenvalue = 5.8) factors two questions that were chosen to form the construct Consumer Preferences (buy from store, return problems).

It is not unusual in information technology research to rely upon two questions as the basis for operationalizing a research construct. For example, in their seminal work on studying the measurement of end-user computer satisfaction and a model for this current study, Doll and Torkzadeh (1988) rely upon two questions in an 18-item instrument to operationalize one of their major study factors. Lederer et al. (2000) use two questions for the construct Information Focus, and Jiang et al. (2000) have two questions comprising the construct Internet Experience. The results of the factor analysis provided the constructs and their associated instrument questions as shown in Table 3.

Dependent Variables

According to Shields (1996): "The Internet raises challenging policy issues of access, privacy, copyright and regulation. It poses cultural problems as information is made available regardless of social and cultural boundaries" (p. 1). Cairncross (1997) observes that national attitudes "differ enormously, reflecting the extent to which citizens in different countries trust their governments and private industries" (p. 196). She also asserts that the "culture and not just the language of the

Table 3. Research constructs

<p>National Control NC1. The government should control the Web to better protect the consumer from fraud. NC2. A nation should be able to control the Web content that crosses its borders.</p> <p>Privacy Cost PC1. I'll gladly give up some privacy information for cheaper prices on the Web. PC2. Loss of privacy is a cost of new technology benefits.</p> <p>Property Rights PR1. Web sites should have the right to resell <i>any</i> user information that is freely given PR2. It is ok to save a copy of anything on the Web.</p> <p>Consumer Preferences CP1. I surf the Web for product information, but I usually prefer to buy from a store. CP2. Returning a purchase is still a problem on the Web.</p>

Internet is also strikingly American. Its quirky blend of technocratic individualism, egalitarianism and passionate resistance to government control all seem to many foreigners quintessentially American” (p. 95). For example, the U.S. government provides a *Framework for Global Electronic Commerce* which says that the private sector should lead and governments should avoid “undue restrictions.”

National Control and Privacy Cost

Hofstede (1997) sees national control of data and the concept of personal privacy as culturally similar under a national index “Individualism” (IDV). He postulates that IDV influences control and the acceptance of government influence, and has an impact upon attitudes about privacy and individual rights. Tavani and Moor (2001), however, distinguish between these concepts. They define privacy in terms of protection from intrusion and information gathering, and control in terms of framing policies that provide privacy protection. They postulate that privacy is best defined in terms of restricted access, and is fundamentally about protection from intrusion and information gathering by others. Control, on the other hand, plays a critical role in the management of privacy and should be understood under that framework. They observe that “virtually all societies establish normative private situations...the details of these... vary somewhat from culture to culture.” Further, they recommend that e-commerce should be designated as an international “zone of privacy”, as per the intent of the European Union’s directive on privacy discussed previously. Thus this study separates these concepts.

Rose (2001) writes that the Internet is at a “crossroads” between the ability to collect and relate personal data, and the potential for misuse. Citing research, he also notes a common hesitancy for consumers to provide personal data, the common practice of providing erroneous data and marketing’s increasing desire to utilize

the potential for data analysis provided by new technology. He notes several common definitions of privacy: “The right to be left alone”, “the right to control...”, “the degree of access others have to us”, “freedom from the judgment of others”, and “a means for creating social context in relationships with others”. Rose concludes that consumer confidence must be established and maintained to get any value from the data obtained and manipulated by technology. National government may play a role in this.

Etzioni (1999) identifies a “privacy paradox”. He observes that privacy is often preferred, in the US, over the common good, and national government is often perceived or characterized as the victimizer. Yet, according to Etzioni, the threats to privacy are more often from the commercial private sector. “When privacy is threatened by the private sector in our culture, policies and doctrines provide a surprisingly weak defense” (p. 10). The solution, he offers, is a greater focus on the corresponding social responsibility and commitment to the common good that was, according to Etzioni, lost after 1965.

Kizza (1998) writes, “Individuals are forced to give up some of their rights in order to protect individual privacy”. He discusses the problems with the private sector, and with data collection; similar to the issues raised by Etzioni (1999). According to Kizza, nations enact laws to protect from the loss of privacy, and that the Internet has heightened the awareness of the potential privacy loss due to technology. He notes that privacy can be protected by information control, property control and the use of anonymity of addresses in Internet communications.

Ferkiss (1969), in his early work defining the *Technological Man*, observes that privacy will present a future problem, based upon both the potential for a large increase in population and the possibility for absolute surveillance. “Spheres of privacy” may be defined, but the threat of absolute surveillance may be prohibitably costly when compared with the benefits. Volti (1992) writes

that technology often leads to a “restructuring of power relations, the redistribution of wealth and income, and an alteration of human relationships” (p. 18). Kelly (1998) notes that society clearly has a need for anonymity and privacy in communications. He then offers some direction in his seminal *New Rules for the New Economy*: “One of the chief chores in the network economy is to restore the symmetry of knowledge.” He discusses this idea by formulating privacy as a type of conversation between two trusted parties. “Firms should view privacy not as some inconvenient obsession of customers... but more as a way to cultivate a genuine relationship” (p. 134). However, questions remain over the role of governments in the national control of data and the price users are willing to pay.

Property Rights

The right of a website to sell information and of a user to freely copy data from the web are prominent issues in e-commerce and the topic of national legislation. Recent intellectual property rights (IPR) law applying to e-commerce includes the international *Trade-Related Aspects of Intellectual Property* (TRIPS) agreement, ratified in 1994 by over one hundred nations. TRIPS provides international IP standards, and specifically provides copyright protection for computer programs as intellectual creations. The US *Anticyber-squatting Consumer Reform Act* (ACRA) of 1999 makes it illegal for a person to “register, traffic in, or use” domain names under certain conditions of “bad faith intent”. The *Digital Millennium Copyright Act* (DMCA) of 1998 restricts the circumvention of encryption software and absolves the Internet Service Provider (ISP) of liability for certain copyright infringement violations by its users. Disputes are resolved by the *Uniform Dispute Resolution Policy* (UDRP) of the *Internet Corporation for Assigned Names and Numbers* (ICANN) and the United Nations’ *World Intellectual Property Organization Arbitration and Mediation Center* (WIPO).

Consumer Preferences

The propensity to prefer the store as the purchase location instead of the Internet and the expectation that those Internet purchases are subject to issues with returns are also common issues in e-commerce. Cairncross (1997) addresses the drivers of the Internet and the resulting new business models, and elaborates about the increased confidence required for consumers to embrace this technology. “The overall low percentage (of Internet sales to total commerce) suggests that the vast majority of customers are perfectly happy to buy at real-world stores” (p. 130). Trust and confidence with this new technology may be factors, as well as differences in consumer location and in buying habits among nations. Rural consumers or consumers in nations where face-to-face agreements are considered important, such as the Middle East, may cause consumers to prefer stores over the Internet. Further, rural customers may not be able to return items purchases on the Web to a store as easily as the urban customer. The impact of culture and other sociologic factors on these consumer attitudes is not understood.

Population Sampling

The respondents were 195 business students at colleges in the U.S., Greece and England. Business students were particularly good subjects because of their homogeneity of education, familiarity with the Internet and e-commerce topics, their availability for study, and their potential for future leadership in the Internet and e-commerce. Students were used as subjects in many similar studies referenced in this paper, including Stylianou et al. (2003), Simon (2001), Jiang et al. (2000), Hoxmeier et al. (2000) and Harris and Davison (1999). The institutions were chosen based upon previous relationships between the researchers and the schools, and compare as shown in Table 4.

Table 4. School profiles

School	Anne Arundel Community College (AACC)	Athens Laboratory of Business Administration (ALBA)	Southwark College
Location	Arnold, Maryland, USA	Athens, Greece	London, England
Class	Undergraduate	Graduate	Undergraduate
Business Enrollment	1000	200	500

AACC serves the Maryland county of Anne Arundel, on the western shore of the Chesapeake Bay. Total enrollment exceeds 13,000 students, with over 7,000 full time equivalent students (FTE). The School of Business, Computing and Technical Studies prepares students to enter the job market with expert skills and training. Hands-on courses provide experience and realistic simulations of the work environment. Transfer options prepare students for entry into four-year institutions. AACC offers Associate degrees in Business, Accounting, and Law, among others. Business students have access to over 160 PCs in eight classroom-laboratories. PC instruction is mandatory for all students.

ALBA was founded in 1992, through a joint initiative of the Federation of Greek Industries, the leading Employers' Union in Greece, and the Hellenic Management Association. ALBA was originally funded by the European Commission and local Athens contributions. ALBA offers MBA and law degrees. The computer network consists of approximately 100 PCs configured with the latest software versions. More than half of the PCs are available to the students at study rooms, the Computer Laboratory and the Library, as well as in the classrooms and amphitheatres, to be used during lectures and case study/projects presentations. Students have free 24-hour access to the Internet. ALBA is located in the suburb of Vouliagmeni, about 25 kilometers southeast from the center of Athens.

Southwark College is in a suburb on the South Bank of the Thames, opposite London. Southwark is a working-class neighborhood. The college's 3,000 FTE and 7,000 part-time students use the college's three campuses, all within the immediate area of the South Bank. Southwark maintains close relations with and often serves as a feeder school for several nearby universities, including the University of London. Students have access to a large research facility containing about 100 new Internet-able PCs and current software. There are also several computer technology labs. Most students have PCs at home and rely on the school facilities primarily for class-related activities. The descriptives for the samples are shown in Table 5.

Analysis

Multivariate Analysis of Variance (MANOVA) was used to test the hypotheses since there was more than one dependent variable (survey questions) under study. MANOVA tests are interpreted by examining the significance level of the F-ratio, which is the comparison of the "Between-groups Means Square" and the "Within-groups Mean Square". As the means of the treatment groups (cultural groups and gender) become similar, the F-ratio approaches 1. The significance is based upon the distribution and the degrees of freedom. Significance is interpreted as the chance of making a Type I error. For this research, the acceptable

significance for assuming a difference in treatment groups was $< .05$.

RESULTS

Note from Table 6 that the significance .012 was $< .05$ for hypothesis H1. The null hypothesis, that the means of the treatment groups are similar, could be rejected, and the hypothesis that there are culture differences in attitude could be supported. However the significance .102 of H2 led to the conclusion that there were no statistically significant differences in gender attitude.

From Table 7 it was noteworthy that national culture was not an influence on the constructs of Privacy Cost and Consumer Preferences. ANOVA generates a significance value indicating whether there are differences among the treatments. This does not indicate, however, what the differences are when the number of treatment groups exceeds 2. To identify the differing treatments in this situation, this research uses Scheffe's Bivariate

Comparison test. There were differences among cultural groups in several constructs. UK ($\mu=4.04$) and GR ($\mu=3.88$) students were more likely to agree with National Control of the Web than their US ($\mu=3.15$) counterparts.

All respondents in this study generally disagreed with giving up privacy as a cost of technology ($\mu=2.31$). Both US ($\mu=1.99$) and GR ($\mu=1.88$) students disagreed with the idea that Web sites should have the right to resell any user information. UK ($\mu=2.58$) students, on the other hand, also disagreed but were less sure about that construct. Cultural groups generally concurred with the construct of Consumer Preferences ($\mu=3.92$), preferring to buy from a store and expecting problems with their purchases.

From Table 8, the general agreement between genders is interesting. Genders were close to disagreement about Privacy Cost (sig. = .052) as females ($\mu=2.11$) tended to disagree more than males about giving up privacy as a cost of technology.

Table 6. MANOVA analysis

Test: If the F ratio > 1 and its significance level at the degrees of freedom for the two mean squares is < .05, the null hypothesis, that the means are the same, can be rejected.

H1D: Consumer Preferences	1.441 .	239		Not Supported.

DISCUSSION

Certainly the world is not in common agreement about e-commerce. Ferkiss, Clark, Hamel, Prahalad, Dertouzos and others expected cultural groups to differ. It is particularly interesting that this research found differences in National Control, given the previously discussed cultural work of Hofstede (1983, 1997), and no differences in

Consumer Preference, given the variety of business models and distribution channels among the nations. Areas of agreement and difference were anticipated by Mittleman (2000), who writes: "...The architecture of globalization is too high to perceive as a whole, but if one moves to a finer scale—more discreet issues - the structures become discernable" (p.13).

On differences in National Control, Castells (2001) discusses Singapore as an example of a government proactive in Internet control. “Attempting to steer a narrow path between (embracing technological modernization and maintaining a sophisticated authoritarian regime), the government of Singapore has tried to expand the use of the Internet among its citizens, while retaining political control over this by censoring Internet service providers” (p.164). Further, the nations of the European Union are developing the “Directive of Distance Selling”, a mandate of standards for Websites to protect the consumer from fraud. Sheff (2002) discusses the emergence of China as an economic power but also as an unpredictable government having the dual role of both expanding the Internet while attempting to regulate and censor it. Zhang et al. (2002) also discuss Chinese research subjects, and report that respondents are more likely to support an increased government involvement for greater privacy protection.

On the common attitudes towards Privacy Cost, this may be important to e-commerce site developers and certainly refutes the common idea that “privacy is dead”. Castells (2001) also writes “Most people waive their rights to privacy in order to be able to use the Internet” (p.174). Clearly any waiving of rights is not done consciously. Zhang et al. (2002) report that among

their Chinese respondents, those with online shopping experience were more likely to trade their personal information for free merchandise and for targeted advertisements. The US and GR strong common disagreement with selling Web information is interesting, and is another message to developers about the nature of e-commerce expected by those nations. That all three cultural groups concurred with Consumer Preferences is also interesting given the diverse business models and different commercial distribution channels present in each nation.

On gender, we hypothesize that the level of education reported by the respondents may be related to this lack of difference. The subjects here were all college students. Other possible factors may include age and technology access, which are areas for further research. Hoxmeier et al. (2000) report that, although gender plays a role in confidence in technology use, the role of gender greatly diminishes with education and with experience. The non-statistically significant differences in attitudes about Privacy Cost are similar to the findings of Zhang et al. (2002). They report that their female respondents were more concerned with unauthorized use of personal information by Web sites than were males. These findings also correlated with recent studies by British Telecom (BT PLC). While over half of

UK males purchase some form of content online, only one fourth of females were willing to pay for content (*Internet Works*, Autumn, 2002, p. 13). Simon (2001) reports that gender may also have different influences in different nations. Stewart et al. (2001) find gender differences in the use of Internet communications. Further, Htun (2000) observes that, while culture is an essential concept, it does not alone explain gender issues.

Limitations

Markus and Soh (2002) discuss structural influences on global e-commerce, including financial (electronic payment systems, credit financing), legal and regulatory (consumer protection, taxes), national policies about promoting or regulating the Internet usage and e-commerce, space and logistics (home size, distance to shopping, transportation, warehousing), telecommunications, IT penetration and use, local business practices (purchasing, payment, financing), language, education, firm size, structure, and control systems, and industry concentration. Markus and Soh conclude that structural conditions may vary widely across countries, and are not fully captured in measures of national culture. This research attempted to control as many of these as possible. The subjects were students with similar interests (business), technology access (via school computers) and language (instruction in English). Many of the structural influences were reasonably not applicable to the subjects. Others may result from culture and physical resources, such as national policies, legal and regulatory infrastructures, and local business practices.

From Table 5 it is clear that gender ratios and the self-reported online hours are reasonably similar across cultural groups. Several other factors may arguably have presented a bias and a limitation to this research. Subject age is not commonly considered in IT research. Harris and Davison (1999) report that age is not a factor in PC anxiety. Education is commonly reported in

research but level differences are not often noted. Harris and Davison (1999) also use both graduate and undergraduate students in their study. Zhang et al. (2002) find that education level is not an issue in attitudes about online privacy. The use of student subjects is criticized for its limited generalizability to the population. However, students are often used (Zhang et al., 2002; Simon, 2001; Hoxmeier, 2000; Jiang, 2000) in IT research. The use of students is supported by their potential as managers and are often more strongly associated with technology utilization. However, the results obtained from such a study of students should be generalized with caution. The difference in sample size may be a limitation in the findings. Harris and Davison (1999) also have similar differences among the six cultural groups in their study. Pelto and Pelto (1981) note that differences may be more difficult to identify with smaller sample sizes. The assumptions for ANOVA do not include equality of sample sizes, but that the samples are independently drawn and selected with some degree of randomness.

It is certainly possible that one group is more culturally homogenous than another. Many researchers who use cultural groups to study technology rely upon national borders to determine those groups (Stylianou et al., 2003; Zhang et al., 2002; Jiang et al. 2000; Hasan and Ditsa, 1999; Harris and Davison, 1999; Straub, 1994). Straub et al. (2001) tested the survey responses against home of birth and report no correlation. That is, while respondents may report other nations as home of birth, their attitudes towards technology are more similar to those in their residence nation than those within their home nation. Harrison and Huntington (2000) discuss this rather pointedly and write that: "The diversity – the vast number of subcultures – is undeniable. But there is a foundation of shared values, attitudes and institutions that binds together the nations... analogous to that of Great Britain ... no one would question the existence of a British culture" (p.67). Finally, the instrument was developed within one culture

and administered to two others. There may be an inherent bias in the wording or interpretation of the questions that was unforeseen and that influenced the responses. However, that the topic was mostly technology use and the shared language English, this bias is not expected to be influential. While noting differences in age and education level, and the possibility of bias from national cultural heterogeneity and from the instrument, these are not considered major limitations to the findings of this study.

Recommendations for Research and Business

It is recommended that future researchers expand this study to other cultural groups to better identify cultural traits corresponding to the use of e-commerce. Researchers should study other populations and subjects with this research model, such as managers and technology workers. Other factors such as the national infrastructure conditions, electronic payment systems, consumer protection, home sizes, distance to stores and information technology penetration should be

investigated. Researchers may test the influence of gender on the attitudes expressed by cultural groups, age groups and those with differing technology access. Although this research attempted to provide a common sample, the results may have been influenced by factors such as local business customs, personal income and credit card access. Nonetheless, businesses must identify national culture as influential on the acceptance of e-commerce, and know that nations may differ on controls and access to this technology. Businesses must also recognize that consumer attitudes about information technology may differ across nations. Not all cultures may react the same way to the need to develop and control the Internet infrastructure, for example. They must pay particular attention to the influence of culture on attitudes about National Control and Property Rights. That is, businesses must remain aware that nationalities may expect governments to control various aspects of e-commerce and the Internet, that ideas about data and software ownership may be different; and that the citizens of other nations may differ on opinions about wholesale Web access and control of facets of the Internet structure such as domain naming.

Table 9. Culture group reactions

Culture Reactions	Research Constructs	F-ratios	Significant Differences
Acceptance.	Consumer Preferences	1.441	None
	Privacy Cost	2.470	
Modification and Rejection.	Property Rights	6.656	UK (2.58) > GR (1.88) UK (2.58) > US (1.99)
	National Control	9.622	UK (4.04) > US (3.15) GR (3.88) > US (3.15)

CONCLUSION

This study found that globalization and common technology have not resulted in common attitudes about e-commerce. It also uniquely revealed several interesting facts about the nature of globalization as perceived by various cultural groups and genders. This study found that culture influenced attitudes about e-commerce yet gender did not. It was clear that cultural groups differed in attitude about National Control and Property Rights. However, and very important, culture played no role in influencing attitudes about Privacy Cost and Consumer Preference. This study found that U.S. e-commerce users were less tolerant of government control of the Web. Gender did not play a statistically significant role in attitudes about e-commerce. It may be that gender differences diminish with education. However, it was noted that females were more concerned about giving up privacy.

One possible explanation of shared attitudes towards aspects of privacy and consumer behavior may be the work of Dertouzos (1997, 2001). He writes of the "Information Marketplace" as exerting a "blending and levelling force on the local and global cultures..." (p.283). He postulates a "thin but universal cultural layer" but casts doubt upon a single universal culture due to local conditions and the "overwhelming power of ethnicity". Similarly, Berger and Huntington (2002) write of cultural "globalization" or synchronomy and of cultural "localization" or autonomy. This study postulates that aspects of privacy and consumer behavior may be early indicators of Dertouzos "veneer" layer, and of the "middle ground of cultural homogeneity" discussed by Berger and Huntington.

Berger and Huntington also postulate several possible consequences for the intersection of globalizing forces and indigenous cultures. These include replacement of the local culture with the new, coexistence of the local and new cultures, synthesis of the new and the local resulting in a

modified local culture, and total rejection of the new. It was interesting to note the correspondence between the work of Berger and Huntington and this research, leading us to uniquely postulate that the constructs of Privacy Cost and Consumerism may be areas of global agreement, while Property Rights and National Control may be areas of local modification across cultures as shown in Table 9.

Chapter 1.22

Collaboration Challenges in Community Telecommunication Networks

Sylvie Albert

Laurentian University, Canada

Rolland LeBrasseur

Laurentian University, Canada

ABSTRACT

This article reviews the literature on networks and, more specifically, on the development of community telecommunication networks. It strives to understand the collaboration needed for innovative projects such as intelligent networks. Guided by a change management framework, collaboration within a community network is explored in terms of the formation and performance phases of its development. The context, content, and process of each phase is analyzed, as well as the interaction of the two phases. User involvement and technology appropriation are discussed. Collaboration challenges are identified and linked to the sustainability of the community network. Policy makers are presented with a model that gives some insight into planning and managing a community network over time.

INTRODUCTION

Collaboration in networks and managing performance across organizations has gained the attention of researchers (Huxham & Vangen, 2000). Our comprehension of collaborative networks² has progressed substantially over a couple of decades (Oliver & Ebers, 1998), but it lacks integration (Ebers, 2002).

Collaborative networks cover a range of purposes such as innovation requiring heavy investment in R&D, international ventures, and the delivery of public services like health and education. This article is focused on telecommunication networks that operate within a physical and shared community space. The more ambitious community networks aim to become “intelligent” communities with broad participation and significant impact on the local social and

economic development. To understand them as a dynamic phenomenon, a framework is needed that can accommodate and organize the conceptual pillars of organizational environment, structure, culture, leadership, and management. Pettigrew (1992, 1987) offers such a framework, and Ebers (2002) and LeBrasseur et al. (2002) demonstrate its effective application.

Organizations in all sectors have become more interested in inter-organizational collaboration to encourage synergy, innovation, and economic development. Although there are many pockets of successful collaborative efforts, there is a continuing need to identify the challenges and opportunities inherent to community networks. With this focus, this article is divided into four main sections. First, collaborative networks are defined and described, and community telecommunication networks and their potential for supporting intelligent communities are analyzed. Second, key collaboration challenges that impact on the development of a community network are introduced. Third, the literature is reviewed and organized according to the context, content, and process involved in these community networks during their two phases of development—formation and performance. The collaboration challenges present in each phase of development are explored, including challenges that the users experience. Fourth, the article concludes with policy implications for network planners.

TELECOMMUNICATION NETWORKS AS AN EXAMPLE OF COLLABORATION

Collaboration is the pooling of resources (e.g., information, money, labour), by two or more stakeholders or partners³, to solve a set of problems, which neither can solve individually (Gray, 1985). It involves an interactive process whereby organizations, using shared rules, norms, and structures, act or decide on issues related to a

problem domain (Wood & Wood, 1991). The intentional goal-oriented collaborative arrangement that emerges is that of a network (Poyhonen & Smedlund, 2004).

Networking represents a particular form of organizing or governing exchange relationships among organizations and is an alternative to markets and hierarchies (Ebers, 2002, p. 23). Network partners maintain their autonomy and retain residual property rights over their resources that have been pooled to achieve mutually agreed outcomes (Bailey & McNally-Koney, 1996; Brown et al., 1998; Gray & Hay, 1986; Huxham & Vangen, 2000; Oliver & Ebers, 1998). The principal coordination mechanisms for allocating resources are negotiation and concurrence. Informal social systems, rather than bureaucratic ones, coordinate complex products or services and reduce uncertainty (Jarillo, 1988; Jones et al., 1997).

Networks have gained in importance over the last two decades. For the private sector, globalization and the speed of change have encouraged collaborative efforts. For government, downloading⁴ since the 1990s has forced new ways to view management of programs and services for resource maximization (Bradford, 2003; Bailey et al., 1996). Municipalities and regions have also demonstrated an increased interest in collaboration efforts and network development to attract new opportunities and maintain their competitive advantage. Collaborative networks typically increase the scale and visibility of program efforts, increase support for projects, and leverage capital to enhance feasibility, speed, and effectiveness (O'Toole, 1997). Synergy is achieved through improved resource management and intensive exchanges on specific projects.

To achieve synergistic gains and programming enhancements from sharing resources, risks, and rewards, stakeholders need to shift their focus toward collaborative rather than competitive advantage (Lowndes & Skelcher, 1998). Too often in the past, public sector organizations built independent silos and their private sector

counterparts viewed potential partners as competitors rather than collaborators. Public policies dealing with ambitious or complex issues, like community sustainability, are likely to require networked structures that allow for the pooling and mobilization of resources from both private and public sectors within a government policy initiative (O'Toole, 1997).

Community telecommunication networks reflect the trend in western society away from bureaucratic government to network governance (Sorensen, 2002): the latter delivers more services efficiently with less risk and uncertainty (Considine & Lewis, 2003; Jones et al., 1997). Stakeholders and collaborators include municipalities, health, education, social services organizations, and private sector organizations. These networks are part of a wider agenda to increase the country's capability for the knowledge-based economy.

There are several kinds of community networks (Gurstein, 2000; Pigg 2001), ranging from those serving a restricted membership (usually called private networks) to those serving a broader segment of the community or region. A private network may, for example, link several schools and/or municipal sites, and members would include the students, administration, and staff of these organizations. In contrast, a community network is built on a platform that gives broad access to community citizens, businesses, and agencies; it encourages many stakeholders to become a user and service provider. These stakeholders may come together simply to upgrade an aging infrastructure, especially when market forces cannot be relied upon to meet community needs or to co-build economic foundations. Leading communities strive to build partnerships and synergy to overcome barriers to access, job creation, and innovation (Agres et al., 1998; Eger, 2001; Tan, 1999; Industry Canada, 2002a, 2002b). Community networks facilitate information dissemination, discussion, and joint activity by connecting neighbours, creating new opportunities, and empowering residents, institutions, and

regions (Carroll & Rosson, 2001; Igarria et al., 1999; Canadian National Broadband Task Force, 2001).

A community network has four basic components: a telecommunication infrastructure with broadband capability, applications or content, devices (such as computers, cellular telephones, i-pods, and blackberries), and users. The development of a community telecommunication network typically occurs through a governing board representing the needs of users, which is supported by a small management structure (e.g., executive committee and network manager). The network relies on information and communication technologies (ICTs) and allows the community to import and export knowledge, encourage innovation, and overcome distance. The opportunities for economic and social development are contingent on attracting many users and creating a culture of "digital" use. The network must fulfill user needs and be attentive to their requirements, which may include a fair price, access to computers and the Internet, and training and education.

Infrastructure investment in the telecommunication network aims for the widest possible coverage of the community and region, with the constraint of reasonable cost. Investment also tries to ensure that users have access devices; some users have modest means, and schools and other organizations may have budget constraints. On the human resources front, technical training of local staff may be required to install the infrastructure and devices, and provide support to users. Organizations may need to re-design processes in order to meet the changing needs of their supplier and distribution partners, and to offer services online to end-users. The transformation effort may also require promotion campaigns to attract both individual and organizational users. These many resource challenges imposed on the community require a collaborative effort to pool resources and find innovative solutions.

A community network has users at the individual, organizational, and community levels of

human activity and endeavours. Individuals or end-users use the network to communicate with friends, play games, access information, obtain training, and occasionally innovate. Organizations are often stakeholders and use the network for a wide variety of purposes (Waits, 2000), including providing information and services, and selling online. They are intermediate users (Williams et al., 2005) and are the drivers of the development of the network. These organizations are the channels through which collective innovation is exercised and community change takes place (de la Mothe, 2004; Rycroft, 2003). At the community level, these individuals and organizations create aggregate demand and use of the network, and determine the sustainability of the network. The challenge is to create a culture of “digital” use that is integrated into the broader culture that is shared by community members.

During the development of the network, user involvement can be traced through participation in articulating a “digital” vision for the community, in the purchase of access devices and services that will connect users to the network (e.g., telephone, cable, wireless, computers, and Internet), and in the utilization of applications being made available through these access devices. Users may also be involved in creating employment by innovating on the network configuration, and in helping to create a culture of use by providing additional attractive applications.

Good governance requires legitimacy with an appropriate range of stakeholders, and involves building cohesion and commitment. Relationships are voluntary, and network survival depends upon the collective will and commitment of the stakeholders. The intentionally-planned network takes on a collaborative structure composed of local residents, non-governmental organizations, private sector businesses, and government. The stakeholders create a product that reflects the concerns, priorities, and aspirations of the local population. If the infrastructure, devices, and applications meet the needs of the users, a culture of

“digital” use emerges as an organic extension of existing community ways and practices. Without broad participation, the network is likely to reflect narrow interests and weaken the community’s social sub-system, which in turn will limit the economic success of the network.

A sustainable community telecommunication network makes consistent and positive contributions to the economic and social development of the community (ITU, 2003), thereby enhancing the community’s capital base. In large measure, these positive outcomes depend upon the collaboration of partners. They also reinforce the efforts invested in collaboration. Networking allows individuals, professionals, and entrepreneurs to access information and knowledge, learn about a wide range of issues, recognize opportunities, and achieve innovative products and services (Suire, 2004; Martin & Matlay, 2003; Corbett, 2002; Ardichvili & Cardozo, 2000; Kickul & Gundry, 2000). Whether a community network realizes its potential depends upon how well it is developed.

The above discussion portrays the formal structure of a community network as a fluid organization composed of volunteers with the purpose of facilitating the community’s transition and participation in the information society. However tempting, this viewpoint is non-critical in nature; it ignores the community context and processes by which the network emerges (Pigg, 2001; Day 2002).

COLLABORATION CHALLENGES FOR COMMUNITY NETWORKS

Communities around the world have demonstrated that transformation is possible using network technology. For example, Sunderland (UK) reduced unemployment from 30% to 4% by moving from a shipbuilding and coal industrial base to a knowledge and technology economy. Similarly, Spokane Washington (USA), once a

railroad town reliant on natural resources, dramatically improved the fortunes of its downtown by installing the highest density of broadband in the country. In Tianjin (China), a major push on broadband connectivity was accompanied by rapid user growth, from 20,000 to 2,700,000 in two years. Their stories make ample reference to the intensive collaboration of many actors, but the patterns of influence are not well articulated.⁵ Bell (2001) compared six urban communities noted for their telecommunication achievements and identified two effective patterns of collaboration: (1) a comprehensive and formal plan, and (2) a coherent pattern of individual initiatives. Similarly, Williams et al. (2005) reviewed numerous ICT initiatives, both small and large, and emphasized the overlapping nature of the planning, implementation, and use stages of development. These patterns are explored under the phases of network development section of this article.

Individuals and organizations involved in the creation of a community network face four collaboration challenges:

1. Defining and agreeing on the transformation effort (includes vision, transformation, and planning)
2. Assembling and mobilizing resources (includes interdependence, tasks, and structure)
3. Assembling and mobilizing trust (includes prior experience, communication, and distribution of power among collaborators)
4. Balancing leadership and collaborative management (includes the broadening requirements of the network, user appropriation, and power).

These challenges are tied to the coherence and adaptability of the network, and specifically to the dynamic relationship between the formation and performance phases of its development. Collaboration is inter-woven in each of these challenges. Network sustainability is achieved

by collaboration efforts that evolve during the network's development.

PHASES OF DEVELOPMENT OF A COMMUNITY NETWORK

We propose that network development takes place in two phases that are iterative in nature. Phase 1, the formation of the community network, is marked by the emergence of a leader and/or a board of directors, to respond to environmental pressures. These pressures may occur as a result of globalization and the need to remain competitive in the face of other communities or regions. It may occur as a result of downsizing or social development pressures (e.g., lack of medical practitioners, youth out-migration). The broad goals of the network are developed, including a representation of the future user. Phase 2, network performance, involves the concrete objectives and steps that the board takes to achieve the community goals that were agreed upon and the measures taken to attract and retain users. User involvement can and should take place in both phases of development.

Smaller communities need collaborators to solve a wide variety of challenges including infrastructure availability. Larger communities tend to have more resources and thus need collaboration to resolve economic and social pressures rather than infrastructure issues. In this second phase, the network can develop a culture and structure that gives meaning and coherence to a variety of projects. Some communities are more liberal and hands-off, allowing the private sector and citizens to develop content and opportunity. Others intentionally plan a vision of community transformation based on an improved telecommunication infrastructure. Phase 1 depends highly on leadership dynamics whereas Phase 2 is closer to managerial dynamics but with a distinctive collaborative flavor. These two phases are interdependent over time in that formation sets the

stage for performance, and performance impacts on the board and leadership dynamics. Positive outcomes at the performance phase consolidate the dynamics of the formation phase; negative outcomes challenge the board and leadership and initiate a re-formation phase. This iterative process was demonstrated in the feedback loop identified by Arino and de la Torre (1998) and Thomas (1993).

Because networks are fluid in nature (pooling from existing resources, changing membership, and varied timelines) and focused on both results and relationships, two interactive phases are considered sufficient. The two phases are supported by case studies of strategic alliances (Doz, 1996) that found that successful partners actively exchanged information, re-evaluated the project (in terms of efficiency, equity and adaptability), and consequently readjusted the initial conditions of their cooperation. They are also consistent with the ICT social learning findings of Williams et al. (2005).

Formation Phase

The push and pull factors in the environment impact on the community members and prompt them to consider uniting their forces to address the issue or opportunity that has been identified. Under the leadership of a visionary, and through ample interpersonal communication, a group is assembled that represents the initial membership

of a potential network. If a consensus on vision and goals is attained, the group becomes the founding board of a network and plans for the performance phase. The principal outcome is a collaborative base on which to build the network. Table 1 provides an overview of the critical factors present in the formation phase.

Context of Formation

The outer context or environment includes factors such as economic, political, culture, demographics, funding opportunities, pressures from government agencies, and technology innovation trends (Agres et al., 1998; Bailey & McNally-Koney, 1996; Igbaria et al., 1999; Keenan & Trotter, 1999; and Tan, 1999). Global competitiveness and turbulence are the underlying catalysts for creating networks for organizations, communities, and governments (Poyhonen & Smedlund, 2004; Scheel, 2002).

Interdependencies exist because organizations possess or control vital resources (material, human, political, structural, or symbolic) and thus are the source of environmental pressures for one another (Wood & Wood, 1991). Organizations seek to reduce these pressures and manage the interdependencies by gaining control over crucial resource supplies. The network form, as opposed to markets and hierarchies (e.g., vertical integration), provides a neutral space within which organizations can meet to explore solutions and synergies.

Table 1. Influencing factors at the formation phase

International bodies such as the World Bank (1999), the United Nations (1998), and OECD (1997) have adopted the paradigm of the information society as a guide to many of their development policies. According to Castells (1996, 1997, 1998), ICTs have produced a network society in which mobilizing knowledge and information have become more important than mobilizing physical resources. He argued that both organizations and individuals can benefit from electronic networks; they support the development and dissemination of knowledge and information, and facilitate innovation. Castells warns that these changes are accompanied by growing wealth disparities, social fragmentation, and dislocation. Governments are addressing these concerns, in part, by financially supporting the creation of community networks with broad accessibility. Locally, these new opportunities are often communicated through the chamber of commerce and other economic development agencies to mobilize or inspire stakeholders into action.

Communities come in all sizes and density, and all are influenced by the urbanization trend. Rural settings are witnessing the exodus of their youth and an erosion of their economic base as cities attract both talent and investment, including initiatives in telecommunications (OECD, 2004). Recent studies of Canadian rural communities concluded that ICTs can act as enablers of community building and development processes (New Economy Development Group Inc., 2001; Canadian Advisory Committee on Rural Issues, 2004). Given that the Internet is content-rich, offers online education, facilitates social networking, and offers a platform for the creation of new enterprises and the expansion of existing ones, the viability of the digital community network becomes crucial for the future of small communities.

When governments create generous programs to create community networks (e.g., Brown et al., 1998), communities are pressured to apply for capital funds even when they may not have the

organizational and resource capacity to sustain the network. Smaller communities have relatively fewer and less diverse resources and a push-style policy may be the only way to spur action. Another example of a push factor is when a major telecom firm seeks a community partner for a demonstration project, or when the private sector chooses to make an investment to upgrade its infrastructure. The telecom supplies the ICTs, but the community stakeholders still need to demonstrate and plan on how the technology can be applied to personal and organizational purposes. Often, infrastructure is built and languishes until there are other pressures in the environment of the community, such as closure of a major employer or the arrival of a strong champion. At other times, communities struggle with the lack of open access that inhibits economic development and competition. Pushing for open access can discourage the involvement of incumbent carriers, at least at the onset. The key here is to evaluate how context issues can stimulate communities into action toward their transformation.

Content of Formation

Stakeholders need to find the community vision attractive and see a benefit for themselves and for their organization. When the problem is broad in scope and complex, such as economic development, it requires a larger variety of stakeholders with legitimate interest to devise solutions and bring sufficient resources to bear. Stakeholders must have the right and the capacity to participate, and include organizations with legitimate power as well as those who will be affected by the network.

Collaborative action necessarily involves interdependence between individuals and organizations (Ouchi, 1980) and can yield both intangible (e.g., image of citizenship) and tangible benefits (e.g., cost reductions and additional revenues). Interdependence is strongly linked to the vision of the network and the factors motivating stakehold-

ers. It allows for an exchange among stakeholders that is built on trust, and an understanding of mutual benefit or advantage. According to Olk and Young (1997), the more ties an organization has to others in a network, the less likely is it to act opportunistically. Blois (1990) argued that collaborators should engage in bargaining on who will accept responsibility for certain elements of the transaction costs. They must come to the table understanding their role and develop a level of interdependence and mutual benefit in order to sustain the network effort.

The economic and social exchanges that take place are mediated by mutual trust. Ring (2002) distinguishes between “fragile” and “resilient” trust. The former is typical of opportunistic settings such as markets and involves the formal processes of negotiation, transaction, and administration. In contrast, the latter is the foundation of successful networks and is based on the informal processes of sense-making, understanding, and commitment. However, prescribing resilient trust does not ensure that it takes place. Ring proposed that it will emerge when the participants have a shared history of experience and when reputations for reliability are well established. On the other hand, Doz (1996) has documented the role of trusted intermediaries in helping other participants to shift gradually from fragile to resilient trust. We conclude that if a community has rich social relations, it can establish resilient trust early, but that parachuting in partners and stakeholders makes fragile trust more likely. However, if trusted intermediaries become involved, they can build the level of trust within the network.

There is a need for legitimate authority, credibility, and multiple memberships (Bailey & McNally-Koney, 1996; Gray & Hay, 1986) if a sustained transformation is to occur. Jones et al. (1997) have argued that networks need to restrict membership access and choose its members according to their reputation and status. Important stakeholders may choose to join a network or a project because of the presence of other members. A smaller number of leaders may allow the net-

work to realize quick wins, reduce coordination costs, and improve interaction frequency. One could argue that success will breed success—trust will increase, motivation will increase, and faster output can be generated. This view is less applicable to community networks where innovation, legitimacy, and broad reach is critical and leads to a large membership and numerous exchanges. Therefore, a smaller, more restricted network may be mobilized quickly and act efficiently, but be less effective in producing varied output. The larger network may slow the pace of change, but may be important enough to attract accomplished leaders. Structure issues become important in managing a larger group of stakeholders and are discussed in the performance phase of the network.

Another content issue is sustainability. Stakeholders want to know, “How much will it cost,” but few ask “How will the network become sustainable in the long-run?” Sustainability is a function of revenues (stemming from the use of the infrastructure and its applications), and the costs of the network (human resources, equipment, and materials). There are opportunities for synergistic gains when partners chose to purchase as a group, or share the operating costs. At the formation phase, the concept of sustainability is hazy, but becomes clearer as projects develop during the performance phase. Nevertheless, the board must carefully address the sustainability issue early to ensure that it becomes incorporated into their common frame of reference.

In the formation stage, the planning includes an explicit model of future users, their communication needs, and their likely use of the telecommunication network. Williams et al. (2005, p. 112, Figure 5.2) identify ways for direct involvement of users, such as user panels, market research, and trials. They also identify sources of indirect evidence about users through information on demand and markets for similar products, and competitive offerings. With the additional input of board members who understand their community, a representation of the users is developed. This user-centered approach is helpful in guiding the

design of the system and identifying training and promotion requirements. However, Williams et al., emphasize its limitations and the design fallacy that it breeds: “the presumption that the primary solution to meeting user needs is to build ever more extensive knowledge about the specific context and purposes of an increasing number and variety of users in the technology design” (p.102). The idea of perfect user representation ignores the reality that users are active agents and appropriate the technology later, primarily in the performance phase of network development.

Communities would be wise to involve users in all facets of their formation stage, but users are often thought of as passive participants that can be surveyed for the eventual purchase of devices or services at the performance stage. Yet, users have concerns over ownership, access and distribution of information, privacy, security, and copyrights (Agres et al., 1998), and most of these issues need consideration early on. However, the design fallacy mentioned above emphasizes the limitations of comprehensive user involvement in the formation phase.

Process of Formation

Leaders and champions can enhance or constrain the development of a community network (Industry Canada, 2002; Jones et al., 1997; Huxham & Vangen, 2000). Leaders tap into the collective awareness of the community stakeholders and mobilize the initial change efforts by supplying a vision and practical steps to realize it (Bailey & McNally-Koney, 1996; Roberts & Bradley, 1991). Sustaining collaboration depends on the emergence of a common view of the community and shared organizational values. Leaders and champions play a role in consolidating and expanding the collaborative initiatives, but a wider involvement is needed to foster innovation. It is important to have a community cross-section of members as well as individuals with sufficient power to rally other stakeholders. The parties must freely participate, knowing and agreeing on who

is involved and in what capacity (Glatter, 2004; Roberts & Bradley, 1991); prior experience and trust facilitate the membership drive.

Network goals are created, implemented, evaluated, and modified through purposeful social construction among network stakeholders and partners (Van de Ven & Poole, 1995; Ring & Van de Ven, 1994). Network effectiveness may be defined as the harmonization, pursuit, and attainment of the goals sought by the various stakeholders and partners. With diverse stakeholders, it becomes difficult to satisfy all parties equally; therefore, managing expectations and potential conflicts help to maintain the social cohesion of the network. Members will likely persist so long as they can positively identify with the intermediate and long term outcomes, whether they are social or economic in nature.

According to Hardy and Phillips (1998), when individuals come to share a vision of the issues and the solutions, they become stakeholders and begin to create a collective identity with mutually agreed upon directions and boundaries that, in time, may become a permanent network. The catalyst is a transformational leader who encourages collaboration as a means to create synergy for innovation, growth, or to protect against future turbulence. Engaging the stakeholders in a planning exercise can address their many concerns; tasks and roles can be organized and assigned within the network to fit their expectations. Because work is complex and elaborate in networks, planning and coordinating task-specialized activities is required (Roberts & Bradley, 1991). However, planning follows the visioning that the leader has enacted.

Challenges in the Formation Phase

Defining and Agreeing on the Transformation Effort

It is argued that a multi-sectoral and multi-organizational network is needed for a transformation to an intelligent community. The wide variety of

stakeholders impact the style of leadership and structure needed for joint initiatives. The leader (or leaders in the case of shared roles) shares a vision of a desirable future and initiates a flexible structure that can accommodate differences in orientation (profit versus not for profit), time horizons (short versus long term), and civic engagement (self versus community focus). Given the diversity of stakeholders, the visioning must be consistent and persuasive, but large enough in scope so that stakeholders can personalize the vision to suit their personal and organizational interests. Key activities include:

- Utilizing context issues to create a sense of urgency and sell the concept of the community network
- Identifying solutions to problems and synergistic opportunities
- Preparing a plan for producing meaningful and motivating outcomes

Agreeing on the vision depends on the availability and abilities of the local leader. Individuals with strong communication skills, an established reputation of trustworthiness, an ability to deliver on promises made, and conceptual skills to craft a vision are in short supply. While large communities have a greater pool of candidates, small communities may have to draw more on external talent and work hard on establishing trustworthiness.

Assembling and Mobilizing Resources

The community network depends upon its board to acquire the physical, financial, and organizational resources that make a broadband network functional. Collaboration among stakeholders and partners facilitates the pooling of their resources. Choosing board members should flow from resource requirements and the likelihood that the stakeholders recruited or volunteering are favorably disposed to sharing with other organiza-

tions. Community citizenship of board members channels the resources to create and enhance the network. Key activities include:

- Assembling the representatives of a variety of public and private sector organizations to form the board, including both small and large stakeholders;
- Mobilizing the resources controlled by board members and reaching out to obtain vital resources from the environment.

Too many resources may harm the development of the network if the board lacks the capability to make good use of them. Waste would damage the network's reputation and make future resource acquisitions more difficult. Likewise, too few resources can harm the network because the scope of activities would be narrow and appeal to only a small segment of the community's population. A narrow focus would appear self-serving and lack broad legitimacy.

Assembling and Mobilizing Trust

For the board to be effective in creating and enhancing the network's resource base, its members must trust each other so that extensive sharing becomes possible. When stakeholders engage in joint efforts and initiatives, they are putting the community first and themselves second, making them vulnerable to exploitation by less citizen-minded organizations. When trust exists on the board, stakeholders can tolerate some exposure. Therefore building and maintaining trust in a realistic manner is essential to the network's resource base and projects. Key activities include:

- Assembling the board membership on the basis of reputation, prior experience, and diversity of stakeholders;
- Creating a shared vision that reflects the underlying values of community spirit;

- Distinguishing between fragile and resilient trust, and building the latter.

Building and maintaining resilient trust is at the core of the inter-dependent culture that emerges in the network. When a transformational vision is complemented with solid resources and trust, the community network has met the challenges of the formation phase of its development and is ready to shift into the performance phase.

Performance Phase of Development

The performance phase of network development is centred on concrete projects that require the pooling of resources by its members. The resources may be tangible (finances, staff secondment, office space, and equipment) and intangible (time, information, influence, and reputation) in nature. Pooling is facilitated by both the culture and structure of the network in which horizontal interactions, exchanges among equals, are based on trust. These resources are organized and controlled to attain the project objectives, and the management style is collaborative and accountable to the membership of the network. Pursuing these objectives gives collaborators opportunities to learn how they can make the network function effectively. In the short term, the level of attainment of the project’s objectives dominates; small wins and their public recognition are important to confirm the value of the network (Bouwen & Taillieu, 2004). Effective project management is

needed. In the long term, the board focuses on the level of attainment of the broad goals of the network. To ensure that the projects and the general management of the network are aligned with the original vision and goals, effective leadership is required. Table 2 provides an overview of the critical factors in the performance phase.

CONTEXT OF PERFORMANCE

The interdependence of members within a community network is reflected in both its structure (O’Toole, 1997) and culture. Structure requires careful attention because a poor structure—one that gives too much power to one partner or that does not embody the values of stakeholders—will affect the performance and longevity of the collaboration.

Poyhonen and Smedlund (2004) and Nootboom (1999) identified three network structures: vertical, horizontal, and diagonal. The latter consists of firms and organizations from several different lines of business. A diagonal structure is appropriate for community networks because it includes as many collaborators as possible to create synergy and innovation within and between sectors; transformational, as opposed to incremental change, is facilitated. The success of collaborative networks is contingent on managing the ambiguity, complexity, and dynamics of the structure. It becomes more important in the performance phase because it must sustain an action plan and

Table 2. Influencing factors at the performance phase

Context	Content	Process

organize resources to carry it out. However, a telecommunication network is developed to resolve dynamic context issues and can only do so within a process of continuous improvement. A rigid structure that minimizes innovation diminishes the network's sustainability. Though difficult to assess, the effectiveness of the structure can be judged by its internal coherence and fit with the culture of the network. This puzzle, identified by Bailey & McNally-Koney (1996), needs a solution that retains the fluidity of communications and decision-making, while providing for a framework for productivity and sustainability.

Collaboration is associated with incremental innovation when partners share on several levels: a larger purpose, explicit and voluntary membership, an interactive process, and temporal property (Roberts & Bradley, 1991). Hardy and Phillips (1998) pointed out that more powerful stakeholders may force collaboration on weaker players to control them. Consequently, there is a lessening of the level of interdependence and common vision. Weaker stakeholders are bound to minimize their participation and find excuses to exit the network when they are being coerced. Though asymmetrical power is a likely reality, leaders that seek innovation must put less emphasis on control and more on incentives and opportunities.

Creating a culture of collaboration gives coherence to the stream of actions that builds the community network. Collaboration is described as a relational system of individuals within groups in which individuals share mutual aspirations and a common conceptual framework (Bailey & McNally-Koney, 1996). Individuals are guided by their sense of fairness and their motives toward others (caring and concern, and commitment to work together over time). Through communication and shared experiences, they create a system of shared assumptions and values, and accepted approaches and solutions to problems, including collective sanctions, to safeguard exchanges and reinforce acceptable behaviors (Jones et al., 1997).

Sanctions may include exclusion from certain benefits (present or future) and opportunities (participation in projects), and as a last measure forced exit (temporary or permanent) from the network.

Collaborators often choose to stay in a poorly performing network based on the strength of their social ties. However, if they conclude that they can meet all of their needs outside of the network, they may view the network as superfluous (Brown et al., 1998). Linkages or interdependence must be solid and intentional (Bailey & McNally-Koney, 1996) and may be a strong indicator of sustainability (Olk & Young, 1997). Conversely, Brown et al. (1998) identified that greater resource interdependence makes successful partnerships more difficult to achieve. In order to find common ground and encourage persistence, the reasons for enhancing an interdependence need to be emphasized, and stakeholders must want to belong and believe in the vision.

Content of Performance (Specific Projects)

The content of performance includes a wide variety of projects that meet the goals of the network, including the needs of stakeholders and users. Among them are projects to launch or upgrade an infrastructure, acquire devices to deliver applications, develop content for the network, and promote the network to potential users. The outcomes include cost savings to deliver services, revenues from users, and additional capability for the social and economic development of the community.

Waits (2000) described collaborative networks in terms of their pursuits:

- Co-inform: actions to identify members and impacts, promote a heightened awareness of the issues, and improve communication among the members;
- Co-learn: educational and training programs sponsored by the network;

- Co-market: collective activities that promote member products or services abroad or domestically;
- Co-purchase: activities to strengthen buyer supplier linkages or to jointly buy expensive equipment;
- Co-produce: alliances to make a product together or conduct R&D together;
- Co-build economic foundations: activities to build stronger educational, financial, and governmental institutions that enable them to compete better.

Some of these pursuits appear easier to realize and only require fragile trust (co-inform and co-learn). They are more likely to give quick “small wins.” Others may be challenging and require resilient trust (co-market, co-purchase, and co-produce); their success will take more time but are more highly valued. Co-building economic foundations appeals less to self-interest and more to a communal interest, and depends on a broad vision that will lead to a series of concrete actions and sustained effort. Waits’ objectives are compatible with each other, but have different time horizons and commitments. The strength of the formation phase influences the commitment of stakeholders in the development phase. In particular, a strong collaborative climate encourages them to be patient and willing to invest additional time and resources to achieve long term goals.

PROCESS OF PERFORMANCE

Leaders require managerial sophistication to recognize appropriate circumstances and tools for collaboration (Glatter, 2004). In networks, collaboration depends upon an ongoing communicative process (Lawrence et al., 1999). Roles and responsibilities are negotiated in a context where no legitimate authority is necessarily recognized (Glatter, 2004; Lawrence et al., 1999; Lowndes & Skelcher, 1998). Like in partnerships, there is

concern for trust, politics, emotions, and results. Furthermore, leaders require an understanding of user appropriation of the digital network to effectively channel the collaborative efforts.

Du Gay et al. (1997) describe the appropriation of technology as an active process in which users make choices around the selection and local deployment of the technological components, and create meaning and sense of the technology. Appropriation has both a technical and cultural side. In this spirit, Williams et al. (2005) have argued that user appropriation has two distinct but inter-related processes: *innofusion* (users adjust and innovate to improve the usefulness of the technology) and *domestication* (users adapt the use of the technology to integrate it meaningfully in their activities). When both processes are fully engaged, the community may be said to have a “digital” culture that sustains the network.

The pace of change within the network must be properly managed. Effective use of communication will allow collaborators to react and contribute. Because of large boards and membership and turnover in representation, some collaborators may not know everyone or their status. Indeed, some may be confused over the degree of autonomy they have in making decisions for their organization (Huxham & Vangen, 2000). Changes in government mandates and organizational priorities create uncertainty as collaborators plan and structure the network. Communication and recognition of accomplishments become important to keep everyone focused.

The board’s effectiveness in tackling problems within their community as well as within their respective organizations will directly influence the achievement of the intelligent community objectives. Leaders need to guide the board and create bridges with important outside players. They must align the requirements of their own organization with the vision of the intelligent community initiative for success; they must create a high performance team environment (Albert, 2005; Wheelan, 1999; Smith, 1994). This standard

is not easily achievable, especially for a volunteer board with diverse membership and affiliation.

Challenges in the Performance Phase

Continuing Challenges from the Formation Phase

The consensus on the community vision that was created in the formation phase needs to be reinforced. The leader can remind stakeholders of the urgency to capture opportunities, but must incorporate measures for sustaining collective efforts. Key transformation activities include:

- Expanding planning and monitoring projects and measures of performance;
- Marketing the network concept to mobilize and gain the support of the wider community and further engage the stakeholders.

In terms of resources, the community network continues to depend upon its board to acquire resources to develop, acquire, and develop applications to attract numerous users. Key activities include:

- Modifying board membership to improve the resource base of the network as projects change over time;
- Engaging both small and large partners for innovation to create new resources;
- Creating a small management structure for the performance phase of the network.

As for trust, the performance phase requires continuing sharing of resources in the face of uncertain outcomes. Key activities include:

- Applying different trust standards as the situation warrants;
- Encouraging the broad sharing of resources instead of specialized contributions.

Resilient trust can block new stakeholders and partners from joining the network; they may have key resources but be deemed untrustworthy. In such a case, the network requires the flexibility to resort to fragile trust with its emphasis on formal agreements and contracts. The reverse situation can also damage the network, when fragile trust dominates relationships. While formal contracts increase accountability of the parties, they are narrow in scope and participation is contingent on self-interests being satisfied. Community considerations remain secondary. In time and through active leadership, these new members may buy into community citizenship through association and success.

Balancing Leadership and Collaborative Management

Both the formation and performance phases of development have their champion. The leader dominates the formation (and re-formation) phase through visioning, planning, and attracting and retaining stakeholders with key resources and disposed to collaborate. The manager guides and maintains the performance phase, and ensures that both tangible and intangible benefits are created for the stakeholders and the community.

The “collaborative” manager is needed to reinforce the user appropriation by supporting the innovation and domestication in which users engage. By encouraging the involvement of intermediaries (e.g., Chamber of Commerce, owner of a cybercafé, entrepreneur who wants to keep control), the network manager allows the network to evolve along lines that reflect the different groups and segments in the community’s population (Williams et al., 2005).

Formal planning becomes less important, as a pattern of coherent projects becomes established. At the same time, these intermediaries (or small groups of individuals in large networks) interact to keep the board informed and reinforce their individual efforts. By working together, they ensure

that the vision of the network creates a coherent set of initiatives and projects, and opportunities and issues relevant to the board meetings are identified. Key activities include:

- Encouraging innovation and proper planning to achieve the transformation effort;
- Reaching out to intermediaries to broaden user involvement;
- Ensuring that the vision that binds the board members remains true to the community values as the network develops and expands;
- Confronting head-on the need to modify the board composition to respond to internal or external factors;
- Managing projects with a blend of fragile and resilient trust, the former with binding contracts and the latter with negotiation and concurrence;
- Choosing projects that are likely to succeed and that are valued by the stakeholders;
- Building and maintaining redundant communication systems, both formal and informal, to reflect the culture of inter-dependence that binds the stakeholders of the network.

The network can be damaged by a dominant leader or manager who insists on being involved at all times and on controlling the process, whether at the board or project level. This situation emerges when there is a failure to share multiple roles and to act as a team. The lack of experienced persons may push one individual to assume both the leadership and managerial role; this solution ensures positive momentum, but may block future sharing of roles as the incumbent becomes entrenched. Similarly, the abundance of strong and experienced personalities facilitates the sharing of roles, but may slow down momentum as too many persons insist on prominence. Developing a team spirit among members of the board and management should be encouraged as early as possible in the network's development (Albert, 2005).

Collaboration Challenges for Users

At the formation stage, the infrastructure and applications are planned and guided by a vision. Stakeholder requirements are addressed in the planning of the network through the methods of user representation. At the performance stage, when the network is functional, the users actualize the network in both expected and emerging ways. A community network is validated by the applications it makes available to its users, and the extent to which the users actually use them. Furthermore, the design features of the telecommunication network influence the collaboration opportunities that the network creates. When the network design enhances collaboration, it has succeeded in creating effective socio-technical patterns (Huysman & Wulf, 2005; Evans & Brooks, 2005).

Challenges for Individual Users

IT and a community network challenge the individual because they put into question existing ideas and routines, and add knowledge and skill requirements. Being open to change means making efforts to understand and use the network. The younger generation makes more use of the internet than the established older generation for social contact and is likely to push for internet connection in the home (Bernier & Laflamme, 2005; Crowley, 2002). The older adults are more likely to be introduced to ICT changes in the workplace. Age aside, the Internet facilitates the local-global link through which knowledge and expertise from around the world can be channelled to community members (Stevenson, 2002). Creative individuals can interact to exchange expertise and create innovations (e.g., open source development), and are motivated by reputation and recognition built into the Web site (Fischer et al., 2004). To generate ideas, group support systems that ensure anonymity appear more effective (Pissarra & Jesuino, 2005). In general, the individual must learn to

assess the trustworthiness of the Internet information sources (Franklin, 1999; May, 2002) and assume risks when making transactions online. Similarly, participating in virtual communities and discussion forums challenges the individual to change roles from spectator to contributor (Ginsberg, 2001) and activist.

Challenges for Organizational Users

Organizations that are stakeholders in the community network need to share their “network” vision with their board members, managers, employees, and organizational partners within their supply chains and customer/client networks. Key individuals likely were involved in the network formation stage to ensure that the design of the systems would support expected transactions and activities. At the performance stage, each organization is challenged to mobilize its ICTs, skill base and network use, and do so in dialogue and coordination with their organizational networks. Internally, this means empowering employees and lower levels of management through information systems and decision-making authority. Externally, this refers to the network of relations and the integration of the organizational and community networks. Failure to have extensive collaboration diminishes the benefits that the community network can deliver to stakeholders. Knowledge sharing (Van den Hooff et al., 2004) and knowledge management (Ackerman & Haverton, 2004) are useful frameworks for channelling this collaboration. In addition, involvement can include intra-preneurship (Von Oetinger, 2005) and joint ventures supported by collaborative groupware (McKnight & Bontis, 2002). The organization can also reach out to innovators and entrepreneurs in the community, who view the network as their business platform, and initiate partnerships. The above array of activities pushes leaders and senior managers to adopt an organizational model that incorporates trust.

Challenges for the Community

As the community network is fully implemented, the stewardship vision (Block, 1993) incipient in the formation phase must be reinforced by extending inclusiveness to all segments of the local population, imagining a broad culture of use, and providing for economic development with a digital component. Community leaders should have concrete programs to diminish access barriers such as network connectivity at a reasonable cost (or at no cost for public terminals) and to training and education. Adoption of the network will vary across socio-economic dimensions, and programs are needed that are adapted to specific groups such as youth, seniors, and the non-profit and small business sectors. Developing and implementing these programs can take place with community stakeholders in collaborative projects. An innovation culture (Martins & Terblanche, 2003), linked to the network, can be encouraged.

A culture of “digital” use is emerging in many communities; the Internet and its many activities are being integrated into everyday routines of social communication, work, and play (Bernier & Laflamme, 2005; Crowley, 2002; Wellman et al., 2001). In contrast, civic participation has had less success. The evidence indicates that internet use reinforces civic participation and makes it more sophisticated, but does not increase the levels of activity (Shah, 2002; Uslaner, 2004; Warkentin & Mingst, 2000; Wellman et al., 2001). Pigg (2001) has argued that networks can be designed to enhance civic participation, but so far, these designs have failed to incorporate the nature of participation. The designs typically focus on customer services and support instead of sharing of information, ideas, and knowledge to influence civic decisions. With a customer focus, the civic authorities may increase the satisfaction of its citizenry, whereas a participation focus obliges the authorities to share decision-making powers and accept more uncertainty in the process and outcomes.

CONCLUSION

A community network faces four inter-related collaboration challenges during its development that are tied to transformation, resources, trust, and management. When these challenges are met, the network will have a solid culture and structure of interdependence, and the flexibility to change over time. The network will maintain a positive momentum that is constructive and manageable, and lead to medium and long-term sustainability. When these challenges are not met adequately, the pace of change will be either too slow or too fast, or blocked at some point in time. Sustainability of the network will be compromised unless the underlying issues are addressed.

These four challenges are anchored in the proposed network development model where formation and performance phases, and adaptation through reformation are critical for the sustainability of the community network. Policy makers and change agents among the stakeholders of community networks are well advised to shape their interventions with the aim of establishing and maintaining positive momentum, while paying continued attention to issues of visioning, resources, trust, leadership, and management. They would do well to expand their views of technology development to include user appropriation and the challenges that users face. They must accept the uncertainty that is inevitable with user involvement to support the goal of network sustainability.

ENDNOTES

- ¹ The authors acknowledge the helpful comments of the reviewers. By addressing their concerns and suggestions, this article found a better balance between organizational and involvement issues.
- ² Multi-organizational collaboration, partnerships, and networks are considered interchangeable terms and refer to a variety of organizations collaborating for a common purpose. "Collaborative network" is proposed as an inclusive alternative.

- ³ A stakeholder is defined as an organization that contributes programs and services to the network. A partner is one that makes a financial contribution to the overall project.
- ⁴ The term downloading has become a popular expression in Canada as a result of higher levels of government shifting responsibility for programs to lower levels of government. Municipalities have inherited a number of costs and responsibilities previously held by the province and the province has inherited responsibilities previously held by the federal government.
- ⁵ These communities have been highlighted at the annual conference of ICF (Intelligent Communities Forum).

This work was previously published in International Journal of Technology and Human Interaction, Vol. 3, Issue 2, edited by B. C. Stahl, pp. 13-33, copyright 2007 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 1.23

Patents and Standards in the ICT Sector: Are Submarine Patents a Substantive Problem or a Red Herring?

Aura Soininen

*Lappeenranta University of Technology, Finland
Attorneys-at-Law Borenius & Kempainen, Ltd, Finland*

ABSTRACT

Multiple cases have been reported in which patents have posed dilemmas in the context of cooperative standard setting. Problems have come to the fore with regard to GSM, WCDMA, and CDMA standards, for example. Furthermore, JPEG and HTML standards, as well as VL-bus and SDRAM technologies, have faced patent-related difficulties. Nevertheless, it could be argued that complications have arisen in only a small fraction of standardization efforts, and that patents do not therefore constitute a real quandary. This article assesses the extent and the causes of the patent dilemma in the ICT sector through a brief analysis of how ICT companies' patent strategies and technology-licensing practices relate to standard setting and by exemplifying and quantifying the problem on the basis of relevant articles, academic research papers, court cases

and on-line discussions. Particular attention is paid to so-called submarine patents, which bear most significance with respect to the prevailing policy concern regarding the efficacy of the patent system.

INTRODUCTION

Background

Our society is filled with various types of standards, commonly agreed ways of doing things. Standards may be sociocultural, political, economic, or technical. Language is a standard, the metric system is a standard, and so is our social etiquette (Cunningham, 2005). Technical standards could be defined as any set of technical specifications that either provide or are intended to provide a common design for a product or a

process. They range from a loose set of product characterizations to detailed and exact specifications for technical interfaces. Some of them control product interoperability, some ensure quality or safety, and some are so-called measurement standards (Grindley, 2002).

Particularly interoperability/compatibility standards are paramount in industries such as information and communications technology (ICT) that are dependent on interconnectivity. In fact, the telecommunications industry has relied on them throughout its history. These standards define the format for the interface, allowing different core products, often from different manufacturers, to use the same complementary goods and services, or to be connected together as networks (Grindley, 2002; Teece, 2000). Thus, interoperability standards enable gadgets to work together and thereby they further the goal of increased communicative potential. This follows that their use may also lead to financial benefits due to so-called network externalities (Cunningham, 2005; Shurmer & Lea, 1995). These strong network effects are present when a product or a service becomes more valuable to users as more people use it. Examples of products that benefit from network effects include e-mail, Internet access, fax machines, and modems (Shapiro & Varian, 1999).

A further economic effect of interoperability standards is that they reduce the switching costs from one supplier to another by preventing producers and consumers from being locked into a proprietary system. Standards, however, do not totally eliminate switching costs. When producers and users become committed to a particular system or standard, and the longer they stay with it, the more expensive and difficult it is for them to switch to another that is comparable (Blind, 2004). Consequently, due to these strong economic effects, control of the outcome of standard setting may yield significant economic advantage on the sale of both core and related products (Hjelm, 2000). Patents that provide their holders with

a defined right to prevent others from making, using and selling an invention can be used to gain that leverage or to control the adoption of a standard. Therefore, potential conflicts between patent rights and the need for standardization affect the ICT industry and the consumers at large, and these economic effects need to be bared in mind when examining the deficiencies of prevailing standard-setting procedures and the legal framework.

This article studies the patent-related dilemmas that may arise both in the course of standard setting and after the standard has been established. Potential conflicts and their causes are identified and exemplified on specific case studies, and the study of Blind, Bierhals, Thumm, Hossain, Sillwood, Iverser, et al. (2002) is used to quantify the problems further. The aim is to find out whether the problem with patents, particularly with so-called submarine patents, is substantial, or whether it is only a minor concern that has attracted undeserved attention. Term “submarine patent” is used here for patent applications and patents that may yield significant economic power because they “read on” a standard and come to the fore after it has been established.

Standardization and Patents in General

Standards can be established in many ways: the markets determine *de facto* standards, and organized standards bodies agree upon *de jure* standards. These bodies could be said to include government legislators, official standards organizations, various industry committees, and consortia. Unlike *de facto* standards, *de jure* standards are usually established in advance and are later implemented by multiple vendors (Grindley, 2002; Messerschmitt & Szyperski, 2003; Mueller 2001).

Standards emerge from all the sources in the ICT sector listed previously. The Internet Society (ISOC), the Organization for the Advancement of Structured Information Standards (OASIS), the

World Wide Web Consortium (W3C), and the Internet Engineering Task Force (IETF) could be mentioned as examples of bodies active in the field of software and the Internet. Then again, the European Telecommunications Standardization Institute (ETSI), the American National Standardization Institute (ANSI), the International Telecommunications Union (ITU), and the International Organization for Standardization (ISO) could be mentioned as organizations operating in the telecommunications industry (Rahnasto, 2003).

