At first, it seemed that the project was quite successful. Many indigenous peoples—in particular, indigenous youth and women—started to explore the new technologies. Based on this demand, the project initiated a capacity-building program for indigenous peoples in the use of ICTs. As a result of the training, in particular indigenous youth quickly learned how to use the technology and started to make contact with the Ashaninka living in Brazil and other indigenous groups throughout Latin America. Based on the new skills, several community members developed a Web site for the community and began using the videoconferencing facility. At this stage of the project in late

2000, the international audience started to become interested in the project, and Mino Eusebio Castro, one of the community’s indigenous leaders and champion of the project, was invited to several international conferences to present the case as a best practice on how the Internet can ‘empower’ indigenous peoples by providing them with an instrument for the reaffirmation of their cultural identity and to contribute to their economic and social self-development.

At the same time, however, the project ran relatively quickly into serious difficulties. Firstly, right from its inception only a relatively few number of people actually used the telecenter and the entire project was controlled by a small group of indigenous leaders. As a consequence many indigenous peoples from within and in the surrounding communities felt excluded and began to envy the ones who were able to use and manage the center. Thus the project aggravated existing social tensions between the different groups within the community. Due to the long assimilation process within the project area, about half of the population in Marakiri Bajo identifies themselves as Ashaninka, with the other half as mestizos who have settled in the community relatively recently. The telecenter was controlled by the Ashaninka and was not open for the general public, excluding the non-indigenous population from its potential benefits.

In addition, the telecenter did not meet the high expectations of many indigenous peoples about its potential benefits, in particular in economic and social terms. At first, many people hoped that the new technologies would enable them to better sell their products of fruits and artisans to the market in Lima. Unfortunately, this objective went unrealized due to the lack of an online market for such products within Peru, as well as the communities’ limited knowledge and experience with e-commerce.

Moreover, many people encountered problems in terms of being able to relate to the new media due to the lack of local content in their own

language. In particular, many women became relatively quickly disinterested in the technology, as they felt that the center did not provide them with any concrete information or services they could use in their daily lives. The only group that continued to use the center was indigenous youth. Finally, the videoconference equipment was entirely underused due to a lack of both the supply of educational programs and a very low demand for this service from the community.

On the night of August 29, 2001, these difficulties culminated, when the telecenter burned down and was almost entirely destroyed. It remains unclear to this date who was responsible for this incident or what the motives might have been for the destruction of the center. After this incidence, several community members decided to rehabilitate parts of the center and restarted the program the following year, giving it clearer objectives and grounding it in a much more realistic approach. After a 6-month period of reflection and internal discussion, the community relaunched the ICT program through the opening of a local radio station. The Ashaninka radio station is now producing and broadcasting local programs about agriculture, education, health, and cultural topics in the Ashaninka language to about 10,000 people in the project area. The Internet continues to be used, but through existing telecenters in Satipo, the closest intermediary city.

This case study raises a series of research questions: What are some of the key lessons learned from this example? What are some of the key factors that led to the difficulties of the program? How could some of the problems have been avoided?

The first important factor that contributed to the difficulties of the project is the overall complex political and socio-economic context of the project area. As a result of almost 100 years of continuous colonization of the Ashaninka territory, many communities such as Marikiry Bajo have been divided and have suffered under tremendous pressure to maintain their cultural

identity. In addition to invasion of their lands, many indigenous peoples became the victims of violence during the confrontations between the Shining Path and government troops in the 1980s. This violence had severe consequences for them, and in spite of the end to the widespread violence, several guerrilla groups remain sporadically active in close proximity to the project area (see Appendix 2).

Secondly, the project entirely bypassed the existing organizational structures of the indigenous peoples of the Amazon region in Peru. In order to represent the interests and to fight for indigenous rights within the political system of Peru, the indigenous peoples have formed AIDSESEP, a national indigenous organization representing the large majority of the indigenous peoples of the Peruvian Amazon. AIDSESEP as a membership organization has six regional offices, one of which is located in Satipo and represents the interests of the Ashaninka people of the central Amazon. By executing the project directly at the community level, without any coordination with the traditional organizational structure of the indigenous in Peru, the project created tensions between the different indigenous communities and alienated many Ashaninka leaders within AIDSESEP.

Thirdly, the project's design overemphasized the role of technology and did not carry out the necessary groundwork for the ICT investment. It seems that the consultative process at the planning phase was much too scattered and did not provide sufficient space for discussion and dissent within the community. The process did not include from the outset the non-indigenous population, which contributed to the raising of tensions within the community. Furthermore, the technological solutions, in particular the videoconferencing facility, were not based on real needs from the communities and thus remained underused.

Finally, the local community was not supported by any local intermediary organization; instead the project was being monitored by the

Colombian foundation, Fundación Multicolor. In this way, the investment on the infrastructure was not adequately complemented by key preparatory steps identified earlier such as the carrying out of an information needs assessment, building of local content, or extensive capacity-building workshops in the use and maintenance of the technology.

KEY CHALLENGES IN THE USE OF ICTS FOR INDIGENOUS PEOPLES' DEVELOPMENT

While the case studies mentioned have demonstrated that new ICTs have the potential to improve the well-being of indigenous peoples, there continue to exist tremendous challenges for indigenous peoples to make meaningful use of ICTs. The following section will highlight several key challenges.

Ownership and Trust

One of the most important issues for indigenous peoples is how they can control the process of the introduction and use of ICTs in their communities. Many indigenous peoples have expressed their concerns that this process is being driven by outsiders and emphasize that there exists a threat that these new technologies can lead to new dependencies for indigenous peoples. In order to avoid such new dependencies, it is particularly important that indigenous peoples are appropriating these technologies in order to be able to adapt ICTs to their own cultural and social context. It seems that the potential benefits of ICTs for indigenous communities can only be fully recognized, if indigenous peoples themselves acquire the necessary technical skills and know-how in managing and “owning” the technology (Gigler, 2001, p. 36). As shown earlier in the case studies, intermediary organizations that enjoy the trust of local communities play an essential role within

this process by providing long-term technical assistance to indigenous communities.

Generation of Local and Relevant Content

Indigenous communities are rich in traditional and indigenous knowledge. At the same time, however, the traditional indigenous information systems are based on an oral tradition, and there are not many experiences through which indigenous communities were able to produce their own local content and to disseminate it through the Internet. As the previous analysis has shown, the large majority of information found on the Internet is being produced by outsiders to the communities, instead of being developed by indigenous peoples themselves. The experiences described in the case studies have demonstrated that the capacity building of indigenous peoples not only in the use of the Internet, but also in the development of their own content, is crucial to allow indigenous peoples to derive more meaningful benefits out of the use of new ICTs. The production and sharing of content is particularly important to enable indigenous communities to share information and lessons learned with each other, and learn from each other's experiences.

Intellectual Property Rights and Indigenous Knowledge

Another important challenge for indigenous peoples is the issue of how they can control and manage their intellectual property rights and protect their indigenous knowledge. Many indigenous leaders have expressed their suspicion about the use of information about their communities by outsiders. They emphasize that the introduction of ICTs has to be based on the recognition of indigenous peoples' basis rights (i.e., self-determination, land rights, etc.), as ICTs cannot be seen in isolation from the overall context in

which indigenous peoples live. Consequently, a key demand of indigenous peoples is to establish clear international and national frameworks for the protection of their intellectual property rights, in order to avoid that the introduction of ICTs threatens their cultural heritage and indigenous knowledge (WSIS Global Forum of Indigenous Peoples and the Information Society, 2003). As the example of the telecenter project from Mexico has demonstrated, frequently ICT projects underestimate the importance of taking the cultural and political context of indigenous communities (i.e., the need to adequately protect indigenous knowledge) into account and subsequently face serious problems in their implementation (Robinson, 2000).

Literacy and Capacity Building

A large number of indigenous peoples speak and write their own indigenous language. In particular, indigenous women have frequently very limited access to formal education and thus are monolingual. Consequently, they have great difficulties interacting with the world outside their own communities. Low literacy levels represent a major challenge in increasing the use of ICTs in indigenous communities around the world. The high correlation between being indigenous and poor is based to a large extent on the lack of equal access to education (Pscharapoulos & Patrinos, 1994). As the case studies have demonstrated, it is crucial that indigenous peoples gradually build up capacities to use and manage modern technologies, so that they can determine by themselves how to make use of ICTs for their own development. The objectives of ICT capacity-building activities hereby should not only be limited to train indigenous peoples in the practical use of ICT applications (i.e., use of e-mail), but also to enhance their ‘informational capabilities’ (i.e., capacity to analyze and evaluate information). In spite of the efforts to strengthen the capacity

of indigenous peoples to use new ICTs, language barriers remain a major challenge when making use of the new technologies. It is estimated that approximately 75% of the content on the Internet is in English, and there exists almost no content in indigenous languages. Consequently the benefits of using the Internet are relatively limited to many indigenous peoples (Kenny, 2003). A very innovative solution addressing this issue represents the multilingual translation system, Atamiri (<http://www.atamiri.cc>), developed by Iván Guzmán de Rojas, a Bolivian scientist. This computer translation system is made up of a set of natural language processing programs based on a set of mathematical algorithms and is capable of automatically translating text from six languages into the Andean language of Aymara and vice versa.

Existing Economic and Social Inequalities

It needs to be stressed that the impact of ICTs has to be seen within a much broader context of existing economic, social, and political inequalities that are key barriers to indigenous peoples’ development. It needs to be fully acknowledged that these structural constraints frequently limit the impact ICTs can have on the well-being of marginalized groups. For instance, the extent to which subsistence farmers can benefit from information provided by the Internet will vary according to other factors such as land rights, proximity to market, available means of transportation, and the overall existing degree to which large-scale producers are dominating agricultural markets. Improved access to market prices represents an important but not sufficient condition to address existing market failures (Curtain, 2004). Thus important challenges remain to make use of ICTs for social change. It seems that the introduction of ICTs can only incrementally improve the well-being of marginalized communities, and needs to

be accompanied with complementary programs addressing existing structural inequalities. For instance, in the case of subsistence farmers, they could form a cooperative in order to join forces and to enhance their overall negotiating power position within the marketplace.

Information Flows Between Different Levels of Indigenous Leadership

A key challenge for the effectiveness of ICTs is the lack of information flows between the different levels of indigenous leadership. This issue addresses the underlying power relationships within the indigenous movements. It seems that a very small number of international indigenous leaders have privileged access to information and do not share this information with national leaders or with the grassroots. While ICTs have contributed to the enhanced access of indigenous peoples to the political arena at the international level and have supported the establishment of strong international networks, it seems that these new technologies have not contributed to the same extent to the democratization and enhanced transparency of the indigenous movement. For instance, the participants of the U.N. Working Group on Indigenous Populations and the U.N. Permanent Forum on Indigenous Issues seemed to be very well connected with each other, while the large majority of national and local indigenous leaders are not aware of the advancements achieved at these global fora. Within countries, there frequently exists a conflict of interest and a certain degree of factionalism between different leaders which impede the free exchange and sharing of information. At the same time, the example of the Fondo Indígena has demonstrated that ICTs have the potential to improve the transparency of indigenous organizations and significantly enhance the information flows between the different levels of indigenous leadership⁷. It needs however to be stressed that ICTs solely remain an instrument, and the main challenge remains

to find the political will of indigenous leaders and organizations to promote the open and free exchange of information.

CONCLUSION

The previous analysis has shown that ICTs under certain conditions can significantly enhance the human and social capabilities of marginalized groups. At the core of the process of introducing ICTs into marginalized communities stands the notion that ICTs can enhance people's control over their own lives. Similarly to literacy, newly acquired informational capabilities can act as an agent for change for individuals and communities — enhancing their abilities to engage with the formal institutions in the economic, political, social, and cultural spheres of their life.

In this context, the issue of whether ICTs are channeling resources away from the real priorities and needs of poor communities seems to be misguided. Instead this question should be rephrased and address the issue of how ICTs could be used to meet the basic needs of the poor.

Furthermore, the chapter has illustrated that there is no direct and causal relationship between ICT and poverty reduction. This relationship is much more complex and indirect in nature, whereby the issue of its impact on the livelihoods of the poor depends to a large extent on the dynamic and iterative process between people and technology within a specific local, cultural, and socio-political context. Frequently, the most immediate and direct effect of ICT programs seems to be the psychological empowerment of poor people, whereby newly acquired ICT skills provide the marginalized with a sense of achievement and pride, thus increasing their self-esteem.

A key recommendation of the chapter is that the human development of people, rather than technology itself, should be the center of the design and evaluation of ICT programs. As has been shown, the important advantage of using the capability

approach as the basis for the evaluation of ICT programs is its emphasis on the ability of ICTs to improve the daily livelihoods of poor communities, in contrast to more conventional approaches that overemphasize the significance of technology itself for social change. Furthermore, evaluations of the impact of ICT programs should focus on an analysis from the vantage point of the poor, rather than from the perspective of outside donors.

In addition the analysis provides the following concrete recommendations on the manner in which ICT programs should be designed in order to be most effective to enhance the well-being of marginalized groups:

- First, the potential benefits of ICTs are largest when they are being fully integrated into other sectoral development programs (i.e., in education or health). As the case study from Venezuela on the use of ICTs in bilingual education has demonstrated, ICTs can make a significant contribution towards reaching the core objectives of this development project — in this case improving the access to bilingual education to indigenous peoples.
- Second, it is essential that ICT programs prior to initiating any project activities carry out a detailed assessment of existing information flows and information needs. Hereby, the analysis should focus on how the new technologies can strengthen existing communication and information exchanges within and in between communities. The assessment should furthermore identify key information intermediaries in the community and analyze existing power relationships as they relate to the transfer of knowledge within the communities. Thus it is essential that poor communities first identify and define their own needs and development priorities before, in a second step, a project can define whether and how ICTs can support the community's development goals. As has been shown in the Ashaninka case, in cases where such a process was not undertaken and the exact objectives of the ICT project were not defined, ICT programs frequently fail.
- Third, it is crucial for the evaluation of the impact of ICTs on the well-being of marginalized communities to analyze the process of how ICTs are being introduced. Hereby, outside agents or intermediaries are playing a key role in supporting communities in appropriating the technologies to meet their own local and cultural needs. Within this process, it is essential that community members gradually gain the skills to make meaningful use of ICTs as well as gradually take ownership of the management of the program. As the case studies have demonstrated, capacity-building activities and the provision of local content through intermediaries are the two important factors that influence whether or not an ICT program will indeed strengthen the capabilities of the poor and thus contribute towards improving their livelihoods.
- Fourth, ICT programs are most effective when combining traditional media with new forms of ICTs. As the case study of the Ashanika community has demonstrated, the convergence between two different technologies — the Internet and community radio stations — is combining the advantages of both media. While the Internet is a powerful tool to connect networks and to exchange large amounts of information across long distance, community radios have a very broad reach, and represent the most accessible and inclusive technology for the poor. Due to the oral tradition of indigenous communities, this is of particular importance, considering that its use does not require literacy.

Finally, the chapter has demonstrated that the most important factors influencing whether an

ICT program has positive or negative outcomes are social, political, and cultural in nature, and in fact technical issues involved in the provision of ICTs frequently do not play a key role. The analysis highlights that frequently, ICT programs are not responding to a concrete need expressed within the communities, but are designed in a top-down supply-driven approach. In order to avoid the potential negative social effects, it is crucial to frame any ICT intervention around the existing social community structures. Thereby, the programs should strengthen traditional information systems, building on existing indigenous knowledge and enhancing existing information channels without undermining the existing structures.

ENDNOTES

¹ No universal definition of indigenous peoples exists, and due to the history of political repression, and discrimination and assimilation policies by states, indigenous peoples usually reject being defined by external agencies. In order to be able to identify rather than define indigenous identities, I am suggesting to make use of the working definitions provided by the International Labor Organization (ILO) Convention 169 and by U.N. Special Rapporteur José Martínez Cobo, both of which emphasize that the self-identification as indigenous should be used as the main criteria for the identification of indigenous peoples.

² The research will use Sen's multi-dimensional approach of well-being developed in the capability approach (CA) (Sen, 1984, 1992, 1993). The approach moves away from an income-based perspective of well-being (utilitarianism) to account for the constitutive plurality of human life. It thus emphasizes the non-material aspects of human well-being (i.e., spiritual, cultural, political aspects). The CA characterizes well-being in terms of what a person is actually able to do or to be (achieved functionings) and the combinations of beings and doings that a person can achieve (capabilities).

³ For the purpose of this research, I will use Hamelink's definition of ICTs: "Information and communication technologies (ICTs) encompass all those technologies that enable the handling of information and facilitate different forms of communication among human actors, between human beings and electronic systems, and among electronic systems" (Hamelink, 1997, p. 3). This functional definition of ICTs includes both the new (i.e., Internet, e-mail) and traditional

(i.e., community-radio) forms of ICT into its definition.

⁴ The definition used for sustainable livelihood framework is one provided by Chambers and Conway (1992): “A livelihood comprises the capabilities, assets (including both material and social resources), and activities required for a means of living. A livelihood is sustainable when it can cope with and recover from stress and shocks, maintain or enhance its capabilities and assets, while not undermining the natural resources base” (pp. 7-8).

⁵ This classification was defined in an interview with Mateo Martinez, Technical Director, Fondo Indígena, on January 14, 2005.

⁶ The Development Gateway is a program of the Development Gateway Foundation (<http://www.dgfoundation.org>) that aims to bring together people, resources, and information on development and poverty reduction. This interactive portal further provides a space for communities to share experiences on development efforts.

⁷ In the case of the Fondo Indígena, the introduction of ICTs supported an institutional change within the organization towards increased transparency. The impetus for the use of ICTs came during the organization’s General Assembly held in 2000 in Mexico, in which the need to restructure the organization and to enhance its transparency was discussed by its international donors, as well as government and indigenous representatives.

TERMS AND DEFINITIONS

Capability: The chapter uses Sen’s definition of capability as developed in the “capability approach” (Sen, 1999). A person’s capability therefore refers “to the alternative combinations of functionings that are feasible for her to achieve.

Capability is thus a kind of freedom: the substantive freedom to achieve alternative functioning combinations (or, less formally put, the freedom to achieve various lifestyles)” (Sen, 1999, p. 75). Capabilities include things that a person actually has done, as well as things people can possibly do. In other words capabilities refer to the extent of one’s positive freedoms.

Indigenous peoples: No universal definition of indigenous peoples exists and due to the history of political repression, discrimination, and assimilation policies by states, indigenous peoples usually reject to be defined by external agencies. In order to be able to identify rather than define indigenous identities, I am suggesting to make use of the working definitions provided by the International Labor Organization (ILO) Convention 169 and by U.N. Special Rapporteur José Martínez Cobo, both of which emphasize that the self-identification as indigenous should be used as the main criteria for the identification of indigenous peoples.

Indigenous knowledge: There does not exist a single definition of indigenous knowledge; the literature however emphasizes the concept’s main characteristics as being: (1) rooted in a particular local community and situated within broader cultural traditions; (2) experimental, meaning that it is being tied to action and based on experiences from trial and error; (3) implicit or tacit, meaning that it is often difficult for people to express this knowledge unambiguously and to find words to express what one knows (Giddens 1984); (4) transmitted orally, or through imitation and demonstration; and (5) being a dynamic mix of past traditions and present innovations.

Information and communication technologies: In the Chapter I use Hamelink’s definition of ICTs: “Information and communication technologies (ICTs) encompass all those technologies that enable the handling of information and facilitate different forms of communication among human

actors, between human beings and electronic systems, and among electronic systems” (Hamelink, 1997, p. 3). This functional definition of ICTs includes both the new (i.e., Internet, e-mail) and traditional (i.e., community-radio) forms of ICT into its definition.

Informational capital: This concept is being defined through the following four components: (1) the extent to which the poor have access to information from the formal institutions of the market, state, and civil society; (2) the ability of the poor to process and evaluate information; (3) the extent to which the poor do not only consume, but produce and share information within their community and networks; and (4) the extent to which indigenous knowledge is used.

Sustainable livelihoods: The definition used for sustainable livelihood framework is one provided by Chambers and Conway (1992): “A liveli-

hood comprises the capabilities, assets (including both material and social resources) and activities required for a means of living. A livelihood is sustainable when it can cope with and recover from stress and shocks, maintain or enhance its capabilities and assets, while not undermining the natural resources base.”

Well-being: The chapter use Sen’s multi-dimensional approach of well-being developed in the capability approach (CA) (Sen, 1984, 1992, 1993). The approach moves away from an income-based perspective of well-being (utilitarianism) to account for the constitutive plurality of human life. It thus emphasizes the non-material aspects of human well-being (i.e., spiritual, cultural, political aspects). The CA characterizes well-being in terms of what a person is actually able to do or to be (achieved functionings), and the combinations of beings and doings that a person can achieve (capabilities).

Chapter 5.19

ICTs and Educational Benefits in Regional Development

James J. Rennie

Simon Fraser University, Canada

ABSTRACT

ICTs can play an important role in improving public education in rural regions. The effects of ICT use in schools can, in turn, bring unexpected economic benefits to the region. ICT developers interested in building economies can use education as a sustainable, grassroots building block for future growth. While many development programs tend to focus on private models for ICT dissemination in remote regions (such as telecenters), public education embodies a spirit of universal accessibility that can bring global technologies into the daily lives of all world citizens. When ICTs are recognized as pedagogical tools, they serve both the long-term economic and cultural needs of communities.

ICT IN A GLOBALIZED WORLD: EDUCATION AND ECONOMICS COLLIDE

Information and communication technologies (ICTs) have changed the way of thinking about the planet by transforming almost every field of human activity, from agriculture to entertainment, from government to education. While many rural regions of developing nations have yet to experience all of the benefits of a high-tech era, significant efforts are being made to bring ICT to all communities around the globe. However, building and maintaining the infrastructure of a networked world is no small undertaking, and many governments strain to justify the costs of bringing cutting-edge technologies to impoverished regions in the developing world. Furthermore, the technologies exported from developed

nations seldom come without considerable ideological baggage concerning their usefulness, as well as their social and environmental impacts. If many communities around the world continue to struggle with basic necessities, it can certainly be asked whether or not an aggressive strategy of ICT development is really a universal priority.

Nevertheless, ICT's potential to bring about radical growth and development is difficult to dismiss. In regions where many development agencies continue to focus on providing clean water and protecting fundamental human rights, other development groups are exploring ICT dissemination as a useful tool in those same projects. Although ICT growth is often at odds with established programs of development, many innovative projects attempt to balance these two, seemingly contradictory sets of demands. ICT infrastructure is an extraordinary expense for many developing governments, but short-term costs must be considered in relation to long-term advantages. Communication networks allow remote regions to interact with urban centers, democratizing trade and protecting against widespread health crises. Telecenters and computer kiosks provide rural communities with increased access to government records and forms, improving democratic transparency and aiding with legal disputes.

Furthermore, and most importantly for this chapter, information and communication technologies radically transform public education, allowing students and teachers to bridge the gap between local communities and global issues. ICT development can introduce young learners to an incredible realm of information and culture, while at the same time allowing students to express their own identities to the world. Technical literacy, supported with the critical skills needed to protect cultural awareness, can open unimaginable possibilities for students, bringing the realities of a global knowledge economy to any schoolroom on the planet.

Accordingly, the international community has long held education as a fundamental and

inalienable human right. Education helps to create citizens for the world in which they want to live, allowing individuals to develop their identities within a context of historical, cultural and ethical norms. As a result, education plays a pivotal role in development projects; as the Director-General of the United Nations Educational, Scientific and Cultural Organization (UNESCO), Koïchiro Matsuura, argues, "Education—in all its forms and at all levels—is not only an end in itself but is also one of the most powerful instruments we have for bringing about the changes required to achieve sustainable development" (UNESCO, 2004, p. 8). Education fosters development because it encourages learners to consider their own, local circumstances in a broader context. Furthermore, it promotes sustainable development by situating new perspectives within historical frameworks; whereas individual development projects may bring about positive changes for a community, long-term initiatives must rely on local knowledges in order to sustain the growth and benefits of development. As a central site for nurturing and teaching local knowledges, schools are invaluable resources for development projects.

The challenge for ICT development programs is to recognize both the pedagogical and economic potential of ICT-enhanced education. Too often, ICT infrastructure is built for a specific set of predetermined functions, ignoring broader community needs and desires. Most ICTs, however, are inherently adaptable; to limit their use is to limit the abilities and outcomes of the people who use them. It is precisely through innovation and ingenuity that ICT finds its most important economic function: that of harnessing human knowledge as a creative, productive force. As Avgerou and Rovere (2003) argue, it is difficult to assign concrete financial value to ICT development, as "The significance of ICT innovation cannot be adequately captured in concepts of economic value; ICT is implicated in social changes that are not driven by norms of economic rationality" (p. 5). In order to achieve long-term economic

success, it is in a government's best interests to allow ICT to develop on its own terms, relying on the individual and collective ingenuity of citizens to transform technological systems into productive industries.

At its best, ICT development can empower communities and individuals alike, allowing for unexpected applications and undiscovered abilities. At its worst, ICT development merely reinforces existing hierarchies of power, ignoring community and identity, subjugating all local knowledges to a singular, technical, expert knowledge. This chapter will attempt to show that when innovative technologies are introduced to communities through private industry, the potential for economic development is severely limited. However, if ICT developers place schools and students at the center of their communities, the resulting dissemination of technology will have an enormous benefit for everyone involved.

A PHILOSOPHY FOR EDUCATIONAL DEVELOPMENT INITIATIVES: ICT IN CONTEXT

Development projects often represent a fundamental conflict between local knowledge and perceived Western hegemony. Aid materials and social programs bring with them the underlying values, assumptions and beliefs of a distant culture, threatening the identities of individuals and communities alike. Programs of ICT development are further burdened with cultural and ideological baggage, as hardware and software are often designed and produced far from the site of dissemination. Development agencies must carefully consider these challenges before undertaking any project, particularly in a field as culturally specific as education. Whereas many economic activities in developing regions are directly tied to modern and colonial interference, education must continue to serve the values and purposes of local communities. These goals, however, need not

be incompatible with the economic development of regions and nations. As Uma Kambhampati (2004) observes, "the process of education is seen to encourage self-discipline, hard work, and an achievement orientation, characteristics pinpointed by modernization theorists as being necessary for the transition from tradition to modernity" (p. 228). The recovery of traditional cultural practices and identities can, therefore, take place inside increasingly modernized communities. Within this transformation, education represents the single most important site for the intersection of tradition and innovation in the developing world.

Tradition and innovation in teaching and learning methods, however, must be considered as only one part of education's role in community life. Thus, even though the challenges facing developing communities are often at odds with sound pedagogical practices, it is imperative that development organizations recognize the role that education can play in addressing broader social issues. UNESCO (2004) has recognized two fundamental characteristics of education and its role in sustainable development initiatives, the first being that "education is a fundamental human right that has its own intrinsic benefits for individuals" (p. 13). The second characteristic is less evident to many developers; as UNESCO argues:

... education is a tool for introducing the values, skills and competencies needed to address the challenges of today's world ... such as poverty, social and political conflicts, gender discrimination, violation of human rights, unsustainable patterns of consumption and production, environmental degradation and unsustainable use of natural resources, and the fight against HIV/AIDS and other infectious diseases, etc. (UNESCO, 2004, p. 13)

Despite the obscured visibility of education's second role, it is essential that developers keep

this role in mind when creating and operationalizing projects.

It is equally important, however, to treat each specific development project as a unique set of circumstances and obstacles. Educational practices and curricula may be standardized across entire regions, but cultural and geographic varieties are unavoidable, as certain pedagogical goals are relatively universal: each community and society hopes to teach their children how to survive in the world; cultures sustain themselves by passing on to children the languages, customs, traditions, and values most important to the group. Students are encouraged to develop a sense of their identity, both personal and collective, as part of their general lifelong education. In order to achieve these educational goals, communities build schools, train teachers, and select appropriate educational content; although development projects can assist in each of these areas, it is imperative that developers recognize the cultural politics that exist at all three stages. If content is developed for local schools by educators who are not part of that community, the result will be an inevitable loss of local culture; no matter how good the intentions of foreign, “expert” educators may be, the value of local knowledge cannot be replaced. The success or failure of ICT initiatives in the developing world will greatly depend on a collective recognition of education’s value in society, coupled with a global respect for local knowledge in all forms.

Although the increasingly global nature of development threatens community identities, it also reminds developers of the richness and vitality that are inherent to diversity. As individual citizens and organizations from developed countries carry out more and more projects, the impacts on remote communities are inseparable from the impacts on the developers themselves. External development groups working in the field of education may act as unwitting cultural crusaders in modern disguise, but they are also unacknowledged ethnographers, explorers, and

innovators waiting to be taught. As John Fien of UNESCO observes:

Globalization is proving to be a particular challenge to education. Its economic impacts have been uneven and its cultural impacts threaten local ways of viewing the world. However, globalization has brought an awareness of the scale of the shared burdens we face and of ways of cooperating with others to address them. (UNESCO, 2004, p. 97)

The practices and priorities of development agencies are always open to renegotiation in the field, allowing for flexible, community-driven additions and revisions to stated developmental outcomes. What is most important is that education developers recognize globalization’s inherent oscillation between universal aims and local realities.

In order to ensure that ICT development recognizes and confronts the various challenges posed by public education, it is imperative that governments and development organizations underpin their projects with appropriate philosophical paradigms. In concrete terms, this would require ICT development projects to thoroughly question their own motivations, assumptions, and ambitions. Epistemological issues might not seem to hold the same economic weight as technical issues of compliance and compatibility, but the broad and unforeseen effects of ICT dissemination necessitate serious consideration during the early stages of a program’s development. Recognizing the educational (and thus long-term financial) benefits of ICT development strategies does not always come easily to the creators and vendors of specific technologies. It is, therefore, essential to any project’s success that community members themselves play an active role in the development of ICT initiatives.

One possible strategy for ensuring such contribution in ICT development is to pursue programs and projects that are conducive to an inclusive arrangement of technology and human-

ity, such as “Community Informatics” (CI) or Clement and Shade’s rainbow model. Michael Gurstein (2003) defines CI as “the application of [ICTs] to enable community processes and the achievement of community objectives including overcoming the digital divides both within and among communities”; more importantly, however, CI approaches can go on “to examine how and under what conditions ICT access can be made usable to the range of excluded populations and communities and particularly to support local economic development, social justice, and political empowering using the Internet” (p. 4). Initiatives grounded in the principles of CI may suffer many of the same pitfalls as any other program of ICT development, but the overarching belief that technology can bring excluded peoples into global economies should be the cornerstone of all ICT projects. Without this belief in the revolutionary potential inherent in ICTs, development projects are condemned to stagnate in their own inherent limitations.

Similarly, Clement and Shade (2000) have developed what they term the rainbow model of ICT infrastructure development, which is “an integrated model for analyzing and discussing access to network services” (p. 35). The rainbow’s seven layers (Carriage Facilities; Devices; Software Tools; Content/Services; Service/Access Provision; Literacy/Social Facilitation; and Governance) must be considered as a unified whole, wherein each factor plays a significant role in the overarching success of ICT initiatives (p. 36). Like Gurstein’s community informatics, the Rainbow model provides developers with an initial framework for development projects, ensuring that ICT infrastructure is developed in a sustainable, socially equitable manner. As Clement and Shade (2000) argue:

The design process must be broadly participative and dynamic. It must be carried out in the face of strong pressures from rapid technological change, ideological opposition, ignorance of technical pos-

sibilities and social implications, strained public resources and societal instability. (p. 49)

Both models recognize the importance of aligning development’s long-term goals with the social and economic needs of communities and countries. Furthermore, both models stress the need to design ICT initiatives that recognize and respond to the marginalized voices in rural settings. Most importantly, by underpinning ICT development projects with models of this type, developers recognize and respect the essential difference between development and modernization; whereas the former seeks to assist societies in their own evolution and progress, the latter, “although it may affect certain groups . . . is always induced; and it is the metropolitan society which derives the true benefits therefrom” (Freire, 2004, p. 161). Keeping pace with technological change may dominate the economic agendas of many ICT projects, but the long-term sustainability of such a narrow focus must now be seen as increasingly untenable.

When considered in greater detail, a model such as Community Informatics begins to generate more specific criteria for ICT development projects. In Gurstein’s model, informatics can be understood to forward the following characteristics:

- A commitment to universality of technology-enabled opportunity including to the disadvantaged
- A recognition that the “lived physical community” is at the very center of individual and family well-being—economic, political, and cultural.
- A belief that this can be enhanced through the judicious use of ICTs.
- A sophisticated user-focused understanding of Information technology.
- Applied social leadership, entrepreneurship, and creativity.

- Networked linkages (particularly ethnic or cultural) in urban communities as compared to the more limited overlapping in rural communities. (Gurstein, 2003, p. 5)

It is worth noting that Gurstein's list recognizes both the economic and cultural wealth of communities, as well as ICT's ability to enhance or hinder both. Development projects that only consider the positive outcomes of ICT dissemination risk any number of unforeseen disturbances in community life. Similarly, development projects that only consider the economic benefits of ICT use can inflict long-term cultural damage, which can ultimately undermine the short-term economic gains of ICT development. By adopting a framework such as CI, developers are encouraged to see economic and cultural factors as inextricably linked.

The interplay of a community's cultural life with its economy is a delicate and complex connection, and any disruption of one will undoubtedly impact upon the other. ICT developers interested in assessing the health and wellness of this important balance would be well advised to use public education as a sort of barometer; schools are a natural space for the forces of culture and business to collide, as their very mandate is to develop future citizens and workers. Providing attention and resources to public education is quite simply one of the easiest and most effective strategies for monitoring the status of community well being. If ICT developers want to know how effectively a new technology has been introduced to a community, they can start by gauging its impact on the local schools; if students are aware of the technology and are intrigued by its possible uses, there is a very good chance that the project will have a lasting impact on the community.

Constructive, sustainable development initiatives in the field of education must confront the twin forces of culture and economics, particularly with respect to actual curricular content. Although ICT development necessitates the addition of technical skills training in public education, the

realities of rural communities necessitate the preservation of skills and values that are often perceived of as outdated in a globalized era. As Fien cautions:

Parents around the world are rightly keen that their children should do well at school and then get a job. However, job opportunities are increasingly difficult to find, especially in rapidly changing economies. Most students will make their living at home, in villages, on farms, working with their families using the resources of their local environment or in the informal or 'popular' economies in cities. Those who continue to higher levels of schooling may find employment in the formal sector, but they will still need knowledge and skills in order to help their communities make informed decisions. (UNESCO, 2004, p. 108)

Development initiatives, and particularly those that promote ICT hardware and solutions, must consider that the changing face of international business and communications will only affect most of the world's citizens peripherally. Thus, the breed of techno-fetishism, which currently consumes many in the developed world, might not be an appropriate export to developing communities in remote, rural regions. Many ICT applications bring with them enormous economic advantages, but some of these advantages are, in fact, culturally and politically specific. For example, ICTs designed to enhance productive efficiency in industrial settings are the result of a unique set of business demands. If developers unquestioningly extol the virtues of these technologies, they ignore the business demands that are unique to every other country and region in the world. This is because, as Kambhampati (2004) writes:

With most research and development being undertaken in capital-rich, labour-scarce Western economies, new technology is more likely to be labour-saving. International competition and

the need for efficiency, together with the reliance on imported capital goods, have reinforced the tendency to use the most up-to-date technology (usually labour-saving) even in labour-rich developing countries. (p. 39)

While the tools and techniques of most ICT initiatives in education are wholly different from the industrial technologies of the economic sector. This example of ideological assumptions and their potentially catastrophic consequences illustrates the dangers inherent in all ICT development projects. There is a pressing need for local solutions to problems, even when those problems recur from one community to the next. It is a mistake to believe that what works in one instance will work in all instances. Therefore, while educational reform is undoubtedly an urgent and ongoing struggle, it is essential that solutions are as varied as the crises are numerous; developers gain nothing from the unquestioned mimicry of standardized reforms.

CURRENT APPROACHES AND CONTROVERSIES: TELECENTERS, KIOSKS, AND THE NEED FOR GRASSROOTS CONSULTATION

Despite the enormous economic and social potential of ICTs for the developing world, current programs for ICT dissemination warrant a more critical appraisal; the telecenter model of ICT access, and how it has failed to properly consider the role of education in development initiatives, is an illustrative example. Broadly defined, telecenters are remote information kiosks that connect specific technologies (typically including phone lines, fax machines, computers, printers, scanners, digital cameras, and Internet access) to national and global information networks. A system of telecenters allows citizens in rural communities to access contemporary technologies from permanent sites in the region, thereby increasing technological literacy and simplifying

the bureaucratic processes of centralized government offices. Many telecenters are built with the assistance of development agencies, in the hopes that increased access to ICTs will improve the daily living conditions of communities and citizens.

For example, in a district of Dhar in Madhya Pradesh, central India, a Rural Intranet Project established a network of “village information kiosks” in order to provide citizens with agricultural information, government forms, and public health announcements. In addition, the network allows public officials to learn of potential crises immediately, so that outbreaks of disease and environmental contamination can be contained (Bhatnagar, 2003, pp. 38-41). Many ICT kiosks in the developing world—such as those in the Dhar project—are operated as private businesses by local entrepreneurs, generating income from customers who can afford the services provided. In an alternate model, paid employees of a central organization, public or private, staff the telecenter networks, ensuring that the kiosks remain open whether there is substantial demand for the services or not. As Colle and Roman (2003) observe, both models depend on the usefulness of the applications provided for financial sustainability: “One of the biggest challenges telecenters face is providing relevant information and services for their stakeholders. To survive, telecenters must be substantially demand driven whatever their sources of income. This translates into the need to have relevant and useful content” (p. 83). ICT kiosks have the potential to connect rural communities with the global world of culture and trade; their potential, however, depends on universal access, reliable service, and above all grassroots content development. If community members are active participants in ICT dissemination, rather than passive recipients of mere tools and techniques, they will have a tangible interest in maintaining and expanding ICT networks.

Consequently, it is imperative that telecenter networks depart from their exclusive relationship with private industry. Despite the economic advan-

tages of privatized telecommunications industries (as demonstrated by Henriques & Sadorsky, 2005, among others), privately owned telecenters dull the effectiveness of ICT networks in two important ways. Firstly, so long as ICT kiosks are operated for profit, they limit their usefulness in any community by attaching a price to information itself. Although many individual citizens may choose to pay for certain conveniences (e.g. submitting government forms electronically in order to avoid travelling to a central office), the majority of citizens will be hard-pressed to justify the cost of casual ICT use. Instead of introducing the benefits of long-range communication, unlimited research opportunities, cultural expression and improved education, ICT risks becoming an expensive gadget for those that can afford its limited use.

The second problem that arises from privately owned telecenters is a broader issue of harnessing knowledge for purposes of control. When the kiosk operator rations out ICT use to individual customers, there is little opportunity for individual community members to learn how these technologies really work. Widespread technical literacy may develop over time, but actual hands-on experience is limited to paying customers. The kiosk operator, usually trained by the network owners, holds a monopoly of technical knowledge in the community. Although he or she may choose to share their skills with customers and community members, there is no necessary incentive to do so.

To avoid the problems raised by private ownership, telecenter networks need to be developed as part of a region's public infrastructure. The costs can be prohibitively high, but the long-term economic advantages are very real. Building and maintaining a system of ICT kiosks seems expensive, but what is the real cost of an illiterate, under-employed community? How expensive is a family that falls sick because they had no way to know that their water supply was contaminated? ICT development forces us to consider the real costs

associated with social and economic progress. If ICT infrastructure is treated as an expensive addition to a nation's economy, it will continue to serve the narrow interests of select individuals and industries. If, however, ICT infrastructure develops in tandem with a nation's educational institutions, citizens and communities will be encouraged to adapt ICTs to existing needs and desires, thereby exploring the real and unexpected benefits of global technology.

It should be noted, however, that in many regions of the developing world, education and learning have long been at the core of economic and social planning. In a study of the Fast Reliable Instant Effective Network for Disbursement of Services (FRIENDS) project, Shirin Madon notes that the Indian state of Kerala, where FRIENDS introduced a network of "one-stop, IT-enabled payment counter[s]" for all government bills, has long benefited from the presence of village libraries (Madon, 2003, pp. 76-78). As Madon writes, "These libraries are now an established part of village life in Kerala, being used as centers for adult literacy and the venue for political meetings and youth events. Education has played a larger role in the evolution of Kerala's society by encouraging the growth of the print media and communication industry" (p. 76). Nevertheless, the FRIENDS project, aimed at simplifying a number of bureaucratic processes through ICT design, operated independently of the village libraries. Faced with the major investments in ICT infrastructure needed to establish the FRIENDS network, the decision was made to keep new technologies away from centers of learning. The failure to recognize this type of ICT dissemination as both educationally and economically advantageous to a region is symptomatic of ICT development projects throughout the world. Even in a state that actively encourages learning and education, the FRIENDS designers chose to build narrow-use telecenters, conceived of for specific bureaucratic functions. Had these ICT

kiosks been developed in coordination with the village libraries, they may have proven to be of far greater value to communities.

In addition to recognizing and respecting the role played in communities by schools and libraries, ICT developers must understand that these educational institutions represent the unique identities of rural communities. Although there are a great many advantages to the high-tech schools in developed nations, there are also a number of ongoing pedagogical debates surrounding the use of ICTs in these schools and, therefore, it is essential that these debates follow educational technologies, wherever they may be adopted. For example, it would be a mistake to assume that ICT-equipped schools can replace traditional, teacher-student models of learning. Although networked computer terminals can facilitate online learning, it does not follow that students in remote communities are best served by distance learning. Online and distance education have plenty of critics around the world, as these models place individual learners at the core of the education process. Introducing ICT-based learning to the developing world runs the risk of alienating students from their actual communities, threatening cultural survival and encouraging individuals to see themselves at global citizens first, community members second. As Bresnihan and Doyle (2004) argue, “virtual communities tend to be based purely on communities of interest leading to narrow discussions on mostly predefined topics which, while giving the contributors a sense of community, can in fact keep them dislocated from the real world” (p. 389). The online communities created by distance and ICT-enhanced learning promote global citizenship at the expense of the very real communities that students inhabit. There are, undoubtedly, significant benefits associated with online and distance-learning models, including improved access to education (particularly for students with physical disabilities or learning disorders)

and standardized delivery of content, benefits that are harder to obtain with traditional methods of communications and teaching. As Quan-Haase and Wellman (2004) argue, “Although face-to-face and telephone contact continue, they are complemented by the Internet’s ease in connecting geographically dispersed people, institutions, and organizations bonded by shared interests” (p. 123). Nevertheless, the potential for misuse (intentional or not) of these technologies must be acknowledged before introducing ICTs into the classrooms of the developing world.

The value of grassroots consultation simply cannot be overstated in development paradigms. Regardless of its economic outcomes, a successful development strategy will recognize local systems of knowledge as the foundation for any real progress. As George Dei (2000) argues in his analysis of African development:

For the idea of "development" to have any credibility at all, it must speak to the social, cultural, economic, political, spiritual, and cosmological aspects of local peoples' lives, as well as to their specific needs and aspirations. Debates about "development" must be situated in appropriate social contexts that provide practical and social meaning to the actors as subjects, rather than as objects of development discourse. (p. 73)

When development projects fail to appreciate the centrality of local culture and knowledge, they risk mimicking the colonial and imperialist adventures of the past. Development requires the community to acknowledge the limitations of their own beliefs and assumptions. As developers attempt to bring the benefits of modern ICTs to the rest of the world, it is imperative that they treat all knowledge systems as equal, valid, and enlightening. Furthermore, it is important to recognize the spectrum of educational differences that exist within countries, as not all regions and communities share common values and needs.

As Gasperini and Lakin (2003) observe, “Most developing countries have a unitary, centrally determined curriculum, which is generally designed for pupils familiar with an urban environment and may contain elements that conflict with local customs and beliefs” (p. 89). Promoting appropriate ICT use in local schools may therefore strengthen community autonomy and identity, as grassroots ICT applications can transform centralized practices and programs.

Developing communities can benefit from the educational benefits of ICT infrastructure in a number of ways, many of which occur outside of traditional classrooms. The increasing use of ICTs in their economic and cultural lives has seen an incredible growth in the field of adult literacy training. People who did not enjoy the benefits of public education in their youth are now adopting the model of the “lifelong learner” in order to keep pace in an increasingly technological world. As Fien argues, this form of literacy:

... is an essential skill for coping with the economic and social changes that are rapidly affecting traditional rural ways of living. Literacy and continuing education projects are needed to help rural people understand the ‘what’ and ‘how’ of production and the marketing of goods and services. ... Above all, adult education must help rural people suffering from poverty to develop positive attitudes and values that enhance their self-esteem and self-confidence. (UNESCO, 2004, pp. 119-120)

Adult literacy programs can introduce mature learners to the benefits and wonders of a networked planet, thereby opening an untold number of doors for future employment and expression. Nevertheless, ICT development projects need to differentiate between the goals of adult literacy programs and primary public education. Although it is economically responsible to *double up* ICT infrastructure in rural regions, it must be noted that technologies cannot always be shared among vari-

ous groups with equal success. Public schools are the long-term caretakers of critical and technical knowledge, as they continue to share information and knowledge with each subsequent generation. Adult literacy must, therefore, be treated as a one-time project aimed at bringing entire communities into a knowledge economy, whereas public schools will ensure that future citizens will have the skills and knowledge necessary to survive and prosper. As the long-term economic benefits of ICT instruction are the responsibility of public education, it would be appropriate for efforts aimed at “doubling up” ICT infrastructure to concentrate their resources in schools. Teachers and students might, however, use ICT resources during regular school hours, and adult education programs could access the same facilities during evenings and weekends.

Certainly, there are a range of ICT applications that can benefit communities and individuals in developing regions. Projects such as FRIENDS, which emphasize bureaucratic processes and governmental business, might best be served by an independent network of telecenters. Had the FRIENDS kiosks been placed in public schools, for example, their usefulness would have been severely limited by their accessibility; had regular business hours overlapped with the school’s schedule, their would have been a never-ending contest for use of the machines. Similarly, the Rural Intranet Project in Dhar could not function as an effective public health advisory system if news of a possible contagion first reached a young child in the classroom. Nevertheless, it is troubling that so many ICT development programs fail to consider the economic importance of public education. The immediate utility of bureaucracy-driven networks is undeniable, but it should not come at the expense of the long-term prosperity of a region.

Unless significant efforts are made to provide technical and critical training to communities, ICT development will quickly reach the limits of its own effectiveness. Warnings of this type tend

to be dismissed as mere neo-Luddism, stemming from Western academics with their own personal axes to grind with all things technological. What should not be lost in the calls for cautious ICT development is the insistence on inclusive, sustainable practices that respect local knowledges in all forms. This is not a crude, Orientalist reverence for all things exotic and rural—the developing world is home to a multitude of voices that continue to be ignored in the dominant discourses of technology and progress. As Dei (2000) argues, “Leaders must include local people—particularly women and the poor, whose knowledge and power have been marginalized—at all stages of the conception, planning, implementation, and evaluation of development activities” (p. 83). If the marginalized voices are not accorded their inherent worth in development initiatives, local and regional economies will continue to be burdened by individuals and communities who cannot or will not participate in the productive activities that fuel economies. Education generally, and public schools specifically, represent the development movement’s best chance at ensuring total, equal participation in local economies.

The single greatest obstacle for ICT development to address is the marked division between internal community needs and external perceptions of need. Newly introduced ICTs must meet some type of existing demand—consciously expressed or not—in order to play a meaningful role in community life. As Avgerou (2003) explains, “the socio-technical analysis suggests that the innovation process depends on the situated actors’ capacity to make sense of the value of the new artefacts and organizing techniques, and to accommodate them in their historically-formed enactments” (p. 157). She goes on to warn that, “The risk—all too visible in the widespread ‘failures’ of IS projects in developing countries—is that technology-diffusion policies which push specific technologies as ‘drivers’ to desirable ‘impacts’ or business ‘best practice’ distort local economic activities and frustrate,

rather than enable, improved performance” (p. 157). When development groups see ICT applications as “drivers” for specific outcomes they fail to recognize existing social and economic practices that constitute community experience. Worse still, prescriptive ICT solutions relegate local community members to passive roles in a networked world. As Paulo Freire (2004) warns, “In cultural invasion the actors (who need not even go personally to the invaded culture; increasingly their action is carried out by technological instruments) superimpose themselves on the people, who are assigned the role of spectators, of objects” (p. 180). Developers must recognize that their technological instruments have the same potential to become cultural invaders as they themselves do.

The inherently flexible nature of ICT tools and techniques is what encourages many groups to actively develop ICT infrastructure in a variety of communities (see, for example, Diane Nelson’s, 1999, discussion of “Maya-hackers” in Guatemala). It is this same degree of flexibility that creates new opportunities for cultural expression and economic growth in communities, and that ensures a healthy balance between global perspectives and local identities. However, as Russell Bishop, a Maori scholar, writes, “When one curriculum, one set of knowledges and narratives is constructed as representing ‘the truth’ or ‘the real,’ and it obliterates or marginalizes alternative conceptions, it is an act of violence” (as quoted in O’Riley, 2003, p. 62). Constructive, successful development initiatives embrace the alternative conceptions that are characteristic of ICTs, because they recognize the short-sightedness of advancing pre-determined goals and outcomes.

Finally, although ICT development has become a priority for many governments and agencies, the enormity of the obstacles to ICT development must be confronted before any serious attempts at dissemination are undertaken. For example, an organization known as Learning

and Development Kenya (LDK) is attempting to build ICT infrastructure that will benefit both the social and economic development of that country. Although the group considers education to be a central area for focus, there are a number of challenges to be faced: “Despite the fact that more educational opportunities have been created in the last decade, many children ages 6 to 13 years are still not in school. ... The enrolment levels are compounded by high rates of dropouts, and the situation is becoming more complicated with high death rates of the parents due to HIV/AIDS” (p. 95); as Philip Ndeti (2003) notes, “This trend is not promising for the successful use of ICT by the majority of Kenyans” (p. 95). LDK’s success is, therefore, inextricably linked to the health and social crises affecting entire communities in Kenya. Although specific ICT initiatives may bring economic benefits to select groups and individuals in Kenyan society, it is impossible to ignore the broader concerns of daily life and their impacts on development projects. Education initiatives are linked to food shortages, the spread of disease, and even to cultural norms and mores of specific regions; if ICT development projects are to achieve any real degree of effectiveness it is imperative that organizers and implementers pay attention to the greatest possible number of considerations.

GENERAL RECOMMENDATIONS

As this chapter has attempted to argue, ICT development in rural communities is most effective when it embodies the values and goals of local knowledges. One of the most effective methods for securing and institutionalizing this link is to build development projects around existing sites of public education. A few simple principles and practices can greatly enhance the effectiveness and sustainability of ICT projects; taken as a whole, the recommendations in this section can provide a sound foundation for future develop-

ment initiatives. Nevertheless, it is important to recognize that this is only a first step; the world of development changes and evolves as quickly and unpredictably as the world of technology, and it is necessary that developers of all types continue to stay informed and alert.

The University and the Schoolhouse: Centralized vs. Localized Knowledges

For many ICT developers, it is tempting to devote significant resources to the most visible, influential sites of education in a country—the universities. For example, the Sudan Virtual Engineering Library—Sustainability Network (SudVEL-SKN) uses centralized resources in order to disseminate knowledge across ICT networks; as Anna McKenzie (2005) writes, “Databases such as these are needed in every country to draw out local material and ensure technology transfer from international sources into the curriculum of engineering students, material for researchers and professional development” (p. 438). Universities and colleges employ a large number of citizens as teachers and researchers, and they tend to be important sites of research and development for ICTs, making them ideal hubs for future investment in ICT infrastructure. For example, in their study of sustainable development initiatives, Colle and Roman (2003) see Universities playing a key role in ICT development around the world. Universities, they argue:

- Conduct continual research on community information needs so that appropriate information resources can be developed.
- Convert their own research and academic knowledge into education, information, and training packages suitable for community use.
- Mobilize, interpret, integrate, and package information from external authoritative

- sources and tailor it to the needs of populations in surrounding communities.
- Design and execute ICT training programs for various community groups, especially those that are likely to be bypassed by conventional ICT training. (p. 85)

Despite these positive outcomes, universities currently occupy too much of the development movement's time and effort. Although universities are important resources for the economic and educational development of a country, their impacts are not always felt directly in rural communities. Public schools and local libraries benefit from actual grassroots involvement, allowing community members to participate in educational initiatives and to see the results firsthand. Universities tend to concentrate resources and personnel in large urban centers, distancing ICT infrastructure from the millions of citizens that the development movement hopes to serve. The SudVEL-SKN initiative, although a useful tool for Sudan's engineering students, draws out *local material* in order to support the advanced learning of a small group. While university staff and students may *design and execute ICT training programs* for use in rural communities, relying on such a centralized model of knowledge dissemination hardly seems practical or desirable. One need only consider the ill-fated notion of *trickle-down economics* in order to see the inherent limitations of a university-centered strategy for ICT development.

Additionally, and perhaps more importantly, the benefits of a university education tend to help individuals rather than communities, whereas primary and secondary schools benefit both groups. Education, generally speaking, benefits both individuals and communities. Although students alone receive formal education in school settings, the effects on the community are palpable and desirable; as Kambhampati observes, "The social returns from education can be higher than the private returns if education leads to technologi-

cal progress not captured in the private returns to education, or if education produces positive externalities like a reduction in crime rates and social security pay-outs, or more informed political decisions" (p. 229). As primary education enhances the collective security and well being of communities, it is funded by local and national governments, which consider long-term social benefits to be a good investment. While similar collective gains are recognized at the level of secondary schooling, tertiary education (universities and colleges) represents a different set of costs and benefits. Thus, although "many empirical studies indicate that tertiary education has higher private than social benefit, and there is therefore a case for it to be privately funded," writes Kambhampati (2004), "most developing country governments spend more on it than its social benefits warrant" (p. 235).

Rather than treating universities as the educational and economic cores of a nation's school system, developers need to treat universities as important, centralized hubs for individual advancement in specific economic and cultural fields. Even though the tertiary educational sector generates and sustains a great deal of a nation's technical and historical knowledge, it should not receive a disproportionate share of a nation's ICT infrastructure. Universities have an important role to play in ICT development, but they must not overshadow the pivotal role of primary and secondary schools, which have a far greater potential to reach the entire population of a country.

Telecenters and the Private Sector: ICT and Profitability

Even though universities and colleges have received a disproportionate amount of resources and attention from ICT development initiatives, it can at least be argued that some portion of the resulting benefits have helped individuals and communities in impoverished regions. Privately operated telecenters and kiosks, however, continue

to benefit only a narrow cross-section of any population. Before governments and development agencies begin to design massive ICT networks in remote rural settings, it is imperative that they appreciate what distinguishes rural ICT applications from their urban equivalents. As Bhatnagar (2003) thoughtfully observes:

Rural areas need to be serviced through low-cost, low-bandwidth solutions that have high reliability. This means that technology solutions will have to be adapted to local terrain and conditions. Demand for information services would have to be generated through aggressive marketing, and overheads kept low to serve a cost-sensitive market. Large organizations in the public or private sector are unlikely to be able to operate in this manner. (p. 51)

The question, then, is whether or not ICT infrastructure in rural regions can (or even should) be expected to generate any real profits. Bhatnagar suggests that large public organizations are unlikely to operate successfully in these economic confines; although this reflects the prevailing attitudes in many countries, the public sector nevertheless remains the only body capable of building and maintaining ICT networks in rural regions.

Whereas a private business model of kiosks and telecenters requires *aggressive marketing* and low overheads, a public model based on existing educational infrastructure does not. It is entirely possible that ICT solutions for rural regions cannot become sustainable investments for private businesses. However, if neither businesses nor governments can perceive benefits to offset investment losses, then ICT development will be mothballed indefinitely. What is needed is either a stabilization of rural markets in order to appeal to private firms, or an effective *doubling up* of community ICT infrastructure with existing government programs and institutions. If stabilization remains unlikely in the near future, then

public schools offer an ideal site for additional investment and development, as the project of widespread, meaningful ICT use significantly overlaps the goals and values of public education. If young people are taught to read, write, and express themselves creatively using ICT tools and techniques, an entire generation of young citizens will be comfortable working with the knowledge tools of a globalized world.

The issue of staffing and maintaining ICT kiosks, too, becomes far less problematic if developers seek out existing institutions and organizations. In their discussion of telecenters and operating practices, Colle and Roman (2003) emphasize the importance of volunteers in maintaining the effectiveness of telecenters: “The challenge for telecenters is to move from largely spontaneous use and management of volunteers to developing an explicit strategic plan for recruiting, training, retaining, and rewarding volunteers” (p. 86). Such a strategic plan can be grounded in the community structures surrounding public schools, so that teachers and students themselves can play an active role in the community use of ICTs. Once ICT infrastructure is a part of school life, the nature of volunteer recruitment drives will be drastically different.

Culture and Language: Long-Term Investments

Although projects aimed at improving educational opportunities carry with them the inherent economic advantages of a well-educated populace, the preservation and promotion of local cultures and languages often seem less imperative than other, more technology-aligned aspects of ICT-enhanced education. Publicly funded initiatives are therefore essential to the success and sustainability of ICT development programs, because they recognize that many important projects cost far more money than they can immediately return. In Thailand, for example, the Inter-village Connectivity and Empowerment initiative introduced

ICT to a number of rural areas, in order to “disseminate knowledge and information to support economic stability and increased international competitiveness” (UNESCO, 2005, p. 7). One of the initiative’s projects was the translation of herbal medicine texts from a traditional, at-risk language, the Lanna script (“which only a few people in the [Ban Samkha] village can read and understand”), into modern languages, in order to preserve historical, cultural knowledge (p. 9). Similar programs include the “Chakma Language Preservation Project” in India and the “Pukllasunchis Primary School” project in the Andean region of Peru (King & Schielmann 2004, pp. 139, 217). These are costly, Labor-intensive ICT development programs with only a few financial incentives. Seen in a long-term perspective, however, the preservation of scripts and medicinal practices may bring enormous benefits, both cultural and economic, to the entire world.