A further distinction is that between open and proprietary standards. The purpose of open standards is to provide an industry with well-documented open specifications that could be implemented without prior business and legal arrangements (Caplan, 2003; Messerschmitt & Szyperski, 2003). Furthermore, with open standards, unlike proprietary standards, development of the specification is open to participants without restrictions. The openness may not always be absolute, however, and as a consequence the term “open standards” has various interpretations in practice (Caplan, 2003; Messerschmitt & Szyperski, 2003). In fact, although patent-free standards have traditionally been preferred in the interests of ensuring their success and promoting their use, it has become more difficult to design standards that do not contain any patentable inventions. This holds true particularly when the aim is to choose pre-eminent technology for a standard (Frank, 2002; Soininen, 2005). Therefore, it is not rare to call a standard open even if it includes patented technology providing that licenses are accessible to all. This definition has been adopted in this article as well.

As to the connection between de facto and de jure standards and open and proprietary standards, privately set de facto standards are typically proprietary in nature (Lemley, 2002) meaning that the patent holder controls their utilization. Then again, official standards organizations typically promote open standards, and those originating

from various industry groups and consortia may fall in either category or somewhere in between depending on whether everyone has been able to participate in the selection of the technical specification, or whether the standard has been agreed upon by a handful of companies having the technical knowledge in the area and who then have it adopted throughout the industry (Rahnasto, 2003). The focus of this article is on open, commonly agreed de jure standards.

As said earlier, although open standards are in principle available for anyone to use proprietary technology may be involved in their implementation, and using the specification may require a license (Rahnasto, 2003). Consequently, many official standards organizations and also some consortia have policies that permit their members to contribute proprietary technology under certain conditions: disclosure of the contributor’s essential patents may be required, and before the technology is elected, patent holders are asked whether they are willing to offer a license at least on a non-discriminatory basis and on fair and reasonable terms (Frank, 2002). The purpose is to protect the patent holder’s interests while fostering standards that incorporate the best technology and have the capacity for worldwide promulgation (Berman, 2005; Soininen, 2005). These organizations are called together as “standards bodies” or “standards organizations” from now on.

From the companies’ perspective the dilemma between patents and open standards arises from the need to ensure returns on R&D investments through the exclusion of others while interoperability requires the inclusion of other parties. In fact, patent holders are free to refuse licensing altogether or they may choose the licensees and the licensing terms freely as long as the practice complies with relevant legislation, such as competition regulation/ antitrust regulation. Thus, companies appear not to be very willing to license their patented technologies to everyone, particularly not to their competitors, on a royalty-free basis or for low returns. It seems, however, that in the context of

common standards a limited exception can often be made for business reasons (Interview data U.S., 2004). Indeed, the use of common protocols and interfaces may expand the markets for networks of products that implement them, and producers then compete by innovating on top of the standardized functions (Peterson, 2002a). Nonetheless, even if a company decided to take part in standard setting, the interests of firms, individual contributors and users participating diverge and patents may be utilized strategically to achieve patent holder's objectives. Consequently, the standardization process may turn out to be burdensome as the mere existence of vested interests, for example, intellectual property rights (IPRs), complicates matters (Farrell, 1996; Shurmer & Lea, 1995; Soininen, 2005). Identifying relevant patents and agreeing on their beforehand cause complications and delays to the standardization process.

The relationship between ICT companies' patent strategies and technology licensing practices discussed earlier in general and in respect to open standards is one of the main questions that need to be addressed further in order to find an explanation to why it is that patents may raise such thorny issues in respect to standards. Moreover, attention has to be paid to the standards organizations' practices and bylaws aimed at reducing that tension in practice.

Standardization and Submarine Patents

As mentioned earlier, different types of standards bodies play an important role in establishing standards in the ICT sector, and many of them allow patented or patentable technology to be submitted, but specifically require disclosure of the patents and occasionally even of pending patent applications during the standardization process, as well as their licensing. This is to clarify relevant rights during the process of standard development and reduce the risks of submarine patents so that patent holders cannot claim infringements

afterwards, and thereby prevent others from using a standard, or to extract overly high licensing fees. If all essential, relevant rights are clarified during the process, a well-informed decision can be made (Kipnis, 2000). It might also be possible to design around the identified patents and patent applications, or to choose another technology for a standard. In fact, since patent-free standards are often the first choice, disclosure may have a negative effect on what technology is chosen (Soininen, 2005). For instance, when selecting the GSM standard another viable option was apparently rejected because it was considered too proprietary (Bekkers, Verspagen, & Smits, 2002).

Since proprietary technology may easily be discriminated, companies may even have an incentive to manipulate the standardization process and hide the fact that they have relevant patents. Standardization namely gives patents market power they did not have before (Rahnasto, 2003), which in turn improves the holder's negotiation position following the election and adoption of a standard. Furthermore, the disclosure requirement has its shortcomings and therefore companies may not even need to break the rules to capture an industry standard. The disclosure requirement is not necessarily extended beyond the personal knowledge of the individual participant, it may not be practically possible for a company to clarify all the patents and patent applications, and the obligation does not always cover pending patent applications, especially unpublished ones (Lemley, 2002). Consequently, a large share of the rights is not necessarily considered during the standardization process. Moreover, since standard setting may take a long time, many years in some cases, undertakings usually continue their R&D projects and file more and amend their existing patent applications during that period. Therefore, if the obligation to disclose does not hold throughout the standard setting, it is even more likely that patents will surface after it has been established (Soininen, 2005).

The optimal scope of the disclosure requirement, what happens if the guidelines are breached, and what course of action should be taken if there was no contractual duty or even a recommendation to disclose patents or pending applications and a patent surfaces after the adoption of the standard, remain matters for debate both outside and inside the courts. The submarine patent risk stemming partially from non-disclosure also involves third-party patents. Indeed, as Lemelson's submarine patent tactic has demonstrated, it is ideal from the patent holder's perspective to have a patent claiming technology that becomes widely adopted within an industry (Soininen, 2005). In fact, the submarine patent scenario could be said to have become more probable in recent years as numerous cases have been reported in which, despite efforts to identify relevant patents, claims have surfaced after the standard has been agreed upon (Blind et al., 2002). Furthermore, the importance of patents in business has increased in many respects and the legal framework constituting of patent laws and competition/antitrust regulation that may pose limits to the utilization of patents could also be described as pro-patent even though the system has been severely criticized (FTC, 2003; OECD, 2004). This has resulted not only in a higher number of applied-for and granted patents, but also in more aggressive enforcement and increases in technology licensing, bare patent licensing and cross-licensing, which in turn has the potential of generating more conflicts (Peterson, 2002). In fact, it appears that there is an increase in all types of patent claims and charges that relate to standards, and particularly in telecommunications, negotiations over such matters cause delays in the development of standards worldwide (Krechmer, 2005). Therefore it is essential to study the patent landscape in the ICT sector further, take a closer look at realized disputes and examine the loopholes of the system. Only by understanding how it is failing, it is possible to implement better practices.

Standardization and Licensing

There is another quandary involving patents and standards in addition to the submarine patent dilemma described earlier, and that has to do with licensing. This dilemma relates mainly to the mainstream obligation to license one's essential patents on fair, reasonable and non-discriminatory terms (RAND). The problem is that this problem may be limited in firms' patent statements in various ways, resulting in unexpected hold-ups. Companies may, for example, agree to license only patents that are essential for using that portion of the standard they have suggested, or they may impose limits by stating that licenses are available to any qualified applicants (Frank, 2002; Rahnasto, 2003; Soininen, 2005). One typical qualification is that licenses are offered only to companies that offer reciprocal treatment or promise not to threaten patent litigation against the licensing company (Berman, 2005). Moreover, specific licensing terms are not typically agreed upon during the standardization process so that the standards organization would play a role in it (Kipnis, 2000). Each company negotiates terms separately, which allows it to apply its own interpretations of what is considered fair, reasonable and nondiscriminatory (Frank, 2002; Rahnasto, 2003). In fact, it is for this reason that manufacturers participating in standards committees may even be forced to delay the standards development in order to negotiate acceptable terms before the final vote. The worst-case scenario is that the sum of license fees exceeds the total profit available to a product manufacturer, and that the standard never becomes adopted (Krechmer, 2005). Ultimately, consideration of the fairness, reasonableness and nondiscriminatory nature of the terms is left to the courts (Soininen, 2005). So far, however, the courts have not provided proper guidelines on how to determine what is fair, reasonable and nondiscriminatory (Rahnasto, 2003).

Thus, the problems related to the adoption of standardized technology may have to do with dis-

agreement over the content of a company's licensing statement, even in the absence of submarine patents. One might even wonder, considering the large number of patents that are being reported as essential in the course of standardization, whether the disclosure obligation bears any significance in practice. Therefore, it is not enough to concentrate merely on the submarine patent problem and its causes when there is a possibility that limiting that particular risk might have only minimal effect.

Research Objective and Methodology

Standard setting is the cornerstone of today's economy, and it is essential particularly in the ICT sector. The most important feature of open standards is that they have the potential to become widely promulgated and used without undue restriction: this is essential to their success and to the very idea of something being or becoming a standard. Patents may, however, be used exclusively and therefore they may jeopardize the purpose for which standards have been created. Indeed, submarine patents as well as perplexity regarding proper licensing terms may result in increased costs in the form of excessive licensing fees, or they may force the industry to abandon the standard altogether meaning that the societal benefits may be lost. Since patents help companies to gain leverage over the standard-setting procedure and the adoption of the standard, potential dilemmas addressed in this article are also a policy concern. One may ask particularly in the context of so-called submarine patents whether the patent system fulfils its goal. These patents have factually been hidden and thus they have not contributed to technological development of that specific industry, as is the purpose of the patent system.

This article examines the patent-related dilemmas and analyses their causes by exemplifying and quantifying them on the basis of newspaper stories, online articles, research papers, and trial

documents. Further data was collected from interviews with eleven Finnish ICT companies and eight U.S. ICT companies in order to illustrate the relationship between patent strategies and licensing practices in general and in the context of standard setting. The interviews with the Finnish companies focused on patent strategies and were conducted by the author in 2003. Those with U.S. companies based in the Bay Area, CA, were more general and related to their innovation models, appropriability strategies and licensing practices. They were conducted by the author in cooperation with Pia Hurmelinna-Laukkanen and were completed in 2004. The interviewed firms included different types of ICT companies operating in the fields of information technology (software, hardware and related services for different purposes), chip interface technology, audio technologies, and digital entertainment products designed for computers and the Internet, and telecommunications. It should be noted that most of the U.S. case companies were larger than the Finnish companies, their revenues spanning from \$60 million to \$19,000 million. Furthermore, the size of their patent portfolios was substantially larger and varied mostly between 300 and 2,000 issued patents (one of the companies did not have patents at all). Only one Finnish company had a substantial portfolio of over 5,000 issued patent families, two of them had a medium-sized portfolio of approximately 60 issued patent families and close to 200 pending applications, and the rest had less than 10 issued patents/pending patent applications. The U.S. companies were also more actively involved in standard setting than the Finnish companies.

Obviously, it is difficult to make generalizations on the basis of such limited data. Thus, the data are used to complement other studies and views presented in the literature. In some cases, however, there were common features applicable to all of the firms, or several of them were found to have certain common denominators. Then again, some of the results are presented as examples of

corporate operational models. One reason for this is that the interviews were in-depth in nature, meaning that the discussion was sometimes focused more on certain areas, and it would not therefore be possible to say whether the expressed views were common to all of the companies or not. Furthermore, in some situations less than 8 (U.S.) or 11 (Finnish) companies yielded relevant data: only a few companies in the Finnish sample were involved in setting standards. In the following, I refer to the interview data as interview data U.S. (2004) and interview data Finland (2003).

I will start by re-examining the submarine patent concept because the original meaning of submarine patents has largely disappeared as a result of legislative amendments. Nevertheless, certain aspects of the current patent law still contribute to their existence. I will then study ICT companies' patent strategies and technology licensing practices in order to demonstrate the general developments in the area and tensions between proprietary and open operation models and their implications on standardization. After that I will review the disclosure and licensing challenges that have been reported in the context of standardization and patents, and examine the likelihood of such conflicts. I conclude the article by considering the extent of the problems and whether the submarine patent problem really exists and can be limited, or whether it is merely a red herring that needs no further attention. It should however be noted that the sufficiency and flexibility of the prevailing legal framework applicable to solving potential conflicts is not particularly examined in this article even though it is clear that applicable legal tools influence companies' negotiation power, and thereby their behavior during and after standard setting. These legal tools could also prove helpful in minimizing the harmful societal effects of submarine patents. This type of in-depth analysis would be the next phase following the recognition of the prevailing problem, its magnitude and main causes.

THE ORIGINS OF SUBMARINE PATENTS

The term submarine patent has been traditionally used to refer to (U.S.) patents that are issued after a long, intentionally delayed pendency at the patent office. The purpose of prolonging the application period by filing continuation applications, for example, has been to keep the invention secret as long as necessary for the industry to mature on the basis of the technology. When the industry is faced with the challenge of changing the technology, the patent is allowed to be issued, and the patent holder is in a position to prevent others from utilizing the invention and to demand royalties from those who began to use the technology while the application was pending (Heinze, 2002). Indeed, in the U.S. it is possible to file continuation applications and to preserve the priority date of the parent application as long as the parent application and the following continuation application disclose the same invention. There are no limitations on how many times a parent application can be continued (Graham & Mowery, 2002). The application period may thus last over a decade, and all this may happen even if the patent has not made any contribution to the development of the technology it covers: if it has been secretly pending for a long time, no-one has had the opportunity to find out about the invention, design alternative technologies, or develop the patented technology further. Thus, the trade-off between the inventor (the right to exclude others) and society (detailed information about the invention), the keystone of the patent system, is not in balance (Soininen, 2005). Figure 1 illustrates the popularity of continuations in relation to software and other patents in the U.S.

It is clear from the statistics in Figure 1 that continuations are filed frequently. Nevertheless, submarine patents as defined earlier are rare. In many cases it is inefficiency in the patent office that causes long delays rather than intentional postponement on the patentee's part (Ferguson,

1999). Nonetheless, Jerome Lemelson's patents in particular, issued after decades of pendency at the patent office, have attracted a lot of public attention (Stroyd, 2000; Varchaver, 2001). Lemelson, who was above all a visionary who anticipated where technology was heading, applied for patents for inventions that he did not himself implement, and amended his applications when necessary to prevent them from being issued. Some of his applications were continued half a dozen times, potentially adding years to the process each time (Varchaver, 2001). He claimed a total of more than 500 patents on basic technologies used nowadays in industrial robots and automated warehouses, as well as in fax machines, VCRs, bar-code scanners, camcorders, and the Sony Walkman. His "machine vision" patent No. 5,283,641 was issued after 42 years of pendency (Stroyd, 2000; Ferguson, 1999; The Lemelson Foundation, n.d.; Soininen, 2005).

Lemelson was active in enforcing his rights. Once someone had developed a product that had some relation to one of his patents, the potential violator was confronted and reasonable compensation was demanded. Aggressive enforcement continues even today, after the death of Lemelson himself. Although quite a few of his patents have been challenged in court, over 750 companies paid royalties for them in 2001 (Soininen, 2005; Stroyd, 2000; Varchaver, 2001). Lemelson is not the only one to have used submarine patenting tactics, however. Another famous example is Gilbert Hyatt, whose patent for a single-chip microcontroller was issued in 1990 after 20 years of pendency. It was successfully challenged by Texas Instruments, but by that time Hyatt had already been able to collect approximately \$70 million in royalties. Submarine patentees also include Olof Soderblom, whose patent for token-ring technology was pending in secrecy in the USPTO for 13 years until it was granted in 1981 (Heinze, 2002). While the application was pending, other companies developed token-ring technologies independently. This development took place in

connection with a public-standard-setting process carried out by the Institute of Electrical and Electronic Engineers (IEEE). Since Soderblom's patent surfaced companies have been forced to pay him more than 100 million dollars in royalties (IPO, n.d; Soininen, 2005).

Legal Changes and the Tactics of Submarine Patenting

Since Lemelson's, Hyatt's, and Soderblom's times the U.S. Congress has taken action and amended patent laws in order to discourage submarine patenting. The change from the 17-year patent term counted from the day of issuance to a 20-year term starting from the application date took place in 1995 in accordance with the GATT agreement (Graham & Mowery, 2002). Consequently, a prolonged application period reduces the life of an issued patent. Another amendment made in 1999 was related to the publication of patent applications within 18 months from filing. Although there are exceptions to this rule, the change has reduced the prospect of surprising an industry before 1999 all patent applications filed in the U.S. remained secret until the patent was issued (Graham & Mowery, 2002; Heinze, 2002; Soininen, 2005). A further modification to the Patents Act that would obligate disclosure of all patent applications within 18 months has also been proposed recently before Congress. The introduced bill, H.R. 2795: Patent reform Act of 2005, is currently in the committee hearing phase (GovTrack.us, n.d.).

Furthermore, the U.S. Court of Appeal for the Federal Circuit held some years ago in the *Symbol Technologies et al. v. Lemelson* case that the equitable doctrine of prosecution laches, which is one of the defenses that can be used in patent infringement cases in order to demonstrate that even though there was a patent infringement, the patent should be held unenforceable, can be applied when the patent is issued following an unreasonable and unexplained delay by the applicant

during the patent prosecution. Here, it does not matter whether the patentee's practice of keeping the application pending for many years has been accomplished strictly in accordance with the rules or not (Calderone & Custer, 2005; Soininen, 2005; *Symbol Technologies Inc. v. Lemelson Medical, Education & Research Foundation*, 277 F.3d 1361, 1363 (Fed. Cir. 2002); *See also Symbol Technologies, Inc et al. v. Lemelson Medical, Education & Research Foundation, LP et al.*, 422 F.3d 1378 (Fed. Cir. 2005)).

Thus, it has been confirmed that the doctrine of laches, a defense based on prolonged patent application period, can sometimes be used for protecting an infringer from the harmful effects of submarine patents. Moreover, it is not only after the patent has been granted that the doctrine of prosecution laches can be applied. The Federal Circuit made it clear in the *In re Bogese* case that it is possible for the USPTO to address the issue before the patent is granted, and to reject it on this basis (*In re Bogese II*, 303 F.3d 1362, 1367 (Fed. Cir. 2002)). As far as Europe is concerned, patent applications have traditionally been automatically published within 18 months from filing, and the 20-year patent term has begun from the filing date. Moreover, although it is possible to file divisional applications, continuations are not allowed (Graham & Mowery, 2002; Soininen, 2005).

Submarine Patents Today

If submarine patents are defined narrowly as meaning patents issued after a long, intentionally delayed, secret pendency at the patent office, they do not seem to exist. Nonetheless, despite the legal amendments, circumstances in which patent applications are concealed long enough for the industry to start using a technology without knowing about the lurking patent arise particularly in fields characterized by fast technological development. In some parts of the ICT industry, for example, 18 months of secrecy may already be too long, and prolonging the application phase intentionally

is not required for achieving the intended result (Soininen, 2005). Furthermore, patent applicants filing only in the U.S. may currently opt out of the 18-month publication rule and file continuations in order to detect industry developments and to postpone the grant of the patent for five years or so. Since the U.S. is a large and relatively lucrative market, particularly in the computer and software sector (Mueller, 2001), many companies do not even seek international patent protection. Also, provided that the numbers of filed ICT patent applications and granted patents continue their upward trend (OECD, 2005; OECD, 2004), it is getting more and more difficult to be aware of all relevant patents and applications. Especially if inventions are systemic, and innovation is fast and cumulative, multiple patented or patentable inventions may be incorporated into one innovation (Bessen, 2003; FTC, 2003), and therefore infringement is not merely a coincidence that can be avoided but is likely no matter how well the patents and pending patent applications are screened (Interview data U.S., 2004; Watts & Baigent, 2002). For this reason, published patent applications and granted patents may, in reality, be hidden (Soininen, 2005).

Another issue that has to be taken into account is that the scope of a patent typically changes during prosecution. Patent examiners often come up with patentability bars during examination, and require that the scope is limited in some way. Furthermore, as mentioned, the applicant may be able to add and amend patent claims during prosecution so that the scope will better reflect developments in the industry. Here the original application sets the limits for such changes, as its claims must support the new claim and no new matter can be included (EPC, Art 123; Mueller, 2001). As a consequence, although patent application might have been deemed non-essential at the time it was first published, the situation may change before it is granted. Certainly, one element of surprise relates to claim interpretation. Although a patent is a relatively well-defined right,

the boundaries are never exact. The scope is not clear until it has been tested in court.

The concept of the submarine patent is understood in this article as broadly referring to patent applications and patents that surface after the standard has been established and take the industry by surprise. Here it does not matter, whether the patent application has been secretly pending or not, even though this possibility certainly contributes to the problem.

Tensions between patents and standards are examined in the following, and the problem of submarine patents and its causes are identified and exemplified further. ICT companies patent strategies and technology-licensing practices are analyzed briefly at first in order to place the dilemmas between patents and standards into a broader context and to find those practical elements that may contribute to them.

PATENT STRATEGIES AND TECHNOLOGY LICENSING PRACTICES IN THE ICT SECTOR

General Developments

With the shift from an industrial economy toward an information economy, the importance of intellectual property rights (IPRs) has increased. Today, a large proportion of companies' assets constitute intangibles, and IPRs are used to protect and profit from certain of these. Patents, for instance, provide their holders with the right to forbid others from utilizing patented inventions. Holders may thus gain competitive advantage due to their ability to stand out from the competition, or they may use their position to choose their licensees, which is one of their core rights due to the exhaustion doctrine (Kipnis, 2000). Then again, if the patent holder issues a license, as a rule he is entitled to secure any monetary or other compensation he is able to extract from the licensee (Shurmer & Lea, 1995) as long as the licensing

terms are coherent with relevant regulation. The objective of licensing is to generate more revenue for the undertaking than it would be able to produce if it manufactured the patented products or utilized patented methods only by itself. Indeed, a well-reasoned licensing program helps a company to position itself favorably in the market place (Megantz, 2002; Soininen, 2005).

Obviously, there are differences between industries with respect to licensing tendencies, but generally speaking, the markets for technology licensing the component of which patents have grown. In fact, in a survey conducted by the OECD/BIAC, 60% of the responding companies reported increased inward and outward licensing, and 40% reported increased cross-licensing. Other types of knowledge sharing have become more common too, and collaboration takes place in the form of sponsored and collaborative research, strategic alliances, as well as in mergers and acquisitions. This has been said to stem from the growing technological complexity, increased technological opportunities, rapid technological change, intense competition, and the higher costs and risks of innovation. As a consequence, companies have namely become more focused on certain areas while they acquire complementary technologies increasingly from other undertakings and universities (OECD, 2004).

The features mentioned previously apply also to the ICT sector, and companies lean heavily on cooperation and networks. Contemporary academic literature refers to this type of innovation as the open innovation model, in contrast to the closed model that used to dominate. Companies applying the closed model seek ultimate control and do everything themselves, while those adopting open innovation realize that valuable ideas do not only originate within their firms, and that it does not have to be the company itself that releases these ideas in the market. Whereas making innovation proprietary and exclusive is a central feature of the closed innovation model, open innovation is characterized by the exploitation of intellectual

property in order to create value. The boundary between the company and its environment is said to have become more permeable, enabling ideas and knowledge to flow more freely (Chesbrough, 2003).

One further characteristic of the competitive environment of the ICT sector is so-called co-competition that was pointed out by one of the U.S. interviewees. Co-competition basically means that companies may very well be business partners in some fields and compete aggressively in others (Interview data U.S., 2004). Naturally, all the elements mentioned before signaling the importance of networks, openness in innovation, and co-competition are reflected in ICT firms' patenting practices, the use of patents in their business, enforcement and infringement avoidance. Furthermore they affect the technology licensing tendencies and licensing terms. Similarly it is possible to detect their implications on standardization and also on settling of disputes as some of the example cases discussed later on demonstrate.

The U.S. Patent Landscape

The patent landscape of the U.S. ICT sector could be described as a thicket to the birth of which strong patent system, technological complexity and fast technological development have contributed. Thus, although a reading of the patent laws gives the impression that there is a correspondence between a product and a patent, this is not necessarily the case: patents may overlap, and the manufacture of one product may require access to hundreds or thousands of patents, or one patent may "read on" many types of products, not just one (FTC, 2003). Therefore, in order to avoid the resulting hold-up problem, many U.S. ICT companies employ defensive patent strategies, and if they have the resources to do so they build large patent portfolios in order to guarantee that others cannot prohibit them from innovating. This in turn increases the number of relevant patents in the industry. Naturally, in addition to the better

negotiation position and increased ability to agree on the licensing and cross-licensing they facilitate, patents also provide the means to prevent outright imitation in these cases (FTC, 2003; Interview data U.S., 2004; Soininen, 2005).

In general, the significance of patents as protection mechanisms used to exclude others and thus to generate competitive advantage appears not to be very high in the ICT field, and it is rather competition that spurs innovation in this sector (FTC, 2003). This was reflected in the patent-enforcement activities of the U.S. companies that were interviewed, and which operated on the basis of a defensive patent strategy. Unlike the company that employed an offensive patent strategy and attempted to generate its revenues from technology and patent licensing, defensively operating firms focused more on their core businesses of making and selling products rather than devoting resources to detecting infringements (Interview data U.S., 2004). Similarly, Messerschmitt and Szyperski (2003) have observed that the exclusionary use of patents is less common in the software industry than in some other industries such as biotechnology and pharmaceuticals. In their opinion this is in part because patents tend to be less fundamental and they can be circumvented easily. Furthermore, according to a quantitative study of U.S. manufacturing firms conducted by Cohen, Nelson, and Walsh (2000), compared to other appropriability mechanisms such as secrecy, other legal tools, lead time, complementary sales, services and manufacturing, patents ranked rather low in effectiveness in fields such as the manufacture of electrical equipment and electronic components, semiconductors and communications equipment, all of which are connected to the ICT sector. Moreover, there were substantial variations between industries: patents appeared to be most important in the chemical industry. This does not mean that they are not acquired for other purposes, such as those indicated earlier, and naturally all of their functions are based on the patent holder's ability to prevent others from utilizing the invention.

Since many ICT companies are dependent on one another as indicated earlier and patents are not vital for protection, they generally have no reason to complicate their business relationships by claiming patent infringement. However, while particularly large U.S. ICT firms seem to be aggressive in building patent portfolios mainly for defensive purposes, offensive patent strategies tend to predominate for individuals and small software companies (Messerschmitt & Szyperski, 2003). Indeed, various sources have reported an increase in companies that derive their revenue purely from patents. These companies, also called patent trolls, do not typically have any R&D of their own, nor do they manufacture any products themselves: unlike most ICT companies therefore, they are not dependent on other firms. Their business is to force companies involved in manufacturing to license their patents by claiming patent infringement (FTC, 2003; Interview data U.S., 2004; Peterson, 2002b; Surowiecki, 2006). Patent trolls seek for direct licensing revenues and do not usually benefit from a cross-license. Therefore a defensive patent strategy that might otherwise help certain ICT companies to maintain their freedom-to-operate, and that has proven successful also in the context of standards as will be illustrated later has only minimal influence on them.

It is not only patent trolls that seek to make better use of their patent portfolios, however. The prevailing trend in the U.S. has been to found patent-licensing programs, sometimes by forming a separate patent-licensing unit, for the purpose of generating extra revenues mainly from inventions that are not considered core to the company's main operations (Rivette & Kline, 2000). This trend is likely to have an effect also on standardization as standards are becoming more and more vital for the ICT industry and thus they also carry a lot of economic significance. Consequently, having a patent that claims a broadly adopted standard may be a dream come true for a company seeking licensing revenues and not operating in that particular technology area.

Basically, patents are viewed as core elements of corporate business strategies in the U.S. ICT sector. They are employed for multiple purposes in different contexts. They may be used as protection measures and as components in joint ventures, in patent pools, and technology licensing arrangements. A license may also be a pure patent license or a broad cross-license providing a company with not-to-sue coverage. Furthermore, patents may be used to attract other types of resources to the company. They serve as indicators of innovativeness, and can be helpful in attracting financing: they can be used as collateral and are seen as a positive indication in the eyes of venture-capital investors and potential buyers. In fact, one trend that is detectable in the U.S. is the increased tendency of selling and buying patent portfolios and individual patents (FTC, 2003; Interview data U.S., 2004). This may happen in conjunction with the acquisition of an entire company, or patents may be bought from bankrupt firms. This follows that it is not easy to avoid patent infringement as patents may easily find their way to unknown parties meaning that a notification of potential patent infringement may practically come from anyone.

There is one further feature about the U.S. patent landscape that should be noted. It has been claimed that a substantive number of patents are being granted particularly in new areas such as software and the Internet that do not actually fulfill the patentability requirements. These so-called bad patents have contributed to various patent-related difficulties and they have been deemed to be one of the main reasons why the U.S. patent system is not in balance (FTC, 2003).

The European Patent Landscape

So far Europe has not faced patent trolling on a large scale, which could be explained by the fact that the consequences of litigation and infringement are less severe: while the average cost of patent litigation in the U.S. amounts to more than \$2 million per side (Vermont, 2002), in Finland

the figure for hearing an infringement the case in the district court is closer to EUR 150 000 per side. Of course the total amount of litigation costs may be fundamentally higher if the case involves various phases such as a precautionary measure claim, and both infringement and annulment actions. Moreover, the damages issued are substantial in the U.S. For instance, in 1990 the Federal District Court awarded \$910 million in damages to Polaroid in its patent-infringement litigation against Kodak, Alpex Computers was awarded \$260 million for patent infringement (litigation against Nintendo) in 1994, and in 2003 Microsoft was forced to pay Eolas \$521 million for infringement of an Internet browser patent (PwC Advisory, 2006). By way of comparison, the largest amount of damages ever awarded in Finland was EUR 252,282 (Labsystems Oy v. Biohit Oy, HO S 94/1922, Court of Appeal).

Furthermore, the patent web in the ICT sector appears to be less complex in Europe than in the U.S., although there are certainly variations between different technology areas. For instance, the European mobile-phone industry and the electronics field are areas in which large patent portfolios are common (OECD, 2004; Watts & Baigent, 2002). However, with the exception of the large telecommunications and electronics companies, patents seem to be regarded not so much as strategic assets, but rather as legal tools applied and used for protecting the results of the company's own R&D efforts, and occasionally for licensing (DLA, 2004; Interview data Finland, 2003).

It was evident, for instance, from the interviews with the Finnish companies that were not involved in the mobile-phone area as manufacturers, and had less than 70 issued patent families, that small-scale portfolio building was the preferred strategy for avoiding otherwise weak patent protection. There were no cross-licenses, however, and the companies appeared to be able to operate freely without paying much attention to the patents of others (Interview data Finland, 2003). In general, the

patent application part of the patent strategy was well thought out, although it should be noted that the process was technology-oriented and lacked the type of business acumen that was present in the U.S. (Interview data Finland, 2003). In fact, this is a conclusion that has been shared also by others. For instance Kratzman (2005) pointed out in his research:

Finnish patents tend to be academic and not written to generate revenue. They are not commercial nor do they cover multiple applications, an essential element in generating licensing interest. (p. 14)

With respect to the utilization of the patents in the company's business transactions and the infringement surveillance, they could be described as incidental, perhaps because patents were not regarded as important contributors to the company's revenue stream, and most Finnish companies had so few of them. Lead time, constant innovation and, in the area of software, copyright protection, were considered more important (Interview data Finland, 2003). Furthermore, attitudes towards patents appear to be largely negative, even indifferent, in the software industry in particular (Interview data Finland, 2003), which, based on Blind et al. (2001), applies not only to Finland but also to the rest of the Europe as far as independent software developers are concerned. It should be noted, though, that even small and medium-sized companies are beginning to realize the importance of strategic patent management, perhaps partially as a response to the attention paid to patents by investors. Generally speaking, there is a steady increase in the propensity of filing patents in the European ICT sector (OECD, 2005), which in turn will probably increase the likelihood of patent-based conflicts, and make it more difficult to design around the patents when selecting a standard, for instance. Currently, however, European companies appear not to be employing their patents as aggressively as U.S. undertakings and therefore there is a chance that

even though European companies had patents that could be characterized as submarines, this would not create substantial hindrances to the industry. On the other hand, markets for technology are international and as the case with GSM standard that will be discussed in the licensing section of this article illustrates, also patent strategies of U.S. companies tend to influence European standardization efforts.

Licensing Practices in the ICT Sector

As regards to companies licensing practices, some companies tend to be more open in their operations than others. Usually it is rather easy to outsource the manufacturing of products, their distribution and marketing, but it is the development that R&D-intensive companies prefer to keep to themselves. This could be detected in the technology-licensing practices of the U.S. ICT companies, which, given the reported increase of 4000% in licensing revenues from 1980 to 1990 (Vermont, 2002) and the recent fascination surrounding the success of open-source software licensing, were surprisingly closed, particularly in terms of licensing in external technologies.

One of the interviewees explained the situation by saying that it was difficult to find useful technologies, and counting on outside technologies was usually considered risky due to potential problems with third-party rights and quality issues, for example. In-house R&D was simply trusted more. When companies did rely on external technologies, they rather acquired the entire company than licensed-in the technology. If they did license-in it was largely limited to non-core elements and design tools. As for licensing-in open-source software, the companies were very careful, and typically had tools in place to make sure that they audited what came in (Interview data U.S., 2004).

When it comes to licensing out their technologies interviewed companies tended to be more open, and there was one company whose business

model was based mainly on this. Furthermore, licensing out was used in order to integrate in-house technologies into other companies' products and to make them compatible so that the market for that technology would expand. The licensing models adopted in the interviewed software companies were basically very broad for distribution purposes, and they licensed software to their customers as a package and to other companies to be used as embedded in their products. However, with the exception of commonly established standards, other types of technology licensing that did not involve a complete product were limited (Interview data U.S., 2004).

The licensing terms companies follow naturally vary depending on the subject matter, the business model adopted for the particular product or technology, and the parties involved. Nevertheless, there are certain typical configurations that reflect the extent of control the licensor or the licensee has. The scope of the license is paramount: the licensor retains more control over the technology if he or she grants only non-exclusive rights, which appears to be the most common form in the ICT sector. The possibility to define the degree of exclusivity, for example, in terms of geographic areas or certain uses, and the ability to assign and sublicense the rights are other key elements in determining the scope of a license (Poltorak & Lerner, 2004). Incorporating technical assistance also gives the licensor control over the licensed technology. In the case of trademarks in particular, the licensor has good reason to control the quality of the licensed products, and to put in place certain procedures for testing them and inspecting the licensee's production facilities (Megatz, 2002). It is also advisable to include a termination clause to enable either party to get out of the contractual relationship if necessary. One of the most intriguing termination clauses that reflects the atmosphere in the ICT industry relates to patent peace: such clauses are frequently used in open-source licenses, for instance, and in their broadest form they provide the licensor with

the right to terminate the license in the face of claims by the licensee regarding infringement on any of its patents. Representations, warranties, and indemnification clauses related to risk allocation, as well as royalty rates, also affect the balance of the contractual relationship.

Most importantly, however, attention needs to focus on terms relating to modifications, improvements, and therefore also grant-backs. From the licensor's perspective, it is often advantageous to obtain the rights to any improvements developed by the licensee, preferably including the right to sublicense the improvements to other licensees. This would prevent the licensee from using a fundamental improvement or an extensive new development to gain control over the licensor's core technology. Then again, access to improvements developed by the licensor is important for the licensee in ensuring the continued viability of the licensed product or technology (Megantz, 2002).

Some of the companies interviewed had adopted a very restrictive approach to modifications, allowing them only rarely and even then often requiring grant-back terms. Control was maintained through the heavy involvement of the licensor's engineers in the implementation phase, and through quality control. The licensor also typically maintained the right to modify the license terms. Then again, in the context of software licenses, the licensees had very few rights, the source code was seldom provided, and reverse engineering was typically prohibited. Obviously, this depended on whether it was an end-user license, an OEM agreement or a VAP bundle agreement. On the other hand, some companies had adopted a more open approach and operated on a more flexible and market-driven basis. Interfaces were opened up, for instance, and one of the companies even licensed out its software under various open-source agreements (Interview data U.S., 2004).

It could be concluded from previous discussion that R&D intensive ICT companies have rather

control-seeking licensing models, but they may be flexible too if it suits the company's business model. Thus, since standards are of crucial importance in this industry, exceptions are often made for the essential purpose of securing product compatibility, interoperability and interconnection (Interview data U.S., 2004). In fact, since many companies may be developing equipment or software for the same systems and platforms, for example, and there are inevitably huge numbers of relevant patents involved (Watts & Baigent, 2002), standardization may prove effective in providing access to essential patents held by various firms. On the other hand, it must be remembered that companies' prevailing licensing practices tend to show also in the standard-setting context, and although the patent policies of standards organizations typically give specified options to the patent holder, different licensing terms can be used to maintain control over the technology as indicated already in the background section of this article. Furthermore, it is only the essential patents need to be licensed when a company participates in setting a standard. As one of the interviewees pointed out, this constitutes a fairly thin layer. Only patents that are technically or commercially necessary to ensure compliance with the standard must be licensed, and only to the extent that it is necessary. Therefore, if the patent holder has waived its rights, for instance, patents cannot be asserted for complying with the standard, but they can be asserted if something extra is being done (Interview data U.S., 2004). Then again those companies that do not benefit from a common standard or are after royalties have generally no interest in taking part in standard setting because doing so could require the licensing of their rights under royalty-free or RAND terms.

The licensing quandaries will be discussed later on, and I will now turn to a more detailed analysis of the submarine patent risk stemming from deficient identification of essential patents to which some of the factors presented in this and the earlier section clearly contribute. Generally

speaking the highlighted importance of intellectual property rights and their substantial role as part of companies' business strategies has made it more difficult to avoid conflicts of interests.

STANDARDIZATION AND SUBMARINE PATENTS

Both patents providing their holders with exclusive rights, and open standards expected to be widely promulgated without exclusive control are important to the ICT sector. As they both want different things resolution is not always easy (Cunningham, 2005). From the perspective of this article the core element contributing to the tension between patents and standards, is that it is not always known in advance whether undertakings have patents or pending patent applications that might cover the standards technology. This complicates matters, since patents that surface after the adoption of the standard may, in the worst case, result in no other choice than abandoning it. Although both licensing and patent identification quandaries that were introduced briefly already in the background section may lead to significant economic losses, it is more difficult to anticipate the consequences and to avoid problems in the latter case. Therefore, submarine patents that surface after a standard has been elected and adopted are not only a practical dilemma but also a policy concern. Submarine patents may face the industry with unpredictable predicaments, and ultimately harm consumers. Cases in which unidentified patents of standard setters have caused concern and resulted in legal disputes include Dell and Rambus litigations. Third-party submarines contain the patents of Forgent Networks, Inc and Eolas Technologies, Inc among others.

The most effective way to reduce the possibility of hidden patents that have the potential to cause complications with respect to the adoption of a standard is to conduct a proper patent due diligence periodically and to agree upon the

contravening issues beforehand. This is where the patent policies of standards organizations that are aimed at creating shared expectations among standardization participants with respect to licensing and disclosure rules come to the fore (Interview data U.S., 2004; Ohana, 2005). Indeed, if companies participate in setting a standard they usually do their best to follow the standardization organization's patent policies, and consider any deviation unethical (Interview data U.S., 2004; Ohana, 2005). Sometimes the rules are simply not very transparent, and since different standardization organizations have different types of policies it may be burdensome to be aware of and to comply with them all, particularly if the company is involved in many standards organizations. In fact, about 40% of companies in Blind et al. (2002) sample group reported that they had problems due to the unclear IPR structure, resulting, for instance, in the late identification of the patent holders. There is a need for rules that hold as few surprises as possible (Interview data U.S., 2004; Ohana, 2005).

The standards organization's patent policies and their shortcomings with respect to the disclosure obligation are examined in subsequent paragraphs. Since companies adopting the standard ultimately bear the responsibility for patent infringement, there is then a brief glimpse into that part of companies' patent strategies that is aimed at reducing that risk. Combined with what has been said earlier about the patent system and the patent landscape in the ICT sector, these sections constitute the analysis of the causes contributing to the likelihood of infringing others' essential patents in the ICT sector and the challenges companies face in settling these disputes particularly due to the emergence of so-called patent trolls. Case studies illustrate the situation further and give examples of actualized disagreements. The fact that many disputes have been handled in court demonstrates that it has not been possible to settle the issues amicably and that there are significant economic interests involved.

Patent Policies

Many, although not all, standards bodies that are responsible or involved in coordinating the development of standards have implemented explicit IPR or patent policies for handling issues to do with standardization and patents. These policies aim at discouraging the manipulation of the process in order to gain market power, and at easing the tension between the open nature of standards and the proprietary nature of IPRs (Feldman & Rees, 2000; Kipnis, 2000; Soininen, 2005). The policies guide the participant's behavior, and from the legal point of view their nature and content affect the determination of whether a company participating in standard setting and failing to disclose its relevant rights has breached a contract, defrauded, competed unfairly or deceptively or abused its dominant position, for example. Therefore, if the patent policy is deficient, it is difficult to challenge the patent holder's right to prevent all others from using his invention, discriminate among licensees or to condition the license however he wants to as long as this is done in accordance with relevant laws. In the following attention is paid to the nature, extent, scope and timeframe of the prevailing disclosure obligations of different organizations such as ITU, ANSI, ETSI, W3C, OASIS, and IETF and their ability to reduce the risk of submarine patents is assessed.

Nature of the Policy

It has been argued that without legally binding policies standards could easily become the subject of "hold-up" because once a standard has been established, all the patents necessary to comply with it become truly essential. The more widely the standard is adopted, the more power the patent holders gain (Shapiro, 2001). Nonetheless, not all standards organizations aspire to control their participants through imposing on them explicit contractual obligations, and many use their policies more as a "code of practice" (e.g., ITU-T

Patent Policy, n.d.). ANSI, for example, has taken the position that it does not mandate disclosure or impose licensing obligations on patent holders because this would overburden the process. It relies more on its participants to voluntarily act in accordance with the policy. Nevertheless, according to Marasco (2003) it has not so far faced abuse of the process. Actually, even though the guideline-nature of the disclosure requirement may narrow down the possibilities to enforce it in court and to claim damages in case of an infringement, non-obligatory rules may also bear significance when it is determined whether a certain participant has operated in good faith under some other principle of law, such as Federal Trade Commission Act, Section 5 that prohibits unfair and deceptive business practices. The case studies of Dell and Rambus examined later will demonstrate this issue further.

The Duty to Disclose

The patent policies of standardization organizations differ in their approach to disclosure in terms of duty to disclose, the scope of the disclosure and its timing. For the most part, they tend to rely on their participants (submitters or members [Perens, n.d.]) to voluntarily disclose all patents that could influence the standard. This is by no means a simple task, and failing to disclose patents that are essential for using the standard may happen by accident. Searching the portfolio is time-consuming and expensive, and therefore companies may not want to make the expense of searching them. Also, it is not always easy to recognize all essential patents and patent applications. This follows that particularly in big companies with large portfolios a company's representative in a standard-setting process may not know whether a proposed standard incorporates a patent within his company's portfolio (Kipnis, 2000; Peterson, 2002b; Soininen, 2005).

It is probably for this reason that standards organizations generally take no responsibility

for finding all relevant IPRs, or for verifying the information disclosed by the contributors (e.g., ANSI, 2003b; IETF, 2005; OASIS, 2005), and they are not keen on imposing such obligations on their participants. Thus, many of them do not require disclosure that goes beyond the personal knowledge of the discloser (e.g., IETF, 2005; OASIS, 2005), nor do they require their participants to carry out patent searches (e.g., ANSI, 2005a; ETSI, 2005; ITU-T, 2005; OASIS, 2005; W3C, 2004), which in turn increases the probability that relevant patents remain undisclosed (Soininen, 2005).

Scope of the Disclosure Requirement

Another contributing factor to the submarine patent risk is that it is not necessarily required for companies to disclose their pending, particularly unpublished, patent applications (e.g., ANSI, 2003b; ANSI, 2003a; Kipnis, 2000; Lemley, 2002). The W3C disclosure requirement is an exception, however. It also extends to the unpublished patent claims that were developed based on information from a W3C Working Group or W3C document (W3C, 2004). The OASIS policy also requires the disclosure of all patents and/or patent applications known to the technical committee member (OASIS, 2005). The problem with announcing pending patents is that, although the protection provided by a patent is always unclear until confirmed in court, the scope is even more ambiguous until the patent is issued, and it is therefore not possible to assess whether it will be essential in order to use the technology. It is also possible that it will never be granted. The problem is, however, that if there is no obligation to disclose pending patent applications, waiting until the standard has been agreed upon before allowing the patent to be issued does not constitute a policy breach. In fact, given the need to make informative decisions about standard “characteristics,” there has been discussion on whether participants should also be obliged to disclose their potential patenting

activity. The U.S. patent system includes a so-called grace period, which allows the inventor to file for a patent up to one year after disclosing it in a printed publication. Thus, it is possible for a company that has submitted a technical proposal to the standards body to then file for a patent covering it after the standard has been elected.

Opinions on the scope of the disclosure obligation are divided. Some people feel that, although companies were required to state their possible interest in patenting their technology, it is never certain that they will apply these patents in reality, or that they will be granted or even essential. On the one hand, if companies had to announce their potential pending patents, other committee members could take them into account when decisions about standardized technology were made (Kipnis, 2000). At the same time, there might be a risk of “sham” announcements in these cases (Soininen, 2005).

Timing of the Disclosure

The timeframe of the disclosure requirement also bears significance in respect to the causes of the submarine patent problem. Since standardization may be valid for years and companies’ R&D development is definitely not frozen during that time, it is likely that pending patent applications will be modified and new applications filed during the process. Therefore, although a company may have no pending patent applications or granted patents at the beginning, it might have them when the standard is finally set. For this reason, some standards bodies, such as W3C, have patent policies that incorporate an obligation to disclose essential patents throughout the entire process (W3C, 2004). The ETSI IPR Policy also requires each member to make reasonable efforts to inform the ETSI in good time about any essential patents, both its own and third-party, of which it becomes aware at any stage (ETSI, 2005). Then again, the IETF policy encourages contributors to update their disclosures if the claims are modified, or if a patent is granted or abandoned (IETF, 2005).

Third-Party Patents

Standards organizations patent policies can never bind third parties and even though some patent policies do encourage also other interested parties as well as contributors to bring attention to potential third-party patents (e.g., IETF, 2005; ITU-T, n.d.; ITU-T, 2005; OASIS, 2005), this is not enough to record all of them. One option to increase the awareness of third-party rights would be to conduct a patent search. Standards bodies are not typically involved in such an activity, however (e.g., IETF, 2005; OASIS, 2005). On the other hand, ETSI is now considering an *ex ante* approach to declaring relevant patents with respect to the Long-term Evolution (LTE) standard (Informamedia.com, 2006). This would at least diminish the likelihood that new essential patents emerge after the standard has been elected and it remains to be seen whether this approach will be adopted on a broader scale.

It could be concluded that patent policies are helpful in reducing particularly the risk of standard setters' submarine patents and even though they could be strengthened in many ways to narrow down the possibility of manipulating the process in order to gain market power, some of the difficulties are mainly practical. Therefore it might not be possible to avoid them even if companies were posed an obligation to disclose their potential patenting activity, for instance. The only effect of doing so could be that companies are discouraged from participating which in turn would increase the risk that patents remain undisclosed and generate problems at a later stage.

Patent Strategies to Avoid Infringement

There may be a room for improvement in standards bodies patent policies but it is not only loopholes in them but also deficiencies in companies' own patent strategies that contribute to the fact that relevant rights may remain unnoticed and standard

adopters may face predicaments due to them. Obviously, it is the company incorporating a standard into its products and services that ultimately bears the risk of infringing others' patents, and therefore identifying relevant rights is not by any means only the responsibility of standards organizations. Indeed, in addition to enhancing a company's own patenting, licensing and enforcement activities, a proficient patent strategy also helps in avoiding patent infringements.

A major goal in managing corporate patent liability is to avoid being sued and paying substantial royalties to other patent holders. What is even more important is to avoid being prevented from using a particular technology, which could force the company out of a lucrative market (Miele, 2000). Furthermore, the costs of patent litigation, particularly in the U.S., could be substantial and a drain on financial and human resources (Knight, 2001). Thus, if it is necessary to prevent significant liability, the company should consider refraining from using technology that infringes others' rights. In some cases this is not possible, and the company has to employ such technology that has been patented by others in order to operate in a particular market. Keeping both situations in mind, there are certain steps that could be taken in order to reduce the liability, the likelihood that patent holders will assert their rights against the company, and the amount of royalties that should be paid in cases in which patent liability cannot be avoided (Miele, 2000). One of these steps includes identifying patent problems early in the product cycles. For instance, a freedom-to-operate search conducted on the basis of patent classification numbers and certain keywords might be useful for identifying close references, which could then be examined in more detail (Knight, 2001) before the product is released onto the market. Another step is to monitor the patent activities of the company's closest and biggest competitors because companies are often particularly sensitive to infringing activities that originate from their competitors (Miele, 2000).

In practice avoiding infringements is not that easy and companies' patent strategies are not flawless. No patent search is or can be 100% thorough (Knight, 2001), and as many Finnish interviewees mentioned, it may be difficult to identify relevant rights and to make sense of the scope of patent rights (Interview data Finland, 2003). Sometimes, a company may not even have any specialized infringement surveillance. Indeed, in Finnish companies infringement checkpoints were rarely incorporated into R&D projects. This does not indicate, however, that there was no knowledge whatsoever about the patent landscape: information regarding other companies' patent position can be obtained as a side product when the company is considering patenting its own inventions and conducts prior art searches for that purpose (Interview data Finland, 2003). As far as the U.S. companies were concerned, the extent of due diligence with regard to others patents varied depending on the situation: some technology areas were more important, and some were known to be more heavily patented than others, thus requiring more thorough clarification. Nevertheless, these companies typically did not have any systematic patent clearance (Interview data U.S., 2004).

A further risk-reducing alternative to freedom-to-operate analysis and other types of patent surveillance is to use the porcupine approach discussed earlier in the section on patent strategy in the ICT sector. This means that a company builds a defensive patent portfolio aimed at reducing potential infringement allocations and making settlement easier. It may also have broad cross-licenses in place, thereby removing a huge block of patents from its surveillance list (Interview data Finland, 2003; Interview data U.S., 2004). This is a strategy that has been favored by large U.S. and multinational Finnish ICT companies, but unfortunately it does not work well against individual patent holders or so-called patent trolling companies. The fact that patents are being assigned more than before, further increases the

risk that they find their way to such parties that do not come up in competitor surveillance and remain unnoticed for that reason.

In sum, companies may take certain precautions to prevent patent liability, but even if they do, the risk of patent infringement remains particularly high in areas in which it is simply not possible to keep track of new filed applications and issued patents. As one of the U.S. interviewees stated, there is always a risk that others' patents will read on your product. You can do all the clearance work and look at all the patents that are out there, but the next week a new patent may be granted (Interview data U.S., 2004). Nevertheless, there are many improvements that could be made in order to strengthen the infringement surveillance, and instead of fighting only their own battles during the standard-adoption phase, companies could pool their expertise and resources and help to limit the submarine patent risk already before the standard is established.

Case Studies of Standard-Setters' Submarine Patents

Standards organizations' IPR policies related to disclosure do not cover every situation, which is understandable, since weight must also be given to the flexibility of the process. Also the means ICT companies have currently implemented in order to avoid infringement of other companies' patents do not help much in identifying relevant rights. The unfortunate consequences are that despite the efforts there still is a high risk that patents surface after the establishment of the standard, and these (essential) patents are much more valuable than they would have been previously: it gets more difficult to change the specification as time passes and the technology becomes adopted. Therefore, particularly if they are not breaching IPR policy, some patent holders may seize the opportunity and seek to hide the fact that they have essential patents, or pending applications—otherwise the standard could be modified so that it no longer covers them.

The problem with standard-setters' submarine patents is not only theoretical, because the risk has actualized also in reality. Cases that have involved undisclosed patenting activities and have resulted in legal disputes include Dell, Rambus and Unocal from which Dell and Rambus cases are discussed in the following. These examples demonstrate further the importance and role of a proficient patent policy since it does not merely help to reduce the submarine patent risk beforehand but it also influences the possibilities to solve the problem later on. The previously-mentioned example cases indicate, for instance, that competition authorities do not take misbehavior during standard setting lightly and are keen on examining doubtful situations even though the merits of the case may not be sufficient in order to find fault from the defendant's side. In the end the result is dependent on the wording of the policy and proof of misbehavior. In a way legal tools that are available provide the last means to solve actualized conflicts. Luckily, litigation is not always needed. For instance IBM's behavior in relation to ebXML standard implies that consequences of the failure to disclose are not always detrimental. Since many ICT companies are largely dependent on one another it may be possible to reach an amicable solution rather easily in some situations.

Federal Trade Commission v. Dell Computer Corp. (1995)

In the Dell (1995) case the Federal Trade Commission (FTC) accused Dell Computer Corporation, on the basis of Section 5 of the FTC Act which prohibits unfair or deceptive business practices, of intentionally concealing its patent during the Video Electronics Standards Association (VESA) VL-bus technology standardization process. Although VESA's IPR policy required that its members disclose any potentially conflicting patents, Dell certified that it did not have such patents. After the standard had been widely ad-

opted in the marketplace, Dell sought to enforce its patent against VESA members. The Commission found that even if Dell's actions were not strictly speaking intentional, the company had failed to act in good faith. It also stated that had Dell disclosed its patents properly, VESA would have incorporated different technology into the standard. Dell's misrepresentation therefore caused restraints on competition resulting in the hindrance of industry acceptance and increased costs in terms of implementing the bus design (Federal Trade Commission v. Dell Computer Corp., FTC File No. 931 0097 (2 November 1995)) (Soininen, 2005).

In the end, a consent decree was agreed upon and Dell promised not to assert its patents against computer manufacturers that complied with the standard (Balto & Wolman, 2003; Hemphill, 2005; Lemley, 2002). It should be noted, however, that even though a satisfactory result was reached through a settlement the case was not decided in court leaving the industry with ambivalence about the proper interpretation. In fact, the Rambus litigation discussed later indicates that the conclusion could have been different if the case had been litigated further.

Rambus, Inc v. Infineon Technologies AG (Fed. Cir. 2003) and Federal Trade Commission v. Rambus, Inc

Rambus has faced two litigations due to its actions in the Joint Electronics Devices Engineering Council (JEDEC). The first one, Rambus, Inc v. Infineon Technologies AG (2003), arose when Rambus sued Infineon for synchronous dynamic random access memory (SDRAM) patent infringement. Infineon counter-claimed that Rambus had defrauded it when it failed to disclose patents and pending patent applications during its membership of JEDEC and while JEDEC was developing the industry standard for SDRAM. More specifically, Rambus had filed for a patent '898 for Rambus DRAM technology

in 1990, it cooperated in forming the standard from 1992 until 1996 when it resigned from the standards body just before the final vote, and both during and after its participation it had filed continuation and multiple divisional applications based on the original 898 application, and by doing so it amended its patent protection to cover the SDRAM technology. Later, it allowed these patents to be issued, and began to defend its own patents aggressively, requiring companies to pay royalties. Nonetheless, the Federal Circuit came to the conclusion that Rambus had not fraudulently failed to disclose its patent applications, but held that its duty to disclose as a JEDEC participant applied only to those containing claims that could reasonably be considered necessary in order to practice the proposed standard, and that this obligation arose only when the work had formally begun. The court held further that the duty to disclose did not cover the participant's future plans or intentions, that is, filing or amending patent applications, and criticized JEDEC's patent policy for its staggering lack of defining details. It thereby left its members with vaguely defined expectations as to what they believed the policy required. (*Rambus, Inc v. Infineon Technologies AG*, No. 01-1449 [Fed. Cir. 2003]; Soininen, 2005).

The second litigation, *FTC v. Rambus, Inc* was based on Section 5 of the FTC Act, and it is still pending. The FTC has accused Rambus of a series of anti-competitive acts and practices, claiming that through deliberate and intentional means it has illegally monopolized, attempted to monopolize, or otherwise engaged in unfair methods of competition in certain markets related to the technological features necessary for the design and manufacture of a common form of digital computer memory. It further claims that Rambus's anti-competitive behavior has, among other things, increased the royalties associated with the manufacture, sale, or use of synchronous DRAM technology, and has reduced the incentive to produce memory using it and to participate in

JEDEC or other industry standard-setting organizations or activities (*Administrative Complaint*, 2002; Soininen, 2005).

The difference between *FTC v. Rambus* and the *Dell* case is that in the former the FTC is attempting to demonstrate that Rambus gained market power through its misbehavior, and thus that the industry is locked into the JEDEC's SDRAM standard. According to the FTC, "It is not economically feasible for the industry to attempt to alter or work around the JEDEC standards in order to avoid payment of royalties to Rambus" (*Administrative Complaint*, 2002). In its initial decision released on 24 February 2004, Judge MacGuire stated that the FTC "failed to sustain their burden of establishing liability for the violations alleged," and dismissed the complaint. In her opinion there was no evidence, for example, that Rambus had violated JEDEC patent policy, or that the challenged conduct had had anti-competitive effects (*Initial Decision*, 2004; Soininen, 2005). To conclude, even though a standard setter has operated unethically and the other participants disapprove his conduct, it may be difficult to challenge it in court particularly if proper guidelines are lacking.

IBM and the ebXML Standard

Even though *Dell* and Rambus attempted to enforce their rights against those who had adopted the standard, patent holders do not always seek royalties although a patent emerges after the standard has been established. One reason for a submarine patent holder to comply with the standards organization's policy is the bad publicity, which may result in the loss of credibility as a fair standardization participant (Sarvas & Soininen, 2002). For example, IBM claimed in April 2002 that it had one patent and one patent application that were relevant for implementing the open, royalty-free ebXML standard developed by OASIS in cooperation with the United Nations, and that it was willing to license them on RAND terms.

IBM's announcement caused strong reactions in the public and in the industry, particularly because IBM had participated in the design of the standard. Furthermore, IBM had previously announced that it was willing to contribute to the standard without any restrictions, but had nevertheless made comments regarding the licensing terms and conditions of the two patents. However, soon after the news reached the public, IBM agreed to license the patents royalty-free (Berlind, 2002a; Berlind, 200b; Wong, 2002).

Case Studies of Third-Party Submarines

Those companies that do not benefit from a specific standard simply do not participate in setting it and therefore it may happen that third parties who are not covered by patent policies have patents that "read on" the standard, and do not appear before its adoption. If the patent holder then decides to enforce his rights, the benefits of the standard may be lost. In fact, many businesses that received patents during the technology boom were either purchased by other companies or landed in holding companies. Thus, in some cases a standards organization may adopt a standard believing it is royalty-free, and then find out that the new owner, which did not participate in the standard-setting process, is aggressively trying to enforce its IPRs (Clark, 2002). For instance, the director of intellectual property at Jupiter Networks Inc has observed a sudden surge in these types of third-party patent-infringement assertions, some of which are valid and some are not. This surge is understandable in his opinion, because patent holders hope to profit from the wide deployment of products that must implement Internet standards. He described a typical patent-assertion scenario in which a patent holder dusts off issued patents directed to old but related technologies or modifies claims in pending patent applications to read on published standards, and then targets standards-compliant network-

ing-equipment manufacturers (Lo, 2002). The case studies presented in subsequent paragraphs illustrate the type of legal disputes that may arise if a third-party patent holder attempts to enforce his rights. Basically, the accused infringer can defend itself by claiming non-infringement or unenforceability, or by attempting to invalidate the patent. These are the strategies followed also in the case studies presented.

Forgent Networks and the JPEG Standard

A third-party claim arose in 2002 when Forgent Networks Inc searched its portfolio of 40 patents and found that it had a patent (US Patent 4,698,672) related to the implementation of a baseline version of the ISO/IEC 1098-1 standard, that is, the JPEG image standard that is one of the most popular formats for compressing and sharing files on the Internet, and is also used in various industries in products such as digital cameras, personal digital assistants, cellular phones, printers and scanners. In its desperate search for profits, Forgent estimated the solidness of its infringement claim and entered into a multi-million-dollar licensing agreement with the Japanese companies Sony and Sanyo before making a public announcement in July 2002 of potential JPEG patent infringement and starting to pursue licensing fees from a range of companies. Forgent had, in fact, obtained the patent in question through the acquisition of Compression Albs Inc. in 1997. Since the inventors who originally filed for the patent in 1986 had not participated in the JPEG standardization process that was going on around that time, according to Forgent, no abuse of the standardization process had taken place (Clark, 2002; Lemos, 2002; Markoff, 2002; Reingold, 2006).

As a result of Forgent's aggressive patent enforcement, many U.S., European, and Asian companies agreed to license the '672 patent, and by April 2004 it had generated approximately \$90 million in licensing fees. Those who did not

agree to license willingly were sued for patent infringement. Indeed, on 22 April 2004 Forgent's subsidiary Compression Labs, Inc sued 31 major hardware and software vendors, including Dell and Apple Computers, for patent infringement, and on 6 August 2004 it initiated litigation against 11 companies (Asaravala, 2004; Forgent Networks, 2006).

Professionals in the field of compression technology and representatives of the JPEG committee doubted the validity of the patent and stated that there could be prior art available that would render it invalid. These doubts have been manifested in legal actions, such as those taken by 24 companies that filed a counter-complaint against Forgent and its subsidiary in the Delaware District Court seeking declaratory relief as to non-infringement, invalidity, and unenforceability of the patent. Even Microsoft, which had not been sued by Forgent at that time, filed a complaint against it on 15 April 2005, claiming that the patent had been obtained fraudulently. Furthermore, the non-profit Public Patent Foundation has filed a request for re-examination of the '627 patent in November 2005. In late January 2006 the U.S. Patent and Trademark Office (USPTO) made a decision to review the patent, which will in any case expire in October 2006 (Forgent Networks, 2006; Lemos, 2002; Reingold, 2006; Red Herring, 2006).

EOLAS and HTML Specification

Another third-party submarine example is the EOLAS case. Here, the dispute arose when Eolas Technologies Inc, which had licensed a patent from the University of California, sued Microsoft for the use of the patented invention, that is, the widely used feature of HTML, the format that describes the format of Web pages. After a long stream of litigation the Federal Circuit (2005) also found the patent valid and infringed (Eolas Technologies Incorporated and the Regents of the University of California v. Microsoft Corporation, Case Nr. 04-1234 (Fed.Cir, 2005)), and the Supreme

Court refused to hear the case (Malone, 2005). At the request of W3C the Eolas patent was also re-examined by the USPTO, which released two preliminary findings claiming that it was invalid. Ultimately, the patent office kept the patent in force, however (Perens, n.d.).

Although a patent holder has a very strong negotiating position if the patent accidentally "surfaces" after the adoption of the standard and those who are accused of patent infringement can mainly defend themselves by trying to invalidate the patent, third-party patents do not always create problems. In many cases reasonable licensing terms can be agreed upon. As with the cases in which the patent holder had participated in the standard setting, business relationships and bad publicity may also be reasons why third-party patent holders comply with a standardization organization's policy and license the patents royalty-free, for instance, although they may have no obligation to do so.

The Risk of Patent Problems and How to Reduce It?

It could be concluded from previous discussion that it is important to implement proficient patent policies that are clear, concise and transparent and hold as few surprises as possible. These policies should be drafted with an intention of influencing companies' behavior both during and after standard setting so that misconduct could be diminished and potential problems solved. The nature, extent, scope and the timeframe of the disclosure requirements are examples of such disclosure terms that could be clarified in order to reduce the submarine patent problem, which taking into account the recent litigations and the fact that 40% of companies in Blind and Thumm's sample group reported problems regarding unclear IPR structure (Blind et al., 2002) is not only theoretical. Furthermore, one way of reducing the problems that may result when not all patents are known prior to the establishment of a standard could be

to require that essential patents granted in the future will be identified and potentially licensed under the same terms as the disclosed patents. In fact, it is a common requirement in patent pools for essential future patents to be subject to grant-back and thus to contribute to the pool. This requirement may occasionally have anticompetitive effects, however, Balto and Wolman (2003) and patent holders would probably consider this type of requirement too restrictive.

As regards to third-party patents that are becoming a more and more relevant concern there is a lot that could be done in order to reduce the risk they may pose to the adoption of a standard. First of all, the standard-setting participants could be encouraged to conduct more thorough patent searches already during the standardization procedure, and to let the standards organizations know about potential third-party claims. Secondly, third parties could be reserved an opportunity to make a patent statement early on, and thirdly, standards organizations could take a more active role in finding relevant patents themselves. Otherwise, if dealing with the increasing number of third-party patents was only left to companies implementing the standard, they would be in different positions and the openness of the standard could be endangered: only those companies that already have cross-licensing agreements in place, have enough leverage in order to negotiate a good deal with the patent holder, or have the resources to fight the patent in court might be able to adopt the standard.

A further way to limit the risk of submarine patent-related troubles arising from both standard-setters and third parties, and to help companies to solve the conflicts better and therefore to reduce the harmful consequences of such patents would be to renovate the legal framework. The possibilities and the need to do so have not been estimated in this article, however. Obviously, when considering the actions needed, the advantages and disadvantages should be estimated and balanced carefully. Therefore, it is in place to examine also the other

patent and standard related quandary that has to do with licensing. These problems are similar to those experienced with submarine patents, and in fact, the GSM example presented later is in essence a submarine patent case. What basically differentiates submarine patent cases and those in which a patent has been properly disclosed is, however, the possibility to make informative decisions about the adoption of a standard, and to design around it or agree upon licensing terms in advance, and thus avoid great societal losses that would occur had the standard been already broadly adopted and if the parties were not able to solve the conflicts.

LICENSING OF PATENTS AND STANDARDIZATION

In case a patent holder has disclosed that it may have patents or pending patent applications that are essential for using a standard, standards bodies typically pose certain licensing alternatives for that company. The patent holder's options are usually the following: (1) the patent holder may state that it is willing to license its essential patents on royalty-free terms, (2) the patent holder may refuse from licensing altogether, (3) the patent holder may promise to license, but negotiate the terms separately, or (4) the patent holder may make a statement of licensing on fair, reasonable and nondiscriminatory terms (RAND). These alternatives are discussed further in subsequent paragraphs, and case studies are used to illustrate the licensing perplexities. The necessity and effects of addressing the submarine patent problem are estimated on this basis.