The issue of language preservation is especially significant in development programs focused on ICT dissemination, because unless ICT applications are developed with grassroots consultation, they will tend to present themselves to communities in the dominant, hegemonic languages of international business and trade. In a list of conclusions drawn from multiple ICT development initiatives, UNESCO (2005) notes that:

Language becomes an important issue at the global and national levels because approximately 80 per cent of the world’s websites are in English. Thus, English literacy is needed to access the global online information network. Likewise, literacy in the national language is necessary to read documents related to local and national programmes. (p. 31)

With this warning in mind, UNESCO (2005) goes on to note that:

There is a certain belief at all levels that ICT tools are something given by outside experts rather than

developed locally. Although external support is essential for initiating new activities and updating knowledge and skills, local people need to develop a sense of ownership of their ICT programmes, including the technology itself. (p. 31)

It is imperative that the development movement recognizes the extreme sensitivity of the hundreds of distinct languages used in remote regions of the world. Although public education can be an effective site for the preservation and growth of cultural practices, ICT tools and applications themselves can greatly undermine these efforts if proper consideration is not given before their dissemination.

THE FUTURE OF ICT AND EDUCATION IN DEVELOPMENT PROJECTS

Future ICT initiatives should begin to look for precedents that are widely regarded as both economically and pedagogically successful. Although it can be difficult to identify such successes, particularly in the short-term, there are several indicators that can alert researchers and developers to good practices and anticipated results. Firstly, developers should look for ICT projects that introduce technologies broadly, allowing local community residents to adapt and innovate as they see fit. For example, project organizers might be well served to consider one of the conclusions UNESCO draws from the connectivity initiative in Thailand: “If the use of ICT is linked to solving different community problems, and not restricted to learning in school, the villagers will realize its functional importance and become more interested in acquiring ICT skills” (UNESCO, 2005, p. 11). ICT development may help businesses, and it may also help schools, but it can also bring with it many unimagined opportunities for additional growth, so long as developers do not limit its use to one single sector. Secondly, it is equally use-

ful to consider how ICTs can solve many, but not all, problems facing rural communities. In the same list of UNESCO's conclusions regarding the connectivity initiative in Thailand, they observe that, "ICT is one tool used to create a good learning environment in the community. So it is not necessary to start with ICT in every learning activity" (p. 11). When developers try to apply ICT solutions to every economic and educational crisis they perceive, the end result is usually far from what had been anticipated.

Thirdly, developers can identify successful ICT initiatives by their commitment to grassroots consultation. From the early planning of a project to ensuring and maintaining its ongoing sustainability, community members themselves—particularly the marginalized, the poor, and women—must play an active role in ICT development. Educational applications in particular must be developed locally, to ensure that local needs are not supplanted by centralized, national imperatives, or by international forces. As a useful template for future projects, Lavinia Gasperini and Michael Lakin (2003) list four guidelines for ensuring that educational content is developed properly:

First, the curriculum should relate to the local context, customs, livelihoods and rural development activities. Second, it should take due account of the teachers' qualifications and training (although ideally these should be in accord with the curriculum). Third, it should make use of locally available skills, knowledge and other resources. Fourth, it should respond to the expressed wishes of the community (i.e., be demand-driven). (p. 145)

Once curricular content is established along these guidelines, developers can begin to support and complement pedagogical practices with ICT tools and applications. If ICT becomes a driver, rather than a useful navigational instrument, it risks wrenching control out of the hands of com-

munities and placing it in the hands of distant ICT experts.

A fourth consideration for ICT development initiatives in rural communities is particularly important to public education, as it stresses the involvement of education's primary audience. Often ignored in grassroots consultations, children and youth must play a central role in development programs focused on ICT applications in education. As UNESCO notes, children offer creative input in a wholly unique manner, as "They can help to alter the mindset of adults by coming up with some unusual, but effective, ways of doing things" (UNESCO, 2005, p. 11). As ICTs allow young people to explore the networked world in greater detail, developers should look to students for innovative ideas that remain grounded in local communities. Therefore, as UNESCO suggests, "Encouraging children and youth to become active partners in the process of community development is an effective way to achieve a higher level of sustainability for both ICT and community development activities" (p. 11). Grassroots consultations can no longer afford to ignore such a vital, fresh source of inspiration and reflection.

Finally, ICT developers need to seek out models for infrastructure development that do not limit their definition of ICTs solely to computers and computer technologies. In order to sustain the benefits of increased connectivity and creative expression, development initiatives should attempt to match community needs and desires with appropriate tools and techniques. UNESCO's summary of findings from multiple projects indicates that, "Although many countries believe that ICT means computers and the Internet, the use of other kinds of ICT such as radio, television, and audio technology are worth further exploration. Some of these media are more useful for raising awareness and also more cost-effective than computers" (UNESCO, 2005, p. 31). Technologies that seem older and less attractive to Western development

agencies may in fact be ideally suited to the immediate needs and desires of rural communities in developing regions.

CONCLUSION

The project of ICT infrastructure development brings with it the promises and dreams of a networked society, where every individual and community can play an active role in the economic and cultural life of the planet. Remote communities and rural centers alike can share the benefits of a connected world, humanized and democratized by the forces of technology. This vision is, of course, still a long way off. Significant economic disparities continue to handicap whole countries and regions, while fundamental issues of access and training prevent millions of citizens from participating in the hi-tech global community. If developers are to realize any form of a vision for the future, they need to begin by addressing the obstacles of access and disparity in the developing world. Public education is quite simply the single most important weapon for social progress in the world. When coupled with the radical transformative potential of ICTs, public education can become a site for economic, cultural, and personal growth on a previously unimagined scale.

For development groups interested in exploiting the potential of ICTs for economic growth, the most important lesson to learn is that economic growth cannot be sustained without a corresponding investment in education. ICT applications must be introduced to communities as tools and resources, and not simply as economic drivers for limited functions. The creative uses and applications of ICTs are bound only by the human spirit of imagination and ingenuity. Historical understandings of ICT use simply do not provide ample space for individuals and communities to develop real world solutions to existing problems. This is particularly true in education, where young

minds and exciting technological opportunities can combine in an infinite number of possibilities. As Stephen Kerr (2001) observes of ICT use in schools, "We tend to see the future, as Marshall McLuhan noted, through the rear-view mirror of familiar approaches and ideas from the past. In order to allow the potential inherent in educational technology to flourish, we need to shift our gaze and try to discern what lies ahead, as well as behind" (p. 164). It is time that ICT infrastructure developers look to what lies ahead. They should start in the classroom.

Chapter 5.20

Support Networks for Rural and Regional Communities

Tom Denison

Monash University, Australia

ABSTRACT

Using a case study approach, this chapter examines the role of organizational networks in the success and failure of information and communications technology projects. Within a framework informed by the literature of information systems failure, the diffusion of innovation and social network analysis, it argues that information systems projects must take into account the social context in which they are implemented. To be successful such networks require a mix of extended and locally based support networks, because they provide access to much needed resources, including innovations, strategic advice, training, and support at the appropriate level. It further argues that the people who are working in a regional setting felt themselves to be in an extremely disadvantageous situation because they typically lacked support from similar net-

works. The author hopes that highlighting the importance of such support networks will lead to a better understanding of systems failure and success, and will contribute to improved policy formulation and practice.

INTRODUCTION

Quite often it is assumed that the mere implementation of technology and some initial guidance and training in its use will result in successful projects and their ongoing effective use. Time after time this has been found to be insufficient. The literature on information systems failure deals with the multiple causes of this phenomenon, but the intention of this chapter is to focus on one aspect that is particularly important in the context of rural and regional development: the role and type of support networks that are needed to properly

plan, implement, and sustain information and communications technology (ICT) projects.

The starting point will be a brief overview of the literature on information systems failure, highlighting recent research that seeks to emphasise the importance of understanding the social context in which systems are implemented and the impact that can have on their success or failure. This will be followed by an introduction to the literature on the diffusion of innovation and social network analysis. Then it will provide a broad theoretical background that can be used to examine the characteristics of organisations as nodes in broader networks, the nature of the relationships they establish within those networks and the importance of those relationships in providing access to information, skills, and resources. These theoretical concerns will then be illustrated by drawing upon a selection of case studies available in the literature, as well as practical experience the author gained when implementing information systems in Vietnam.

The case studies have been chosen because they provide examples of the theoretical issues in rural or regional settings. While some, such as the attempt to implement geographic information systems in India (Barratt, Sahay & Walsham, 2001), serve to illustrate the extent of the problems that can arise when a lack of local knowledge and infrastructure is not addressed, most of the studies illustrate more positive outcomes and act to reinforce insights derived from the theory. As a whole, they demonstrate that network relationships are essential for development in rural and regional areas because they provide access to new ideas and innovations, strategic advice, training and support, as well as a host of other necessary resources. They also demonstrate that some resources, such as access to new ideas, should typically continue to be provided through extended networks, but successful and sustainable projects require the development of a localised infrastructure capable of harnessing resources in a trusted environment.

INFORMATION SYSTEMS FAILURE

There is a significant body of literature that has been found discussing the causes of information systems failure from a project management perspective, for example, the work of Lyytinen and Hirschheim (1987), Keil, Cule, Lyytinen, and Schmidt (1998), and Schmidt, Lyytinen, Keil, and Cule (2001). These have tended to focus on management issues, such as the lack of top management commitment to the project, failure to gain user commitment, misunderstanding the requirements, lack of adequate user involvement, lack of required knowledge/skills in the project personnel and lack of frozen requirements (Schmidt et al., 2001) although recently there has been significant interest in concepts such as learning organizations (Lyytinen & Robey, 1999) and their role in nurturing projects. The main thrust of the literature, however, relates to the ability of large organisations to successfully undertake new systems development.

Given its importance, the focus of this chapter is to assist those who seek to implement information systems in regional areas, specifically in the creation of the infrastructure or framework necessary for the successful diffusion and sustainability of technology. It complements the work of others such as Kling (2000) and Orlikowski (2000) who, having recognised that technology is not socially neutral, have attempted to broaden the understanding of the factors that contribute to systems failure by considering the social context in which information systems are implemented. The importance of such an approach has clearly been recognised by the United Nations Development Program (UNDP) Evaluation Office which identified six generic challenges that critically affect ICT for development initiatives: awareness; politics; access; relevancy and meaningful use; sustainability; and coordination (UNDP, 2001).

The work of Heeks (2002) is also important in this context, as he has attempted to model the implementation of information systems in

developing countries in such a way as to identify the potential for failure, including what he terms “sustainability failure.” He identified “design-actuality differences” as a powerful contributor to systems failure and suggested that systems which allow “contingent improvisation” – that is the ability to accommodate design changes and adapt to local needs – are more likely to be successful, and proved to be sustainable. As he notes, however, the success of this approach is based on environments in which the necessary skills and resources to adapt and successfully implement systems are available locally. This raises the question, then, of just what skills and resources are required, and how access to them can be provided. In this respect, this chapter provides significant insights relating to the diffusion of innovation and to network analysis.

DIFFUSION OF INNOVATION AND NETWORK ANALYSIS

The literature on the diffusion of innovation is dominated by Rogers (2003), who defines innovation as “an idea, practice, or object that is perceived as new by an individual or other unit of adoption” (p. 12). He describes five attributes of innovations: relative advantage, compatibility, complexity, trialability, and observability. According to Rogers, the way in which these attributes are perceived by those who are the beneficiaries of the innovation determines both the speed of adaptation and the degree to which a specific innovation is adopted, modified or ignored. This framework has been successfully used to model the diffusion of innovation in a wide range of studies, for example, Grover and Teng’s (1992) study on the take-up of database technology, and Garrison’s (2001) study on the adoption of online technology by news organisations.

Studies on the diffusion of innovation have been enriched by adding insights derived from social network analysis which, as Wellman (1988)

explains, is based on the relationships between units, rather than the categorisation of those units into predefined categories, and on interpreting behavior in terms of structural constraints on activity rather than in terms of inner forces. In this theory, networks structure collaborative and competitive activities in order to secure scarce resources including information, support, and power. So, to understand the behavior and capabilities of those units it is necessary to consider the relationships between all groups and individuals in their immediate environment. These relationships are important to innovation, because it is through them that many of Rogers’ five attributes are realised.

A highly influential work in this field is that of Granovetter (1973), whose work centered on the strength of weak ties, defined as a casual or infrequent connections between two people or organisations. He emphasised the importance of social networks in the distribution of information and resources, arguing that those with networks of weak ties are best placed to receive new information and resources, since they can act as bridges to the broader community. He also found that the longer linked the network – that is the more links required to establish a connection between two people or units – the less effective it is.

In contrast, Coleman (1988) studied dense closed networks—those with multiple strong internal links but few weak links—finding them to be important for the enforcement of social norms, obligations, and expectations. These, he argued, are important in facilitating effective action. He further argued that those with limited ties to external communities have structural holes that, if they are not closed, can result in a lack of access to the information and resources necessary to facilitate action, particularly innovation. Burt (2000), building on this, argued that all networks can have structural holes and that those who can arrange relationships spanning across those holes may achieve a competitive advantage because they are best placed to obtain new ideas, information,

support, and other resources. In this view, network closure is about maintaining the status quo while brokerage is about change. However, a number of researchers (Aldrich & Zimmer, 1986; Kadushin, 2002) have found that both brokerage and cohesion networks are required for the successful diffusion and exploitation of resources.

Considering the issues relating to brokerage and cohesion networks in more detail, Aldrich and Zimmer (1986) emphasised that the maintenance of effective networks requires the continual creation of weak ties so as to prevent a few strong ties from closing them to opportunities and alternatives, while Kadushin (2002) argued that “safety drivers,” which act against change, are common when the costs of interaction are low, visibility is high, and moral obligations are more salient—a situation typical of rural and regional networks. And, in work of special significance for the diffusion of innovation, Valente (1995, 2005) found that a significant difference between effectiveness (brokerage) networks and safety (cohesive) networks is the location of trust, which is an important factor in the realisation of Rogers’ (2003) five attributes.

Others have attempted to identify issues that relate to the development and success of regional groupings, and their work has obvious implications for developments in rural and regional areas. For instance, Hakansson (1990) suggested that networks are a new organisational form necessary to supplement internal competencies and that this implied a mutual dependence between government and business, particularly in regional areas where location has a strong impact on the availability of resources. Steward and Conway (2000) examined the conflicting goals and cultural variations that are likely to exist between organizations with extended supply chains, and identified that differences in culture, language, and business practices at the levels of individuals and organizations are potential sources of tension.

Finally, Furst, Schubert, Rudolph, and Spieckermann (2001) related the concepts of cohesion

and brokerage to the complementary categories of stationary and mobile social capital. In their view, regional networks need a high degree of stationary capital to ensure self governance but also need to be able to lock in mobile social capital in order to bring in new ideas and the flexibility needed for development. Bebbington (1997) provided a clear example of this in the author’s study on communities in the Ecuadorian and Bolivian Andes that had managed to improve their local economies, reversing trends in both migration and environmental protection, via a program of agricultural intensification based on the use of new technology. He demonstrated that this could not have been achieved without a broadening of support networks and the access to ideas, contacts, and resources they bring, nor without the involvement of strong local community groups that helped create the pre conditions to take advantage of those networks and opportunities when they were presented.

In summary, the successful diffusion of technology, particularly in rural and regional areas, is in large part dependent on the flow of resources and the capacity for local improvisation. Organizations and communities seeking to implement technologically based change, require both brokerage and cohesion networks: brokerage networks because they provide access to opportunities, innovation, strategic advice, new skills and support; cohesion networks because they provide a trusted environment in which to operate, harness local capacity and manage “contingent improvisation.”

CASE STUDIES

There are a significant number of case studies in the literature that explore these issues, but for the purposes of this chapter it will be sufficient to highlight five. The first, a study by Sherry (1998), illustrates a straightforward analysis of a technology diffusion program, using Rogers’ (1995)

framework to evaluate IT training programs in regional school districts in the United States. In the second, an ambitious, three year longitudinal study by Barratt, Sahay, and Walsham (2001), the efforts of the Indian Ministry of Environment and Forests (MoEF) to apply geographic information systems (GIS) technology to forestry management and wasteland reclamation are examined. Issues of trust are explored in some depth, as are the types of problems can arise when local conditions and expertise are not adequately acknowledged, themes that are further developed in an Australian study by Terziovski and Howell (2001). They examine network linkages connecting multiple stakeholders, demonstrating that interaction between government, business, and the community is important in facilitating new initiatives, particularly if trusted local connections can be harnessed.

An extended examination of the author's experiences in implementing a series of information systems in regional Vietnamese university libraries is then provided. This is a prime example of a project that was struggling to succeed because the technology was implemented without regard to the local context, but which was revitalised when gaps in local infrastructure were identified and the need to establish local support networks recognized (Johanson, Denison & Otis, 2004). This is complemented by the final case study, that of Gibb and Adkihary (2000) on the work of non-government organisations (NGOs) in South Africa. They explore the nature and role of NGOs as network brokers capable of supporting external interventions by using their relationships to assist in the development of local stakeholder networks.

Training and the Diffusion of Skills: Boulder Valley Internet Project

Sherry (1998) used Rogers' (1995) framework for studying the diffusion of technology to evaluate the Boulder Valley Internet Project (BVIP), a five-

year collaborative venture between the University of Colorado at Boulder and the Boulder Valley School District (BVSD). The project was funded by the National Science Foundation (NSF) and aimed to incorporate Internet-based technologies and strategies into the teaching program of the District, by developing training programs and integrated telecommunications throughout.

Commencing in 1992, the project used a trainer-of-trainers model to create a core group of 26 teachers. Their mission was to become proficient in the use of e-mail and in investigating Internet resources, and experienced in integrating these into school curricula, so as to pass on their skills to other teachers within the district. Using a participatory design model, the bulk of the training concentrated on the needs of classroom teachers. Workshops and classes were given in BSVD classrooms, using the very platforms that the teachers would use once their classrooms were connected. Sherry found that the program achieved considerable success and that, as of January 1996, there were 435 teachers on the BSVD network who logged in regularly. However, she also reported that the project later lost much of its momentum when it lost the support of the school administrators and key policy makers at the district level.

She made the following points with respect to the level of success that was achieved:

- Rogers' (1995) framework emphasises the role of change agents in influencing their clients' behavior, and their ability to help them realise change. In this case, the project used BSVD teachers drawn from the district as change agents rather than relying on outside experts that could have been drawn from the project's partner organizations. This ensured a significant level of client/agent empathy.
- By focusing on providing an authentic context (dealing with real issues in an actual work environment) in which situated learning could take place, the project presented

the opportunity for clients to observe the benefits of the technology firsthand, another critical factor in Rogers' (1995) model.

- The self-reflection involved in the participatory design process ensured that trainers and trainees explored the issues, dealt with conflicts and solved problems together, contributing substantially to the success of the training program.
- At least in its initial stages, the district as an organization ensured that the effort was aligned with district-wide visions and policies and integrated into the established telecommunications channels. As a result, the project had strong grassroots support from the local teachers who were the primary participants in the training program.

As Sherry (1998) noted, however, the project was not a complete success. The reason for this was that, as the project evolved, the attitudes of the policy makers became more conservative and the project gradually ceased to address the needs of all stakeholders, specifically the school administration and the district's policy making bodies. As a result, it received a lower priority and stalled. Sherry concluded that "If there was a single lesson to be learned from the BVIP experiment it is ... [that] information technology interventions cannot be separated from their ecological contexts or from the educational activities that they enhance" (p. 141).

Rogers' (1995) model postulates five stages that a successful intervention must pass through. They are: (a) seeking information about the innovation's existence and some understanding of how it functions; (b) forming a favourable or unfavourable attitude towards it; (c) engaging in activities that lead to a choice to either adopt or reject the innovation; (d) putting the innovation to use; and (e) seeking reinforcement of an innovation decision that has already been made (Sherry, 1998). In the case of the BVIP project, it can be seen that external linkages (brokerage

networks) were used to successfully introduce new technology as in step (a), while the strong peer-to-peer (cohesive networks) represented by the teachers within the district assisted steps (b) to (d). However, the ultimate failure of the project was due to the poor management of its broader internal stakeholder network, allowing Kadushin's (2002) "safety drivers" to take affect, thereby cutting off access to the required resources and external support needed to reinforce the innovation as in step (e).

The Role of Trust in Local Adaptation: GIS Systems in India

Barratt et al. (2001) also undertook an in depth case study of a technology diffusion program. It was a three-year longitudinal study of the efforts of the Indian Ministry of Environment and Forests (MoEF) to apply geographic information systems (GIS) technology in the areas of forestry management and wasteland reclamation. For their analysis they used a framework strongly influenced by both Giddens (1990, 1991) and Kling (2000) to explore the types of problems that can arise when local conditions and expertise are not adequately acknowledged and utilised during the introduction of new systems.

The project commenced in 1991, initiated by the U.S. Agency for International Development (USAID), which also provided seed money, training, and software. Phase 1 of the project aimed to establish the technical feasibility of using GIS in eight scientific institutions. Phase 2 envisaged the subsequent transfer of those systems to local district offices. Although Phase 1 was completed in 1993, by the end of the research period only minimal progress had been made in transferring the technology to district level and it is this failure that the analysis focuses on.

While acknowledging variable management support that affected the enthusiasm with which the project was undertaken in different districts, Barratt et al. (2001) identified a number of specific

issues that contributed strongly to the failure of Phase 2:

- There was no work culture based around the use of IT because there was no history of access to technology. At the same time, the social structure, organizational forms, and existing work arrangements were not taken into consideration. The pressure for change had come from external sources—governmental agencies and international bodies such as the World Bank and the United Nations (UN). These pressures confronted strong existing traditions and systems of work, but while the process of technology transfer was useful in providing know how, technology, and funding, it promoted western values and management techniques that were often incompatible within the context of a developing country. The difficulties caused by these unresolved tensions hampered the development of the restructured and standardised work practices required to introduce GIS at the local level.
- Compounding the problems mentioned in the first point, the technology itself was not neutral. GIS systems were built on western notions of rationality and coordination, while the depiction of space as an objective was a value-free reality. Assuming the widespread use of maps and knowledge of spatial planning concepts, the new systems required a reorientation from planning based on non-spatial parameters such as development schemes and households, as was the existing practice, to planning based on spatial criteria, such as “watershed units” and “wasteland distributions.” These concepts were in conflict with local practice and, as a consequence, the system was perceived to be less relevant to local need.
- There was a lack of relevant professional skills. The effect of the first two points may have been ameliorated had more attention

been given to providing support and building local expertise and capacity. Forestry officials needed to develop new conceptual skills to translate their forestry related problems into the spatial terms required by the GIS models, but they also needed the skills to adapt those models to local conditions in order to facilitate contingent improvisation. The professional skills that were locally available enabled the achievement of success in Phase 1, but not in Phase 2. However, the models developed in Phase 1 reflected the view of the institutes as scientific research and development centers by placing little emphasis on other important socioeconomic variables in the context of the districts, for example population and livestock data.

- Regarding professional skills requirements, it was recognized by a number of the institutes that there would be problems in transferring the technology to the districts, because they considered that their technical resources and the skills of institute staff were inadequate to provide sustained support in the field. They lacked a core group of people with GIS expertise who could nurture the projects over time and, in any case, many scientists considered that their institutional mandate was limited to developing the technology, not its transfer to the district level.

As can be seen, this was an intervention that required significant changes in professional culture, technical skills, and work practices. Remote organizations were encouraging the take up of the technology, and although the project provided support networks sufficient to ensure implementation by the scientific institutions, the networks that were provided were inadequate to ensure the transfer of skills and the conditions required to effectively exploit the technology at the local level.

The analysis by Barratt et al. (2001) is also of interest because of the way in which it uses Gid-

dens' (1990, 1991) theories to explore notions of trust, the lack of which they consider contributed to the problems that arose. Giddens identified two types of trust, distinguishing between situations in which the actors are face-to-face and those in which they are not. In this case, a typical situation in which information systems are implemented for the first time, it is a prime example of the latter, and required reconciliation between traditional and new knowledge systems and the development of new trust systems. However, the effectiveness of these processes depended on the manner in which the technology was introduced and the nature of support provided and, in this case, these were inadequate to the task. As a result, the disembedding of traditional practices of forestry management did not occur, and made it difficult for standard methodologies to be modelled, codified, and applied.

The introduction of GIS technology also exposed workers at all levels to new networks of people, required to introduce and support the technology. For the project to be successful, they needed to develop trust in these new networks. But this could not happen in conditions where an unresolved tension existed between local requirements and the introduced system.

Barratt et al. (2001) argued that the project was not successful because it attempted to impose a new professional and technological framework without taking local conditions into account. There seems to have been little provision for local contingency in design, and little recognition of the types of support and support networks that would be required to implement and sustain the new environment. Significantly, there seems to have been little recognition of the need to develop trust in this new environment or the impact that that might have on the success of the project. Their final comment, noting that "the entry of the private sector into government GIS projects is one factor that can potentially lead to more rapid changes in the future" (2001, p. 15), clearly indicated an important issue. This comment is

significant because it recognises that the private sector represents a means of providing additional expertise and support, localised in a way that enhances trust.

The Role of Trust in Technology Diffusion: E-Commerce in Regional Australia

The issue of trust also arises, albeit in a slightly different form, in an Australian study by Terziovski and Howell (2001). Reviewing a series of e-commerce projects undertaken by local government in regional Victoria, they found that while network linkages connecting external stakeholders were important to drive new initiatives, trusted local connections were also essential for their proper implementation and ongoing exploitation.

The scheme in question, VEEM (Victorian E-Commerce Early Movers) Scheme, was funded by the state government with the aim of identifying linkages that could aid and support local government usage of e-commerce and its subsequent take up by local industry and the wider community. A number of local government areas were funded to develop a range of projects, including promotional events such as e-commerce business planning workshops and regional expos, and more specific activities such as the development of regional business portals and the development of business plans to enable local businesses to adopt online fulfilment and procurement.

Feedback from participants confirmed that the scheme was a success, with e-commerce being embraced by business and communities alike. They also noted that, as the project progressed, many of the activities had been customised to better fit community and private sector expectations, reflecting the flexibility that had been built into the scheme, and the willingness of the responsible government agency to work with local government in a meaningful way.

Terziovski and Howell's (2001) report highlighted several strategies that were critical to this

success, but noted that to achieve sustainability it was necessary for participants to develop their own expertise, and it was important that strategies had been framed with that end goal in mind. Specifically, they commented that:

- Participants recognized that the projects would not have been undertaken without the stimulus provided by the state government, nor would they have been seen as a high priority for local government without that support, which provided credibility, resources, and a secure working environment.
- While participants acknowledged the important role of the state government, they also understood that, in order to ensure meaningful participation, it was essential to devolve decision making to local government and communities. In this context, local government saw its role as seeding community or industry based networks, and providing infrastructure support and training.
- As local small businesses were intensely focused on their own immediate needs, it was considered far more effective to use local experts to talk to local people, maintaining the focus on their needs rather than those identified by external stakeholders. These grassroots champions were seen as important because they could provide examples of success and act as marketing agents for uptake of technology. These are important factors in reducing local indifference. It was also considered more effective to have a number of champions, drawn from different business sectors, who had existing relationships with other local centers of influence such as banks, accountants, and community business groups. For example, one local government office sponsored six business champions from three targeted industry sectors – transport/distribution,

manufacturing, and services industries – and was instrumental in connecting them to the economic development in the region by providing better access to its networks.

- While it was recognized that external expertise was essential to the success of the diffusion process, and that that expertise would be required on an ongoing basis, it was also recognized that much expertise could, and should, be localised. To facilitate this, the report recommended that the state government should fund an ICT Center in each regional area, using a local body such as part of the council or a university or the local e-commerce association, to deliver information, training, and so forth. These centres could not only provide trusted support, but could also strengthen the relationship between the State Government, local councils, and the community, thereby providing a sound foundation for future programs.
- Finally, it was recognized that something as simple as a database of service providers could be invaluable in assisting both local government and local businesses, by preventing duplication of time and resources when identifying and evaluating existing service providers.

Reflecting these considerations, the report proposed a model of best practice based on a tripartite relationship between state and local government, and local government and the community. In this model, the state government provides the vision, policies, initiatives, and funding, while local government provides a leadership role to facilitate e-commerce diffusion, working with local businesses and the community to address real needs.

All of the strategies adopted by the project built on existing networks and relationships to facilitate the successful diffusion of e-commerce, using them to establish and reinforce existing trust systems and to develop strong relationships on a regional,

business and individual basis. The creation of support (brokerage) networks that facilitate a flow of information, skills and resources was absolutely essential, but it was recognised that these would only be useful if they were combined with the strengths and resources of the local community (cohesion networks). As in the MoEF project (Barratt et al., 2001), trust in the ability of those managing the project to understand local needs and conditions was identified as a significant factor, but unlike the MoEF project, trust was harnessed and the project achieved its goals.

Building Support Networks: University Library Systems in Vietnam

Many of the themes and issues raised in this chapter found practical application in a series of projects in which the author participated, involving the diffusion of new technology among regional universities in Vietnam. In this case, which has been documented by Johanson et al. (2004), the NGOs managing the project not only brokered networks to support the initial diffusion of technology and distribution of resources, but also assisted in the development of more localized networks capable of exploiting the technology on an ongoing basis.

The first of these projects began in 1999, after Atlantic Philanthropies (AP), a US based NGO, decided to contribute to the educational infrastructure of Vietnam by developing a series of Learning Resource Centers (LRCs) in collaboration with regional universities in Da Nang, Hue, Can Tho, and Thai Nguyen. Each project involved the design and construction of a modern library facility based on western models and standards of information service, together with the provision of state of the art technology, and high quality teaching and learning facilities.

The initial project, the Da Nang University Information Resource Center (IRC), was completed in 2001 with high expectations. Staff had

received training in the form of a short study tour to Australia and an introduction to the use of library management systems. The initial collection included 10,000 monograph and serial titles, in both English and Vietnamese, and access to a range of electronic resources. A Vietnamese company was contracted to provide both a local area network and an integrated library management system (ILMS) to manage housekeeping and public access functions. Although well resourced in comparison with other university libraries, it quickly became apparent that it was under utilized. Management decided not to circulate material and, partly in consequence of that decision, staff used only a fraction of the functionality of the ILMS. Further, without a support contract for either the communications infrastructure or the ILMS, there were ongoing problems with the stability of the technology.

AP was surprised by this result and delayed work on the remaining LRCs while a review was conducted. That review, undertaken by RMIT University Vietnam, found that strong and committed management had been provided and, although there were a number of resourcing issues, the most significant problems related to the fact that the IRC was operating without the supportive infrastructure that its western counterparts take for granted:

- The proposed operating environment of the IRC was essentially new to academic libraries within Vietnam and, although there was a training program for staff, it was both limited in scope and had no provision for ongoing support. There were only a few librarians with whom they could discuss ideas and share experience. The library schools were not producing appropriate graduates and the limited number of similar libraries were scattered throughout the country. Somehow, with little advice from the scanty professional infrastructure, traditional tasks such as cataloguing fared well, but new

areas such as circulation, the use of IT, and the identification, acquisition, and use of electronic resources, did not.

- Also, apart from the inability to obtain immediate practical advice at a local level, the overall professional library infrastructure within the country was underdeveloped. There was little support for activities such as the adoption and promotion of national standards, the nurture of a national professional association or the encouragement of local systems vendors. That made it difficult for management to obtain strategic advice.
- Neither staff nor vendors had the experience to develop procedures that would allow them to incorporate the automated system into the new style of operation, nor to identify problems with the system that would allow them to recommend appropriate modifications. There was little capacity for local adaptation.
- Modern western libraries make intense use of IT, relying on a shared infrastructure that allows them to reduce the real costs of that technology as well as the resources required to manage it. Typically, that infrastructure includes consortia to support the purchase of electronic resources, the shared development of IT strategies and applications, interlibrary loan networks, and shared cataloguing. None of this was available to the IRC.
- The decision on how to proceed with acquiring an ILMS was crucial to the successful operation of the IRC. At that time the available choices were limited to importing an international system or developing one locally. Importing one had the advantage that it could be expected to be fully functional and would comply with the relevant standards, but there would also be several disadvantages: none had a Vietnamese language version; none provided local support; and none provided support in Vietnamese. Furthermore, the cost of the initial purchase

and of ongoing maintenance was unaffordable. Eventually, a Vietnamese company was commissioned to develop an ILMS for the IRC. The chosen company was new to libraries and although it learnt quickly, the system it initially delivered had a number of serious problems.

- There were, and there still are, serious limitations in the national infrastructure with regard to the availability of trained IT staff, particularly in the regions where, although the number of IT staff is growing, there remains a shortage because there is an increasing demand for their services from other developing industries.

AP had come to realise that developing a sustainable service required a significantly broader perspective than that was at first apprehended. One other thing they recognised was that the LRCs not only had to be effective in themselves, but also they had to be integrated within the broader educational and professional communities. To advance their interests it was necessary to work within the already established framework in the country, putting emphasis on those aspects that had been identified as being important to the LRC projects and their further development. The profession within Vietnam had already instigated work on a program of modernization but had been hampered by lack of funds. AP sponsored a workshop to discuss further on the adoption of standards at a national level. That workshop also explored issues of cooperative and collaborative activity, including the possibility of developing a national organisation of professional librarians and library educators, as well as recommending a national strategy for the development and acquisition of library management systems within the country. Working closely with the profession, AP subsequently initiated projects in a number of these areas.

From the view point on the diffusion of innovation and Rogers' (2003) framework, this

intervention was strong enough in terms of relative advantage, but at the same time was weak in terms of compatibility, complexity, trialability, and observability. It became obvious that the success of the first IRC was dependent on the broader national infrastructure and it could not be considered successful if it was treated as self-contained. It could only be considered successful if it was treated as a first stage in the overall development of services within the country. In their analysis, Johanson et al. (2004) argued that support networks were essential to the success of these projects because they provided access to strategic advice, skills transfer, and an ongoing professional culture. Hence, the LRCs could not achieve their full potential until stakeholder communities had themselves progressed to the stage where they could provide the required additional support. In network terms, the first IRC had been created with numerous structural holes that could not be effectively closed until a shorter linked brokerage network and a stronger internal (cohesive) network had been established. Therefore, the other elements of Rogers' (2003) framework could come into play until that had been done.

The project is also of interest from the point of view of developing local capacity in order to support local adaptation or contingent improvisation. As mentioned earlier, the library management system was plagued with problems and the resolution of these problems was beyond the reach of the staff of the IRC and the vendor. An outside expert was called in to evaluate the system and to work with both parties to recommend improvements so that the resultant system would at least provide the necessary core functionality and meet international standards. This strategy resonates well with the views of Heeks (2002) because it allowed the staff of the local vendor and the IRC to build up the expertise required to take future development of the system under their own control. In this case, even though the need for local adaptation had been recognized, the capacity to

undertake it was only achieved when the relevant support networks had been established.

Concluding their analysis, Johanson et al. (2004) reported that these issues were addressed directly in the development of the subsequent LRCs. They found that not only were the subsequent projects more successful, but that their success contributed to a revitalization of the Da Nang IRC.

Using NGOs to Build Support Networks: The CEFÉ Network in South Africa

A common question running through these case studies is the question of how best to maximise the effectiveness of external interventions. The work of Barratt et al. (2001) highlights some of the problems that can occur, and although Terziovski and Howell (2001) describe a more successful case, they are clearly considering a technically potent and culturally homogenous environment. The projects documented by Johanson et al. (2004) are useful in that they provide examples of a successful intervention in a developing country, but a more general consideration of the issues is provided by Gibb and Adkinary (2000) who examine the role of NGOs in this process. In their view, NGOs can provide a useful mechanism for promoting the diffusion of innovation and development because they are more likely to be embedded in their communities and, as a consequence of that, are more likely to be capable of helping to develop the networks of trusted stakeholders that lead to sustainable outcomes.

They studied the Competency-based Economies through the Formation of Enterprise (CEFE) Network, an alliance of six NGOs in South Africa. In South Africa, the role of small business is seen as critical in supporting government policy, in meeting targets for new job creation, and as an effective means of redistributing income and opportunity to the indigenous population. NGOs, such as those of the CEFÉ Network, are important because they

are seen as a means of delivering financial and business development services, including training and consultancy, and establishing the necessary support structure for small businesses to thrive. CEFÉ is important because it forms part of a national grouping of NGOs operating with a broader stakeholder group comprising major national players, including government organizations and public funding sources, national and international, private businesses (large and small), professional service companies, local and regional government, business representative organisations, and the media. Thus, it is in a position to broker a wide range of services.

Gibb and Adkihary (2000) chose the CEFÉ Network to study because, since its inception in 1995, it had successfully met a number of challenges, including the need to deliver services over a broad geographic area by focusing on local need and underpinning sustainability. As a result, it had been successful in helping its member NGOs to distribute resources and provide training, while developing a more standardised range of services that allowed them to mesh better with national priorities. By studying their experience, Gibb and Adkihary aimed to identify and promote new forms of partnerships and governance that could be used to assist the development of small and medium enterprises (SMEs) more generally.

They found that NGOs can play an important role in this type of activity because they are essentially bottom-up organizations which are more likely to be embedded in their communities and are thereby more likely to reflect local needs. Not only that, but they also have the ability to act as brokers, capable of connecting those communities to the support networks that can provide them with the access to external expertise and the resources they require to meet their needs. In this way, they can act to identify the local needs and close structural holes.

Gibb and Adkihary also recognised that NGOs are not without potential problems, though they are intrinsically connected with their strengths.

For example, NGOs often have a weak resource base, and as a result, can fall into the trap of expending their energies on chasing funding to ensure their continued existence rather than on fulfilling local needs. By focusing more on the requirements of their funding bodies, they react more to supplier needs rather than those of the community they seek to serve. Another potential problem is that, because of their commitment to meeting local needs, they may find it difficult to standardize service delivery by harming their ability to fit into national networks and to align with national priorities.

Gibb and Adkihary observed that, to be successful in helping their communities, NGOs must develop strategies to neutralise those problems. To that end, they proposed a Stakeholder Assessment Model (SAM) of NGO effectiveness, based on a series of key evaluation questions, including:

- To what degree the overall focus of the NGO on meeting the needs of the stakeholders?
- How well is the NGO known by the stakeholders?
- How clear is the mission/objectives of the NGO to the stakeholders?
- How well is the NGO perceived by the stakeholders to be meeting its objectives?
- To what extent does the NGO undertake joint ventures in partnership with stakeholders?
- Are these initiatives perceived as being successful? (Gibb & Adkihary, 2000, p. 145)

The model as developed, focuses on the requirements of NGOs as organizations at the center of stakeholder networks that need a clear understanding of their own missions and the needs of their various stakeholders. Gibb and Adkihary observed further that, if used correctly, the model can not only ensure a focus on client needs, but also can help in setting management objectives by contributing to NGO sustainability.

The study concluded by reporting that the CEFÉ Network was continuing to deliver success-

ful programs and gain greater acceptance from government. By increasing its range of strategic alliances, it was also improving its ability to broker new services. Gibb and Adkihary's (2000) examination of the CEFE network demonstrates that, despite the potential problems, NGOs that focus on the issues identified in their SAM model can successfully act to facilitate network development and achieve the mutual support that derives from bringing local groups and external stakeholder communities together.

FUTURE TRENDS

International agencies that are involved in development projects, for example the World Bank, are including social capital measurements in their analyses and are starting to acknowledge the role of social factors in their strategies for systems development (UNDP, 2001). Significant research is being undertaken in the areas of technology diffusion, social capital and network analysis. However, despite the examples provided in this chapter, much of it relates to the role of business and the corporate world, which are generally seen as the most important drivers of economic growth. Furthermore, much of the work in regional areas is actually undertaken through the agency of NGOs, and therefore, there needs to be more intensive research into characteristics, role, and operating culture of NGOs.

This is particularly important in developing countries and there are a growing number of organizations working to explore those issues, for example, the research being undertaken by the Institute for Development Policy and Management at Manchester University, which focuses on policy formulation and implementation, and organisational design (Baark & Heeks, 1998; Madon, 2000). The emergent field of community informatics is also making a strong contribution in this context. For example, two recent conferences focusing on technology for development,

and framing the issues in terms of sustainability and the social appropriation of technology, are of special relevance to the issues raised in this chapter (Erwin, Taylor, Bytheway, & Strumpfer, 2005; Johanson & Stillman, 2004).

CONCLUSION

The projects discussed in this chapter demonstrate that an over-emphasis on technology and technology-based services, and their development in isolation from the communities that they are intended to serve, will not lead to successful and sustainable outcomes. Successful, sustainable projects are the result of a careful interplay of controlled variables, many of which may need to go through a complex iterative process based on changing stages of organizational culture. Projects targeted at rural and regional communities must address the real needs of the communities they aim to serve. That requires not only long term commitment and strategic funding, but also, meaningful participation and proper consideration of all influences within and between the affected communities.

This chapter has used a framework provided by the diffusion of innovation within a network environment to highlight how necessary resources can be provided to make such developments a sustainable reality. Successful, sustainable projects require access to a complex infrastructure maintained by a range of stakeholders. Network relationships are essential in both the development and maintenance of such infrastructure because they provide access to new ideas and innovations, strategic advice, training, technical support, and a host of other resources. While some of these resources, such as access to new ideas, typically should continue to be provided through extended networks, successful and sustainable projects require a localized infrastructure capable of localizing and harnessing resources in a trusted environment. Specifically, it is important to recognise

this sort of support network in rural and regional areas, and even more so in developing countries, because it is precisely these network structures that they lack.

The case studies examined, particularly those of Johanson et al. (2004) and Gibb and Adkinary (2000), highlight the fact that those networks are often brokered through the agency of NGOs, who provide access to contacts and resources that would otherwise be inaccessible to local communities. And while it could be argued that broad networks could be established without NGOs, the case studies emphasise that their importance derives from the fact that they are more often embedded within their communities, so that they can make use of existing trust systems and local links to identify and close structural holes which would otherwise deny those communities access to much needed resources and expertise.

ABSTRACT

In this chapter, we want to state shortly the basic components and manifestations of the digital-divide problem, as well as the ways of its solution in a specific country with its specific regional, social, historical, and political features. Moldova is taken as such a country. The problem is interesting to consider in the example of such a country because it is especially manifested in countries of such type: those that are waking up to development and are limited in means.

INTRODUCTION

“The love for one’s country impels and imperiously dictates to everyone, who intends to describe the customs of one’s nation, to praise the nation, to which he belongs by birth, and to laud the population of the country which gave him birth (generally speaking, not many strangers know the customs of moldovan people). On the other hand, the love for truth hinders and forbids praising of what is to be condemned upon a fair balance. It will be more useful for country if we will not hide

from its citizens' eyes the shortcomings, which are current among them in abundance..."

(Demetrii Cantemirii,
"Descriptio Antiqui et Hodierni
Status Moldaviae," Petropoli, 1727)

No problem could be explained if we speak only about a problem in general. When putting forward some general conclusions and discussions, one should always examine them with concrete examples. In real life, the problem is manifested by concrete facts, at a concrete place and at a concrete time.

In the previous chapter, we examined basic statements of the digital-divide problem: a short history, the situation in the world, and basic manifestations and approaches to its solution that the world community undertakes and recommends. These discussions were illustrated by some examples from the history of different countries. In the present chapter, the authors base their arguments on the judgments and conclusions stated in their chapter for the examination of the digital-divide problem, and give possible ways to its solution in a specific country. Moldova is chosen as such a country.

Moldova is a country that just now became aware of the necessity to create the information society. Though scientists of the country have told about this for more than 10 years, extreme poverty and instability did not allow people to even think about any purposeful actions in spite of having a comparatively good infrastructure. The concrete, real steps have been started only since the year 2003, although the corresponding rhetoric sounded in different documents and speeches earlier.

The chapter describes the economic situation in the Republic of Moldova (RM) as one of the countries with strongly pronounced symptoms of the digital divide, and describes Moldova's steps in the creation of the information society and the problems that it faces. The chapter shows the degree of the complexity of the digital-divide

problem in this country, and what priorities and difficulties occur.

Naturally, national peculiarities are present in Moldova as in any other country. This is not just a type, but a real country. The authors have no pretension about Moldova's oneness, but want to emphasize only that every country, when resolving the digital-divide problem, should take into consideration general statements and the country's individuality as well. In the course of the whole chapter, the authors compare Moldova with other countries by all measured and available indices.

The situation in Moldova is considered in the context of other countries, namely, its direct neighbors (Romania, Ukraine) and a set of other countries from the former socialist camp and that are just passing or has just passed through the phase of transition from planned to market economies (Estonia, Slovakia, Slovenia, etc). Certainly, the analysis includes also those countries in which the solution of the digital-divide problem can serve as a guiding line for ones just starting the problem solving.

On the basis of this analysis, the complex actions that, in the authors' opinion, can provide the solution of the problem in Moldova are offered.

MOLDOVA'S E-PLACE IN THE WORLD

For more precise understanding of manifestations of the digital-divide problem (in particular, the domestic one) and ways of its overcoming, it is useful to consider it with an example of a specific country. Most sharply, this problem is manifested and more difficult to be tackled in poor countries with a prevailing agricultural population. An example of such a country is Moldova, the small (with an area of 338,000 km²), poor, agrarian country located in the southeast part of Europe, with its capital Chisinau (see Figure 1). Moldova, formerly part of the Soviet Union, now belongs to

Digital Divide

Digital Divide

a group of underdeveloped countries. According to the preliminary data of the population census from 2004, the population of the country is 3.386 million inhabitants (Biroul National de Statistica [BNS], 2005b). According to the state's official statistical data (BNS, 2005a), the urban population makes up 38.6% of the total population, and rural population makes up 61.4%; the gross domestic product (GDP) per capita has grown from \$458 in 2002 up to \$719 in 2004.

Let us consider Moldova among other countries according to Web presence and e-readiness. The world community carried out the huge amount of work on the development of methods and the calculation of parameters. For the definition of Moldova's place in the world, the authors of the chapter, in their analytical study (Burtseva, Cojocar, Gaidric, Magariu, & Verlan, 2004b) made for the United Nations Development Program (UNDP), had based their data on two international analytical reports:

- A UN report (American Society for Public Administration & United Nations Division

for Public Economics and Public Administration [ASPA & UNDPEPA], 2002) on the basis of 2001 data

- A review (UN, 2003) made by the Department of Economic and Social Affairs of the United Nations (on the basis of 2003 data)

In 2001, a statistical analysis was done comparing the ICT infrastructure and human-capital capacity for 144 out of 190 UN member states. One hundred forty-three countries from them were listed as using the Internet in some capacity. In 2003, the coverage was expanded to include all UN member states. Only 173 out of 191 member states had a Web-site presence. In both surveys, an assessment of the e-government index was done. Different methodologies were used for this index calculation, but each of them takes into account such important indices as Web-presence measure, infrastructure measure, and human-capital measure, which in their turn are calculated on the basis of several other characteristics. In the 2003 survey, the rank of the e-government index and Web-presence measure were determined for each of the 173 assessed countries.

Figure 1. Moldova's geographical position

Thus, the e-readiness index (readiness of the countries for transition to e-governance) allows one to estimate in any measure the degree of the use of ICT in the country, and hence to judge about the digital divide between countries. For comparison, the authors chose the following categories of countries:

- Those with the highest values of the e-readiness index (USA, Australia, Norway, United Kingdom, Netherlands, Denmark, Sweden, Spain)
- Geographical neighbors of Moldova, and countries from the former USSR and from the former socialist community (Estonia, Russian Federation, Ukraine, Romania, Azerbaijan, Kyrgyzstan, Slovakia, Slovenia)
- Agrarian countries, where the percent of the rural population is close to (or lower than) the Figure in Moldova (Bosnia and Herzegovina,¹ Albania,¹ Honduras, Guatemala,

Kenya, Madagascar, Sierra Leone, Ethiopia, Liechtenstein,¹ Papua New Guinea¹)

- Table 1 contains the following information about the chosen countries.
- E-readiness index values for 2001 (ASPA & UNDPEPA, 2002) and for 2003 (UN, 2003), which allow one to judge about the degree of ICT use in the country
- Population number for 2003 (GEOHIVE: Global Statistics, n.d.), which allows us to judge about the size of the country
- Percent of urban population for 2003 (GEOHIVE: Global Statistics, n.d.), which characterizes the degree of the rurality of the country
- GDP per capita in U.S. dollars in 2003 (GEOHIVE: Global Statistics, n.d.), which allows one to judge about the level of well-being or the degree of poverty in the country
- Note that because the year 2003 is the latest one for which data on e-readiness are avail-

Figure 2. Comparison of e-government indices for the years 2001 and 2003 (Source: Diagram is made by the authors of this chapter data from the UN reports: ASPA & UNDPEPA 2002 & UN 2003)

able, the rest of the data in Table 1 were also from this year. To carry out the comparison² on the basis of the latest data (year 2005), we took the Internet-users penetration index—the percent of the country’s population that use the Internet (see Table 2)—for the same country range as in Table 1.

In Table 1, countries are ordered according to the decrease of the 2001 e-government index so that by the position of the country in that list, we are able to judge about the digital divide between chosen countries.

In 2001 and 2003, calculations were made by using different methods, and therefore absolute values of these indices are incomparable. However, one may observe the ratios of values of each country to the values of others and how these ratios evolved (see Figure 2).

One may notice the progress of Australia, Norway, Great Britain, Holland, Denmark, and Sweden, which came close to the United States. It means that the digital divide between them and the United States decreased. Estonia made

considerable progress. Slovakia, Slovenia, and Romania also progressed. Moldova and Azerbaijan remained at the same low level and did not change their positions relative to the other countries. Their ranks in 2003 were correspondingly 95 and 94. They remain amongst the countries for which the digital divide is the largest as compared with leading countries.

The global e-government reports (West, 2001, 2002, 2003, 2004, 2005) present annual results on global e-government: the delivery of public-sector information and online services through the Internet. In Figure 3 we show the e-government rank orderings gathered from all these reports for the chosen range of countries.

It is necessary to note once more that the absolute values for different years for the same country are not comparable and not indicative. However, they are indicative of the correlation between countries for one year. So, Moldova in 2001 was situated among lagging countries and occupied the 155th place with an e-government rank value equal to 21.6. Only Azerbaijan came after Moldova in the selected range of countries.

Figure 3. E-government ranks for the range of countries (Source: Digram is made by the authors of this chapter using data from the reports for the Center for Public Policy by Darrell M. West 2001-2005)

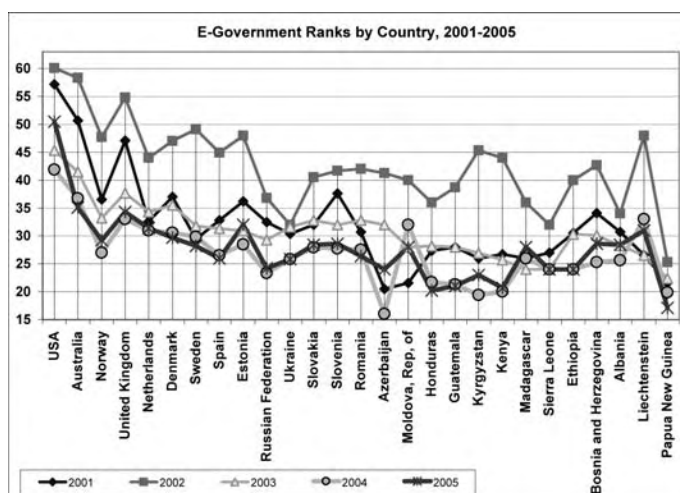

Figure 4. Comparison of levels of urban population and GDP per capita for the range of countries (Source: Diagram is made by the authors of this chapter using data from the Web site GEOHIVE: Global Statistics, n.d.)

Figure 5. Percentage of Internet users in a country's population for the range of countries (Source: Diagram is made by the authors of this chapter using data from the Web site Internet World Stats, 2005)

Digital Divide

In 2002, Moldova occupied the 105th place with an e-government rank value equal to 40.0. Then, nine countries from the selected range came after Moldova. In 2003, Moldova came out at the 62nd place, in 2004 at 21st place, and in 2005 it was at the 61st place. The abrupt improvement in 2004 is evidence not so much of abrupt development acceleration in Moldova as it is of slackening speed in other countries (if we exclude the possibility of the inaccuracy of the data on the basis of which the calculations were made). The fact that the results for the years of 2003 and 2005 are close confirms this conclusion.

Now we shall compare the e-government index (that is, the degree of ICT use) with the percent of the urban population and with the GDP per capita of the countries.³ Since the data for this comparison are for 2003, it is logical to arrange the countries in decreasing order of e-government index for 2003 (see Figure 4).

One can precisely trace the following dependence: The percent of the urban population and the GDP per capita in the countries with a high degree of ICT use are higher, and vice versa. Consequently, the resulted Figures confirm that the degree of the digital divide is influenced both by the ratio of the city population to the rural one, and by the country's standard of living. Moldova, with its poverty and high percent of rural population,⁴ alongside other agrarian countries, is at the end of this spectrum.

There are some slight (and quite explainable) deviations from the described tendency. For example, Estonia and Slovenia, by their position in the list of chosen countries, possess high-enough values of the e-government index with a rather low percent of urban population and a low GDP per capita. Slovakia and Romania, with lower percents of urban population than Ukraine and Russia have (and approximately identical GDP per

Figure 6. Comparison of Internet-usage growth for the range of countries for the period 2000-2005 (Source: Diagram is made by the authors of this chapter using data from the Web site Internt World Stats, 2005)

Table 3. General socioeconomic data of Moldova (Source: The Table is made by the authors of this chapter using data from official reports, DSSRM, 2004; BNS, 2005a)

Type of Data	1999	2000	2001	2002	2003	2004	2005
Total Area (thousand km ²)	33.8						
Number of Population ^a (million inhabitants)	3.6493	3.6435	3.6345	3.6272	3.6177	3.6068	3.3860
Population of Urban/Rural (in % of the total)	42.0/58.0	42.0/58.0	41.3/58.7	41.4/58.6	41.4/58.6	41.4/58.6	38.7/61.3
GDP (million \$US, current prices)	1170.83	1288.46	1480.71	1661.83	1957.81	2595.00	-
Indices of GDP (previous year = 100)	96.6	102.1	106.1	107.8	106.6	107.3	-
Economically Inactive Population (in % of the total)	53.9	54.6	55.6	55.5	59.2	60.3	-

Note: ^aData from the official annual report for year 2004 (DSSRM, 2004) are the result of recalculation by the methodology applicable in the periods between population censuses.

capita), possess higher values of the e-government index. As to Moldova, its place according to the value of the e-government index corresponds to its percent of urban population among the chosen countries. If we analyze the parity of the values of GDP per capita, we see several countries with lower e-government index values but with higher values of GDP per capita: Guatemala, Albania, Bosnia and Herzegovina, Honduras, and Papua New Guinea.

These examples and deviations show that agrarianism and the poverty of the country are not unique factors that determine the digital divide.

Figure 5 helps to draw the conclusion: The rank of the countries based on Internet penetration in 2005 basically meets the same order (the decrease of the e-government index value for 2003) with some exceptions. The obvious exception represents Liechtenstein: For its number of Internet

users in 2005, this country takes an essentially higher place than the one for its e-government index value in 2003. Some of the less advanced countries have made a greater step forward than more advanced countries. Moldova is among them, too. This proves to be true also by the data on Internet growth as shown in Figure 6. In several less developed countries, the number of Internet users has increased during 5 years by more than 1,000%, including Moldova (1,052%). With that, the index of Internet penetration in Moldova is still very low. Compare the 7.4% in Moldova with the 68.5% in the USA, the 35.5% in Europe, and the 13.9% in the whole world; the index value of usage growth is equal to 1,052% in Moldova, 112.8% in the USA, 151.9% in Europe, and 146.2% in the whole world.

Having considered the position of Moldova among other countries, we shall examine the

Digital Divide

dynamics of the parameters influencing the digital divide in Moldova, its current condition relative to the digital divide inside the country, what was undertaken, and what is necessary to undertake for overcoming the digital divide. In the beginning, we shall consider the dynamics of the basic socioeconomic indices during the last few years.

THE GENERAL SOCIO-ECONOMIC DATA OF MOLDOVA

The general socioeconomic data of Moldova from official reports (BNS, 2005a; Departamentul Statistica si Sociologie al Republicii Moldova [DSSRM], 2004) are presented in Table 3.

Figure 7. Distribution of employment by economic activities in Moldova (Source: Diagram is made by the authors for this chapter using data from official reports of DSSRM 2004; BNS 2005a)

Figure 8. Incomes and living standards of the population in Moldova (Source: Diagram is made by the authors of this chapter using data from official reports of DSSRM 2004; BNS 2005a)

The data show that Moldova's population is rural to a great extent (61.3%), and the percent of the rural population in the country is growing. The same tendency is true for a number of economically inactive populations. The indices of GDP are slightly growing from year to year, but it is most likely due to inflation. The level of living standard has grown a little, too. Nevertheless, as the data in Table 1 show, the GDP per capita in Moldova is very low.

Regarding the employed part of the population, one can see that the rate of the agricultural sector is dominant (see Figure 7).

The comparison of population incomes and its living subsistence also bears eloquent evidence of the population's poverty. The corresponding data are presented in Figure 8. The monthly average per member of a household (not to mention the average size of awarded monthly pension) is essentially lower than the living subsistence.

Table 4. Telephone means for public use (Source: The Table is made by the authors of this chapter using data from official reports, BNS, 2005a; DSSRM, 2004)

Type of Data	1996	1997	1998	1999	2000	2001	2002	2003	2004
Number of House Telephone Sets in Public Network or Connected to It (per 100 inhabitants total)	11.5	12.4	12.5	13.3	14.1	15.6	17.3	19.3	21.2
In Urban Network	18.8	20.4	21.5	22.5	24.5	26.1	27.5	29.2	30.3
In Rural Network	5.2	5.5	6.0	6.6	6.9	8.1	10.1	12.2	14.7
% Rural of Urban	27.66	26.96	27.91	29.33	28.16	31.03	36.73	41.78	48.51

Figure 9. Rural-area and urban-area provision of common telephone connection in Moldova (Source: Diagram is made by the authors if this chapter using data from official reports of DSSRM 2004; BNS 2005a)

Digital Divide

When estimating the cited data, it is necessary to take into account the situation in the country. For example, part of the population illegally works outside the country, and this number is beyond all calculation. People leave their native places in search of jobs for which they can earn some money to keep their families in Moldova. Offi-

cially, this part consists of 366,000 inhabitants, but according to independent experts' estimations, it includes about 1.3 to 1.6 million inhabitants who in 2004 transferred to the country approximately \$970 million. So, not all statistical data are present, and those we have are not always absolutely authentic. The data from different sources do not

Figure 10. Nonuniformity of access to Internet in settlements of Moldova (Source: Data is given by the Department of Informational Technologies of Moldova. This data is collected from economical agents only.)