Royalty-Free Licensing

Royalty-free standards often have more chances of being broadly accepted and widely used than standards requiring licensing payments. For instance, the Internet has been said to require

freely available standards in order to work effectively. Patent-based standards requiring royalty payments inhibit its development because they slow down or discourage the adoption of new technologies. As a consequence, companies frequently agree to make their patented technology available on a royalty-free basis, and hope to generate more profits by selling products that use their standardized technology (Clark, 2002; Interview data U.S., 2004).

As mentioned, given the benefits, standardization participants are often willing to license their patents on a royalty-free basis for the specific purpose of using the standard. This holds true particularly if they are able to make sure that the patents could nevertheless be utilized for defensive purposes if the need arose (Interview data U.S., 2004). Naturally, participation and agreement to license to everyone require that such conduct is in accordance with the firm's commercial interests: having its superior technology chosen for a standard may provide it with a head start in incorporating that technology into its products, for example. Then again, companies seeking licensing revenues through incorporating their proprietary inventions into a standard do not typically have a business motivation to participate in designing royalty-free standards (Soininen, 2005).

Refusal to License

If a royalty-free licensing scheme cannot be negotiated, and the patented technology cannot be designed around, it may nevertheless be in the interests of the public to get the patent holder to agree to license it at least on RAND terms. If the patent holder refuses to license on these vague terms, the standardization process is halted and other solutions are sought (Hjelm, 2000). Refusing to license at all is rare, however, although it is the most influential form of leveraging one's patent rights (Rahnasto, 2003). As the following case study demonstrates it has nevertheless played a major role in making the ETSI Wideband Code

Division Multiple Access (WCDMA) standard backward compatible with the IS-95 standard favored by Qualcomm Inc, for instance (Soininen, 2005).

What happened in the WCDMA dispute was that Qualcomm accused ETSI of intentionally excluding Qualcomm's technology from its standards, thereby creating an unfavorable position for Qualcomm in the European third-generation telecommunications market. In order to make its voice better heard, the company claimed that the key technologies needed for WCDMA infringed its patents, and refused to license this technology unless the WCDMA was made backward compatible with the IS-95 standard. It seems that Qualcomm expected that a harmonized standard would increase its licensing revenues fundamentally (Hjelm, 2000; Westman, 1999; Soininen, 2005).

Ericsson, who was another key patent holder in the technology involved, was of the opinion that Qualcomm's patents were not infringed, and to gain a better negotiation position it also sued Qualcomm for the infringement of Ericsson's CDMA patents (one of the U.S. standards) Qualcomm was employing. Finally, consensus was reached as a result of cooperation between Qualcomm and Ericsson. The companies entered into a series of definitive agreements that resolved all disputes relating to CDMA technology, and as a part of the settlement Ericsson acquired Qualcomm's terrestrial CDMA wireless infrastructure business, including its R&D facilities. Furthermore, the companies gave a promise to license essential WCDMA patents (Hjelm, 2000; Westman, 1999). The standardization process was practically frozen during this period, which lasted roughly a year (Sarvas & Soininen, 2002).

Indeed, as the previous example demonstrates companies operating in the ICT sector are dependent on each other and therefore conflicts in one area may result in complex legal battles in another. Nevertheless refusing to license may be a feasible strategy for a company that opposes a

certain standard. A firm may also wish to delay the acceptance of a standard to give it more time to develop products that incorporate it.

Blank Promise to License

Firms typically agree to license their patents royalty-free, or on RAND or other terms, or they may merely agree to license but make no statement of the terms and conditions. Particularly if the last-mentioned option is available and chosen, there is likely to be a fight over the proper licensing conditions. One example of a disagreement over proper licensing terms was the one that arose during the formation of the European GSM standard in the 1980s, which was first coordinated by CEPT (Conference Europeenne des Administrations des Postes et des Telecommunications) and later by ETSI. In fact, this particular licensing dilemma, which involved Motorola, contributed to the change in patent culture that took place in the European telecommunications sector in which patenting had until that time been regarded as a secondary issue—specifically among the national telecommunications service providers whose markets had previously been monopolized but were now deregulated (Bekkers, Verspagen, & Smits, 2002; Granstrand, 1999).

What basically has been presented in literature to have happened in the context of the GSM standard was that a U.S. company, Motorola, for which patenting was a natural and integral part of doing business, entered the European scene and employed the aggressive patent strategy it was used to. While other standard setters operated in accordance with a “gentleman’s agreement”, shared their ideas and specifications during the standardization process in an open atmosphere, and refrained from patenting once the basic technical decisions had been made, Motorola pursued patent protection in the course of the process (Granstrand, 1999). Furthermore, Bekkers, Verspagen & Smits (2002) have argued that while most other companies agreed on licens-

ing their essential rights on fair, reasonable and nondiscriminatory terms, Motorola refused to make general declarations. It declined monetary compensation and was only willing to cross-license its patents to certain companies. Although Siemens, Alcatel, Nokia and Ericsson were able to negotiate cross-licenses, Motorola’s licensing strategy effectively prevented various other companies from entering the market. When a number of non-European companies finally managed to obtain all the necessary licenses to build GSM terminals in the late 1990s, the cross-licensees had already built up a strong market position. Moreover, since the cumulative licensing fee paid for a GSM handset was very high as confirmed by studies of Bekkers, et al., the price made it difficult to compete if the company was not part of a cross-licensing agreement. In fact it has been argued that the licensing fees have totaled as much as 29% of the costs of the GSM handset (Bekkers et al. 2002)

RAND-Licensing

Even under the RAND system, specific licensing terms are typically not agreed upon during the standard setting. Revealing the terms after adoption can generate conflicts and hamper the parties’ ability to compete in the affected market. Peterson (2002b) lists the following situations that could arise in this context: (1) the patent holder seeks a broad grant-back that appears non-discriminatory but has different effects on different parties; (2) the patentee requires a minimum annual royalty based on “administrative costs”, which may have the effect of excluding smaller rivals and new entrants; (3) the patentee seeks royalties from downstream providers such as manufacturers of finished goods, and refuses to license to suppliers of upstream inputs such as IC vendors, and thus to increase its income, which however may increase competitors’ costs and time to market; (4) the patent holder acquires admissions of infringement and validity, and/or retains the right

to immediately terminate a license if the licensor challenges infringement or validity; (5) the patentee requires acceptance of venue, which might constitute a major problem for small companies or foreign competitors; and (6) the patent holder seeks a royalty that it considers “fair” but that exceeds the average profit margin of all the parties who need licenses. For instance, one of the U.S. interviewees mentioned that his company had been approached with a royalty requirement as high as 10% (Interview data U.S., 2004).

Furthermore, even though the company may have made it clear in its licensing statement that the license was only available under certain conditions it considered as fair, reasonable and nondiscriminatory, these terms may come as a surprise to some and cause disputes. For instance, the *Townshend v. Rockwell International Corp. and Conexant Systems* (N.D.Cal.2000) litigation arose when Townshend, whose patents “read on” the V.90 standard for 56K chipset modems and who had promised to license them on certain terms, filed a patent-infringement suit against Rockwell and its successor Conexant. In response Rockwell and Conexant asserted two antitrust counterclaims based on the Sherman Act Sections 1 (conspiracy) and 2 (monopolization and its attempt) among others, and claimed that Townshend and 3Com had conspired to restrain trade by deceiving the ITU into incorporating Townshend’s patent into the industry standard, denying competitors access to the technology, and filing a patent-infringement lawsuit to prevent Conexant from using Townshend’s technology. Furthermore, Townshend and 3Com were accused of having attempted to monopolize the market for 56K modem chipset products (Kirsch, 2000; *Townshend v. Rockwell International Corp. and Conexant Systems, Inc.*, 55 U.S.P.Q.2d 1011 (N.D.Cal.2000)).

I am not going to go into the legal specialties of the case here, but the Court found all Rockwell’s and Conexant’s counterclaims unfounded. With regard to the antitrust-based claims it noted, among other things, that there had been no col-

lusion, and since 3Com—to which Townshend had non-exclusively licensed its essential patent prior to the setting of the ITU V.90 standard—had declared during the standardization procedure that Townshend had relevant patents pending, ITU had not been deceived. Since 3Com had also made a proposition prior to the acceptance of the standard to license those patents for a per-unit royalty fee, or to cross-license them in return for technologies that were specified in the standard, or related to it and were otherwise practically necessary or desirable for technical or economic reasons in order to make a commercially viable product compliant with the standard, and further that it had not been shown that Rockwell and Conexant could not have obtained a license under those terms, Townshend’s actions could not be held anticompetitive (Kirsch, 2000; *Townshend v. Rockwell International Corp. and Conexant Systems, Inc.*, 55 U.S.P.Q.2d 1011 (N.D.Cal.2000)).

The previous case illustrates that it is particularly difficult to defend oneself against such patent holders that have disclosed their patents properly and declared their licensing terms during the standard-setting procedure. Indeed, due to the flexibility in the interpretation of RAND, having patents in standardized technology could also become a valuable source of royalties or other resources. For instance, Qualcomm relies on a royalty stream resulting from others utilizing its patented technology incorporated into various standards. In fact, the pricing of Qualcomm’s licenses has led to huge disagreement between Qualcomm and six other companies involved in the WCDMA 3G standard. Basically, Broadcom, Ericsson, NEX, Nokia, Panasonic Mobile Communications and Texas Instruments have all claimed that Qualcomm, who promised to license its essential WCDMA patents on RAND terms, is charging excessive and disproportionate royalties for them. Qualcomm has been claimed to charge the same royalty rate on the WCDMA 3G standard as it does for the CDMA2000 standard adopted in the U.S., although it has fewer essential patents

in it. Furthermore, it offers lower royalty rates to handset customers who buy chipsets exclusively from Qualcomm than to manufacturers of chipsets for mobile phones, making entry into the market more difficult for chip makers (Nokia, 2005a; Outlaw.com, 2005; Nokia, 2005b).

As a result of this disagreement, all six of the previously-mentioned companies filed complaints to the European Commission in October 2005 requesting it to investigate and to put an end to Qualcomm's anticompetitive conduct (Nokia, 2005a, 2005b; Out-law.com, 2005). Qualcomm has responded to the allocations stating that they are legally without merit, and appear to be nothing more than an attempt by these licensees to renegotiate their license agreements. In a separate move, Qualcomm then filed a patent-infringement action against Nokia claiming that Nokia was infringing 12 of its patents that related to GSM, GPRS, and EDGE standards (Jacobs, 2005; Nokia, 2005c; Wireless Watch, 2005b).

This is not the end of Qualcomm's legal disputes, however. Previously, in July and again in October, the company had filed infringement suits based on the previously-mentioned patents against Broadcom. These actions were a follow-up of Broadcom's claims that included a patent-infringement action filed against Qualcomm in May 2005, a complaint with the U.S. International Trade Commission (ITC) suggesting that Qualcomm was unfairly importing products that infringed Broadcom's patents and requesting that the ITC investigate Qualcomm's imports, and a separate antitrust suit raised in July. This U.S. antitrust claim was based on similar grounds as the complaint made to the European Commission. In its antitrust complaint Broadcom charged Qualcomm with abuse of the wireless technology standards-setting process, failure to meet its commitments to license technology for cellular wireless standards on RAND terms, and various anticompetitive activities in the sales and marketing of chipsets based on CDMA technology (Gohring, 2005a, b; Regan, 2005).

As can be seen from the volume of suits and counter-suits discussed earlier, Qualcomm's strategy of using its essential patents as revenue generators is challenging and particularly litigation-sensitive, and it is not considered viable by all technology/patent-licensing firms even though their business model would support such activity. One of the U.S. interviewees stated, for example, that taking into consideration the current legal situation and the IPR policies adopted by many standards bodies, it was not beneficial for it to take any part in the standardization. Its business was based on technology and patent licensing, not on manufacturing products, and there was simply not enough monetary compensation involved in standards (Interview data U.S., 2004).

Cross-Licensing

As mentioned earlier, agreeing upon exact licensing terms is not part of the standard-setting procedure, and negotiations are held between the companies interested in using the standard. This follows that another reason beyond the technological benefits for promoting the selection of patented technology for a standard is the possibility to cross-license patents with those of other participants that also "read on" the standard. The more patents companies have, the less they have to pay others for using the standard. Cumulative royalties might otherwise reach the point of unprofitable manufacture (Alkio, 2003; Soininen, 2005). For this reason, companies have an incentive to obtain patents that are essential for using the standardized technology. They may therefore amend their pending patent applications and file for new ones during the standardization process in order to make sure that if a certain technology is chosen for a standard, their patents cover some of its elements. For example, with regard to the CDMA2000 standard, Qualcomm held 28%, Nokia 16%, NTT DoCoMo 13%, Ericsson 8%, Motorola 7% and Hitachi 5% of the essential patents involved. Then again, Ericsson

has 30%, Nokia 21%, Qualcomm 20% and Motorola 14% of the essential patents included in the WCDMA standard (Alkio, 2003). In fact, it has been estimated that some of these major patent holders will end up with a total royalty of 7% of costs or less, while a nonpatent holder could pay 25% of the wholesale price in GSM and WCDMA royalties (Wireless Watch, 2005a).

In order to diminish the problem with too high royalties, some manufacturing firms and operators have declared that they would prefer to agree upon cumulative royalty caps beforehand (Wireless Watch, 2005a). For instance, Nokia was behind such a proposal in respect of 3G patents (Naraine, 2002a). Nevertheless, there are different views on whether agreeing on licensing terms is the job of the standards organization at all, and Qualcomm, in particular, has opposed the royalty-cap proposition actively (Naraine, 2002b). Also one of the U.S. interviewees pointed out during the interview, that in the end, the markets determined whether a product was feasible at a certain price or not. This was not the licensor's responsibility. He further noted that the game in the industry seems to have turned into a price competition rather than the building up of value to customers and communicating that value to them (Interview data U.S., 2004). However, as far as the next version of the 3GPP-based radio standard, Long Term Evolution (LTE), is concerned, ETSI is considering getting all relevant patent holders to sign up to a pre-agreed cumulative cap of approximately 5% for royalties on the cost of LTE equipment (Informamedia.com, 2006).

Licensing and Submarine Patents

As explained earlier, standardization participants have diverging business interests that, combined with control over certain aspects of technology, complicate the standardization process and the adoption of standards particularly if monetary or other licensing compensation is pending. In fact, quantitative research conducted by Blind et al.,

(2002) has indicated that the dilemma is not rare at all: over 30% of European companies reported that they had faced dilemmas involving the high licensing fees demanded by the IPR/patent holders, and approximately 25% had had problems with cross-licensing (Blind et al., 2002; Soininen, 2005). However, if there were no compensation, fewer patent holders might be inclined to allow anyone to utilize their patented inventions, and technologically inferior technology might be chosen for the standard. In fact, it has been suggested that incentives offered to patent holders are not sufficient given the positive effects of standardization. Another quantitative study also conducted by Blind and Thumm (2002) demonstrated that the tendency to join standardization processes is lower if an undertaking has intense patent activity than if it does not. It is suggested that this could be an indicator that the use of IPRs, reflecting the success of the company's own R&D activities, and participation in standardization are, to certain extent, alternative innovation strategies (Blind et al., 2002, Soininen, 2005). Unfortunately this finding also indicates that a large chunk of patents may fall into the category of third-party patents that have a high likelihood to remain unnoticed.

What basically differentiates submarine patent cases and those in which a patent has been properly disclosed is the possibility to make informative decisions about the adoption of a standard, design around it or to agree upon licensing terms in advance. However, standards organization's patent policies only require a general promise to license on RF or RAND terms. Exact licensing conditions are negotiated separately between the parties and this is often done after the standard has been elected. Therefore, with an exception of the fact that a licensing statement has been given and therefore there are more changes of challenging the company's licensing terms, these situations bear a lot of similarities to submarine patent cases. Obviously, if licensing terms were specified better and RAND terms were determined in

accordance with the situation that has prevailed prior to the establishment of the standard, there would be less room for interpretation, and the patent holder would not be in such a good negotiation position. This follows that, even though it was possible to diminish the dilemma with submarine patents discussed earlier, licensing perplexities would probably continue to prevail. On the other hand early disclosure could at least diminish those significant economic losses that would occur if the submarine patent surfaced after the standard had been used broadly and various complementary products and services had been based on it. It should be pointed out, however, that the advantages of clearing all relevant patents beforehand also depends on whether the standard is such that it is constantly evolving as new features are incorporated into the system after the original standard has been set, or whether it remains unchanged after its establishment. In the former situations it would be important to be able to gain information also on those rights, which are essential for the purposes of implementing the standard in its amended form, while those rights that were initially essential may no longer be relevant at this phase.

DISCUSSION

In the previous sections I have identified multiple situations in which patents have caused concern during and after cooperative standard setting. These situations could basically be divided into those in which the holder of the disputed patent has participated in setting the standard and those in which the patent holder is a third party. Furthermore, a distinction could be made between patents that have been properly disclosed to the other participants, and the rights that come as a surprise either because the patent policy has not required their disclosure and no attention has been drawn to them, the patent holder has intentionally concealed them despite the patent policy, or

the rights holder has accidentally neglected to disclose them.

The number-one reason for the disputes that have arisen in the previously-mentioned situations is that patent holders use their position of being able to prevent others from using an invention that is essential for operating the standard to require licensing fees or other terms that are unacceptable to companies operating in the industry. When talking about properly disclosed patents, the patent holder may have made a declaration prior to the publication of the standard specification to the effect that it was willing to license its essential patents royalty-free, or that it was willing to license them on fair, reasonable and non-discriminatory terms. Here, the patent holder may have posed certain limitations, or the patent holder may have made only a blank promise of RF or RAND licensing, and a dispute may arise afterwards over what the correct interpretation of such a promise is. Sometimes, there may not be any kind of a promise.

The consequences of the patent holder refusing to license at all, or on terms accepted by most companies, depend on when the dilemma comes to light. The longer it takes for the dispute to arise the worse are the consequences from a societal perspective. Before the standard is set it may well be possible to design around the patents or to choose other technologies over heavily patented ones, and even after the standard specifications have been published, the abandoning of the standard altogether, or its modification, may not be detrimental as companies may have alternative standards to choose from. Of course, the time and the money invested in setting a standard would be lost. On the other hand, if the standard has already been broadly adopted it may be difficult and very costly to change the specifications without losing the network benefits. Ultimately, doing so would harm consumers who are already using a system in which various products are interchangeable and interoperable. Obviously, from the patent holder's perspective, the situation is reversed: the

later his patent comes to the surface, the more leverage he gains.

I posed the question in the title of this article whether especially the submarine patent problem truly existed or whether it was a red herring. Although the evidence is largely anecdotal and further quantitative research is needed, I have to conclude that problems to do with unidentified patents do come to the surface after the standard has been established. Obviously, even though there is a high likelihood that plenty of relevant patents remain unnoticed, it is only a minor aspect of the variety of conflicts that patents give rise to during or after standardization, and plenty of standards can be adopted without actually having to face troubles with submarine patents. Particularly those situations in which it can be proven that a standard-setting participant breached the patent policy and purposefully concealed the existence of relevant patents or patent applications and thus misled the industry and manipulated the process in order to gain market power, appear to be rare. Companies typically try to do their best to comply with the patent policy.

Avoiding problems with submarine patents seems to be getting more challenging all the time, however. This is because ICT patents, some of which are valid and some of which are not, are increasing in number making it more difficult to avoid infringement. Furthermore, patents are being assigned more often than before and therefore they may end up in companies that did not participate in setting the standard. Patents are also utilized more aggressively in the field, and the more patent-holding companies are seeking to extract as high royalties as they can get from those implementing a standard the less likely it is that an amicable solution can be reached. As a consequence, particularly the U.S. red herring population seems to be growing quickly in number, even though certain legal provisions such as the U.S. Sherman Act, sections 1 and 2, which prohibit conspiracy and monopolization or its attempt, and the FTC Act, section 5, which prohibits the use

of unfair and deceptive business practices, have been and could be used in an attempt to wipe out the most colorful individuals. Other legal tools include fraud, equitable estoppel that prevents a party that has not operated fairly from enforcing his rights, the doctrine of prosecution laches applicable to patents that have been issued following an unreasonable and unexplained delay during patent prosecution phase, and the implied-license and patent-misuse doctrines (Lemley, 2002; Mueller, 2001). Furthermore, non-infringement clarification and patent invalidation either in court or as an opposition (EPO) or re-examination (USPTO) procedure in the patent office could be attempted. In Europe the EC treaty, Art 81 (prohibits agreements and concerted practices that prevent, distort or restrict competition) and 82 (prohibits the abuse of dominant position) could offer limited help as well. Unfortunately, the legal means have not appeared to be very effective so far. The fact that legal disputes have arisen demonstrates that the dilemmas are serious and that they bear significant economic weight, however.

What makes particularly the submarine patent problem interesting from the societal and patent policy perspective is that in this case companies implementing the standard have not, for some reason or other, been able to identify the relevant rights or to plan their operations so as to avoid infringement. Moreover, the consequences of not being able to continue to use a specific standard may have far-reaching effects not only on the competition in a certain field but also on consumers. Therefore, the purpose of the patent system—to promote innovation and facilitate technology transfer through granting the inventor an exclusive right in return for publishing his invention—may not merely restrain trade in the traditional sense, that is, legal monopoly versus free competition, but may also contravene the public interest in a way that is no longer reasonable given the role of patents in enhancing innovation. This, incidentally, has been seriously questioned in areas such as software and semiconductors. In

fact, patents and standards are a policy concern linked to a more general concern regarding IPR protection and the possibility of using it in order to control product interoperability.

This article suggests that further attention should be paid to analyze the efficacy of the legal framework and the need for legislative amendments particularly in the context of standards and so-called submarine patents that come to surface after the standard has been established and adopted. As a practical matter for diminishing potential conflicts, clarifying patent policies in respect to disclosure and licensing obligations, conducting more thorough patent due diligence, and developing guidelines on how to determine RAND terms are recommended. It is further noted that limiting only the risk of submarine patents will not get us far in reducing the conflicts between patents and standards.

Chapter 1.24

Factors Influencing the Lifetime of Telecommunication and Information Technology Standards: Results of an Explorative Analysis of the PERINORM Database

Knut Blind

*Fraunhofer Institute for Systems and Innovation Research, Germany
Berlin University of Technology, Germany*

ABSTRACT

This article presents the results of an explorative study for the lifetimes and survival rates of formal standards in telecommunication and information technology. The analysis reveals that the survival rate depends on the dynamic development of technologies and on country-specific characteristics. In a second step, we tried to identify factors influencing the lifetimes of standards. In general, standards replacing an already existing document have an expected survival time compared to documents without a predecessor. Standards with a successor document have, as anticipated, a shorter expected lifetime. Finally, the increased speed of technological change reduces the life-

times of standards. Based on these first insights, we derive the following recommendations. First, standardisation bodies should adapt their standard maintenance according to the specific requirements of technologies and the related markets, but should also harmonise their processes at the international level in order to avoid frictions for the development of technologies and markets.

INTRODUCTION

The dynamic technological changes in information and communication technology (ICT) influence the lifetimes of standards. The need to change or adjust standards according to new

trends in the ICT sector has definitely increased in the last decade. Furthermore, some standards became obsolete, because new technologies led to completely new generations of standards. Consequently, standards have a life cycle.

Despite the high dynamics in ICT and the high relevance of standards for the development of ICT and the related sectors, there is no systematic quantitative analysis which tries to investigate the dynamics of ICT standards and its driving factors. An exception is the contribution by Egyedi and Heijnen (2005), who focus on the internal revision processes of ISO (International Organization for Standardization). This article presents first explorative results comparing different technologies and countries, based on the data of the PERINORM database published by the national standard development organisations (SDOs), BSI (British Standards Institute), DIN (Deutsches Institut fuer Normung) and AFNOR (Association Française de Normalisation). Another kind of evolution of standards is discussed and illustrated by Swann (2000), who analyses the interplay between innovation and standardisation. Starting with a basic standard, which defines the specifications of some platform technology, the field for further innovation is set in using this basic technology for various applications. We are not able to analyse this kind of interrelationship referring to the database used for this analysis. In contrast to the rather few quantitative studies, we can rely on a long tradition of theoretical analyses done by economists starting the 1980s by the work of Arthur (1989) applied in David's study of the typewriter keyboard standard QWERTY (David, 1985) and Farrell and Saloner's (1985, 1986) game theory approach. Based on network externalities, increasing returns but also information asymmetries these authors mainly explain the lock in effects of standardisation and the missing dynamics. Besides these very theoretical approaches to deal with standards dynamics, several case study analyses exist, which focus on the standard maintenance and succession (Egyedi

& Loeffen, 2002) in order to answer the question how to deal with heritage relations between standards and on standard integrity (Egyedi & Hudson, 2005) and in order to discuss control mechanisms that safeguard the integrity of (de facto) standards. This article adds an additional methodological dimension to the analysis of the dynamics of standards.

The remainder of the article is structured as follows. First, we analyse the average lifetimes of standards in a quantitative manner, taking into account differences between countries. The country differences are caused by institutional differences in the countries considered, like different time lags regarding the implementation of international and European standards, but also by the heterogeneous quality of the data delivered to the central database. Since the simple approach of calculating the average lifetimes of historical standards does not allow us to include standards which are still alive, we have to apply a more sophisticated methodology, the so-called survival analysis, which was initially mainly applied in medical science. The application of this statistical approach produces average lifetimes of standards, taking into account the expected lifetime of standards which are still valid. This approach is crucial, especially for the analysis of ICT standards, because the number of valid standards relative to historical standards is rather high. Due to the very high relevance of international standards in the ICT sector and the high quality of this subsample, we concentrate the survival analysis especially on the international standards including the standards released by the European standardisation bodies. The results of this analysis provide us with new insights about the expected lifetimes of standards differentiated by technology in the ICT area. The final step of our analysis tries to answer the question which causal factors influence the lifetimes of standards in the ICT sector. We present first insights by applying the so-called Cox regression, which allows us to identify whether some selected additional characteristics of a standard, like cross references

or references to international standards, but also the dynamics of technical change during its lifetime measured by a patent indicator have a significant impact on its actual or expected lifetime. The approach to assess the importance of a technical document by analysing its references to other documents or being referenced in other documents has a long tradition in evaluating the value of patents by counting and analysing their citations (see, for example the recent publication by Hall, Jaffe, and Trajtenberg, 2001). The article concludes with a brief summary of the main results, but also with some general recommendations regarding standardisation processes and the maintenance of standards.

HYPOTHESES AND THE DATABASE

As already indicated in the introduction, several factors influence standards dynamics, that is, changes, supplements or withdrawals of standards. However, we are restricted in our analysis by the information provided in the standards database we rely on. Therefore, we will concentrate in our analysis on testing the following general hypotheses, which will be explained in more detail and tested by various statistical approaches in the subsequent sections.

H1: The dynamics of standards depends on the type of technology, that is, ICT standards implemented in hardware infrastructure have a longer life expectancy than software standards, because of higher investments necessary to implement new hardware compared to new software (Egyedi & Heijnen, 2005; Katz & Shapiro, 1994). Furthermore, the network externalities and the switching costs of technologies have an influence on the likelihood of changes in a standard (Shy, 2001).

H2: The higher the speed of technical change, the higher the pressure to adapt, change or

withdraw an existing standard (Blind, 2004; Blind & Grupp, 2000).

H3: The institutional framework in which a standard is embedded matters, because cross references in general, references to international standards, links to predecessor or successor documents will change the life expectancy of a standard. In addition, the type of document is essential for its lifetime. Draft documents are changed or withdrawn more often than finalised standards.

H4: Although the differences between technologies should be more distinct than the differences between countries, we still observe significant institutional differences between national standardisation bodies, like the time lags in implementing international and European standards. Therefore, country differences regarding the lifetimes of standards should be expected.

We will apply different methodological approaches to test these hypotheses. We will perform simple descriptive statistics of average publication and withdrawal years, then continue with survival time analyses, which allow us to take into account the numerous still valid documents, and finally conduct Cox regression analyses in order to identify significant factors influencing the lifetimes of standards, at least in the fields with sufficient information and observations.

For our analysis we use the PERINORM database edited by the three major national standardisation bodies in Europe, BSI in the United Kingdom, DIN in Germany, and AFNOR in France. The database is also available online, but we use the CD ROM version.

The main characteristics of PERINORM edition 2004 relevant for our analysis are the following. Since we concentrate on the ICT sector, we select only the documents in the field of telecommunication and information technology, including office machines, by relying on the international classification of standards (ICS).

Telecommunication is identified by the ICS code 33, information technology by the ICS code 35. The next level of subdivision of the two ICT-related fields will be illustrated in the tables used. In total, we rely on more than 78,000 documents in the field of telecommunication and more than 31,000 documents in the field of information technology, and office machines. The majority of the documents have been published since the beginning of the 1990s.

In our analysis, we cover the following European countries: Austria (AT); Belgium (BE), Czech Republic (CZ), Switzerland (CH), Germany (DE), Denmark (DK), Spain (ES), France (FR), Great Britain (GB), Italy (IT), Netherlands (NL), Norway (NO), Poland (PL), Russia (RU), Sweden (SE), Slovakia (SK) and Turkey (TR).

In addition, the set of international and European standards are included (IX). The data on international standards do not include standards by the European Telecommunication Standards Institute ETSI published after 1997, which generates some bias in the results on international telecommunication standards. The data quality is rather heterogeneous, since the databases of the founding countries France, Germany, and Great Britain are of higher quality than those of most other countries. The data about the standards released by the international bodies is also of good quality. It has to be noted that the European and the international standards should be included in the set of national standards, because of the requirement of CEN and ISO members to integrate and implement the European, respectively the international standards.

Although each document is described by almost 50 characteristics, we rely in our analysis mainly on the following search fields: classification, cross references, expiry date, international relationship, issuing body, origin code, publication date, replaced by, replaces, status, withdrawal date.

In the more sophisticated analyses, we have to restrict ourselves to those countries which

provide high quality data for most of the relevant classification fields.

Due to the large number of documents and descriptors, we have set up two separate databases, one for the telecommunication standards and one for the information technology, office machines standards.

DESCRIPTIVE RESULTS

In a first step, we analysed the average publication and withdrawal dates, differentiated both by technological area and by country. In this first analytical step, we concentrate on all standards documents, that is, including drafts and prestandards, by calculating the average of their publication date. In calculating withdrawal dates, we just consider those documents which are already withdrawn by calculating their average withdrawal dates.

In Table 1, we present the average publication and withdrawal dates by technological area in telecommunication technology. The average publication dates vary between 1993 and 1998. The oldest documents can be found in the area of measuring equipment for use in telecommunication with an average publication date as far back as 1993. Standards on components and accessories for telecommunication equipment were published on average more than 10 years ago in 1994, those on telecommunication terminal equipment in 1995. In contrast, if we look at the standardisation fields with more recent average publication dates, we find standards for fibre optic communications with an average publication year of 1999. Standards for telecommunication services and mobile services are on average published in 1998. This first picture is in line with the technological and market development in telecommunication. First, standards are needed to solve the general measurement and testing problems, then to secure the compatibility between components of the equipment and the terminal equipment itself. With the maturing of

Table 1. Average publication and withdrawal dates in telecommunication differentiated by area of standardisation

Fibre optic communications	1999.03	1999.43
Telecontrol telemetering including supervising, control and data acquisition	1997.11	1997.94

the technology and the market itself, we observe a shift in the focus from fixed to mobile telephone technology. This is also reflected by the delayed publication of standards for mobile services. Furthermore, the telecommunication industry experiences a further shift to service-related applications. Consequently, at a later stage we observe the publications of standards structuring telecommunication services. In summary, the ranking of the average publication dates presents the historical development of a technology.

Although Egyedi and Heijnen (2005) indicate that the average withdrawal dates are not good indicators for the expected lifetime of standards, we report in this section also the average withdrawal dates. However, we perform a more sophisticated analysis which allows us to calculate

the expected lifetimes of standards in the next section. In general, we observe a rough correlation between average publication and withdrawal dates. However, the fields of standardisation which started relatively early are characterised by larger differences between withdrawal and publication dates. In the emerging fields of telecommunication standardisation, the differences between average withdrawal and publication date are smaller, which is caused by the fact that the majority of the standards in these areas are still alive. An exception is the area of telecommunication services, where a significant share of standards has obviously already been withdrawn.

In Table 2, we present the average publication and withdrawal dates differentiated by country. The overview confirms that the country-specific

Table 2. Average publication and withdrawal dates in telecommunications for various countries

Country	Number of Standards	Publication Date	Withdrawal Date
International standards	18154	1995.26	1997.46

Slovakia	4654	1999.71	2000.69
Turkey	1422	1998.16	2002.00

databases differ significantly. On the one hand, we observe only small differences between averages of the large central European countries. On the other hand, the data of the eastern European countries indicate for Russia relatively old standards documents based on an average publication date before 1990, but for the Czech Republic, Slovakia, Poland, and Turkey a rather young set of standards with an average publication year close to 2,000. Whereas the Russian case is certainly influenced by a rather old and small national stock of standards, which has only recently been linked to the international standardisation activities. The other three countries are meanwhile linked to CEN, which means that they implement the stock of European standards in their national standardisation system. Since they possessed only a small stock of domestic standards, the implementation of the European stock of telecommunication

standards rejuvenated the national stock of standards drastically. The European effect can also be observed in Belgium, which has no significant own standardisation activities.

In the next step, we look at the dynamics of standards in the field of information technology. In Table 3 we are again able to detect the life cycle of information technology in the averages of the publication dates. Standardisation started obviously in the field of office machines in general with an average publication date in 1986. In a next step, standards for data storage devices were published with an average publication date of just after 1990. A further standardisation step, microprocessor systems, underwent a standardisation phase with an average publication date of 1992. The remaining average publication dates do not differ significantly, because they are all within the interval between 1994 and 1996. The

Table 3. Average publication and withdrawal dates in information technology differentiated by area of standardisation

Office machines	1986.26	1993.52

only exception is standards for the application of information technology, which were published on average in the year 1997.

The average withdrawal dates correlate rather closely with the average publication dates. Obviously, the historical standards for office machines are characterised by the largest difference between average publication and withdrawal date. Historical software standards have much shorter lifetimes.

The differentiation of information technology standards by country in Table 4 reveals a much more heterogeneous picture than in the field of telecommunication. The average publication year varies from 1992 to later than 1998.

For the eastern European countries, we find the pattern similar to the field of telecommunication of rather late publication and withdrawal dates. Russia is again characterised by a rather early average publication year of its standards. For the Netherlands, we even observe that the average pub-

lication year is later than the average withdrawal year, which is caused by the fact that only a few documents were withdrawn during the 1990s, but the majority of the documents were published since the end of the 1990s. However, the homogeneous picture among the central European countries observed in the telecommunication sector cannot be detected in the information technology sector. Consequently, country-specific analyses are required in the following analytical steps.

Results of the Survival Analysis

As already indicated in the previous section, the approach to compare average withdrawal and publication dates is not robust and reliable enough to give indications about the average lifetimes of standards. In addition, the survival times indicate the dynamics within a field of standardisation, whereas the average publication dates of standards may provide information about the development

Table 4. Average publication and withdrawal dates in information technology differentiated by country

Country	Number of Standards	Publication Date	Withdrawal Date
International standards	9429	1995.44	1997.14

Slovakia	814	1996.96	1999.39
Turkey	663	1996.93	n.a.

of a technology, which is likely to start out with standards for hardware components and may later move to applications and services. Therefore, we apply the so-called Kaplan-Meier survival analysis see Norusis (1996). Survival analyses have their application origin in testing the effectiveness of medical treatments, especially on the survival times of patients. Meanwhile, the application of the methodology has been extended to analyses of the duration of unemployment and other economic phenomena for example, lifetime of companies (Cantner, Dressler, & Krüger, 2004).

In the following, we present the results of survival analyses only applied to the final standard documents differentiated by country and technological area. In an explorative analytical step we compared the expected survival times of draft or prestandards with those of standards themselves.

We found very short survival times for all the draft and preliminary documents, irrespective of country and technological field. Therefore, we restrict our analysis to the subsample of final standard documents in contrast to the approach presented in the previous section. Since we differentiate in this analysis by country and field of technology, the number of observations is sometimes reduced to a level which does not allow the application of the survival analysis, which is a kind of regression analysis. As we already observed significant differences between the considered countries in the average publication and withdrawal dates, it is no surprise that the expected survival times differ significantly between countries. In Figure 1, we present the expected survival times of telecommunications and information technology standards differentiated by country. The average

Factors Influencing the Lifetime of Telecommunication and Information Technology Standards

international standard is supposed to live for 22.5 years in telecommunication and 16.5 years in the field of information technology. The eastern European countries Poland, Russia, and Slovakia are characterised by expected survival times of over 30 years; the same is true for Belgium with an expected survival time of over 40 years. In the database of these countries, there is a dominance of rather old standards, which are still alive. However, these results can also be generated by a very few standards published early which are still alive, and a majority of rather new and probably international and European standards, which are also not yet withdrawn. Whereas the results of these countries are rather biased by some special effects, the calculations for the other European countries are more reliable. For these, we observe three clusters of countries. The survival times of standards in France and Great Britain are longer than the European standards. The Nordic and the central European countries, including the Czech Republic, have lower survival times. Whereas France and Great Britain still have a significant and

slightly older stock of national standards, the other countries are obviously more heavily influenced by the standardisation activities at the European and international level, which requires the withdrawal of respective existing national standards. Here we also observe a difference between Germany, on the one hand, and France together with Great Britain on the other hand; Germany is obviously under a stronger international and European influence in the area of telecommunication standards. In general, the survival analysis confirms the country-specific heterogeneity of the standards life cycle data already observed by analysing the average publication and withdrawal dates.

The variation of the survival times between countries can also be observed among the information technology standards. For most of the countries, we observe partly similar patterns as in the telecommunication area. On the one hand, Belgium and the eastern countries Poland and Russia are again characterised by very high expected survival times. On the other hand, in most central European countries, for example,

Figure 1. Survival times of telecommunication and information technology standards in years by country

Germany, the survival times of information technology standards are not very different from the set of international and European standards. Again, Austria represents an exception by having very low survival times of less than ten years. In contrast to the general pattern of shorter survival times of information technology standards in comparison to the telecommunication standards, the Dutch information technology standards last on average more than seven years longer than the Dutch telecommunication standards. The same is true for Norwegian, and to a limited extent, for Swedish standards.

The comparison of the survival times of telecommunication and information technology standards reveals the country-specific influence by the high correlation of the survival times in both technological fields. The major conclusion from the results of this working step is the requirement to calculate the data in a country-specific way. In the next step, we check whether—as expected and already indicated by the average publication and withdrawal dates—we find also technology-specific differences in the survival times.

In our presentation of the survival times differentiated by field of standardisation, we concentrate on the European and international standards, because the relevance of European and international standards for telecommunication and information technology is of much more relevance than national standardisation activities. Furthermore, the database of the European and international standards is much larger and more complete than the databases of the national standards, which allows much more differentiated analyses. Bearing in mind the average survival time of 22.5 years of telecommunication standards in general, we concentrate just on the largest deviations from this mean value. The expected survival times for telecommunication terminal equipment standards are ten years longer than the average. This indicates, on the one hand, that standardisation started in this area earlier than in the other sub-areas. Furthermore, the average

lifetimes of historical documents, which are already withdrawn, has to be sufficiently long. Both explanations are consistent with reality. Since there is no other sub-area with significantly longer survival times than the average, we concentrate now on the sub-areas with rather short survival times. At first, we observe the rather short survival times of standards for mobile services, which are even lower also the very recent ETSI standards are taken into account. This phenomenon conforms to the explanation already made in the context of the average publication and withdrawal dates. The development of mobile services started rather late in comparison to telecommunication standardisation in general, and consequently the expected survival times are rather short. Whereas the development of services always occurs in a rather late stage of the development of a technology and an industry, in telecommunication we observe the emergence of fibre optic communication since the late 1990s. Consequently, standardisation activities started later than in telecommunication in general. The standardisation activities to ensure electromagnetic compatibility (EMC) also started rather late, as seen in Table 4, the presentation of the average publication dates. Therefore, the expected survival times of these standards are around ten years and much shorter than those of telecommunication standards in general. Finally, the rather short survival times of standards related to integrated services digital network (ISDN) must be discussed. Although standardisation started rather early in this field, the expected lifetimes are shorter than comparative sub-areas (see Table 1 with the publication dates). Obviously, there have been more revisions of standards leading to withdrawals of existing standards and to a shortening of lifetimes.

Summarising the results of the survival analysis of international telecommunication standards, three main results have to be noted. First, the average survival times depend very much on the starting of respective standardisation activities, that is, since standardisation for telecommunica-

Figure 2. Survival times of international telecommunication standards in years by area of standardisation

tion hardware already took place before the 1990s, the expected survival times of these standards is much higher than those related to standards for mobile services, which were mostly released after the mid 1990s. This result confirms also that telecommunication standards are in general rather stable. Second, the survival times of standards in telecommunication reflect—in the same way as the average publication years—the life cycle of telecommunication technology which started out with traditional hardware and equipment, then followed by application and services. Since fibre optic communication technology emerged only recently, the respective standards appeared in recent years, causing rather short survival times. Third, we still detect some technology-specific dynamics in the survival times, that is, there are sub-areas of standardisation in which standards are more frequently revised and withdrawn than in other areas. One example for such a sub-area are the international ISDN standards, which have consequently much shorter survival times than standards in other fields, which were published on average at the same time.

After the presentation and the analysis of the survival times of the international telecommunication standards, in the previous section of this section we will have a look at the survival times of the international information technology standards (Figure 3). On average, the survival time of an international information technology standard is 16.5 years and therefore five years less than the average telecommunication standard. This difference underlines that there is much more dynamics in the information technology standardisation compared to the telecommunication technology standardisation.

In contrast to the average survival times, we find an expected survival time of more than 20 years for standards for data storage devices. This result is caused by the fact that standardisation in this area started rather early, already in the 1980s. Standards for software development and system documentation also have a survival time of 20 years, but the standardisation activities in this area were initiated on average five years later than for data storage devices. From this difference, we are able to conclude that in the latter field

Figure 3. Survival times of international information technology standards in years by area of standardisation

standards are more frequently revised, adjusted to new generations of storage devices or even storage technologies than the more basic standards for software development, which focus more on general principles and terminologies. These obviously need less revisions and withdrawals over time.

If we focus on standardisation sub-areas with relatively short survival times, we identify open systems interconnection (OSI), networking, and computer graphics. The latter field is obviously characterised by relatively high dynamics especially triggered by a rapid technical change, since standardisation activities started already relatively early. The OSI related standards have also a rather limited lifetime. However, if we use the additional information on the average withdrawal dates, we find an early withdrawal year relative to the publication year. Taking this information together, we derived that in the field of international OSI standards, few standards have already been withdrawn, causing the rather short expected survival time. If we compare the OSI standards with the networking standards,

we observe, on the one hand, a similar survival time, but a much later average withdrawal date, which allows us to conclude that in this sub-area a larger number of standards has already been withdrawn.

If we summarise the results of the survival analysis of international telecommunication and information standards together, we observe the following main new insights. The survival times of telecommunication standards are much longer than for information technology standards, although the average publication dates do not differ significantly. Consequently, the dynamics within standards of information technology is much higher than those in telecommunication technology. In the latter field, the heterogeneity of the survival times is much higher, with rather low survival times of standards for mobile services and high survival times for telecommunication terminal equipment. In information technology, we just observe that standards for data storage devices and for software development and system documentation have a much higher survival time than the average for information technology standards. In the next

section, we will try to identify factors influencing the lifetimes of standards.

Factors Influencing the Survival Times of Standards: Results of the Cox Regression Analysis

In the previous section, we calculated and interpreted the survival times of telecommunication and information technology standards. Despite the fact that country differences exist, partly caused by country-specific data quality, the analysis of the European and international standards showed that technology-specific reasons influence the survival times. In this final section, by applying the Cox regression methodology for a small selection of countries, we analyze which influences standard-specific characteristics have on the survival times of standards.

Based on the data which is available for each standard document, we developed the following specific hypotheses derived from the more general hypotheses listed previously:

- If a standard amends another standard, then the expected lifetime is increased, because it has the character of a more basic and therefore longer lasting standard.
- If a standard is amended by another standard, then the expected lifetime is decreased, because the likelihood of a general substitution is higher.
- If a standard replaces another standard, its expected lifetime is higher, because the weaknesses of the predecessor standards have been solved.
- If a standard is replaced by another standard, its expected lifetime is lower, because of the replacement.
- If a standard has a cross reference to another standard, its expected lifetime is higher, because it is embedded in a whole network of standards, which is more stable than single and isolated standards.

- If a standard has a cross reference to another standard, its expected lifetime is lower, because it is embedded in a whole network of standards, which is more likely to be affected by external influences.
- If a standard has a reference to an international standard, its expected lifetime is lower, because the international standard is likely to change faster.
- If a standard has a reference to an international standard, its expected lifetime is higher, because the change of an international standard is likely to take more time.
- If a standard has a reference to regulation, its expected lifetime is higher, because changes in legislation take longer and its relevance is higher.
- If a standard contains more pages, its expected lifetime is higher, because the volume of codified knowledge is higher, which may cause further inertia (it may even represent the merger of various standards).
- If the speed or the amount of technical changes increases, the expected lifetime of a standard is lower. The impact of the national technical change is lower than the impact of the whole European technical change, especially for the smaller countries.

Since some data fields are not filled out for the selected countries, we had to restrict ourselves to testing some hypotheses only for a few or even a single country. Furthermore, we differentiate in general not by the sub-areas, because the number of observations is then insufficiently low.

In order to test the hypotheses, we apply the so-called Cox regression model see for technical details (Norusis, 1996). This approach allows us to investigate whether and how exogenous variables influence the survival probability of the standards documents. The methodology is a multiple regression or logistic regression analysis, which allows the inclusion of the still valid documents, like the Kaplan-Meier survival analysis.

The cumulative survival function $S(t)$, the proportion of the surviving cases at a particular point of time t , is the dependent variable. Then, the cumulative survival function at point t is calculated under the influence of the exogenous variables x_1 to x_n , which relate to the hypotheses listed earlier, as:

$$S(t) = [S_0(t)]^p, \tag{1}$$

with $S_0 = S_0(t)$ as baseline survival function at time t , the exponent p is determined by

$$p = e^{(B_i x_i)} \text{ with } i = 1 \text{ to } n \text{ explaining variables.} \tag{2}$$

The estimation of the coefficients B_1 to B_n will be solved by the Cox regression analysis. If all coefficients B_1 to B_n were equal to zero, then p would have the value of one and the baseline survival function would not be influenced by the exogenous variables (covariates). Positive coefficients B_1 reduce the survival probability, negative ones increase the survival probability.

In Table 5, the exogenous variables for explaining the survival times of standards documents are summarised:

At first, we calculate separate models for each variable. In the Tables 6 and 7, the results for the telecommunication and information technology

standards are summarised. We concentrate our analysis on the data of international, Austrian, Swiss, German, French, British, and Dutch standards, but have to restrict ourselves to a subset of these countries for the variables “Amended”, “Amended by” and “Legislation”.

The results for the variables “Amended” and “Amended by” confirm for the few selected countries that both documents which amended and were amended by another document have a significantly higher survival time than documents without this kind of cross references. Therefore, the first hypotheses, that if a standard amends another standard, then the expected lifetime is increased, because it has the character of a more basic and therefore longer lasting standard, is confirmed. However, if a standard is amended by another standard, then the expected lifetime is increased and not decreased. The explanation for this result to be observed in some countries may be that amendments obviously stabilise a standard in general and reduce the likelihood of a general withdrawal.

For the second couple of hypotheses focusing on replacements, we find a consistent picture for the evident hypothesis that if a standard is replaced by another standard, its expected lifetime is lower. However, the hypothesis that if a standard replaces another standard, its expected

lifetime should higher, because the weaknesses of the predecessor standards have been solved, can only be confirmed for half of the countries considered. In the Netherlands, we even find a confirmation for information technology and a rejection for telecommunication standards. In telecommunication technology, the hypothesis is rejected only in Great Britain, in information technology also in France and Switzerland.

The testing of the hypotheses focusing on cross and international references reveal rather ambivalent results. For the standards in telecommunication technology, the hypothesis that if a standard has a cross reference to another standard, its expected lifetime is lower, because it is embedded in a whole network of standards, which is more likely to be affected by external influences, is confirmed by international, German and British standards. The analysis including instead the continuous variable of number of cross references confirms this result. However, the data from Austria, Switzerland, France, and the Netherlands confirm the counter hypothesis. For the standards in information technology, the latter hypothesis is confirmed for all countries except for Germany and France. If we use the number of cross references, the data for Great Britain also confirm the hypothesis that the expected survival time of a standard will decrease with an increasing number of cross references.

The reference to an international standard decreases the expected lifetime of a telecommunication standard for the international, the Austrian and the German sample, whereas the longevity of standards in the British database increases. In information technology international references lead to a reduction of the lifetime, with the exception of the international and the Dutch database. If we use the counts of international references, only the expected lifetime of standards of the Swiss and international databases increases with the number of international references.

Due to data restriction, we are only able to test the hypotheses for Germany that, if a standard has

a reference to regulation, its expected lifetime is higher, because changes in legislation take longer and its relevance is higher. We find a rejection of this hypothesis in the telecommunication area and no significant relationship for information technology. One explanation for the rejection in the telecommunication area may be the liberalisation and deregulation of the telecommunication sector causing a rather frequent change of regulations, which also causes the pressure to adapt the referred standards more often.

Finally, we wanted to test whether the quantity of content in a standard measured by the number of pages has an impact on their survival times. In contrast to our hypothesis, that the more pages a standard contains, the higher its expected lifetime, the counter hypothesis is confirmed for most of the regressions. Only in Austria did larger standard documents have a longer expected life. The reason for this counterintuitive result is the recent trend to produce larger standards documents.

Since we observe rather heterogeneous results between the few countries considered, we had a more in-depth look at the sub-areas of the international standards. For the following hypotheses, we find rather strong empirical evidence.

Whereas there is no empirical support for the hypothesis that standards which amend other documents have a longer expected survival time, standards which are amended by other documents have a longer life expectancy in the majority of the subclasses. This contrasts our hypothesis, that a standard amended by another standard has a reduced expected lifetime, because the likelihood of a general substitution might be higher. In line with our hypothesis, there is strong empirical support for the fact that standard documents which replace previous documents have a longer life expectancy. Consequently, the number of documents being replaced increases the survival time of the respective standards. In addition, the ambivalent role of the existence of cross references or international cross references supports the two contradicting aspects of cross references. On the

Factors Influencing the Lifetime of Telecommunication and Information Technology Standards

one hand, a standard with cross references to other standards is embedded in a whole network of standards, which should be more stable than single and isolated standards. On the other hand, a standard has cross references to other standards may be also influenced by changes in the area of the referenced standards. The link to a regulation is negative for German telecommunication standards, but slightly positive for German information technology standards. This means only for the later area, our hypothesis, that the expected lifetime is higher with a link to regulation, because changes in legislation take longer and its relevance is higher, is not confirmed. Finally, the survival time in the two areas in most countries decreases with an increasing number of page representing a largere volume of codified knowledge even the merger of various standards.

In addition to the PERINORM internal database, we have included external information about the speed of technological change to each document. Based on the assumption that every new technology may question the state-of-the-art of technology codified in a standard, we postulate that the more new technologies are developed, the higher the likelihood that a standard document has to be changed or even withdrawn. Based on a long tradition of literature (e.g., Grupp, 1998), we assume that patent applications are an adequate indicator for technical change. Then, we calculated the average number of patent applications either in telecommunication or in information technology (source of raw data: Schmoch, Laville, Patel, & Frietsch, 2003) related to the lifetime of a standard. For all documents, we computed the average annual number of all patent applications from the former 15 Member States at the European Patent Office related to their lifetimes. For selected countries, Austria, Belgium, Germany, Denmark, Spain, France, Great Britain, Italy, the Netherlands, and Sweden, we are also able to compute the respective indicator for national applications at the European Patent Office. The differentiation of two technology fields telecom-

munication and information technology in the sub-areas is not feasible because the international patent classification IPC does not allow a clear-cut separation into these sub-areas. This would allow to test the hypotheses whether standards related to technologies in a more mature phase have longer lifetimes than standards in rather emerging fields of the telecommunication and information technology.

The country-specific results of the Cox regression for the two technology fields are presented in the Table 8. The outcome of the Cox regression confirms impressively the hypotheses that if the speed or amount of technical change increases, the expected lifetime of a standard will be lower. The analysis of the international standards differentiated by sub-areas confirms the overall picture of a negative relationship between speed of technological change and the survival times of standards. This result is also confirmed for other technology fields based on Swiss standards (Blind, Jungmittag, & Grupp, 2000). The higher the average annual patent application at the European Patent Office related to the lifetime of a standard, the lower its expected survival time is. This result holds also for the country-specific patent applications at the European Patent Office. If we have a look both at the coefficients and the magnitude of the total European and the national patent applications, we find empirical support for the hypothesis that the impact of the national technical change is lower than the impact of the whole European technical change, because of the international technology spill-overs, that is, a standard within the body of German standards has also to take account of technological developments abroad.

Summarising the results of the Cox regression, the following general new insights have to be reported. First, technical change measured by a patent indicator has a negative impact on the survival times of standards. This is confirmed for the datasets of all countries considered. Furthermore, due to international spill-over effects

the international technical change measured as the sum of European patent applications has a stronger impact on the survival time than the sole national technical change. Second, the document-specific information on predecessor and successor documents confirm, on the one hand, for the majority of countries and technological sub-areas that standards which replace a preceding document have a longer survival time compared to documents without a predecessor. On the other hand, standards with a successor document have as expected a shorter expected lifetime. Third, the existence and the number of cross references have a heterogeneous influence on the lifetimes of standards, depending on the country and technological area considered. References to international information technology standards reduce the lifetime of standards at least for the majority of country-specific documents. Finally, the length of standard document measured by pages correlates negatively with its survival time, which is at first glance counter-intuitive. However, this result can be explained by the fact that standard documents published earlier are much shorter than recently published documents.

CONCLUSION

An analysis of the telecommunication and information technology standards published by formal international, European and national standardisation bodies was performed in order to identify patterns of the dynamics of standards and factors influencing the dynamics of standard. We were able to detect the patterns of dynamics both based on quantitative statistics of average publication and withdrawal years and expected survival times, which are consistent with technology and market-related characteristics. However, we also find country-specific patterns which are caused either by institutional reasons, like the participation in the European standardisation activities, or by the quality of the database. For

the most important countries, the quality of the database is so homogeneous that comparative analyses are possible.

The analysis of factors influencing the dynamics of standards is restricted by two dimensions. First, we have to rely in general on the additional information which the database provides. Consequently, only a limited number of hypotheses can be tested. In order to test the major hypotheses whether the speed of technical change has an influence on the lifetimes of standards, we calculated for each document a patent indicator characterising the speed of technical change during its individual lifetime. The patent data allowed us only to calculate two indicators, one for telecommunication technology and one for information technology. Second, the quality of the document-specific information is rather heterogeneous. Consequently, we had to restrict our analysis to a few selected countries and to the international and European standards. Nevertheless, the results of the analysis confirmed some of our hypotheses, but also revealed new insights. In general, the dynamics of standards depend both on country, but also technology-specific characteristics.

Since both the institutional framework and the characteristics of technology are responsible for the lifetime of standards, further analyses have to take into account these two dimensions. Therefore, the approach by Egyedi and Heijnen (2005) to focus on just one standardisation body is confirmed by this general analysis. Furthermore, approaches have to be developed which will allow us to match systematically additional information to each standard document, because this facilitates the testing of further more sophisticated hypotheses about the causes influencing the dynamics of standards.

The observations that the lifetimes of standards are influenced both by related technology and the institutional framework should be considered by the standardisation bodies. First, different technologies require obviously specific adjust-

ment or withdrawal strategies in standardisation. Consequently, standardisation bodies should be more aware of this heterogeneity and adapt their processes accordingly, always taking into account the continuous change in science, technologies and markets. The differences between countries call for two strategies. First, benchmarking exercises may help to identify best practices in the adaptation of processes to adjust, modify or even withdraw existing standards. Second, and even more important, is the necessity to homogenise the maintenance processes among countries in order to avoid frictions causing risks for the development of technologies, but also common markets. This includes also a more homogeneous implementation or transfer of international and European standards into the body of national standards.

ACKNOWLEDGMENT

The author thanks for the financial contribution for the NO-REST project (507626) by the European Commission within the 6th Framework Programme. The paper was developed within the workpackage on the dynamics of standards of the NO-REST project. A previous version of the paper was published in the proceedings of the IEEE SIIT 2005 conference in Geneva. Valuable comments by the coeditor of the special issue Mostafa Hashem Sherif significantly increased the quality of the paper. Remaining shortcomings are in the sole responsibility of the author.

ABSTRACT

The learning capacity of individuals is becoming recognised as the most valued commodity in a knowledge and information society and this has fostered an increased attention on the innovation, transfer, and management of knowledge. To explain these processes, it is necessary to move beyond what has traditionally been conceived of as a learning environment and to develop alternative models that acknowledge and accommodate the learning competencies required to successfully engage with a contingent and dynamic learning culture, the changing nature of knowledge, and the influence of the cultural background of learners. Such models need to explain the lifelong and

continuous nature of learning as learners move seamlessly among a range of diverse learning environments. This chapter proposes the concept of learning agency which incorporates the intelligence inherent in learning environments as a mechanism to explain seamless learning within and across environments, particularly those that are rich in technology.

INTRODUCTION

The rapidly changing international social, economic, and political order has fostered an increased attention on innovation, transfer, and management of knowledge. While many believe

that the emergence of the centrality of knowledge to society's growth is a consequence of economic reform and the proliferation of communication technology (Jentzsch, 2001), others argue that it is also an outcome of a gradual evolution of our social, political, and economic models (Lank-shear, 1997). Irrespective of what might have triggered the focus on learning and knowledge creation, both the above assumptions imply that a very diverse and complex mix of concepts, principles, and variables may influence what constitutes knowledge, information technology, learning context and processes, learner motives, and social and political imperatives. This diversity and complexity challenges us to re-conceptualise learning and teaching.

As a consequence of the above complexity and the contingent nature of our society, the learning capacity of individuals is increasingly being recognised as the most valued commodity in a knowledge and information society (Department for Education and Employment, 1998; Hargreaves, 2003). The search for models to support contingent yet sustainable learning, accelerated deep approaches to learning and the development of an understanding of the distributed and complex nature of learning has resulted in intensive research focussing on understanding human cognition and the meaning-making processes (e.g., Collin & Tynjälä, 2003; Lave & Wenger, 1991). This increased research activity, while contributing new insights, has tended to be narrowly defined and focussed on specific aspects of problems rather than investigating how the various aspects complement and/or hinder each other. For example, despite the development of the actor-network theory and its application in research (Latour, 1988, 1993; Somerville, 1999), it has not been used to explore the relationships between learners' motives, beliefs and values, and their engagement with the various aspects of the actor-network systems. Similarly, the acknowledgement that learning permeates all aspects of our lives has resulted in the emergence

of constructs such as "learning society" (Nonaka & Teece, 2001), "knowledge workers" (Maxwell, 2003; Rifkin, 2000), and "learning communities" (Shapiro & Levine, 1999). These constructs challenge the traditional conception of learning environments as they are all underpinned by principles of lifelong learning and continuous learning—principles that assume learning occurs seamlessly throughout individuals' lives and types of learning environments, as they negotiate their way within and among different contexts, contents, strategies, tools, and artefacts.

Against this backdrop, we explore and revise the existing concept of what constitutes a learning environment and speculate on ideas that may assist in understanding how learners identify and engage with the diversity and complexity of those environments.

RECONCEPTUALISING LEARNING ENVIRONMENTS

Most assumptions underpinning research into learning environments have emerged from models derived from the discipline of psychology. Such research has furthered our general understanding of learners' affective and cognitive needs in formal settings by identifying a number of influential psychosocial dimensions and also provided coherent models that can be satisfactorily adapted for teaching in specific versions of such environments. For a recent extensive review of this type of learning environment research, see Harington (2001).

Current literature on learning environments can be synthesised into a matrix comprised of environments, processes, and approaches. There are a number of different types of learning environments such as institutional, workplace, home, and social and community networks wherein a number of learning processes, such as face-to-face, distance learning, mentoring, experimentation, observation, and online learn-

ing can be utilised in a blend of independent and instructor supported approaches. Each of these combinations of learning environment, process, and approach presumably has their own peculiarities and unless researched, understood, and managed appropriately, may not produce their intended outcomes. For instance, motivation in a face-to-face learning environment is often created by the instructor's personality and ability to engage learners whereas in an on-line situation, it is more likely to be the user friendliness and types of interaction embedded in the design of the instruction. However, most of the research summarised in reviews such as Harington's (2001) tends to have a uni-dimensional focus. There is extensive research into online learning environments (Teh, 1999) most of which explore only the characteristics of the technological support and the technological capabilities of learners while ignoring cultural influences that may affect the differential engagement of learners with such a learning environment. They may vary in their methodology or the aspects of technology they pursue, but still have the focus on technology which is only a tool and thus may not have all the answers. Similarly, while the workplace is often considered a rich learning environment because of the authentic experience available to learners in such contexts (Beckett & Hagar, 2000), little is known about the impact of learner capabilities in workplaces to deal with online learning or learning more abstract principles that underpin practices (Edwards, 1998; Eraut, 2000).

An examination of the current approach to learning environment research suggests that it is based on two fundamental assumptions. First, it assumes learning environments to be isolated entities, "bounded" in nature. This has hindered rigorous research into investigating learner behaviours as and when they traverse boundaries of traditionally defined learning environments. The current convergence of the formal learning (school), informal learning (at home and on excursions) and social learning (sport and social

events) challenges the perimeters of boundaries of learning, yet very little research is available that attempts to explain this emerging notion of seamless learning environments. An illustration of this "bounded" approach can be seen in Teh's (1999) comprehensive study on formal learning environments where the informal learning experiences are not given any consideration. Similarly, little is known about the mechanism of the transfer of learning skills and knowledge from one learning environment to another or how learners simultaneously deal with several learning environments. The shift of vocational education from institutions (formal) to workplaces (informal) generated considerable interest in transfer (Lave & Wenger, 1991) and as this change was very distinctive, it was relatively simple to study. But with the increasing overlap between the traditional learning environment and the choice options available to learners, attempting to map learning skills and knowledge has become much more complex and fluid. Further, the processes of learners negotiating and navigating through a range of learning environments will increasingly become common practice and will need to become the focus of serious research. Both the negotiation of and navigation among fluid learning environments are critical attributes needed by learners in a rapidly evolving knowledge society.

Secondly, learning environments are currently viewed as essentially homogenous entities with a lack of appreciation of the diversity and complexity contained within a specific environment. There is a need to explore the nature of the learning environments and their associated elements (Jamieson, Fisher, Gilding, Taylor, & Trevitt, 2000; Luppardini, 2003; Newhouse, 2001). Each environment has its own set of underlying ideologies, software and hardware (physical and human resources), optimum strategies, etc., and variables which can have a significant influence on how, when and why learners engage in learning. Investigating this issue, Pillay and his co-researchers (Pillay, in press; Pillay & Elliott, 2002; Pillay

& McCrindle, 2005) have proposed a distributed framework to conceptualise and deal with some of the significant variables in a holistic yet differentiated manner that recognises the different elements in an environment and allows them to exist as separate but connected systems. The framework has identified four key factors that the authors believe capture all significant sources of influence on learner engagement and subsequent pragmatic action: (1) socio-cultural and political dispositions and ideologies which provide a personal rationale for learners to appreciate why they need to engage with learning, (2) domain knowledge which is constantly evolving and being redefined. Understanding the functional and relational aspect of the evolutionary process and the content will encourage sustained engagement, (3) strategies and processes which provide learners with ways to optimise their learning outcomes. This is often referred to as the “software of learning systems,” and (4) tools and artefacts which extend our capacity to research, access, and collect data, simulate activities to illustrate the effect of input variables and provide support for, and the enhancement of, learning. In this distributed framework, the attributes of each factor can have different sub-elements depending on the type of learning environment under scrutiny. Nevertheless, the key factors and sub-elements all may variously and simultaneously influence learner engagement in learning tasks in a reciprocal manner with the influence also extending to the motives and the choice of strategies adopted by students.

While this model provides a framework for thinking about ways in which some of these elements may interact, it is essentially descriptive and lacks any explicit reference to the energy that entices the learners to consciously reflect, reason, and perform the necessary learning activity. A possible way of conceptualising that energy is considered next.

CATERING FOR COMPLEXITY AND DIVERSITY IN LEARNING AND LEARNING ENVIRONMENTS

Acknowledging the complex mix of variables that influence learning, our current longitudinal research into e-learning (Taylor, Pillay, & Clarke, 2003, 2004a, 2004b) provides the basis for our theorising that the influence of learning environments on learning can be thought of as an outcome of the knowledge and/or intelligence designed into that environment. In order to design the intelligence in the environment we need to consider the elements and the possible influence they might have on learner engagement. As an example, take one of the elements in the distributed learning model, variously referred to as tools, objects or artefacts (including ICTs). We are in agreement with Csikszentmihalyi and Rochberg-Halton (1981) in that we argue that they have an epistemology of their own which together with the learner’s own epistemological beliefs about learning, trigger a reciprocal engagement similar to Bandura’s (1997) “triadic reciprocal causation” (p. 6) which in turn fosters subsequent pragmatic actions (Taylor et al., 2004a). To explain the energy that fosters this reciprocal engagement, we have introduced the term “learning agency” to represent the mediating reciprocity emerging from the environmental effects (Pillay, Clarke, & Taylor, 2006). The term “learning agency” is derived from the original Bandurian concept of “learner agency” (Bandura, 1997). We argue that Bandura’s “triadic reciprocal causation,” where the triad is the person, the environment, and behaviour is not only triggered by chance but can also be engineered by designing the environment in ways that may stimulate the reciprocity. Therefore, the influence of the knowledge designed into and available within a learning context can influence how learners engage in and with that environment. Considering the possibility of dif-

differentiating each of the triadic nodes in Bandura's model and investigating the reciprocal causal links may contribute to our understanding of the energy that entices learners to consciously reflect on the various elements in an environment, to reason and to perform the necessary learning activity (Pillay et al., 2006).