Figure 11. Ratio of provision of telephone sets in rural areas to this provision in urban areas of Moldova (Source: Diagram is made by the authors of this chapter using data from official reports of DSSRM 2004; 2005a)

Figure 12. Density of mobile-telephone communication (Source: Data is taken from Annual Report 2004; NRATI 2005)

Figure 13. Capacity of service market in the field of data transmission, Internet access, and channel renting (Source: Data is from Annual report 2004; NRATI 2005)

always coincide. Inside the country, the regular gathering and processing of statistical data on all parameters and techniques accepted in the world is not adjusted yet. Nevertheless, the data we have help us to track the tendency and ratio of the parameters we are interested in.

These factors, along with others, constitute the serious obstacles in the way of the implementation of ideas about the information society in Moldova.

DOMESTIC DIGITAL DIVIDE IN MOLDOVA BY FIGURES

Table 4 presents the data about the number of house telephone sets in the public network disaggregated by the urban area and the rural one for the period from 1996 to 2004. These data show that during this period of time, the provision of the rural area with common telephone connection is much less than it is in the urban one (see Figure 9).

Digital Divide

Figure 14. Number of providers of Internet-access services broken down by type of connection (on January 1, 2005) (Source: data is from Annual report 2004; NRATI 2005)

Figure 15. Dynamics of the number of connections for Internet access broken down by type of connection (Source: Data is taken from Annual report 2004; NRATI 2005)

The same tendency of weak provision of ICT technologies in rural areas is confirmed by the data from the National Regulatory Agency in Telecommunications and Information (NRATI) site (n.d.) about granted licenses. On July 1, 2005, only 1 in 27 holders of the date-transfer license was from the village Bardar. All 21 holders of licenses for IP (Internet protocol) phone services are from the capital of the country, Chisinau. All six holders of licenses for fixed phone services are from Chisinau, too.

In Figure 10, the data for the year 2003 about the number of registered Internet users per 10,000 inhabitants as distributed by different districts of Moldova are presented. They show the nonuniformity of access to the Internet. It is one of the sharpest problems for Moldova. This urgency has been taken into account by the development of the action plan on overcoming the problem, that is, first of all, to direct efforts and means for the creation of the minimal conditions for inhabitants of rural areas. The state should give to citizens

Table 5. Data on ICT infrastructure development in Moldova (Source: The Table uses data from official reports, BNS, 2005a; DSSRM, 2004)

Type of Data	1996	1997	1998	1999	2000	2001	2002	2003	2004
Share of the Length of Lines with Optic Cable in the Total Length of Cable Long-Distance Lines of Telecommunications (%)	17.1	-	23.7	-	23.9	-	43.3	-	-
Share of Channel Length in Total Length of Long-Distance and International Telephone Channels (% of digital transmission systems with optic cable)	8.5	18.2	38.6	49.4	69.1	59.6	99.6	100.0	100.0
Number of Mobile-Phone Service Subscribers (thousand)	0.92	2.20	8.50	17.93	109.64	224.78	338.30	475.94	786.94
Number of Internet Networks and Access Points	6	10	32	55	223	386	415	415	415

Table 6. NRATI licenses (Source: The Table uses data from NRATI, n.d.)

Total	230	247	230
Inclusive for Rural Area	1	21	110

at least a minimal but guaranteed set of services that will allow them to not remain outside of the modern information society.

As a result of current natural, social, historical, economic, and political conditions in the country, it is possible to note the pronounced digital divide, both international and domestic. The Figures indicate the negative specificity of the country, at the same time emphasizing the sharp necessity to pass to modern technologies, and the difficulty to implement these technologies as well.

POSITIVE DYNAMICS TOWARD THE INFORMATION SOCIETY

Although the previous section of the chapter showed that Moldova is at low level of development, the following data demonstrate that the situation becomes better from year to year.

ICT Infrastructure

Let us see the Figures in Table 4 from another point of view: Compare the ratio of telephone-set provision in rural areas to this provision in urban areas. One will see the sTable, positive dynamics from the year 2000 (see Figure 11).

The dynamics of ICT infrastructure development are also demonstrated by data in Table 5.

According to the data for year 2004 (NRATI, 2005), the development of mobile-phone services

in RM made essential progress. During the period from 2000 to 2003, the number of new connections in the market grew from 110,000 to 130,000 subscribers per year. In the year 2004, 317,500 subscribers were connected to networks; that is 67.6% more. As a result, in 2004 the density of mobile telephony essentially increased (see Figure 12).

Let us consider the market of telecommunications in Moldova: Services for data transmission, Internet access, and the renting of channels make up about 6.66% of the total amount of services (NRATI, 2005). In 2004, the cost of the market of these services increased in comparison with the previous year by 95% (see Figure 13). Figure 14 presents the distribution of providers of Internet-access services broken down by the type of connection on January 1, 2005.

In 2004, the number of Internet connections increased by 22,004 in comparison with 2003. The progress is due to the following connections: WAP connections grew by 19,291; coaxial cable by 738; xDSL connections, in particular, ADSL (asymmetric digital subscriber line), by 1,084; radio connections by 372; dial-up connections by 505; and other kinds of connections by 14 (see Figure 15).

According NRATI (2005), in 2004 the amount of broadband Internet connections increased by 4.75 times, having reached 2,791 connections by January 1, 2005 (compare to 597 connections in

Table 7. Data on Higher Education Institutions (Source: The Table uses data from official reports, BNS, 2005a; DSSRM, 2004).

Type of Data	1996/ 1997	1997/ 1998	1998/ 1999	1999/ 2000	2000/ 2001	2001/ 2002	2002/ 2003	2003/ 2004	2004/ 2005
Higher University Educational Institutions	24	28	38	43	47	47	45	40	35
Students (thousand)	58.3	65.6	72.7	77.3	79.1	86.4	95.0	104.0	114.6
Students (10,000 inhabitants)	162	180	199	212	217	238	262	288	318
Pedagogical Staff (thousand)	4.4	4.6	4.7	5.1	5.3	5.3	5.5	5.7	5.9

2003). It has taken place, basically, due to the increase in the amount of connections of twisted telephone pairs by 1,084 connections. The increase in the number of connections through the twisted telephone pairs is caused by the development of xDSL broadband technologies, in particular, ADSL. Note that the world community recognizes xDSL as prospective technologies, but the implementation of xDSL services in the CEE 10 is still at a very early stage.

The NRATI data about granted licenses are evidence of ICT infrastructure improvement, particularly in the rural sector. The licenses issued by NRATI (n.d.) are distributed as in Table 6.

Toward the beginning of the second half of year 2005, NRATI had registered 333 holders of the licenses that allow the provision of services of computer science in public places, 84 of them working in rural settlements (Server, n.d.).

The data brought to this subsection confirm that there exists a national satisfactory structure of communication highways, which may serve as a foundation for the implementation of the actions directed to the information society's creation.

Educational Level

According to the data of the UNDP (2003, 2005) human-development reports, the following parameters are evidence of the high literacy rate of the population.

- Literate adult population (older than 15): 99.0% in 2001 (UNDP, 2003), 96.2% in 2003 (UNDP, 2005)
- Literate youth of ages 15 to 24: 99.8% in 2001 (UNDP, 2003), 98.7% in 2003 (UNDP, 2005)
- Net secondary enrollment ratio (number of students enrolled in a level of education who are of official school age for that level as a percentage of the population of official school age for that level): 68% in 2000 to 2001 (UNDP, 2003), 69% in 2002 to 2003 (UNDP, 2005)
- Tertiary students in science, math, and engineering (percent of all tertiary students): 44% in 1994 to 1997 (UNDP, 2003); later data are absent

Figure 16. Graduation of students of higher university educational institutions by groups of specialities related to ICT (Source: Diagram is made by the authors of this chapter using data from official report of DSSRM 2004)

Digital Divide

Note that in spite of economic difficulties, there remains the big craving for higher education in the country. See data on higher education institutions presented in Table 7. The ever-growing number of students in the country testifies to it. Also note that the share of students training in the ICT area is great enough and also grows. One can see it by analyzing the data in Figure 16.

So, regardless of the pauperization of the population, there persists the consciousness of the knowledge necessity. Moreover, a lot of people, not only the young, receive a second (and sometimes a third) higher education, aspiring not only to have the big opportunity to get a prestigious and well-paid job, but also to get more opportunities for self-realization.

The described situation in the country is confirmed by UN report Figures (UN, 2003). From the point of view of electronic-government implementation, Moldova occupies the 95th place among 173 estimated countries. As to presence on the Internet, Moldova occupies the 146th place. It is lower than any European country, although the indices of human capacity are rather high: 0.9 (the maximal one is 0.99).

Political Will

An important component on the way to bridging the digital divide is political will. Within the last 10 years, activity in this area in Moldova bore a rather declarative character. At last, during the latest 2 years, the specific steps and results have appeared. The presence of political will in the country is shown by the chronology of the issued decisions of the government and accepted laws.

1. **November 21, 2003:** The parliament of RM passed the law about informatization and state information resources.
2. **March 19, 2004:** The decree of the president of RM about the creation of an information society is issued.
3. **May 2004:** The program SALT, which assumes the maintenance of physical access to the Internet for all schools in the country, is accepted.
4. **July 15, 2004:** The parliament of RM passed the law regarding electronic documents and digital signatures.
5. **February 22, 2005:** RM is among the first countries from the Commonwealth of Independent States to sign in Brussels the plan of action “European Union: Moldova,” which has a section about information-society development.
6. **February 23, 2005:** The government has accepted the strategy of information-society creation called “Electronic Moldova” and the action plan for its implementation.
7. **In 2005,** in the structure of the newly elected government, the Ministry of Information Development appeared.

The authors of the present chapter are the eyewitnesses and participants of the process of national strategy development. This document was developed on the basis of numerous meetings, seminars, and round Tables with the participation of scientists, experts, and advisers in the field of ICT, representatives of civil society, and also governmental and commercial structures. Results of the analytical research that has been carried out in various relevant directions by commissions of experts have been taken into account. This process passed iteratively in some stages, thus in full conformity to recommendations of the Genoa Plan of Action, Point I:

These strategies, generated by the countries themselves, should be the result of a consultative process involving all relevant interested parties in the country, including the private sector and non-profit organizations (NPOs). Such eStrategies should be regularly reviewed and updated, and benchmarked internationally; they should,

where appropriate, be reinforced by regional and sub-regional coordination efforts, notably in the context of economic integration.

(Digital Opportunity Task [DOT]
Force, 2001, p. 13)

There are a lot of programs in which the specific steps, directed at increasing the living standard and improving the life conditions of the population, and connected with ICT introduction into daily life, are stipulated. The examples of such programs in Moldova are the Program of Economic Growth and Struggle Against Poverty, the Moldovan Village, and SALT. Besides these, nongovernmental organizations have their own programs focused on information-society development.

Other Facts and Events

There are also other manifestations in society that testify to the positive dynamics in overcoming the digital divide.

- **Example 1:** The State Office of Public Prosecutor (SOPP) of Moldova is the first and, for the time being, only establishment of RM in which computers on a multifunctional network provide fast and protected information interchange between the SOPP and other state structures (E-uriadnik, n.d.-a).
 - This information-telecommunication center provides Internet services and e-mail on 150 computers that are interconnected and offer opportunity for further expansion. The center is connected to information-telecommunication systems of local public bodies. Furthermore, the connection of all territorial divisions of SOPP and all law-enforcement bodies to the new telecommunication center is supposed.
- The work is carried out within the framework of the project the Protected Information System of the SOPP of RM with financial support from the European Union (EU) and the UNDP, and at the additional support of experts of the state enterprise the Center of Special Telecommunications.
- **Example 2:** Since June 15, 2005, the Moldavian FinComBank has offered a new service: the payment for municipal services through the Internet (E-uriadnik, n.d.-b). Owners of Visa and MasterCard credit cards can pay for municipal services at <http://www.fincompay.com>. The client also has the opportunity to view archives, receive extracts from the account, and get information on the rest of the card.
- **Example 3:** On August 19, 2005, the official Web representation of the RM government opened (E-uriadnik, n.d.-c). The governmental Web site <http://www.gov.md> contains information on the structure of the agency, the ministers' biographies, information on the next government assemblies, and agendas.
 - Citizens can be familiarized with government activity for 2005 to 2009, laws on the state budget, the strategy for economic growth and decrease in the level of poverty, the plan of action European Union: Moldova, and various strategies and plans of activity. One can also access news information as press releases, communiqué, and so forth at the site. The Web site has three language versions: Romanian, Russian, and English.
 - On the basis of cited Figures and facts, and also on the basis of analysis of the level of e-government development and of the volume of e-services rendered in Moldova (Burtseva, Cojocaru, Gain-

dric, Magariu, & Verlan, 2004a, 2004c; Cojocaru & Gaidric, 2003), it is possible to consider that the preconditions for information-society creation in the country exist.

THE SOLUTIONS FOR THE DIGITAL DIVIDE PROBLEM IN MOLDOVA

All the aforesaid shows that Moldova is at a low-enough economic and social level that naturally influences its e-state. Nevertheless, it is possible to take available advantages and to bypass certain obstacles.

The priorities are the following:

1. Attraction, vocation, and orientation of the majority of youth to the information-society technologies
2. Absence of viable alternatives of economy relaunching and the creation of new workplaces
3. Communications facilities and means for data processing have constantly decreasing prices, reduce energy consumption, and are not pollutants.
4. Existence of national structure of communication lines
5. Absence of real dependence on outdated information systems
6. Favourable international context (European, UN, and World Bank initiatives)
7. Still good-enough quality of higher education for relevant specialities

Some vulnerable points include the following:

1. Internet access is expensive and unreliable, and has reduced speed
2. Reduced access to new technologies (caused by the low purchasing capacity of the popu-

lation), correlated with nonuniform Internet penetration and great discrepancies between urban and rural areas

3. Inertia of officers of central and local public administration
4. Bureaucracy, fraud, and corruption cause some to look at the evolution toward the information society as the irreducible enemy
5. Absence of sufficient information distribution for the general public
6. Massive migration of gifted and qualified youth, accompanied by the growth of the population older than 50
7. Chaotic and noncorrelated mode of informatization of public institutions, as well as the inclination toward individualized solutions that are not harmonized on the basis of unitary conception
8. Tendency to invest mainly in equipment (to the detriment of management and knowledge-exploitation tools), without analysis, the preliminary setting of needs, and adequate personnel policy
9. Relatively reduced interest of investors and absence of trust of financial institutions that could place investments
10. Presence of the insufficiency of knowledge in relevant domains within secondary education

On the other hand, alongside the described manifestations of the digital divide, there are positive factors in the country promoting the development of the information society, such as the presence of political will on the part of the state, a good corresponding ICT infrastructure, and the high educational level of the population.

In our previous chapter, the basic directions of the balanced nationwide-system approach to the digital-divide problem are listed as (a) policy, (b) access, (c) services, (d) content, (e) knowledge and skills, and (f) motivation. Also, the steps to overcoming the digital divide that are necessary

to undertake in these directions are described. In the present chapter, it is appropriate to consider in detail the state of affairs in Moldova regarding these basic directions.

1. The national strategy for building the E-Moldova information society has been formulated. In all government programs, including those for economic growth and poverty reduction, there are sections for information-society creation and the wider granting of services to the population by the government.

Moldova actively participates in the Southeast Europe initiative on the integration into the information society. The parliament accepted the law that stimulates firms working on ICT development and introduction. The firms dealing with software development received a “tax vacation.”

2. The state has provided the creation of a communication infrastructure. All regional centers are connected by optical cable. There are two rings of optical cable that provide communication reliability.

Within the framework of SALT (Jump), 1,364 schools of 1,644 already have physical access to the Moldtelecom network (since February 15, 2006), as the minister of education V. Tsvirkun asserts (personal communication, February 16, 2006). All 1,364 schools, 140 sport schools, and children’s creative houses will be connected to the Internet by the first of September, 2006. Prime Minister V. Tarlev formed the working group for this monitoring program.

The relations between the state and local governments and the private sector are still very weak. There are practically no joint projects for providing information services to the population. The rate of growth in providing information services (see Table 6) has sharply increased recently. It especially concerns the rural area. The number

of licenses for providing information services in villages granted during the first half of 2005 is more than the number achieved during the whole year of 2004 (see Table 6). For this period, NRATI granted licenses to 68 companies, 35 of which are working in villages.

3. Unfortunately, it is necessary to establish the fact that the e-services the government provides the population and business are not enough and do not respond to population demands. These services are limited to providing information: addresses, phone numbers, work schedules, lists and prices of provided services, samples of documents for filling out, and normative and legislative documents related to institution activities (Burtseva et al., 2004b, 2004c). Unfortunately, this information is not always full and updated in time. Interactivity is actually absent.

However, there are successes. For example, take the modern information system at the SOPP (example 1 previously in this chapter). It is the first step to the introduction of automated systems for document circulation in SOPP.

As to commercial structures, there is already an example of interactive services: the payment of municipal services through the Internet (example 2).

4. For 2005, the government, on behalf of the Ministry of Information Development with the assistance of UNDP, provided the development of the following:

- A functioning e-governance-portal model with at least two available pilot services for citizens (e.g., tax payment)
- A standard for governmental Web sites and a data-storage and communications protocol

Digital Divide

- A regulatory mechanism for the implementation of online services

In this development, both the governmental structures and representatives of the scientific organizations, universities, and civil society are involved. This provides taking into account various aspects of Moldova development (national, economic, world outlook, etc.). The first steps are made already, and there are first successes: The site has already opened (example 3). However, for the time being, the site is only informative. The declared interactive services are planned to be available by the beginning of 2007.

5. Teaching and skills in ICT use are stipulated in all training programs at schools, lyceums, and all university faculties. However, the challenge is that this knowledge is to be sufficient and focused on the future specialist's needs. The president of Moldova has set the objective that in all schools, each pupil will have Internet access. Surely, the objective formulated is general enough. Various ministries carry it out on their own understanding. Having quite a good ICT infrastructure, Moldtelecom successfully supplies cable to the schools. However, the Ministry of Education has not actually started the process of training the teachers (besides those of computer science). One important problem, for which the Ministry of Education has not yet determined how to approach, is the problem of content. Ensuring that pupils are supplied with the necessary information in their native language is a problem not only of pedagogical science, but also of sociologists, mass media, and the whole society as well.
6. Problems in the creation of motivation for ICT use remain for the time being without the attention of both the government and the civil society. The program Moldova-e of the public broadcasting company has been

carrying out the broadcast of "Information Society" for almost 1 year. But this program, unfortunately, is not thought over enough, and there is no confidence that it will waken the motivation for ICT use in the work of businessmen, farmers, and others. For the present, the most powerful incentive for business is the example set by partners from other countries and the necessity of entering into regional and European structures. Banks and other financial structures, insurance companies, and so forth, in which the level of ICT use is essentially higher than in other branches, can serve as examples. Let us address again example 2 from earlier in this chapter. To implement such an interactive service (the payment for municipal services through the Internet), undoubtedly, it was necessary to use advanced ICT achievements, basing on the last legislative acts concerning electronic signatures, person identification, and the right to use authorization. Motivation is important here, too: Such a service undoubtedly is attractive for the population as it allows one to save time and to carry out this operation in any one moment convenient for the citizen.

Taking into account the weak provision of literature in libraries, it is sharply necessary to create in Moldova an electronic library accessible free of charge for the population. The library should contain educational, national, and classical literature. This action will help to develop the motivation and the long-term habit to use ICT in daily life, study, and work for the majority.

As to daily life, it is not just the most competent people who can find applications of the newest technologies if only the availability of these technologies would be provided. The bright, real episode from village life illustrates this idea well. Two already elderly farmers are talking. The question arises about mobile phones. One farmer tells another, "Yes, mobile phone—it's

great! Can you imagine, Ion, I'm pasturing cows far in the field, and suddenly a 'gentleman' became urgently necessary for your cow. I call you by mobile phone and inform: 'Urgently take away your cow. It has alarmed the entire herd!' Now you can act immediately, and the problem is solved!" (P. Pastoohov, personal communication, June 25, 2005)

As regards the motivation for Internet use by the elderly (especially rural) people in Moldova, there also are special reasons. As we already mentioned above, a great number of inhabitants who are able to work have been compelled to leave their families in search of earnings in other countries. To maintain communication with their families—with the grandmothers and grandfathers with whom they have left their children—some of these persons before departure had taught the old men not only to use e-mail, but also to use multimedia means for online conversations.

Complex Conditions Necessary for Overcoming the Digital Divide in Moldova

Note that the basic obstacle in bridging the digital divide is the fact that today in Moldova there is no cooperation between the state sector and private capital. It is possible to understand what the government sees: that the gross national product is very small for the present, that most of the population able to work does not find workplaces in the native land, that industry is not restored yet (production has not reached the level of 1993), that agriculture is noncompetitive, and that import strongly outstrips export. This tendency is being amplified; investments do not grow at the necessary rate. Therefore, clearly, the basic care is an aspiration to raise the standard of life for the population. Unfortunately, not everyone understands that wide introduction of ICT is able to not only promote but also speed up economic growth.

Such problems arise not only in Moldova. Even the World Summit on the Information Society (WSIS) in its *Tunis Agenda for the Information Society*, when writing about financial mechanisms for meeting the challenges of ICT for development, it stated, "We recognize the existence of the digital divide and the challenges that this poses for many countries, which are forced to choose between many competing objectives in their development planning and in demands for development funds whilst having limited resources" (WSIS, 2005a, p. 1).

Nevertheless, it considers ICT development of great importance and writes the following: "We encourage all governments to give appropriate priority to ICTs, including traditional ICTs such as broadcast radio and television, in their national development strategies" (p. 3).

When speaking about complex conditions and the actions necessary for overcoming the digital divide, we shall see that not all of them are carried out. Therefore, it is especially important for a country to find its own way of overcoming deep digital divides.

Let us consider the complex of necessary conditions:

1. There is a lack of physical access to the Internet. As it was already mentioned, there is an advanced network of optical lines. Within 2 years, all schools will be connected to the Internet. Meanwhile, the share of people having a PC at home is too small. Therefore, the majority of users have access at their workplaces. There are not enough public Internet-access points (PIAPs). Internet access is expensive.
2. Only a part of the society (those who have graduated from universities during the last 10 years, employees of banks and insurance campaigns, and some employees of state machinery) understands the value and realizes the necessity of ICT use for work.

Digital Divide

Probably, other parts of the society would like to use ICT, but they are too poor to buy a computer.

3. According to the reports of the UN and other organizations, the degree of democratization in Moldova for the time being is not too high. However, recent events (elections of the parliament; the accepted laws on liberalizations of the press, radio, and TV; economic activities' liberalization; the law of "guillotine"; and orientation to integration into Europe) convince some that the degree of democratization will increase and be sufficient for information-society construction. It, in its turn, will promote wider democratization of the society.
4. The level of population literacy is high enough.
5. The laws accepted during the last 2 years serve as a strong basis for information-society creation.
6. We already mentioned the weak interaction between state and commercial structures.

Practically, each of them works independently. However, commercial structures already give an impulse of ICT penetration into the countryside. In cities, private firms influence ICT distribution, though it is not enough.

7. The financial assets put into ICT are too small. The basic share of the investment is the resources of private enterprises. However, according to the action plan European Union: Moldova, the action plan for the implementation of the national strategy for information-society development e-Moldova, the budget for 2007 will have the separate expense item for ICT introduction in the economy, education, public health services, and local management.

The problems of attracting investments into e-government development and services provision to the population remain sharp. The United Nations Development Program assists some of the nongovernmental organizations, but it is obvi-

Table 8. Public places for PIAPs in different countries (Source: The Table is made by the authors on the basis of an analysis of a number of different Web sources, Burtseva, Cojocar, Gaidric, Magariu, & Verlan, 2005)

Country	Schools	Libraries	Telecommunications	Other
France			Yes	
Austria	Yes		Yes	
Finland		Yes	Yes	
Greece	Yes			
Croatia	Yes			
Estonia	Yes	Yes	Yes	
Brazil				Yes
Romania			Yes	
Latvia		Yes		
Scotland	Yes	Yes	Yes	Yes
Lithuania	Yes	Yes	Yes	Yes
Slovenia	Yes	Yes		
Moldova	Yes	Yes	Yes	

ously insufficient. The investments of those who understand that all expenses will be repaid and will result in economic growth are necessary.

8. If 5 to 7 years ago state support was only declarative, the last 2 to 3 years were the turning points (see subsection “Political Will”).

Note that the problem of information distribution among the population remains on the second plan up until now. The state so far is going to invest in systems that will give results quickly. Those stated above, the concrete measures accepted and planned for the nearest 1 to 2 years, and the worldview of people that came into the state structures allow us to offer public Internet-access points as a way to accelerate overcoming the digital divide. Basically, the majority of actors influencing information-society development in Moldova supports these measures; at least we have not met open opponents.

Taking into account the current situation and limited financial opportunities, the coordination of actions in all programs for more expedient use of investments is necessary. As the first stage for such coordinated actions, the opening of PIAPs in all settlements with the participation of the state, nongovernmental organizations, and commercial structures is supposed. It corresponds to Point II of the Genoa action plan (DOT Force, 2001, p. 14):

The establishment of public and community ICT access points in developing countries should be supported as a key means to facilitate timely, broad, affordable and sustainable access to ICT; for this purpose facilities such as post offices, elementary schools, Internet cafés or community multimedia centers could be used; emphasis should be placed on providing both access and training... Approaches to promote universal access for rural and remote areas in developing countries should be pursued...

This question remains the actual one. So, at the last WSIS forum devoted to information-society problems, including the digital divide, in the Tunis Commitment it was written (WSIS, 2005b, p. 3), “We urge governments, using the potential of ICTs, to create public systems of information on laws and regulations, envisaging a wider development of public access points and supporting the broad availability of this information.”

PIAPs could provide the following:

The basic parts of the information society (such as e-government, e-democracy, e-culture, e-medicine, e-commerce, etc.) to be created locally

- Nondiscriminated access of all of the population to information (which is more important)
- Participation in the e-democracy
- Services of e-government

Let us explain now the method of choice in Moldova and consider our propositions about PIAP development, supply, and maintenance.

Description of PIAPs Proposal

The PIAP functionality supposes the presence of necessary items: hardware, software, room, connection, personnel, training, user’s payment, traffic cost, and technical maintenance. The implementation of these items requires financial aid and technical efforts. An at-once realization of such a project is impossible with the current situation in Moldova, so we propose to move from stage to stage.

At the first stage, the PIAP creation is offered on the basis of schools (after hours). The following circumstances that are specific for Moldova underlie this choice:

- School is one of not many public institutions that are active in the countryside.

Digital Divide

- Schools have their own buildings.
- Schools in the countryside have the necessary ICT infrastructure.
- There is the presence of personnel (informatics teachers) for initial training to use the computer and Internet.

Similar ways were chosen by Austria, Greece, Croatia, Slovenia, Estonia, Scotland, and Lithuania. One can see that Croatia and Slovenia are in this list of countries, and they have similar social-economical conditions. Our closest neighbor, Romania, took another way.

Certainly, each country solves this problem individually, proceeding from national features (Table 8). As a rule, public places convenient for inhabitants that people already visit and also that already are a part of their daily life are being chosen: schools, libraries, post offices, national bank branches, railway and bus stations, airports, shops, cafes, hotels, clubs, churches, and so forth.

The mentioned-above circumstances, specific for Moldova and which cover some necessary items of PIAP, do not resolve the problems of hardware equipment and the technical maintenance of PIAP. Intending to use the school hardware at the first stage, we take in consideration the fact that many of rural schools have no computer class. This problem requires collaboration with state education authorities; in Moldova, this is the Ministry of Education, Youth, and Sport. The payment for traffic and other supplies is also a significant problem. At the first stage, it is supposed that the local budget can be implemented only by persuading the local authorities. The principal companies dealing with Internet-traffic support and electricity can give a discount for state programs. For resolving the problem of PIAP maintenance, we propose to initially get the teachers of computer science for this work, who will receive additional payment. Cascade training (as supposed in SALT as well) be offered by engaging teachers, rural intellectuals, and, further on, people with secondary education.

This stage fulfilling allows the second stage to expand further the PIAPs network by opening these points in city halls, libraries, post offices, and other public places. This way, the necessary supplies can be covered by the corresponding institutions. The state or joint enterprises can be created for PIAP's technical maintenance.

Then, at the third stage, the telecenters can be established in hotels, bars, and so forth. This stage requires business investments from Internet providers, banks, and the ICT sector.

The implementation of the second and third stages would be impossible without mutual coordinated actions of local administration and business. According to this plan, the local administration should find a way to awake business interest to support the PIAPs.

To reduce expenses and ensure the PIAP functionality, we propose the establishment of a standard for the minimal information services guaranteed to each member of society irrespective of whether he or she lives in the countryside or not: e-mail; access to the legislative database; access to the membership of the local networks created for different business branches; weather reports; and so forth. For this, it is necessary to establish Internet content for these services and to provide each PIAP with a minimal software set supporting these services.

Now we argue for our choice of software tool kit for PIAP. This tool kit is set by each country according to its specific social-economic situation. Several initiatives, for example, Cambridge Online City (*About Cambridge Online City*, n.d.), prefer complex solutions by Microsoft. However, we share the position with those who propose open-source solutions.

Open-source software or free software (OSS or FS) are programs that have licenses that give users freedom to run, study, and modify the programs, and to redistribute copies of either the original or modified programs (without having to pay royalties to previous developers; *Open Software License v. 2.1*, 2005).