There is a need to move away from a homogenised model of learning environments as emphasised in Harington's (2001) review paper and to engage with and investigate the complexity and diversity in learning environments together with the elements and relationships contained in them. We are increasingly recognising that the optimum competencies required to successfully engage with a contingent and dynamic learning culture cannot be appreciated by viewing learning environments as bounded and learning processes as linear and unidirectional. In real life contexts, learners do not stay in bounded learning environments but frequently navigate through several environments, each of which may have several different learning elements. The motivation for learners to stay engaged also varies and oscillates between the traditional intrinsic and extrinsic values. In addition, increasing recognition is being given to *strategic* rather than exclusively *surface* or *deep* approaches to learning. Therefore, what is required is a framework that has the capacity to go beyond the boundaries of specific environments and redefine/expand some of the traditional constructs such as motivation, deep learning and transfer of skills and knowledge in order to explain the seamless and continuous nature of learning. As we see increasing diversification in what constitutes a learning environment, the challenge is not only to open the individual environments for deeper and closer scrutiny but also to explore bridges across new learning environments to ensure and support seamless learning. Thus we are challenged to seek alternative frameworks that have the capacity to explain the dynamic and temporal nature of learning culture which transcends specific learning environments, some-

thing that the traditional approach to researching learning environments cannot do as it is, by its very nature, "environment-bound."

The concept of *learning agency* provides a mechanism to represent these seamless learning environmental effects (Pillay et al., 2006). This notion of learning agency is consistent with the core concepts associated with actor-network theory (Law, 1992). Law uses the metaphor of "heterogenous networks" to suggest and recognise that society, including education systems and organisations, "are all effects generated in patterned networks of diverse (not simply human) materials." Further, actor-network approaches see "knowledge" as a product or an effect of those networks of heterogenous materials, rather than simply individual or social agents. For example, in our longitudinal study (Taylor et al., 2003, 2004a, 2004b), a large number of part-time students recognised themselves as not only knowledge learners but also knowledge creators for other students by drawing on their workplace experiences. They were able to move in and out of work environment (as consumers and creators) and the university environment (as learners and creators) experiencing seamless learning.

In our longitudinal study of e-learning at a university campus (Taylor et al., 2003, 2004a, 2004b), we asked students about their approaches to learning, perceptions of their learning environments, and epistemological reflections on themselves as learners. A counter-intuitive result of a mismatch between espoused learning motives and strategies emerged—students tended to have significantly lower surface strategies scores than surface motive scores; and students tended to have significantly higher deep strategies scores than deep motive scores. This meant that the students' behaviour (manifested in their learning strategies) could not be explained by their individual characteristics (learning motives). However, based on their perceptions of the learning environments and their epistemological reflections, the counter-intuitive finding was explained by the influences of the

technology-rich learning environment which included the usual ICT tools and peer networks, suggesting that individuals' approach to learning arises from mutual interactions between individual and contextual agency (ICT tools plus peers) which we labelled learning agency.

Our proposed driver of learner engagement, learning agency, is the total of the inherited ideas, beliefs, values and knowledge which guides the pragmatic action in social, cultural and professional environments. Learning agency is seen as implicit rather than explicit knowledge—it is *experienced* rather than *taught*—which makes it all-pervasive and relatively resistant to change. In our attempt to make it explicit in a learning context, we see learning agency as providing a strong sense for the design of institutional structures and their functions which in turn can impact on learner engagement in learning activities.

CONCLUSION

While this theorising deals with the recognition of the complexity and influence of a learning environment, the emergence of a knowledge society (Takeuchi, 1998) has seen an increased diversification in what are regarded as learning environments. This is due in no small way to the proliferation of ICTs in teaching and learning which have provided the opportunity to expand the range of legitimate learning environments from the traditional face-to-face modes. In this chapter, we are extending our previous theorising to address the increasingly diverse types of learning environments such as on-line learning, computer-based learning, workplace learning, institutionalised learning and their hybrids. In particular, we have argued the limitations of current theorising and understanding of learning and learning environments interpreted in terms of the reciprocal influence of agency, usually confined to the individual in the form of learner agency (Bandura, 1997). This tends to give limited attention to

the nature and influence of the environment and assumes that learning environments are isolated entities, bounded in nature. In real life contexts, learners do not stay in bounded learning environments but frequently navigate through several environments. Further, the notions of lifelong learning and seamless learning are central to a knowledge society and the extended theorising aims at accommodating these concepts.

The chapter offers a view that learning environments are a complex mix of teaching and learning tools or artefacts (ICTs), strategies (informal and formal individual and group learning), philosophy and ideology of learning (learning to learn, life long learning, seamless learning), the structural and functional aspects of discipline knowledge, and the physical design and furnishing of learning environments. The contradiction evidenced in the current public and private sector discourse towards promoting lifelong and continuous learning, both of which can presumably happen when working across several different learning environments, and at the same time encouraging a fragmented and highly contextualised approach to dealing with this complexity, needs to be challenged. Support for the above challenge can be seen in Winn's (2002) call that "educational researchers should...study which characteristics of these environments help or hinder learning" (p. 114). The notion of learning agency may provide a key to understanding the diversity and complexity of the seamless learning environments that are co-emerging with the knowledge-based society.

Chapter 1.26

Learning Styles and Adaptive ICT Based Learning Environment

Zlatko J. Kovačić

The Open Polytechnic of New Zealand, New Zealand

ABSTRACT

This chapter has two aims. First, to provide an overview of learning styles research and secondly, to provide an overview of research in adaptive hypermedia learning environment systems, those where different learning styles are considered and used to create a personalized learning environment. For most distance education institutions individualization of the learning environment for each student is not an option because economies of scale are the determining factor of cost reduction. However, the latest advances in database management, artificial intelligent systems and intelligent agents provide a technological infrastructure for individualizing the learning path for every learner at a lower cost. This chapter focuses on learning styles and how we can integrate and use them as a source of adaptation in an adaptive hypermedia learning environment systems.

INTRODUCTION

Teachers and researchers have long recognized the differences between learners and the impact these differences can have on learning. Concern for these differences has been the focus for academics and practitioners for decades and led to research on learning styles, i.e., “the composite of characteristic cognitive, affective, and physiological factors that serve as relatively stable indicators of how a learner perceives, interacts with, and responds to the learning environment” (Keefe, 1979). Research efforts in the theory and application of learning styles have proliferated a wide spectrum of models and instruments. Coffield, Moseley, Hall, and Ecclestone (2004a), who provided the latest and the most comprehensive overview of the learning style theories and instruments, have identified and critically discussed 13 major models of learning styles among the 71 models reported in literature.

Important messages emerge from the learning style research both for educators and course designers. Teachers should identify the learning styles of their students, encourage them to reflect on their own learning styles, and provide a teaching approach and support that will cater for individual learning styles. Course designers should create a learning environment that would address differences between learners. Though the idea of individualization is not new to education many of the larger distance education institutions offer little individualization for the students because economies of scale are the determining factor of cost reduction.

In the last few decades, with the emergence of information and communication technologies (hereafter labeled ICT) and their use in education research, we have witnessed new revival of interest in the individualization of learning and learning style research. There is a strong belief that ICT will provide the necessary foundation to individualize instruction, even in further education with large class sizes and a modular curriculum. At the same time emerging ICT raises expectations, as was pointed out by Kolb, the teacher's role will change from "dispenser of information, to coach or manager of the learning process" (1984, p. 202).

In the distance education we may achieve true individualization of the learning process by using emerging technologies such as intelligent agents and artificial intelligence systems which could store relevant data into a database and generate ad hoc completely customized course material, (i.e., an individualized learning path) for every single learner, according to their individual needs and preferences. An intelligent system which uses information about learners' preferences to dynamically organize course material is labeled an adaptive learning environment. If this learning environment involves the use of hypertext and multimedia (and most recently is Web-based) then we are describing an adaptive hypermedia learning environment (hereafter labeled AHLE). Peter

Brusilovsky (1996, 2001) provided an overview of adaptive hypermedia systems from the early 1990s until now. He shows that the research on adaptive hypermedia systems in the last decade produced framework, techniques, prototyping models and authoring tools to create courses deliverable in the AHLE.

There are many different criteria for the adaptation of the learning environment to suit individual learner's needs and preferences. In this chapter we are focusing on the use and integration of learning styles as the only criteria for adaptation of the learning environment.

This chapter has four objectives: (a) to summarize and present learning style models in a systematic manner using proposed learning styles meta-models, (b) to review systematic efforts to establish and implement adaptive hypermedia systems in education, particularly those based on using learning styles as an adaptation criteria, (c) to discuss the problems and limitations of the current approach in using learning styles in adaptive hypermedia systems, and (d) to discuss the implication of the adaptive hypermedia systems based on learning styles on pedagogy, course design, and developers of an adaptive hypermedia system.

OVERVIEW OF LEARNING STYLE MODELS AND INSTRUMENTS

There is a proliferation of definitions, concepts, models, and instruments related to individual learner's preference which makes it very difficult to summarize and classify learning styles models. What makes such an effort even more difficult is that there is no clear separation between the various models, as De Bello (1990, p. 217) suggests, "there are many areas of overlap among the models."

The taxonomy of learning styles models proposed by Lynn Curry (1983) uses an onion metaphor consisting of three layers. The core,

the innermost layer of Curry's "Onion Model" deals with the most stable component of style, (i.e., cognitive personality style). Models from this layer focus on impact of personality on the ability to acquire and integrate information. Models from the middle layer are labeled as "information processing models" which concentrate on the ways learners obtain, sort, store, and utilize information. The models from this layer are more stable than the models from the outer layer ("instructional preference models") but are still modifiable by learning strategies. Finally, environmental, emotional, sociological, physiological, and psychological features of both learners and teachers are included in the models from the outer layer—"instructional preference models." Claxton and Murrell (1987) added a fourth layer, social integration, which they placed between Curry's outer two layers. Models from this layer focus on how a learner interacts with other learners during the learning process. Finally, Given (1996) included physical elements (such as visual, auditory, tactile and kinesthetic) between social interactions and environmental/instructional layers to make the metaphorical model more complete.

In this chapter we have adopted the classification proposed by Coffield, Moseley, Hall, and Ecclestone (2004a). Presenting the learning style models in a continuum, they have allocated each model to one of the "families of learning styles." This continuum is based on the extent to which the authors of learning styles models and instruments appear to believe that learning styles are fixed. They have identified the following five families of learning styles:

- Constitutionally-based learning styles and preferences
- Cognitive structure
- Stable personality type
- "Flexibly stable" learning preferences
- Learning approaches and strategies

The first family encompasses those models which consider influence of genetics on fixed inherited traits and the interaction of personality and cognition as the dominant factors. Moving along the continuum, we locate learning style models which are based on the idea of dynamic interaction between personality and experience. On the opposite side of the continuum is a family of learning styles models where the authors paid particular attention to personal factors, curriculum design, institutional and course culture and their impact on learning.

Using learning style as a source of adaptation of the learning environment raises the question of which learning style model to select and build in the AHLE system. Sampson and Karagiannidis (2002) proposed a certain number of conditions that each candidate, for use in AHLE systems among learning styles models, should be tested against. They suggested a check on the theoretical and empirical justification of the model, the suitability of the learning style model in the specific learning context; whether the model or its constructs are measurable or not; the time effectiveness in applying a particular model; does the model provide sufficient instruction about what should be adapted for each learner category and finally the cost of using a particular learning style instrument.

In this chapter we focus on those learning styles models which could be used or are already built in the AHLE systems (both prototyping and conceptual AHLE systems are considered). Most of these learning styles models belong to the middle layer of the Curry's model or to the stable personality type or "flexibly stable" learning preferences family in case of Coffield, Moseley, Hall, and Ecclestone classification. The reason for this is that the models which belong to this layer or family are more stable than the others, and do not interact directly with the environment, though they are modifiable by learning strategies (Atkins, Moore, Sharpe, & Hobbs, 2001).

We begin with the first family of learning styles (i.e., constitutionally based). The most prominent representative of this family of learning styles is the Dunn and Dunn model (Dunn, 2003) based on five dimensions that mark various preferences: environmental, emotional, sociological, psychological, and psychological. However, from the perspective of using learning styles models in the AHLE systems Del Corso et al. (2001) did not recommend the Dunn and Dunn model, because this model is focusing on less relevant aspects of learning such as the senses and environmental factors.

Next, we consider learning style models which belong to the cognitive structure family. Coffield, Moseley, Hall, and Ecclestone (2004a) provided a detailed analysis of the Riding's model of cognitive styles (Riding & Cheema, 1991) as the representative for this family. However, in the research literature about AHLE systems, Witkin's model (Witkin, Moore, Goodenough, & Cox, 1977) or better known as the Field Dependent/Field Independent model, was more frequently used than any other from this family of learning styles. Witkin's model divides learners into two groups: Field Dependent learners (externally motivated, like collaborative work and are people-oriented) and Field Independent learners (intrinsically motivated, prefer to work alone and take an impersonal approach to learning). Degrees of field dependence or field independence could be defined as a continuum with field independent at one end and field dependent at the other end. In the middle of the continuum is the group termed as field mixed who do not have clear orientation like the group of field dependent or field independent. This has a practical implication for use of Witkin's model in the AHLE system. According to Sampson and Karagiannidis (2002) criteria in case of field-mixed learners we may say that the model did not provide sufficient instruction on what should be adapted for this particular learner category.

The stable personality type family of learning styles models was rarely used in AHLE systems. The most popular learning style model which belongs to this family is the Myers-Briggs model. This model is based on psychologist Carl Jung's theory of psychological types and uses four bipolar dimensions to characterize people according to 16 personality types. Each of these types has a primary orientation toward the world, one which affects their ability to learn and to work. Del Corso et al. (2001) recommended not considering implementation of the Myers-Briggs model in the AHLE systems. According to them, this model goes beyond cognitive controls and behavior related to learning, focusing on the whole personality rather than information perceiving and processing dimensions which is the main focus of the Kolb's and Honey and Mumford's model.

The flexibly stable learning preferences family comprises, among other models, Kolb's experiential learning cycles model (1984), Honey and Mumford (1992), McCarthy (1990), and Felder-Silverman model (1988). Honey and Mumford's and McCarty's model were inspired by the Kolb's model and share basically the same pedagogical approach to learning. This family of learning styles was most frequently implemented as one of adaptation criteria in the AHLE systems. The Kolb model uses the learner's experience as a starting point in the learning process. Learners are perceived as passing through four stages of learning. Initially they are experimenting with the topic accumulating enough concrete experience to be able to reflect in the second stage on the observation gathered in the concrete experimenting stage. As a result of reflective activities, learners derive abstract concepts and make generalizations in the third abstract conceptualization stage. Finally, new concepts are subject to testing to see if they provide a solid explanation in new situations. In other words, learners begin a new learning cycle, gathering new evidence, and concrete experience. Though learners are moving through each stage, they tend to use a specific learning mode.

Therefore we can describe them as a learner with a preference for a particular mode. By looking at the quadrants, Kolb identified four types of learners: Diverger (creative, generates alternatives), Assimilator (defines problems, creates theoretical models), Converger (practical applications, makes decisions), and Accomodator (takes risks, gets things done).

Initially the Felder-Silverman model was developed as a five-dimensional model, with the following dimensions: Perception, Input, Processing, Understanding, and Organization. Later the organization dimension was omitted because Felder (1993) believes that the best approach to teaching undergraduates is always inductive and therefore his learning styles instrument does not differentiate between inductive and deductive learners. Both the Kolb's and Felder-Silverman's models are based on the same educational philosophy of John Dewey, which emphasizes the nature of experience as of fundamental importance in education.

There appears to be a close relationship between the Felder-Silverman and the Kolb model. They share the same two dimensions: processing (the preferred way learners are processing information, with two poles: actively/reflectively) and perception (the preferred way learners are perceiving information, with two poles: sensing/intuitive). However, the Felder-Silverman model also partly belongs to the second and third families of learning styles, (i.e., cognitive structure and stable personality type, because it adds two new dimensions, which address the learners' approaches to adapting and assimilating information.) These two dimensions are: input (the preferred way learners are inputting information, with two poles: visually/verbally) and understanding (the preferred way learners are adapting information, with two poles: sequentially/globally).

The last family of learning styles we are considering is labeled "learning approaches and strategies." The well-known model in this family

is the Grasha and Reichmann model (Hruska-Riechmann & Grasha, 1982). They developed a set of student learner types that indicate the likely attitudes, habits, and strategies students will take toward their work. Grasha (1996) indicates ways in which teachers can adjust their teaching styles to create better connections with various types of students. This model has three personality dimensions: (1) competitive—collaborative, (2) avoidant—participant, and (3) dependent—independent.

We would expect that when the learning environment and teaching methods are modified to cater for various learning styles, that the student outcome, (i.e., academic performance) would improve. Therefore, as an illustration of the applied learning styles research that might be relevant for AHLE systems, the relationship between learning styles and academic performance is discussed. There are many factors which influence academic performance in addition to learning styles, such as gender, age, and work experience (Dille & Mezack, 1991). While it is preferable that a student uses and develops an array of learning styles to deal with course content and the real world, most of the applied work in this area focus only on a student's currently preferred learning style. Though there have been numerous studies on the relationship between preferred learning styles and academic performance (Zywno & Waalen, 2002), the evidence remains contradictory. For example for first-year programming courses, Thomas, Ratcliffe, Woodbury, and Jarman (2002) suggest that there is a relationship between student learning style and academic performance, while Byrne and Lyons (2001) suggest that no such relationship exists. Weak evidence of a relationship and impact on academic performance has been found for the way students on an IT course are inputting and understanding the information by using the Felder-Silverman model (Kovai & Green, 2004).

IMPLICATIONS OF LEARNING STYLES RESEARCH FOR PEDAGOGY

Each of the learning styles models has its own specific implications for pedagogy. In this section we are addressing two general issues related to pedagogical implications which are relevant for all presented models: meta-cognition and “matching hypothesis.” We conclude this section with critiques of the learning style models and instruments.

Even if the idea of learning styles is not fully accepted we believe there might be a benefit from discussing the concept. Coffield, Moseley, Hall, and Ecclestone (2004a, p. 120) stated that “A knowledge of learning styles can be used to increase the self-awareness of students and tutors about their strengths and weaknesses as learners.” This self-awareness of learners and teachers is known in literature as the meta-cognition. By increasing meta-cognitive abilities learner can take full ownership of his or her learning. When we are able to understand how we learn, how deeply we learn and our reasons for learning then we can, in some situations, manipulate the learning strategy to best suit our learning styles. At the same time learners with developed meta-cognitive abilities can be expected to be more adaptive to changes in the learning environment.

“Matching hypothesis” describes the situation in education when there is congruence between teaching styles and learning styles. Whichever model of the learning styles one prefers or implements the expectation is that there is a mismatch between learning and teaching style preferences. To minimize conflict between teacher’s and student’s style, some researchers in the area of learning styles recommend teaching and learning styles be matched (e.g., Charkins, O’Toole, & Wetzel, 1985; Griggs & Dunn, 1984; Smith & Renzulli, 1984). On the other side we can argue equally well that mismatches are sometime desirable and that learners should be exposed to mul-

iple alternative teaching-learning strategies for their own benefits. Exposure to different teaching styles or deliberate mismatching is what Grasha (1996) recommends. He argued that people need to be “stretched” to learn, and such a situation he describes as a “creative mismatch” between teaching and learning style. Therefore, the issue remains whether to teach to learners’ strengths or to challenge them and expand their styles?

A mismatch can lead to poor teaching outcomes, low retention of students on courses (Felder & Silverman, 1988), and to poor academic performance (Ford & Chen, 2001). Though Felder (1993) advocates teaching strategies that incorporate all of the learning style preferences, there is still discussion on whether mismatches of teaching and learning styles should be sought or avoided and whether there is a benefit from eliminating mismatches or not. Coffield, Moseley, Hall, and Ecclestone (2004a, p. 123) for example, claim they “failed to find...hard empirical evidence that matching the styles of learner and tutor improves the attainment of the learner significantly.”

The learning styles model continues to be the subject of debate and critique. Curry (1990) identified three problems with making the learning style model the basis of educational practice. Firstly, different learning style models and instruments use different style categorization to define the learning style continuum. Even the fundamental elements such as definition of learning style are not unanimously accepted and almost every author has his or her own definition. Though there is an overlap among concepts and models it is not an easy task to classify these models or to compare them. Secondly, evidence of the reliability and validity of learning style instruments is weak. Coffield, Moseley, Hall, and Ecclestone (2004b, p. 55) go even further by saying “that some of the best known and widely used instruments have such serious weaknesses (e.g., low reliability, poor validity and negligible impact on pedagogy) that we recommend that their use in research and in practice should be discontinued.” Thirdly, the

pedagogical implications and changes in educational practices that complement particular learning styles are in some cases hard to identify or it is not clear whether the increase in performance should be attributed to other factors rather than to the implementation of a learning style model. More comprehensive critical reflection on the theory and practice of learning style is given in Coffield, Moseley, Hall, and Ecclestone (2004a, 2004b).

ADAPTIVE HYPERMEDIA LEARNING ENVIRONMENT

The birth and the rapid growth of the Internet have transformed education and the way we learn. The dominant paradigm in today's education uses a traditional hypermedia based learning environment which assumes that "one size fits all." However, since the early 1980s, with advances in artificial intelligence research, there has been a significant development of systems to provide an individualized and intelligent response to users interacting with computers. These artificial intelligence systems were based on strategies to "learn" users' interactions with the learning environment and respond accordingly. Brusilovsky (2000, 2001) described two phases in the historical development of adaptive systems. Before 1996 adaptive systems were based on pre-Web hypertext and hypermedia. The most dominant systems at that time were intelligent tutoring systems, which were from a pedagogical perspective, teacher-centered systems with the main focus in problem-solving support. After 1996 research interest moved toward Web-based adaptive hypermedia, along with a shift in pedagogy toward a student-centered learning, based on constructivist approach. In regard to the application of adaptive hypermedia in education Brusilovsky (2004b) identified three generations of AHLE systems. The research focus of the latest generation of AHLE systems is the integration of adaptive hypermedia technologies

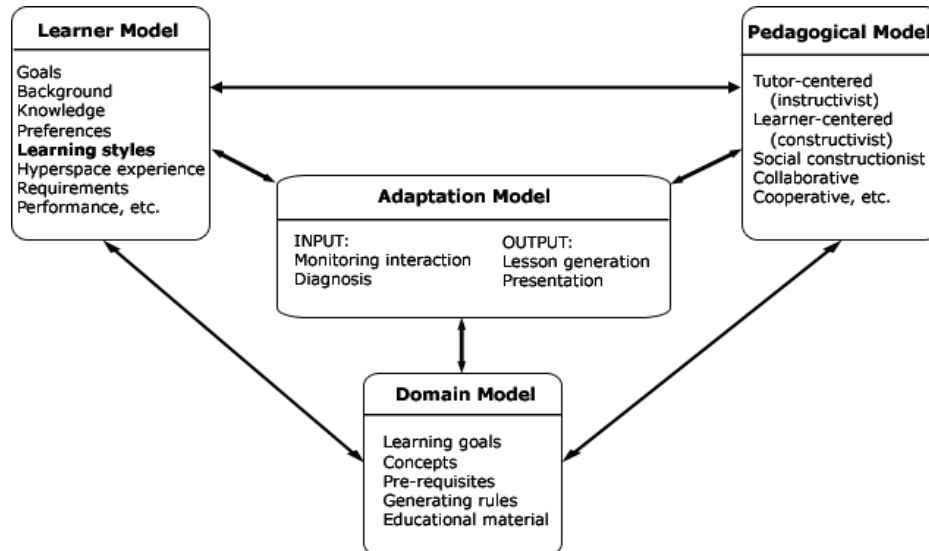

into the regular educational process, answering the challenge posed by dominant learning management systems such as Blackboard and WebCT.

AHLE systems usually provide two forms of adaptation: adaptability and adaptivity. Both terms describe personalization on the Internet. However, they are two quite different concepts dependent upon whether the learner or the system is in control of the adaptation. Kay (2001) discussed different levels of adaptation which should be considered when designing an AHLE system: (a) *adaptability*—the system is adaptable when the learner modifies the visual appearance of the learning environment; and (b) *adaptivity*—the system is adaptive when it monitors a learner's behavior and updates a learner model. Then the presentation is updated according to the learner model, which in turn is updated during browsing process.

Summarizing the various conceptual and prototyping models of the AHLE systems we came up with a generic model which encompasses most of the existing AHLE systems. The conceptual model of an AHLE system is presented in Figure 1 and consists of four sub-models:

1. **Learner model:** Stores information about each learner (user profile) including a learning style profile in the database. Magoulas, Papanikolaou, and Grigoriadou (2003) provided a detailed structure of the learner model (goals, knowledge, learning styles, preferences, background, and hyperspace experience). A learner's understanding about the domain in this model is typically represented as an overlay model of the domain model. This means that for every "concept" in the domain model there is a corresponding "concept" in the learner model that represents how the learner relates to that concept (De Bra, Aroyo, & Chepegin, 2004). Alternative models describing the learner's knowledge level of domain are listed in Danchak (2004).

Figure 1. Conceptual model of an adaptive hypermedia learning environment system

2. **Domain model:** Contains information content of the course, which includes also the relationship between course components (Kelly & Tangney, 2004; Wu, 2002).
3. **Pedagogical model:** Defines the roles of each person, such as instructor and learner, and stores details about pedagogical approach used. This model has not been included or discussed in most of the AHLE systems. Shute and Towle (2003) argued that existing AHLE systems concentrate more on the adaptation of the format of the content rather than on adaptive instruction. In other words, the pedagogical component of AHLE system is quite often neglected.
4. **Adaptation model:** Consists of a description of how to update the learner model by monitoring a learner's behavior and also how to generate the adaptation.

There are some variations of the presented conceptual model. Paramythis and Loidl (2004) for example, added the Group Model to the AHLE model. It captures the characteristics of groups of learners, which is important when collaborative instructional design is used.

In order to select the appropriate technology of adaptation we need to answer the following

questions: what features of the learners or their environment are used as the source of adaptation and which features of the AHLE system can be different for different learners. Most of the AHLE systems use the learner's previous knowledge of domain as a source of adaptation. Recently, learning style information has been used as a source of adaptation in AHLE systems (see Table 1). The answer to the second question brings technologies of adaptation into focus. Brusilovsky (1999, 2001) identified the following adaptive and intelligent technologies for Web-based education:

1. **Curriculum sequencing (or instructional planning) technology:** Adapting the sequence of the content to the learners' learning preferences (Brusilovsky & Vassileva, 2003).
2. **Problem solving support technologies:** The intelligent analysis of learner solutions, example-based problem solving, and interactive problem solving support.
3. **Adaptive navigation support:** Direct guidance, adaptive annotation, adaptive sorting, and adaptive link hiding and disabling. Helps the learner orientation and navigation in hyperspace by changing the appearance of visible links (Brusilovsky, 2004a; Brusilovsky, Chavan, & Farzan, 2004).

Learning Styles and Adaptive ICT Based Learning Environment

Table 1. Adaptive hypermedia learning environment systems that use learning styles as a source of adaptation

AHLE system (working/ conceptual model); author(s)	Learning style model and author(s)	Initial identification & dynamic adaptation	Adaptation technology	Teaching/learning approaches
3DE; Del Corso et al. (2001)	Honey & Mumford (1992)	Questionnaire. Learners' profiles are described on all four basic dimensions.	AP	Content is stored as a set of micro modules, specifically designed for each learning style. Teacher supervises course creation.
ACE; Speeth & Opperman (1998)	Model not specified. Learner's media preferences	Learner directly modifies learner model.	ANS (adaptive annotation and incremental linking), CS	Teaching strategy is modifiable by the system.
AES-CS; Triantafillou, Demetriadis & Pomportsis (2002)	Witkin et al. (1997)	Questionnaire. Learner directly modifies learner model.	ANS (link annotation)	Learners can switch between different instructional strategies.
AHA!; Stash, Cristea, & De Bra (2004) Stash & De Bra (2004)	Any could be used. Honey & Mumford (1992) Witkin et al. (1997)	Learners initially specify their learning style. System adapts learner model.	CS, AP, ANS (adaptive annotation)	Learners can switch between different instructional strategies and change attributes of the concepts in their learner model.
Arthur; Gilbert & Han (1999, 2002)	Any could be used. Witkin et al. (1997)	Alternative styles of instruction differ in the type of media they use.	CS	Mastery learning – dynamically adapts the instructional style according to learner's performance.
CS383; Carver, Howard, & Lavelle (1996, 1999)	Felder & Silverman (1988)	Questionnaire	AP	Media elements are sorted, ranked and presented according to learners' learning style
Danchak (2004)	4MAT; McCarthy (1990)	Questionnaire. Naïve Bayes Classifiers and Case-based Reasoning.	AP	Reflective teaching method of instruction
ILASH; Bajraktarevic, Hall, & Fullick (2003a, 2003b)	Felder & Silverman (1988)	Questionnaire	ANS (adaptive annotation and hiding of links), AP	Adapt the method of navigation with special emphasis on the approaches of global and sequential learners.
INSPIRE; Papanikolaou, Grogoriadou, Kornilakis, & Magoulas (2002, 2003)	Honey & Mumford (1992)	Questionnaire. Direct manipulation of learner model.	ANS (adaptive annotation and hiding of links), AP, CS	Adapt method and order of presentation of multiple types of educational resources.
iWeaver; Wolf (2002, 2003)	Dunn & Dunn; Dunn (2003)	Questionnaire. System allows for fluctuations in learning styles.		Learners can switch and combine media representations and system adapts dynamically.
MANIC; Stern & Woolf (2000)	Model not specified; Text vs. graphic	System adapts learner model. Naïve Bayes Classifiers	AP	Presentation of content objects using <i>stretchtext</i> which allows certain parts of a page to be opened or closed.
Peña, Narzo, & de la Rosa (2002)	Felder & Silverman (1988)	Questionnaire. Case-Based Reasoning	ANS (adaptive annotation and hiding of links), AP	
TANGOW; Paredas & Rodríguez (2002a, 2002b, 2004)	Felder & Silverman (1988)	Questionnaire. Learner directly modifies learner model.	AP, CS	Learning style was used to adapt the exposition-example sequencing (sensing/intuitive learners).

4. **Adaptive presentation:** Adapts the content to learners' learning preferences.
5. **Learner model matching technologies:** Adaptive collaboration support and intelligent class monitoring—uses the system's knowledge about different learners to form a cohesive group for different kinds of collaboration, or to identify a mismatch between learners.

The most frequently used adaptation techniques in the AHLE systems are: adaptive presentation, curriculum sequencing and adaptive navigation support (see Table 1, column "Adaptation technology"). On first use of an AHLE system which uses learning style preferences as a source of adaptation, the learner has to complete a learning style questionnaire; the result from this questionnaire initializes the learner model and classifies the learner into a particular learning style group. Most of the AHLE systems assess the learning styles through psychometric questionnaires (Stash, Cristea, & DeBra, 2004). The disadvantage of this approach is that the learners are classified into stereotypical groups and assumptions about their learning styles were not updated during the subsequent interactions with the system in most of the early AHLE systems. However, in the latest AHLE systems, during the use of the system, the learner model is dynamically updated in terms of preferred learning components and changes in learning preferences. In other words, these systems assume that learning preferences are not fixed, and that a learner's learning style may change from one occasion to another. These systems do not require an initial diagnosis of a learner's learning preferences but simply pick them up from browsing behavior of the learner. Danchak (2004) suggests using two alternative techniques for dynamic adaptation of learning preferences, namely the Naïve Bayes Classifiers and the Case-Based Reasoning (see Castillo, Gama, & Breda, 2003; Funk & Conlan, 2003; Zukerman & Albrecht, 2001). These techniques could be used to dynamically update learning preferences in the learner model. Furthermore, an ideal AHLE system should provide learners

with full control over the learner model, allowing them to change their learning preferences in spite of initial classification in a particular learning style group.

Although systematic efforts have been made to evaluate adaptive systems (Weibelzahl, 2003; Weibelzahl & Weber, 2001) only a few empirical studies, mostly small scale studies conducted in experimental conditions, have been conducted that seek to prove the effectiveness of the adopted approaches based on learning styles (Papanikolaou & Grigoriadou, 2004).

CONCLUSION

Awareness about learning styles is very important both to academic staff and learners. Learners will gain an understanding of why academic staff is using different teaching approaches on the course and how they can benefit from them. Academic staff will recognize the diversity of learning styles among learners and adjust their teaching style to take account of this. The discussion in this chapter also sends a clear message to instructional designers to create a learning environment that will support the construction of knowledge in learners.

Coffield, Moseley, Hall, and Ecclestone (2004b) answering the question in the title of their study "Should we be using learning styles?" claim that there are no clear implications of learning styles research for pedagogy. They state that, for example, there is no consensus on whether the style of teaching should be consonant with the style of learning or not. However, one of the benefits that an AHLE system with learning styles could have over a non-adaptable learning environment is that it could help students to develop meta-cognition skills. An AHLE system provides learners with alternative paths through the course material based on different learning styles. Learners could reflect on the way they are learning and then decide to use an alternative path through the course, i.e., a different learning approach to the course material. In other words, AHLE systems

could stimulate learners to think more about the way they are learning and what the best learning strategy for them is. Of course an AHLE system to some extent should also expose learners to teaching styles and instructional material which is different from their preferences to increase their readiness for the real world (Felder, 1993, 1996; Montgomery & Groat, 1998).

Learning styles which belong to the stable personality type and “flexibly stable” learning preferences families in Coffield, Moseley, Hall, and Ecclestone’s (2004a) classification of learning style models, are used in AHLE systems as a source of adaptation more often than others. These models are the Felder and Silverman, Honey and Mumford, McCarthy, Dunn and Dunn, and Witkin models and provide sufficient information for AHLE systems designers to incorporate them in the system. They also fulfill most of the conditions stated by Sampson and Karagiannidis (2002) for any learning style model, which is a candidate for use in an AHLE system as a source of adaptation. Of course this does not mean that the other learning style models should not be tried in an AHLE system. This may be a possible topic for further research in this area.

Most of the AHLE systems which incorporate learning preferences as a source of adaptation use the following adaptation technologies: adaptive presentation, curriculum sequencing and adaptive navigation support to adapt learning environment to individual learning preferences. However, because of the increasing role of collaborative learning in distance education, adaptive collaborative support technologies together with learning style information should be considered for the construction of groups and implementation in an AHLE system in future development.

FUTURE TRENDS

One of the reasons why AHLE systems are not widely used as an alternative for course management systems such as WebCT and Blackboard, lies in fact that most of them are not content-free, (i.e., they are developed for a particular domain

and/or particular learning style model). In other words, domain and learning style are embedded in the code of the AHLE system. This is the area where Brusilovsky (2001, 2003b) expects future progress and the development of new architectures and authoring tools for AHLEs. He predicts that “we may expect better markup-based and form-based tools. I also expect the appearance of a new kind of ‘really graphic’ user interface design tools” (2003b). At the moment the only available content-free authoring tool is De Bra’s AHA.

The use of learning style as a source of adaptation in a new generation of AHLE systems raises the following question: How do we address the meta models of learning styles in adaptive hypermedia? (Brusilovsky, 2003a). In other words the question is whether the AHLE system is capable of addressing not only one selected learning style, but whole families of learning styles. Berlanga and Garcia (2004a, 2004b) proposed a flexible design of an AHLE system with learning preferences as a source of adaptation where learning styles approach and adaptation rules are not prescribed. They argued that different learning style approaches should be used for different knowledge and types of learners. The idea is not to set down any particular learning style, but a flexible structure where the different learning style approaches can be easily described and used to characterize the learning style of learners and activities.

Future AHLE system should provide learners with full access to the learner model. Learners should be able to choose a particular path through the course material, even if it is not the same path recommended by the system and based on their learning styles. As was recommended before, learners should be exposed to different approaches to learning to improve their meta-cognition skills and to gain an understanding of how other people in their collaborative team learn. Future AHLE systems should have built-in options similar to the computer chess game, where a player might select an opponent with certain characteristics,

for example, a defensive or offensive player.

Learning style processing may require fuzzy logic in the diagnosis (Triantafillou, Pomportsis, & Georgiadou, 2002), allowing for the fact that not all users are located at the poles of each dimension of the learning style model (for example, global and sequential poles in the case of Felder and Silverman model), but they combine the characteristics of both global and sequential dimensions. However, as they argued, it is questionable if all different shades of learning styles can be handled by an adaptive hypermedia system, or if the system should be simpler for the user's benefit. It is a matter of future research to find a trade-off between the degree of adaptation and the level of complexity of an AHLE system.

There are also other issues related to learning styles in AHLE systems that need to be addressed in the future, such as delivering an adaptive course for mobile devices (Brusilovsky & Rizzo, 2002c, 2004; Kinshuk & Lin, 2004) and creating a framework or at least adaptive navigation support, which would integrate closed corpus course material (a standard AHLE system with well-structured homogeneous course material) with open corpus Web material, i.e., all the other relevant resources on the Internet (Brusilovsky & Rizzo, 2002a, 2002b).

Chapter 1.27

Behavioral, Cognitive, and Humanistic Theories: Which Theories Do Online Instructors Utilize?

MarySue Cicciarelli
Duquesne University, USA

ABSTRACT

This article presents fifteen different design theories from the behaviorism, cognitivism, and humanism schools of psychology. Information about the theories is presented as a response to three research questions. Descriptions and online learning empirical evidence of eight of the theories are illustrated first. Then, descriptions of seven additional design theories which have not yet been researched in connection with online learning are offered. Finally, results from a study that investigates how often online instructors utilize nine of the theories is presented. Conclusions are made in connection to the three research questions, and further research studies related to the topic are suggested.

INTRODUCTION

An increasing number of individuals have chosen distance education when taking a course or earning a degree because it is a flexible alternative that meets their needs (Chu & Hinton, 2001; Course-Management Systems, 2005). An online course is one type of distance education where an instructor and the students interact through an online venue, such as a course management system. When taking an online course, the course may occur at different times from different places, or it can occur at the same time from different places (Course-Management Systems, 2005; Simonson, Smaldino, Albright, & Zvacek, 2000).

There are advantages to taking an online course, and there are challenges that students and instructors must overcome. Synchronous and asynchronous discussion boards are features of a course management system that instructors make use of because these tools can be used to individualize instruction, encourage goal-based exploration, and guide students to construct new schemes of knowledge (Prester & Moller, 2001). Challenges that occur include feelings of isolation, waiting for responses to asynchronous posts, absence of impulsive discussion, and lack of non-verbal isolation (Figueroa & Huie, 2001; King, 2001; Northrup, Lee, & Burgess, 2002; Prester & Moller, 2001).

Designing effective courses is one way that instructors reduce the disadvantages (Collins & Berge, 1996; Makrakis, 1998; Prester & Moller, 2001; Williams, 2001). Instructors often use design theory to guide the development of courses so they can be more effective. Instructors may have problems in mind from past experiences with teaching online that they want to avoid, or they can recognize a problem as it is occurring and implement a strategy to help reduce the difficulty. Instructors may accept the idea of using theory to guide course design and solve problems, but they may have questions that they want answered. The purpose of this article is to answer three of the following questions that online instructors may have: (a) According to empirical evidence, what does the research show about online instructor use of different design theories? (b) According to lack of empirical evidence, which design theories have not been researched in regard to online instructor utilization of theory? and, (c) According to a recent study, how frequently do online instructors use nine of the design theories?

REVIEW OF LITERATURE

There are three schools of psychology in which theories are categorized; behaviorism, cognitivism and humanism. It is believed that one school of theory is not better than the other, and indi-

viduals are encouraged to apply the theory that is the most appropriate for the student (Joyce, Weil, & Calhoun, 2000; Pinar, Reynolds, Slatery, & Taubman, 1996; Tomei, 2007).

Behaviorism, Cognitivism, and Humanism

Behaviorism

Experimental psychologists William James and Edward L. Thorndike, questioned the use of memorization as a strategy for learning. Experiments showed that memory did not increase after the participants had memorized sets of information. These results guided a turn in research toward stimulus-response behavioral psychology. James and Thorndike believed that the environment served as a stimulus, and it could be used to change the way individuals responded. As behaviorism became more established as a part of the school of psychology, psychologists began to focus on individual's responses to feedback when they performed a task. Other behavioral psychologists that have made contributions to the field of behavior psychology include Ivan Pavlov, B. F. Skinner, Albert Bandura, and Benjamin Bloom (Joyce et al., 2000; Pinar et al., 1996).

Cognitivism

Theories that are cognitive in nature are based on learning tasks that are practical, and they are seen being used in authentic learning environments. Cognitive theorists such as Jean Piaget, Lev Vygotsky, Erik Erikson, and David Ausubel have developed theories that are not only widely accepted, but they have begun the path for the development of other cognitive theories. When instructors utilize theories that are cognitive in nature, they tend to develop learning experiences that help students make connections that are meaningful to themselves (Grabinger, 2004; Tomei, 2007).

Humanism

Theories that focus on a student's affective needs come from the humanism school of psychology. These theories attend to students' feelings, emotions, values, and attitudes. Some of the earliest work that reflected humanism came from Colonel Parker, who encouraged child centered learning in a democratic school environment. His work later influenced the progressive work of John Dewey. Theorists such as Elliot W. Eisner, Ross Mooney, and Paul Klohr supported the development of learning experiences that focused on self value. Carl Rogers and Abraham Maslow wanted educators to concern themselves less with curriculum development and give more of their attention to understanding curriculum. The work of these psychologists eventually influenced the development of other theories based on Humanism. Collective common factors of theories rooted in Humanism include the attention toward student-centered learning and individualism (Pinar et al., 1996).

ACCORDING TO EMPIRICAL RESEARCH: THEORIES SEEN BEING USED BY ONLINE INSTRUCTORS

Theories of Behaviorism

Social-Cultural Model of Learning

An online course that incorporates the social-cultural model of learning is reflective of behaviorism because patterns of communication are utilized. The social-cultural model of learning uses written and oral dialogue. Threaded asynchronous discussions, synchronous discussions and e-mail are examples of the tools implemented by instructors during the course design process. The pattern of behaviorism begins when the instructor poses a question, students respond to the question, and the instructor responds to the students' responses with positive or negative reinforcement comments.

In a study that explored Web-based online meetings, researchers found that learners wanted to interact with each other and their instructor through discussion. However, results showed that precautions need to be taken by the instructor to help promote effective discussion (Berge & Fjuk, 2006). Results from a four-year study on threaded discussions had outcomes that favored use of asynchronous discussions (Schwartzman, 2006).

In another study, researchers looked at the behavior of 96 individuals who participated in an asynchronous discussion. Results from a Myers-Briggs test were used to divide the participants into 24 groups based on personality type. There were eight introverted type groups, eight extroverted type groups, and there were eight mixed groups. Participants from the extroverted and mixed groups posted more asynchronous messages compared to the participants from the introverted groups. However, it was the participants from the mixed groups who showed a greater amount of metacognitive interaction. Online instructors are encouraged to create mixed groups because instant feedback and new ideas presented by extroverted members may stimulate introverted members, and the in-depth discussion prompted by arguments from the introverted members could further stimulate the extroverted members to increase participation (Lee & Lee, 2006).

Mastery Learning

Mastery Learning is a practice originally created by John B. Carroll and Benjamin Bloom. John Carroll's perspective holds that a student's aptitude correlates with achievement. His view of aptitude considers how long it takes for the learner to learn the material as opposed to the learner's ability to master the material. According to this view, every learner can learn as long as the appropriate materials and instruction are provided. Benjamin Bloom's work focuses on organizing the curriculum so that students have the necessary time and ability to benefit from instruction. Now that modern instructional tech-

nology has afforded educators with new choices, curriculum developers are encouraged to develop comprehensive curriculum that includes self-administering multimedia units and programmed learning procedures (Joyce et al., 2000; Pinar et al., 1996).

In a study that explores the use of strategies to engage the whole learner, mastery learning is utilized as a strategy to promote significant learning. According to the researchers, an online course should be designed so that different parts of the course encourage deep learning. The syllabus should be detailed, comprehensive, and it should contain direct instruction about interaction. Objectives should be clearly presented so they form the course structure, and the assignments should directly relate to the objectives. Finally, they talk at length about asynchronous discussions and the use of different activities. They indicate that the most effective discussions that lead to deep learning are supported with facilitative directions and rubrics because the learners know what is expected. Interactive discussion activities, discussion tasks, and reflective and exploratory discussions are said to be successful strategies that instructors can use to encourage mastery learning that is significant (Majeski & Stover, 2007).

Simulations

Learning from simulations through training and self-training is another example of a behavioral learning theory. When simulations are utilized, students take on the role of someone from a real life experience. To succeed when performing the role, students make use of concepts and skills to perform specific tasks. Instructors take the role of explaining, refereeing, coaching, and discussing the simulation experience with the students. They explain the rules, place the students into teams, and they assign roles based on student ability to ensure participation and communication between the students. When coaching, the instructor needs to be supportive, yet avoid interfering with the natural play of the simulation. Students are ex-

pected to make mistakes and adjust from those mistakes. Finally, instructors hold a discussion in which students have the opportunity to reflect and identify similarities and differences between the simulation and the real world (Joyce et al., 2000; Pinar et al., 1996).

Online role playing is not seen as a common practice in online courses. Data collected from a study on role playing that was part of an online course showed that students who participated enjoy taking part in the role plays, and they found that students considered the learning experience beneficial. Participants also indicated that the interaction made the classroom experience feel more personal. Students were seen making use of their knowledge to add to the role play experience (Lebaron & Miller, 2005).

Theories of Cognitivism

Theory of Multiple Representations

Applying multiple representations that connect to content of subject matter is thought to be a valuable practice because students can build mental representations with the information and make information meaningful to themselves. Web environments and computer mediated discussions are said to be conducive to the application of multiple representations during course design (Huang & Liaw, 2004). Researchers provide support and they raise cautions when it comes to using multiple representations during instruction. (Gfeller, Niess, & Lederman, 1999; Huang & Liaw, 2004; Moreno, 2002; Ying-Shao & Fu-Kwun, 2002).

A Web based lesson created to promote situated learning involved one hundred ten high school students from Taipei. Participants in the study were asked to connect a realistic situation with their own life. Social learning theory and multiple representations were used by the students to make connections. Results showed that when multiple representations were used along with situated learning during an asynchronous discussion that the students were able to cultivate and integrate the knowledge (Ying-Shao & Fu-Kwun, 2002). In

another study on use of multiple representations, the researcher found that students with stronger technology skills were more successful when it came to using multiple representations. Since their technological skills were stronger, they had a lower amount of cognitive overload compared to students whose technology skills were not as strong (Moreno, 2002).

Bruner's Three-Form Theory

Bruner (1990) states that there are three ways from which individuals see the world, through action, icons, and symbols. They use action to perform or demonstrate what it is they see about the world from their perspective. Icons or mental images are used to present a path, summary, or pattern. Symbolism, which is an abstract way of visualizing reality through the use of words and numbers, is the third form that individuals use. According to Bruner, these three forms of representation are founded on the theory that development must be effectively related to theories of knowledge and instruction.

Studies on the dual-coding theory show an influence on learning when visual and aural modalities are combined (Alty, 2002; Beacham, Elliot, Alty, & Al-Sharrah, 2002; Rieber, Tzeng, Trubble, & Chu, 1996). In a study conducted by Rieber et al., (1996), 52 college students interacted with a computer simulation created partly with the dual-coding theory as a framework. Visual modalities were presented as animated graphics and numeric displays were presented as aural modalities. Results were better for students who were provided with the visual and aural support compared to the students who were provided with one of the two modalities.

Moore's Theory of Transactional Distance

Moore's Theory of Transactional Distance, unlike the Web-based theories already presented, is a distance theory. Many online instructors have applied

this theory because its three dimensions have an affective influence on teaching procedures. Those three dimensions are referred to as interaction, course structure, and learner autonomy (Huang & Liaw, 2004).

Results from a study conducted by Huang (2002) showed that learners do not need to interact with other learners to develop a relationship with an instructor. The researcher found that course structure is easily implemented and adjusted in an online course, and it was found that the more technologically skilled an individual was, the better the individual was at working independently. Kanuka, Colett, & Caswell (2002) noted from a two-year study which observed 12 online university instructors that the instructors were more apprehensive about course structure, dialogue, and autonomy when they first began teaching online. Instructors who participated in the study needed to assess learners' autonomy, they needed to provide students with more feedback when the students did not have enough self-discipline to work independently, and they found that the learners wanted flexibility to be a part of the course structure.

Theories of Humanism

Theory of Immediacy and Social Presence

A model of online learning that considers social presence during asynchronous discussion to be a significant part of mediated discussion is presented. Theorists who hold that learning takes place through the interaction of three core components: cognitive presence, teaching presence, and social presence (Rourke, Anderson, Garrison, & Archer, 2001).

After a more in-depth look at social presence responses, three forms of social responses were identified and called affective responses, interactive responses, and cohesive responses (Martyn, 2004). These responses were used as indicators by Rourke et al., (2001) when analyzing content

during their exploration of computer mediated discussions and affective behaviors among participants. It was found that learners' perceptions were an important factor that instructors kept in mind when designing online courses.

Additional important factors related to social presence were found in other studies. Gunawardena and Duphorne (2002) found in a study that focused on an academic computer conference environment that comfort with participating in discussions, easiness with interacting through text, and assurance with ones self significantly impacted perceptions. Murphy (2004) found that sharing, recognition of group presence, appreciative communication between learners, and the opportunity to express feelings and emotions to be indicators of social presence in an online discussion. It is Murphy's conjecture that learners must be able to contribute their own social presence before moving to higher levels of interaction.

Cooperative Learning Theory

Five facets of the basic elements of cooperative learning help others understand how to design learning experiences that utilize the cooperative learning theory. Positive interdependence takes place when students work together, and they perceive that they are moving toward the same goal. Direct interaction occurs when students discuss what they plan to do and how to go about it. Individual accountability encourages individuals to master learning while sharing and working with others. Attaining collaborative skills involves individuals working together before they cooperate and learn. Finally, group processing takes place when the individuals in the group discuss and evaluate their work. Upon evaluation, the group members found that they work well together. Instructors who have applied this theory guide their students through each facet of the model. The more students develop, the better they work in a cooperative learning situation (Joyce et al., 2000).

A study that explored the online collaborative experiences and attitudes of twelve graduate students found, after assessing asynchronous posts, that poor communication, conflicts between members, and poor attitudes challenged the success of the online collaboration. Groups that did not have these challenges produced projects of higher quality. The researchers suggest implementing strategies to reduce the challenges so that chances for effective collaboration can increase (Thompson & Hing-Yu, 2006). Another study that investigated the impact of cooperative learning showed that cooperative learning did impact cognitive learning outcomes. Researchers found that learners become more involved with the online learning experience when they work cooperatively with others compared to when they worked independently (Riley & Anderson, 2006).

ACCORDING TO EMPIRICAL RESEARCH: THEORIES NOT SEEN BEING USED BY ONLINE INSTRUCTORS

Theories of Behaviorism

Elaboration Theory

Elaboration Theory, which is reflective of behaviorism, is a practice that is concerned with the organization of materials for a course. While cognitive aspects to this theory exist, it is also considered reflective of behaviorism because the instructor adjusts the learning environment to meet student needs. This theory holds that new learning should be presented first in the simplest form and carefully move to more complex forms of content and learning. For this reason, online instructors tend to begin with knowledge that students are already familiar with. Then, they transition to the exploration of new knowledge which helps students make the appropriate connections to help them understand the content (Huang & Liaw, 2004; Ludwig, 2000).

Direct Instruction

Direct instruction is referred to by behaviorists as “modeling with reinforced guided performance.” The focus of this model of learning involves dividing performance into goals and tasks, breaking the tasks into smaller tasks, creating training activities that directly target the objectives and ensure mastery of each task, and the inclusion of prerequisites that students have to achieve before they can go on to more advanced concepts. Critics of the direct instruction theory note that the application of this theory should be used with caution because it is not appropriate for all educational objectives and all students (Joyce et al., 2000). A study that focused solely on the use of direct instruction was not available in the literature, however there is information that suggests using direct instruction as part of an online course when presenting specific directions to students and when providing information needed to participate (Bellefeuille, 2006).

Theories of Cognitivism

Cognitive Flexibility Theory

Jonassen (2003) explains that a great deal of research looks at the presentation of problems to learners and identifies two conflicts with how problems that need to be solved are presented. First, it is a conflict when the problems are presented as structured problems because real life problems are ill-structured. The other conflict is that students do not transfer problem solving skills very well. Jonassen suggests using the cognitive flexibility theory to prohibit the conflicts.

Active learning, through discussion and the exchange of ideas, is an important aspect of learning (McAlpine & Ashcroft, 2002). For effective distance learning to take place, constructivism and cognitive flexibility need to be present. Learners should be active participants and instructors can not be distributors of information since students

process information differently. According to the researchers, students should solve problems in ways that are best for themselves (Notar, Wilson, & Montgomery, 2005).

Gagne’s Conditions of Learning

Huang and Liaw (2004) identify Gagne’s conditions of learning as an instructional learning process that is methodical and logical. Gagne’s conditions of learning is a descriptive theory of knowledge that contains five separate categories of outcomes labeled as intellectual skills, verbal information, cognitive strategies, motor skills, and attitudes. Having the ability and knowledge to categorize and use materials are characteristics of intellectual skills. Abilities that allow individuals to show “what” something is or means are verbal information abilities. Cognitive strategies have to do with the learning skills individuals own. Simple and complex movements make up an individual’s motor skills, and attitudes are the feelings that we develop as a result of interactions that are either constructive or unconstructive. Researchers note that Gagne’s work has grown into a system of nine practices: gaining attention, informing learners of the objective at hand, stimulating recall of prior learning, presenting the content, providing learning guidance, eliciting performance, providing feedback, assessing performance, and finally, enhancing retention and transfer (Gagne, 1985; Gagne, Wager, Golas, & Keller, 2005; Molenda, 2002; Smith & Ragan, 1996).

Merrill’s Instructional Transaction Theory

This theory holds that learners can be motivated by processes of transactions that help them make connections. This theory has a set of conventions to which objects of knowledge are selected and sequenced (Huang & Liaw, 2004). Identifying relationships between educational and technical factors are possible with the instructional transac-

tion theory. The instructional transaction theory consists of two facets: schemes of knowledge and procedures for applying the knowledge. Merrill's position states that for learning to take place, the learner needs to have more than one knowledge structure illustrated for anything to make sense. According to the researchers, instructional transaction theory learning consists of the object that is to be learned or the content that is to be taught. It is possible to combine the different facets of content that need to be taught and group them into one structure of knowledge. Individuals have internal representations of knowledge and structures of knowledge are external. The theory utilizes transactions as a way to categorize the content that is to be taught (Buendia et al., 2002).

It is believed that there are three data types used when a transaction of knowledge takes place. There is a knowledge base, a resource base, and there are instructional boundaries. These three facets of instructional transaction are then subdivided into more descriptive categories. A knowledge base is, for example, divided by entities, activities, and processes. Resource databases, among other possibilities, are subdivided by mediated representations of the knowledge field, presentation techniques, and communication techniques. Instructional boundaries, of which vary by situation, can be divided according to population, learning task, and the environmental situations. So, when an online instructor applies the instructional transaction theory to course design, empirical research is used to help set the categories in a knowledge base, build resource database classes, and define the parameters that are used to set the boundaries (Zwart, 1992).

Theories of Humanism

Phenomenal Field Theory

A humanistic theorist named Arthur Combs presented his phenomenal field theory with psychologist Donald Snygg. According to this theory, to understand human behavior, the time must be

taken to consider the point of view of another. They believed that if one wanted to change another person's behavior, they must first modify his or her beliefs or perception. One had to "walk in their shoes" if they wanted to understand and guide change. By taking this line of thinking, educators had to recognize that the learner needed to find meaning and understand the learning as opposed to learning and understanding the strategies (Boeree, 2007; Tomei, 2007).

Combs and Snygg felt that if they were to understand and foresee the behavior of another that they had to reach into the person's phenomenal field. Since it was impossible for them to physically look into another person's mind, they had to make inferences from what was observed. When educators utilize this theory, they cannot choose a topic of instruction, implement a strategy, and expect every child to be motivated by what has been placed before them because the information does not connect to their own lives. Instead, the educators have to get to know the learner's phenomenal self and create learning experiences that have meaning to the learner. Once instructors take this path, the student that was not motivated to learn at one time will become connected to the learning experience (Boeree, 2007; Tomei, 2007).

Self-Actualization Theory

Maslow believed that strong beliefs about one's self are connected to the thought of self-actualization. According to his thinking, individuals with strong self-actualization interacted well with others, and they found ways to develop and contribute to the world around them fairly easily. Those who did not have strong self-actualization choose to live within their environment and accept what comes their way instead of reaching into their environment and making new opportunities happen for themselves (Joyce et al., 2000; Pinar et al., 1996; Tomei, 2007).

For a person to reach the level of self-actualization, he or she has to be fulfilled at each level

of what Maslow referred to as the hierarchy of needs. The first level is the biological level. At this level, an individual's need for food and shelter must be met before the individual can move to another level. At the next level, the individual has to feel secure. Level three of the hierarchy of needs demands that the individual feel as though he or she belongs and is loved. Needs for self respect, achievement, attention, and recognition must be fulfilled if an individual is to move past the esteem level of the hierarchy. When an individual has past each of those levels, he or she has reached the final level, the level of self-actualization. At this point, the individual's ability to reach potential can take place. While each level has to be fulfilled, they do not have to stand alone and one behavior can satisfy more than one level on the hierarchy. Instructors who utilize this theory when designing and conducting a course look to see if their students needs have been met to help them understand student behavior (Joyce et al., 2000; Pinar et al., 1996; Tomei, 2007).

FREQUENCY OF DESIGN THEORIES UTILIZED BY ONLINE INSTRUCTORS

In a recent study, online instructors were asked how often they utilized nine design theories when creating an online course. Questions about the design theories were presented as part of a larger study on online instructor support for the practice of telementoring (Cicciarelli, 2006).

Methodology

During the quantitative exploratory study, based on descriptive research design, 2000 online instructors were sent a link to an anonymous contingency survey. Nine of the survey questions asked the online instructors how often, according to a Likert scale, they utilized each theory when designing an online course. Once 323 responses to the survey had been submitted, access to the

survey was turned off and the data was collected for analysis. A univariate, descriptive level analysis of frequency distributions was run for each variable. Bivariate relationships between the independent and dependent variables were examined using Spearman Rho tests, and cross-tabulations were calculated to provide a deeper look at the data.

Results According to Theory

Theory of Multiple Representations

Spearman rank order of coefficient of correlation (Spearman rho) was computed to measure the strength between the two variables. Results showed that the correlation at a .01 level was significant for a two-tailed test ($r = .113$, $p = .045$). According to cross-tabulation results, 32.6 percent of the online instructors said that they always utilize the theory of multiple representations, 32.9 percent indicated that they used the theory more often than occasionally, and 20.8 percent indicated occasional use. There were 7.3 percent who said they utilized the theory less often than occasionally, and 6.4 percent said they never made use of the theory of multiple representations.

Theory of Immediacy and Social Presence

Spearman rho results for a .01 level two-tailed test that correlated online instructor use of the theory of immediacy and social presence were significant ($r = .187$, $p = .001$). Cross-tabulation results showed that 36.8 percent always use the theory of immediacy and social presence, 36.1 percent utilize it more often than occasionally, and 15.2 percent use it occasionally. There were 8.1 percent who said they utilize the theory less often than occasionally and 3.9 percent said they never utilize the theory of immediacy and social presence when designing an online course.

Elaboration Theory

Results from a .05 level two-tailed Spearman rho test that correlated online instructor use of the elaboration theory was significant ($r = .146$, $p = .010$). Cross-tabulation results showed that 31.5 percent of the online instructors always use the elaboration theory, 41.2 percent said that they use the theory more often than occasionally, and 16.2 percent indicated that they use it occasionally. There were 6.8 percent who said that they utilize the theory less often than occasionally and 4.2 percent who said that they never use the elaboration theory when designing an online course.

Dual-Coding Theory

Spearman rho results for a two-tailed test that correlated online instructor use of the dual-coding theory was not significant ($r = .076$, $p = .179$). Cross-tabulation results showed that 23.5 percent always utilize the dual-coding theory when designing an online course, 23.5 percent more often than occasionally use the theory, and 18.3 percent occasionally utilize the theory. There were 17.7 percent who said that they utilize the theory less often than occasionally and 17.0 percent said that they never use the dual-coding theory when designing an online course.

Moore's Theory of Transactional Distance

Results from a .01 level two-tailed Spearman rho test that correlated online instructor use of Moore's theory of transactional distance was significant ($r = .233$, $p = .000$). Cross-tabulation results showed that 39.5 percent always utilize Moore's theory of transactional distance when designing an online course, 37.5 percent use the theory more often than occasionally, and 14.9 percent indicated that they utilize the theory occasionally. There were 5.5 percent who said that they utilize the theory less often than occasionally and 2.6 percent said that

they never utilize Moore's theory of transactional distance when they design an online course.

Merrill's Instructional Theory

Spearman rho results for a .01 level two-tailed test that correlated online instructor use of Merrill's instructional theory was significant ($r = .181$, $p = .002$). Cross-tabulation results showed that 22.4 percent of the online instructors said that they always utilize Merrill's instructional theory when designing an online course, 39.3 percent indicated that they utilize the theory more often than occasionally, and 21.8 percent said that they utilize it occasionally. There were 8.6 percent who said that they utilize the theory less often than occasionally and 7.9 percent said that they never utilize Merrill's instructional theory when designing an online course.

Gagne's Conditions of Learning

Results from a .01 two-tailed test that correlated online instructor use of Gagne's conditions of learning was significant ($r = .257$, $p = .000$). Cross-tabulation results showed that 28.9 percent of the online instructors indicated that they always utilize Gagne's conditions of learning when designing an online course, 42.8 percent said that they utilize the theory more often than occasionally, and 13.8 percent said that they occasionally utilize the theory. There were 9.0 percent who indicated that they utilize the theory less often than occasionally and 5.5 percent said that they never utilize Gagne's conditions of learning when designing an online course.

Cognitive Flexibility Theory

Spearman rho results for a .01 level two-tailed test that correlated online instructor use of the cognitive flexibility theory was significant ($r = .226$, $p = .000$). Cross-tabulation results showed that 30.1 percent of the online instructors indicated that

they always utilize the theory when they design an online course, 36.9 percent said that they utilize the theory more often than occasionally, and 22.4 percent said that they occasionally use the theory. There were 5.4 percent who indicated that they utilize the theory less often than occasionally and 5.1 percent said that they never utilize the cognitive flexibility theory when designing an online course.

Bruner's Three Form Theory

Results from a .01 level two-tailed test that correlated online instructor use of Bruner's three form theory was significant ($r = .169$, $p = .003$). Cross-tabulation results showed that 14.6 percent of the online instructors indicated that they always utilize Bruner's theory when designing an online course, 27.3 percent said that they utilize the theory more often than occasionally, and 26.0 percent said that they utilize the theory occasionally. There were 17.9 percent who said that they utilize the theory less often than occasionally and 14.3 percent who said that they never utilize Bruner's theory when designing an online course.

CONCLUSION

Information presented in this article focused on answering three questions that individuals interested in use of design theory may have in connection with creating an online course. The first question asked, "According to empirical evidence, what does the research show about online instructor use of different design theories?" The evidence showed that there is empirical evidence available on eight of the 15 theories presented in this article. Researchers found positive experiences and made suggestions for online instructors to follow when utilizing these theories. According to what has been presented, it would be an effective choice to frame course development with the different theories based on the course and the needs of the students.

The second question presented asked, "According to the lack of empirical evidence, which design theories have not been researched in regard to online instructor utilization of theory?" Considering that evidence on the use of these seven theories has not already been published in the literature, a signal has been made for the need for research. It would be beneficial to the field if online instructors decided to present how they utilize these theories as part of their online course, and it would be even better if researchers conducted studies that explored the use of these design theories.

Finally, the third question asked, "According to a recent study, how frequently do online instructors use nine of the design theories?" Of the nine theories presented, there were significant findings for all but one theory. This indicates that online instructors are making use of theory to support course design and it points to which theories they tend to use and how often. Other online instructors may find this helpful when they question the use of the different theories. Further research on this topic should investigate to find a description of the online instructors who indicated how often they utilized nine of the different theories when designing an online course. Researchers could also conduct a study that asked online instructors to provide a qualitative explanation of how they use design theory when creating a course. This would be a favorable way for instructors to share their work so that others could learn and possibly develop other unique ways to make use of the theories for the purpose of creating effective online courses.

Chapter 1.28

ICT Based Learning: A Basic Ingredient for Socio–Economic Empowerment

Hakikur Rahman

Sustainable Development Networking Programme (SDNP), Bangladesh

ABSTRACT

ICT mediated learning provides utilities for achieving the goal of education for all, and in turn acts as an enabler in reducing the digital divide, reducing poverty, and promoting social inclusion. However, the integration of ICTs in education deserves considerable investment in time and resources. Consequently, during planning to integrate ICTs in evidence-based information for making sound decisions by the end users incorporate extensive research and sharing of critical information along different phases of planning. Furthermore, implementation of ICT based learning demands in depth analysis and intelligent feedback of the processes. Technology does not improve learning in a straight way and the fundamental question remains always unanswered, in assessing the effectiveness of ICTs or assessing the effectiveness of instructional treatments that were initially (and effectively) less than perfect. This chapter has tried to critically analyze the effective role of ICT methods in learning

and put forwards several success cases of learning mechanisms that assisted in socioeconomic empowerment and at the same time, provided a few futuristic recommendations in establishing similar endeavors in promising economies.

INTRODUCTION

ICTs can increase access to information and this information helps communities to work more productively as well as in new opportunities. Increasing common people's access to ICTs should involve increasing availability of ICT infrastructure where most of them live. The infrastructure should be highly subsidized for at least a number of years so that the investment costs are not passed on to the end users (Mijumbi, 2002).

ICT can improve the learning process by making it faster, cheaper, and wider reaching that were not possible before. This form of learning can be treated as an interactive process among many entities and supporting the improvement

of this process is expected to produce better results. However, innovative processes have to be incorporated both in terms of pedagogy and technology. Pedagogy should be universal and technology should give ubiquitous access with ambient intelligence.

In the area of education and training several hundred projects with thousands of participants around the globe have produced acceptable results in the areas of general education, specialized skill development training, and life long learning and have contributed positively to horizontal issues such as standards, metadata, interoperability, and sustainability.

Among them in 2001, an ambitious project, Prometheus, was built to establish a forum for expert opinions where participants from a wide range of countries, activities, professions, cultures, and languages productively interact towards the establishment of a community of cooperation in the field of educational technology and applications. All those contributions were taken into consideration and the contributors referenced in a position paper. Its aim was to bridge the gap between research and actual use of learning technologies, content and services, through direct contribution in an open consultation process (Bottino, 2001).

In 2002, Appeal launched a project on ICT Application for Non-Formal Education Programs with the support of the Japanese Funds-in-Trust. During its first phase, five countries (Indonesia, Lao PDR, Sri Lanka, Thailand, and Uzbekistan) implemented programs and activities to empower communities through the effective use of ICT.

However, in 2003 a study in this area entitled "Quality and e-learning in Europe training" was conducted and found that through a survey among 433 teachers and trainers from public and private sectors, about 61% felt that the quality of e-learning was fair or poor (Attwell, 2005). So, investment in this sector will remain a fair trade for many investors, including the development partners.