Many countries accept the OSS solution at their administrative level (Wong, 2004).

- OSS is used for local government network support:** This choice is made by countries with both high and low levels of ICT. The countries with high ICT levels use OSS mostly because of the necessity for independence from software developers: the governments of the USA (Aitoro, 2005), Australia (“Government Open Source Guide Coming Next Month,” 2005), and Italy (“Italian IT Leader Engineering Ingegneria Informatica,” 2005). Certainly, countries with low ICT levels take OSS solutions mostly because of financial and copyright reasons. Several specific projects of OSS-usage advancement have been initiated for different regions of the world: Asia (International Open Source Network, 2004), Africa (FOSSFA, n.d.), and so forth. In this context, it is remarkable that such populous countries as China (“China’s Bet on Linux,” 2005), India (Noronha, 2002), and Indonesia (“Indonesia Government Opts for Open Source,” 2004) choose OSS for government networks. The Government Information Technology Officers’ Council (GITOC; 2003) in South Africa promotes OSS in its strategy. Brazil’s government announced its intention to change from Microsoft’s operating system to OSS on 300,000 government computers (Goldmark, 2005).
- OSS is used for Internet provision at schools:** The corresponding projects were announced in 2005 by the governments of France (Marson, 2005a), South Korea (Ilett, 2005), and New Zealand (Marson, 2005b). In New Zealand, 2,600 state schools will use Novell’s software for a reduced price. The Republic of Macedonia in 2005 decided to deploy Linux at 468 schools and 182 computer labs nationwide (“Macedonia Deploys 5,000 GNOME Desktops in Public Schools,”

2005). The School-to-School Project in China plans to load nearly 140,000 PCs with a national Linux version (“Largest Asian Linux Rollout Ever,” 2005).

- OSS is used for PIAPs (considered in detail as follows):** There are a lot of reasons for using OSS in noncommercial domains (schools, local government, state PIAPs). The first reason for OSS usage for PIAPs and especially for local government networks is the independence from software manufacturers. Despite the different financial situations in countries that supply PIAPs by OSS, the reason of economy is equally significant. The main objections of opponents are the inadequacy of OSS regarding users’ needs and the absence of support. The thesis of inadequacy became baseless with the modern development of OSS. For example, the Microsoft solution for an ordinary PIAP hardware set includes the Windows 2003 Enterprise Server operating system for 25 clients (\$1,875); the e-mail server Microsoft Exchange 2000 Server 25-Client Enterprise (\$6,899); and the RDBMS server Microsoft SQL Server 2000 Enterprise Edition (\$7,500). The prices are from an Internet shop’s (Amazon.com, n.d.) price list. However, the corresponding OSS solution, for example, Linux, provides for an unlimited number of clients. E-mail and RDBMS servers are embedded in the operating system. Any OSS scripting tool can be used. So, the OSS now has functional completeness. OSS security can also be set to the due level.

BZ Media LLC, a privately held high-tech media company, issued BZ Research. Its survey of 6,344 software-development managers shows that Linux is superior to Windows for operating-system security attacks, and OSS was in most categories considered equal or better at the application layer (“Linux Wins on Security in

survey,” 2005). From the point of view of performance and reliability, OSS also shows results that are comparable to or better than the results of commercial software. Eighty percent of the top 10 most reliable hosting providers ran OSS or FS (“Most Reliable Hosting Providers During May,” 2004). The performance of “heavy” RDBs like Oracle under Linux was so preferable (Burleson, 2003) that software giant Microsoft with Windows 2003 Server started lagging.

Although OSS has no developer support, this lack can be converted to an advantage, especially in the case of PIAP. The active developing of new OSS products and new versions of existing ones eliminates the main fear of users about update difficulty. The distribution of OSS by free CDs made by state or business-state enterprises, for example, like the French government does, resolves the problem of obtaining software.

So, maintaining the software is the only feature of developer support that remains to be discussed.

Let us consider this feature in the specific situation of PIAPs in Moldova. The backcountry districts are hardly reachable for developers’ help. Being in use by nonprofessional persons, computers of PIAPs are always at risk of hardware or software damage. So, the preinstalled type of software is inconvenient. The boxed software versions require the presence of a specialist for software installation, and moreover have a higher price. Usually, this problem is resolved by the creation of easily installable pirate software versions.

The OSS license allows software recompiling without breaking privacy. Recompile gives the PIAP suppliers wide possibilities to resolve their specific problems. First of all, they can adapt the software exactly to the spoken language, hardware, and executing services of the specific PIAP. As it was mentioned above, the possibility to develop easily installable software is also important. In Moldova, there are professionals who

can handle the recompiling process. Moreover, in autumn 2005, a center for Linux training and certification by international standards was opened at the State Technical University of Moldova.

Thus, the OSS license combines the significant financial economy with wide possibilities of maintenance. The software realized under this license today has due functionality and has less of the disadvantages of the early years. The OSS can be successfully used for PIAP supply, especially in financially weak states with poor ICT infrastructure in rural areas. Thus, in Venezuela in 2004, numerous info centers and PIAPs with free software were opened throughout the country (Wilper, 2004). As well, in Romania since 2002, the number of PIAPs and of used Linux servers have been growing (Sandu & Nagler, 2005).

Generalizing the discussion above, we can formulate the solution below. We propose to establish a network of PIAPs with the following characteristics:

- Use the financial support of state and local administrations
- Have a supply of standard software
- Give access to a standard minimal set of services

The standard software tool kit consists of the following:

1. Interactive guides and tutorials (for computer usage, Internet navigation, installed software, and the development and support of personal Web pages)
2. Editors (for text, Web pages, graphics, and presentations) and miscellaneous programs (spell checkers, dictionaries, and support for small databases)
3. Internet browsers (access to a free e-mail service, to global and local search engines, and to online dictionaries and translation systems)

Indices for Digital-Divide Monitoring in Moldova

The WSIS Thematic Meeting on “Measuring the Information Society” resulted in the recommended core list of ICT indicators and its broad involvement (“Final Conclusions,” 2005). Taking into consideration Moldova’s specificity and more precise monitoring of the digital divide in Moldova, the following indices can be recommended additionally by this chapter’s authors.

1. Number of PIAPs per 10,000 inhabitants
2. * Number (and percent) of settlements that have PIAP
3. * Number (and percent) of PIAPs where inhabitants use services gratis
4. ** Number of computer classes per 1,000 pupils
5. ** Average number of subjects at schools in which ICT are used in teaching

An asterisk identifies specific indicators for Moldova.

Two asterisks identify indicators whose influence will affect the digital divide afterward (they contribute to population training).

The authors of this chapter will endeavour to promote these indices so they will be taken into consideration in the state policy in the process of information-society creation in Moldova.

CONCLUSION

The digital-divide problem is a reality that is present in any society. It will be present later on as well, reflecting the immanent objective, social, economical, and confessional peculiarities inherent in a country or ethnic groups. A striking example from the life of our country (Moldova) is the fact that some Orthodox believers made a protest and refused to get identity cards with personal codes. Obviously, these persons will not be able to use the opportunities that ICTs

give. However, in any democratic society, the tendency to provide every member of the society with equal possibilities will promote decreasing the digital divide.

One should not automatically transfer the methods of the solution of the digital-divide problem from one country to another. Nevertheless, the experience accumulated by some countries is certainly useful for others since the common elements—the necessity of state political decisions, of attracting economic agents and civil society, and so forth—should find reflection in decisions that are specific for each country. Even negative experiences of other countries, for example, the termination of the PIAPs and telecenters on the completion of state or other grants, are rather valuable, too, inasmuch as they reveal those aspects of the problem that would be difficult to deal with.

Starting from the specific economic conditions in our country, we consider that the proposed measures and those that are already being realized in Moldova are able to decrease people’s differences regarding the possibilities to take part in public and economic activities; that is, they enable the country’s development.

Certainly, it might do well to speed up realizing these measure, but the real possibilities of the country, and chiefly the very low GDP, do not allow the majority of the population to purchase computers (the cost of which is about five average nominal monthly salaries per employee in the economy in November 2005) or Internet connections (the cost of a monthly subscription for the Internet is about 17% of the average nominal monthly salary). From this follows the proposed solution for the rural population (which constitutes 61.4% of the total population):

- Usage of school computer classes as PIAPs
- Local administration participation in PIAP financing

Digital Divide

- Determination of a standard for minimal services that are provided for any person in any settlement of the country. It is not an obstacle in the way of widening the provided possibilities when the local administration can permit itself such widening.
- Training the population in necessary skills for working with computers and for Internet usage by using the cascade method
- Along with the European indicators for e-readiness monitoring, the introduction into state statistics the specific indicators for Moldova

Several social programs are carried out nowadays in the Republic of Moldova.

- Program for economic growth and poverty reduction, which includes the establishment of PIAPs along with the measures for economic growth
- Moldova's Village, which includes measures for economic and cultural development, for ethical-norms revival, and for the provision of elementary conditions of life (provision for drinking water and gas in each village)
- SALT, providing schools with Internet connections and equipping them with computers
- European Union: Moldova

The main condition for the successful implementation of each of these programs is the coordination of their actions. Certainly, the problem of the digital divide will be resolved indirectly as well. But the purposeful opening of a PIAP in every settlement by means of attracting the existing infrastructure, the possibilities of local self-government, and the good will of teachers of informatics and volunteers can speed up the solution of the problem.

It is very important to establish a system of statistical indicators for monitoring information-

society creation, and in particular, the digital divide.

We hope that Moldova's approach, stated in this chapter, will fill up the "money box" of world experience, too, and that it can be useful in those countries where there are similar conditions, mainly those with an agrarian economy and a mainly rural population, which, at that, has a high-enough educational level and keeps a strong thirst for knowledge. The presence of good ICT infrastructure in combination with the implementation of a state program to connect all schools to the Internet became the precondition of the approach suggested (and proved) by us, based on the creation of PIAPs at schools. We have tried to fix the whole spectrum of problems arising at the acceptance of such an approach and to plan possible solutions to them.

ENDNOTES

- ¹ For these countries, the values of the e-readiness index for 2001 are absent. Nevertheless, they are included in the range of countries because they are agrarian countries close to Moldova in their percent of rural population. In Table 1, they are at the end of the list, and in the comparative analysis presented in Figure 2 they are not included. However, in the subsequent analysis they are examined.
- ² Not all of the desired data were available for all countries, years, and indices (in particular, for countries from the chosen list), so the authors tried to make the comparative analysis of the state and dynamics of digital-divide development on the basis of the information found to be available. At that, the data are taken from different sources. The data given for the same country by different sources are not always comparable since they are calculated by different methods. However, the authors set for themselves the objective to follow up on the tendency of the development of conditions in the country and between countries. For this purpose, the described state of affairs with data was not an obstacle.
- ³ Moldova's national source (NRATI, 2005) gives the GDP figure for Moldova in MDL (Moldova's national currency), which, when recalculated in U.S. dollars, differs from the figure given in GEOHIVE: Global Statistics (n.d.). The difference is not large (compare \$541, the result of our recalculation, and

Digital Divide

\$460; GEOHIVE) and does not essentially change the picture. So, in our research, we use the UN statistics.

- ⁴ The data on the percent of the urban population in Moldova, 46% (GEOHIVE: Global Statistics, n.d.), are a little bit overestimated in comparison with the data given in the national statistical report: 41.4% (DSSRM, 2004). The data from the national statistical report in the greater degree met the described tendency.

Note: ^a The site <http://www.internetworldstats.com> gives this Figure. However, the national source NRATI (2005) gives the following

Figures: 288,000 Internet users in 2003 and 406,000 in 2004. As well, we should say the same about Internet penetration. The Ministry of Informational Development of Moldova gives the following information: According to the sociological questioning made in 2004, the number of Internet users in Moldova constituted 17.4% of the total population. This Figure is closer to the one of NRATI. However, in our research, we use the *Internet World Stats* (2005) data to keep the world picture given there.

Chapter 5.22

Digital Opportunities, Equity, and Poverty in Latin America

Simone Cecchini

United Nations Economic Commission for Latin America and the Caribbean (ECLAC), Chile

ABSTRACT

This chapter examines the digital divide that exists within Latin American countries. It argues that information and communication technology is creating new opportunities that can be seized to support human development and poverty-reduction strategies. However, it also clarifies that ICT on its own cannot leapfrog the old institutional and organizational weaknesses of Latin American economies and societies. The author hopes that understanding the deep-rooted inequalities that underlie ICT access in Latin America will not only inform researchers on the challenges for the development of the information society in the region, but also assist policy makers in the preparation and implementation of appropriate public policies.

REALIZING THE HUMAN-DEVELOPMENT POTENTIAL OF ICT IS NOT AN AUTOMATIC PROCESS

Poverty and inequality represent two enormous challenges for the countries of Latin America. In

2004, about 220 million people—43% of Latin Americans—were poor, and the average incomes of the richest 20% of the population were between 10 (Uruguay) and 44 times (Bolivia) higher than the average incomes of the poorest 20% (Economic Commission for Latin America and the Caribbean [ECLAC], 2005b). The region is considered the least equitable in the world, with vast disparities not only between rich and poor, but also between urban and rural areas, men and women, African descendants, and indigenous and nonindigenous people (ECLAC, 2005a).¹

In an age where information and communication technology² is bringing about profound changes to societies in the developed world—where it is becoming essential for economic success and personal advancement, entry into good career and educational opportunities, full access to social networks, and opportunities for civic engagement (Norris, 2001)—it is thus relevant to analyze whether these technologies can contribute to human development and poverty reduction in the Latin American region, and what the impact on inequality may be.

Consensus exists that the primary task for the countries of Latin America is the transformation of

their productive structures in a context of progressively greater social equity. Such a process should make it possible to achieve some of the objectives inherent to development: growth, improvement of income distribution, consolidation of the democratization process, greater autonomy, establishment of conditions that will halt the deterioration of the environment, and improvement of the quality of life of citizens (ECLAC, 1990).

It is also apparent that ICT can be utilized to support human development and poverty-reduction strategies in at least two areas: developing poor people's capacity, mainly by enhancing their access to education, health, and government services, and increasing their opportunities by improving their access to markets and the labor force (Cecchini & Scott, 2003; World Bank, 2000). However, as highlighted by Kirkman (1999, p. 1), translating the potential of ICT into reality is not simple:

In practice, whether or not a developing country can build an ICT-based economic or social sector depends on overcoming many of the same macroeconomic and microeconomic barriers that have long contributed to its underdevelopment—What is the state of its educational system? How are telecommunications costs regulated? Is there a reliable transportation network? Are there limits on direct foreign investment? What sources of investment capital are there for small or medium sized businesses?...The list goes on and on.

Indeed, while ICT such as the Internet and mobile phones is growing significantly in Latin America (Table 1), its increased penetration goes hand in hand with the persistent structural heterogeneity of the region's economies, characterized by the presence of a great number of low-productivity firms and workers in the informal sector, as well as with high levels of social inequality. It is thus clear that ICT on its own cannot leapfrog the old institutional and organizational weaknesses of Latin American societies and economies. Digital

technologies can be used as a tool to execute solutions to poverty, but cannot root out poverty on their own; the risk that ICT actually ends up contributing to higher inequality is thus very much real (Cimoli & Correa, 2003).

Drawing on micro- and macroeconomic theory and empirical data, this chapter argues that realizing the pro-poor potential of ICT requires attentive public-policy formulation and careful policy design. Insufficient information and communication infrastructure, high access costs, and low levels of education have so far bestowed the benefits of ICT on the better off, urban segments of the population rather than on the poor and rural areas. In order to reach the poor, policies that foster the supply of low-cost and accessible telecommunications and information-technology infrastructure are needed. This chapter maintains, however, that the success of ICT projects and programs for development also depends on policies that promote the demand of ICT. These policies include the provision of locally contextualized information and pro-poor services, as well as investment in ICT training and awareness-raising campaigns. Furthermore, it suggests that successful projects are led by grassroots-based organizations that have the appropriate incentives to work with marginalized groups, and are characterized by the use of appropriate technology, local ownership and participation of the community, financial sustainability, and the use of monitoring and evaluation (M&E) techniques.

LITERATURE ON THE INTERNAL DIGITAL DIVIDE

In this chapter we will focus on the gaps that exist between different socioeconomic groups within the countries of the region—the “internal” digital divide—rather than on the divergence in ICT access between Latin American and developed countries—the “international divide.” Accord-

ingly, we present at this point a very brief review of some of the literature related to the internal divide.

Rogers' (1995) diffusion theory provides an important interpretation of social stratification in technological adaptation, showing that early adopters of new innovations are characteristically drawn from groups with higher socioeconomic status. Rogers also suggests that the adoption of successful new technologies often reinforces economic advantages so that the rich get richer and the poor fall farther behind. This pattern, however, is not inevitable since the conditions under which an innovation is implemented determine, in part, their social consequences. These conditions include the existence of initiatives to broaden technological access by the state and nonprofit sectors, the degree of inequality in the society, and the financial resources and educational skills required to access technology. Without state intervention, for instance, a relatively costly ICT requiring high educational skills such as the Internet is expected to exacerbate existing social divisions (Norris, 2001).

Cecchini and Scott (2003) come to similar conclusions by using a microeconomic model showing why the rich and the poor use different communication techniques and how the nature of technological change has until now been biased toward the rich, widening the digital divide. Since the value of time is lower for the poor, due to underemployment, and the cost of ICT capital is high,³ when ICT consists of communications techniques such as oral (person to person), written word, and fixed-line telephony, the poor tend to communicate orally. The rich, who face the opposite constraints, choose to communicate via fixed-line telephony, which is relatively capital intensive. When the Internet, requiring more capital per unit of information communicated than any other existing technique, becomes available, the rich switch from fixed telephony to Internet usage,⁴ while the poor continue to communicate orally. Therefore, the model has two implications

for a pro-poor ICT policy. First, the relative price of capital for communications purposes should be reduced for the poor. Second, the focus of research and development in ICT has to favor user-friendly hardware and software for the poor.

Indeed, mobile phones, which unlike the Internet can be easily used even by illiterates and do not need a permanent electricity supply, are now seen by some observers as potentially the most effective response to the digital divide ("Technology and Development: The Real Digital Divide," 2005).

Using macroeconomic evidence, Forestier, Grace, and Kenny (2002) show that historically telecommunications rollout has benefited the wealthy, with a positive and significant impact on increasing income inequality within countries. The authors' regressions illustrate that countries with high initial teledensity (allowing for income) and countries that have high growth in teledensity (allowing for growth in income) see significantly higher growth in income inequality. The diffusion of the Internet in developing countries is said to be following a similar pattern, suggesting that it is a force for growing income inequality. Without intervention, ICT might be even more strongly "sub-pro-poor" than has been true for the telephone. The Internet, in fact, requires not only more ICT capital, but also a higher level of education and skill to operate than the telephone (Forestier et al.).

As Heeks and Kenny (2002) point out, the diverging effects of ICT may be a consequence of the fact that ICT was almost entirely developed within the context of high-income countries. ICT was thought of for a capital-rich setting and embodies significant quantities of technical, human, and institutional capital. Since rich countries already have a large stock of personal computers (PCs) and telephone lines, Internet access represents a small marginal investment compared to the existing fixed stock of ICT capital. They also have more educated, highly skilled employees to install, operate, and maintain ICT.

In developing countries, with few PCs, limited telephone networks, and lower levels of human capital, the same is not true. Furthermore, ICT embodies within it rich countries' assumptions about ICT-friendly institutional strategies at the organizational level and ICT-friendly laws and regulations at the national level. For developing countries, where such institutional arrangements are less likely to exist, ICT warrants a range of investments in institutional reform.

ACCESS TO ICT WITHIN LATIN AMERICAN COUNTRIES⁵

During the 1990s, access to ICT grew at exponential rates, and today Latin America and the Caribbean is one of the developing regions with the highest penetration rates of fixed and mobile phones, the Internet, and PCs. ICT access rates, however, are still much lower than those in the developed world (the international digital divide) and testify that countries of the region are still far from reaching universal access (see Table 1).

Here, we will thus again focus on how access is distributed within countries (the internal digital divide) using data from household surveys that support some of the ideas presented in the previous section on ICT literature.

The internal digital divide is a multidimensional phenomenon tapping many social divides (Norris, 2001) related to differences in incomes, education, and geographical area of residence. Starting with the income dimension, we can note that within Latin American countries, the poor have much worse access to ICT than rich citizens (Table 2). In Chile, in the year 2000, only 32% of the poorest 10% of households had a fixed or mobile phone; computer presence (1.9%) or Internet connection (0.8%) in the poorest households was even more infrequent. Among the richest 10% of Chilean households, contrarily, 60% had a computer and 38% an Internet connection; almost all (95%) had a fixed or mobile phone (SUBTEL, 2002). In Paraguay, in 2001, the percentage of people with access to ICT in the poorest quintile of the income distribution was close to zero, with the exception of mobile phones (6.1% of the

Table 1. Percentage of ICT in Latin America and in the world, 1990 and 2003 (Source: United Nations Statistics Division [UNSD], 2006)

Region	Fixed & mobile phones		Internet users		PCs	
	1990	2003	1990	2003	1990	2003
Latin America and the Caribbean	6.4	40.4	0.0	9.0	0.6	6.8
Transition countries of Southeastern Europe	13.8	57.7	0.0	13.5	0.2	6.5
Eastern Asia	2.4	47.3	0.0	8.9	0.3	5.6
Western Asia	10.0	45.8	0.0	7.2	1.2	5.6
Commonwealth of Independent States	12.5	29.4	0.0	3.6	0.3	6.8
Northern Africa	2.9	21.0	0.0	3.4	0.1	3.4
Southeastern Asia	1.4	20.4	0.0	6.1	0.3	2.8
Oceania	3.4	10.1	0.0	3.8	0.0	6.1
Southern Asia	0.7	7.1	0.0	1.7	0.0	1.1
Sub-Saharan Africa	1.0	6.0	0.0	1.1	0.3	1.2
Developed countries	45.4	124.7	0.3	44.8	11.1	44.9

poorest quintile declared possessing a cell phone). However, among the richest quintile, more than half of the people had a fixed or mobile phone in the household, 22% owned a PC, and 4.6% had Internet access. In Peru and in the urban areas of Ecuador, we can observe similar results. Table 2 also suggests that, with the exception of data on fixed phones in Paraguay, access to PCs and the Internet is worse distributed than access to telephones.

In a region characterized by the stratification and inequality of its educational systems, which

over time have tended to become more elitist (Hopenhayn, 2002), more educated people have better access to, and make better use of, ICT. Data from household surveys show that in the countries of Latin America, between 19% (Nicaragua) and 68% (Brazil) of people with 15 years or more of education have a PC in the household. Ownership of a PC by those with less than 2 years of education ranges instead between 0.4% (Nicaragua) and 11% (Uruguay). Similarly, Internet access rates of more educated citizens are between 6 (Uruguay) and 107 (Chile) times higher than those of less

Table 2. Access to ICT by the poorest and richest quintile of the income distribution; selected countries, 2000-2002 (Source: Author; SUBTEL, 2002).

ICT	Country (year)	% of people with access to ICT in the household		
		Quintile 1	Quintile 5	Quintile 5/ Quintile 1
Fixed telephone	Chile (2000) a/	22.0	86.0	3.9
	Ecuador (2002) b/	33.0	81.0	2.5
	Paraguay (2001)	0.6	56.5	94.2
	Peru (2001)	7.8	46.4	5.9
Mobile phone	Chile (2000) a/	13.0	79.0	6.1
	Paraguay (2001)	6.1	55.6	9.1
	Peru (2001)	1.7	10.2	6.0
PC	Chile (2000) a/	1.9	59.7	31.4
	Paraguay (2001)	0.0	22.2	-
Internet	Chile (2000) a/	0.8	38.0	47.5
	Paraguay (2001)	0.0	4.6	-

Table 3. Percentage of urban and rural access to ICT in Peru, 2002 (Source: INE Peru, 2003).

	Lima	Other urban areas	Rural areas
Households with fixed telephone	44.7	21.6	0.4
Households with mobile phone	17.9	7.9	0.5
Households with computer	14.1	6.4	0.1
Households using public Internet service	44.2	30.2	3.6
Households with Internet	2.3	0.5	0.0

Digital Opportunities, Equity, and Poverty in Latin America

educated citizens.⁶ As a consequence, in a country like Chile, about 89% of Internet users have had tertiary education (UNDP, 2001).

Urban areas are much better connected to ICT than rural areas. The case of Peru is illustrative: In Lima, the national capital, 45% of households have a fixed-line phone at home and 18% own a cellular phone, while only about 0.5% of rural households own a fixed-line telephone or a mobile phone. The divide is no better with respect to PCs and the Internet. In Lima, 14% of households have a computer and 44% use public Internet services, while in rural areas of Peru, these percentages are 0.1 and 3.6, respectively (see Table 3; INE Peru, 2003). In Chile in 2000, only 0.8% of rural households had access to the Internet, compared to 9.4% of urban households (SUBTEL, 2002).

It must be noted, however, that in Latin America a great heterogeneity of incomes and human

development also exists within urban areas. This is reflected in different levels of access to ICT. In one of the richest municipalities (Las Condes) of the capital of Chile, Santiago, 85% of people have access to a PC, while in La Pintana, one of the poorest, access is only 20% (see Table 4; Raad, 2004).

The internal digital divide is not limited to income, education, and geographical area of residence, but also extends to gender, age, race, and ethnic inequalities. The percentage of female Web users in Latin America and the Caribbean has been estimated at around 38%, which is far from gender parity,⁷ although the gender gap seems to be closing in many countries (Bonder, 2002; SUBTEL, 2002; UNDP, 2001). Older and indigenous people are also at a disadvantage. In Mexico in 2002, 36% of people aged 20 to 29 used the Internet, against 9% in the age group of

Table 4. Access to ICT in selected municipalities of Santiago, Chile, 2000 (Source: Raad, 2004, on the basis of the 2000 CASEN survey)

	Las Condes	La Florida	La Pintana
Monthly average household income (US\$)	3,833	964	445
Poor (%)	0.2%	8.5%	31.1%
Average years of schooling	14.3	11.3	8.7
People with access to a PC (%)	85.4%	56.5%	11.3%
People with Internet access (%)	71.7%	20.1%	8.7%

Note: Exchange rate CH\$/US\$: 620.

Table 5. Percentage of household ICT access by racial group in urban areas of Brazil, Costa Rica, Ecuador, and Honduras, 2000 census (Adaptation of Rangel, 2005).

Country (year)	Telephone lines		PCs	
	African descendants	Others	African descendants	Others
Brazil (2000)	8.1	16.1	1.3	5.1
Costa Rica (2000)	17.4	18.2	3.7	5.2
Ecuador (2001)	7.0	13.1
Honduras (2001)	6.3	6.6

40 to 59. In the 60-and-above age group, Internet use was only 4%. In the year 2000 in Costa Rica, Mexico, and Panama, the probability of having a computer at home was 5 times higher for nonindigenous sectors of society than it was for indigenous people (ECLAC, 2003). Furthermore, data from the 2000 census show that in urban areas, household access to telephones and personal computers is lower for African descendants than for the rest of the population, especially in countries such as Brazil and Ecuador (see Table 5).

PUBLIC POLICIES: ICT SUPPLY

The careful formulation and design of national strategies to promote the information society is essential for countries to realize the potential of

ICT for human development. Examples of such strategies in Latin America are the Digital Agenda in Chile, the Connectivity Agenda in Colombia, and e-Mexico (ECLAC, 2003). Specifically, an effective mix of public policies to foster both the supply and the demand of ICT is required to improve poor people's lives and to contribute to equitable development. Supply-side policies focus on increasing connectivity and lowering information infrastructure costs, and are a crucial prerequisite for poor people to be able to access ICT.

Universal Access to ICT

Low-cost access to information infrastructure is the basic necessary but insufficient condition to reach the poor, as inadequate or absent con-

Table 6. Telephone main lines and mobile telephones in Latin America, 1990-2003; per thousand people (Source: World Bank, 2005)

nectivity, expensive hardware and software, and unstable power supply reduce the economic viability of ICT projects (Kirkman, 1999). Given the budget constraints faced by Latin American governments, it is not realistic to provide telephone lines, computers, or Internet access to all households (“universal service”). Government and regulators in the region are thus concerned with policy instruments for achieving universal access, of which community telecenters⁸ and public pay phones are the most common examples.

Countries such as Argentina, Brazil, Chile, Peru, and others have focused their universal-access policies on the extension of telephone lines to isolated rural areas and on the provision of free Internet access for low-income citizens through community telecenters. Indeed, in Latin America, telecenters represent one of the most common public-policy tools to provide universal access to ICT (Proenza, Bastidas-Buch, & Montero, 2001). In Argentina, the National Program for the Information Society focuses on universal access to the Internet through a countrywide network of 1,350 community technological centers that give free Internet access to lower income citizens (Finkelievich, 2003). In Chile, various governmental organizations have contributed to the creation of a network of more than 1,300 telecenters (Díaz, 2003).

Telecommunications: Competition and Regulatory Mechanisms

During the 1990s, fixed-line teledensity and especially mobile-phone penetration grew greatly in the region. Indeed, data presented in Table 6 suggest stagnation in the growth of fixed-line phones given that in most countries mobile phones’ penetration is now higher than fixed-line phones’ penetration. The widespread diffusion of mobile phones in Latin America can be explained in part with the existence in several countries of forms

of prepayment, which are particularly appealing for low-income citizens. The International Telecommunications Union (ITU, 2001) cites, together with competition and lower connection rates, the introduction of prepaid services in Bolivia in 1999 as one of the key factors for the rapid growth of subscribers to mobile phones in the country. Before, many people did not have a credit rating sufficient to ensure post-payment mobile-phone services.

Prices of residential telephone and Internet connection remain high, both in absolute terms as well as in terms of percentages of per capita incomes, especially in the poorest countries of the region. While in developed countries such as the United States or France Internet access charges—about \$15 per 20 off-peak hours—represent less than 1% of monthly per capita income, in Latin America, where charges go from \$13 (Argentina) to \$51 (Nicaragua), there are countries (Bolivia, Ecuador, El Salvador, Guatemala) where charges are more than 20%, 37% (Paraguay), 53% (Honduras), or even 139% (Nicaragua) of monthly per capita income (see Table 7).

One explanation for high costs is the existence of impediments to effective competition: During the 1990s, first entrants in the business after privatization often got generous exclusivity periods, as was the case of the Telefónica Group of Spain (Estache, Manacorda, & Valletti, 2002; Rozas Balbontín, 2003). Furthermore, the market by itself has not been able to provide a sufficient level of connectivity to the poorest and most isolated rural areas. Large telecommunications companies give priority to more lucrative urban markets and are reluctant to enter the smaller, less profitable rural markets. In Peru, the fixed-line telephony market is officially liberalized, but the incumbent Telefónica del Perú offers the only wireline service outside Lima. Many telecenter operators outside of the capital complain about bottlenecks, delivery at much lower speeds, and slow response to problems. Telecenters in Lima,

where there are multiple service providers, are more likely to lease faster connections and pay lower rates (Best & Maclay, 2002).

The key to achieving connectivity for poor and rural areas is to determine how far market forces will carry the rollout of voice and data networks. The gaps left by the private sector can then be remedied by public intervention through

regulatory mechanisms. One alternative is to invite private operators to bid for services in areas that are not commercially viable in return for a subsidy financed from a universal access fund. A concession contract is then awarded to the company requesting the smallest subsidy. In Chile, this mechanism was used by the telecommunications secretariat to leverage \$40 million

in private investment on the basis of just over \$2 million of public subsidy. As a result, 1,000 public telephones have been installed in rural towns at around 10% of the costs of direct public provision. In Peru, since 1999, OSIPTEL (n.d.) has subsidized the provision of public pay phones and community telecenters to about 4,500 rural villages and 500 rural district capitals. Another alternative is represented by “microtelcos,” small-scale telecom operators that combine local entrepreneurship, and municipal and community action to extend ICT services in areas that are unattractive to large private operators. The advantage of microtelcos lies in the mobilization of local resources, such as in-kind labor and private rights of way, as well as in the use of new low-cost technologies and innovative business models. In Latin America, a variety of microtelcos, ranging from telephone cooperatives in Argentina to small private operators in Colombia, are effectively servicing areas of little interest to traditional operators (Galperin & Girard, 2005).

PUBLIC POLICIES: ICT DEMAND

Even if information infrastructure becomes available at a very low cost, there is no guarantee that the poor will access ICT applications in a meaningful way. What are some of the public policies available to foster the demand for ICT?

Locally Contextualized Information and Pro-Poor Services

Content provided through ICT should not be limited to the knowledge that can be accessed from outside sources, but rather extended to ensure that the poor have the means to speak for themselves, as they know their needs, circumstances, worries, and aspirations best. In summary, the poor may demand access to locally contextualized information more than access to existing information from an alien context (Heeks, 1999). It is also advis-

able that ICT projects focus on a limited number of well-run pro-poor services and expand them incrementally rather than offer a great number of services that end up unutilized. Among the core services that telecenters can offer to attract clients and generate revenue, voice and text communication services are among the best candidates. Information systems that connect people to each other despite barriers of time, distance, literacy, and ownership of a telephone or PC are in fact in high demand among poor rural communities (Best & Maclay, 2002).

“Old” ICTs such as the telephone have demonstrated to be able to contribute in important manners to improve the economic opportunities of small farmers and entrepreneurs in isolated regions. An evaluation of the use of public telephones installed in poor rural areas of the Frontera Norte region of Peru in 1999 reveals that around 20% of the population use the telephone to conduct economic activities, and of that 20%, about 72% use the phone to get information on market prices. With respect to the economic impact of the project, people highlight improvements in agriculture, cattle raising, and trade. In particular, they emphasize improvements in the access to market information, which allows them to negotiate better prices and to sell more products, as well as in their contacts with clients and suppliers, in technical assistance for agriculture and cattle raising, and in the coordination of products transportation (see Table 8; OSIPTEL, 2002).

Innovative examples of the provision of content relevant for human development are Agronegocios in El Salvador and Viva Favela in Brazil. Agronegocios⁹ is a project launched in 2000 by the Ministry of Agriculture that offers technical and entrepreneurial training to small farmers and fishermen through computer centers, videos, and a Web site with practical information. Ten Agronegocios centers throughout the country offer technical and commercial assistance as well as free access to a Web site with information on recommended crops, market prices, financial

Other	6.8	1.2	7.6

costs and benefits of agricultural activities, investment opportunities, and a virtual market where product supply and demand can be published (Op de Coul, 2003). Viva Favela¹⁰ is a Web site offering information on job opportunities, credit sources, taxes, and other topics relevant for the informal sector.

In order to provide information and services that truly respond to the necessities of low-income communities, it is critical to make use of participatory surveys, such as the participatory rural appraisals (PRAs), which ensure community participation and ownership of development projects. In the rural and isolated Peruvian Alto Amazonas province, the Hispano-American Health Link program (EHAS) carried out a study on the information and communication needs of primary health-care personnel before launching a low-cost voice and e-mail communication system. The study identified poor infrastructure, time spent traveling to transmit administrative reports, lack of feedback information on epidemiological topics, and insufficient training as the main problems faced by health-care professionals. As a result, EHAS decided to center its services on remote access to health information

and on distance training. Each week, an electronic health training publication is sent to health-care personnel, and courses on childhood and maternal health, childhood diarrhea, infectious diseases, nutrition, and other prevalent diseases of rural areas are sent through e-mail. These distance courses can be used off-line and have a system for self-examination and remote evaluation. Furthermore, health-care personnel can now use e-mail to receive information from health experts (A. Martínez, Pozo, Seoane, & Villaroel, 2002; F. A. Martínez, 2003).

Awareness Raising and Training

The presence of useful ICT applications does not guarantee that the poor will make use of them. Raising awareness among the poor about the potential of ICT (for instance, in the creation of new opportunities in the job market) is thus another key aspect of successful ICT projects and programs. Word of mouth is often a very powerful tool for publicity: Leaders of poor communities, as well as schoolchildren, could be brought to telecenters for a demonstration that shows what ICT can do for them. Furthermore, investment in custom-

ized training in information-technology skills represents one of the most important factors that may facilitate access to new ICT by low-income citizens (Norris, 2001). In particular, training for poor people with low levels of education should focus on innovative, interactive, and participatory training approaches as learning is more effective through practice.

In Brazil, the Committee for Democracy in Information Technology (CDI) has provided computer and civics training to young people living in urban slums, or favelas, since 1995. CDI emerged from the belief that computer literacy can maximize opportunities in the job market and promote democracy and social equity. Along with training in word processing, spreadsheets, accounting programs, and Web design, CDI teaches civic participation, nonviolence, human rights, environmental awareness, health, and literacy. There is growing anecdotal evidence of CDI's success on several fronts. After a 3- or 4-month course, graduates are said to find well-paid jobs, start microbusinesses, or become certified teachers within the organization. Some CDI graduates who had dropped out of public school have decided to go back and complete their formal education;

many others put their computer skills to work in various community activities, including health education and AIDS awareness campaigns. A survey conducted in 2000 by Instituto de Estudos da Religião (ISER), a research institute, confirmed that the program is reaching the poor and that 87% of students consider that CDI courses have contributed to positive changes in their lives (see Table 9). The teaching environment, however, is a difficult one: Sometimes students cannot get to school because criminal gangs do not let them (CDI, n.d.; World Bank, n.d.).

At the national level, it is important to launch countrywide awareness campaigns to sensitize the population to the potential of ICT and to train poor people in the use of the new technologies. In 2003, the government of Chile trained about 100,000 people in the use of personal computers and the Internet through a national campaign of digital alphabetization. The campaign, which will continue up to 2005, is directed at workers and microentrepreneurs. These take 18-hour courses that help them learn word processing and Web surfing (Gobierno de Chile, 2003).

Public schools can also play an important role in the diffusion of knowledge about ICT through

Table 9. CDI student profile and impact of courses in Brazil (Source: Author; on the basis of the Information and Development Program, infoDev, 2003)

	%
<i>Student profile:</i>	
Aged between 10 and 18	65
Women	56
African descendants	65
Live in households with four or more members	77

Courses corresponded to expectations	90
Courses contributed to a positive change in the life of the student	87

programs that provide computer and Internet access to students. These programs are currently under way in several countries of the region, such as Brazil, Chile, and Costa Rica (Hopenhayn, 2002, 2003). However, while it is important to train and sensitize students about the use of ICT, to expect PCs to be a source of deep changes in classrooms seems naïve and could lead away from a thorough analysis of what prevents institutional reforms of education. Research from the United States, where the average number of students (from kindergarten to grade 12) per PC in school went down dramatically from 125 in 1981 to only 5 in 2000, shows no evidence that computers can be credited with any student achievement gain at any level (Cuban, 2001).

IMPLEMENTATION OF PUBLIC POLICIES

Appropriate Technology

Some prerequisites are needed to make the introduction of ICT in development projects and programs cost effective and sustainable, including not only a stable electric power supply and good connectivity, but also the human capacity to manage hardware and software. If these essential factors are not present, it may be better to look for low-tech but more appropriate solutions.

For instance, in Latin America, the use of electronic commerce on the part of micro and small businesses still faces enormous obstacles. Among the most important challenges to the financial sustainability of micro and small electronic-commerce activities, we should highlight the high costs of deliveries; the low levels of the quality of telecommunications infrastructure, especially in rural areas; the lack of human capital needed to fix equipment when problems arise (SustainIT, n.d.); and the low penetration of credit cards in several countries of the region. In Bolivia, for example, at the end of the last decade there were only 200,000

credit cards in circulation, corresponding to less than 2% of the population (ITU, 2001).

Clearly, no single technology constitutes a “magic bullet,” and the type of ICT that will be appropriate depends on the circumstances (Organisation for Economic Cooperation and Development [OECD], 2005). In Peru, EHAS devotes special attention to the maintenance of its low-cost voice and e-mail communication system based on VHF (very high frequency) radio and solar power. The program has set up local security backups for all hard drives and a remote maintenance system to reach all the computers through radio links (A. Martinez et al., 2002; F. A. Martinez, 2003). In Bolivia, Prodem Private Financial Fund (Prodem FFP) employs smart cards,¹¹ voice-driven ATMs (automated teller machines), and fingerprint-recognition technology to provide financial services to low-income communities. Many of its 50,000 customers are illiterate, speak only the local Quechua or Aymara languages, have no familiarity with modern financial services, and often live in rural areas lacking a reliable telecommunications infrastructure. In order to serve this market, Prodem FFP offers secure access to ATMs with color-coded touch screens. When customers use an ATM, they can choose to receive audio instructions in Spanish, Quechua, or Aymara. Since the customers’ account balances are stored in the smart card, it is not necessary for the ATM to connect to the Internet to complete a transaction. ATMs are assembled in Bolivia at half the cost of a traditional ATM with limited functionality (Hernandez & Mugica, 2003).

Radio programming, cheap enough to be produced locally and in a range of languages, can be used to inform farmers about agricultural techniques and commodities prices. In Latin America, most radio programming (as opposed to Internet content) is produced locally or nationally. In Peru alone, an estimated 180 radio stations offer programs in Quechua, a language spoken by around 10 million people and almost completely absent

from the Internet (Kenny, 2002). Furthermore, in areas with poor connectivity, databases that can be accessed off line as well as the delivery of documents and certificates on floppy disks may be an alternative to Internet-based versions of e-government.

Community Participation and Ownership

The advantages of community ownership¹² have long been demonstrated in infrastructure projects in developing countries. Whether in irrigation or electricity projects, community ownership and participation means that the community is willing to invest in the projects, that the projects are well maintained, that the infrastructure can better address community needs, and that community resources can be leveraged (Girard & Ó Siochrú, 2005). Organizations planning ICT projects and programs should thus ensure that ICT applications respond to the priorities of the community as the ownership and development of ICT applications in collaboration with local staff foster the success and resilience of ICT projects. In Brazil, CDI schools are created through partnerships with community organizations, nongovernmental organizations (NGOs), and religious groups. Communities have complete ownership of the schools and are responsible for their staffing, management, and maintenance. To develop a CDI school, a community sets up a committee to assess local demand, identify future instructors and a suitable location, and establish security measures for the computers. CDI trains the instructors, works with the school to obtain a hardware donation from sponsors, helps the school install the computers, and once a school has been established, serves as a consultant. It is the community that is responsible for making the school self-sustainable (CDI, n.d.; World Bank, n.d.).

In contrast, outside control and top-down approaches waste resources in the initial periods of projects, endangering their future sustainability.

A 2000 survey of Internet access centers set up by the government of Buenos Aires found that although the program was providing free Internet access, it did not provide training to users nor did it promote the participation of the local community in the decisions related to the project. Researchers that analyzed the survey observed that telecenters can have an impact on society when the members of a local community have a sense of ownership and take active participation in management activities, promoting the telecenter sustainability (Finkelievich, 2001). Menou, Poepsel, and Stoll (2004, p. 48) noted that governmentally initiated telecenters set up without adequate preparation on the part of the institutions hosting them (schools, public libraries, and others) have been characterized by a “continuing seesaw between emphatic promises, delayed and/or partial implementation, and occasional implementation especially in pre-election times” more than by sustainable development. Others in Latin America have observed that purely commercial telecenters have a particularly limited capacity to benefit low-income populations with little education (Proenza et al., 2001).

Grassroots ICT Intermediaries

In Latin America, direct ownership and use of ICT, for instance, through a PC with Internet access, applies only to a relatively small fraction of the population. Poor people have to rely on a human intermediary between them and ICT, in what is termed a “reintermediation model” (Heeks, 2001).

In Chile, for instance, the majority of Internet users belonging to middle and lower middle socioeconomic classes access the Web through a third person, while high-income citizens are usually direct Internet users (Instituto de Estudios Mediales UC, 2004).¹³ The profile of the intermediaries who add human skills and knowledge to the presence of ICT is thus critical for projects that want to reach the poor (Heeks, 1999). Successful examples of ICT projects for poverty reduction

are conducted by grassroots intermediaries that have the appropriate incentives and proven track record of working with poor people. A study on telecenter initiatives in Latin America noted that to achieve economic and social development, they need to “be run by someone that is personally committed to the project, willing to contribute his or her own capital and time, backed by the community in which the center operates, and willing to address the community’s objectives and needs” (Proenza et al., 2001, viii). If these intermediaries are grassroots based, understand the potential of ICT for social change, and can be held accountable to the communities they serve, they can be tremendously effective in promoting local ownership of ICT projects. Given the right incentives and opportunities, these intermediaries are keen to make access to information easily available for everybody and are willing to train others in the community.

Financial Sustainability, Monitoring, and Evaluation

A major challenge for ICT projects is reaching financial sustainability, but, since most ICT projects are recent, experience in sustainability is limited. The spending capacity of the poor is low by definition and limits the chances to provide for operating costs, which are higher in rural than in urban areas. In rural areas, telecommunications cost much more, computer equipment maintenance is hard to find and expensive, and skilled operating and maintenance personnel are practically nonexistent. Deficiencies in the rural power supply make additional devices necessary, such as voltage stabilizers, surge suppressors, backup power supplies, shock protection, and grounding. Where no electricity is available, recourse must be made to solar or wind energy, which raises costs (Proenza et al., 2001).

How will we know whether the benefits derived from existing ICT projects outweigh the costs? In order to answer this question, rigorous monitoring

and evaluation of the social and economic benefits of ICT projects are needed. M&E measure performance, identify and correct potential problems early on, and improve the understanding of the relationship between different poverty outcomes and ICT policies (Kenny, Navas-Sabater, & Quiang, 2001). M&E are especially needed to measure the success of many pilots currently under way. In fact, in the case of pilots, successful outcomes might be implicitly biased due to the choice of favorable places and conditions. Projects might not yield the same results in more challenging and realistic situations. Some (infoDev, 2005) even go as far as suggesting that while undertaking M&E during and after an ICT pilot project is a standard good practice to address the immediate purposes of a project, this is not sufficient; ICT pilot projects should thus be viewed as applied research, addressing specific hypotheses and generating appropriate ideas. In particular, ICT pilot projects should be assessed in terms of their contribution to core development priorities and as to whether they can be taken to scale.¹⁴

CONCLUSION

In Latin America, as in much of the developing world, reaching the poor and realizing the potential of ICT for human development and poverty reduction is a difficult endeavor. Low-cost and accessible telecommunications and information-technology infrastructure are necessary but insufficient conditions to reach the poor. Key to the success of ICT projects for development are “soft” issues such as local ownership and participation of the community, implementation by grassroots-based intermediaries that have the appropriate incentives to work with marginalized groups, and provision of access to locally contextualized information and pro-poor services. Attention must be also placed on training, awareness-raising campaigns, financial sustainability, and monitoring and evaluation.

ENDNOTES

¹ In Latin America, indigenous people (who account for more than 25% of the population in Bolivia, Ecuador, Guatemala, and Peru)

and African descendants (who account for more than a quarter of the population in Brazil, Nicaragua, and Panama) are, to a large extent, the poorest in the region, have the worst socioeconomic indicators, and receive scant cultural recognition or access to decision-making levels (ECLAC, 2005a).

² ICT can be defined as the set of activities that facilitates the capturing, storage, processing, transmission, and display of information by electronic means (World Bank, 2002).

³ In this model, ICT capital consists of hardware, software, and human capital.

⁴ Of course, in practice the rich are likely to use both mobile phones and the Internet, but each for different purposes. Furthermore, mobile phones can in certain circumstances provide access to the Internet.

⁵ As highlighted by Fink and Kenny (2003), the digital divide should not be measured only on the basis of access to ICT, but also on the basis of the impact of the use of the new technologies. However, the current availability of data substantially limits measurement possibilities and, therefore, we will have to focus on access to ICT.

⁶ Again, we are comparing persons with 15 years or more of education with persons with 2 or less years of education, and are referring to Internet access in the household.

⁷ Given that women have a life expectancy (75.2 years in Latin America) higher than men (68.8 years), and that the elderly have less access to ICT than other age groups, it would be advisable that gender parity indices on ICT access take into account the age structure of the population.

⁸ In Latin America, telecenters have fairly standard features. They consist of premises stocked with several PCs located on desks or tables and with chairs for users. The main service offered is access to the Internet and to software such as word processing and spreadsheets (Proenza et al., 2001).

⁹ See <http://www.agronegocios.gob.sv>

¹⁰ See <http://www.vivafavela.com.br>

¹¹ A smart card looks like a plastic credit card and has a microprocessor or memory chip embedded in it. The chip stores electronic data and programs that are protected by security measures enabling controlled access by appropriate users. Smart cards provide data portability, security, convenience, and transparency of financial records and transactions.

¹² Community ownership can refer to three related concepts, often found in some combination: a process of internalisation of responsibility for a development process and its outcomes, a determining degree of

decision-making power, and full or majority legal ownership of an initiative (Girard & Ó Siochrú, 2005).

¹³ The study excluded the poorest Chileans, those with household monthly incomes lower than \$160, corresponding to 13.5% of the population (Godoy & Herrera, 2004). It is to be expected that the proportion of Internet users through intermediaries among the poorest is even higher than in other socioeconomic levels.

¹⁴ It must be noted, however, that the rapid pace of technological innovation and social adaptation often makes studies on the impact of ICT what Norris (2001, Chap. 2 p. 1) has called “blurred snapshots of a moving bullet.”

Acevedo-Ruiz, pp. 1-28, copyright 2004 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 5.23

Integrating ICTs in African Development: Challenges and Opportunities in Sub-Saharan Africa

Bobak Rezaian
The World Bank, USA

ABSTRACT

This chapter reviews the role of information and communication technologies in socioeconomic development and poverty-reduction programs in sub-Saharan countries. To this end, the author first provides an overview of the status of ICTs and national ICT strategies in sub-Saharan Africa. He then analyzes the treatment of ICTs in three major policy documents that provide the framework for economic growth and poverty reduction efforts in most developing countries. These are (a) national poverty-reduction strategies, (b) country assistance strategies of the World Bank, and (c) poverty-reduction support credits. The analysis reveals that while a majority of national ICT policies strongly promote the use of ICTs for socioeconomic development, the poverty-reduction

and country assistance strategies focus primarily on the use of ICTs in public-sector management. Hence, there is a persistent disconnection between the ICT policies and the poverty-reduction strategies. The author identifies some of the main challenges and the substantial opportunities that would arise from the mainstreaming of ICTs in national development initiatives.

BACKGROUND

The contribution of information and communication technologies to economic growth in developed countries has been the subject of research, discussion, and debate since the early 1990s.¹ The Organization for Economic Cooperation and Development (OECD) has quantified the positive

contribution of ICTs to gross domestic product (GDP) growth in several advanced economies.² Some of these countries have taken the necessary steps to create an information society by educating citizens and gradually organizing their economy around knowledge and information.

The potential impact of ICTs on socioeconomic development and the possible use of ICTs as effective tools for facilitating service delivery to the poor have led to a global debate on the role of ICTs as enablers of poverty reduction in developing countries. Based on a series of ICT success stories in developing countries, various researchers suggest that ICTs can help promote local economic growth, expand social and cultural opportunities, increase the efficiency of markets and institutions, facilitate public-service delivery, and provide the poor with a voice in decisions that affect their lives and communities.³

Developing countries and their development partners are investing considerable resources in harnessing the promise of ICTs for poverty reduction and economic growth.⁴ Yet, most ICT success stories have remained anecdotal as scaling up pilot initiatives on a sustainable basis has proven difficult.⁵ This trend has been more pronounced in sub-Saharan Africa (SSA), where the development efforts are often exacerbated by the complexity of challenges in adapting the global knowledge and technology to local conditions and needs.

Clearly there are major differences between the developed and developing countries in terms of requirements for the effective use of ICTs. These requirements include adequate information and communication infrastructure, affordable access to ICTs, well-trained human resources, and incentives for the use of appropriate technologies to improve productivity and efficiency in service delivery and production. These differences are bound to influence how ICTs can play an effective role in the socioeconomic development process.

In September 2000, the United Nations Millennium Summit adopted eight specific millennium development goals (MDGs) to measure the prog-

ress of global development efforts. These include the eradication of extreme poverty and hunger; universal primary education; gender equality and the empowerment of women; the reduction of child mortality; the improvement of maternal health; the combating of HIV/AIDS, malaria, and other diseases; the ensuring of environmental sustainability; and global partnerships to attain a more peaceful, just, and prosperous world.⁶

The MDGs are now a benchmark for measuring the success or failure of most poverty-reduction programs, and the more recent national poverty-reduction strategies have incorporated the MDG targets as an integral part of their goals and objectives.

In what follows, the national poverty-reduction strategies, country assistance strategies (CASs) of the World Bank, and the poverty-reduction support credits (PRSCs, which are often a multidonor basket fund for providing budget support to developing countries) are reviewed for their discussion of ICTs as development tools. Key categories for identifying the appropriate ICT discussions in poverty-reduction strategy papers (PRSPs), CASs, and PRSCs are selected from different aspects of the ICT sector, as well as the priority sectors in each country, for example, in health, education, agriculture, and the environment.

The broader categories selected for this review include telecommunications infrastructure; broadcasting; computer technology; local content and applications; human-resource development; public-sector applications; policy and regulatory environment; information generation, access, and dissemination; ICT applications in agriculture, health, and education; rural connectivity; service delivery to the poor; ICT-sector development; small- and medium-enterprise development, and poverty monitoring.

In this chapter, the author reviews the set of available policy documents (30 PRSPs, 25 CASs, and 21 active or closed PRSCs). He then normalizes the results within each category to allow for a more meaningful comparison. At the

time of this review (mid-2005), there were only 11 countries in Africa that had prepared all three poverty-reduction strategy documents (PRSP, CAS, and PRSC). Therefore, the author makes a comparison between the results for the above group of 11 countries and the larger set to examine the consistency of his findings.

The majority of national ICT policies strongly promote the use of ICTs for economic growth, improved governance, public-service delivery, and private-sector development. However, these recommendations often have neither been integrated into the strategies and action plans for poverty reduction in their respective countries, nor have they strongly influenced them. Some of the contributing factors to this endemic disconnection are discussed, and a few practical steps are proposed for closing this gap.

It must be noted that the analyses in this chapter are qualitative in nature since the available data on the role and impact of the ICTs in developing countries are very limited. Quantifying and measuring the impact of the ICT activities proposed in PRSP, CAS, and PRSC documents also pose very significant challenges. In the absence of more reliable quantitative data, however, it is hoped that the qualitative assessments of this information will contribute to a better understanding of the challenges and opportunities, and will lead to a more effective integration of appropriate technologies in development efforts.

THE DIALOGUE ON ICT FOR DEVELOPMENT

The past decade has witnessed a series of high-level international efforts to integrate information and communication technologies into development programs and poverty-reduction efforts. We define poverty to mean more than inadequate income or the inability to meet basic needs like nutrition, clothing, and shelter: It also incorporates disadvantages in access to land, credit, health,

and education, and vulnerability to violence, external economic shocks, natural disasters, and social exclusion.⁷

In 1996, the United Nations Economic Commission for Africa (UNECA) initiated the African Information Society Initiative (AISI) as a common vision for Africa to create effective digital opportunities to speed up the continent's entry into the global information and knowledge economy.⁸

Several international initiatives have supported the use of ICT for development (ICT4D), the most prominent being the G-8's (group of eight major industrial democracies, namely, Canada, France, Germany, Great Britain, Italy, Japan, Russia, and the United States) Digital Opportunity Task Force, the United Nations' ICT Task Force, and the World Summit on the Information Society (WSIS).⁹ Encouraged by the support of various bilateral and multilateral development organizations, most African countries have begun developing policies and strategies for the use of ICTs in their broader national development programs.¹⁰

Accenture Consulting, the Markle Foundation, and the United Nations Development Programme (UNDP; 2001) reviewed the record and potential of ICTs in development and presented their findings in *Creating a Development Dynamic: Final Report of the Digital Opportunity Initiative*.¹¹ This report includes several case studies, including some from Africa. A key finding of the report is that when strategically deployed, ICTs can trigger a development dynamic that gains momentum as targeted steps are taken in key areas of policy, infrastructure, human capacity, entrepreneurship, and development of locally relevant content and applications.

MDGs have now become the global yardstick for measuring the success or failure of poverty-reduction efforts in many developing countries. In most developing countries, they have also become the framework for development policies in general, and ICT4D initiatives in particular.

At the regional level, the secretariat for the New Partnership for Africa's Development (NEPAD)

Box 1. NEPAD and ICTs in Africa (NEPAD, 2002)

“The problem of inadequate access to affordable telephones, broadcasting services, computers and the Internet in most African countries is due to the poor state of Africa’s ICT infrastructure, the weak and disparate policy and regulatory frameworks and the limited human resource capacity in these countries. Although African countries, in recent years have made some efforts to facilitate the ICT infrastructure deployment, rollout and exploitation process in a number of areas, Africa still remains the continent with the least capability in ICT and least served by telecommunication and other communications facilities.

The threat posed by the digital divide to the rapid development of African countries can on the whole be attributed to their inability to deploy, harness and exploit the developmental opportunities of ICTs to advance their socio-economic development. There is therefore an urgent need to put in place and implement ICT initiatives to bridge the digital divide at four levels namely: (i) bridging the divide between the rural and urban areas within a given country, (ii) bridging the gap between countries of a given sub-region, (iii) bridging the inter-regional gap and (iv) bridging the gap between Africa and the rest of the world.”

has prepared an integrated socioeconomic-development framework for Africa. This framework includes proposals for various initiatives to bridge the digital divide in Africa (see Box 1).¹²

During the past decade, most African countries’ initial focus on ICTs has been on (a) the computerization of public-sector operations, (b) the expansion of telecommunications infrastructure, (c) the liberalization of telecom value-added services, and (c) the introduction of ICTs in higher education institutions.

This trend is still evident in several ICT strategies, PRSPs, CASs, and PRSCs. In the public sector, for example, African governments are showing increasing interest in the computerization of their budget and expenditure management, payroll, customs, and other operations.

Various international agencies and bilateral and multilateral development organizations support the computerization of public-sector operations in African countries. They find this approach

consistent with their own public-sector capacity building and good governance objectives and initiatives. The governments’ desire for modernization of the public sector, and the international organizations’ advocacy of improved public-sector management and telecom-sector liberalization have been major factors in the framing of national ICT strategies in Africa.