Therefore, the shift to the information society throws new challenges for learning processes and acquisition of knowledge through learning. In a society where information is becoming a strategic raw material and knowledge a value added product, how this resource is used is critical to the performance potential of each entrepreneur. The information and communication media provide necessary technologies to make knowledge available worldwide and transform the information society into a knowledge society. However, in response to individual needs, it is becoming increasingly important to harness appropriate information and systematize knowledge. A falling "half-life" of knowledge formulates life-long learning and up-to-date information becomes critical. Hence, in times of increasing globalization and networking, flexible access to information must be guaranteed at any place and at any time (Massey, 2003).

In this context, economic freedom plays an important role, in addition to technology update and information management. The 2006 Index of Economic Freedom measures 161 countries against a list of 50 independent variables divided into 10 broad factors in terms of economic freedom. The higher the score on a factor, the greater the level of government interference in the economy and the less economic freedom a country enjoys. In the ranking the top five countries (with lower scores between 1.28 and 1.74) are Hong Kong, Singapore, Ireland, Luxembourg, and United Kingdom, whereas North Korea, Iran, Burma, Zimbabwe, Libya, and Venezuela are among the bottom five (with higher scores between 5.00 and 4.16)¹. This shows the level of ICT improvement in those countries, especially applicable to Hong Kong and Singapore in Asia.

The European Union has taken a lead role in reforming its member countries, improving their ICT situation, and establishing enhanced learning processes through ICT. The diverse e-learning visions, experiments and programs launched by individuals, organizations, institutions, nation-

states of EU are found to be potentially more efficient in fostering flexible learning than traditional methods. The dominant view of e-learning has been, therefore, purely instrumental in legitimizing its *raison d'être* as an ideal method to match the learner's choice and demand with more autonomy (Apollon, 2005).

The process of integrating ICT in the lower level of the education system involves a paradigm shift with new insights and new challenge facilitating new forms of understanding through earlier understandings to create new perspectives and interpretations. Integration should also incorporate an embedding of ICT in the institute's organizational structures and the organization of teaching (Walsh, 2002).

With the development of ICT a new brand of leaders are emerging, in instructional and transformational forms through commitment and enthusiasm for learning, working in partnership with colleagues across the curriculum to embed ICT into the learning process. These leaders have often come up very quickly through their ranks and subsequently their ICT skills have been learned on the job (Walsh, 2002).

At the same time, there is a growing interest with regards to ICTs being used to extend educational opportunities in developing countries. While many governments paid specific attention to integrate ICTs into compulsory schooling during the 1990s, more recently the focus has been shifted to post-secondary (K12) education. In essence ICTs need to be encouraged to make post-secondary teaching and learning more effective and more equitable by offering a diverse range of learning opportunities to a diverse range of learners in a convenient and cost-effective manner (Selwynn, 2003).

Henceforth, the ability to continue to learn throughout life is seen as a prerequisite to the development and sustainability of knowledge economies as countries, corporations, and communities require workers and citizens with flexible, *just-in-time* skills, competencies, and

knowledge. Particularly the need for diverse and accessible learning opportunities has drawn policy makers in many countries towards the use of ICT as an educational delivery mechanism (Selwynn, 2003).

ICT-based learning can be formal (institutionally sponsored and structured), non-formal (non-credential but still institutionally-based and structured) or informal (happens incidentally or during everyday activities). This form of learning can, therefore, take place in the office, institution, home, or community, at different times for different purposes (Selwynn, 2003).

Hence, attempting to encourage full and effective participation of all stakeholders in ICT based education now forms a central part of current educational and economic policymaking in most developed countries (Selwynn, 2003). ICT in learning processes should not merely be used to acquire knowledge and skills; the processes should be more interactive and self-directed uses of ICTs should be encouraged so that the learners can actively construct new ideas, concepts, and meaning while transforming their existing knowledge (Rosen, 1998).

BACKGROUND

Learning is the cognitive process of acquiring knowledge² or skill through study, experience, or teaching. It is a process that depends on experience and leads to long-term changes in behavior potential. Behavior potential describes the possible behavior of an individual (not actual behavior) in a given situation in order to achieve a goal³.

ICT-mediated learning is a process used to acquire data, information, skills, or knowledge. It is a form of learning that enables learning in a virtual world where technology merges with human creativity to accelerate and leverage the rapid development and application of deep knowledge⁴. ICT-based learning covers a wide set of applications and processes such as Web-based learning,

computer-mediated learning, virtual classrooms, and digital collaboration. It includes the delivery of content via Internet, intranet/extranet (LAN/WAN), audio and videotape, satellite broadcast, interactive TV, PDA, mobile phone, CD-ROM, and other available technologies⁵. This chapter, specifically focuses on ICT-based learning to enable empowerment and socioeconomic development.

Empowerment is the process and practice of deriving power from within the self, or assisting others to do so through power within⁶. It is the process of equipping communities with knowledge, skills, and resources in order to change and improve the quality of their own lives and their community. Empowerment may evolve from within or it may be facilitated and supported through external agencies⁷. However, in terms of knowledge acquisition, empowerment is a consequence of liberatory learning and created within the emerging praxis in which co-learners are also engaged. The theoretical basis of this process is provided by critical consciousness; its expression is collective action on behalf of mutually agreed upon goals. Empowerment through knowledge is distinct from building skills and competencies that are being commonly associated with conventional schooling. Education for empowerment differs from schooling both in its emphasis on collective participation (rather than individuals) and in its focus on cultural transformation (rather than social adaptation)⁸.

Whereas, socioeconomics is the study of the social and economic impacts of any product or service offering, market promotion or other activity on an economy as a whole and on the entrepreneurs, organization and individuals who are its main economic actors. These effects can usually be measured in economic and statistical terms, such as growth in the size of the economy, the number of jobs created (or reduced), or levels of home ownership or Internet penetration (or number of telephones per inhabitant); and in measurable social terms such as life expectancy

or levels of education⁹. This chapter provides emphasis on raising socioeconomic capacity of the economic actors through learning: information, content and knowledge; to lead into a knowledge-based economy.

A dynamic knowledge-based economy is capable of sustainable economic growth, but to achieve it, the economy not only needs a radical transformation within it, but also a modernized education system. The Lisbon Council of European Commission (EC) envisioned this in their March 2000 meeting, while in 2002 the EC stated that by 2010 Europe would be the world leader in terms of the quality of its education and training systems. To achieve this, a fundamental transformation of education and training has been taking place throughout Europe (European Commission, 2004). ICT-based education always demands a longer term strategy which the EC has initiated in 2000¹⁰. This strategy has been taken with a 10-year work plan to be implemented through an open method of coordination aiming at coherent community strategic framework of cooperation in the field of education and training. To support the implementation of the shared objectives for education and training systems at the national level through exchanges of “good practices,” study tours, peer reviews, and so forth¹¹, EC has been working through twelve working groups since 2000.

Table 1 (*above*) shows a few initiatives taken by the European Commission to enhance the ICT-based learning in Europe. To date, the whole work has been carried out in four stages:

- First, decide upon key issues on which to focus future work.
- Second, focused on good practices and sharing policies to develop better quality education through ICT.
- Third, gather good policies and formulate recommendations learning from their problems.

Table 1. Initiatives taken by EC for ICT-based learning

Year	Groups/Councils	Strategies Taken
2000	Lisbon Council	To form the most competitive and dynamic knowledge-based economy
2001	Ministers of Education	To achieve coherent community cooperation in the fields of education and training
2001	Working Group on ICT in education and training	To work on indicators and benchmarks, exchanging good practices and peer review
2002	Standing Group on Indicators and Benchmarks	Indicators and benchmarks were developed to monitor the progress
2003	Working Group on ICT in education and training	Focused on policy practices aiming at better quality education through integration of ICT

- Fourth, gather examples to map those recommendations on good policy practices¹².

Integrating ICT in learning can mean anything from complete online training, with specific learning platforms using virtual microworlds and laboratories, to online access to and control of distant physical set ups such as cyber kiosks, or telecenters, or physics laboratories. This form of learning may also include a face-to-face situation in a laboratory with digital controls and computer-based mathematical tools. However, the question will remain: How is ICT-mediated learning taken into account by current school architecture decisions, or what are the priorities in setting up costly permanent establishments that will include such ICT-based activities?

Hence, the objectives for ICT based learning should be “to develop technologies to empower individuals and organizations to build competencies to exploit the opportunities of tomorrow’s knowledge society. This is achieved by focusing on the improvement of the learning process for individuals and organizations, and of the intertwined learning process between individuals and organizations” (The Learning Citizen, 2003, p. 2).

Table 2 (*above*) illustrates a few figures on non-capital investment of the European Union (EU) for learning purposes.

In this way, the ICT (specifically, the WWW, or the Internet) offers itself as a tool to increase formal education as well as “ambient” learning that may be treated as electronic-mediated learning, or e-learning. During a survey done by the Oxford Internet Institute (OII), 78% of users say they use the Internet to look up a fact, while 47% say they look up the definition of a word. Nearly 40% of the respondents say they use the Internet to find information for school, and 20% of them use it for distance learning (OII, 2005).

MAIN THRUST

Given the critical changes in education and given the potential of ICT, it is vital that policies and strategies in the area of ICT be driven by long-term educational objectives, such as:

- ICT supported learning provisions in the services sector.
- ICT inclusive educational policies.
- ICT conducive research programs incorporating solutions to problem locale.
- Optimal use of ICT for educational purposes.
- Integrating ICT in bringing fundamental transformations in education.

Table 2. Non-Capital investment for learning in EU countries (Source: *The Learning Citizen*, 2003)

Items	Increase in 2001	Increase in 2002
Spending on training products and services	7%	7%
Raise in e-learning content	70%	50%
Growth rate of e-learning products expenditure	17%	23%

Transformations with ICT can be limited to learner-centered multimedia learning, without changing the school curriculum and progressively invalidating the changes. Thus, school reform is not a spontaneous consequence of the introduction of ICT in education. Furthermore, as learners enter into education system with a growing ICT familiarity, the definition of basic skills, to be addressed by the educational integration of ICT, needs to embrace more and more higher-order thinking skills. Therefore, a global vision of ICT supported education has to be prepared for common citizens to actively take part in an increasing communication setting to improve their own values and thoughts. In this context, utilizing available utility software, exciting ICT-based e-learning materials can be developed with an absolute minimum of effort.

The main thrust of this chapter comprises of a few case studies that are being treated as success stories in the aspect of ICT mediated learning, and at the same time act as empowering tool in terms of socioeconomic development. Emphasis has been given to incorporate cases that involve ICT for community learning, and they have been portrayed with analytic approach. It is expected that these cases will be able to justify inclusion of ICTs in community learning and regional development.

CASE STUDIES

Case 1

Asia Pacific Information Network (APIN)
A regional network working to achieve information for all

Among key five areas of interests, one is to promote ICT literacy and the application of ICT in education, science, culture, and communication.

Broad aims are to:

- Encourage the development of strategies, policies, infrastructures, human resources, and tools for application of ICTs.
- Prepare policy advice to member states for use of ICT in national targets, especially for improvement of education, (APIN, 2004).

Specific focus areas are to:

- Promote ICT based learning opportunities for all.
- Enhance learning opportunities through access to diversified contents and delivery systems.
- Assist in establishing networks for learners and educators.
- Assist in promoting universal and equitable access to scientific knowledge.

ICT Based Learning

- Support the development of code of practice involving scientific information chain by using ICT.
- Strengthen capacities for scientific research, information and knowledge sharing. (APIN, 2004)

Case 2

Adult Basic Education (ABE)

Integrates the use of ICT into teaching practices for organizational realignment and empowerment

Established in 1990, ABE provided ICT supported courses in the South Wales Valleys in UK that is a post-industrial area with low levels of education, widespread illiteracy and innumeracy in adult population and growing digital divide. The program has established community based Open

Learning Centres (OLCs) dedicated to teaching basic literacy, communication, and numeric skills to adult groups. It introduced a network of personal computers with broadband Internet since 1997 and gradually led to the design and development of many innovative courses utilizing multimedia technologies. This has created increased participation of learners, tutors, and volunteers resulting in changes to the structure of learning content and techniques acting as a catalyst among the adult communities (Harris, 2002).

Table 3 shows the ICT based courses that evolved since its inception in 1997. This table not only shows the necessary modification of courses to meet the demand of the community throughout this period, but also adjusted contents that show the development trend of ICT based courses.

Table 3. ICT based ABE courses during 1997-2002 (Adapted from Harris, 2002)

Year and Duration of Courses	Courses	Activities
1997-98, 4 hrs/week	Internet Club	<ul style="list-style-type: none"> • Web browsing and searching • email • HTML authoring
1998-99, 6 hrs/week	Internet Club2	<ul style="list-style-type: none"> • Web browsing and searching • Email • HTML authoring • Computer graphics • 3D Animation
1999-2000, 8 hrs/week	Internet Club3 under network	<ul style="list-style-type: none"> • Web browsing and searching • Email • HTML authoring • Computer graphics • 3D Animation
2000-01, 16 hrs/week	<ul style="list-style-type: none"> • Computer Club • Creative Computation • Web workshops 	<ul style="list-style-type: none"> • Web browsing and searching • Email • HTML authoring • Computer graphics • Digital Video • Computer Programming
2001-02, 24 hrs/week	<ul style="list-style-type: none"> • Computer Club • Creative Computation • Web workshops • Film workshops • DTP workshops 	<ul style="list-style-type: none"> • Web browsing and searching • Email • HTML authoring • Computer graphics • Digital Video • Computer Programming • Desk Top Publishing

Case 3

Gateshead Testbed Learning Communities (GTLC)

Demonstrates how communities and individuals develop through learning and share good practices in UK¹³.

Priority areas are to:

- Build on success.
- Listen to local demands and needs.
- Recognize all aspects and levels of community learning.
- Recognize barriers and address them properly.
- Improve quality of life, not just qualifications.
- Unlock national digital resources.
- Encourage establishment of remotely based stations with subsidies.

Case 4

EdComNet (Humanistic Urban Communal Educational Net)¹⁴

Aims to enhance the participant's sense of autonomy and dialogical belonging

Based on Autonomy Oriented Education (AOE) for personal empowerment and personal growth, users of this network actively utilize Internet content and features for their learning processes to reflect and explore elements of self and the alternatives available. According to AOE, gaining knowledge is to learn as per a personal plan that stems from one's self knowledge, and it portrays one's personal interests, performance styles, and capabilities. EdComNet incorporates AOE principles and offers an empowerment tool for the European Citizen.

Case 5

EducaNext¹⁵

Supports acquisition of high skills as per demand of the European industry and need of the global market

This program supports the creation and sharing of knowledge between educators. It also enables collaboration among the participants by providing a complete package of services to support the exchange and delivery of learning resources. EducaNext acts as a collaboration facilitator and at the same time as a marketplace. It is primarily considered as a business-to-business service and enables partnerships among institutes of higher education and industry to provide the right expertise at the right time.

Case 6

Pan Asia Network (PAN) in Bhutan¹⁶

Establishment of ICT supported distance education

In 2003, PAN started a project supporting Bhutan's National Institute of Education (NIE) to establish ICT based distance education programme for educators. The project developed and tested appropriate ICT based learning support system and assessed whether ICTs improve the quality of and access to learning. The project aims to implement 16 distance education courses, including development of online tutorials, support services, counseling services, and multimedia contents. This project also emphasized the development of key performance indicators for distance educators, especially for those that may be replicated across the PAN regions (PAN, 2005).

Case 7

Scottish Workforce Empowerment for Lifelong Learners (SWELL) Project¹⁷

Promotes lifelong learning for working people in Scotland

The project has successfully facilitated new learning opportunities to more than 700 learners till May 2005 across Scotland's urban and rural labor markets. SWELL support has enabled partners to develop and deliver innovative learning solutions, by empowering "non-traditional" learners through offering new opportunities to the disadvantaged communities; learners that are remotely located, with disability, not adequately literate, and jobless. The organizational leadership has been carried out efficiently through innovation, transnationality, mainstreaming, empowerment and equal opportunity. The most successful SWELL activities have involved mainstreaming education providers to deliver a wide ranging and high quality training provision. It has contributed to a "community of learning" by equality of learning opportunities through ICT (McQuaid & Lindsay, 2005).

Case 8

S2NET in EU Region¹⁸

ICT-based learning as a tool for social inclusion

The project prepared a guide to support the target groups in the design, delivery, and evaluation of training actions for disadvantaged individuals, provided directives to develop learners' meta-competencies and train them in order to sustain an empowered attitude towards their practical lives (Dondi, 2003).

Main objectives are to:

- Encourage use of e-learning for training educators and policy makers.

- Support innovation in training and education methods using ICT based learning.
- Promote good practices in the use of ICT for real life application.
- Raise awareness on e-learning to prevent social exclusion.

Case 9

E-learning for sustainable development by IGES (Institute for Global Environmental Strategies)

Promotes community-based learning for sustainability

This project provides community learning programme on sustainable development through ICT. E-courses are designed for teachers novice in computer-based learning and these courses act as stand alone training material replacing face-to-face trainings on community learning. The course content is built based on ten years experience of the Institute of Sustainable Communities, USA in Central and Eastern Europe, USA, and Japan¹⁹.

FUTURE ISSUES

The question about the quality of ICT based learning remains opaque and fraught with difficulties. These difficulties further compounded when it comes to evaluate the quality of the use of ICT for learning en masse. However, the development of ICT based learning products and opportunities are rapidly expanding in areas of education and skill development. The media varies from intranet, Internet, multimedia, email, interactive TV, teleconferencing, video conferencing, or other computer mediated learning methods²⁰. But, until now innovative approaches have been missing to evaluate the development, growth, impact, and potential of this form of education system. Despite global efforts in diversified platforms, distance education or e-learning, or ICT

based learning has not attained a suitable state; governments remain hesitant (often mismanaged or misguided) in funding, private investors behave in unfamiliar ways, and development actors stay away from investing in this sector.

In the near future, education will be online or at least blended with online teaching and learning activities. However, the strategies should focus on constraints and normalization of educational interactions, without much restricting on initial investments. Similarly, standardization of education system should be object oriented and encouraging. Learning models should pass through technical and quality as standards, rather than just *industrialization* or *professionalization* and focus on extensive research to achieve fundamental educational objectives.

The opening to higher education should ensure better links between education and research. Higher education has to be at the forefront of knowledge production, management, and dissemination. Moreover, the use of ICT in education at all levels requires new pedagogical and organizational settings. Therefore, cross-partnership among education, social science, pure science and within different fields of research is needed.

Innovative e-learning should aim to empower the lifelong learners and vocational trainees. This form of ambient learning provides access to high quality learning materials suiting individual's demand and pace. To achieve this, ICT based learning should utilize multimodal broadband access and content management. Furthermore, the provision of content integration will allow access to new e-learning materials, as well as existing resources from those repositories (Paraskakis, 2005). There is a need to develop policies and action plans in using technological and non-technological means to address the social, economic, and cultural factors underlying educational problems. There are also clear needs to redevelop educational and pedagogical understandings on effective ICT across life long learning in its many forms (Selwyn, 2003).

CONCLUSION

Looking at the success cases around the globe, it is apparent that educational policy makers are tempted to deal with ICT based learning as a potent bridging method used to flexibilize individuals and make them adequate to the needs of the community, thus empowering them to act as an element of socioeconomic development. The main educational, social, and economic discourse related to new professional, social, and learning needs tends, therefore, to relapse recurrently into the flexibilization rhetoric, according to which the adaptability of the new demand evolves, if one adopts this perspective to a new flexibility of individual's desire (Apollon, 2005).

The development of e-learning up to this point has been largely demand driven, the two principal players being the technology and the content. Perhaps for this reason the majority of products developed in this sector have followed two basic and well-tried business models, by providing:

- Distance education to individuals, which is a technologically enhanced continuation of the previous correspondence course model;
- Online environments to permit existing educational institutions in extending their services through the use of virtual classroom.

The technology driven and network intensive nature of these *virtual classrooms* however, restricts the number of users to those who have specialist, up to date equipment and broadband access, shutting out the majority of marginal learners. Furthermore, in both models e-learning approaches are based on assumptions about the pedagogical focus and organizational structure of existing educational institutions, rather than potentially validated research (PROMETEUS, 2003).

Many recommendations floated around focusing the potential for development of more

appropriate ways of learning through ICT, but at the same time suffered the lack of a solid framework of learning theory in providing a more comprehensive and less anecdotic understanding. Only in this way can it be ensured that many positive experiences taking place already across the globe can be reproduced in other countries. There are thousands of handbooks on e-learning but they lack good validated research. In this context, intensive analysis of e-learning processes is needed and particularly there is a need for a conceptual framework for lifelong learning, and for the development of models derived from non formal settings and self organizing communities of learners (PROMETEUS, 2003).

To realize that ICT is not another passing fad or innovation, which might or might not affect learning and to be able to change the way the institutions work accordingly, is perhaps one of the most important requisites for leaders in this field. Emphasis should be given in communicating the vision, and at the same time efforts should be given for skills development and involvement of all teaching and non teaching staff who might have come through the conventional system of learning (Walsh, 2002).

ICT based education and training leads to improved learning environment. However, as with most research on education and technology the effectiveness of ICT-based mass learning is still fragmented. It is also suggested that learning with ICT leads to a more reflective, insightful learning with more empowered and democratic diffusion amongst learners (Doubler, Harlen, Harlen, Paget & Asbell-Clarke, 2003; Jeris, 2002) as well as proving to be an attractive and motivating medium of learning with basic skills (Lewis & Delcourt, 1998). Furthermore, engagement in e-learning is also leading to wider educational outcomes, such as increases in learners' self-esteem and propensity to engage in further learning. Therefore, as Kennedy-Wallace (p. 49) reminds, "whether learning online in the workplace, in college or at home, e-learning is still about learning and

culture, not just technology and infrastructure" is a true reflection of the transformation of communities in this respect.

Chapter 1.29

Between Tradition and Innovation in ICT and Teaching

Antonio Cartelli
University of Cassino, Italy

INTRODUCTION

During the past few decades, the expanded use of PCs and the Internet introduced many changes in human activities and cooperated in the transformation process leading from the industrial society to the knowledge society.

Among other things, the above instruments played a special role in education, and two main phases can be easily recognized: the former one where computing and ICT were mostly used to enhance individuals' learning features (i.e., teachers mainly had the role of educational worker: planning, controlling and evaluating students' learning processes); the latter one, more recent and centered on ICT use, where teachers had to adopt situated and collaborative learning strategies, build communities of learners (CoLs), organize students' work for enhancing problem finding and solving, while helping the development of their ZPDs (zones of proximal development, meaning individuals' cognitive areas marked by the distance between the subject's knowledge/

experience in a given field and the same knowledge/experience in the best skilled individuals in the community).

The above transformation modified not only teachers' functions, but also the whole school environment and the students' role within it.

The same ICT will help teachers and professors in finding solutions to learning problems by giving them new instruments for the analysis and continuous monitoring of students' learning processes.

BACKGROUND

As already stated, computers entered very early into educational processes, often under the influence of pedagogical and psychological theories. As regards the influence of IT on individual teaching-learning processes, one of the most relevant contributions in defining the ways computers could be used in education came from Taylor (1980), who proposed three metaphors for them: tutor, tool, and

tutee. The first one refers to the computer support to teachers' work, the second one to instruments or tools autonomously used by students, and the third one to computer programming skills students must have to let problems be solved by computers. Galliani and others (1999) extended these metaphors while considering the great deal of software tools devoted to education and developed with the time. Tutor appellation describes how computer systems support or substitute (in the specific situation of auto-instruction) teachers and tutors in their work. Computer-assisted instruction (CAI), computer-assisted education (CAE), and computer-assisted learning (CAL) software are examples of the above systems. The former ones, CAI and CAE, implement into the topics to be taught the structure of the software the designer makes up (i.e., they force the user to follow a well-defined learning route within them); good examples for this kind of software are: 1) tools for theorems' demonstration or physical phenomena emulation, and 2) surveying/testing software made by questions with pre-built multiple answers or yes/no answers. CAL software, with respect to the other tools, gives more importance to learning than to teaching; that is, users can now freely move within different scenarios and can decide by themselves what to do, or can browse in a personal way the context the software proposes. Good examples for these software packages are educational games, edutainment (acronym for education-entertainment) tools, simulation systems (often used for training), and many multimedia or hypermedia tools.

A further extension of tutor metaphor comes from the results of artificial intelligence application in education and especially: intelligent computer-assisted instruction (ICAI) systems and intelligent tutoring systems (ITSs). In these systems, with respect to CAI and CAL tools, there is no pre-determined teaching route or strategy, but there are three independent modules interacting among themselves: an expert (i.e., a knowledge basis on a very specific domain), a pupil (implementing the knowledge representation of a student interacting

with the system), and a teacher (implementing the teacher behavior rules of everyday teaching and determining the didactic strategies to be adopted during the student-system dialogue).

With respect to the tool metaphor, its extended version now includes (together with the software students can use to produce information, i.e., editors or at most word processors) office automation suites and special tools for the analysis of a large amount of data and for browsing specific contexts (usually provided with authoring, co-authoring functions).

Finally, the extension of the tutee metaphor is mainly represented from tools for the creation of special developmental environments, such as the ones Papert created with LOGO.

It must be noted that Taylor's metaphors and their extensions are not the only ways for interpreting the influence of computer use in individuals' learning processes; a relevant role in the analysis of computing effects comes also from meta-cognitive hypotheses. Strictly speaking, people supporting the above hypotheses think that computer use stimulates functions' development more than learning topics so that meta-cognitive attitudes are developed by students systematically working at a computer (Cornoldi & Caponi, 1991). Furthermore hypertexts and hypermedia, due to their features, induce the development of transversal and meta-cognitive skills.

The main feature of the educational use of IT in this phase has been the introduction of computers in school and educational systems, without any great innovation in teaching and management organization (i.e., the most relevant interventions carried out by public institutions for all levels of schools were projects for teachers' training, allocation of funds for buying computing laboratories, etc.).

Radical changes in ICT influence on teaching/learning processes came from the spreading of networks and especially of the Internet (with its exponential growth in last few years). The reasons for the changes in knowledge construction hypotheses and educational effects—that is, for

the passage from individual to social analysis of educational phenomena—is mostly due to computer-mediated communication (CMC) and its role on individuals, communities, and societies.

It must also be noted that the ICT influence on education can be analyzed from two different points of view: the former one looks at the possible creation of new knowledge structures; the latter one refers to the different ways ICTs can be used in learning contexts and to innovations they can induce in the same contexts.

Regarding the first point of view, many scholars proposed new definitions and interesting ideas. Rheingold (1994) proposes the concept of virtual communities as groups of individuals who can never meet themselves or physically know one another, but who use the Net for their interpersonal communication, such as for sharing information and building new knowledge. The Lévy (1996) idea of collective intelligence is strongly dependent on the increase of the interpersonal communication speed and on the great amount of information the Net makes available. Furthermore Calvani and Rotta (1999, 2000), while collecting hypotheses from many other scholars, state that ICTs introduce new elements for knowledge structure—that is, it has no more only linear, sequential, closed, and hierarchical features; in addition, it also has hypertext and multimedia features. They state also that the Net extends the social negotiation aspects of knowledge and contributes in its distributed features supporting in this way the construction of meaningful learning in the subjects using it. Actually the results coming from knowledge management experiences suggest for networks and especially the Internet the role of the technical infrastructure on which a community memory (shared knowledge basis supporting a professional CoP) can be built (Trentin, 2004).

Regarding the second point, the Internet inherits and strengthens the results of previous distance education experiences and proposes for itself two main features: 1) repositories within which information, documents, and other infor-

mation can be found; and 2) virtual environments where individuals can interact and build learning communities.

The above features and the improvement in education/training requests from large layers of people induced further changes in educational systems and especially universities. The definition brick-and-click university, recently introduced to describe the relevance universities assign to the presence of online courses and e-learning in their didactical offer, gives an idea of the importance ICT gained in educational contexts. But the effects of ICT on universities are not only nominalistic; they also modified the places and the actors of educational processes. Regarding the places, Ardizzone and Rivoltella (2003) hypothesize the proliferation of the environments to be used for training and suggest five possible rooms: 1) the traditional classroom, where the usual presence lesson is made or special activities like knowledge exposition, rules description, and sharing of experiences are carried out; 2) tele-didactics, that is, the teaching work strongly based on audio-video channels, with synchronous-asynchronous fruition and individual-group activities; 3) the online course, with which a virtual classroom is made and the usual teaching/learning activities are carried out without the need of teacher and/or student presence; 4) the virtual group, marked by the presence of cooperative activities within online courses and by a less important function of the teacher with respect to group interactions; and 5) the students' community, where the role of social interactions and the multiplication of virtual groups strongly extend the students' interactions in cyberspace.

As for the actors of educational processes, the same authors state that together with the well-known and traditional figures of teacher/professor and student (obviously with modifications in their features and functions), another professional gains importance—the tutor (in some cases two different tutors are proposed: the discipline and the system tutors).

NEW AND OLD PROBLEMS IN TEACHING WITH ICTS

It is probably too early to say if the changes induced by ICTs in higher education (especially university education) will give the right answers and solutions to the questions and problems that knowledge society puts to individuals and society.

In the author's opinion further changes are required because many problems still unsolved ask for adequate solutions. Among them, the following ones will be analyzed: 1) the presence of preconceptions, misconceptions, and mental schemes in students' minds; 2) the possible dependence of students' meaningful learning from their learning styles; and 3) the assessment of students' knowledge and skills, and the importance that portfolios have in the evaluation process.

Preconceptions, Misconceptions, Mental Schemes, and ICTs

It is well known that people often manifest wrong ideas that can be interpreted in at least two different ways (Driver & Erickson, 1983): a) mental schemes, if only the coherence of people's ideas in the interpretation of phenomena is considered (with no reference to scientific paradigms); and b) preconceptions or misconceptions (when people's ideas are compared and evaluated with respect to the right scientific paradigms).

Studies (Cartelli, 2002) carried out all over the world with differently aged people (from students to workers, professionals, and teachers) show that:

1. Almost all disciplinary fields report the presence of wrong ideas.
2. A lot of strategies and instruments have been proposed until now to help students in overcoming the problems they meet in their study, based or not on IT strategies (like the ones described in the first part of this article), and adopting or not constructivist strategies

(supported or not by ICT). A good percentage of success has been measured in those experiences. Nonetheless they were rarely compared with traditional teaching experiences and were never used systematically or adopted on a large scale in education.

3. Wrong ideas can persist in students' minds after the above instruments and strategies have been used and the best practices have been adopted.

The author's experience in basic computer science (CS) courses led him to hypothesize that a special e-learning platform continuously monitoring the didactic process could make easier for the students the learning of the CS topics (while giving to professors a powerful instrument for the management of their teaching). The information system the author planned and carried out (Cartelli, 2003) was very similar in its features to an e-learning platform. Most notably:

1. It had a well structured knowledge tree of the topics to be taught/learned,
2. Special auto-evaluation tests, integrated within the pages of the course (they were planned on the basis of the detected wrong ideas) were available for students,
3. Various communication areas implementing virtual environments for teachers/professors, tutors, and students could be accessed from everyone,
4. A careful management of the students' evaluation and assessment tests were available for teachers, and
5. Two functions for the analysis of the students' access to the course materials and the use they made of the communication services could be used.

The management of all information in the site was guaranteed from five types of protected accesses: the system administrator, professors, tutors, students, and lastly, didactic researchers and

scholars (who could only retrieve the information on the students' access to the course materials).

The system was experimented with two different sets of students and had positive results regarding the number of students passing ending examinations; there was in fact only 20% student loss, and more than 65% of the students had positive, if not excellent scores. But a careful analysis of the data stored in the database showed some limits for the system: 1) many students still evidenced the presence of misconceptions (more than 43% of the whole population); 2) the amount of data generated by the second set of students (more than 300 subjects) made impossible the continuous monitoring of the didactic process by means of the two functions (reporting the number of single students or groups of them to the course materials and the temporal sequence of their access to the system).

Meaningful Learning, Learning Styles, and ICTs

It must be noted that until now, a unique definition of meaningful learning has never been proposed by scholars, but at least two main definitions are in fact available. The former one, credited to Ausubel (1990), is based on the following elements: a) logical meaningfulness of the topic to be learned; b) presence in that subject of special elements (subsumers), making easier the insertion of new knowledge into previous knowledge; and c) motivation to learn. The latter definition credits Jonassen (1995) with stating that knowledge construction (internal and external negotiation), context (meaningful and authentic environment), and cooperation (among students and teachers) are the basic elements for the definition of an environment leading to meaningful learning (which has to be active, constructive, cooperative, intentional, conversational, and reflexive).

Also under the hypothesis of both the above definitions of meaningful learning, no dependence

has been shown until now among the development of such a learning by students, their problems, and their performances, neither in traditional contexts nor in virtual environments, online courses, and so forth.

More recently many studies have been carried out on the possible dependence of students' success from their learning styles.

First of all the research of Kovacic and Green (2004) on a computer concepts class (at the Open Polytechnic of New Zealand) is reported here. The authors had the main aim of identifying those students requiring additional learning support and adopted for their analysis the Felder-Silverman model for students' learning styles. After having evaluated and classified the students' learning styles according to the Felder-Soloman Learning Style Index, the authors found statistically significant differences in performance between the different learner types they identified in their class—that is, students with reflective, sensing, verbal, and global learning preferences had the best performances both in in-course assessment and in final examination. The explanation the authors give for this result is in the advantage that the above type of learners receive from current teaching styles and the learning environment (course material and online students' support).

Furthermore other scholars (Kumar, Kumar & Smart, 2004) used pre- and post-tests based on the Grasha-Riechman Student Learning Styles Scale (another model for the analysis of students' learning styles) on a sample of 65 students (both graduate and undergraduate). They found relevant changes in the final presence of some types of learning styles with respect to the others in the class they analyzed. For the authors the observed changes depend on the instructional strategies and the technologies they adopted (i.e., the use of collaborative projects and course management software increased the number of collaborative, participant, and independent learning styles among students).

Students' Assessment and ICTs

Knowledge society, and lifelong learning, with the continuous improvement in education and training, put the problem of a more efficient evaluation of the knowledge and skill people obtain while attending courses. The portfolio of competences has been one of the instruments developed during the last few years having great success in certifying the students' success in educational activities. Over the last three years, there has been also a significant increase in the use of online portfolios in tertiary, secondary, primary, and professional education, to combine the benefits of traditional portfolio-based assessment with the paper-saving and other benefits of online environments. Love and Cooper (2004), while investigating the key factors necessary to design information systems for online portfolio-based assessment in tertiary, professional, secondary, and primary education, identify four weaknesses: 1) design brief omitting most of the key educational and administrative issues, and focusing mostly on identifying technical means; 2) "online portfolios" made only of a single essay, project report, or term paper presented as a Web-based electronic facsimile of a conventional document; 3) designs for online portfolio assessment systems based on an over-narrow view of value distribution that does not take all stakeholders into account; and 4) designing of online portfolio assessment systems not well integrated with overall course design processes.

In other words the authors found that online portfolio systems felt significantly short of their potential, and in many cases were inferior to conventional portfolio assessment and other more traditional assessment approaches. They suggested an alternative approach to designing online portfolio assessment systems, whose primary focus was the creation and distribution of benefits and value to all stakeholders. The main points of this alternative approach are: a) the identification of the nature and characteristics

of the educational and institutional contexts for which the online portfolio assessment systems is designed (and evaluated); b) the identification of potential benefits and increase in value for all stakeholders; c) the development of heuristics for prioritizing value distributions; and d) the development of an online system through the use of best practices in course design, the fulfillment of the requirements of the course criteria, the integration of the designing of the online portfolio system with the broader course design processes, and the focus on process automation to create and distribute increased value to all stakeholders.

CONCLUSION

The studies reported above show that ICTs can still play a relevant role in new educational fields with respect to the ones described in the background.

If further research is needed before we have solid results, it seems that the above data assign a new role to teachers/professors in the didactic process: the monitoring, analysis, and assessment of individuals' learning processes by means of the ICT.

The examples discussed above show how the improvement of the efficacy of teaching work can be obtained with the introduction of functions (based on ICT use) analyzing the students' data stored in an electronic repository so that:

1. The acquisition of the starting situation for each student can be easily detected and the didactic process can be personalized.
2. The change in the features of a student can be analyzed with respect to the ones of the whole population (by means of the comparison of suitable indices describing individual behaviors and learning styles, and the same indices describing the features of the whole population).

3. The change in the time of the features of individual students or groups of them can be detected.
4. Possible differences existing in groups of students experimenting different teaching strategies can be described, and the influence of different environments on the evolution of the teaching process can be detected.

The systematic use of ICTs in the above processes can transform teaching in an event-driven process where students' learning styles, the use of self-assessment tests, documents produced, scores obtained, and so forth lead to the complete control of the teaching-learning process. In other words, online action-research strategies have to be adopted, and teaching teams using Web technologies (together with RDBMS and the storage of the data produced from the students accessing the Web) must be developed for a complete and successful analysis of that process.

KEY TERMS

E-Learning Platform: An information system that schools, universities, and institutions can use for teaching (only online or supporting traditional teaching) which can have the following features (all together or individually): a) be a content management system (CMS), guaranteeing the access to didactic materials for the students; b) be a learning management system (LMS), where the use of learning objects makes easier the learning of a given topic; c) be a computer-supported collaborative learning system (CSCLS), which makes easier the use of collaborative and situated teaching/learning strategies; and d) build a virtual community of students, tutors, and professors using knowledge management (KM) strategies.

Learning Style: The personal way individuals think and learn. Also, if each individual develops a preferred set of approaches to learning, many authors suggest a well-defined set of learning models. Research seems to agree on the following elements: a) the adoption of special teaching strategies can make easier learning for students or not, depending on their learning styles; b) learning styles can evolve with individuals; and c) individuals' learning styles can be modified by special learning environments.

Mental Scheme: The set of concepts, and dependencies among them, that individuals carry out

for facing the problem of interpreting phenomena, without any reference to scientific knowledge or disciplinary paradigms.

Misconceptions (Preconceptions): Wrong ideas people manifest while explaining phenomena, with respect to scientific paradigms (i.e., people's ideas are evaluated with respect to scientific ones). The term preconception is adopted when the wrong idea appears before people meet curricular disciplines. The term misconception is used to mark the students' mistakes in phenomena interpretation.

Online Action Research: Uses the Internet for extending the features of traditional action research and its cyclical structure, based for many authors on five different phases: diagnosing, action-planning, action-taking, evaluating, and specifying learning. The Internet allows the continuous monitoring of action-research events and gives the researcher a further instrument to study phenomena and intervene on them.

Portfolio: The report collecting documents, scores, interviews, and so forth, and demonstrating the students' skills, achievements, learning, and competencies, with respect to: a) previously defined areas of skill, b) specific learning outcomes from these areas, c) appropriate learning strategies that have to be developed by the student, and d) performance indicators.

Web Technologies: The set of all instruments that allows people to use the Web and its protocols for improving communication and acquiring information. These are based on hardware, which are mostly networks of computers, and software resources, which are mostly Web servers using the HTTP protocol for communicating, interfaced with RDBMS (relational data base management systems).

Chapter 1.30

Sociocultural Animation

Marcus Foth

Queensland University of Technology, Australia

INTRODUCTION

The emergence of global computer networks and the widespread availability of advanced information communication technology (ICT) since the mid-nineties has given rise to the hope that the traditional disadvantages faced by regional economies and regional communities could be alleviated easily and swiftly. Yet, the experience of both researchers and practitioners in community informatics and community development tells a different tale. Although the potential of ICT is in fact realised in some situations and locations, and does provide a means to ensure sustainability in some regional communities, elsewhere it has not achieved change for the promised better. Too many communities are still faced by a centralised structure in the context of commerce, service provision or governance and by various degrees of digital divides between the connected and disconnected, between the media literate and illiterate, between young and old, between consumers and producers, and between urban and rural.

Many attempts to close or bridge the digital divide have been reported with various degrees of success (e.g., Menou, 2001; Servon, 2002). Most

of these accounts echo a common voice in that they report similar principles of action, such as people-centred approaches, and they reflect and advocate—in most cases unconsciously—practices of sociocultural animation.

This article seeks to shed light onto the concept of sociocultural animation—a concept which is already commonplace in various forms in the arts, in education and professional development, youth work, sports, town planning, careers services, entrepreneurship and tourism. It starts by exploring the origins of sociocultural animation and draws comparisons with the current state of research and practice. It unpacks the foundation of sociocultural animation and briefly describes underlying principles and how they can be applied in the context of community informatics and developing regional communities with ICT.

BACKGROUND

Before the dominant meaning of the term “animation” was taken over by the film and computer graphics industries which ‘animate’ virtual characters, avatars and cartoons, it was—and

still is—used to describe the act of encouraging, motivating, involving, empowering, engaging real human beings. The word derives from the Greek/Latin “anima” which means “life” or “soul” and thus stands literally for the act of giving life or spirit to someone or something, or the state of being alive.

Most current accounts of sociocultural animation trace its origin back to post WW2 France where “animation socioculturelle” “was discovered as a way of invigorating democratic values lost as a result of the occupation and other wartime hardships” (Kurki, 2000, p. 162). It has also been suggested that the French colonial heritage made for an invigorating environment in which previous traditions aimed at rather dubious objectives overseas could be re-purposed mainly to animate French youth for leisure activities in, e.g., “maisons des jeunes et de la culture” (youth and cultural centres), “centres sociaux” (social centres) or “maisons de quartier” (community centres) (Cannan & Warren, 1997).

The concept of sociocultural animation spread throughout Europe in the 1970s when the increasingly self-confident community arts movement (known as “neighbourhood arts” in North America) was first being recognised and taken seriously by the established arts institutions and by public cultural policy makers. Previously, two misconceptions were prevalent: First, art is not created by “the plebs” but by few highly talented artists who create cultural works of supreme value; second, cultural development will occur in society by simply exhibiting these works. Thus, conventional arts policy at the time aimed at the “democratisation of culture” by fostering the dispersion of cultural institutions such as opera houses, theatres, galleries and museums, and by funding professional artists only (Adams & Goldbard, 1990; for an American perspective see Levine, 1988).

Advocates of “cultural democracy” opposed these notions and—initially through the work of the Council for Cultural Cooperation (CCC), part of the Council of Europe (cf. www.coe.int)—introduced a broader notion of sociocultural animation to a wider political arena. Sociocultural animation was defined as all actions which are “concerned to offer each individual the means and the incentive to become the active agent of his own development and of the qualitative development of the community to which he belongs” (Grosjean & Ingberg, 1974, p. 4). The notion of “democratising culture” was regarded as “patronising”; instead, the idea of “cultural democracy” suggests that “culture is synonymous with movement, and that each individual must not only be entitled to acquire culture, but also have full control over how that culture is defined” (Grosjean & Ingberg, 1974, p. 7).

Parallels can be drawn to today’s information society which still tries to come to terms with the vast opportunities ICT offers and to find best practices to “democratise” ICT and internet access, effective usage and the role of government itself. The foundation of sociocultural animation holds some insights and opens up perspectives which present-day community informatics researchers and practitioners may find useful and may benefit from.

THE FOUNDATION OF SOCIOCULTURAL ANIMATION

Kurki distinguishes three dimensions of sociocultural animation: “The educational goal is personal development; the social goal is to reinforce the group and the community and to increase people’s participation; the cultural dimension, in turn, aims at developing creativity and many-sided expression” (Kurki, 2000, p. 163). These three dimensions and their underlying principles and

practices are explored in the following in the context of community informatics.

The Social Dimension

Anthropologists and sociologists have created a plethora of definitions for the term “community” with the only common term of reference being “people”. The social dimension of sociocultural animation refers to a people-centred approach that is guided by the imperatives of personal and group participation (cf. Gumucio Dagron, 2001). In the field of community informatics, areas of application include sociocultural animation and ICT for developing countries (Gonzalez & Fernandez, 1990), communities of practice (Millen & Fontaine, 2003; Wenger, McDermott, & Snyder, 2002), and residential community networks (Foth, 2004), especially in the context of networked individualism (Wellman, 2001) and social networks (Watters, 2003).

The Cultural Dimension

Apart from the before mentioned prominence of sociocultural animation in European public policy making under the influence of the cultural democracy movement, it also implies a more simple and immediate cultural dimension in that it encourages people and community members to express themselves creatively through the arts. This dimension of sociocultural animation evokes the emergence of cultural heritage and gives rise to the formation of community memory. Smith (2002) illustrates the cultural dimension through the work of Brazilian theatre director and writer Augusto Boal and the “Theatre of the Oppressed” or “Forum Theatre” which is used as a way of developing creativity and eliciting an emotional response to political and economic questions from working class people.

Certain arts practices, especially dance, theatre and drama continue to play a significant role today in school education, youth and community

work. One example of this use of sociocultural animation are the Rock Eisteddfod festivals in Australia (www.rock_challenge.com.au) which combine choreography, costume and stage design, music and dance to animate not only youth but also parents, teachers and the wider community.

In the context of developing regional communities with ICT, the possibilities within the nexus of sociocultural animation and new forms of creative expression afforded by digital technology are just beginning to be explored. A prominent example in community informatics is digital storytelling which usually takes the form of a personal movie which integrates photographs, music, video, and voice (Freidus & Hlubinka, 2002). Digital storytelling workshops have been employed by both researchers (for a streaming media example, see Hartley, Hearn, Tacchi, & Foth, 2003) and practitioners (cf. www.bbc.co.uk/wales/capturewales).

The Educational Dimension

“Tell me and I forget, teach me and I remember, involve me and I learn,” a proverb attributed to Benjamin Franklin, summarises the educational dimension of sociocultural animation.

From early misuse during WW2 where forms of sociocultural animation have been applied in Germany to develop a social environment consistent and favourable with the Nazi regime and ideology (Sunker & Otto, 1997), it has now found its legitimate place in the field of social pedagogy in Germany (Moser, Müller, Wettstein, & Willener, 1999) and other European countries (cf. www.enoa.de and Lorenz, 1994), including Spain (Ander-Egg, 1997) and Finland (Kurki, 2000). In France, sociocultural animation is well established as an independent profession of “animateurs” who work in various social, cultural and educational contexts (Augustin & Gillet, 2000; Gillet, 1995; Mignon, 1999).

Effective use of ICT in a community context often requires training. The educational dimension

of sociocultural animation and the existing body of experience in participatory action learning and community media may prove valuable to better communicate the possibilities technology holds for regional development. Digital storytelling workshops are designed to allow for creative expression, but at the same time community members learn to use technology and how to make technology work for them effectively.

UNDERLYING PRINCIPLES AND PRACTICES

Sociocultural animation is “a state of mind rather than a specific action, a matter of form rather than of content” (Grosjean & Ingberg, 1974, p. 8). As such, sociocultural animation is a framework which can contain any primarily people-centred practices or methodologies. These methods are almost always directed at activating or mobilising a group or community and the members of that group or community to:

1. Embark upon a joint discovery of their own situation and reality in order to create a critical awareness of the issues and problems found
2. Analyse and diagnose reality in a dialogical fashion in order to envision the dream of a better future
3. Find ways of changing and improving reality by means of self-reflection and action
4. Constantly and continuously evaluate and assess the context and purpose of the action in order to adjust goals and direction.

Sociocultural animation can take the form of and borrow principles and practices from participatory action research (Reason & Bradbury, 2001) or ethnographic action research (Tacchi, Slater, & Hearn, 2003), yet—due to its non-academic origins—animators have in many cases foregone the academic rigour required in favour of focusing

on community action and change. This is in fact where synergies between academics and practitioners could emerge in the future: by combining the strengths of sociocultural animation—that is, activating and interacting with people—with the strengths of participatory action research—that is, analysing and interpreting reality from the different perspectives of community members with academic rigour. That said, the ethical rationale for a people-centred, solidary and democratic approach is very similar in both cases (cf. Hearn & Foth, 2005; Reason, 1998).

Sociocultural animation is usually employed by an “animator” (French, “animateur”) who can be a neighbourhood artist, a youth worker or researcher from within the community or from outside the community. If the animator is already part of the community, the initial phase of immersion and orientation may be easier to accomplish, however, animators from the outside bring the potential of seeing the community reality in a fresh and unbiased light. The key phases that a sociocultural animator goes through comprise sensitisation/animation, facilitation and progressive redundancy (Thapalia, 1996); the latter phase is to ensure continuity of the action, so the community can carry on without depending on the ongoing presence of the animator.

The animator is a catalyst, a mediator and facilitator who seeks to raise self-awareness and motivation (cf. Csikszentmihalyi, 1997; Fogg, 2003), to build confidence to increase both self-efficacy and community efficacy (Carroll & Reese, 2003), to engage community members and to encourage them to participate in self-reflection and action.

Any kind of agile, adaptive and people-centred methods of practice and evaluation (e.g., Checkland & Scholes, 1999; Mumford, 2003) employed by a sociocultural animator need to work towards a holistic representation within the contexts of both the community and the individual. In the context of the community, it is imperative to ensure that it is not only the perspectives of selected

Table 1. Cold world vs. hot world animation

“Cold world” animation	“Hot world” animation
Works to allay symptoms of problems	Works to remedy causes of problems
Instrumental use of ready-made methods	Reflective use of adaptive methods
Works towards social cohesion and consensus to retain the status quo	Works towards personal and collective participation to create conscious solidarity
Top-down approach	Bottom-up approach
Animation is ‘social engineering’	Animation is ‘human horticulture’

community members such as the opinion leaders and their individual requirements that are heard and taken into account, but also the views of the community as a whole, in order to create a vision which is supported by the entire community.

In the context of the individual community member, “the only true source of knowledge is people’s own social activity” (Kurki, 2000, p. 165). Hence, methods have to be applied that work towards capturing more than just explicit knowledge and also seek to elicit different types of tacit knowledge sources (Polanyi, 1966); that is, “from simple facts that were too obvious to be worth mentioning, to deeply ingrained skills that might be impossible to articulate, yet become visible through interaction” and creative expression (Foth, 2003, p. 35).

Table 1 is an attempt at creating a dichotomy of sociocultural animation as a heuristic aid based on two extreme types defined by Gillet (1995)—with additions by Kurki (2000) and Gilchrist (2000). These extremes oppose, yet at times also complement, each other.

CONCLUSION AND FUTURE DIRECTION

Ongoing issues and areas of discussion that are prevalent in the study and practice of sociocultural animation in the context of community informatics require further investigation and advancement. These include:

- The imperative of academic rigour in the work of sociocultural animators on the ground
- The shift of emphasis in community development from “access to technology” to “effective use of technology” for creative expression, social networking and the generation of economic assets
- Lack of clarity and guidance in the ambiguous nature of the animator who is usually employed *by* a funding body but employed *for* a community group
- Implications for public policy making and public funding programs in regards to the arts, media, ICT and community develop-

ment, especially new definitions and practical interpretations of “accountability” and “sustainability.”

Sociocultural animation holds exciting potential to be used in economic community settings. The social, cultural and educational dimensions of animation for ICT have already been exploited by businesses in what has been termed “viral marketing” (Godin, 2001; Goldsmith, 2002); however, its application for place-based social networking, community-led innovation and regional entrepreneurial initiatives is yet to be explored.

Kretzmann and McKnight point out that members of disadvantaged communities often “begin to see themselves as people with special needs that can only be met by outsiders. They become consumers of services, with no incentive to be producers” (Kretzmann & McKnight, 1993, p. 2). Far too often are regional communities given access to ICT without an existing strategy for how the technology can be effectively used to make sense in the lives of community members. Sociocultural animation represents a key concept to overcome these flaws in that it regards community members as social beings, as creative content producers and active agents of change.

Finally, this is the time to embark upon the quest to sketch and establish a new adaptation of sociocultural animation that is purpose built for the opportunities and challenges of community informatics research and practice.

KEY TERMS

Action Research: A research approach which is operationalised by constant cycles of planning, acting, observing and reflecting, which

encourages the participation of local subjects as active agents in the research process, and which works hand in hand with people-centred research methodologies.

Animator: The “keeper of the vision” who is a catalyst, mediator and facilitator seeking to raise self-awareness and motivation, to build confidence to increase both self efficacy and community efficacy, to engage community members and to encourage them to participate in self-reflection and action.

Cultural Democracy: A set of related commitments to protect and promote cultural diversity, and the right to culture for everyone in society; to encourage active participation in community cultural life; to enable people to participate in policy decisions that affect the quality of their cultural lives; and to assure fair and equitable access to cultural resources and support. (cf. www.wwcd.org)

Sociocultural Animation: All actions which are “concerned to offer each individual the means and the incentive to become the active agent of his own development and of the qualitative development of the community to which he belongs” (Grosjean & Ingberg, 1974, p. 4).

Tacit Knowledge: We draw upon tacitly held knowledge to perform and act but it cannot be easily and explicitly articulated: “We can know things, and important things, that we cannot tell” (Polanyi, 1966, p. 22).

Viral Marketing: A recent contribution to the marketing mix that uses technical networks such as the Internet or mobile phone network, to start an epidemic that spreads an idea or message (“the virus infection”) through social networks.

Chapter 1.31

Biographical Stories of European Women Working in ICT

Andrea Birbaumer

Vienna University of Technology, Austria

Marianne Tolar

Vienna University of Technology, Austria

Ina Wagner

Vienna University of Technology, Austria

INTRODUCTION

There is a deep gender imbalance in information and communication technology (ICT) professions which are only about 17% female (compare Valenduc et al., 2004, p. 19) and, simultaneously, an unsatisfied demand for ICT professionals at intermediate and high levels. Although varying in different sectors and countries, a gender imbalance and a skills shortage are common features of the ICT labour market in Europe. This is an obstacle to the development of the knowledge economy and the achievement of social cohesion.

The project WWW-ICT¹ implements an integrated approach to the various aspects and dimensions of gender gaps in ICT professions, covering explicative factors linked to education and training, working and employment conditions,

professional and technical culture. Most existing studies have limitations and gaps. They are often limited to classical computer professions, while WWW-ICT intends to encompass new professions linked to new communication technology, also taking into account the vocational training system. Studies of the shortage of ICT professionals are mostly centred on the demand/supply relation, while we focus more on the role of professional models and professional trajectories as a factor of integration or exclusion.

In general terms, employment in the ICT sector has been growing very markedly across the EU in recent years. The sector is increasingly dominated by specialist firms, which have taken over the provision of computing services for client companies. Computer services in the EU are dominated by SMEs; the majority of computer

services businesses are micro-businesses employing less than ten employees (Björnsson, 2001). Despite the predominance of micro-businesses, there is a huge concentration of employment in bigger companies. This is the context within which women are employed in ICT.

BACKGROUND

Under-representation of girls and women in computing is a reality and “the reasons why women are not attracted to engineering in great numbers are subtle and complex defying monocausal explanations and solutions” (Adam, 2001, p. 40).

Much of the current discourse around the gender gap in computing is grounded in the debate on women in science and technology that dates back to the early 1980s. This debate revolved around some of the fundamental theoretical difficulties of addressing gender issues. One of these difficulties is to do with a dualistic notion of the world. Criticism of a dualistic construct of gender led to an increasing interest in “difference” (rather than sameness) on the one hand.

On the other hand the first studies of practising women scientists suggested that women choose science for similar reasons as their male colleagues: for the adventure of abstract thought, for the intellectual pleasure that analysing a problem, looking for details, isolating and manipulating variables provide (e.g., Carter & Kirkup, 1990). It was argued that people with the bodies of women do not necessarily have the minds of women. Evelyn Fox Keller (1987) was among the first feminist scholars who used gender not as an empirical category but as an analytical tool to elaborate and concretise the idea of difference and dissent within the sciences. Feminists introduced notions such as polyvalence, epistemological pluralism, and partial translations into the discourse on gender and technology (Wagner, 1994).

Much of this older debate has been absorbed by Judith Butler’s notion of gender as “performed”

(Butler 1993). It has been taken up by many feminist scholars and, interestingly, extended to technology. Jennifer Croissant argues: “We gender a technology by painting it blue and handing it to a boy. We gender the boy in this interaction, providing a frame of reference for appropriate technological and masculine identity associations and expectations. We of course provide a frame of reference for the girl to whom we do not hand it. We perform with technologies. The technology, with its scripts, schemes, and codes, also performs us in that we become subject to its affordances designed or there by happenstance when we start the performance” (Croissant, 1999, p. 278).

This argumentation leads to a second difficulty of theorising about technology and gender. Assumptions about the technologies that are examined in studies of gender differences are often quite general and superficial. In an early essay on women and technology Knapp (1989) argued that women’s ways of doing and thinking are not independent of the object world. Her main criticism of studies of women’s relations to the natural and technological world was that these almost exclusively look at the subject—women—disregarding the interactive nature of appropriating a technology. Not only are computers different from other technologies in ways that may affect the ways women and men interact with them. The range of computing applications dramatically expanded during the last decade and with it the range of computing professions. Looking at gender as performance and performed and at computers as highly specialised and varied technologies, has consequences for the method of ‘measuring’ gender differences. Kay (1992) has argued, “that to fully understand whether gender differences exist in human-computer interaction, a qualitative, contextual, developmental approach should be employed to examine specific tasks. He stresses that without this comprehensive understanding, researchers will continue to identify only pieces of a very complex puzzle” (quoted in Mitra et al., 2001, p. 228). A good example of such a con-

textual approach is Linda Stepulevage's (1999) reconstructing her own making into a technology expert using the method of autobiographical narrative. She emphasises the actual everyday practices that surround technologies—"people making and doing things." Understanding this "making and doing" is tied to particular locations and contexts (Stepulevage 1999).

It has been argued that in IT as a relatively young field women would not face the same barriers for working careers existing in other fields with a traditional male dominance. Ahuja (2002) argues that this viewpoint does not "adequately take into account the variety of structural and social factors that inescapably and inevitably shape women's careers in IT throughout industry and academia" (p. 22). Noticing a lack of academic studies on gender differences in IT careers she claims that it is important to understand the role of women in the field of IT and "how or if IT differs from other professional endeavours in offering opportunities to women" (p. 21). With that aim she proposes a conceptual framework that covers social factors as well as structural ones influencing women's professional careers in IT.

METHOD

Our qualitative research is based on biographical interviews. The analysis attempts at preserving the biographical aspect of informants' narratives while at the same time looking at more general patterns across individual biographies.

The aim of a biographical interview is to develop an understanding of a person's biography or trajectory—her development as based on opportunities, choices, and individual coping strategies. Crucial concepts are developmental tasks in particular phases of one's life, individual coping strategies in relation to given structures, detours and their implication for the person's biography, transitions (changes of field of work, occupation, life situation, etc.) and life themes

(Thomae, 1996) (i.e., topics that emerge in the women's own accounts as crucial for understanding their choices).

The focus of our interviews was on the women's work biographies, with an understanding that these are inseparable from their identity and concept of a good life. Silvia Gherardi's narratives of "women travellers in a male world" come closest to this notion of biographical interviews (Gherardi, 1996). Our interviews are what Flick (1995) calls episodic interviews with a strong narrative character. The main idea is to stimulate a person to tell "stories"—significant episodes in her life that illustrate the whys and hows of important events in her biography. We interviewed 107 women (15 or 16 in each of the seven countries) who were selected according to a set of criteria (see Table 1).

LIFE STORY PATTERNS

The categories we use in our analysis of biographical (life story) patterns are not theory-based but empirical, grounded in the material itself. They reflect some of the colour the women themselves gave to their narratives. We discovered eight main patterns. Each pattern has its own characteristics and its influence on the informants' career paths in ICT.

For this article we have selected four patterns that we found among the women interviewed. These patterns represent different paths into or in ICT professions. All the women belonging to the selected examples manage their working life rather successfully and are on the whole satisfied with their jobs. This selection is due to our focus, namely to emphasise successful careers, in order to find a new quality of research and recommendations. As a lot of existing studies focus on deficiencies, we try to find out positive role models of women, who found a way to manage their professional lives in the ICT sector. To our opinion women's careers are rather defined

Table 1. Characteristics of interview partners

Age	from 22 to 55, highest proportion between 31 and 40 years
Qualification	from no ICT related initial training to university degrees in ICT and other subjects
Job Profiles	project management, developing, leading position, Web design, support, marketing, teaching
Firms	large/small companies (more/less than 100 employees)
Status	salaried, self-employed, full-time, part-time
Residence	city/countryside, different regions within the countries

by their contents, their work practices, interests, opportunities and motivations behind than by obstacles and barriers. Positive examples in this sense give us the possibility of formulating recommendations for “agents of change” more precisely and realistically.

Straight Careers in ICT

Straight careers in ICT can be found in all the different national cultures. They are moved by strong interest in math and sciences and in some cases, looking for a field with good job prospects. This is reflected already in the first educational choices the women take: They follow a technical education from the start, studying computer science or maths or engineering. One of the women says that what she likes about her work is “solving riddles and generally the curiosity to get to the bottom of things.”

These women follow one of the predefined trajectories in ICT. They pursue a university career or very consequently climb up the career ladder in the ICT industry. They are extremely hard working. They may have a broad range of interest in their private lives but in their work they are very focused, taking extreme pleasure

in mastering the intellectual challenges of their discipline. They have high ambitions and strive to the top. The conditions for being successful—a hierarchical structure, a competitive environment, and long working hours—are accepted. One woman describes that work had become very much a life style. The definition of her identity included late working hours and socialisation over a drink.

Combining Art with Technology

In these careers, it is not technology that is in the foreground but a passion for art or journalism, with ICT entering later as an important tool and skill.

These women work in publishing or advertising. Typical of all these careers is the ease with which the women integrated ICT into their work, developing a passion for both fields, but with their artistic interests and ambitions staying in the foreground. Regarding their life style and way of working they are more artists than computer professionals.

Typically for these careers that are close to the arts is that there are no boundaries between professional work, social commitment and private life.

From the Margins to a Field of Opportunities

There are life stories in which ICT is strongly connected with moving out from one's milieu or region into promising and relatively secure jobs. While in several cases informants come from marginal regions—the countryside in the case of Austria, the South (Sicily) in the case of Italy—in a few other cases it is ethnicity which creates a potentially marginal position from which the women escape. In some cases the women rebel against their home environment. For example for one British woman of Indian ethnic origin the expectations of her parents that she would simply marry and have children in fact gave her a strong motivation to pursue her education and get a good job. However, in most cases the women stay emotionally attached to their original family offering them different kinds of support.

These women are interested in working with technology but not passionate. ICT opens a field of opportunities to these women. Entries into ICT vary. While some of the women studied informatics or something related, others encountered ICT in their first (clerical) jobs, seizing the opportunity to qualify themselves, either through learning by doing (the older ones) or through additional training. One of the prime movers of these careers is the chance to get a well paying job offering security, possibly in a large company.

Building One's Own Environment

Some informants' stories show a strong will and skill to shape their own environment so that it fits their idea of good work and a good life. This is a theme in their accounts which they address explicitly as "building". These women are very self-confident. They have clear goals and set the steps to achieve their ideas and ambitions. Their strong motivation takes them into different directions. It includes going abroad as a single woman to be exposed to other cultures, being in charge of

their own life from a quite young age on, founding their own company, carving out their own field of expertise, building things on their own, fighting for a good position.

Some but not all of them come from supporting families. Their parents and often especially the mothers encouraged them to go their own way and get independent. Many of these women also chose supporting partners with whom they share child caring responsibilities and who support their careers. However, there are also women who have to manage job, household and family on their own with no encouragement or help from other family members.

These women define themselves through the content of their work. This may also include broader interests, such as political commitments or artistic interests. Some of the women work as mentors and encourage other women in ICT.

CONCLUSION

Among our interviewees we found a great variety of jobs, entry routes, education as well as motivations and interests in working in the ICT sector. With the life story patterns we tried to capture this diversity without disassembling it into single "influential factors." For the women in our pattern of "Straight careers in ICT" the focus of their motivation is clear on technology. They like the challenges of their work and they are very ambitious. Contrary is the motivation of women who come "From the margins to a field of opportunities." For them ICT offers the chance to get out of their milieu. They usually have a quite "natural" relationship to technology, seeing it as a means to fulfil their tasks, but they are not passionate about it. Women who are "Building one's own environment" are very successful in realising their goals. They actively use the openness of the ICT sector that often lacks predefined job profiles to create their own working environment. The ICT sector is also open in another sense. This can

be seen from the experience of women who are “Combining art with technology.” These women come from other educational backgrounds and find ICT as an important tool for their work in art, graphic design, or journalism.

Our results from the interviews and case studies show that ICT professions are more varied than often assumed. By using a qualitative approach we were able to understand the motivation of women working in ICT professions from their own viewpoint in the context of their life stories. The result is a lively picture of the situation of women in the ICT sector that sheds light on the women’s motivations and needs as well as on the working conditions in the ICT sector. These insights can be used to formulate recommendations² that are based on women’s experiences from their work practices in ICT professions and that go far beyond the elimination of constraints.

FUTURE TRENDS

The ICT sector is a rather dynamic field. The permanent changes of the sector are tightly connected to the development and the growing of new jobs and new professional areas. Due to the rapid technical improvement it is a challenge to imagine future scenarios. As the ICT sector is a rich area of opportunities for men and women with different educational and qualification backgrounds we notice the necessity of continual research to analyse what is changing. It would be very helpful to improve and update the existing job descriptions and opportunities and to connect research institutions, labour market experts, and counsellors. We observe a great lack of comparable quantitative data as well as a sufficient number of qualitative studies, among them our study is just one contribution to a deeper understanding of the ICT sector. Quantitative and qualitative research should lead to better information about the chances and career options women may have in the ICT

sector and so work against the under-representation of girls and women in this area.

KEY TERMS

Agents of Change: Experts and institutions connected to the labour market, the educational and vocational area, industry and politics who should work against the gender imbalance in ICT following the recommendations of research projects. Agents of change are e.g. vocational advisors, counsellors, human resources managers, trade unionists, European and national institutions, social partners, public institutions, teachers, parents and students.

Biographical Interviews: Qualitative interviews, partly pre-structured with a strong narrative character; stimulates a person to tell “stories”—significant episodes of his/her life. Normally the interviewee covers several topics in his/her narration in his/her sequence.

Gender Imbalance in ICT Professions: Various aspects and dimensions of gender gaps in ICT professions, covering explicative factors linked to education and training, working and employment conditions, professional and technical culture.

ICT: Information and communication technologies.

ICT Professions: Rely on professional ICT skills in the ICT industry and in the user industries and services; characterised by the predominance of ICT knowledge; cover a range of tasks including conceptualisation, design, development, implementation, upgrading, maintenance or management of ICT systems and tools.

Life Story Patterns: Typologies drawn from biographical data of the interviews; clusters covering several criteria including career paths, background, education, etc. as well as individual life styles, coping strategies, cultural aspects, etc.; categories of the analysis are not theory-based but empirical, grounded in the material itself. They reflect some of the colour the interviewees gave to their narratives.

Life Themes: Topics that emerge in the person's own accounts as crucial for understanding their choices both in working and private life; can be drawn from biographical interviews. One person may have several different life themes.

Chapter 1.32

The Beijing World Conference on Women, ICT Policy, and Gender

J. Ann Dumas

The Pennsylvania State University, USA

INTRODUCTION

The 1995 Fourth World Conference on Women, Beijing, China, addressed gender equality issues in many areas of global society, including information, communication, and knowledge exchange and the associated technologies. The Beijing Declaration called for action to promote gender equality in human rights, economic autonomy, domestic responsibility sharing, participation in public life and decision making, access to health services and education, and the eradication of poverty and all forms of violence against women. The Beijing Platform for Action contained strategic objectives and actions for governments and others to implement to increase gender equality in 12 critical areas, including Section J, Women and the Media. Article 234 of the Beijing Platform Section J acknowledged the important need for gender equality in information and communication technology:

...advances in information technology have facilitated a global network of communications that transcends national boundaries and has an impact on public policy, private attitudes and behaviour, especially of children and young adults. Everywhere the potential exists for the media to make a far greater contribution to the advancement of women. (United Nations [UN], 1995, p. 133)

Section J defined two strategic objectives that address issues of access to and participation in ICT and media development:

J.1. Increase the participation and access of women to expression and decision making in and through the media and new technologies of communication.

J.2. Promote a balanced and nonstereotyped portrayal of women in the media. (United Nations, 1995, pp. 133-136)

Governments agreed to implement the Beijing Platform for Action and use gender-disaggregated data to report national progress on objectives during Beijing +5 United Nations General Assembly Special Session (UNGASS) in 2000 and Beijing +10 in 2005. This article reviews progress reported on ICT-related Section J strategic initiatives and trends for ICT and gender between 1995 and 2005.

BACKGROUND

The gender equality objectives in Section J have been rooted in international agreements among United Nations member nations since 1947. The Universal Declaration of Human Rights (UDHR) recognized that “the inherent dignity and the equal and inalienable rights of all the human family is the foundation of freedom, justice and peace in the world” (UN, 1948, p. 1). UDHR Article 19 affirms the right to communicate and “to seek, receive and impart information and ideas through any media and regardless of frontiers” (UN, 1948, p. 1). These human rights, equally inalienable for women and men, are affirmed in the international treaty Convention on the Elimination of all forms of Discrimination Against Women (CEDAW; UN Commission on the Status of Women, 1979). Prior to the Beijing conference, CEDAW was referenced in the preamble preceding the 1989 UNESCO Convention on Technical and Vocational Education, which “provides for the right to equal access to technical education and pays special attention to the needs of disadvantaged groups” (Hamelink, 2005, p. 128).

The United Nations Commission on the Status of Women organized four world conferences on women. The first was in Mexico in 1975 at the beginning of the United Nations Decade for Women and focused on equality, development, and peace with the subthemes of employment, health, and education. The second was in Copenhagen in 1980. The third, in Nairobi in 1985, produced

the Nairobi Forward-Looking Strategies for the Advancement of Women (1985), which affirmed that the:

...realization of equal rights for women at all levels and in all areas of life will contribute to the achievement of a just and lasting peace, to social progress and to respect for human rights and fundamental freedoms. (United Nations, 1985, p. 1)

Beijing 1995

The Fourth World Conference on Women in Beijing in 1995 built on the Nairobi strategies and created the Beijing Platform for Action (1995). Just prior to Beijing, the United Nations Commission on Science Technology and Development Gender Working Group (UNCSTD-GWG, 1995) compiled research on gender, science, and technology interactions, particularly on applications that serve basic needs in the developing world. Most of the case studies focused on technical change that had differentially impacted the lives of women and men, and found men benefiting more from technical change. Further analysis identified male dominance in the decision-making chain as a prime reason for gender inequalities (UNCSTD-GWG). The Beijing Platform for Action helped situate gender equality as central in the global development-policy agenda by creating a gender-sensitive policy framework for achieving development goals through action targeted to human needs. Governments agreed to the Beijing Platform for Action and committed some resources to implement the objectives of its 12 target areas and to monitor progress at 5-year intervals.

Beijing + 5

The Beijing Platform for Action Section J had affirmed the importance of gender inclusion in ICT policy development at local, national, regional, and international levels. By 2000, policies to direct the

ICT tools, so celebrated for their potential to effect change in developing nations, were only sparsely implemented toward programs for women's development. UNIFEM executive director Noleen Heyzer (2000) voiced concern that "globalization has failed to generate formal employment for women, but instead shifted their work to the informal and casual sectors." She stressed the "pressing need to assist countries to develop new frameworks that transform globalization to become pro-poor and pro-women, a globalization that is more socially accountable" and to utilize "the possibilities for connecting women and markets worldwide through the democratization of information and communication technologies and policies." She addressed the issue of the representation of women and called for greater gender equity in "expression and decision-making in and through the media and new technologies of communication."

Toward this objective, UNIFEM partnered with Cisco Systems to host the gender and ICT session at the Beijing +5 UNGASS. The session reported on women's leadership in ICT capacity building and information sharing for development. Discussion focused on best-practice action programs for the Section J objectives expanded to include ICT. New media ICT access and participation had moved toward gender equality in ICT-rich nations. In ICT-poor nations, data were less available. Many cases were reported of women's empowerment through ICTs for education, political voice and decision making, employment, and capacity development, but key obstacles of poverty and illiteracy kept most women in developing countries from ICT access and participation (United Nations, 2000).

The United Nations (2000) report on trends and statistics published for Beijing +5 identified the "need for new data on new media" (p. 100) and found new media boundaries are blurred between "genres and delivery systems" and "producers and users" (p. 100). Support for gender equality in hiring and gender sensitivity in programming was

recommended in order to address escalating trends of gender stereotyping, pornography, and other degrading images of women and girls in media. The 2000 report also found "almost no data" (p. 100) on gender portrayal in new media, including Internet broadcasts, games, and newsgroups. The report recommended the development of complex measurement instruments to do this because "representations of women cannot be separated from construction of identity, use of language and new styles of interaction" (p. 100).

Beijing +10

Ten years after Beijing, the United Nations Research Institute for Social Development (UNRISD, 2005) analysis and report on progress focused more on the broad global challenges to women's well-being than on the specific progress of Section J, Women and Media, including ICT. The Beijing +10 UNRISD report found overall "uneven progress in an unequal world" (p. 5) in part because the state, a central instrument for human rights protection, must be "democratized to deliver gender justice" (p. 258).

UNRISD (2005) reported that "market fundamentalism has reduced the legitimacy of the state as the maker of national rules about the obligations and rights of citizens" (p. 258). The report acknowledged some gender-equality gains in primary education, political representation, and reproductive rights, and the fact that there are more women in the labor market. However, ILO data in the report showed increased jobs for women in ICT and other sectors, but most were in informal and low-wage labor, so there was little overall economic progress for women since Beijing +5. ICT and economic development progressed concurrently in China and India, but without concurrent development of gender equality in education, health, and economic distribution (UNRISD).

The Beijing platform and subsequent progress assessments in 2000 and 2005 also considered

research evidence that policies, guidelines, and perhaps technologies are more gendered than gender neutral, strengthening the argument for gender-inclusive data collection and analysis:

Project-level data has well established that telecommunication and ICT are not gender-neutral. They impact men and women differentially, and in almost all cases, women have lesser access to and use of the media and lesser representation in the power and decision-making positions related to telecommunications and ICT... special attention is needed. Without it, women will have fewer opportunities to benefit from the myriad possibilities of the information age. (Hafkin, 2003, p. 1)

Nations and international organizations continue to monitor progress on the Beijing objectives, which remain a policy framework to guide the slow progress toward gender justice in ICT and other development areas.

FUTURE TRENDS

Beijing 1995, Beijing +5, and Beijing +10 have influenced the development of gender-focused research, analysis, and advocacy in ICT in the International Telecommunications Union (ITU), the UN ICT Task Force, and the 2003 to 2005 World Summit on the Information Society (WSIS). The ITU Task Force on Gender Issues (ITU-TFGI, 2001) developed “gender-aware guidelines for policy-making and regulatory agencies” intended to assist decision makers in their work to ensure that “both women and men are considered in the process” (p. 1). TFGI also found that:

...so-called gender-neutral policies or rules are not enough... women are vastly under-represented in government, business, political and social institutions; men still hold most of the management and control positions in telecommunication companies

and regulatory or policy making bodies; regulatory decisions are often made without impact analysis; and service licenses are attributed to companies without equal opportunity policies and are controlled mostly by men. The following are a set of guidelines ... They can be used to ensure that gender-sensitive analysis becomes an integral part of licensing and regulatory activities. Successful implementation of these guidelines requires the development and promotion of such policies within the institutions seeking transformation into a gender-aware environment. (p. 1)

The United Nations formed the UN ICT Task Force in 2001 to help mainstream ICT into development as a tool for digital opportunities and Millennium Development Goal (MDG) achievement. Gender inclusiveness and awareness have been evident in UN ICT Task Force policy and practice. Members are just under 20% women, and gender issues are regularly addressed in task-force work. The UN ICT Task Force has collaborated with the WSIS Gender Caucus and UNIFEM on the Kampala conference Bridging the Gender Digital Divide through Strategic Partnerships, which produced policy recommendations for gender and ICT including more research on ICT and gender issues.

Society of Women Engineers (2005) research using U.S. data showed that women in ICT education for electrical engineers, programmers, and software engineers progressed slowly from less than 10% of enrollment in the 1970s to 20% in 2000. Data showed similar ratios in these same ICT professions.

Graham and Smith (2005) found U.S. college-educated women represented only 24% of science and engineering (S&E) jobs. Women were underpaid, making 22% less than men. Though gender differentials in pay were even greater in non-S&E jobs, the authors recommended increasing S&E pay overall with policies to reduce gender earning discrimination in S&E jobs

because gender inequalities negatively impact the growing information society's need for scientists and engineers.

Women are underrepresented and underpaid in S&E fields outside the United States as well. Data for world nations ranked by the United Nations Development Program (UNDP) Human Development Index (HDI) showed that women held less than half of professional and technical jobs in 26 of the top 50 nations. A comparison of earned-income data for all of the top 50 showed that women's pay ranged between 17% and 63% less than men (UNDP, 2004).

Research has established strong links between ICT growth and economic development, and between gender equality and human development, but ICT growth alone does not necessarily lead to gender equality or human development. King and Mason (2001) compiled substantial research that demonstrated the gendered nature of poverty and its effects, and therefore the need for gender-aware programs to combat poverty. Proactive policies for overcoming gender-equality obstacles in ICT access and growth are more common in ICT-resource-rich countries. Yet it is as important in ICT-resource-poor countries. A gender-sensitive ICT policy, even with scarce ICT resources, can direct ICT applications to the needs of women, their dependent children, and the poor.

A specific policy for gender equality in ICT development is needed if ICT is to contribute significantly to achieving an end to poverty as envisioned in the 2000 Millennium Declaration's eight MDGs.

Gender equality, one of the MDGs, is central to achieving the other goals. Women and their dependent children represent more than two thirds of the world's hungry, poor, and illiterate (UNDP, 2004). Understanding this, the UNDP developed the Gender Development Index (GDI) compiled from economic, education, and health indicators using gender-disaggregated data. The GDI is used to help assess progress toward the

MDGs and the advancement of women in all areas of development. Gender-focused ICT education programs can prepare women for more skilled ICT jobs, improve local family incomes, and expand the national ICT skills base, addressing both poverty and gender inequality toward MDG achievement.

Gender research and analysis were part of the civil-society work prior to, during, and after the WSIS during the 3-year summit process. Plou (2005) described how gender relations in the ICT field sometimes reinforce old gender roles and power relationships, sometimes change them, but always require gender awareness in the developing information society. Plou says it is:

...not possible to think of new communication technologies as gender neutral. The absence of women's voices and perspectives in the information society also shows us that power relations in the new media replicate in many ways those in conventional media... Women's access to information sources and communication channels are crucial if they are to attain democratic participation, respect for their human rights and an equal voice in the public sphere. (p. 11)

Women are ICT users and content developers, particularly in new media, but are underrepresented among ICT policy makers. WSIS working groups for global policy development included Internet governance in their focus, which addressed technical standards, security, privacy, intellectual property issues, and financial mechanisms, and considered the Digital Solidarity Fund. Though women were well represented among the civil-society participants of WSIS, few women were represented among the thousands of government and business decision makers at WSIS (author's observation at Geneva WSIS; gender-disaggregated data not yet available). Even with much gender advocacy throughout WSIS, gender imbalance in policy making was still evident in the formation of

the UN Working Group on Internet Governance (WGIG), which included only 4 women of 40 members (ITU, 2005).

The WSIS Gender Caucus and the NGO Gender Strategies Working Group negotiated strongly for gender to be included as a fundamental principle for action in the policy development process. Gender Caucus convener Gillian Marcelle (2003) said:

Women's perspectives can contribute to making the difference between an Information Economy where gambling and pornography account for the most profitable applications and a true Information Society that serves human development ... making that leap will require radical transformation of the ICT sector so that all people, including girls and women of all ages, participate fully, not only as consumers but as citizens. This vision requires dramatic changes in the policies, practices and values of the ICT sector and the governance of the sector.

ICT and gender were critical issues debated and eventually included in the World Summit on the Information Society Declaration of Principles and Plan of Action. *The ITU World Telecommunications Report* (2003) focused specifically on how ICT applications could contribute to the achievement of gender equality, the empowerment of women, and the fulfillment of the other MDGs. Research and evidence show that continued attention to gender in monitoring the progress toward all the goals could help catalyze their achievement.

CONCLUSION

Gender-equality strategies, action plans, policy development, and monitoring processes were initiated through the UN decade for women, CEDAW, and the world conferences on women. The 1995 Beijing conference recognized and ar-

ticulated how creating greater gender equality in ICT access, participation, and capacity building was important to the achievement of sustainable development with gender justice. Gender-equality conditions in the rapidly changing information society are interactive with progress toward ending poverty, hunger, illiteracy, preventable disease, violent conflicts, and social isolation. ICT also plays an essential role in creating informed political participants and decision makers. The Beijing process and the ongoing evaluation of Section J objectives continue to support proactive efforts through WSIS, the UN ICT Task Force, and the MDGs to create more gender-inclusive and gender-sensitive ICT policy-making bodies capable of enhancing gender justice in the information society.

Chapter 1.33

Gender Inequalities for Use and Access of ICTs in Developing Countries

Sushil K. Sharma
Ball State University, USA

INTRODUCTION

Internet, wireless, mobile, multi-media (voice, video, 3D), broadband, and other information and communication technologies (ICTs) are rapidly consolidating global communication networks and international trade with implications for people in developing countries. Extensive literature suggests that use of ICTs have a great impact on society for improving their economic means and life styles. However, various studies conducted in different regions of the world indicate that the advantages of ICTs have not reached all sections of society, particularly rural communities, and women. Women face many obstacles before they can harness the benefits of ICTs (Accascina, 2001; Alloo, 1998; The Commonwealth of Learning, 1998, 1999, 2000, 2001).

Information and technology development, adoption, and access are far from adequate in developing countries. Large scale illiteracy and disabling environments, including uncompetitive markets, restrict opportunities to harness ICTs.

For example; in India only 0.6% of the population uses the Internet and the penetration rate of the personal computer is only 1.2% (Hafkin & Taggart, 2001; Nath, 2001; World Bank Report, 2002). Information chasms follow socioeconomic divisions, particularly income and education disparities, separating well-connected elites from the less privileged who remain detached from information access and use. Most women within developing countries are on the lowest side of the divide, further removed from the information age as compared to the men whose poverty they share (Accascina, 2001; Nath, 2001; Tandon, 1998, The Commonwealth of Learning, 1998, 1999, 2000, 2001). If access and use of these technologies is directly linked to social and economic development, then it is imperative that women in developing countries be taken into consideration while developing ICT diffusion strategies. ICTs can be an important tool in meeting women's basic needs and can provide the access to resources to involve women as equal partners in socioeconomic development (Cole et al., 1994).

Addressing gender issues in the ICTs sector has shown significant results where women have been made a part of ICT use and access. For example, women have benefited greatly from South Korea's push to make higher education available online. In corporate South Korea, more than 35% of high-level IT positions are now held by women. In Africa, 70% of agricultural produce is handled by women (World Bank Report, 2002). By using farm radios, women farmers can obtain information in local languages on markets, agricultural inputs, food preservation, and storage without traveling far, or being dependent on a middleman. ICTs use and access by women can offer significant opportunities for them in developing countries, including poor women living in rural areas. However, their ability to take advantage of these opportunities is contingent upon conducive policies, an enabling environment to extend communications infrastructure to where women live, and increasing educational levels. It is now, particularly appropriate to ensure the inclusion of gender concerns in national IT policy, as most developing countries are either in the process of or about to start elaborating these policies (Accascina, 2001; Marcelle, 2000; Ponniah & Reardon, 1999; The Commonwealth of Learning, 1998, 1999, 2000, 2001).

Women face considerably higher barriers in terms of literacy, access to education and information, productive and financial resources, and time. Many of the obstacles women face in accessing and using technology are entrenched in behavioral, cultural, and religious practices. Unless explicit measures are taken to address these divides, there is a risk that ICT will increase gender disparities and that the impact of ICTs will not be maximized. Integrating gender considerations into ICT strategies and policies will enable policy-makers and implementers to address these differences, which in turn will lead to remove gender inequalities for ICTs use and access (The Commonwealth of Learning, 1998, 1999, 2000, 2001).

BACKGROUND

ICTs bring the promise of new and better jobs and businesses for women, fuller participation in the political process, communication with worlds outside the boundaries of home and community, easy access to information and resources that can change lives, and the ability to acquire education and skills and to transcend social restrictions. These all can empower and enhance the quality of women's lives in developing countries. The Internet and other ICTs are proving to be a powerful tool to empower women to inform and change global and local realities. The opportunities and the benefits as well as the challenges of new information and communication technologies, as a tool of communication and knowledge transfer to support development and advancement of women in social and economic arenas are proving critical to women's networking and political action around the world. Considering odds against women taking part in the information super highway, women's groups and even poor communities are making full use of the Internet to defend and advocate for their rights. A key strategy for women's empowerment, especially in marginal and poor communities, is to give women access to new information technology in appropriate ways that support women's everyday work and help them fight for and defend their human, social, economic and political rights (Green & Trevor, 2002).

Even as the power and potential of these technologies are recognized and celebrated in most policy circles, the fact remains that unless the poor and marginalized are actively involved they will remain marginalized. Hence, there is a need for actions that are explicitly aimed at introducing the poor/marginalized, of which women are the majority, to these technologies. The gender gap in the digital divide is of increasing concern; if access to and use of these technologies is directly linked to social and economic development, then it is imperative to ensure that women in developing countries understand the significance of these

technologies and use them. If not, lack of access to information and communication technologies becomes a significant factor in the further marginalization of women from the economic, social, and political mainstream of their countries and the world. Unless women are provided effective access to ICTs, they will be left behind in their participation in the global world of the twenty-first century.

BARRIERS FOR WOMEN OF ICT USE AND ACCESS

Most women in developing countries who use information technology use it at work. Except in upper-income enclaves, home access to a computer and the Internet is not a common. E-mail is the major ICT application that women in developing countries use. Also, since women are given roles to manage the home and kids and their school tasks, women find very little time to use ICTs for any recreational or communication purposes (Ranchod, 2000). Broadly speaking, the barriers to women's use of ICTs have been:

- General literacy and language
- Lack of technical training
- Lack of access to hardware, software or access to the technologies
- Cost of connections still high for the lower income women
- General “technophobia” among women
- Social and cultural barriers—women are still the primary care-takers for their children and carry the bulk of household responsibilities, therefore have less time to explore the uses of new ICTs
- Full Internet access is limited in the academic sector and in corporations to those who hold managerial and/or technical posts, and the number of women in these positions is relatively small compared to men

Many of these barriers arise directly from the status of national illiteracy levels and national connectivity information infrastructure. However, systemic problems of general illiteracy combined with infrastructural barriers work against women. Some of these barriers are described in detail in the next section.

Cultural Barriers

Cultural and social attitudes often discriminate against women's participation in the fields of science and technology and limit their opportunities in the area of ICT. In several countries, the most binding constraint to the diffusion of ICT is often not technology *per se*, but the culture surrounding the use of information in general. In some countries, the benefits of an open information culture, including direct exchanges among citizens, between citizens and government and internationally, has not percolated yet to a critical mass capable of creating substantial upstream changes. De-learning old habits is probably needed before embracing new ICT. Most women will not perceive the benefits of ICTs, nor will they be able to use them to their full potential, unless they can see an immediate benefit or result of participation in ICTs.

Language

Language usage also plays an important role. Although some regional information mechanisms have been created and are being maintained today, the languages used are primarily English. This exacerbates the hub-and-spoke effect. A number of initiatives are taking place to facilitate the use of ICT in local languages but so far, numbers are far behind. Lack of standardization, limits the use of the local language. English is the established language of the Internet. English is used among the more educated members of the society in India. Non-English speaking women find it hard to use ICTs due to language barriers.

Financial and Budgetary Constraints

Women are often financially dependent upon men or do not have control over household expenditures. This makes accessing ICT services more difficult. In some countries, women's seclusion from the public arena makes accessing community Internet centers difficult. The prohibitive costs are a major constraint. The costs involve the purchase of the necessary equipment, obtaining and maintaining connectivity, and usage charges.

While many women may be interested in using and accessing the Internet, the cost limit constrains them. Aside from budgetary constraints, women cited internal constraints such as culture, and attitudes.

Telecommunication Infrastructure

The majority of women who have access today for ICTs are from research institutions, governments, and some businesses. Access among poorer and rural classes is currently non-existent, but critical for women's development. The benefits from ICTs and the adverse effects that might ensue from not accessing them cannot be embraced without adequate telecommunication infrastructure. Under-developed telecommunication infrastructure remains an important impediment to the expansion of ICT use in most countries. While computer prices have declined closer to international standards, telecommunications continue to be both costly and of limited availability. In India, all electronic media, ranging from satellite television to e-mail and the Internet, are accessible only to the privileged classes and cater almost exclusively to their predominantly male culture.

Illiteracy

Given the low levels of literacy (reading and writing), let alone computer literacy in many developing countries, the opportunities presented by new digital information systems are a long

way from reaching the hands and eyes of the majority. ICT is not the answer in itself to poverty and social exclusion—design of applications, accessibility of 'access points', and the design and delivery of training in ways adapted to women's needs, concerns and purposes for usage will determine whether and how they are used by women. Approaches to training women to use ICTs need to be appropriate to their interests and usage. Women also have awareness barriers for use and access of ICTs. There are three types of awareness issues that act as obstacles to women's use of communication technologies: awareness of personal ability, awareness of the utility of communication technologies, and awareness of available resources.

Education and Training Skills Barriers

A fundamental barrier to women's use of ICTs in developing countries is illiteracy. The danger in such a situation is that ICTs will widen and deepen the gap between the haves and have-nots as economies become more and more information-based. Inequitable allocation of education and training resources often favors boys and men. Education and training opportunities are not available in developing countries to educate women in use and access of ICTs. Women are marginalized in accessing education and training due to cost and access factors resulting in tremendously uneven IT skills between men and women. Most of the women's IT skills are self-learned. Although there may be ICTs training facilities, few women take advantage of these courses due to a variety of reasons: high fees, a feeling of intimidation in joining male-dominated courses that are moreover often taught by male trainers, and the ever present demands of family responsibilities.

Measures be Taken by Policy Makers

In order to ensure women's ability to take advantage of opportunities presented by ICTs,

gender and development policy makers need to be sensitized to ICT issues. Proactive policies and programs that meet the needs of women for use and access of ICTs. Matching the most appropriate communications technology with people's needs and capabilities is a crucial task for ICT providers. Steps must be taken to address the needs of languages and cultures through longer-term vision to make all ICTs accessible to women. This will involve significant investment and support for local content (in broadcasting and the Internet) and software design.

Increasing women's access to information and communication technologies in developing countries involves increasing availability of communication in areas where women live, most women in developing countries live in presently underserved areas. Extension of infrastructure, particularly wireless and satellite communications, to rural areas and semi-urban areas is crucial to increasing women's access to information technology. Emphasis needs to be on common use facilities, such as tele-centers, phone shops, and other forms of public access in places convenient and accessible to women. The policy makers should devise policies to improve the ability of girls and women using ICTs in developing countries. Such improvement requires interventions at all levels of education. A key strategy for women's empowerment, especially in marginal and poor communities, is to give women access to new information technology in appropriate ways that support women's everyday work and help them fight for and defend their human, social, economic and political rights. The use and access of ICTs offer many new opportunities for women in developing countries a lifeline for economic, social, and political empowerment. ICTs can be empowering for individual women and for women taking collective action. This requires core funding for women's organizations as well as investment in equipping them with ICT resources (Unpublished manuscript, 2002).

Costs are a significant barrier to usage and training for poor women, for whom household

needs will always be a first priority. All costs associated with access and training must therefore be met: transport, appropriate childcare, and/or disability or elder care, and making appropriate practical arrangements to accommodate other needs. If proper diffusion strategies are adopted for ICTs, with women in focus, they can certainly meet women's basic needs and access to resources. Removing barriers to women's ICT access offers potential to connect low income women to the democratic process, improve their access to services and resources, and strengthen their roles as community net workers (Accascina, 2001; Marcelle, 2000; The Commonwealth of Learning, 1998, 1999, 2000, 2001).

Since cost, technology expertise, repair and infrastructure issues will ensure that ICTs stay out of the reach of most individuals for the foreseeable future, alternative systems of access, delivery and information will need to be developed that are more appropriate to the situation of women. This is especially true for women, who tend to have less economic power, training, and technical expertise.

FUTURE TRENDS

Growing numbers of girls and women are doing things previously presumed to be the preserve of boys and men—computer enthusiasts, game players and, in some places, computer science courses. The ICT sector in many countries, including developing countries, is contributing to increased employment and economic opportunities for women. For instance, in the Kerala Technopark in India, women form nearly 40% of the computing work force. ICT allows access to a global market for even a small business with minimum initial investment. ICT, therefore, provides a unique opportunity to promote the growth of women-run small businesses. Women compose a significant share of micro, small, and medium entrepreneurs in developing countries. In order

for them to participate in the new knowledge-based economy, appropriate training and support to use ICTs are needed. The policy makers need to include women in policy dialogue and provide them women-friendly ICT access infrastructure. They should be provided training and testing in a structured, culturally-acceptable environment. More number of success stories of women using ICTs need to be prepared where they can be depicted as role models for young girls. Role of ICT in building positive role models is very crucial. Especially in the context of the Middle Eastern region where access to ICT has a strong male bias and Internet cafes are not women-friendly. Apart from government agencies, many other NGOs organizations need to work together to reach to women of different socio-cultural and economic considerations to attract women for participating in ICT projects. Access to loans, credit, and capital remains a barrier in ICT-based entrepreneurial activities among women.

In order to facilitate access for women from all classes and sectors, ICTs will need to be located in local institutions to which women have open and equal access, such as health centers, women's NGOs, women's employment centers, libraries, women's studies departments and institutes, and perhaps even churches. The location in these types of contexts also pertains to the practical, specific kind of information that women require as a result of their time constraints.

KEY TERMS

Digital Divide: The digital divide is the disparity in access to technology that exists across certain demographic groups. A term used to describe the discrepancy between people who have access to and the resources to use new information and communication tools, such as the Internet, and people who do not have the resources and access to the technology. The term also describes the discrepancy between those who have the skills, knowledge, and abilities to use the technologies and those who do not.

ICTs: ICTs include telecommunications technologies, such as telephone, cable, satellite, and radio, as well as digital technologies, such as computers, information networks, Internet and software.

Information Infrastructure: Information infrastructure refers to all telecommunications and computer networks world-wide to store, process, and disseminate information. The Internet is considered the de facto global information infrastructure right now.

Internet: The Internet is a worldwide communications network originally developed by the U.S. Department of Defense as a distributed

Gender Inequalities for Use and Access of ICTs in Developing Countries

system with no single point of failure. It is a system of interconnected networks that electronically links computers from around the world via the TCP/IP protocol.

Literacy: There are no universal definitions and standards of literacy. Unless otherwise specified, all rates are based on the most common definition—the ability to read and write at a specified age.

Chapter 1.34

WSIS Gender and ICT Policy

J. Ann Dumas

The Pennsylvania State University, USA

INTRODUCTION

The World Summit on the Information Society (WSIS) was organized by the United Nations (UN) and the International Telecommunications Union to address the need for international policy and agreement on ICT governance, rights, and responsibilities. It convened in two phases: Geneva in 2003 and Tunis in 2005. International representatives of governments, businesses, and civil society raised issues, and debated and formed policy recommendations. The WSIS Gender Caucus (2003) and other civil-society participants advocated for gender equality to be included as a fundamental principle for action and decision making. The voting plenary session of delegates produced the *WSIS Declaration of Principles* (UN, 2003a) and *WSIS Plan of Action* (UN, 2003b) in Geneva, with gender included in many of the articles.

Two major issues WSIS addressed in Geneva and Tunis were Internet governance and the Digital Solidarity Fund. UN secretary general Kofi Annan established the Working Group on Internet Governance (WGIG) to define Internet and Internet governance to “navigate the complex

terrain” (GKP, 2002, p. 6) and to make recommendations for WSIS in Tunis in 2005. WGIG addressed three Internet-governance functions: technical standardization; resources allocation and assignment, such as domain names; and policy formation and enforcement, and dispute resolution. Relevant issues not initially addressed by WGIG included gender, voice, inclusiveness, and other issues rooted in unequal access to ICT and to the decision-making process including governance, now shaping the information society. On February 23, a joint statement on Internet governance was presented in Geneva at the Tunis Prepcom by the Civil Society Internet Governance Caucus, the Gender Caucus, Human Rights Caucus, Privacy Caucus, and Media Caucus on behalf of the Civil Society Content and Themes Group. The statement asserts, “gender balanced representation in all aspects of Internet Governance is vital for the process and for its outcomes to have legitimacy” (WSIS Gender Caucus, 2005a).

The Digital Solidarity Fund was proposed at WSIS, and the UN Task Force on Financial Mechanisms for ICT for Development was formed. In the 1990s, official development-assistance (ODA) support declined for ICT infrastructure develop-

ment. In the new millennium, this decline has been offset by funds to integrate ICT programs into development (Hesselbarth & Tambo, 2005). The WSIS Gender Caucus (2003) statement on financing mechanisms affirmed that ICT for development must be framed as a development issue, “encompassing market-led growth but fundamentally a public policy issue.” Public finance is central to achieving “equitable and gender just outcomes in ICT for development.”

This article examines the WSIS political dynamics over the issue of gender equality as a fundamental principle for action in ICT policy. The WSIS civil-society participants, particularly the Gender Caucus, continued to advocate for gender equality as a fundamental principle for action and decision making within the multiple-stakeholder WSIS process of government delegates and private-sector representatives.

BACKGROUND

The WSIS Gender Caucus was formed at the 2002 WSIS African regional preparatory meeting. The WSIS Gender Caucus presented the following six recommendations for action to the WSIS voting plenary session in the spirit of “creating richness in the information society through inclusion, diversity and gender equality.” Gender equality must be a fundamental principle for action. There must be equitable participation in decisions shaping the information society. New and old ICTs must be accessed in a multimodal approach. ICTs must be designed to serve people. ICT empowerment for women and girls is necessary for full participation. Research analysis and evaluation must guide action. These recommendations helped inform the development of the WSIS platform for action.

Many civil-society representatives lobbied the voting delegates for the inclusion of gender equality as a fundamental principle for action in ICT policy. The WSIS Gender Caucus, the NGO Gender Strategies Working Group (NGOGSWG),

and other representatives to WSIS advocated for gender equality, basing arguments on the precedent agreements of the *Universal Declaration of Human Rights* (UDHR of 1948), Convention on the Elimination of all Forms of Discrimination against Women (CEDAW; UN Commission on the Status of Women, 1979), the Beijing Platform for Action (BPFA; UN, 1995), and the Millennium Development Goal commitments of 2000.

Global Knowledge Partnership (GKP) helped to structure and coordinate the WSIS civil-society participants at WSIS in the ICT4D civil-society forum. GKP (2002) made recommendations to the digital opportunity task force, an initiative of the G8 nations in 2000, to expand the “digital revolution” to the underserved, particularly women, rural residents, and youth in developing areas. Gender inclusion and mainstreaming were recommended:

GKP experience suggests that gender mainstreaming should be a component of every ICT project to ensure sustainability. A gender perspective must be built into plans, policy and practice, from preliminary project design through implementation and evaluation. The following case studies show that women who are involved in meaningful ICT projects improve their economic and/or social well being in the community. (GKP, 2002, p. 6)

The WSIS Gender Caucus and the NGOGSWG gender advocacy produced results in the documents of the Geneva phase of WSIS. The *WSIS Declaration of Principles* states that the common vision of the information society includes the Millennium Development Goal (MDG) challenges: “promotion of gender equality and empowerment of women; reduction of child mortality; improvement of maternal health” (ITU, 2005, p. 9).

The documents state that gender equality and sustainable social and economic development are crucial for an equitable information society. Civil-society involvement is acknowledged as key to creating broad-based acceptance and therefore

sustainable policy and plans for the information society. Civil society has also developed significant content and provision for a critical perspective. The *WSIS Plan of Action* calls for the removal of gender barriers and the development of gender-sensitive capacity building, e-learning and e-health, and early intervention programmes in science and technology that “target young girls to increase the number of women in ICT careers” (ITU, 2005, p. 45).

The WSIS Gender Caucus contributed to the UN Commission on the Status of Women’s Beijing +10 review of the platform for action. Section J: Women and Media called for gender equality in media creation and delivery. The caucus reported on how radio, telecenters, and teleconferencing had enabled experts to share knowledge with rural women in agriculture and to respond to information needs. The caucus stressed the value of these ICTs in helping to deliver services to women in health, education, agricultural extension, law, and social justice. Women’s participation helps to ensure that women benefit. Women can demand more accountable governance with transparent information access, and can participate more fully informed in public discourse. ICT can help empower women as development tools for better business, education, and governance participation. All the new ICTs and media provide connection and networking spaces where women can find voice, own and control information and knowledge, and tackle issues of everyday life, sometimes in new and innovative ways (United Nations Research Institute for Social Development [UNRISD], 2005).

Economic disempowerment and illiteracy are major issues of gender inequality that impact ICT in policy and practice. Two thirds of the world’s poor and undereducated are women. Even among the 55 countries with the highest United Nations Development Program (UNDP) Human Development Index (HDI), the ratio of estimated female to male earned income ranged between 34:100

and 74:100. Sweden was the lone exception with a ratio of 82:100. The United States ratio was 62:100 (UNDP, 2004). The income disparities exist despite the fact that gross tertiary enrollment is higher for females than males in all but six of these countries. The equalized education and training of women where it occurs has not yet equalized the ICT-sensitive process of input to the world’s knowledge resources. Political representation by women has grown since 1990, but for the 55 top HDI countries, the percentage of positions in government held by women still ranges between 0 and 38%. Sweden again was the exception with 45% women in parliament (UNDP, 2004).

Most development research and policy recommends reduced birthrates, found to promote infant and maternal health. Smaller families and improved health allow women more time for education and employment. Gender-equality advocates lobby for ICT skills training for jobs that offer women opportunities for growth from unskilled labor to small-business entrepreneurial efforts, such as the agriculture and cottage industry.

Gender-equality issues in ICT received mention in the WSIS documents, but only nominal attention in the ongoing WSIS process of policy development for Internet governance and financing mechanisms, key issues of the WSIS Tunis phase. UNIFEM continues to fund the WSIS Gender Caucus and efforts to bring greater gender equality to the information society through research, education, and policy decision making.

The WSIS Gender Caucus identified six policy issues during WSIS Geneva, and some were incorporated in the two WSIS documents. By 2005, WGIG had virtually sidelined the gender-equality issue as a fundamental principle for action without mention in the draft report to the UN secretary general. The caucus issued a statement for the June 2005 WGIG open consultation on Internet governance and the report draft:

We believe that the published WGIG outcome criteria lack the basic and fundamental criterion of gender balance and awareness and suggest that these criteria be amended to become

- *equitable distribution of resources,*
- *access for all,*
- *stable and secure functioning of the Internet,*
- *multilingualism and*
- *gender balance and equity*

... We further request that the WGIG consider gender balance as a fundamental issue in its ongoing assessment of Internet Governance mechanisms (current and future), with the aim of equal representation of women and men at all levels in any and all governance mechanisms proposed by the WGIG. (WSIS Gender Caucus, 2005a)

Sabanes Plou (2003) identified patriarchal structures that perpetuate gender-unequal power relations in the media, in ICT research and development, and in ICT labor and policy. Plou examined gender issues of ICT access, participation, and decision making in the information society. Media are the “vehicle for transmission of ideas, images and information,” and new media need “new patterns with a gender perspective” to challenge old patterns of control and decision making on access and content (p. 16).

Though ICT labor has been a source of economic growth for some, overall, women work in less skilled, lower paid, and non-decision-making positions in ICT (UNRISD, 2005). ICT access and participation depend on policy and action to address the primary gendered obstacles. Poverty requires affordable ICT. Illiteracy requires education and capability building, and a gendered approach to ICT integration into human communication systems. Patriarchal institutional structures of political, social, and economic power and relationships will continue in ICT without

policy and action initiatives for change toward gender equality at all institutional levels.

FUTURE TRENDS

UNIFEM affirmed and supported the WSIS Gender Caucus’ continued efforts to provide policy input for the development of Internet governance and the Digital Solidarity Fund financial mechanism for WSIS Tunis. UNIFEM also supported the WSIS Gender Caucus’ cooperative work on ICT gender advocacy with the WSIS NGOOSWG, the Association for Progressive Communications (APC), the World Association of Community Radio Broadcasters (AMARC), the WIN network, which coordinated the WSIS media pool, and the Global Knowledge Partnership, which coordinated civil-society WSIS participation in major WSIS process meetings.

WSIS Gender Caucus achievements during the Geneva phase of WSIS were summarized at the closing plenary session (Marcelle, 2003). The caucus advanced some important research trends including support for gender and ICT research, encouraging increased gender-disaggregated-data collection and analysis. Critical gender analysis of the ICT policies of institutions was also encouraged as another important research area. The idea of developing an archive of gender and ICT research was advanced. The caucus organized events and activities in Geneva “enabling decision makers to interact with gender advocates and scholars on alternative visions of the information society” (Marcelle). Current research and expert perspectives were shared throughout WSIS with plans for a post-WSIS “global platform for reporting back to the development community and women’s organizations” (Marcelle) in order for governments to be held accountable for the commitments made during WSIS.

Case studies of ICT for development projects that contribute to poverty elimination for women,

men, and children are also part of the ongoing research catalyzed by gender advocacy at WSIS. These include projects on “women’s applications of ICTs for mobilization, peace and conflict resolution, enterprise creation, trade, education, and health” (Marcelle, 2003).

During WSIS, UNIFEM announced the Digital Diaspora Initiative set up with an E-Quality Fund for African Women and Innovation to provide flexible funding for African women to have opportunities for capacity development and economic security in the information society.

Beyond the concrete WSIS direct outcomes, civil-society participants developed strong networks for information sharing and knowledge building through face-to-face and ICT communication forums. The WSIS Gender Caucus developed its portal (<http://www.genderwsis.org>) containing useful resources on gender-equality research and advocacy in ICT, and expanded its communications and outreach network.

The WSIS Gender Caucus, a committed group of gender advocates, continued to work with all stakeholder partners, including “governments, international agencies, the private sector and civil society ... to build an Information Society that benefits all of humanity” (Marcelle, 2003). WSIS Gender Caucus efforts support ongoing policy and action committed to gender equality and ICT applications that further the BPFA and MDGs.

The UN ICT Task Force has been “a global forum for placing ICT at the service of development” (Gilhooly, 2005) since 2001. Its mission and action plan were built on the guidance of the Millennium Declaration. It helped advance the multistakeholder discussion on Internet governance. The ICT Task Force helped to create an enabling environment toward the MDGs and to advance the practice of measuring, monitoring, and analyzing ICT impact on the MDGs. It developed an ICT strategy for knowledge creation and promoted cross-sectoral and cross-regional dialogues and partnerships. This included strengthening rela-

tionships with the research scholarship organizations International Communications Association (ICA) and International Association of Media and Communications Researchers (IAMCR). The ICT Task Force mandate was extended to 2005 to facilitate the WSIS process.

The ITU Task Force on Gender Issues (ITU-TFGI) has advanced the issues of gender mainstreaming and gender-disaggregated ICT data collection. ITU-TFGI also developed gender-aware guidelines for policy-making and regulatory agencies. The guidelines promote the establishment of gender units in regulatory bodies, gender-sensitive policy analysis, and gender-disaggregated data collection (Jorge, 2001). Research identified that women are “conspicuously absent from decision making structure in information technology in developed and developing countries” (Hafkin, 2003, p. 4), and recommended action to address the inequity.

The many cooperative gender-equality advocacy efforts have contributed to the WSIS decision making and created a policy for change. The future will unfold how these policy agreements will interact with patriarchal institutions over time to bring about real change in practice and real access to ICT with gender equality.

CONCLUSION

WSIS affirmed the MDGs to end poverty and illiteracy, two main obstacles to ICT access for women. International case studies affirm in practice how ICT applications have improved resource and service distribution for health care, education, economic empowerment, conflict resolution, and political, social, and cultural participation.

Gender equality in ICT access, power sharing, and decision making at all levels will continue as issues for dialogue, debate, and research. Active, perseverant voices for change call for humanizing the technology beyond market-economy indicators and creating an environment of cooperation

and sharing rather than competition and modification.

The argument for gender rights and equality in decision making for the information society continues to be advanced through many advocates and venues beyond WSIS. The importance of decision making was articulated well by Nobel Peace Prize winner and world leader Nelson Mandela (2004):

Our freedom and our rights will only have their full meaning as we succeed together in overcoming our divisions and inequalities of our past and in improving the lives of all, especially the poor. Today we are starting to reap some of the harvest we sowed at the end of a South African famine. Many...have spoken of a miracle. Yet those who have been most closely involved in the transition know it has been the product of human decision.

WSIS, gender, and ICT policy are integrally connected within the process of human decision making, capable of creating a world of gender justice, equality, and peace.

KEY TERMS

Beijing Platform for Action (BPFA): Action program produced during the 1995 Beijing Fourth World Conference on Women. The BPFA defined strategic objectives for action in 12 areas identified as essential to developing gender equality and compliance with the 1979 Convention on the Elimination of all Forms of Discrimination against Women. Global progress on the BPFA was reported at the 2000 Beijing +5 United Nations General Assembly Special Session (UNGASS) and the 2005 Beijing +10.

G8: Group of eight nations with the strongest economies, including, Canada, France, Germany, Italy, Japan, Russia, the United Kingdom, and the United States.

Human Development Index (HDI): An index used by the United Nations Development Program to measure development. HDI is composed of health indicators, infant and maternal mortality

and life expectancies, education indicators of literacy, and economic indicators of gross domestic product (GDP).

NGO Gender Strategies Working Group: Formed at the first WSIS Prepcom Meeting in Geneva in July 2002 as one of the subcommittees of the Civil Society Coordinating Group (CSCG). The groups currently involved in this effort are the African Women's Development and Communications Network (FEMNET), Agencia Latino Americana de Informacion, Association for Progressive Communication-Women's Networking Support Programme (APC-WNSP), International Women's Tribune Centre (IWTC), and Isis International-Manila. The working group is open to all NGOs and individuals interested in gender issues and the information society (<http://www.wougnet.org/WSIS/wsisgc.html>).

WSIS: The World Summit on the Information Society is a two-phase international summit from 2003 to 2005 organized by the United Nations and the International Telecommunications Union to address the need for international policy and agreement on ICT governance, rights, and responsibilities.

WSIS Declaration of Principles: It affirms gender equality and other MDGs:

Our challenge is to harness the potential of information and communication technology to promote the development goals of the Millennium Declaration, namely the eradication of extreme poverty and hunger; achievement of universal primary education; promotion of gender equality and empowerment of women; reduction of child mortality; improvement of maternal health; to combat HIV/AIDS, malaria and other diseases; ensuring environmental sustainability; and development of global partnerships for development for the attainment of a more peaceful, just and prosperous world. (ITU, 2005, p. 9)

WSIS Gender Caucus: Formed during the WSIS African Prepcom in Bamako in 2002 when representatives of organizations responded to an invitation by UNIFEM to contribute to ensuring that gender dimensions are included in the process of defining and creating a global information society that contributes to sustainable development and human security; they issued the WSIS Gender Caucus Bamako Statement (<http://www.genderwsis.org>).

This work was previously published in the Encyclopedia of Gender and Information Technology, edited by E. Trauth, pp. 1318-1324, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 1.35

Gender ICT and Millennium Development Goals

J. Ann Dumas

The Pennsylvania State University, USA

INTRODUCTION

Gender equality and information and communication technology are important in the achievement of the Millennium Development Goals (MDGs) in policy, planning, and practice. The 2000 Millennium Declaration of the United Nations (UN) formed an international agreement among member states to work toward the reduction of poverty and its effects by 2015 through eight Millennium Development Goals:

1. Eradicate extreme poverty and hunger
2. Achieve universal primary education
3. Promote gender equality and the empowerment of women
4. Reduce child and maternal mortality
5. Improve maternal health care
6. Combat HIV and AIDS, malaria, and other major diseases
7. Ensure environmental sustainability
8. Develop global partnership for development

Progress toward gender equality and the empowerment of women is one goal that is important to achieving the others. Poverty, hunger, illiteracy, environmental threats, HIV and AIDS, and other health threats disproportionately affect the lives of women and their dependent children. Gender-sensitive ICT applications to education, health care, and local economies have helped communities progress toward the MDGs. ICT applications facilitate rural health-care workers' access to medical expertise through phones and the Internet. Teachers expand learning resources through the Internet and satellite services, providing a greater knowledge base for learners. Small entrepreneurs with ICT access and training move their local business into world markets.

ICT diffusion into world communication systems has been pervasive. Even some of the poorest economies in Africa show the fastest cell-phone growth, though Internet access and landline numbers are still low (International Telecommunications Union [ITU], 2003b). ICT access or a lack of it impacts participation, voice,

Gender ICT and Millennium Development Goals

and decision making in local, regional, and international communities.

ICTs impact the systems that move or inhibit MDG progress. UN secretary general Kofi Annan explained the role of the MDGs in global affairs:

Millennium Development Goals are too important to fail. For the international political system, they are the fulcrum on which development policy is based. For the billion-plus people living in extreme poverty, they represent the means to a productive life. For everyone on Earth, they are a linchpin to the quest for a more secure and peaceful world. (UN, 2005, p. 28)

Annan also stressed the critical need for partnerships to facilitate technology training to enable information exchange and analysis (UN, 2005). ICT facilitates sharing lessons of success and failure, and progress evaluation of work in all the MDG target areas.

Targets and indicators measuring progress were selected for all the MDGs. Gender equality and women's empowerment are critical to the achievement of each other goal. Inadequate access to the basic human needs of clean water, food, education, health services, and environmental sustainability and the support of global partnership impacts great numbers of women. Therefore, the targets and indicators for Goal 3 address females in education, employment, and political participation. Progress toward the Goal 3 target to eliminate gender disparity in primary and secondary education, preferably by 2005, and in all levels of education no later than 2015, will be measured by the following indicators.

- Ratio of girls to boys in primary, secondary, and tertiary education
- Ratio of literate females to males who are 15- to 24-year-olds
- Share of women in wage employment in the nonagricultural sector

- Proportion of seats held by women in national parliaments (World Bank, 2003)

Education is positively related to improved maternal and infant health, economic empowerment, and political participation (United Nations Development Program [UNDP], 2004; World Bank, 2003). Education systems in developing countries are beginning to offer or seek ways to provide ICT training as a basic skill and knowledge base.

Proactive policy for gender equality in ICT access has not always accompanied the unprecedented ICT growth trend. Many civil-society representatives to the World Summit on the Information Society (WSIS) argue for ICT access to be considered a basic human right (Girard & Ó Soichrú, 2004; UN, 1948).

ICT capability is considered a basic skill for education curriculum at tertiary, secondary, and even primary levels in developed regions. In developing regions, ICT access and capability are more limited but are still tightly woven into economic communication systems. ICTs minimize time and geography barriers.

Two thirds of the world's poor and illiterate are women (World Bank, 2003). Infant and maternal health are in chronic crisis for poor women. Where poverty is highest, HIV and AIDS are the largest and fastest growing health threat. Ninety-five percent of people living with HIV and AIDS are in developing countries, partly because of poor dissemination of information and medical treatment. Women are more vulnerable to infection than men. Culturally reinforced sexual practices have led to higher rates of HIV infection for women. Gender equality and the empowerment of women, starting with education, can help fight the spread of HIV, AIDS, and other major diseases. ICT can enhance health education through schools (World Bank).

Some ICT developers, practitioners, and distributors have identified ways to incorporate gender inclusiveness into their policies and practice

for problem-solving ICT applications toward each MDG target area. Yet ICT research, development, education, training, applications, and businesses remain male-dominated fields, with only the lesser skilled and salaried ICT labor force approaching gender equality. Successful integration of gender equality and ICT development policy has contributed to MDG progress through several projects in the developing regions. Notable examples are the South-African-based SchoolNet Africa and Bangladesh-based Grameen Bank Village Pay Phone. Both projects benefit from international public-private partnerships. These and similar models suggest the value and importance of linking gender equality and empowerment with global partnership for development, particularly in ICT.

This article reports on developing efforts to coordinate the achievement of the MDGs with policy, plans, and practice for gender equality beyond the universal educational target, and with the expansion of ICT access and participation for women and men. The article examines the background and trends of MDG 3, to promote gender equality and the empowerment of women, with particular consideration of MDG 8, to develop global partnership for development, in ICT access and participation.

BACKGROUND

The United Nations convened the Millennium Summit in September 2000, which produced the Millennium Declaration and eight Millennium Development Goals to eliminate poverty and its effects. Targets were defined for each goal to be achieved by 2015. The evaluation of national progress on each goal has been ongoing since 2000. The UNDP and the Millennium Campaign are affirming national accountability through monitoring progress on the measurable indicators for each target. The UN struggle to uphold human rights to equality and freedom from want

began with its founding mission and the United Nations *Universal Declaration of Human Rights* (UDHR; UN, 1948).

All UN member nations committed to the MDGs and targets developed through the summit. Each nation regularly reports its progress and is accountable for national achievement toward the goals.

The goal of gender equality has been advanced internationally through treaties and agreements. Arguments for gender equality in ICT policy and development were supported by the precedent agreements of the *Universal Declaration of Human Rights* (UN, 1948), the Convention on the Elimination of all Forms of Discrimination against Women (CEDAW; United Nations Commission on the Status of Women [UNCSSW], 1979), the Beijing Platform for Action (UN, 1995), and then the Millennium Development Goals declared in 2000.

Development research links gender equality to the MDGs for poverty reduction. Gender equality is linked to the sustainability of development strategies. Policy to promote gender equality through institutional reform can strengthen the sustainability of economic development programs with more equal participation and resource distribution (World Bank, 2003; King & Mason, 2001). A main source of development funds, the World Bank is positioned to provide material support for gender-equality policy. In 2005, the World Summit on the Information Society reached closure with open issues on financial mechanisms, such as the Digital Solidarity Fund to expand digital rights for all.

World Bank (2003) research focused on ICT's role in addressing poverty:

ICTs have enormous potential to reach dispersed and rural populations and provide them with education and training, job opportunities, access to markets, availability of information important to their economic activities and greater participation in the political process. (p. 7)

Gender ICT and Millennium Development Goals

Research was centered on gender-based differences in how ICT was used to enable poor women and men to participate in the world economy. Gender-focused analysis has resulted in a critique of the MDG targets and assessment indications as being too focused on economic issues and not enough on social- and political-justice issues. The goal targets do not address war and domestic violence against women, a significant health threat and factor in social, political, and economic gender exclusion (Ain Tahmina, 2005).

The International Telecommunications Union, one of the earliest international organizations, was formed in 1867 in the early days of telegraph and telephone. Now an agency of the UN, the ITU facilitates the international coordination of telecommunications resources like spectrum and technical standards, and provides a forum for policy making and ICT development. The UN and the ITU convened the World Summit on the Information Society to develop a policy framework for the information society, including Internet governance. The documents *WSIS Declaration of Principles* and *WSIS Plan of Action* clearly link the purpose of ICT policy to the furtherance of the MDGs (UN, 2003a, 2003b). The UN ICT Task Force, the ITU Task Force on Gender Issues, the UNDP, and the Global Knowledge Partnership (GKP), which coordinated the civil-society segment of WSIS, have all addressed the MDGs in their plans, policies, and practice.

The ITU *World Telecommunications Report 2003* examined linkages between ICT and the MDGs, specifically articulated in Target 18 of Goal 8: “in cooperation with the private sector make available the benefits of new technologies, specifically information and communications” (ITU, 2003a, p. 71). Cooperative efforts targeting the goal help advance gender-equal ICT access and participation, and extend communication, information dissemination, and knowledge building to further the process of creating social change.

Gender equality in ICT development helping to advance progress toward MDG achievement

was the idea given at WSIS by gender advocates. The WSIS Gender Caucus (2003) presented six recommendations for action to the WSIS plenary voting session in the spirit of “creating richness in the information society: inclusion, diversity and gender equality.” The following main issues were identified and promoted by the WSIS Gender Caucus. Gender equality must be a fundamental principle for action. There must be equitable participation in decisions shaping the information society. New and old ICTs must be accessed in a multimodal approach. ICTs must be designed to serve people. ICT empowerment for women and girls is necessary for full participation. Research analysis and evaluation must guide action. These recommendations helped inform the development of the WSIS principles and platform for action (WSIS Gender Caucus).

The Global Knowledge Partnership (2002) was a major part of WSIS and recommended the following:

Include everyone in the digital revolution... expand networks to reach underserved populations ... gender mainstreaming should be a component of every ICT project to ensure sustainability. A gender perspective must be built into plans, policy and practice, from preliminary project design through implementation and evaluation. (p. 10)

GKP recommendations included eight case studies of women involved in meaningful ICT projects that improved their economic and social well-being in developing communities around the globe. GKP recommendations to the Digital Opportunity Task Force suggested nine action points that included “[enhancing] human capacity development, knowledge creation and sharing” (p. 41). Policy goals to advance this action were the increase of Internet use in education, digital literacy with an emphasis on gender balance and youth, distance learning promotion in underserved areas, and the creation of a network of centres of

excellence for research in ICT for development (GKP, 2003).

Chen, Vanek, Lund, Heinz, Jhabvala, and Bonner (2005) reported extensive research on women, work, and poverty, and defined six strategies for intervention into the identified trend of growing and gendered gaps in economic and overall well-being between and within regions:

Generally, women in the informal economy have not had much chance to learn different types of skills. This contributes to the difficulty their organizations have sustaining themselves and influencing employers and policy makers. Building capacity and skills at the grass-roots level through partnerships with other organizations and various supportive agencies can help remedy this. It is also increasingly important for organizations, especially larger ones and networks, to learn how to use communication techniques and modern information technology to link with each other. (p. 85)

The MDG international policy has been challenged as deflecting government attention and resources from CEDAW and the Beijing Platform for Action (BPFA) strategic objectives (Ain Tahmina, 2005).

FUTURE TRENDS

Government efforts toward gender equality and empowerment through ICT receive support through partnerships for development, which bring ICT applications in education, health care, and small business.

SchoolNet Africa is an example of a successful trend in coupling gender equality and empowerment through education with ICT development policy. SchoolNet Africa is an education and ICT model operative in 31 African countries. SchoolNet represents a productive public-private global partnership for development as recommended

in the MDGs. SchoolNet Africa partnered with Microsoft and direct-to-home (DTH) satellite service provider Multichoice, based in Mauritius. International business, government, and non-governmental organization (NGO) support facilitate their network of 31 national SchoolNets. The enhanced information and knowledge exchange is building ICT skills in a new generation to participate as information-society citizens. Gender equality has been a key principle of SchoolNet Africa. The Web site <http://www.schoolnet africa.net> updates its gender watch with research and information on gender networks, advances in ICTs, and the education of women and girls (World Bank, 2003).

Grameen Bank Village Pay Phone represents a successful trend of coupling gender equality and empowerment through business with ICT development. The ICT business entrepreneurs of Village Pay Phone are primarily women, who receive microcredit to purchase cell phones and provide pay-phone service in villages. The project began in Bangladesh, and its success has inspired replication projects in 30 developing countries. (Dumas, 1999)

The women entrepreneurs represent 4% of cell-phone subscribers but 16% of the airtime. Grameen Bank founder Muhammad Yunus (2005) described the value of their work in expanding ICT access and the family economy:

Grameen Bank has provided loans to 129,232 borrowers to buy mobile phones and offer telecommunication services in nearly half of the villages of Bangladesh where this service never existed before ... Telephone-ladies play an important role in the telecommunication sector of the country, and also in generating revenue for Grameen Phone, the largest telephone company in the country. (Article 26)

Other countries have gender-inclusive ICT development. Senegal, for example, has well over 7,000 small-business phone shops or telecenters,

mostly operated by women. As local demand requires, some telecenters include computers, Internet access, duplication, printers, scanners, and fax machines (Dumas, 2002).

The UNDP (2004) report, 5 years after the commitments, found that much more work must be done in order to reach the targets and goals by 2015. The MDG campaign has brought visibility to world poverty, hunger, and health crises, as well as efforts to eliminate them. MDGs were on the agenda of the July 2005 meeting of the group of eight (G8) wealthy nations: the United States, Canada, United Kingdom, France, Germany, Italy, Japan, and Russia. Prior to the meeting, Jimmy Carter, former president of the United States, and others including the millions who participated in the LIVE 8 concerts, called on the G8 to make a greater contribution toward efforts to achieve the MDGs. During the meeting, the G8 responded to the call for expanded official development aid (ODA) to the poorest nations facing the greatest challenge to meet the MDGs. The innovative LIVE 8 concerts attracted the largest media audience in history and helped focus world and G8 attention on the MDGs.

CONCLUSION

Women are just over half of the world's population, but over two thirds of the world's poor and undereducated. Even in developed countries, women earn significantly less than men without exception (UNDP, 2004). The MDGs address the need for distributive justice to end poverty, hunger, and illiteracy in our world and bring greater peace and freedom to our collective lives. ICTs make global conversation and knowledge sharing possible, but unequal resource distribution has inhibited these communications. ICT has helped improve resource and service distribution for health care, education, economic empowerment, conflict resolution, political participation, and cultural enjoyment. Expanded access for and

participation by women and youth is needed. The world nations are still far from achieving the eight MDGs (United Nations, 2005). The gender justice goals of UDHR (UN, 1948), CEDAW (UNCSW, 1979), Beijing (UN, 1995), the MDGs (2000), and the civil-society voices of ITU (2005) can be realized with the political will to do it. Nations have made the good-faith promise to achieve the MDG targets by 2015. Their mutual commitments within the UN forum with civil society's vigilance help reinforce accountability and resolve, and keep the goals and problems they address always in public view.

Section 2

Information Communication Technologies Development and Design Methodologies

This section provides in-depth coverage of conceptual architecture, enabling the reader to gain a comprehensive understanding of the emerging technological developments within the field of ICT. Research fundamentals imperative to the understanding of developmental processes within information management are offered. From broad examinations to specific discussions on electronic tools, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs as well as abstract developments are explained within these chapters, and frameworks for implementing ICT in education, healthcare, and government are explored.

Chapter 2.1

Connecting the First Mile: A Best Practice Framework for ICT-Based Knowledge Sharing Initiatives

Surmaya Talyarkhan

ABSTRACT

This chapter characterises the use of information communication technologies (ICTs) to share information with people at grassroots as connecting the first mile. It examines the literature about connecting the first mile and identifies the key debates: whether solutions should be participatory or top-down, technological or social, whether they should focus on global or local information, and the overall potential of ICTs for development. The chapter synthesises the lessons from a range of practical studies to identify the factors that contribute to the success of a project. A framework of best practice is offered, divided into three dimensions: the environment, the project level, and the local level. Whilst recognising that ini-

tiatives will vary according to the local context, the authors offer the best practice framework to support practitioners in addressing the challenges of connecting the first mile and empowering marginal communities to participate effectively in the information society.

INTRODUCTION

The international development sector has focused in recent years on the need to share knowledge more effectively in support of poverty reduction efforts. Multi- and bi-lateral agencies and NGOs are increasingly putting knowledge sharing at the centre of their organisational strategies. And, in the context of a perceived knowledge divide, they

are addressing the challenge of how to respond to the knowledge needs of people living in poverty in developing countries.

Information and communications technologies (ICTs) such as the Internet, mobile phones, and radio offer opportunities to connect people to information quickly and in large numbers, transcending geographical barriers. The challenge for information providers in development is how to share information with people who have little access to ICTs, low levels of literacy, little time or money, and highly contextualised knowledge and language requirements. For many years reaching people living in poverty with information was characterised as the *last mile* problem, a term borrowed from the telecommunications field, where it referred to difficulties of improving connectivity in remote rural areas. In recent years, this *problem* has been reconceptualised in terms of *connecting the first mile*, which privileges the needs of people living in those remote areas (Paisley & Richardson, 1998). In this chapter, connecting the first mile refers to ICT-based projects aimed at sharing information at grassroots.

This chapter aims to identify best practice in development projects using ICTs to connect the first mile, through a review of existing literature and case studies. It begins with a discussion of the role of ICTs in development and an examination of the different ideological approaches adopted by authors, before drawing together a framework based on the lessons and recommendations from the literature. It concludes by examining the trends that will impact on information networking for communities at the first mile and discussing potential applications of the framework.

DEVELOPMENT AND ICTS

The concept of development has been evolving since its origins after the Second World War. Sachs (1992) dates the age of development as beginning when President Truman at his inaugu-

ration described regions in the South as *underdeveloped*. International organisations such as the World Bank and the United Nations (UN) were established to support international relations, and their agendas have influenced the discourse on development ever since.

The priorities of the international development community have shifted over the years. From a focus on economic development and growth, international bodies have begun to focus on poverty as a multidimensional phenomenon and to acknowledge the various contributory factors to poverty such as a lack of access to markets and services or vulnerability to shocks.

Communication has consistently been central to the work of development agencies, but in recent years the recognition of information and knowledge as contributing to growth, as well as the vogue for knowledge management and the massive expansion of ICTs, has highlighted the importance of knowledge for development.

Many international initiatives have been established to harness ICTs for development on a global scale, in particular since the publication of the World Development Report on Knowledge for Development (World Bank, 1998). These include the Global Knowledge Partnership (founded in 1997), the DOT-Force (created in 2000), and the UN ICT Task Force (created in 2001). The International Telecommunication Union (ITU) hosted an international summit on the Information Society in 2003, the second phase of which took place in early 2005. These initiatives aim to build partnerships among civil society, the public, and private sectors to harness ICTs for development (Chapman & Slaymaker, 2002).

There is a consensus that ICTs can play an important role in development, for example by connecting people to more accurate and up-to-date information, equipping them with new skills or connecting them to an international market. However, there is concern that the digital divide is increasing the gap between the *information haves and have-nots*, and this is the preoccupation

of many of the initiatives established to address ICTs for development.

PERSPECTIVES IN THE LITERATURE

In recent years, many studies have been published, particularly by practitioners in the development field, on the use of ICTs for development. The term *ICTs for development* incorporates a variety of different uses of ICTs, for health, e-governance, agriculture, advocacy, and many more. There is not a coherent body of literature one can search for about connecting the first mile. This framework is based on a review of case studies collected from the Eldis portal, where development practitioners publish their findings (<http://www.eldis.org>). Studies were selected according to the following criteria:

- Is there a knowledge sharing and development focus to the ICT project?
- Are the end users people at grassroots?
- Is the document a good source of information?

The studies which scored highly against each criterion were reviewed to compile the framework.

This chapter also refers to more general literature on ICTs and development selected through cross-branching from existing literature reviews and searches of academic journal databases. The database searches (on Proquest and EBSCO) found fewer articles or studies relevant to the first mile, perhaps because the majority of this research is conducted by practitioners.

The gaps that exist in the literature about connecting the first mile either represent areas where there has been little convincing evidence collected to date or where authors cannot reconcile their perspectives on the role of ICTs in development.

Previous literature reviews in this field have commented on the promotional nature of literature, the paucity of baseline and evaluation studies to date, the relatively recent emergence of frameworks for evaluation, and the emphasis on telecentre projects and literature about Africa (O'Farrell, Norrish, & Scott, 1999; Adeya, 2002).

This literature review highlights key concepts around which practitioners are polarised. An understanding of the different perspectives is essential to illustrate the different meanings of best practice in discourse on ICTs and to situate this study against an ontological background. Commentators have attempted to divide the literature in development into different factions: sceptics and pragmatists, optimists and pessimists, globalists and localists. In this study, it is suggested that authors diverge along four dimensions:

- Top-down vs. participatory solutions to development problems,
- Global vs. local solutions to development problems,
- Technological vs. social solutions to development problems, and
- Optimism vs. pessimism about the role of ICTs in development.

These different perspectives shape authors' discourse and priorities, their concept of impact, and their understanding of best practice. The rest of this section examines each perspective in turn. The clash of perspectives is illustrated for example in the terminological debate over the *last mile problem*. For some authors the term typified a top-down approach to development, viewing the delivery of technologies to people living in remote areas as a solution to development problems (Paisley & Richardson, 1998). In contrast, the concept of *connecting the first mile* starts from the needs of marginal communities and marks the connection between the local context and global information systems.

Top-Down or Participatory Solutions

ICT for development projects are criticised for failing to build on existing systems or work in a participatory way. Critics argue that top-down projects, driven by the donor agenda, fail to achieve local ownership (Aley, 2003b; Gumicio Dagrón, 2001; Lloyd Laney, 2003c). The concept of the *design-reality gap* (Duncombe & Heeks, 1999) highlights the distinction between the context in which an ICT project or application is designed and the context of its use in developing countries.

In many cases projects are driven by the donor agenda, which has a short-term horizon and may not recognise or be able to address the multi-dimensional causes of poverty due to a narrow focus on donor objectives (Stoll, Menou, Camacho, & Khellady, 2001). Gumicio Dagrón (2001) is especially critical of the role of donors and their focus on large-scale projects:

The international donor community is still reluctant to acknowledge 30 or 40 years of failures and millions down the drain because of ill-planned macro programmes. The eagerness to go fast, to show short-term results, and to extend coverage to large numbers of people has actually backfired. (p. 11)

For him, donors' concern with scale serves to multiply models that clash with culture and tradition and paralyse communication, instead of linking communities and facilitating exchanges.

Global or Local Solutions

ICTs for development initiatives often seek to increase access to a *global pool of (codified) knowledge* (Stiglitz, 1999), but have been criticised for failing to acknowledge the local context (Gomez & Casadiego, 2002; Moroow, 2002). Ballantyne (2002) highlights the emphasis on external content pushed at people living in poverty and the struggle

faced by efforts to push local content (e.g., research conducted in the South or Southern arts) onto a global stage. Many initiatives are criticised as offering one-way transfer of information (usually from the global to the local level), but failing to promote genuine, two-way knowledge sharing. For example, van der Velden's (2002) analysis of the Development Gateway suggests that the project was designed without a concept of knowledge as contextually defined, and therefore does not address the needs of key audiences:

The critique of the Bank's approach in this case indicates that knowledge needs to be presented in the appropriate context and be meaningful in the local situation in order to be useful and effective. (p. 31)

Technological or Social Solutions

There is a distinction between authors who see technology as a solution to development problems and those that seek social solutions. Articles cite particular types of technologies and applications, such as Wireless Fidelity (WiFi), open source software, low-cost devices, translation engines, as *stepping stones* toward *digital inclusion* (Primo Braga, Daly, & Sareen, 2003). This technological determinism recognises the difficulties of communicating to the local context (such as language or access barriers), but locates the potential to overcome them in new technologies, rather than in social factors. Concerns are raised by other authors (Boyle, 2002) that technology is increasingly determining the solutions sought to development problems:

What I am concerned with is the degree to which complex social development goals become seen as functional or technical problems when ICTs are introduced and how technology becomes particularly determinant in how larger goals are understood and acted upon. (p. 102)

Optimism or Pessimism

Some authors are extremely optimistic about the contribution that ICTs can make to development goals. Heeks (2002) comments on the *current prevalence of positive and technologically deterministic viewpoints*, which he sees as influenced by the climate among international development agencies:

A number of factors among agency staff may explain the emergence of this viewpoint. They include naivety about ICTs, desire for career advancement, pressure from ICT vendors, a lack of alternatives to the trends/fads of the Northern private sector, and pressure from political masters for quick solutions to development problems. The viewpoint also emanates from those seeking funds or guidance from the development agencies. They tend to mimic the views and messages of those agencies. (p. 4)

An examination of the different perspectives in the literature leads to the conclusion that different ideologies shape authors' understandings of best practice and what they conceive of as a successful project. For some authors ICTs are in themselves a contribution to development, whereas for others they need to be part of a wider development solution, a means rather than an end. Authors' perspectives determine how project impact is evaluated in the studies and how lessons are drawn for best practice. The next section examines the different approaches to evaluating the impact of projects at the first mile.

BEST PRACTICE AND IMPACT

In this chapter, impact is conceived of as the reported outcomes of the project, and best practice is taken to mean the processes that have contributed to a project's success. In order to identify examples of best practice from the literature on connecting

the first mile, in addition to understanding authors' perspectives, it is necessary to understand how they are defining impact and why they choose to view the project in a particular light. For example, the power relations inherent in development projects affect how impact is demonstrated (Stoll et al., 2001; Gumicio Dagron, 2001). Practitioners need to demonstrate success to receive further funding, donor organisations are unwilling to invest in monitoring activities by donor organisations, and 'beneficiaries' have relatively low input into the monitoring and evaluation process. Factors such as these suggest that demonstrating results can be more important than demonstrating a development impact for beneficiaries.

Practitioners and academics struggle to define a causal link between development outcomes and ICT projects. Although frameworks and targets exist that aim to model how poverty reduction can be achieved and where interventions could be successful, the contribution ICTs can make is not easily defined. The rest of this section compares authors' differing concepts of impact at the first mile — where some start from frameworks and targets to assess how ICTs contribute to development, others look to the sustainability of ICT projects or their ability to disintermediate transactions to demonstrate their success. Other authors adopt a universal access approach whereby access to information is seen as a human right and the use of ICTs is in itself a developmental outcome.

Applying Frameworks to Define Impact

The Sustainable Livelihoods Framework has been used to illustrate some of the contributions of ICT projects, for example their contribution to social capital, human capital, or improved livelihoods strategies (Batchelor, Norrish, Scott, & Webb, 2003; Chapman, Slaymaker, & Young, 2003). The World Development Report of 2000/2001 identified three priority areas for reducing poverty: increasing opportunity, enhancing empowerment,

and improving security. Some studies have taken these as ways of assessing the contribution of ICT projects to poverty reduction (Op de Coul, 2003; Cecchini & Scott, 2003). These studies group examples of projects according to the three priority areas, but little evidence is presented that, for example, increased empowerment has led to poverty reduction. In places these case studies seem to present ICT adoption as increasing opportunity in itself, which becomes a circular argument. The Rockefeller Centre has adopted a model of communication for social change (Figueroa, Kincaid, Rani, & Lewis, 2002) which theorises communication as “dialogue rather than monologue, as a cyclical process of information sharing which leads to mutual understanding, mutual agreement, and collective action” (Figueroa et al., 2002, p. 2), and develops indicators on that basis although this review has not located cases where these are used.

Defining Impact in Terms of Sustainability

Some studies evaluate ICT projects on the basis of sustainability. The emphasis on sustainability partly reflects donor concern with short-term investments, but also a more commercial approach that suggests that sustainability represents demand for a service. Batchelor et al. (2003) evaluated projects according to how sustainable they were in terms of economic sustainability, social sustainability, and institutional sustainability. In their definitions, economic sustainability is achieved when a given level of expenditure can be maintained over time, social sustainability is achieved when social exclusion is minimised and social equity maximised, and institutional sustainability is achieved when prevailing structures and processes have the capacity to perform their functions over the long term.

Economic sustainability is seen by some as a key indicator of success of a project because it is seen to reflect a genuine demand for that service.

At the same time, in many development projects, donors are funding information dissemination as a public good as Tschang, Chuladul, and Le (2002) comment: “The nature of telecentre sustainability is complicated by the point that it may initially be a public good, especially in disadvantaged areas, yet must be ultimately self-supporting” (p. 130).

A great deal of research has been published on economic sustainability, in particular with regard to access initiatives such as telecentres or information kiosks, which have high set-up and maintenance costs and customers with little spare cash. The complicated objectives of providing information services as a public good and making them self-supporting have proved extremely difficult to reconcile, and few initiatives have succeeded in covering their costs, even if they have developed viable charging mechanisms (Batchelor et al., 2003).

Authors concerned with participation tend to identify it as the locus of social sustainability, arguing that the active involvement of users minimises social exclusion and perpetuates support for the project:

The concept of establishing a dialogue with beneficiaries all along the process of conceiving, planning, implementing and evaluating a project has been gradually consolidating. At first, implementers understood that beneficiaries should be involved in the activities leading to social and economic development of a community, for the purpose of building up a sense of ownership within the community. This was at last perceived as important especially in terms of the sustainability of the project once the external inputs ended. (Gumicio Dagon, 2001, p. 10)

Institutional sustainability is primarily a question of resources and capacity building, amongst project staff and partners, empowering those institutions to take control in local development issues.

Defining Impact in Terms of “Disintermediation”

ICTs are also seen as contributing to poverty reduction through *disintermediation*, whereby local producers have direct access to the market and can therefore charge market rates for their goods without having to pay an intermediary. Op de Coul (2003) cites an example from Central America:

Agronegocios in El Salvador helps farmers to become traders as well and to establish direct contacts with buyers, instead of selling to middlemen (called “coyotes”). This is done through bi-weekly markets in the capital but also through a virtual market on the Web site where offers and demands are published. In Agronegocios centres spread around the country the farmers and their children are taught how to enter their offers and how to find possible buyers. Though the farmers in general prefer personal contacts with their customers, the virtual market has the advantage of offering “business to business” opportunities and bigger quantities can be sold. Furthermore, trade is not restricted to the province or country the farmers live in; deals with foreign traders are an option as well. (p. 7)

Although some ICT initiatives succeed in disintermediating commerce, Batchelor et al. (2003) comment that there is a need for ICT intermediation instead (although the users are less vulnerable to these intermediaries than in traditional transactions).

Defining Impact in Terms of Universal Access

Donor agencies have focused on improving access to ICTs since the early 1990s, and telecentres have been seen as playing a key role in that strategy (Etta, 2003). Practitioners and policy makers who aim for universal access to ICTs can perhaps

demonstrate impact most easily because for them access to information and ICTs in themselves can constitute a developmental impact. Therefore, indicators such as the number of people who can access the Internet in rural areas will be meaningful indicators of development for them, regardless of how useful they find the content they access.

Best Practice and Impact in this Chapter

This literature review has demonstrated that in the literature on connecting the first mile, authors have very different ideologies and evaluate project impact according to different types of outcomes. There is a strong case for working in a participatory way and connecting local and global information, as the field is littered with examples of failed initiatives that did not prove to be useful to the end users.

It is also clear that monitoring and evaluating the impact of a project is a political undertaking and that reported best practice may not represent development outcomes for the beneficiaries, but the achievement of goals set by donors or development agencies, such as sustainability or access to ICTs. Therefore, when researching best practice, the author’s definitions of impact must be considered before accepting that an experience has been valuable at grassroots.

In this chapter, the development needs of people living in poverty are prioritised over the technologies shaping current discourse. However, the next section reviews existing research and highlight the critical factors at the local level, the project level, and in the environment of the project, which make the projects successful and how projects can achieve these.

IDENTIFYING BEST PRACTICE

In the literature on connecting the first mile, best practice is described through the use of examples

of successful projects, examples of unsuccessful projects, and recommendations based on project experience. Several studies have collected a group of cases and compiled guidelines for practitioners or highlighted the lessons learned from existing projects. The success of many projects is *situated success* in the sense that the project has worked due to a particular combination of local factors such as a strong champion or good timing. This framework focuses on the processes that contribute to the success of a project, in order to make it applicable in wider contexts.

This framework divides the success factors into three levels of analysis: the local level, the project level, and the environment. The local level is the point at which end users at grassroots access information services. The project level deals with the project planning and implementation. The environment consists of all the factors that affect a project's success but are external to the project.

All of the elements in the framework have an impact on connecting the first mile and on the project as a whole. The distinction between the levels is artificial, but is a convention that helps to identify which actors are key to success and the nature of their contribution. Each level can impact on the others, for example delayed funding from donors can have an impact at the project level and local level. Project managers need to find ways to integrate the levels so that, for example, information from the local level reaches policy makers outside the project.

The sections below detail the success factors identified in the literature (i.e., WHAT elements appear to lead to successful projects) and also highlights suggested best practice (i.e., HOW practitioners can work towards these factors).

THE ENVIRONMENT

Forces external to a project, such as the regulatory context, infrastructure, or the role of donor

organisations, can play a key role in the success of the project.

Policy Environment

The policy environment can affect the day-to-day working of an ICT initiative. Batchelor et al. (2003) cite the example of ACISAM, an NGO in El Salvador that was unable to bid for radio or television space due to policy restrictions. An analysis of ICT stories collected by Infodev suggests that dealing with local authorities can be an issue if the project challenges their power:

Co-operation from local government is to be taken into account in a lot of projects. Either because project initiators need authorisation from the local government to start their project, or because the local government may even be a partner...they will not co-operate to the fullest if they feel that the empowerment coming from the project will challenge their positions of power. (Infodev, 2004, p. 1)

Studies on advocacy suggest that best practice is to research the policy environment, recognise the existing power relationships, and develop strong relationships where possible with policy makers (Lloyd Laney, 2003a). One example of good practice is the Gyandoot initiative in India, which adds value to existing policy structures by giving communities to access government services locally from kiosks.

Infrastructure

In ICT projects, the lack of local telecommunications infrastructure can be "one of the biggest challenges, especially in developing countries" (Infodev, 2004). Best practice in overcoming this challenge includes analysing telecommunications and IT infrastructure deficiencies to plan for realistic measures (Chapman et al., 2003), adopting innovative technologies such as the wireless connectivity technology used by the n-Logue project

in India (Badshah, Khan, & Garrigo, 2004), or developing more accessible devices such as the Simputer (Primo Braga et al., 2003). A most recent contribution in this aspect could be the \$100 computer that Nicholas Negroponte at MIT is designing with the ICT industry.

Relationship with Donors

The role of donor organisations can also be a determinant in the success of a project: “The initiatives having less financial problems are the ones implementing online activities and the ones whose hosting organisations have good relationships with donors” (Op de Coul, 2003).

A case study on a project in Thailand that stalled suggests it was partly due to poor donor relations:

APRTC had only been in existence for a short time and did not have the solid relationships of more established organisations. Also, its approach was unique and relatively unproven even though initial results were promising. That it was an NGO with no connection with any national government or focus on a particular country seems to have put off potential supporters. Donors seem to prefer working with government agencies or organisations closely aligned with national efforts. (Infodev, 2004, p. 12)

Practical Action’s experience would suggest that forming individual relationships with donors is important, as well as communicating project progress in a timely way. An analysis of the impact of research on policy (Crewe & Young, 2002) suggests that establishing credibility and communication, influence, and legitimacy contribute to help an organisation to achieve policy change.

THE PROJECT LEVEL

In managing a project connecting the first mile, much of the literature suggests that success de-

pends on understanding development priorities at the community level, and planning, monitoring, and evaluating to ensure that projects are having an impact on those priorities. For implementation to be successful and sustainable, there is a need to partner with other organisations and devise a sustainable business model for the project. Projects need to share best practice with other practitioners to understand how replicable a project can be.

Working with Communities

Recent articles on ICTs have made powerful arguments for participation by target groups throughout a project, from inception to evaluation and beyond:

If technologies are to be developed that suit poor end users, then these people must be a part of the design process from the outset. The principles of participatory technology development are as important as ever, whether it be designing a bull-ock-drawn plough or an electronic information technology. Poor people must be empowered to express their requirements and allowed to play a leading role in technology development. People living in poverty understand their situation better than any “external expert”. Without end-user involvement, well-intentioned outsiders will make mistakes, which poor people might not even be inclined to point out! (Aley, 2003a, p. 33)

The key to best practice at the project level is to start from communities’ development priorities (Stoll et al., 2001) and begin with a needs assessment which could draw on PRA or RRA methodologies (Bridges.org, 2004; Cecchini & Scott, 2003; Lloyd Laney, 2003c). Cecchini et al. (2003) point to the failure of an Indian e-governance initiative due to a lack of local understanding:

In Rajasthan, the state-sponsored RajNidhi e-governance program has failed to deliver, despite the fact that the software is easy to use and in Hindi,

because of extremely centralised planning that did not take local conditions into consideration. Content, in fact, lacks regular updating because of communications problems between the state and the local government. (p. 13)

Project Planning

Like any development project, a successful ICT for development project will have clear objectives, clearly identified target groups, and realistic plans for implementation (Batchelor et al., 2003; Bridges.org, 2004). An example of good practice on the ICT Stories Web site is the Jharkhand-Chattisgarh Tribal Development Programme (JCTDP), an 8-year livelihood improvement and empowerment programme targeted at resource-poor rural households in nine largely tribal blocks in the Chattisgarh state in India, which has identified its audience and developed its project plans according to their needs.

Monitoring and Evaluation

Although many initiatives are too new to demonstrate impact (Meera, Khamtani, & Rao, 2004), commentators are concerned that monitoring and evaluation indicators relate to use of technology more than to the impact for example on livelihoods (Stoll et al., 2001). There are suggestions for best practice in the literature, which ensure that in addition to data collection, the process supports learning and change. These include linking the project goals, variables, and indicators to community priorities (Stoll et al., 2001), critically evaluating efforts, reporting back to clients and supporters, and adapting as needed (Bridges.org, 2001). Best practice involves monitoring throughout the life of the project, not only once a project is completed (Lloyd Laney, 2003b).

Partnerships

Partnerships and institutional arrangements are given central importance in the literature. In order

to deliver information services to the poor, information providers need to form strong partnerships with other information providers (Batchelor et al., 2003) and organisations that promote services, and raise awareness amongst end users (Cecchini & Scott, 2003) as well as organisations offering the technological infrastructure and finance to keep the project afloat. Best practice involves selecting partners from the public, private and civil society sectors (Saravia, 2005). Bridges.org (2003) describes the case of the Satelife PDA, whereby physicians, medical officers, and medical students tested PDA devices in the context of their daily work environments. Partner organisations working on that project in Uganda included the American Red Cross, Makerere University Faculty of Medicine, and HealthNet Uganda, which provided technical support and project assistance. Medical texts were obtained from Skyscape, an online information provider.

Incentivising partners to participate in the project is crucial to success. Donor organisations are looking at public-private partnerships (Carlsson, 2002), and there is a case for businesses to partner with businesses, NGOs, and community groups already established in developing country markets to minimise risk and maximise infrastructure (Pralhad & Hammond, 2002).

Few studies make recommendations for best practice because each project will require a different set of stakeholders to be involved, but the comments from the Max Lock Centre (1999) are instructive: “The key to achieving real partnership in local development is negotiating conflicting interest, discovering overlapping interest and mutually beneficial means of achieving individual interest” (p. 1).

Partnerships with organisations at the local level are also key to the success of a project and will be discussed in detail in the next section.

Sustainability

Many studies relate best practice to how sustainable a project is. Badshah et al. (2004) highlight

Connecting the First Mile

some initiatives that have developed innovative solutions to financial sustainability:

Several projects have a self-sustaining commercial focus as the driving factor — Drishtee (India), Cabinas (Peru), Warnet (Indonesia), n-Logue (India), Telecottages (Hungary), are all based on a business model. According to Amin, one way to structure a business driven kiosk model is as a franchise and many of the successful efforts analysed have adopted this approach. (p. 223)

Tschang et al. (2002) suggest that for telecentres, returns are increased through economies of scope and scale, network externalities, vertical integration and agglomeration. They also highlight the importance of partnerships to overcome initial costs:

The high initial investment costs in equipment and infrastructure make it difficult to base expansion plans on local owner-operators' means. In-kind investment partnerships — e.g., the Indonesian government's vocational school system's partnering with local businesses to sponsor cybercafé, and private sector assistance; or the Indian Andhra Pradesh state government's scheme to involve long distance telephone companies — may be solutions to these problems. (p. 130)

The involvement of the private sector in sustainable ICT projects can often reduce costs and improve service quality and efficiency (Badshah et al., 2004). The private sector is waking up to the “bottom of the pyramid” as a potential market, and multinational corporations are adopting new business models and partnership models to exploit these markets, such as the shared access model popularised by the Grameen Bank (Pralhad & Hammond, 2002). Whereas public initiatives can be slow to recognise services that fail to meet demand, Prahalad and Hammond (2002) suggest that through competition, multinationals are likely

to bring a superior level of accountability for performance, which could benefit end users.

Therefore, best practice in developing a sustainable business model will include identifying which services are being provided as a public good and where the project could adopt a commercial model and increase returns through partnerships, in particular involving the private sector.

Building Staff Capacity

Op de Coul (2003) raises the high turnover of trained technical staff in ICT for development projects as an institutional sustainability issue. Best practice suggestions are offered by Batchelor et al. (2003):

Institutional sustainability is said to be achieved when prevailing structures and processes have the capacity to continue to perform their functions over the long term ... The studies show three mechanisms for gaining capacity: it is possible to buy-in expertise when necessary, to hire specific skilled staff or to train existing staff (or volunteers). (p. 17)

In knowledge sharing projects there can be a need to extend capacity building to partner staff such as intermediaries or technical partners.

Scaling Up Through Communication and Replication

Sharing findings with other development practitioners is important to communicate best practice (Op de Coul, 2003) and to understand the degree to which a project could be replicated in a different context (Cecchini & Scott, 2003). Besemer, Addison, and Ferguson (2003) make a convincing case for sharing findings with donors to influence policy and recommend donor dialogue as a best practice. A recognised problem with ICT for development is that most initiatives

are pilot projects, which are then not scaled up into programmes (Weigel & Waldburger, 2004), although the warnings from Gumicio Dagon (2001) suggest that concern with scale can lead to more failures. In any case, it is necessary to develop an exit strategy to ensure that projects are sustainable after funding is withdrawn (Ballantyne, Labelle, & Rudgard, 2000).

THE LOCAL LEVEL

Knowledge management theory recognises the centrality of context to meaning. For Nonaka and Takeuchi (1995), information and knowledge are context-specific: "...both information and knowledge are context-specific and relational in that they depend on the situation and are created dynamically in social interactions between people" (p. 59). Therefore taking account of the local context is crucial when sharing information at the first mile, to make sure that information can be understood and internalised by local people.

Building on Existing Systems

In the literature relating to the first mile, there is an emphasis on building on existing systems (Chapman et al., 2003; Lloyd Laney, 2003c) instead of introducing new ones and undermining the ways people currently receive information. "The ICTs revolution can undermine traditional, local communications, by supplanting them and by taking attention away from them" (Chapman et al., 2003, p. 2). Recommendations are that projects conduct research into existing information systems and design initiatives that build on these. Projects should also connect to traditional knowledge (Ballantyne, 2002) and promote local participation throughout the project.

Appropriate Materials

There is a vast amount of literature recommending approaches to designing information appropriate to the local context (Batchelor et al., 2003; Lloyd Laney 2003c; Aley, 2003a; Aley, Waudo, & Muchiri, 2004). Authors highlight the following dimensions to appropriate information: language, cultural context, information delivery channel, information format. For instance, in an assessment of WorldSpace radio, Aley et al. (2004) found that:

A common request is for more information that is appropriate to their specific context, meaning it must be locally relevant and applicable. Many people prefer information to be exchanged orally in their own mother tongue, and appreciate practical face to face demonstrations and follow-up. (Aley, 2003a, p. 5)

Therefore, best practice requires that practitioners research the information systems of their target group and understand their information needs, address local language issues, and then develop materials in the right format for use.

Appropriate Technology

The studies also highlight the need for appropriate technology to be chosen. In terms of sustainability, Batchelor et al. (2003) highlight the need for local repair and operational skills to maintain the technology. Primo Braga et al. (2003) discuss the use of low-cost technologies and free or open source software at the grassroots. Chapman et al. (2003) highlight the need for *realistic technologies* to be used that are appropriate to the local context and suggest the need to blend communications approaches, citing the example of the Kothmale

project in Sri Lanka where a community radio station browses the Internet at the request of listeners: “A combination of linking old and new technologies, use of mass media and technology sharing can reach the greatest number of people, over the largest distances and with the least infrastructure investment” (p. 28).

Schilderman’s (2002) research shows that successful examples of strengthening the knowledge and information systems of the urban poor are rarely based on a single method of communication and that incorporating traditional media can promote two-way knowledge sharing.

Information Intermediaries

Where there is little access to technology, an information intermediary can help communities to find the information that they seek. Different studies define information intermediaries in different ways. For Cecchini et al. (2003), they are the human intermediary between poor people and ICTs. For Lloyd Laney (2003), they represent the face-to-face contact which is essential in turning information into knowledge for poor people. For Raab, Woods, and Abdon (2003), they are employed to provide information: “Knowledge intermediaries are the many individuals employed by government extension systems, non-government organisations, academia and the private sector who have the responsibility to provide information and educational opportunities [for farmers]” (p. 269).

For Schilderman they are “information producers and suppliers, who do so out of duty or desire” (2002, p. 5), such as the public sector, NGOs, or religious organisations.

Cecchini et al. (2003) offer examples from rural India of best practice by intermediaries:

Successful examples of ICT projects for poverty reduction are conducted by intermediaries that have the appropriate incentives and proven track record working with poor people. In Andhra Pradesh,

ANMs have been working with poor villagers on a daily basis for years. SKS, the microfinance institution, adheres to a philosophy of reaching out to the poorest women in rural areas. In Gujarat, dairy cooperatives have been the best agent to target small farmers. If these intermediaries are grassroots-based and understand the potential of ICT for social change, they can be tremendously effective in promoting local ownership of ICT projects. In rural India, many telekiosk operators are young, educated, computer-savvy, and very attached to their communities. They are also extremely entrepreneurial. In the case of Gyandoot, successful telekiosk operators — besides offering e-government services — often create and manage database and work on data entry for private clients, offer PC training, provide voice, fax, copy, Internet and many other services. (Cecchini et al., 2003, p. 12)

In working with infomediaries then, best practice involves identifying grassroots-based infomediaries with a track record of working with poor people. There is a need to provide appropriate incentives for partnership and perhaps to find entrepreneurial infomediaries who can make a living. In ITDG’s experience of running an online service offering information for small, informal enterprises in Kenya, the infomediaries were crucial in connecting to the first mile. One infomediary sold new information to a local businessman about the availability of a peanut butter making machine for Ksh 2,500 (about US\$35), which illustrates some demand for information services at the first mile that can currently be met best through infomediaries.

Building Capacity of Infomediaries

Schilderman (2002) recommends best practice for projects with regard to infomediaries, which includes developing appropriate materials, sharing good communications practice, and capacity building:

Development agencies should sensitise state institutions towards more courteous and efficient information provision and, where resources are a real constraint, aim to provide additional resources and capacity building. Where this research has shown that smaller authorities are often better at communicating with their target population, this could be an argument in seeking wider decentralisation [...] There is furthermore a need to recognise, document and share good practice in communicating with the urban poor. Whereas many infomediaries are obviously not functioning optimally, some do exist that do well or have some exemplary projects or services, but often these are not widely known. (Schilderman, 2002, p. 49)

Infomediaries need to acquire what Ballantyne (2002) terms *adaptation skills*, for example translating information materials to suit local conditions.

Two-Way Knowledge Sharing

As the term *connecting the first mile* shows, development organisations are moving away from one-way knowledge transfer models towards the ideal of two-way knowledge sharing:

Community knowledge partnerships that can develop mechanisms to deal with the problems of connectivity and information literacy, and incorporate local and external knowledge, can directly benefit poor people. This approach could replace the traditional process of a “one-way” flow of information from a scientific, information rich core to a remote information poor community, with dynamic information sharing partnerships with a two-way flow of information at every level. (Chapman et al., 2003, p. viii)

Ballantyne (2002) comments on the importance of local content in this two-way flow and suggests that best practice in facilitating local

content creation includes valuing and motivating local content (through rights and incentives) and building the capacity of the target group in content creation. For him, best practice involves making local knowledge visible — for example by incorporating local and external knowledge into information materials and connecting the target group to policy makers.

Many of the most inspiring ICT projects have involved local appropriation of ICTs such as community radio or video, which have empowered communities to make a political impact: “Content provided through ICT should not be limited to the knowledge that can be accessed from outside sources, but rather extended to ensure that the poor have the means to speak for themselves” (Cecchini et al., 2003, p. 14).

For example, Practical Action’s Women’s Voices project (Practical Action, 2003) trained women’s groups in the slums of Nairobi in using video so they could communicate directly to policy makers about their situation and development priorities. The videos were shown to an audience of government ministers, housing directors, donors, and NGOs. Later the videos were shown on national television and won an international award, the Betinho Award for Technology and Social Justice. The women gained confidence and made contacts regionally, and now have plans for setting up a local resource centre with access to information on tenure, health, training, and job opportunities.

Chapman et al. (2003) also emphasise the importance of horizontal knowledge sharing, in particular between communities: “Knowledge transfer and sharing at a local level can have a particular impact on livelihoods because it is at this level that the majority of the poor are located within local knowledge and information systems” (p. 31).

Minimising Social Exclusion

Best practice in connecting the first mile requires that the projects be socially sustainable.

Minimising social exclusion in project planning can involve developing an understanding of the power dynamics at the local level (Michiels & Van Crowder, 2001) and focusing on marginalised groups such as women or the disabled:

Too often, agencies solely communicate with the more active members in a community, leaving others behind who may remain poorly informed, thus perhaps increasing their exclusion. Agencies should avoid that and may also have to specifically target groups that have difficulties accessing information or have particular information needs, such as female heads of households, the young, the disabled or ill, or the homeless. (Schilderman, 2002, p. 48)

For Schilderman (2002), building community social capital supports improved information sharing through social networks, which is how people living in poverty tend to get information. He distinguishes between bridging social capital, bonding social capital, and linking social capital, and suggests that best practice includes deliberately stimulating people to undertake a joint activity or action related to particular local needs and providing a space for the community to get together and meet.

Table 1 draws together the success factors and examples of best practice highlighted above into a best practice framework. The aim of the framework is to guide practitioners through the key processes that contribute to successful knowledge sharing at grassroots through ICT projects.

REFLECTIONS AND TRENDS

Lessons learned from a first generation of ICT projects have shaped thinking about how to proceed. Development agencies recognise the difficulty of creating sustainable solutions at the first mile and highlight the importance of multi-stakeholder partnerships for the success and sustainability of

ICT projects. Local appropriation is understood as necessary to the success of projects, and projects are therefore privileging participatory methodologies, capacity building, interactive solutions, local content, and knowledge. Projects acknowledge the need to understand existing information networks and power relations to support local appropriation, and methodologies are being developed to support those processes (Beardon, 2004). The monitoring of ICT projects focuses increasingly on the social or economic impact for the beneficiaries (such as increased participation in decision-making processes, increased incomes, etc.) instead of the use of the information systems. Although many lessons have been learned from pilots, few projects have yet been able to scale up their initiatives or replicate them in other contexts.

Developments in the IT industry will have an impact on information networking for marginal communities. ICT tools are becoming cheaper and more efficient, digital convergence is changing our understanding of traditional media and interactivity, and the Free/Open Source Software movement offers opportunities for developing countries to develop affordable solutions and customise them to suit local contexts. Mobile telephony is allowing many developing countries to leapfrog fixed-line telephony solutions, and innovative business models are being developed to make it affordable, for example by Grameen Telecom. As media converge, combining technologies and combining online and off-line media offer positive lessons for the future, with many commentators highlighting the importance of radio as a communications tool in conjunction with the Internet (Girard, 2001; Chapman et al., 2003).

ICT policy need to be integrated into development programmes such as Poverty Reduction Strategy Papers (PRSPs) and national strategies. To create an information society, commentators highlight the need for freedom of expression, competitive markets, independent regulators, and a universal service fund in countries (Weigel & Waldburger, 2004). Policies are required to fund

Table 1. A best practice framework

Dimension of best practice	Success factor	Best practice
Environment	Working within the policy environment	Research the policy environment
		Recognise power relationships
		Develop strong relationships with policy makers
		Work within existing policies
	Understanding and addressing infrastructure issues	Analyse telecommunications and infrastructure deficiencies
		Plan for realistic measures
		Adopt innovative technologies
	Building relationships with donors	Develop more accessible devices
		Establish credibility, influence, and legitimacy
Project	Starting from communities' development priorities	Communicate project progress in a timely fashion
		Work in participation with communities
		Conduct a needs assessment
	Planning the project effectively	Involve target group in project planning and design
		Define clear objectives
		Identify the target group
	Learning from monitoring and evaluation	Plan realistically for implementation
		Link project goals to priorities
		Evaluate efforts critically
		Empower target groups to evaluate
	Forging strong partnerships	Adapt the project in response to findings
		Monitor regularly
		Select partners with complementary strengths
	Developing a sustainable business model	Provide partners with incentives
		Negotiate conflicting interests
		Identify which services are provided as a public good and which can be commercial
	Building staff capacity	Involve the private sector
		Buy in experience
		Hire skilled staff
	Scaling up	Train existing staff/volunteers
Communicate best practice to practitioners		
Share findings with donors		
Local level	Building on existing knowledge systems	Develop an exit strategy
		Research existing systems
		Incorporate existing systems into the project
		Connect to traditional knowledge
	Creating appropriate materials for local context	Promote local participation in the project
		Research information systems of target group, literacy levels, and so forth
		Understand information needs of target group
		Address local language issues
	Using appropriate technologies for communities	Develop materials in the right format for use
		Adopt technologies that local people can repair
		Choose technologies that people can afford to use
	Working with infomediaries	Blend communications approaches
		Identify grassroots-based infomediaries with a track record of working with poor people
		Provide appropriate incentives for partnership

continued on the following page

Table 1. (cont.)

Dimension of best practice	Success factor	Best practice	
Local level	Building capacity of infomediaries and target group	Provide training in efficient information provision	
		Provide useable information resources	
		Recognise, document, and share good practice in knowledge sharing at grassroots	
		Build adaptation skills, such as translating content to suit local conditions	
	Two-way knowledge sharing		Value and motivate local content through rights and incentives
			Build capacity of target group in content creation
			Incorporate local and external knowledge in information materials
			Connect target group to policy makers
			Promote knowledge sharing at a local level
	Minimising social exclusion and building social capital		Understand power dynamics at local level
			Focus on marginalised groups
			Build social capital through joint activities and communal space

content from minority language groups and support the design of ICT applications in local languages.

There has been so much hype about ICTs and their role in development that ICT projects appear to have taken on a life of their own, becoming an end in themselves. Just like biotechnology or nanotechnology, ICTs are just a technology, and marginalised communities need to be empowered to participate in the debates about how the technologies are used and how the use could affect their lives and livelihoods.

There is a danger that ICTs could reinvent the paradigm of development, without learning the lessons of the Green Revolution or other extension programmes, or of participatory technology development (PTD). This framework aims to offer practitioners a way of critically examining ICT projects to ensure that they are adopting best practice and putting the needs of people living in poverty first.

CONCLUSION

This chapter has examined the literature about connecting the first mile and shown that authors

are polarised around key debates: whether solutions should be participatory or top-down, technological or social, whether they should focus on global or local information and overall how optimistic to be about the potential of ICTs for development. Authors' ideological perspectives around these debates determine how they evaluate the impact of a project and what they determine best practice to be.

The best practice framework proposed in this chapter has synthesised the lessons from a range of practical studies to identify the factors that contribute to the success of a project. Recommendations for best practice are divided into three dimensions: the environment, the project level, and the local level. The framework focuses on processes that contribute to project success in order to offer lessons in a wide variety of contexts. Whether a project chooses to define impact according to poverty reduction, ICT access, or project sustainability, the processes outlined in the framework will still be relevant to the practitioner.

Further research would take a set of primary case studies from various contexts and develop the framework on the basis of their experience. Adding measurable indicators would allow practitioners to benchmark their projects against the framework.

An analysis of the lessons of previous development initiatives such as participatory technology development or the Green Revolution could offer further suggestions for best practice.

Recent research used the framework to evaluate an ICT for development project in Cajamarca, Peru (<http://www.infodes.org.pe/siru>). The project aims to share livelihoods information with local producers (predominantly agricultural producers) and connects a network of local infocentres to agricultural information providers via a central information processing unit. The exercise generated learning about the project's successes and deficiencies and also about the viability of the framework. Applying the framework helped project staff to view their activities in a more holistic way and understand the impact on the project of actors outside the information value chain, such as funders, telecommunications companies, and local government bodies. It prompted a re-evaluation of partnership models and the need for re-formatting information for rural audiences, and a reconsideration of the role of ICTs in reaching illiterate rural populations.

In the future, the framework could be used to evaluate potential projects prior to funding, so projects meeting many of these criteria could be prioritised. The framework could also be used to benchmark different projects, for example by the Ministry of Agriculture in Peru to compare the various agricultural information systems in the country. Learning from the research in Peru, it is necessary to provide practitioners with a clear explanation about the distinction between the local level, the project level, and the environment. The framework needs to be integrated with other tools (such as an information value chain or a matrix of actors and activities) in order to understand the information flows in knowledge sharing projects at the first mile, and latent and explicit demand for information.

In this chapter it has been shown that ICTs can make a valuable contribution to development outcomes, provided they are viewed as a means,

rather than an end in themselves. It is also abundantly clear that initiatives will vary according to the local context, if they are to share knowledge with local communities. It is possible, however, to generalise about the processes that practitioners can adopt to constitute best practice. In the best practice framework, the authors' aim to synthesise these processes to support practitioners in addressing the challenges of connecting the first mile and empowering marginal communities to participate effectively in the information society.

TERMS AND DEFINITIONS

Best Practice: A set of guidelines or recommendations based on a study of the most effective approaches to performing a given activity.

Information Communication Technologies (ICTs): The technologies that enable the handling of information and facilitate different forms of communication among human actors, between human beings and electronic systems, and among electronic systems (Hamelink, 1997, p. 3).

Information Sharing: The exchange or transfer of information between people or systems.

International Development: Efforts, by developed and developing countries, to bring people out of poverty and so reduce how much their country relies on overseas aid. Many different things can contribute to development which reduces poverty, such as settling conflicts, increasing trade, and improving health and education (DFID, 2005).

Knowledge: A fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers (Davenport & Prusak, 1998, p. 5).

Chapter 2.2

A Framework to Build Process Theories of Anticipatory Information and Communication Technology (ICT) Standardizing

ABSTRACT

Standards have become critical to information and communication technologies (ICTs) as they become complex and pervasive. We propose a process theory framework to explain anticipatory standardizing outcomes post hoc when the standardizing process is viewed as networks of events. Anticipatory standards define future capabilities for ICT ex ante in contrast to ex post standardizing existing practices or capabilities through de facto standardization in the market. The theoretical framework offers the following: a) a lexicon in the form of the ontology and typol-

ogy of standardizing events; b) a grammar, or a set of combination rules, for standardizing events to build process representations; c) an analysis and appreciation of contexts in which standardizing unfolds; and d) logic yielding theoretical explanations of standardizing outcomes based on the analysis of process representations. We show how the framework can help analyze standardization data as networks of events as well as explain standardizing outcomes. We illustrate the plausibility of the approach by applying it to wireless standardization to explain standardizing outcomes.

INTRODUCTION

Over the past decade, successful standard-setting has become critical for innovation, while Information and Communication Technologies (ICTs) have become networked, ubiquitous, and complex (David, 1995; Mansell & Silverstone, 1996). ICTs are technologies dedicated to information processing; in particular, they involve the use of computers and software to convert, store, protect, process, transmit, and retrieve information (Wikipedia, 2005). Recently, traditional standard-setting mechanisms have become rife with problems: They do not respond well to the increased scope, pace, and complexity of technological and market change associated with ICTs (Garud, et al., 2002; Schmidt & Werle, 1998; Werle, 2000). This is the case, in particular, with the exponential growth of *anticipatory* ICT standards—standards that embed significant technological or process innovations into the technical specification—and which are “intended to guide the emergence of new technologies and consequently indicate far ahead in advance of the market’s ability to signal the features of products that users will demand” (David, 1995, p. 29). Anticipatory standards define future capabilities for ICTs in contrast to recording and stabilizing existing practices, or capabilities *de facto*. Failures with anticipatory ICT standardizing are common (Steinmueller, 2005; Markus, et al., 2006) and our ability to explain their failure with the existing body of knowledge is poor.

In this article we advance process theorizing of ICT standardizing—the mission of describing, revealing, understanding, and explaining processes, features, and outcomes of ICT standardizing (Weick, 1995). To this end we formulate a theoretical framework which helps formulate plausible, generalizable, and valid explanations of *why* and *how* certain ICT standardizing outcomes emerged (Weick, 1989). The framework posits that ICT standardizing can be seen as a network of events that create and coordinate the adop-

tion of institutionally-bound and contextualized technological repertoires (capabilities) among a set of heterogeneous actors. We draw upon Actor Network Theory (ANT) and Social Construction Of Technology (SCOT) studies (Howcroft, et al., 2004) to explicate these necessary theoretical constructs.

ICT standardizing is viewed in this study as collective engineering of technical specifications (David, 1995; Steinmueller, 2005; Baldwin & Clark, 2005). By drawing upon SCOT (Bijker, 1987), we view anticipatory standardizing as technology framing—sense-making—which at the same time builds durable socio-technical networks (Callon & Law, 1989; Latour, 1995). The framework analyses of event networks of such engineering, sense-making, and negotiation activities offers: a) a *lexicon* in the form of ontology and typology of standardizing events; b) a *grammar*, or set of combination rules for events to build *process representations*; c) an analysis of *contexts* in which events unfold; and d) a set of *logical rules* to yield explanations of standardizing outcomes.

The proposed framework is not a *process theory* of anticipating ICT standardizing outcomes. First, it is not a theory of anticipatory *standards* as ready-to-adopt fixed artifacts, but instead it moves towards theorizing about *standardizing as a stream of social, political and design events which connect ideas, artifacts, people, and institutions to yield a specific technical specification*. Like all process theories, it cannot be used to accurately predict standardizing outcomes, but rather to analyze why specific processes took place in the way they did, and why certain outcomes emerged (Mohr, 1982; Markus & Robey, 1988; Langley, 1999) as to anticipate outcomes of future standardization situations. Second, it is not a complete process theory, as it offers at current state theoretical constructs to compose statements to understand and explain concrete standardizing outcomes.

The remainder of the article is organized as follows: In the second section we define anticipatory ICT standardization and critically review past literature on anticipatory ICT standards to identify core concepts for our integrative framework. In the third section, we build on this review by integrating concepts from the review and developing our theoretical framework, which consists of process theories, the lexicon, the grammar, the context analysis, and the logic. We show how these concepts can account for anticipatory ICT standardizing outcomes. In particular, we illustrate the benefits of the framework by analyzing a small standardizing episode. The fourth section summarizes the main findings, compares the proposed theoretical framework with other accounts of standardization, and explores avenues of future research.

RECEIVED STANDARDIZATION THEORY

Anticipatory ICT Standardizing Defined

In general, “a standard defines a uniform set of measures, agreements, conditions, or specifications between parties (buyer-user, manufacturer-user, government-industry, or government-governed, etc.)” (Spivak & Brenner, 2001, p.16). Technology standards offer agreed upon, external points of reference to which the physical and performance characteristics of current or future technologies can be compared (Hawkins, 1995; Spivak & Brenner, 2001). For this article, we limit ourselves to anticipatory ICT standards that integrate and embed significant technological innovations¹. Such standards are very challenging to formulate and enforce as they do not just record existing practices (e.g., quality standards), or establish some new practices that need just to be coordinated (e.g., measures). Their intent is to generate new principles to existing solutions, or

to create totally new solutions. Because of this they offer significant upside economic yields and embed significant challenges related to intellectual property, scale of economic benefits and costs, and means to enforce standards and their deviations, yet also pose significant risks of failing.

We define *anticipatory ICT standardizing* as a process in which two or more actors come to agree upon and adhere in a contract to a set of publicly available original and novel technical specifications for an ICT system, service, or capability, including its parts, features, or functionality (David & Greenstein, 1990). Typically, anticipatory ICT standards emerge as multi-firm agreements about technologies, e.g., Bluetooth standard (Keil, 2002) and GSM standards (Mouly & Patet, 1991), as vertical industry standards, e.g., Markus, et al., 2006; Damsgaard and Lyytinen (2001),; as de facto standards constituting an open standard, e.g., SUN’s Java platform (Garud, et al., 2002), or as open specifications which later can become de facto standards, e.g., IETF’s RFCs (Tuomi, 2001) or W3C drafts or RFCs (Berners-Lee, 1999).

Due to its *innovative* nature, anticipatory ICT standardizing is akin to cooperative, multi-actor R&D and indicative of *collective engineering*, where standard setters create capabilities to displace existing capabilities (David, 1995), and seek thereby new markets (Gabel, 1991). Because of this, anticipatory ICT standards share four features: 1) they record and coordinate advances in information and communication technology capabilities (Mansell & Silverstone, 1996); 2) they are intended to guide future compatibility or interoperability requirements-related ICTs, including physical products, service platforms (David, 1995), or data exchange or process standards (Markus, et al., 2006); 3) they are often created in international and/or national institutional contexts to promote industry-level coordination (Hawkins, 1995); and 4) they are conveyed in public domain documents to which different parties have *open access* and can thus be influenced through institutions (Gabel, 1991).

FOUR PERSPECTIVES OF ANTICIPATORY ICT STANDARDIZING

An in-depth review of all research in anticipatory ICT standardization is beyond the scope of this article. Rather, we will in the following summarize four broad theoretical perspectives and examine how each stream has approached anticipatory ICT standardizing problems (Table 1a/b). We will discuss what specific theories have been deployed in each perspective and what are the strengths and weaknesses of each perspective

Practitioner Literatures

There is a relatively large body of practitioner-oriented literature that discusses practice-related issues relevant to ICT standardization (see, e.g., Cargill, 1989). While this literature covers the whole process of standard creation and selection, thoroughly documents standardization institutions and associated processes, and offers useful rules of thumb for approaching standardizing situations, it lacks a theoretical underpinning that limits its explanatory power to account for standardization processes and outcomes.

Economic and Management Theories of Standardization

In a second stream of research, standardization has been analyzed as an economic or managerial decision problem (Shapiro & Varian, 1998; Swann, 2000). It is driven by the following research questions: Why do producers or users choose a specific ICT standard, and what is their rational justification for such a choice? In addressing these questions, researchers use economics or management theories to explain the economic benefits of standards and identify conditions that maximize individual users' or collectives' welfare. Early economics literature focused on market-based selection (Farrell & Saloner, 1985; Farrell &

Saloner, 1986). Recent studies have also focused on explaining the dynamics of standard adoption by utilizing asymmetric switching costs (e.g., Brynjolfsson & Kemerer, 1996; Farrell & Saloner, 1988a), network externalities (David & Steinmueller, 1994), or increasing returns (Arthur, 1989). Relatively few studies have analyzed standard selection within standardization institutions, or within hybrid arrangements, such as standardization alliances (Axelrod, et al., 1995).

While the body of economics literature is large and growing, these studies suffer from a number of deficiencies when we try to understand anticipatory ICT standardizing. First, these studies focus completely on standard choice and ignore technological, social, structural, or institutional forces that shape standard creation and selection (Markus, et al., 2006; Weitzel, et al., 2006). Accordingly, a standard-to-be-selected is assumed to be a natural state to which companies and other actors respond passively. Yet, this is not the case with anticipatory standards. While economic models often provide deep insights into counterintuitive outcomes of standard choices, they are limited in analyzing relatively simple choice situations where the choice shifts fast and unpredictably. Accordingly, they are not well suited to account for outcomes of complex anticipatory standardizing that have had a significant strategic impact (Funk, 2002; Markus, et al., 2006). In addition, these studies ignore the influence of social or institutional context and the "shadow" of history that affects standard creation.

Legal and Public Policy Studies

Although most legal and public policy studies do not address the issue of standardization *per se*, many such studies have either analyzed the broader context in which standardizing takes place, or subsumed standardization as a form of regulation. This connection is obvious as regulatory environments provide the context in which standardizing takes place and standards are en-

Table 1a. Theories to analyze anticipatory ICT standarding outcomes

Perspective	Theory	Domain/Focus/Phase	Research Question	Explanatory mechanisms	Strengths/Deficiencies	References
<i>Practitioner</i>	A-theoretical	Domain: ICT standard Focus: Any standard Phase: Standardization as a process	How are standards created and how do standardization institutions operate?	Rules of thumb, normative principles, descriptive narrative	<i>Rich descriptions of actual processes and rules of thumb</i> What should I do or how should I go about in standardizing in this situation. Lack of theoretical underpinnings, difficult to generalize	(Cargill, 1989; Schmidt & Werle 1998)
	Game theory: Standard creation	Domain: General Focus: Any standard Phase: Standard Creation	Selection of a type of standardization strategy	Rational expectations of firms in game setting	<i>Explains choice of body,</i> General focus, and domain, ignores nature of standardization, little emphasis on process, no explanation of technology	(Farrell & Saloner, 1988a)
	Game theory: Standard selection	Domain: General Focus: Any standard Phase: Standard Selection	Selection of de facto standard	Rational expectations of firms in game setting	<i>Explains choice of existing standard.</i> General focus and domain can take into account innovation by risk/ yield, no emphasis on standardization process, no explanation of technology	(Farrell & Saloner, 1986; Weitzel, et al., 2006)
<i>Economics</i> <i>Management</i>	Increasing returns and network effects	Domain: General Focus: Any standard Phase: Standard Selection	Selection of de facto standard	Network effects, positive externalities	<i>Explains choice of existing standard.</i> General focus and domain, with no focus on social context, no emphasis on standardization process, and no explanation of technology	(Arthur, 1989; David, 1985; Katz, 1986; Shapiro & Varian, 1998; Weitzel, et al., 2006)
	Asymmetric switching cost	Domain: General Focus: Any standard Phase: Standard Selection	Selection of de facto standard	Asymmetric switching cost due to installed base	<i>Explains inertia in switching between standards.</i> General focus, ignores nature of standard and social forces, no emphasis on standardization process, no explanation of technology	(Brynjolfsson & Kemerer, 1996; Farrell & Saloner, 1988b; Shapiro & Varian, 1998)
<i>Legal and Public Policy</i>	Theories of regulation	Domain: General Focus: Any standard but recently mainly ICT Phase: Standard as a regulation	How do intellectual property rights and antitrust law affect standards and vice versa? How can a standard be viewed as regulation?	Standard as regulation. Regulatory actors. Intellectual property rights and antitrust law	<i>Provides rich explanation of the context for standardization processes.</i> Static view of technology, fails to develop a process perspective of regulation	(Lessig, 1999a; Hosen, et al., 2003; Jarvenpaa, et al., 2003; Patterson, 2002)

A Framework to Build Process Theories of Anticipatory ICT Standardizing

Table 1b. Theories to analyze anticipatory ICT standardizing outcomes

Perspective	Theory	Domain/Focus/Phase	Research Question	Explanatory mechanisms	Strengths /Deficiencies	References
<i>Sociology of Technology</i>	Actor Network Theory (ANT)	Domain: General Focus: Any standard Phase: Standardization as a process	How are standards created? How do standards become selected so that technologies become stable?	Enrolment into actor networks through translation Paths in networks. Passage points	<i>Explains how standards are stabilized within socio-technical networks and how they become irreversible</i> Descriptive language to explain standardization processes and outcomes as a set of translations. General theory of technology as inscriptions. Focus on structure of the actor network, downplays individual's innovative role in anticipatory standards	(Allen, 2004; Callon & Law, 1989; Faraj, et al., 2004; Hanset, et al., 1996; Howcroft, et al., 2004; Latour, 1997; Law, 1992; Mangematin & Callon, 1995; Mähring, et al., 2004; Ramiller, 2005; Walsham, 1997; Walsham & Sahay, 1999)
	Social Construction of Technology (SCOT)	Domain: General Focus: Any standard Phase: Standardization as a process	How do standards embody specific problem-solving strategies? How do standards reach a closure, i.e., become standard ways of defining technology?	Designer and user communities. Technology frames Closure	<i>Explains how technology is interpreted over its lifetime and how such interpretations stabilize.</i> Descriptive language to identify and analyze design choices and rationale associated with standards. Views design and use of ICT systems as a framing process. Focuses mostly on sense-making after design, little focus on sensemaking during design. No process study methodology	(Bijker, 2001; Davidson, 2002; Orlikowski & Gash, 1994; Pinch & Bijker, 1987; Sahay & Robey, 1996; Swanson & Ramiller, 1997)

forced. For instance, legislation about intellectual property rights (Patterson, 2002; Weiser, 2003) and antitrust legislation (Sheremata, 1998; Teece & Sherry, 2003) directly influence anticipatory standardizing. By the same token, new anticipatory technological standards and their proliferation generate forces that shape regulation (Hosein, et al., 2003). This has led some scholars to suggest that standards can be viewed as a form of regulation (Hosein, et al., 2003; Jarvenpaa, et al., 2003; Lessig, 1999a, b). For instance, Jarvenpaa, et al. (2003) draw parallels between standardization and regulation by arguing that any market player that affects the ICT architecture is acting as a regulatory agent.

Although legal and public policy studies of standardization improve our understanding of how standardization processes are embedded in an institutional context, and are shaped by and contribute to enacting this context, these studies are limited in their ability to inform our understanding of anticipatory ICT standardizing. First, the institutional regulatory environment and the standardization contexts differ radically. Regulation is carried out by national or international legislative institutions based on a public mandate and force. By contrast, anticipatory standardizing takes place in a wide variety—ecology—of institutions that range from informal alliances within an industry to formal standard development organizations associated with nation states (SDOs) (Schmidt & Werle, 1998). This difference suggests that a less institution-bound theory might be needed for standardizing.

The literature that focuses on technology standards as a regulatory actor has also been criticized as static (Hosein, et al., 2003). In particular, within anticipatory ICT standardizing, a more dynamic view is needed that covers simultaneously the emergence of new technologies and the social forces—institutions—that are tied with these technologies and shape actors' expectations, channel resources, and mobilize bias (King, et al., 1994). Finally, the regulatory literature, while

emphasizing parties' incentives to create regulatory mechanisms, has failed to provide a process theory of how regulatory mechanisms themselves are created (Croley, 1998). This also weakens the suitability of this stream to explain anticipatory ICT standardizing outcomes.

Social Theories of Standardization

A fourth stream of standardization research is rooted in the sociology of technology research (Williams & Edge, 1996). The bulk of this literature draws upon either the Actor Network Theory (ANT) (Latour, 1997, 1999) or the Social Construction of Technology research (SCOT) (Bijker, 1987). For a general overview and discussion of both literatures, we refer to Howcroft, et al. (2004). Both of these literatures share an interest in examining standardization as interactions between socio-technical elements in which the technology-to-be-standardized becomes invented, introduced, invested, and stabilized (Latour, 1999). Though recently these two approaches have converged, as actor-centered analysis has been extended into broader settings of technology assessment (Sørensen & Williams, 2002), these literatures are somewhat distinct in how they account for technology creation and adoption.

In SCOT, the emphasis is on the evolution and mobilization of interpretive schemes and associated engineering skills as the technology becomes invented and stabilized. Its *leitmotif* is to explain why technology obtains a certain shape and how such shaping is socially conditioned and produced. This explanation is organized around a theory of *technology frames*—a set of community-wide, shared mental schemes “composed of... the concepts and techniques employed by a community in its problem solving” (Bijker, 1987, p.168). In particular, SCOT research has suggested the notion of *closure conditions* (Pinch & Bijker, 1987) that determine when and how technology frames stabilize. Accordingly, an investigator of standards should trace backwards from a “closed”

technology standard to situations where specific alternatives were excluded while addressing critical challenges during standard design (Hughes, 1987). This unpacking reveals why and how technological choices are made. SCOT complements economic research in that it identifies and narrates interpretive processes associated with design and foregrounds *sense-making* associated with any technical innovation—including anticipatory standards (Pinch & Bijker, 1987).

Actor-Network Theory seeks to understand why and how a technological solution was created as a carrier of a network of *both* technical and social relations. It aspires to reveal how a technology “embodies the innovator’s beliefs, social and economic relations, patterns of use, legal limits, and assumptions as to what the artefact is about” (Akrich, 1992a). ANT leads an investigator to ask the following questions: How did actors become aligned? (Callon, 1986) What reasons did they have for entering the network and how did this change their behaviors (inscriptions) (Akrich, 1992a)? To explain anticipatory standardizing, ANT would trace the designed and agreed standard back into set of “translations” (Callon, 1986) where actors became “enrolled” in a network. Though ANT theorists do not assume sequential processes in such network constructions, nearly all ANT studies explain network emergence as an orderly sequence of specific types of events (Callon, 1986). This ordering is subordinated to a movement towards an *obligatory passage point* (Callon, 1986): “a situation through which the heterogeneous actors involved... must be made to pass” (Ramiller, 2005, p.57). One such passage point, for example, would be the agreement about the final contract, while another one would be to make the technology to behave as specified in the standard.

ANT shares with SCOT the interest in revealing why standardizing followed one trajectory and thus stabilized, and by doing so excluded other alternatives. Yet, the notion of stabilization in these streams is different. In ANT, stabilization

is seen to result from an expanding enrolment that leads the actor-network to grow whereby the content and intensity of the connections in the network changes (Mangematin & Callon, 1995). The ANT literature thus provides insights into how increasingly complex socio-technical networks emerge, and how, due to intricacies of the translation *process*, the standards become *stable*, i.e., *agreed* and *irreversible*. In SCOT, in contrast, standardizing is about closing, typifying, and objectifying frames that “read” technologies-in-making.

Both ANT and SCOT have been adopted in ICT standardizing, or innovation, research. SCOT researchers have studied managers’ sense-making during IT innovation (Swanson & Ramiller, 1997), how users and designers interpret requirements (Davidson, 2002), how users make sense of the technology (Orlikowski & Gash, 1994), and how technologies maintain interpretive flexibility (Sahay & Robey, 1996). Past ANT research has studied system implementations as translations through passage points (Mähring, et al., 2004; Ramiller, 2005), and how systems create social orders (Walsham & Sahay, 1999).

Research focused on ICT standardizing has also drawn upon both strands of social theory. First, Hanseth, et al. (1996) examined how standards are inscribed during standardization processes by using ANT. Likewise, Egyedi (2005) analyzed how the institutional context of SDO affects standardization outcomes based on ANT. She investigated negotiations within an actor-network in explaining standardizing outcomes. She analyzed, in particular, the meaning, purpose, or role of the network, actors’ positions in the network, and the boundaries of the network. Likewise, Jakobs (2006) examined relationships between standardization and user-side innovation by using SCOT. He observed mutual influence between standardization and innovation sense-making in which technology standards are being developed. Likewise, Stewart and Williams (2005), drawing upon SCOT, discussed user sense-mak-

ing during innovation and suggested that “in this process, artifacts are often reinvented and further elaborated (“innofusion”)” (Stewart & Williams, 2005, p.195).

Despite their merits in explaining technology evolution, ANT and SCOT remain broad theories of technological and social orders. This makes them too general to capture critical aspects of anticipatory ICT standardizing. They suffer among others weaknesses in accounting anticipatory ICT standardizing as collective engineering in specific institutional contexts. From the ANT viewpoint this introduces a challenge in explaining who should be enrolled, why, and how, and what is the organization of the network when design is fluid, shifting, and ambiguous. Some ANT assumptions, like actors’ interests, remain relatively stable (Allen, 2004); they know within whom/what they need to enrol, and are not plausible in this context (Ramiller, 2005). During anticipatory standardizing, designers do *not* know what networks they must pull together: Designs remain ambiguous, their consequences cannot be predicted, and most relationships between the actors are up for grabs (Van de Ven, et al., 1999). Actors discover their interests dynamically by enrolling in different networks in different ways over time, and their interests emerge hand-in-hand with advances in various designs (Ramiller, 2005).

Likewise, SCOT suffers the lack of integrating individual creativity in its concept of technology frame. It is not clear what role breakthrough ideas, novel innovations, and exceptional individual talent play in the evolution of technology if technologies are directed and shaped by community sense-making. In addition, SCOT views “technology framing” primarily as a user-related sense-making around finished designs (Pinch & Bijker, 1987). Yet, as a form of innovation, anticipatory standardizing involves surprises that unexpectedly change the direction of design, and it is driven by shifting individual design-triggered framing. These shifts are produced by individual designer’s wits in framing their designs *differ-*

ently, which, in turn, will affect how they locate into social and technological networks. When designers weigh in new design options, both the design and its interpretation change, and “they are themselves transformed, ‘redesigned’ as actors, as they learn about the possibilities of the technology” (Ramiller, 2005, pp.71-72). Thus, due to both SCOT and ANT’s focus on established and fixed actor networks, or community wide “technology frames,” they are limited to accounting for how an individual designer and later a design team can shape standardizing outcomes. Although some attempts to resolve this problem have been made (Akrich, 1992; Faraj, et al., 2004), how individual cognition is currently brought to bear in understanding standardizing is limited to finished designs.

Motivation for the Proposed Process Theory Framework

ANT and SCOT together offer an excellent starting point for developing a process theory for anticipatory ICT standardizing. They both focus on processes that make technologies stable and irreversible—a goal also shared in anticipatory standardizing. However, both approaches are broad descriptive “sensitizing devices,” and do not aspire to produce process explanations that are specific to ICT standardization context. They offer little guidance how accounts of ICT standardization processes can be formulated and systematically analyzed. We believe, however, that more localized theoretical frameworks can be useful in building process theories of standardizing that are accurate and theoretically adequate to identify, analyze, and synthesize standardizing events and their connections into networks. These networks can then be used to build explanations why and how an ICT standardization outcome was produced (Langley, 1999). In what follows, we formulate a process theory framework to build anticipatory ICT standardizing theories (Weick, 1989).

A PROCESS THEORY FRAMEWORK FOR ANTICIPATORY ICT STANDARDIZING

A theoretical framework for standardizing process theories consists of a set of constructs (lexicon) and their relationships (a grammar) that help formulate process theories (a theory logic), and a set of criteria to evaluate such theories (Bacharach, 1989). A general discussion of process theories is beyond the scope of this article (see Langley, 1999; Van de Ven, et al., 1999; Pentland, 1999; van de Ven & Poole, 1995; Mohr, 1982). We just note that process theories differ mainly in types of constructs, their relationships, and the logical way inferences are made from the data (Mohr 1982; Van de Ven, et al., 1999). A problem in available process theory guidelines is that they are about broad social processes and do not take into account differences, e.g., in accounting a small project change, a disruption in a team's behavior, or a strategic change. They are mainly distinguished by the level and nature of constructs used, type of analysis method, or complexity (Langley, 1999). To build process theories of anticipatory standardizing demands, however, it is necessary that we increase the domain level detail (vertical theorizing) among constructs used and the richness in their connections (Weick, 1989). This must be reflected in the consequent choice of constructs and the ways in which we advance explanations with those constructs.

In general, we define a *process* as a set of events that unfold over time in a context (Petigrew, 1997). We call any set of such events organized over time an *episode*. Standardizing events accordingly range from imagining use scenarios to designing specifications and testing, to choosing between design options². An ICT standardizing process theory is about the types of events that unfold, how they relate, and how they explain standardizing outcomes (Markus & Robey, 1988; Mohr, 1982; Van de Ven & Huber,

1990). In short, it explains *why* and *how* an ICT standardizing outcome emerged.

We propose the following constructs following Bacharach's (1989) suggestions for theory building to build ICT standardizing process theories:

1. A *context* in which the events take place. This construct is critical for two reasons: a) most process explanations are context-dependent and the notion of context is needed for increasing internal validity, and at the same time b) context is necessary for generalizing across other situations and improving external validity of the proposed theory. Overall, context construct is needed to align with Bacharach's (1989) idea of the utility of the conceptual relationships and their explanatory potential and related assumptions.
2. A *lexicon* of event types and outcomes. The lexicon defines the content and granularity of standardizing events that will be brought to bear in explaining the outcome. This element corresponds with Bacharach's (1989) concept of theory constructs that define theory variables, and the theory's scope.
3. An *event grammar* that characterizes the nature of relationships into which the standardizing events enter. The grammar establishes a focal means of arranging events into relationships and chronicling event networks as defined by their temporal ordering, or by other relationships. This element relates Bacharach's (1989, p. 510) concept of construct relationships and criteria by which one assesses the logical adequacy of those relationships.
4. A set of *logics* to infer from the events, their networks and contextual relationships, statements how and why the process was organized as it was, and why certain outcomes emerged. This element corresponds to Bacharach's (1989) demand for theory-

based explanations that are grounded on propositions.

THE CONTEXT

Generally, a process emerges from interactions between events and a context (Van de Ven, et al., 1999). A context is instrumental in process explanations, as it relates events into nested arrangements of associated structures and processes (Pettigrew, 1997). Accordingly, we need to examine how events “of one period lead to changes in the context that affect action in the subsequent periods” (Langley, 1999, p.703). In line with this approach, we assume that standardizing events are constrained by the context, but they also shape that context by preserving or altering technological capabilities, modifying institutional arrangements, or changing the actors (Pettigrew, 1997).

During standardizing, the context can be separated into a nested structure of focal actors, the technological environment, the market environment, and the institutional environment. The technological environment includes existing and emerging ICT technologies, past design choices in deploying these technologies, and emerging technological trends. The technological environment defines what is technologically possible and desirable. Actors include firms, organizations, and individuals who are directly participating in the standardizing process. In anticipatory ICT standardizing, firms from varied industries as telecommunications equipment, telecommunications services, information technology, semiconductor manufacturing, packaged software, or many user industries participate. Organizations such as the ITU, ETSI, or other industry associations might participate actively in standardizing. The market environment includes existing or emerging markets that the standard is targeting or that might be influenced by the emergence of the standard as well as the firms and organizations or individuals operating in these markets. Finally, the institu-

tional context includes institutional arrangements as well as regulatory and legal frameworks within which the standardizing takes place. Institutional arrangements might include standardization fora, alliances, or standardization bodies in which the standardizing takes place. In particular, regulations about the telecommunications or information technology domain and anti-trust laws play an important role in shaping the standardizing.

A LEXICON OF EVENTS

We assume each such standardizing *event* accounts in some way, either directly or indirectly, for the observed outcome. This defines the profile of each event, and covers the type of outcome, its content (what the event is about), and related actors. We assume that standardizing events can be analytically distinguished based on their primary outcomes—the content—and that each event is associated with an output of a specific type (as reflected in resulting documents, ideas, artifacts, or agreements). Such output is later regarded instrumental in explaining the ensuing process and its outcomes. Events that do not have such impact can always be discarded during the process as irrelevant for the current theory building effort. An event can be triggered by other events, or by changes in the context, and such causes of events need to be identified in the event description.

In general, several different types of outputs can be related to any standardizing episode, such as a standards meeting. These episodes have multiple and diverse outputs that need to be carefully separated and associated with specific individual events. In addition, to account for the temporal dimension, each identified event must be tagged with start and end times so that they can be ordered in temporal sequences. Such baseline sequences of events offer a basis for formulating process explanations.

Traditionally, process theories have used a singular concept of an event, which is defined as

an observed change in the process state marked by a point in time. In this regard, we find current process theories to be too general, and propose here a richer domain-specific typology which classifies standardizing processes into three types of events. As our primary interest lies in understanding what goes on during standardizing while an ICT standard emerges as an “agreed upon” specification, we need a typology that distinguishes between various aspects of standardizing in the same manner as Simon (1977) distinguished between different aspects of decision making. Simon drew his distinctions based on the idea of cognitive orientations that characterize three recursive phases of decision making that completely describe decision outcomes. His cognitive orientation included a set of cognitive elements and processes that had to be foregrounded in each phase. Completeness was about finding out which types of cognitive orientations were necessary so that a decision-making process could be successfully completed. Accordingly, he proposed three decision phases 1) *intelligence*: defining a problem space; 2) *design*: structuring a problem space; 3) *choice*: searching in that space. He also demonstrated their completeness in exhaustively explaining decision outcomes.

Likewise, we will define ICT standardizing events based on their essential *cognitive orientations*. We distinguish three cognitive orientations whereby ICT standardizing can be broken down into: 1) *design*, 2) *negotiation*, and 3) *sense-making*. Here, 1) *Design* orients itself towards the creation of technical specifications and draws upon engineering principles that lay out design architectures, components, and their specifications; structural, functional and observable behavioral features (e.g., reliability) of the artifacts dominate the reasoning; 2) *Negotiation* orients itself towards reconciling technical solutions with regard to the interests of the involved actors; strategies and interests of actors and anticipations of their behaviors towards other actors dominate the reasoning, and 3) *Sense-making* orients itself

towards “reading” technical specifications in ways that relate them to the life-worlds associated with the use of produced artifacts and/or shaping institutional contexts that surround specified technology. Here, design artifacts’ relationships to users’ experience, designer’ experience and others’ life-worlds dominate the reasoning. All these types are necessary to define and produce an anticipatory standard. Design events are necessary to yield specifications that can include novel principles which are shown to work. Negotiations are needed to reach agreements between actors, while sense-making is needed to contextualize the specification and negotiation events into an unfolding business, insitutional, and user context (Weick, 1995).

In formulating the typology, we also recognize the notion of a closure and stabilization that is needed in creating the standard. Each event type distinguishes a separate dimension along which standard setters must stabilize the standardizing results. Consequently, a successful anticipatory ICT standardizing includes: 1) a *design closure*: the technical specification has been formulated and fixed completely in light of engineering goals and criteria (Simon, 1977), 2) a *negotiation closure*: actors know what has been agreed upon, and what the implications of such agreement are for their interests. Most actors are also aware that such an agreement has been achieved (Callon, 1986), and 3) a *sense-making closure*: each actor interprets the standard in relation to technological, social, and business contexts in a meaningful and stable way. The meaning of technology has become typified and institutionalized for involved actors, and they enact relatively stable technology frames (Pinch & Bijker, 1987).

Design (D-events)

Anticipatory standards emerge neither by God’s finger nor by recording existing practice. They involve spurts of innovation where technical designs are proposed, implemented, and evaluated.

Anticipatory ICT standardizing is fundamentally about *collectively engineering a new tangible (or intangible) technical artifact through a set of design events (D-Events)*. Design events echo the “science of the artificial: finding occasions for making a decision, finding possible courses of action, choosing among courses of action” (Simon, 1977). Design choices are made by selecting from alternatives that have been deemed possible during preceding D-events. Identification of D-events unpacks a standard setter’s winding cognitive process and his or her constant struggle to articulate design alternatives and make choices.

A design closure is achieved through a set of D-events which gradually produce a technical specification that is innovative, i.e., defines novel technological capabilities that can be implemented and at the same time submits to good engineering practices. Such principles include general design goals and architectural norms that state that specifications need to be simple, elegant, efficient, and involve acceptable and better trade-offs between performance, cost, and reliability, than existing solutions, etc. When engineers/ designers reach a closure, they will know collectively how the new technology will work, what its basic properties will be, and how it changes engineering, design, manufacturing, or use practices. A failure to reach a design closure involves a failure to produce technical specifications, or to produce specifications that include errors, are ambiguous, too complex, or costly to implement. This is either due to a failure to generate feasible design options or a failure to choose correctly among them.

When explaining how a design closure is reached, investigators need to come to grips with how technical specifications can actually be derived. This resembles the process of trial and error learning (March, et al., 1991). Accordingly, ICT standardizing takes place predominantly in distributed laboratories, but also covers joint work in committees where technical specifications are reviewed, revised, and modified in all minutiae (Schmidt & Werle, 1998). A large

proportion of standardizing is about “every day” engineering—arduous elicitation, elaboration, and refinement of the technical details, and arguing about design options. Accordingly, D-events are communicated in genres appropriate to these communities: technical reports, memoranda, prototype solutions, test results, etc.

The scope of design events ranges from simple design tasks, such as specifying a software or hardware interface, to decisions concerning the encompassing design architecture around which the whole standard will be built and which will affect a trajectory of future innovations and standard refinements (Baldwin & Clark, 2005). For example, the design of a wireless phone standard involved myriad design choices: articulating the architecture of the system (and its service model); specifying open and proprietary sub-system interfaces; and validating their non-functional features (reliability). But, it also involved smaller events such as specifying a speech codec or usability constraints for the interface (Manninen, 2002; Fomin & Lyytinen, 2001). The designs are path dependent in that they draw upon existing technological capabilities and factor in installed base compatibility and interoperability. Designs are also path dependent in that they build on previous technological advances and well-known solution spaces.

The collective and heterogeneous nature of standardizing designs adds *complexity* to the process and forms a significant barrier to reaching a stable design. This can be due to a great number of proposed solutions or due to the need to apply multiple conflicting design principles or requirements. This complexity is reflected in massive piles of documents and large committee sizes. For instance, a complete GSM standard already covered thousands of pages of detailed technical documents (Mouly & Pautet, 1992) and the complexity of 3G standards has grown exponentially. Standard setters must master this complexity by setting their ambitions wisely, and by applying modular designs (Simon, 1977).

Good architectural control becomes crucial as architectural decisions define critical interfaces and allow separate communities to work in parallel (Simon, 1977). Thereby multiple parallel and iterative design processes are implicated when engineers choose a modular design for standards. Likewise, higher ambitions lead to increased uncertainty and a larger number of iterations. For instance, during Bluetooth standardization, the first version of the standard was delayed since its technological implementation proved significantly more complex than expected due to its high ambition level (Keil, 2002).

Negotiation (N-events)

In the end, each standard is about excluding alternative technical specifications in light of “positive” political and economic consequences of such exclusions. Designers become negotiators when they ask how their designs will align with other actors’ interests³. Therefore—metaphorically speaking—during standardizing, a set of technical specifications transforms itself from a “pure” cognitive state—a design idea—into an institutional force to reckon with embedded in the standard. This transformation happens through negotiation between actors. In fact, great or less than great design ideas can travel to the material world only through the gates of negotiation (Suchman, 2000), and an anticipatory standard “can be conceived as a complex (socio-technical) system resulting from a long and laborious process of negotiation” (Gherardi & Nicolini, 2000). Such a negotiation result creates irreversibility as “the displacement, the creation of a link that did not exist before and that to some extent modifies the original” (Latour, 1999, p.197), while actors enter into irreversible networks (Hanseth, et al., 1996).

The standard as a negotiated order contains binding technical repertoires that are institutionally bound, recognized, and legitimate. Accordingly, *we call a standardizing event an N-event if it supports the goal of reaching an agreement*

about a specification through negotiation. Each result of N-events defines the nature, content, and form of a part or a whole set of specifications *as agreed* and thereby declares commitments, rights, and duties implicated by the agreement across standard setters, adopters, and other parties (e.g., regulators). Per definition, the final standard is established if and only if the whole specification is closed by an agreement concerning the substance of technical specifications and its implications for each actor. Moreover, all actors must recognize the agreement as legitimate. The final agreement must be preceded by a set of other N-events that gradually transform the status of non-legitimate and disagreed upon specifications into legitimate and agreed upon. Thus the set of final specifications create formal contractual relationships between standard setters and can also produce new regulations for standard-setting institutions. A failure to reach negotiation closure leads actors to reject technical specifications or their implications, and in so doing, break down the network.

The negotiations are also *path dependent* in that they draw upon existing contracts, contractual arrangements, and institutional practices that recognize, record, and enforce such contractual arrangements (regulatory statutes by standardization organizations, patent laws, trade secrets, etc.). Negotiations are also *path dependent* during the standardization in that they build on previous negotiation moves as well as known “negotiation spaces” in which actors have entered previously. This intrinsic connection between negotiation and network irreversibility explains also the immense difficulty of creating anticipatory standards. Standard setters can ensure the durability of technical repertoires only if the agreed upon standard will travel well across time and space. This occurs only if subsequent N-events constantly create, solidify and expand *new* actor-networks, which require either connecting to, or demolishing existing networks – both of which are extremely difficult to accomplish.

The form and content of N-events vary depending on the institutional context. Negotiations are not necessarily carried out during a single N-episode. As noted, they often refer to earlier umbrella agreements, rest on prevailing practice, or trigger a series of additional N-events across multiple institutional contexts (Schmidt & Werle, 1998). Negotiations take place often at official meetings, but often the deals are struck in hallways and in unofficial discussions (Haug, 2002). Negotiations are carried out by spokespersons who have a mandate (Latour, 1987). These include prominent engineers, strategy and IPR professionals, technology managers, and even politicians. The mandates are defined and enabled through the intermediation of rule makers and enforcers (other spokespersons, standard-setting organizations, committee chairpersons, etc.). The mandates are about technical choices, licensing, sharing of IPR, market shares and market making, enrolment of new actors, or their disconnection. Each mandate is defined by its characteristics, including the scope of technical specifications, types of contracts, IPR pool documents, etc.

Sense-Making (S-events)

Anticipatory standardizing exhibits a form of technological imagination that writes technology repertoires for the future world (Latour, 1999). Metaphorically it is “persuasive and constitutive storytelling about the future” (Suchman, 2000, p.319). By telling a different story, standard setters expand their horizons and become aware of prejudices they bring to their interpretations of current technology use (Gadamer, 1975). Such story telling is named in ways from organizing visions, futuristic scenarios, to technology fads (Swanson & Ramiller, 1997) and documented in policy and market reports, strategy formulations and technology road maps, consumer focus group reports, or memos that record ongoing conversations among standard setters (e.g., minutes).

Overall, standardizing creates and enacts meanings about designs, artifacts, design and use processes, agreements, and actors and their identities which, over time, transform and renounce standard setters’ interpretive frames about the technology (Karnoe, et al., 2005; Latour, 1992). Actors at the same time attach meanings (perspective making) to standards and make sense of others’ meaning projections (perspective taking) (Boland & Tenkasi, 1995). In so doing, they rationalize what they are doing or have been doing, and shift their cognitive strategies in relation to the technology-to-be-standardized, the actors involved, or the institutional context (Callon, 1986; Latour, 1995; Weick, 1993). This ebb and flow builds and questions technological frames and leads to the attribution of new meanings to standards, actors, and the context (Bijker, 1995).

No anticipatory standard will be agreed upon unless actors *make sense* of it and can imagine the types of repertoires embedded in it operating in a future world. In a narrow sense (no pun meant here), sense-making is about how the design meets set-up engineering criteria, such as simplicity or elegance in design. In a broad sense it embraces a broader set of cognitive tasks that help designers understand how proposed designs relate to the future social, technological, and institutional world, and how they shape and are shaped by these worlds. In the following, we will talk about sense-making in a broad sense.

After Weick (1995), we define sense-making as an actor’s interpretive response to observed and imagined changes that result from design or negotiation events, or changes in the standardizing context. *Events that read meanings into anticipatory standardizing events and actors are called sense-making events (S-events)*. Sense-making closure means that there is a set of S-events that produces a set of stable interpretive frames among the involved actors, which defines the meaning of the standard for their context. A failure to reach such a closure is common. It signals controver-

sies around what the technology is supposed to do, or how it relates to future use or institutional contexts.

S-events draw upon actors' past experience and inherited technology frames that coordinate sense-making. Therefore, anticipatory standardizing poses significant challenges when such frames diverge or break down. For instance, in the early phases of the Bluetooth standardization, participants from the computer and telecommunications industries had to pour significant efforts into formulating a joint understanding of the scope of the technology-to-be-standardized because their views on what would make the standard successful differed (Keil, 2002). Failures in sense-making generate unstable technical specifications, shifting actor identities, and a fluid institutional context, all of which can result in disagreements.

Though anticipatory sense-making is proactive, it is simultaneously retroactive. Standardizing starts with a retrospective reading of current technology that erects a context that is *path dependent*. Anticipatory standardizing becomes proactive when it attributes a *different* meaning to a not-yet-invented technology, and thus enacts a new environment (Weick, 1995). It generates mindful deviations so that the technology becomes re-defined, re-evaluated, and re-contextualized (Garud, et al., 2002).

EVENT GRAMMAR

An event's significance is produced by its place and role in an event sequence. We need therefore to combine identified events into sequences. Such networks of events connect all events to process outcomes (Pentland, 1999). Given that anticipatory ICT standardizing is highly complex, non-linear, and chaotic (Markus, et al., 2006; Nickerson & Zur Muehlen, 2006), and takes years to unfold, the event grammar—a way to connect events—has to be built on assumptions about the complexity. We therefore assume non-linearity among design,

sense-making, and negotiation events: They can be connected by relationships that exhibit circularity, concurrency, and hierarchical organization. We next extend the process analysis to event network analysis. We explore first how events will be organized into sequences and thereafter how we can infer why and how outcomes relate to such sequences.

We devise an *event grammar* that articulates multiple heterogeneous relationships between design, sense-making, and negotiation events. The grammar consists of two levels. The first level—called *binary grammar*—describes how any two events can be positioned into adjacency pairs. Second, a *choreography grammar* offers a set of principles that help string adjacency pairs into larger sequences. Overall, the proposed *grammar*—by organizing events into sequences—integrates three separate perspectives that underlie design, negotiation, and sense-making activities. In so doing, we account for a problem noted by Langley (1999): How can different theoretical perspectives be combined in process explanations? In our analysis, each event type is germane to understanding one critical dimension of anticipatory standardizing. Yet, each dimension alone is insufficient in explaining the final outcome. Utilizing multiple perspectives simultaneously and by integrating them through the event grammar, offers a feasible strategy to carry out a multi-perspective analysis and arrive at plausible process theories.

Binary Grammar

The binary grammar detects *reasons* for moving between the events and expresses their natural temporal order (before, after, and parallel). The first step in the analysis is therefore to relate any event to its preceding and/or succeeding events. Each event can thus be connected to two sets of adjacency pairs: a set of events that lead to this event, and a set of events that follow it.

Building our binary grammar rests on two main principles. First, events of *any type* can be organized into adjacency pairs based on their temporal properties (before and after). These properties arrange events into sequences that maintain chronological (topological) order. Second, any event can trigger and be triggered by any other event type. For instance, a new design can trigger sense-making about potential technology applications in the market, it might trigger negotiation about intellectual property rights regarding the design, or it might trigger additional design to integrate it into a new architecture. Third, we distinguish in each event an actor’s *choice* that shifts his or her cognitive orientation from one type of “activity” into another, or from one activity into another activity within the same type. These relationships define the “logic” of standardizing events, and will form the kernel in explaining the outcomes. We do not expect that any preceding event will *causally* determine the type or the

content of the succeeding event. Rather, any event type can trigger another type of event, subject to the outcomes of the preceding events, and actors’ conscious or unconscious choices, and the impact of contextual conditions. For instance, a technical design can trigger negotiation among actors in the same industry who share a similar understanding of its application, while the same design can trigger sense-making in a broader community that needs to relate the design to its environment as to arrive at a common understanding. Succeeding events can also be multiplied into several sub-events through decomposition. For instance, during negotiation, sense-making events might be triggered to find out how each design alternative relates to the goals of engaged actors. Negotiation can thus only continue after the sense-making in each alternative path is completed.

Table 2 classifies a space of possible event adjacency pairs. Many of the defined patterns were identified in several empirical investigations that

Table 2. Binary Relationships Between D-, N-, S- Events

Preceding/ Following Event	D-event	N-event	S-event
D-event	DD1: Decompose and refine technical specifications (Baldwin and Clark 2005) DD2: Test, Evaluate (Manninen 2002, Haug 2002)	DN1: Compromise between designs; (Haug 2002) DN2: Agree on final design; (Manninen 2002) DN3: Agree on design parameters/ evaluation criteria (Manninen 2002)	DS1: Justify design feature (Fomin and Lyytinen 2001) DS2: Evaluate use scenarios (Schmidt and Werle 1998) DS3: Imagine new contexts of using technology (Keil 2002)
N-event	ND1: Refine and search for a negotiated solution (Haug 2002) ND2: Develop a solution to counterattack existing designs (Funk 2002), (Garud et al 2002)	NN1: Negotiate rules; (Manninen 2002) NN2: Negotiate actor composition; (Garud et al 2002, Keil 2002) NN3: Negotiate after disagreement (Haug 2002)	NS1: What does a compromise mean? (Haug 2002) NS2: Does the negotiated standard make sense? (Garud et al 2002) NS3: What does the standard mean for technology evolution? (Haug 2002)
S-event	SD1: Develop a new scenario to reconsider design (Manninen 2002)	SN1: Change use context to negotiate design options (Faraj et al . 2004)	SS1: New use scenario triggers sense making of other technologies (Funk 2002)

we have listed in the table. In the table each row defines a type of the preceding event and each column a type of the following event. Overall, the table lists a set of possible event pairs and reasons why they are connected together. The table was derived based on a content analysis of empirical investigations of standardization processes as shown by the references. Within each reference analyzed we identified a set of two different types of events and then analyzed what triggered the shift from one event to the next. Overall, the table outlines a number of event pair *archetypes* and helps identify typical event pairs. For instance, a design-design event pair consists first of an earlier event that triggers a later decomposition refinement. A typical negotiation-sensemaking pair could consist of first negotiating technical commitments and then engaging actors in sense-making to explore what this compromise entails in the future market. The table is not, however, complete in the sense that the reasons for these relationships were empirically identified and additional reasons to connect events might emerge from future studies. Nor does it replace an in-depth analysis of detailed relationships between events and their context. Overall, the binary analysis demands a careful articulation how events and their contexts interact in order to find specific reasons why such moves took place.

Event Network

An event network identifies the connections among *all* standardizing events organized over time as defined by temporal and adjacency relationships. A network of events thus represents how standardizing reached a closure with respect to design, negotiation, and sense-making, and overall produced a standard, or how it failed to do so, and if so, what events “failed.” We need this level of aggregation in our analysis as event pairs alone show how events relate to one another, but not why specific standardizing results emerged. By integrating the events into a network, the

result is shown to be generated by a multi-path event sequence that takes place in a set of shifting contexts. It involves both chronological and activity-based relationships between events. By increasing the complexity of the network level analysis, we increase the accuracy in our process accounts (Weick, 1989).

In formulating an event network, we can deploy visual mapping techniques (Langley, 1999) that use graph theory to organize event pairs into networks depicting both time and activity-based dependencies between events. These graphs can be analyzed for their structural properties and at the same time they offer a holistic overview of the event networks. We build an event network in three steps. First, we aggregate events into a *temporal sequence* by sorting events into chronological chains by utilizing their start and end times. Temporal ordering creates a timeline of the standardizing process and allows us to identify both sequential and concurrent events. Second, since each event can be triggered or trigger other events, we need to aggregate event pairs into *sequences according to their functional outcomes*, i.e., their activity-based relationships. We further need to identify which events change the context, or are shaped by the context. An *activity-based ordering* creates a functional map of the standardizing processes and observes which events are decomposed into sub-events (Simon, 1977), and which events lead to other events by changing the type of the event, its content hops between types of events, or the content of the event.

In a third step, we *compare and integrate the temporal, functional, and activity-based networks*. The resulting event network describes a) temporal (x ended before y), b) functional (x produced input to y, or x needed type-y input), and c) activity-based dependencies (what types of events x lead to an event y). This network organizes events *sequentially, in parallel, and iteratively*. The outcome is not a pure sequential model that most process theories utilize (Pentland, 1999), as it integrates multiple, including iterative, connections between events.

PROCESS LOGIC

Logical Inference Rules and Deductive Process Explanations

The event networks chronicle event sequences that either lead to a standard (closure) or fail to do so. By being grammatically “correct,” the choreography conveys one logical premise to explain the observed outcome. Yet, knowing which design, sense-making, and negotiation events took place, and when and how they were related, does not explain yet what generated the pattern and its outcome (Pentland, 1999). To explain why such outcomes emerged, we need to draw upon logical and theoretical rules that are applied to the “structural characteristics” of the event network and the context (Pentland, 1999). An analogy with stories might help here to illustrate our point: grammatically correct sentences are necessary, but not a sufficient condition of telling a plausible story. To be plausible, a story requires a narrative (a story line) in addition to being composed of grammatically correct sentences. Similarly, the story of a standardizing process requires a narrative (story line) that informs why events were strung together the way they were. To accomplish this, explanations require a logical narrative from the used process representation that creates a plausible scenario of how the standardizing unfolded, and how and why a standard emerged. To create such narratives, we need theoretical and logical rules that conceptually connect events and outcomes (Pentland, 1999). Discovering these connections, however, does not yield a strong causal explanation: event sequences are *not* both necessary and sufficient conditions for producing the outcome. In contrast, we show why Y resulted in process X though there can also be other situations under which Y can be achieved.

While crafting process explanations we draw upon a set of inference rules. A *rule of inference* is a scheme for constructing valid inference. In logic, such schemes establish syntactic relations

between a set of formulas called *premises*, and an assertion called a *conclusion*. These relations are used in inference to arrive at new, true assertions. Rules also apply to semantic and pragmatic arguments, but here their formulation is more difficult and controversial (Toulmin, 1959). Yet, the discovery and use of rules and associated theoretical models that connect events, standardizing contexts and standardizing outcomes in plausible ways equates with the goal of building process theories (Pentland, 1999; Langley, 1999). In our case, this calls for formulating inferences that address the following question: Why and how was a standardization closure reached given the event sequence and the context? Formulating such an explanation poses a significant intellectual challenge since inference rules for process data are not well axiomatized as are rules of inference for variance-based explanations (Shadish, et al., 2003). For example, the validity and reliability of process explanations are difficult to establish (Pentland, 1999).

We are often left with our imagination in formulating such rules and must rely on their intuitive appeal. No wonder that Langley (1999) calls process theorizing a “synthesis” and claims that no matter how carefully we execute the process analysis, this alone does not guarantee a good result. Synthesis requires leaps of imagination to organize events into plausible narratives by inventing new worlds and logics (Weick, 1989). Langley (1999) suggests theoretical triangulation and matching of heterogeneous models as one means of developing such rules. This was already followed above in formulating rules to build up event networks. This construction by itself generates iterations between data and their explanations. Though unavoidable, we think that such iterations can be further reduced by applying some rules to analyze a given event network at any time point during the analysis.

One method of reducing iterations is to match taxonomies of generative mechanisms with produced event networks. Pentland (1999) suggests the

following mechanisms: 1) life cycle; 2) teleological (goal seeking); 3) ecological (variation, selection, and retention); and 4) dialectical “motors” (Van de Ven & Poole, 1995). Yet, these taxonomies do not provide good “meta-rules” regarding which type of explanation one should choose for a given data set. In fact, most process descriptions can be cast into multiple explanations (Pentland, 1999). For example, standardizing can be viewed as a teleological process from an actor’s viewpoint, as an ecological process from the viewpoint of a technological system, or as a dialectical process from the viewpoint of multi-actor negotiation. Many generative mechanisms can be matched with any observed process “surface structure” leading to what Langley calls the “alternative templates strategy,” where an investigator proposes “several alternative interpretations of the events based on different, but internally coherent sets of a priori theoretical premises” (Langley, 1999, p.698). This strategy is followed in our process framework in that each sequence of types of events (closure) imposes alternative explanations about the process. Yet, none of them offers a complete account, and therefore dynamic interactions between design, sense-making and negotiation, and associated local perspectives need to be accounted for in the analysis.

Inductive Inference Rules Based on the Content of Event Networks

We propose next an inductive strategy to craft process explanations. This strategy helps exclude alternative explanations by iteratively applying inference rules that explore and test internal validity threats associated with proposed explanations. These rules can be organized according to increasing complexity and generality. We differentiate between inference rules that operate on: 1) singular events, 2) binary event pair rules, and 3) event network rules.

Singular Event Rules

These rules operate on each event and seek to confirm that the event description reflects the empirical reality, and that its classification into event types and a related event profile is valid. These rules guarantee that the narrative that will follow is based on validated events and event constructs.

Rule SER1: *The description of each design, sense-making, and negotiation event needs to be complete for a valid narrative to emerge (Pentland, 1999).*

Here, complete means that each event description must fully express critical properties, i.e., input, output, type of event being applied, actors associated with the event, and context and timing of that event. Applying this rule improves the internal validity of explanations. Omitting elements leads to misleading inferences, given the complexity of anticipatory standardizing and the frequency of unforeseen events, such as new technological possibilities, or changes in the context. A more complete description helps clarify the reasoning behind an actor’s moves that underpin events. In particular, when we explain *why* actors behaved in a particular way and *why* specific events ensued, completeness is the first criterion for internal validity. In addition, a careful depiction of events in a narrative form helps detect serendipities that shaped the process trajectory (like unexpected technological discoveries).

Rule SER2: *The classification of events into design, sense-making, and negotiation events integrates alternative theoretical perspectives to account for the process and its results and helps detect multiple explanations for observed events, and excludes or foregoes proposed explanations.*

By using this rule we improve the internal validity of the explanation by urging the investigator to apply multiple theoretical perspectives to the same set of events, thereby applying and excluding alternative explanations. Multiple perspectives allow the investigator to identify additional events that might be triggered by other events. For instance, when an event is analyzed through the design, sense-making, and negotiation lenses, it might become apparent that while it is a design event, during the event, a sense-making or negotiation event is spawned that was instrumental. Particularly, when events sequences fail to reach closure, such spawned event might be the underlying reason for the failure. For example, an investigator may ask why there was no closure on sense-making. Was it because the design was so novel and incomplete that actors could not imagine the implications of its use, or was it just not designed well?

Binary Event Pair Rules

Binary event pair rules operate on event pairs and seek to validate and infer explanations of changes in actors' cognitive orientations.

Rule BEPR1: *Shifts in event types signal changes in the actors' cognitive orientation.*

When one or more standardizing events produce a standardizing event of a different type (e.g., a design event triggering a sense-making event), we can detect two reasons for this change. First, when one cognitive activity is completed, that is, the event is finalized, standardizing will continue with a new event type. For instance, once the design of a set of components has been completed, the actors might proceed to sense-making or negotiation on how to integrate these components into the system. Identifying the event pairs in which new types of events were triggered helps the investigator to trace change in cognitive orientation during different time periods.

Rule BEPR2: *Shifts in event types prior to reaching closure help identify critical events that changed standardizing trajectory.*

More important than events that trigger just new event types are events that trigger new event types before the process reaches a closure. For instance, during design the engineers might encounter technical alternatives that would force them to select through sense-making multiple new use scenarios and then to negotiate which of these scenarios help drive design. Events that trigger these different event types before a closure is reached signify situations where main challenges (Hughes, 1987, calls them "reverse salients") that emerge during standardizing were resolved by adopting a fresh approach. By applying this rule, investigators can observe critical moments in the standardizing process and identify what shifted when critical path dependency shaping and breaking events took place.

Event Network Rules

Event network rules operate whole event sequences. Here we seek to use pattern matching rules to increase the internal validity of explanations by generating all possible explanations for the observed outcome, and excluding them iteratively. Such internal validity analysis is applied to event sequences for one standardizing process at a time.

Rule WCAR1: *All event paths in the event network should be consistent with the observed process outcome.*

The first rule at the event network level is that all event paths should be consistent with the observed outcome. For instance, if a standard fails to emerge, the observed process sequence should include a failure to reach closure either in design, negotiation, or sense-making. Similarly, if a successful standard emerges, the narrative

A Framework to Build Process Theories of Anticipatory ICT Standardizing

should entail a sequence that explains closure in all three types. Event sequences that are inconsistent with the observed process states suggest omission of critical events or the omission of critical interactions with the context.

Rule WCAR2: *Deviations from the process signify important junctions in standardizing.*

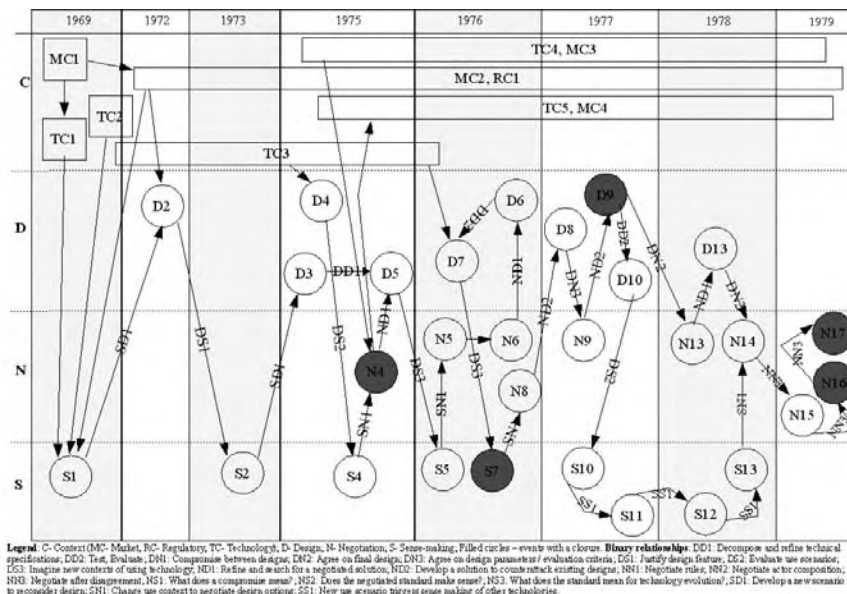

Per definition, a complete standardization plan should define activities that lead to closure in design, sense-making, and negotiation. In most cases, such completeness is lacking and difficult to achieve due to a high level of ambiguity in anticipatory standardizing. Comparing the actual event network with the planned process activities provides important insights into episodes that explain the different process outcome. It first shows the level of ambiguity and incompeteness in the original plan. Second, deviations show when the standardizing process became chaotic and therefore moved to an unanticipated trajectory. This happens often when the external environment shapes the process in an unexpected way, or the

process generates unexpected outcomes. For instance, a deviation from the plan can suggest that critical events shaped the context that triggered unforeseen sense-making or negotiation events.

DEVELOPMENT OF THE MOBILE SWITCHING SYSTEM (MTX) FOR THE NMT SYSTEM

We will next illustrate how to use the process theory framework by analyzing the standardizing of the Mobile Switching System (MTX) for Nordic Mobile Telephone (NMT) by drawing upon the rich description offered in Manninen (2002). The NMT 450 standard was published in 1979–3 years before the first NMT service—and it formed the first public standard for mobile telephony. The standardizing of a key component of the standard—its switching platform (MTX) specification—offers a vivid and interesting episode for analyzing anticipatory standardizing processes. Due to its virgin origin NMT standardization, it involved high levels of uncertainty both in terms

Figure 1. MTX event choreography

of service, architecture, and technology choices. Using Manninen's (2002) narrative as a baseline, we identified first all key events in the standardization process (Appendices 1 and 2). Then applying event rules SER1 and SER2, for each event we identified type, context, timing, actors involved, as well as input and output (preceding and following events—see Appendix B).

Having compiled the complete event list enabled us to draw a visual representation of the events and their relationships (Figure 1) for the subsequent analysis. This MTX choreography needed to be interpreted in the overall context of the NMT's mission: (1) its ambiguous scope and unclear objectives; (2) and the rapid change in digital switching capabilities during the standardization process. The graphical representation forms a matrix, where rows contain event types (context, design, negotiation, and sense-making), and the columns—timing (the start date) of each event. The process presentation shows how the MTX standardizing process was carried out through D-, N-, and S-events, and how these events connected. The final graphical representation can then be used for subsequent process analysis by applying binary and network event rules.

From the graphical representation, we can identify clusters of events that were critical in producing the final standard. To illustrate how some of these clusters can be identified we will focus next on some clusters. We can note first in Figure 1 several critical context events (market and technology change) marked by squares (e.g., MC1, MC2, TC1, TC2, TC4, and TC5). These concentrated in two intervals—at the outset of the project in 1969, and around 1975, when the digital switching technology became available and a decision had to be made about it. As shown, the project initiation context was dominated by the design and sense-making activities (S1 and D2). The MTX design choice (N4) contributed critically to the overall NMT success, since not only was closure reached in design, negotiation, and sense-making about switching, but these closures

also critically influenced other standardization activities within the NMT standardization as can be seen by analyzing the outward links from S7 or D9. Overall, multiple closures were reached which correspond to four core design issues faced with MTX development: 1) the type of network (N4), 2) the network architecture (S7), 3) the specifications for the MTX (D9, N16), and 4) the adoption of the MTX (N17).

Several insights emerge from the process analysis. When we investigate Figure 1, we can identify two periods where either D-, S-, or N-activities dominated the process. Between 1975 and 1977, we observe more design (D) and negotiation (N) activities, while after 1977 the design activity diminished and the sense-making (S) intensified. These centres of activity highlight one feature of event network analysis, i.e., what was the main focus of the process at different time periods. Figure 1 also shows how the context and the process interact, how events trigger and interact with each other, and what types of changes take place as a result (the symbols refer to Table 2 transitions above). Finally, it shows the linearity (e.g., S1, D2, and S2 events), temporal dependencies (S1 comes before S2), functional dependencies (D3 and D5), iteration (D5-D7, or N17 as a repeated attempt of N14) and decomposition in the process structure (D7 should have been followed by N9, but instead S7, N8, and D8 were triggered for the process to proceed, or failure to reach closure in N14 triggers N15 and N16).

Finally, from the methodological standpoint, we can see how the analysis follows the analysis rules outlined in Table 3, and how the application of these rules increased the reliability and internal validity of the analysis. It allowed building of a systematic explanation of process outcomes that could be described as an emerging process theory of the NMT standardizing. Specifically, graphical representation presents vividly the overall complexity of the process. Besides giving a simple yet comprehensive view of interdependencies between different events,

Table 3. Application of inductive inference rules for process analysis

Rule	Application
Rule SER1:	Each event type was derived from a detailed description of events using standardization committee minutes and interview data. Their classification is complete and all events that resulted in outcomes were identified.
Rule SER2	The classification of events to event types allowed us to identify moments where new ideas of mobile telephony emerged and where these were negotiated with other players like telecommunication manufacturers.
Rule BEPR1	We could observe significant shifts in standardization focus as a result of event type changes. One example is the re-thinking of service concepts after the initial design is completed—an example is a realization that the cost MTX exceeds the expectations, which results in rethinking the network structure and the number of suppliers: D6-D7-S7-N8-D8.
Rule BEPR2:	We observe situations where a failure to shift standardization focus leads to a successful closure—an example is the failure to start design again after D9, to which Ericsson did not yield (N16).
Rule WCAR1:	We could detect all observed closures based on the analysis of preceding events.
Rule WCAR2	The shift to design a digital switching platform resulted in a deviation in the original standardization plan (TC1, S1, D2), but at the end defined a different capability and scope for the service (TC5, MC4, S7, D9).

we also gain a more accurate description of the dynamics of the process (changing patterns of the event networks). We also obtain a better grasp of the dominating cognitive orientations based on which event types dominated the process at any given period of time.

DISCUSSION

This article set out to improve our understanding of anticipatory ICT standardizing by developing a process theory framework. The aim of the framework is to support generating plausible and generalizable explanations of *why* and *how* anticipatory ICT standardizing outcomes emerge. To this end, we developed a *lexicon* that consists of a typology of design, sense-making, and negotiation events, a *grammar* in the form of combination rules for events to develop *process representations* of anticipatory ICT standardizing events, *logic* rules that yield theoretical explanations based on the inductive analysis of process representations, and a discussion of the *contexts* in which standardizing unfolds.

CONTRIBUTIONS TO SOCIAL THEORIES OF STANDARDIZING

We expand process theories to explain ICT standardizing. The past years have seen a dramatic increase in the research on anticipatory ICT standards (David, 1995; Mansell & Silverstone, 1996) while we have witnessed increased problems with traditional ICT standards research (Garud, et al., 2002; Schmidt & Werle, 1998; Werle, 2000). While all recognize the increased role of *anticipatory standards*, our *actual* understanding of successful standardizing has decreased. Our article inches toward an improved understanding of anticipatory ICT standards by moving from the study of *standards* to the study of *standardizing*. This is a significant intellectual shift as it suggests that the study of standardizing is pivotal to our ability to understand this complex phenomenon.

The main contribution of this work lies in the expansion and integration of concepts derived from social theories of technology to anticipatory standardization research. Recent research in ANT and SCOT (e.g., Hanseth, 2006; Jakobs,

2006; Stewart & Williams, 2005) has begun to recognize that design, negotiation, and sense-making are all critical for understanding many standardizing processes. However, this work has remained largely fragmented. Our article addresses this weakness by developing an integrated, yet modular, framework that explicates relationships among these key concepts, and defines roles each theoretical perspective can play in explaining anticipatory ICT standardizing. Due to its complexity (Hawkins, 1995), process explanation needs to decompose the phenomenon into smaller building blocks (Hanseth, 2006). Yet, rendering a meaningful explanation of the whole and its outcomes demands an integration of these building blocks. We proposed here that design (D), negotiation (N), and sense-making (S) activities and their analytically controlled interactions offer one set of such building blocks.

The strength of this framework is that it draws on multiple streams of research on standardization in ICT: social process theories, where each is well suited to examine a specific “simpler phenomenon” in isolation. It organizes them into modular and comprehensive process accounts. The novelty of our work is not necessarily in *what* concepts we introduce, but in *how* we position them, and how we conceive them as a family of interrelated theoretical lenses. By bringing the design, sense-making, and negotiation elements together, we outline a basis for formulating rigorous, theory-based process analysis of ICT standardizing. This helps conceive each successful anticipatory ICT standard as, “a specific configuration of knowledge and industrial structure—it involves distributed knowledge, a precise definition of physical interfaces between components in a system, and an industrial structure with considerable division of labour and specialisation” (Steinmueller, 2005).

Anticipatory standardizing demands that individual designs, collective designs, and shifts in technology framing interact. Our emphasis on individual and distributed sense-making expands SCOT’s “technology framing” from a user-re-

lated activity about finished designs (Stewart & Williams, 2005) to sense-making about early designs by engineers and standard setters. This expansion is important given that anticipatory ICT standardizing embodies one key engine of ICT innovation and involves technical discoveries. Our study also goes beyond recent accounts of anticipatory ICT standardization offered by SCOT and ANT by highlighting the importance of collective engineering. Anticipatory standardizing rests on inventing genuine designs, as actors constantly generate designs and reconcile them. Focusing on the criticality of design has broader implications for Actor Network Theory studies. Anticipatory ICT standards will entail novel changes in technological capabilities and involve a high level of uncertainty. Accordingly, designers are simultaneously building multiple ambiguous and poorly understood networks, and they cannot predict consequences of their designs (Van de Ven, et al., 1999). This renders construction of actor networks an iterative process that has not been accounted for in ANT’s linear view of translation. We argue that such insight should also be reflected in process accounts. Therefore, we have outlined an iterative model of process analysis, which circumvents the limitations of linear process models.

CONTRIBUTIONS TO PROCESS ANALYSIS AND EXPLANATIONS

Our article makes a useful research contribution to process theorizing (Mohr, 1982; Langley, 1999; Pentland, 1999; Van de Ven, et al., 1999). Past research on processes has not explicitly discussed the refinement of process ontologies that are sensitive to the studied domains. For example, Langley’s (1999) excellent review focuses mainly on how process approaches can manipulate one-dimensional event data to yield process accounts. However, she never explores different *types* of events as one critical aspect

of formulating explanations. We feel that our amendment offers one useful way to improve the accuracy of process theories while keeping them still relatively simple (Weick, 1995).

Proposing a separate analysis layer of a “grammar” offers a flexible way to organize events into event sequences. The concept of grammar allows us to control how much iteration and parallelism will be allowed in process explanations. Most past process models assume a linear sequence either through successive stages, e.g., ANT’s translation model, or through linear sequences associated with a specific narrative (Pentland, 1999). While both templates are useful, the proposed expansion helps control the level of complexity and, if need be, tap into chaotic and random processes involving iteration that are frequent in innovative contexts (van de Ven, 1999). Finally, introducing a separate layer of inductive inference rules augments the narrative-based deductive “grand narratives” of process theorizing (van de Ven & Poole, 1995) with a set of validity-enhancing rules. The more complex process structures generated by our method can draw upon the improved computer-based tools that have been proposed (see, e.g., Ethno at <http://www.indiana.edu/%7Esocpsy/ESA/home.html>). We expect that such tools will help to better manage inherently complex process traces resulting from our analysis. Such more rigorous modeling of event interactions and sequences will also offer possibilities to simulate process behaviors using system dynamics, and to predict their outcomes under different contingencies⁴. Another alternative is to use emerging computational models of dynamic network analysis (Carley, 2006)

LIMITATIONS AND FUTURE RESEARCH

We emphasize that the proposed framework is not the same as a complete process theory. Rather, it offers an ontology of events and event sequences, a way to organize and represent event sequences and

a set of rules geared toward formulating plausible process explanations. As a general theoretical framework, in its current form it is not open to direct empirical validation. *We emphasize that only local theories formulated by using such a framework can be used explain standardizing processes and can thus be subjected to empirical validation.* The intellectual value of the framework lies in its domain-specific, systematic formulation of theoretical concepts that will permit investigators to craft, formulate, advance, and validate new types of empirical claims about anticipatory ICT standardizing. Such a framework hopefully will promote systematic building and validation of process theories that account for complex ICT standardizing phenomena.

Due to its modular structure, the proposed framework is not closed. In fact, any part of the framework—its lexicon, grammar, and inference rules—is open to further expansion and refinement. Such expansions are welcome when the framework is applied in local research settings. In future, we expect that the framework can be used to build process theories that approach anticipatory standardizing as a non-linear, emergent, and path-dependent process. Some recent research drawing upon our ideas suggest that this avenue is fruitful (Virilli, 2003; Mitra, et al., 2005) and they show that different standardization processes allow for design, sense-making, and negotiation events in proportions and they organize them differently over time. They also show that processes are chaotic and non-linear. Beyond these studies, we expect research in the following areas in the future: What designation of non-linearity—random or chaotic—can be detected (Van de Ven, et al., 1999) in ICT standardizing? Do specific sequences exhibit tipping effects towards a closure (Axelrod, 1984)? Can different types of event sequences be related to increasingly innovative outcomes (Autio, 1997)? What context changes create deviations from prevailing standardizing paths, and are there differences in how to respond to such deviations (Karnoe, et al., 2005)?

The framework can also be used to derive empirical accounts of some aspects of anticipatory ICT standardizing. For example, fast cycles between both D- and N-events punctuated by diffusion and experimentation resulted in successful standardization during Internet development in contrast to traditional SDO standardization where a long cycle of D events was followed by a singular N event (Abbate, 1999). Likewise, incentives and governance structures within the actors may radically shape interactions between the events (Benkler, 2001) raising the following question: How do the events shape the organization of standardizing actors? Finally, the framework can help critique and expand normative ICT standardization models that originate from product development and regulation theories (Schmidt & Werle, 1998). These models view ICT standardizing mainly as a linear refinement over one dimension: design or negotiation. Yet, our framework suggests that such models are inadequate as they prioritize design over negotiation or vice versa and ignore sense-making.

ACKNOWLEDGMENT

We are grateful to John King, Ari Manninen, Juha Knuuttila, Ping Gao, and Joel West for inspiring discussions that led to some ideas in the manuscript. Thanks go also to Dick Boland, Michel Callon, Michael Cohen, Sandeep Puro, Timothy Schoechele, Francesco Virili, Karl Weick, Youngjin Yoo, and Lynne Markus for detailed comments on earlier version of the manuscript. Apologies for remaining errors apply.

ENDNOTES

¹ The list of such standards is growing but covers, among others, standards on mobile technologies. See <http://www.3gpp.org/>; Web services—see [http://www.w3.org/2002/ws/\(GSM\)](http://www.w3.org/2002/ws/(GSM))—see <http://www.gsmworld.com/index.shtml>; mobile services (OMA)—see <http://www.openmobilealliance.org/>; Interoperability and loosely coupled computing services around the Semantic Web—see <http://www.w3.org/2001/sw/>; short range communication standards (Bluetooth)—see <http://www.bluetooth.com/>; programming platform standards (Java)—see <http://java.sun.com/>; networking standards (IETF)—see <http://www.ietf.org/>; web standards (W3C)—see <http://www.w3.org/>; or vertical information standards (Rosettanet)—see www.rosettanet.org

² We could as well use the term “activity,” but because the existing literature on process theories extensively uses the term “event,” we will follow this term.

³ To engage in such events designers must do one of the following: a) signal their willingness to reach an agreement or accept another’s invitation about designs; b) accept the principal concept and scope of the agreement; c) agree on the content and technical form of the agreement; d) agree on “gives” and “takes” (commitments) in relation to the standard and its outcomes (e.g., IPRs); e) agree on how to access the agreement; and f) agree on what conformance to the agreement means.

⁴ We are thankful to one of the reviewers for pointing this out.

⁶ Further in text as PTTs.

APPENDIX A

The Narrative of the MTX Development Process

The idea of a pan-Nordic cellular telephony system was conceived at the Nordic Teleconference in 1969. The decision included a plan to investigate possibilities for creating a common traffic radio system—as it was called at that time—for Nordic countries (Denmark, Finland, Norway, and Sweden). This decision (sense-making) was prompted by the market context—the growth of manual national car-telephone systems beyond expectations. The original design idea established a lasting technology context was about *creating a common and compatible Nordic auto-radio service*, which required novel market and regulatory context. Because of this, the scope of the innovation, during NMT standardizing was open for a long time and involved multiple designs over the next six to seven years while their feasibility and service quality was evaluated. The aforementioned events forming the context for the launching of the NMT project can be presented as follows:

MC1: The growth of manual national car-telephone systems beyond expectations.

Event Type: Sense-making (Market Context–MC); Timing: 1969; Input: none; Output: TC1; Actors: National PTTs⁵; Context: Growth of car-telephone systems.

TC1: Investigate possibilities for creating a common auto-radio service.

Event Type: Design (Technology Context–TC); Timing: 1969; Input: MC1; Output: S1; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system.

MC2: Creating a novel pan-Nordic market for the proposed common auto-radio service.

Event Type: Sense-making (Market Context–MC), Timing: 1969; Input: MC1; Output: S1, D2; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system.

RC1: A need for new regulatory context for the proposed common auto-radio system.

Event Type: Sense-making (Regulatory Context–RC); Timing: 1969; Input: MC1; Output: S1, D2; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system.

The design of the MTX subsystem formed a crucial element in the design of the NMT. Its design would largely determine the future of Nordic mobile telephony service—for example, how closely it would resemble normal telephony and how relationships between actors during mobile telephone use and installation were arranged. The architectural choice centered on the switching strategies, and whether to use digital switching platforms. This choice had not been fixed when the decision to develop the service was originally made (TC1). One reason for this was the lack of expertise among people who advocated the new radio system—radio engineers, and their inadequate knowledge of switching—which constituted a specific technology context (TC2). Because of the lack of expertise, the first system design idea (TC1) of possibly automatic switching gave way to an idea (sense-making) of an intermediary manual system (S1) (Fomin & Lyytinen, 2000).

S1: An understanding that an intermediary manual system would serve the needs.

Event Type: Sense-making; Timing: 1969-1975; Input: TC1, TC2, MC2, and RC1; Output: D2; Actors:

National PTTs; Context: Idea to create a pan-Nordic radio telephony system. Inadequate knowledge of switching of the radio engineers for the development of automatic switching system.

When the idea of developing an intermediary manual system had been accepted, possible design solutions for the manual system were proposed (D2). The NMT group made a summary of the types of exchanges (MTX), which were to be used for connectivity with fixed networks (PSTN) in the 1980s. Each of the proposed solutions was investigated for the suitability for MTX use (S2).

D2: A need to develop an intermediary manual system.

Event Type: Design; Timing: September 1972-September 1973; Input: S1, MC2, and RC1; Output: S2; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system. Initial MTX design scope.

S2: Inquiry about the suitability of the exchanges for MTX use.

Event Type: Sense-making; Timing: September 1973-October 1975; Input: D2; Output: N3; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system. Initial MTX design scope.

These events formed the first stage of the MTX development process. In 1975, the development context had changed—in 1975 automatic switching (D4) was chosen based on economic criteria (N4) (Toivola, 1992) after the NMT work group had analyzed the cost of alternative switching systems (S4). Yet, the design of an automatic switch after the decision was not something that could be easily done. At that time, cellular communication design was dominated by radio system concerns without considering the needs of switching (Lyytinen, et al., 2000) as radio engineers did not have expertise in designing automatic switches (TC3). As one switching engineer who participated in NMT development noted (Lyytinen, et al., 2000):

What the radio people were saying was that the challenge is now here on the radio side.... They didn't talk about analogue or digital switches, because they didn't have a clue about those, or microprocessor-controllers, anything....

To overcome this weakness, MTX design was carried out by expanding the actor network to Nordic telecommunication manufacturers (TC4, MC3). The design evolved between 1975 and 1978 through several cycles of design (architecture, switching capability, and service concepts), negotiation (cost, commitments and feasibility aspects), and sense-making (receiving feedback from manufacturers re-evaluating the service concept) (see Appendix B for the complete list of events).

The MTX design contributed critically to NMTs success (TC5, MC4) as it implicated several closure points for design, negotiation, and sense-making. Overall, five closures were reached which corresponded to four core design issues faced with MTX development—the type of network (N4), the network architecture (S7), the specifications for the MTX (D9, N16), and the actual adoption of the MTX (N17):

- **N4—The type of network and service concept.** The decision on an automatic digital switch was critical for the future sense-making and negotiation. When the issue was closed it affected broadly how the future service was conceived, the composition of the actor network, and added a new set of negotiations.

- **S7–The network architecture.** The Closure in the MTX sensemaking affected the whole image of the network-to-be among system developers. This closure was critically influenced by the technological expertise offered by telecom manufacturers and their market knowledge. As a result, designers re-conceptualized the network architecture. This resulted in a closure in sense-making, as the new conceptualization—an idea of a regular phone service in cars across all Nordic countries—had to be implemented in the network.
- **D9–The complete MTX specification.** The final specifications from three manufacturers were received in 1977 and the design specifications were frozen, i.e., the standard reached the design closure.
- **N16–The contract negotiation. Intensive negotiations took place around the MTX procurement.** Though specifications were frozen, the NMT group demanded changes as costs and service ideas need to be matched. The vendor—LM Ericsson—refused to make changes, closing negotiation.
- **N17–Sealing the MTX deal.** The negotiation closure was reached when the Finnish PTA finally gave in.

APPENDIX B

The Complete Event List

The Initial Context for the Commencement of the Project

MC1: The growth of manual national car-telephone systems beyond expectations.

Event Type: Sense-making (Market Context–MC); Timing: 1969; Input: none; Output: TC1; Actors: National PTTs⁶; Context: Growth of car-telephone systems.

TC1: Investigate possibilities for creating a common auto-radio service.

Event Type: Design (Technology Context–TC); Timing: 1969; Input: MC1; Output: S1; Actors: National PTTs; Context: Idea to analyze the technical feasibility of a pan-Nordic radio telephony system.

MC2: Creating a novel pan-Nordic market for the proposed common auto-radio service.

Event Type: Sense-making (Market Context–C); Timing: 1969; Input: MC1; Output: S1, D2; Actors: National PTTs; Context: Examine the need for a pan-Nordic radio telephony system.

RC1: A need for new regulatory context for the proposed common auto-radio system.

Event Type: Sense-making (Regulatory Context–RC); Timing: 1969; Input: MC1; Output: S1, D2; Actors: National PTTs; Context: Idea to anticipate the regulatory needs of a pan-Nordic radio telephony system.

Initial MTX Design Scope

S1: A inquiry to develop an intermediary manual system.

Event Type: Sense-making; Timing: 1969 to 1975; Input: TC1, TC2, MC2, and RC1; Output: D2; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system. Inadequate knowledge of switching of the radio engineers for the development of an automatic switching system.

D2: A plan to develop an intermediary manual system. The NMT group made a summary of the types of exchanges (MTX), which were to be used for connectivity with the fixed network (PSTN) in the 1980s.

Event Type: Design; Timing: September 1972 to September 1973; Input: S1, MC2, and RC1; Output: S2; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system. Initial MTX design scope.

Investigating the Suitability of the Exchanges for MTX use

S2: NMT group made preferences for the choice of suitable exchanges: AKE-13 (LM Ericsson) for Denmark, 11B, 11C (STK) for Norway, ARM (LM Ericsson) for Finland, A-205 (Teli) for Sweden.

Event Type: Sense-making; Timing: September 1973; Input: D2; Output: D3; Actors: National PTTs; Context: Idea to create a pan-Nordic radio telephony system. Investigating the suitability of the exchanges for MTX use.

D3: PTTs make their choices for exchanges: Denmark chose AKE-13, “unless there was a cheaper solution.” Norway chose AKE-13 for Oslo and Östland, separate MTX for other regions. Sweden chose A-205. Finland voiced no opinion.

Event Type: Design; Timing: September 1973 to January 1975; Input: S2; Output: D5; Actors: National PTTs; Context: Investigating the suitability of the exchanges for MTX use.

Choosing between Manual and Automatic Switching Systems

D4: NMT group considers an automatic switching system as a replacement for the manual one.

Event Type: design; Timing: 1975; Input: TC3; Output: S5; Actors: National PTTs; Context: Choosing between manual and automatic switching systems.

S4: Analyzing the development and maintenance (operational) costs of manual versus automatic switching systems.

Event Type: Sense-making; Timing: 1975; Input: D4; Output: N4; Actors: National PTTs; Context: Choosing between manual and automatic switching systems.

N4: Automatic switching system chosen based on economic considerations.

Event Type: Negotiation; Timing: 1975; Input: S4, TC4, and MC3; Output: D5, TC5, and MC4; Actors: National PTTs; Context: Choosing between manual and automatic switching systems.

Making Rough Draft for MTX Specifications

D5: NMT group started to work on MTX specifications. The specifications scheduled to be completed by May 1976.

Event Type: Design; Timing: September 1975 to June 1976; Input: D3; Output: S5; Actors: National PTTs; Context: Making rough draft for MTX specifications.

A Framework to Build Process Theories of Anticipatory ICT Standardizing

S5: In May 1976 potential suppliers were identified.

Event Type: Sense-making; Timing: May 1976; Input: D5; Output: N5; Actors: National PTTs; Context: Making rough draft for MTX specifications.

N5: Completed in June 1976, draft specifications sent to the suppliers.

Event Type: Negotiation; Timing: June 1976; Input: S5; Output: N6; Actors: National PTTs, suppliers; Context: Making rough draft for MTX specifications.

Bi-Lateral Negotiations with the Suppliers on the Technical Specifications of their Proposed MTXs

N6: Negotiations with suppliers were held in August 1976.

Event Type: Negotiation; Timing: August 1976 to October 1976; Input: N5; Output: D6; Actors: National PTTs, suppliers; Context: Bi-lateral negotiations with the suppliers on the technical specifications of MTX.

D6: On October 15, 1976, eight preliminary MTX offers received.

Event Type: Design; Timing: October 1976; Input: N6; Output: D7; Actors: National PTTs, suppliers; Context: Bi-lateral negotiations with the suppliers on the technical specifications of MTX.

D7: Evaluation of the received preliminary MTX offers. Decisions reported in December 1976.

Event Type: Design; Timing: October 1976 to December 1976; Input: D6, TC5, and MC4; Output: S7; Actors: National PTTs, suppliers; Context: Evaluation of the preliminary MTX offers for the economic and technical feasibility.

S7: The cost of MTXs was found to exceed the expectations (the smallest capacity MTX /1000-7000 subscribers/considered unsuitable). As a result, the number of ordered MTX was reduced significantly, which had a direct bearing on the network structure.

Event Type: Sense-making; Timing: December 1976 to December 1977; Input: D7; Output: N8; Actors: National PTTs; Context: Evaluation of the preliminary MTX offers for the economic and technical feasibility.

Limiting the Number of Suppliers

N8: NMT group negotiating on the number of manufacturers, which will be receiving the final MTX orders.

Event Type: Design; Timing: October 1976 to Q1 1977; Input: S7; Output: D8; Actors: National PTTs; Context: Limiting the number of suppliers for the initial MTX specifications.

D8: It was finally decided to limit the number of manufacturers to the following five: LM Ericsson, Motorola, NEC, C. Itoh, and Telefenno.

Event Type: Design; Timing: Q1 1977; Input: N8; Output: N9; Actors: National PTTs, suppliers; Context: Limiting the number of suppliers for the initial MTX specifications.

Sending Out Tender Invitations for MTX bids

N9: A tender for MTX specifications bids sent out to suppliers, requesting the bids to be received by December 1, 1977.

Event Type: Negotiation; Timing: September 1977 to December 1977; Input: D8; Output: 9; Actors: National PTTs, suppliers; Context: Tender for the initial MTX specifications.

D9: LM Ericsson, Motorola, and NEC have submitted their bids.

Event Type: Design (closure); Timing: December 1977; Input: N9; Output: D10; Actors: National PTTs, suppliers; Context: Tender for the initial MTX specifications.

Evaluation of the Bids

D10: Upon receiving bids from the manufacturers, the proposed MTX specifications are evaluated.

Event Type: Design; Timing: December 1977; Input: D9; Output: S10; Actors: National PTTs; Context: Evaluation of bids for the initial MTX specifications.

S10: A rough assessment has shown that there were shortcomings in LM Ericsson's offer, incompleteness in Motorola's offer, and minor weaknesses in NEC's offer.

Event Type: Sense-making; Timing: Q4 1977; Input: D10; Output: S11; Actors: National PTTs; Context: Evaluation of bids for the initial MTX specifications.

Re-Working the Deficiencies of the Initial MTX Specifications (Proposals)

S11: The uncertainties in the manufacturers' bids necessitated the NMT group to send a list of questions to the manufacturers in order to obtain clarifications.

Event Type: Sense-making; Timing: February 1978 to May 1978; Input: S10; Output: S12; Actors: National PTTs, suppliers; Context: Re-working the deficiencies of the initial MTX specifications (proposals).

S12: Reliability assessments were finished.

Event Type: Sense-making; Timing: December 1977 to May 1978; Input: S11; Output: S13; Actors: National PTTs; Context: Re-working the deficiencies of the initial MTX specifications (proposals).

MTX Delivery Negotiations

S13: Estimates of the costs stemming from the delay with NMT system's introduction are made. Sweden projected the loss of SEK 16 million if the NMT was delayed by one year.

Event Type: Sense-making; Timing: Q1 1978; Input: S12; Output: N14; Actors: National PTTs; Context: MTX delivery negotiations.

N13: LM Ericsson promises to ship the MTX to Sweden on May 1, 1981, to Norway on July 1, to Denmark on September 1, and to Finland on November 1.

A Framework to Build Process Theories of Anticipatory ICT Standardizing

Event Type: Neogtiation; Timing: August 1978; Input: D9; Output: D13; Actors: National PTTs, LM Ericsson; Context: MTX delivery negotiations.

D13: NMT recommends that the National Authorities to sign the corresponding contracts for the proposed MTX specifications. Denmark, Sweden, and Norway intend to sign the contract with LM Ericsson.

Event Type: Design; Timing: August 1978; Input: N13; Output: N14; Actors: National PTTs; Context: MTX delivery negotiations.

Signing a Contract for MTX

N14: All but Finnish National Authorities sign a contract with LM Ericsson. Finland considers the offer too expensive, seeks supplementary offers from LM Ericsson and NEC.

Event type: Negotiation; Timing: August 1978; Input: D13; Output: N15; Actors: National PTTs, LM Ericsson; Context: Signing a contract for MTX.

NMT Group Proposing Changes to MTX Specifications

N15: The NMT group approached LM Ericsson with the request to make changes to MTX specifications.

Event Type: Negotiation; Timing: 1979; Input: N12; Output: N16; Actors: National PTTs, LM Ericsson; Context: Choosing LM Ericsson's AXE exchange as the MTX for all Nordic countries.

N16: LM Ericsson refuses to implement the changes to MTX specifications, unless the delivery dates are postponed.

Event Type: Negotiation; Timing: 1979; Input: N15; Output: N17; Actors: National PTTs, LM Ericsson; Context: Choosing LM Ericsson's AXE exchange as the MTX for all Nordic countries.

LM Ericsson's AXE Exchange—The MTX of Choice in all Nordic Countries

N17: Reaching closure on negotiation—Finland signs the contract with LM Ericsson.

Event Type: Negotiation; Timing: 1979; Input: N14; Output: none; Actors: Finnins PTT, LM Ericsson; Context: Choosing LM Ericsson's AXE exchange as the MTX for all Nordic countries.

Chapter 2.3

How the National E–Strategy Shapes Competitiveness in the Information Economy

Alf Neumann

University of Cologne, Germany

INTRODUCTION

The ongoing discussion on what e-strategy does and what it can do for national information and communication technology (ICT) development has brought up a variety of government functions for the ICT environment, readiness, and usage in a country. The ICT sector plays a key role in furthering the ICT development process. This paper sheds light on the connection between e-strategy and the development of dynamic ICT businesses in Tunisia. The central question is how far e-policies may not only create a supportive environment for ICT, but also contribute to sustained success and competitiveness of ICT firms.

FROM ICT TO COMPETITIVENESS

Tunisia is one of the leading developing countries regarding its achievements in information and communication technologies (ICT) and competitiveness. Recently published comparative indica-

tors illustrate some remarkable performances in both fields. Tunisia is ranked 34 in the Networked Readiness Index (NRI) which covers 82 countries (Dutta & Jain, 2003). The country holds the highest ranking in Africa and in the Arab world. In the Growth Competitiveness Index (GCI) the country is ranked 34 (Cornelius et al., 2003), and in the Microeconomic Competitiveness Index (MICI) it ranks 32nd out of 80 countries (Porter, 2003). With the exception of South Africa, Tunisia's competitive indicators outperform all African and Arab states in the rankings. Also, with regard to government efforts to successfully promote ICT competitiveness, Tunisia is clearly showing the way among poor and middle-income countries (Lanvin, 2003).

The government e-strategy defines the overall framework for national ICT development. In Tunisia the underlying e-policy framework is embedded in the national development plan, currently the Tenth Plan 2002-2006. This intends software and information technology (IT) service companies to play more of a key role in

furthering the Information and Communication Technology (ICT) development process both as suppliers of technology at the core of the Tunisian information economy and increasingly as exporters (Ministère du Développement et de la Coopération internationale, 2001). The question is, beyond all the indicators, how far the e-strategy creates not only a supportive environment for ICT, but also contributes to the competitiveness of ICT firms, especially regarding software and IT service exports.

LINKING E-STRATEGY AND COMPETITIVENESS

Through development priorities set by the government e-strategy for the information economy and society, supply and demand conditions for ICT in a country are essentially influenced by the state. According to Lanvin (2003), the influence is more or less direct on four crucial determinants of ICT supply and demand. These are human and financial resources, and domestic and international market conditions. The role of the government changes from directly producing and using technology to indirectly fostering the information economy and society as both facilitator, by providing a supportive environment for ICT, and as leader by providing visions for ICT and its role in social and economic development.

However, the e-strategy integrates a variety of policy areas, and pursues a diverse set of social and economic development goals. Thus, it does not necessarily address the development of a specific economic sector or its competitiveness. The impact the e-strategy has on competitiveness depends primarily on the overlaps between the proximate business environment of firms and the national ICT environment. The more overlaps exist, the more the national conditions achieved and envisaged for ICT can affect the pool of essential input factors including the skills and knowledge firms can draw on and the corporate

goals that determine investments. According to Porter (1990), there are four attributes determining the business environment and its eligibility to support the capabilities of firms to develop and enhance competitive advantages. These are factor and demand conditions, the presence of related and supporting industries, the context of strategy, and rivalry.

The sector that is most dependent on the e-strategy regarding the effects of competitiveness is the ICT sector itself. The role of the government which either directly or indirectly takes part in ICT development has an impact on all relevant attributes of the proximate business environment (Lanvin, 2003).

As public ICT producer and buyer, the government may provide the fundamental ICT infrastructure and generate demand for ICT on the one hand, but may stand also in rivalry to private ICT producers on the other. Therefore a key question is, how much public demand and rivalry to public enterprises may affect the competitiveness of ICT firms (Porter, 1990), especially concerning software and IT service exports.

The more a government moves towards indirect ways of influencing ICT development, the more important is the focus of the e-strategy on improvements of macroeconomic conditions for the information economy, the generation of technological expertise, and the setting of market signals to trigger dynamic ICT businesses (Lanvin, 2003).

THE TUNISIAN GOVERNMENT AS ICT LEADER

Tunisia gave a high priority to ICT in its national development plan (Ministère du Développement et de la Coopération internationale, 2001). In so doing, the government made clear that it is a visible and driving force for technological progress in the country. For instance, Tunisia together with Singapore, Taiwan, and Finland has taken the lead

in the international comparison of governmental ICT readiness (World Economic Forum et al., 2003). Regarding ICT usage, the government is also more advanced than many other countries in Europe, or Asia, such as France, Portugal, Spain, Hungary, and India (World Economic Forum et al., 2003).

LAYING THE FOUNDATIONS FOR THE INFORMATION SOCIETY AND ECONOMY

Building the ICT Infrastructure

For the period of the Ninth Plan between 1997 and 2001 the Tunisian government invested \$1.016 billion US dollars¹ in ICT infrastructure, including telephone networks, Internet backbone, and other digital communication networks. The Tenth Plan provides \$2.070 billion US dollars to advance this process between 2002 and 2006 (Ministère du Développement et de la Coopération internationale, 2001).

Despite these investments, the country still has a below-average position regarding the availability and quality of access to communication networks (World Economic Forum et al., 2003). As with many other countries, Tunisia is still working on the densification of its existing telecommunication infrastructure. However, it is important to note that significant progress has been achieved over the last years regarding access and affordability (Dutta & Coury, 2003).

The number of fixed-line and mobile phone subscribers per 100 inhabitants increased from 6.5 in 1997 to 15 in 2001. Further progress of the network densification can be expected due to the liberalization of the market for mobile communication in 2002 when the monopoly of Tunisie Telecom was broken and a second mobile provider, Orascom Telecom Tunisie, entered the market. The costs of mobile telephony are

declining constantly and the number of mobile phone subscribers is increasing significantly. For example, in 2002 there were 400,000 subscribers and by 2006 the government estimates up to 3,000,000 users (Ministère du Développement et de la Coopération internationale, 2001).

Regarding the Internet, Tunisia plays a pioneer role for the region. In 1991, it was the first country connected to the Internet in Africa and the Arab world. Currently there exist 12 Internet service providers (ISP) in Tunisia. The Internet access for individuals and businesses has been improving constantly (*factor conditions*). With 12.83 per 100 inhabitants in 2002, the number of Internet accounts still remains low internationally. Whereas, Tunisia is the most advanced country in the Maghreb region in successfully facing the densification challenge for Internet access (World Economic Forum et al., 2003).

Eventually, the question is how far the priorities concerning the extension of infrastructure to reduce the digital divide on a broad social scale stand in conflict to the infrastructure improvement with special regard to the competitiveness of ICT firms through, for example, policies that support low costs for international communication (*factor conditions*).

Government Prioritization of Software and IT Services

Public investments in ICT contribute an important share in the overall turnover of the ICT sector (*demand conditions*). The public budget for hardware, software and IT services has expanded continuously. The Tenth Plan intends to increase investment from \$668 million to \$1.296 billion U.S. dollars between 2002 and 2006. Whereas, the government puts stronger emphasis on software and IT services with an average annual budget extension of 18.6% for services compared to 12.3% for hardware (Ministère du Développement et de la Coopération internationale, 2001).

Public ICT Production