ICTS IN AFRICA

The growth of ICTs in SSA is a story of uneven development, with discernible general patterns dotted with exceptions. Three major trends emerge from the data: (a) Other factors being equal, the middle-income sub-Saharan countries are performing consistently better in the ICT sector compared to the lower income countries, (b) countries with smaller populations are generally doing better in terms of ICT competitiveness

compared to more populous countries, and (c) sub-Saharan countries are generally far behind in terms of connectivity infrastructure and the use of new technologies compared with rest of the world.

Of the 48 sub-Saharan countries, 38 fall in the low-income category (based on the 2004 gross national income, or GNI, per capita of \$825 or less).¹³ The SSA countries that are performing well in the ICT sector are all middle-income countries. For example, the GNI per capita for Botswana, Mauritius, Namibia, and South Africa is \$3,530, \$4,100, \$1,930, and \$2,920, respectively (World Bank, 2005). These countries also have higher levels of per capita telecommunications infrastructure, personal computers (PCs), Internet hosts, telephone main lines, and mobile phones compared with other SSA countries. The economic performance of these countries has a direct bearing on their state of education, infrastructure, availability, and affordability of ICTs for public, business, and private applications.

Between 1 to 9% of the population of every middle-income SSA country uses the Internet. Among the smaller middle-income SSA countries (both in terms of size and population), Cape Verde and Seychelles stand out in terms of the number of telephone main lines and personal computers per capita.

With the exception of South Africa, all these middle-income countries have relatively small populations (see Table 1). As a result, South Africa's performance in any of the ICT categories has a significant impact on the overall performance of the subcontinent.

For example, in 2002, the number of personal computers in sub-Saharan Africa was 11.9 per 1,000 people. Excluding South Africa, this number would decrease to 7.02 computers per 1,000 people. Also, in 2000, the average number of Internet hosts for sub-Saharan Africa was 3.1 per 10,000 people (see Table 2). However, excluding South Africa, this number would decrease by an order of magnitude to 0.32 Internet hosts

per 10,000 people. The impact of South Africa's performance on the overall performance of the region in the telecom sector is also very significant (see Table 3).

It is important to note that the official data from international sources do not fully reflect the fast pace of growth in the telecommunications sector in some SSA countries, particularly in the mobile segment (e.g., the Democratic Republic of Congo and Ethiopia). This fact notwithstanding, the overall teledensity in the sub-Sahara still remains far below other regions.

The Global Information Technology Report (Dutta, Lanvin, & Pua, 2004) provides the Networked Readiness Index (NRI) ranking for 102 countries, including 21 sub-Saharan African countries. The NRI is defined as the degree of preparation of a nation or community to participate in and benefit from ICT development. NRI is a composite measure of three components: the environment for ICTs offered by a country, the readiness of the countries' key stakeholders (individuals, businesses, and governments) to use ICTs, and the usage of ICTs among these stakeholders. The Networked Readiness Index is therefore a good indicator for evaluating a country's relative development and use of ICTs.

The Africa Competitiveness Report 2004 (Hernandez-Cata, Schwab, & Lopez-Claros, 2004) provides data on the Growth Competitiveness Index, reflecting the combined effects of public institutions, macroeconomic environment, and technology indices. This report also provides a Technology Index for the same group of African countries. The Technology Index is a measure of innovation, technology transfer, and ICTs in the country. These data confirm that the performance of countries like Botswana, Mauritius, Namibia, and South Africa is in fact consistently better than the rest of the SSA countries in all these assessment categories, while still lagging considerably behind the rest of the world (see the rankings in Table 4).

The same data show that compared to rest of the world, even the best performing SSA countries are barely keeping up with other regions as demonstrated by their global ranking among the 102 countries considered. It appears that the higher GNI per capita and the lower population of most middle-income SSA countries are making it easier for them to deal with the questions of infrastructure development, investment in information technology, and human-resource development.

However, a closer examination of the in-country variations in terms of per capita income, telecom access, and other factors demonstrates

that while the overall national statistics may appear impressive, there is a high level of disparity among the larger and smaller urban centers, and between urban and rural populations in terms of income, connectivity, access to resources, literacy, and related factors that make the use of ICTs possible.

The prevalent lack of adequate connectivity infrastructure, human resources, an enabling policy environment, and local content in most sub-Saharan countries require more in-depth assessment. The disparities within and across countries in the access to and use of ICTs also require more serious attention by government

policy makers, regional organizations, and development partners.

At the regional level, it is also important to point out that the existence of connectivity infrastructure does not necessarily translate into affordable access to communications for consumers. For example, the SAT-3/WASC (South African Telecommunications/West African Submarine Cable) project connects several West African countries to international networks. However, the price of local access to this infrastructure has been high, and its development impact has therefore remained low so far.

More recent initiatives like NEPAD's backbone infrastructure development in Southern and Eastern Africa and the Regional Communications Infrastructure Program (RCIP), which is a multipartner initiative to overcome the major bottlenecks to growth and competitiveness in the region, are initiatives that require strong support. RCIP's key difference with SAT-3 is that RCIP plans to ensure that access to its infrastructure will be priced competitively so that it can bring benefits to users. These programs could to a large extent address the lack of adequate regional ICT infrastructure in Eastern and Southern Africa, and could facilitate access to affordable ICT services. The RCIP initiative is proposed as the lead instrument for a broader NEPAD regional connectivity program supported by many development partners.¹⁴

NATIONAL ICT POLICIES AND POVERTY REDUCTION

Since the 1990s, a few middle-income sub-Saharan countries such as Mauritius have completed several cycles of e-strategies as part of their broader development programs. Most other SSA countries, however, have started looking seriously at the potential role of ICTs in their development efforts since the beginning of the new millennium.

By mid-2005, close to 30 African countries had already developed national ICT policies and/or e-strategies, and 15 more were in the process of doing so.¹⁵ At this pace, all major African economies will have the first generation of their national ICT policies in place before long.

Various bilateral and multilateral development organizations (e.g., UNECA¹⁶, UNDP, the International Development Research Center [IDRC; Canada], and others) have supported the development of national ICT policies in sub-Saharan Africa with some variation in their approach to the process of policy development.¹⁷ By and large, however, the countries' national development priorities are proposed as the framework within which the role of ICTs as enablers of change and growth are defined.

In reviewing the national ICT policies and e-strategies of sub-Saharan countries, the first challenge is accessing the existing documents. Several of the 30 or so sub-Saharan ICT policy documents are not publicly available. Others are available in draft form, often in multiple versions, making it difficult to verify their official standing. During the preparation of this chapter, the author had access to 18 of these documents. Therefore, to ensure that any other available information on these ICT policies was taken into account, several review papers were consulted, the most significant of which are listed below.

UNECA has published several reports on national, sectoral, and regional ICT policies, plans, and strategies in Africa (see, for example, UNECA 2003a, 2003b, 2004a, 2004b, 2004c). These documents provide an overview of ICT policy-development efforts in Africa, UNECA's framework for policy development, and its role in that process.

Tipson and Frittelli (2003) summarize the experience from various national strategies and initiatives on ICT for development, including some examples from Africa. Their basic conclusion is that despite major opportunities to take advantage of the development potential of ICTs, the results

of most national strategy efforts to date have been disappointing. The authors believe that national strategies frequently flounder or fail by becoming focused on particular technologies or applications in isolation from broader policy, resource, and training initiatives necessary to exploit their capabilities in specific settings.

Wild (2003) reviews the evolution of ICT strategies in various regions, and analyzes the connection between e-strategies and poverty-reduction strategies. She finds that many e-strategies recognize a social dimension but do not systematically address poverty and achievement of the millennium development goals. Among her conclusions, Wild suggests that the international community has now clearly recognized the importance of developing a stronger poverty focus in e-strategy work, and makes a number of recommendations on the steps that can be taken to help countries incorporate an MDG dimension into their national ICT planning process.

Adam (2004) critically discusses the implications of e-strategies for civil-society organizations in Africa by drawing on lessons from the ICT policy-making experience during the past decade in the region. He asserts that:

[i]n practice, although the number of countries aiming to benefit from ICTs by developing their e-strategies is increasing and some of the ICT policies were useful in mobilizing resources and attracting collaborators, by and large, the result of broad-based ICT policy implementation has been inadequate. (p. 3)

He further concludes that:

[c]onsequently, the formulation and implementation of e-strategies has been sluggish in Africa—mired by faulty assumptions about the role of ICTs in development in the region, overestimation of the capacities and underestimation of structural obstacles in the countries and by occasionally cumbersome processes under which policies are promoted, developed and implemented.

As part of the explanation for this, Adam suggests that:

[f]or the most part the debate on e-strategies does not involve countries and institutions who need the ICTs the most. It takes place amongst ICT professionals, donor agencies and a few policy experts

Box 2. Poverty reduction and ICTs in Zambia (Republic of Zambia, 2004)

“1.3 POVERTY REDUCTION & ICTs IN NATIONAL DEVELOPMENT

The need to integrate ICTs as part of the holistic national development agenda means taking ICTs as part of the tools and services in Poverty Reduction Strategy Programmes (PRSP) as well as in developing National Development Plans (NDP). Therefore, it is expected that each sector will mainstream ICTs in their action plans to address the PRSP and the NDPs. The communications sector has registered significant progress and contribution to the GDP1 over the past ten years (1994-2004). This signifies that with further positive policy direction, integration of ICTs in poverty reduction programmes and restructuring of the ICT sector; greater achievements can be recorded. Therefore, this policy framework is by design integrating ICT implementation in all key economic and social sectors with a view of making the ICT sector one of the positive contributors to job creation and other empowerment opportunities.”

independent of the mainstream development professionals and empirical research. Limited involvement of development professionals means that beyond a list of [sic] menu of opportunities there is less substance on the actual impact of ICTs in key development sectors like health, education and agriculture. (p. 10)

He further suggests that civil-society organizations can play a key role in influencing local policy development and promoting broad participation and representation, among other activities.

Adamali, Coffey, and Safdar (2005) provide an overview of how countries are formulating national e-strategies and what they are focusing on. They examine the trends in the national e-strategies of 40 countries, including 8 from sub-Saharan Africa, and evaluate the strength, scope, and direction of these countries' ICT programs based on the goals stated in these countries' e-strategy documents. Adamali et al. identify four themes that appear in over 85% of the e-strategies. These are e-government, infrastructure expansion, e-education, and an enabling legal and regulatory environment. They also identify five additional themes that appear in at least 40% of e-strategies. These are the creation or expansion of the domestic ICT industry, the development of human resources with ICT skills to support the domestic ICT industry, e-business, the creation of locally relevant content, and ICTs to support more effective provision of health services. Based on these reviews and lessons learned, they then offer recommendations for formulating effective e-strategies.

The author's own field experience and his review of the available ICT policies are consistent with most of the above assessments. Several ICT policies consider poverty reduction as a major objective or a key driver of the policy (e.g., Cameroon, Ghana, Mozambique, Nigeria, and Tanzania). Zambia's second-draft ICT policy defines ICTs as tools for poverty reduction and development¹⁸ (see Box 2). Other national policies

and strategies discuss the role of ICTs in poverty reduction either explicitly or in the context of ICTs as tools for the achievement of MDGs through the mainstreaming of ICTs in business and trade, education, health, tourism, agriculture, public-sector services, community centers, and other types of service delivery to the poor.

While the process of ICT policy preparation may vary across countries, the general objectives and areas of priority are similar in most policy documents. These priorities include improvements in the broader ICT-sector policy and regulation, infrastructure, human capacity, content and applications, and an enabling environment for active private-sector participation.

The national ICT policies often include a framework for the use of ICTs as enablers of service delivery to the poor, improved governance, and economic growth. The policies generally encompass a subset of the following topics: (a) expanding the telecommunications infrastructure; (b) using new technologies in public administration, service delivery, and e-government; (c) fostering the use of ICTs in academic, educational, and research institutions; (d) creating a conducive policy, legal, and regulatory environment for the growth of ICTs; (e) creating opportunities for private-sector development and the growth of the ICT sector; (f) developing human resources in the ICT sector; (g) producing local-language content and applications; (h) providing rural connectivity and universal access; (i) facilitating e-commerce; (j) supporting access to ICTs by civil society and NGOs (nongovernmental organizations); and (k) facilitating applications of ICTs as enablers in health, education, agriculture, mining, environment, trade, art and culture, tourism, and other sectors. Malawi's proposed ICT policy is typical of some of the focus areas that are normally found in African ICT policies with an emphasis on certain national priorities (see Box 3).

To establish a clear link between ICT policies and poverty-reduction efforts, a few countries have also developed implementation strategies or

Box 3. Specific goals of the Draft Malawi ICT policy (Republic of Malawi, 2003)

- To facilitate the creation of the necessary enabling environment to support the deployment, utilization, and exploitation of ICTs within the economy and society
- To promote the development of a globally competitive local ICT industry
- To support the development of the nation's human-resource capacity
- To facilitate the deployment and exploitation of ICTs within the educational system to improve on educational access and delivery
- To aid the process of improving Malawi's scientific and industrial research capacity as well as its research and development (R&D) capabilities to support economic development
- To promote and support the development of the nation's information and communications infrastructure as well as the physical infrastructure
- To facilitate the modernization of civil and public service through the deployment and exploitation of ICTs to improve on the effectiveness and efficiency of its operations and service delivery
- To promote and facilitate the development and implementation of the necessary legal, institutional, and regulatory framework and structures required for supporting the development, deployment, and exploitation of ICTs in the country
- To support and encourage the development and promotion of the necessary standards, good practices, and guidelines to guide the deployment and exploitation of ICTs within the society and economy

action plans for their ICT policies that are aligned with their broader poverty-reduction strategies. Mozambique, for example, has developed an implementation strategy that proposes specific projects and activities for each focus area of the national ICT policy, with corresponding implementation schedules and budgets. Other countries have engaged in large-scale rollouts of connectivity or ICT-enabled applications for development. Ethiopia's national secondary school network initiative is one example of such initiatives.

Evaluating the impact of such programs in poverty reduction and economic growth in sub-Saharan countries, however, requires careful

monitoring of various initiatives over longer periods, and detailed impact assessment at various levels. These are tasks that require more attention by all parties involved in the promotion of ICTs for development.

Despite some promising progress, in most SSA countries, the development of an ICT policy has not led to the flourishing of the ICT sector or the large-scale use of ICTs as effective tools for development. A major contributing factor is the starting point (initial conditions) of each country with respect to the main prerequisites for the growth of ICTs, including the communications infrastructure, human resources, the policy

and regulatory environment, affordable access, entrepreneurship, and relevant applications (see Tables 1, 2, and 3). This is particularly more visible in lower income countries, where the level of readiness in various areas of ICT development (e.g., infrastructure, human resources, etc.) lags considerably behind those of middle-income countries. For example, countries like South Africa, Mauritius, Botswana, and Namibia are in a better position to deliver on the promises of their respective ICT programs compared with lower income SSA countries.

Size also matters. Countries like Mauritius and Botswana, with smaller geographic areas and populations, can be more agile and effective in the expansion of their ICT infrastructures across their countries and the mainstreaming of ICTs compared to, say, South Africa.

Disparity between urban and rural areas also matters. For example, Namibia is a middle-income country with a well-developed communications infrastructure that connects the major urban areas. However, the majority of the population lives in the rural areas, and there is a marked difference between the urban and rural communities in terms of income, access to affordable communications infrastructure, and ICT tools and services. This could make it more difficult for Namibia to attain its ICT policy goals in an equitable manner across the country.

Other impediments to the growth of ICTs in many African countries include (a) the inadequacy of the infrastructure, human resources, local-language applications, and funding for large-scale rollouts of ICTs in government, education, and other public-service areas, (b) an overestimation of the existing implementation capacity on the ground, (c) the affordability of the ICT tools and services for the general population, (d) the lag between the fast rate of technology introduction (automation factors) and the slow rate of adaptation to change (human factors), and (e) the “brain drain” due to inadequate local incentives.

A reliable and continuous supply of electricity as a basic requirement is still a problem even in major urban areas across the continent. While countries like South Africa are trying to develop the required power and telecommunication infrastructure for effective use of ICTs, most SSA countries are trailing behind.

For example, South Africa’s annual average power consumption per capita is 3,739.9 kWh (World Bank, 2005). The same indicator for SSA countries excluding South Africa is 116.4 kWh, which is only about 3% of South Africa’s corresponding power usage per capita. Nigeria and Ethiopia’s average power consumption per capita are 73.1 and 22.4 kWh, respectively, reflecting the fact that most rural areas are yet to have access to electricity. In the absence of these prerequisites for the growth of ICTs, the scope of some ICT policy documents appears rather unrealistic.

Despite these obstacles and challenges, the introduction and mainstreaming of appropriate technologies in development programs, when and where possible, are necessary for the growth of ICTs in Africa. This is an effort that will require considerable coordination among the various local and global stakeholders and partners involved.

ICTS IN POVERTY-REDUCTION STRATEGY PAPERS

PRSPs are documents prepared by countries as the frameworks for their development programs. Since 1999, the preparation of a PRSP has become a standard requirement for countries that wish to benefit from the concessional credits, grants, and debt relief offered by the International Monetary Fund and the World Bank Group. The development of PRSPs (or their equivalents under different names) has become prevalent among developing countries, particularly in Africa. By mid-2005, there were a total of 58 countries with PRSPs, of which 30 are in Africa.¹⁹

The approach to preparing PRSPs has evolved over the past few years, moving steadily toward a more participatory and consultative process. As a result, while the earlier PRSPs are mainly focused on government priorities, recent ones are more representative of the needs of diverse communities and stakeholders.

Like the PRSPs themselves, the discussion of ICTs in PRSPs is a new phenomenon, gradually starting in late 2000 (e.g., in Mauritania) and becoming a fairly common topic in PRSPs by 2002 and beyond (e.g., in Benin, Malawi, and Senegal).

The OECD (2003, 2004) is among the few international organizations that has studied the discussion of ICTs in PRSPs. In these studies, OECD reviews whether the PRSPs define or position ICT as a strategic component for poverty reduction and discuss it as an independent item. The OECD studies found that worldwide, over 40% of the PRSPs (12 out of 29, including 8 sub-Saharan countries) meet these criteria (OECD, 2003). The rest mention telecommunications-sector development as an important factor for rural and agricultural development, or as one of the components of the infrastructure for economic growth.

The current study reviewed the 30 sub-Saharan African PRSPs that were available in mid-2005. The results indicate that 16 PRSPs and 1 interim PRSP refer to ICTs as a component of their poverty-reduction efforts or as a means for facilitating economic growth. Some define a more specific role for ICTs as tools for improved communication, public-sector modernization, improved service delivery, and applications in health, education, and rural development.

About half of the PRSPs make references to information and communication technologies as a significant tool for development. These documents also emphasize the telecom sector as an important part of their infrastructure development needs

and significant for economic growth. Over 20% of the PRSPs discuss one or more of the broadcast media (radio and television) and Internet as relevant tools for information dissemination and communication on development issues.

The majority of PRSPs (70%) emphasize the important role of information technology in improving public-sector management and service delivery. These PRSPs include a discussion of improved governance through the appropriate use of ICTs in budget tax, customs, payroll and personnel management, and the establishment or improvement of integrated financial-management information systems (IFMISs).

Over 50% of the PRSPs include fairly extensive references to the potential role of new information and communication technologies in diversifying the economy for accelerated growth, job creation, improved performance in the productive sectors and government services, better access to regional and global markets, and other benefits. An example from the Ghana PRSP is given in Box 4.

In the area of government service delivery, 67% of PRSPs discuss one or more services that focus on streamlining and/or computerizing the corresponding activities. These include developing national health information systems and HIV/AIDS monitoring, legal issues, water and sanitation, social security, and other services. In the education sector, over 30% of the documents refer to one or more of the following actions to improve the efficiency and effectiveness of the corresponding activities: creating or improving higher education networks, strengthening institutional administrative capabilities, establishing computer labs and access to the Internet in secondary schools, introducing computer-based instruction, establishing sector-wide computerized performance-tracking systems, and strengthening distance education programs.

An interesting finding is that only 17% of the PRSPs propose ICT activities that will directly benefit civil society and the private sector, such

Box 4. New ICTs in Ghana's PRSP ("Ghana Poverty Reduction Strategy", 2003)

“Utilising information and communication technology to further enhance our development efforts.

6.1.11 Information and Communication Technology (ICT). The creation of awareness in information access is recognized as being of prime importance. With respect to ICT usage and application, an information technology policy framework is currently being developed which recognizes that the dynamics of global economic growth are changing at a very fast pace. The role of the Internet as a pervasive phenomenon and its implications for the traditional factors of production is taken into account. Economic potential is recognized as being increasingly linked to the ability to control and manipulate information. Within this policy context also, the need for an effective legal and regulatory framework is identified. A National Communication Authority is operational and a National Information Technology Agency is to be established as part of the regulatory and licensing environment. Also to be established is a national communications backbone facility to provide access throughout the country.

In the medium term, the intention is to support the development of electronic commerce to enhance production, productivity and to facilitate business transactions. Government intends to establish Information Technology (IT) parks and incubator areas equipped with the necessary infrastructure for ICT related businesses and to develop human resources that support the deployment and rehabilitation of modern ICT. Government will re-negotiate the existing telecommunications agreements to introduce more competition and accelerate access to telephones, Internet and information technology in the country.”

as the development of streamlined and computerized business registration and market information systems.

On rural-development issues, about 20% of the documents propose plans for the extension and/or expansion of rural connectivity through the establishment of community telecenters, wireless phones, and some use of ICTs for agricultural development.

Regarding information technology (computer technology, hardware, software, networks, applications), almost every document has some

discussion on computerization, networking, information systems, and related topics as shown in Figures 1 and 2.

About one third (33%) of PRSPs include some reference to content development and information dissemination. These include the promotion of rural and community radios, expansion of radio-programs development, production of farmer newsletters, translation and distribution of training materials in local languages, provisions for citizens' access to government information, delivery of meteorological information to farmers

Figure 1. ICT Subsectors in PRSPs.

Figure 2. ICTs in PRSPs

and fishermen, and dissemination of information on health and agricultural market information.

The coverage of ICTs in PRSPs is encouraging. However, the PRSP documents often reflect the generic global discourse on the potential of ICTs for poverty reduction. There is very little detail in terms of whether the necessary conditions exist on the ground to make the ICT4D interventions successful and effective in a sustainable manner. It is therefore not surprising to see that there is a visible disconnection between most PRSPs

and the corresponding national ICT policies and e-strategies. Only a few PRSPs (Benin, Cameroon, Ghana, and Rwanda) discuss or refer to the existing national ICT policies or e-strategies and their relevance to poverty-reduction efforts. Most other PRSPs and the ICT discussions therein are not informed by the ICT policy documents or the ongoing ICT efforts and initiatives that are already under way in the country.

Several factors contribute to this situation. The process of ICT policy development is often led

Integrating ICTs in African Development

by national organizations and ICT professionals who are well familiar with the global discourse on the role of ICTs in development. The international partners who support the ICT policy-development efforts are also eager to introduce ICT policy frameworks that are driven by the broader poverty-reduction MDGs and economic-growth objectives. Therefore, most national ICT policies (particularly those supported by international

partners) have an ICT4D orientation. However, these ICT advocacy groups are not necessarily involved in the national poverty-reduction strategy planning, and therefore have little influence on such policy formulations.

The local stakeholders involved in poverty reduction and economic-development planning, on the other hand, are mainly focused on identifying and prioritizing the specific national development

Box 5. Examples of ICTs in PRSPs (Republic of Benin, 2002; Republic of Cameroon, 2003)

Benin: New ICTs

“96. New Information and Communication Technologies (NTIC). The Government also intends to promote the development of new information and communications technologies to benefit from their economic and social potential. These technologies will spur economic growth by better integrating the Beninese economy within the global economic and trade systems, as well as by creating new economic activities and jobs. The development of NTIC and their use in the health and education sectors will lead to a noticeable improvement in quality and a greater range of services offered to poor people and thereby contribute to poverty reduction. The planned actions involve the drafting of a national development strategy for NTIC, support for the dissemination of NTICs and their introduction in the health and education sectors, arrangements to exempt imports of computer equipment from duties and taxes, of these measures to consumers.”

Cameroon: Economic Potential of ICTs

“242. During the participatory consultation, the difficulty of accessing, and the lack of information were mentioned as a determinant of poverty. Moreover, the United Nations considers access to information, this is, access to the knowledge required for basic life functions, to be a major human development indicator. Given the requirements of the New Economy, which is heavily reliant on information, communications, and artificial intelligence, the government will take measures to greatly improve citizens’ access to information. 243. The government intends to: (i) open multimedia community centers in each of the 10 provinces to provide the landlocked population with Internet access to important health, education, agricultural, live-stock, and environmental information; and (ii) install, with support from the UNDP and UNESCO [United Nations Educational, Scientific, and Cultural Organization], new rural radio stations in addition to the 15 already operational stations. The authorities also intend, through the Ministry of Communication, to support the national HIV/AIDS strategy through the implementation of a sector communication plan.

244. The government understands the economic potential of information and communications technologies (ICT) and is committed to promoting the development of this sector. In addition to reducing or eliminating some import duties and taxes for computer equipment, it created a National Information and Communication Technologies Agency (ANTIC) in April 2002. Within its missions, the agency must promote broader access to ICT as well as activities related to these new technologies, which are becoming increasingly popular among the population.”

objectives in traditionally well-established sectors such as health, education, agriculture, water and sanitation, roads, and so forth. In this process, the potential role of ICTs as crosscutting tools for development is often treated as a side issue and not a priority. Consequently, the preparation of existing ICT policies and PRSPs has often taken place on two independent parallel tracks with limited influence on each other.

As the global discourse on the role of ICTs in development continues (e.g., WSIS and NEPAD), it is expected that the integration of ICTs into poverty-reduction strategies will continue to grow in a more substantive manner.

The international development organizations are often consulted during the preparation of PRSPs. Therefore, they may be in a position to point out the need for a more holistic articulation of the potential of ICTs for development in line with the specific development objectives of the PRSPs.

These international partners could also coordinate their technical advice and financial contributions in such a way that the multisectoral and crosscutting nature of ICTs as enablers of socioeconomic development is more clearly understood, assimilated, and articulated by all stakeholders, including the donor community and the bilateral and multilateral development organizations. Box 5 provides some additional examples of ICT discussions in PRSPs.

ICTS IN COUNTRY ASSISTANCE STRATEGIES

The multilateral and bilateral development agencies provide their country assistance to developing countries based on development frameworks that highlight the focus areas of mutual interest. Examples include UNDP's country program out-

Box 6. Telecom examples from CAS documents ("Uganda Country Assistance Strategy", 2000; "Senegal Country Assistance Strategy", 2003)

Uganda

"A recent noteworthy success was the privatization of the telecommunications utility in the spring of 2000 and the accompanying sector reform which have brought in a second national operator and a second cellular licensee, expanding service options and lowering prices."

Senegal

"The advent of private participation in infrastructure, notably telecommunications and water, has accelerated economic growth, and extended service access.* New information technologies are widely available in Dakar and in the larger secondary cities. Rapid growth in coverage is now common."

* The bank estimates that the privatization of the national telephone company, SONATEL, and the related introduction of two cellular phone licenses has added 1% each year to GDP growth since 1997.

line and country cooperation framework (CCF) documents, DFID's (Department for International Development) country assistance plan (CAP), and the World Bank's country assistance strategy.

The CAS is a document that describes the World Bank Group's framework for working with a country based on an assessment of priorities in the country as reflected in its PRSP or equivalent documents.²⁰ It also delineates the bank's intended level of assistance based on its comparative advantage and the country's portfolio performance.

The CAS normally outlines the sector-specific and/or programmatic operations that are planned in support of achieving the PRSP objectives. It also specifies whether there is a mutual agreement with the government to provide multisectoral budget support to the government through a PRSC. PRSPs generally provide the framework for the CAS, which in turn will inform the formulation

of the PRSC for achieving the midterm goals of the poverty-reduction strategy. There is, therefore, a sequential yet iterative process that is normally followed in formulating these three documents.

A review of the 25 current CAS documents for African countries reveals that by far the most significant discussion of ICT issues is focused on telecommunications infrastructure and telecom reform. Over 84% of the CAS documents discuss one or more of the following aspects of the telecom sector in the country: (a) challenges in terms of the existing shortcomings and the required investments to improve and expand the telecom infrastructure, (b) plans for the introduction or expansion of privatization, liberalization, or competition, and (c) the necessary reforms to improve access and connectivity through the licensing of new or additional mobile operators. Despite the high frequency of these discussions,

“The draft Freedom of Information Bill is intended to bring about fundamental improvements in political and bureaucratic culture as regard access to information on government business.”

Figure 4. ICT in PRSPs and CASs

Box 8. Examples of ICTs in CASs from various years (“Uganda Country Assistance Strategy”, 2000; “Mauritius Country Assistance Strategy”, 2002; “Ghana Country Assistance Strategy”, 2004)

Uganda (2000)

“Information and communication strategy and policy: It is recognized that the use of information and communication technologies (ICTs) and modern information management systems can increase the credibility and effectiveness of efforts to improve access to information, transparency in public sector decision-making and build private and public sector capabilities. To promote the use of ICTs in Uganda, the Bank will support the Government’s efforts to (i) develop a National Information and Communication Strategy to establish a national ICT policy framework to promote the use of information and communication technologies for development; (ii) implement an integrated Public Sector Management Information System to promote fiscal oversight, transparency and accountability; and (iii) provide support for the establishment of the Uganda Country Gateway web-site.”

Mauritius (2002)

“38. To support the move to a more service based economy, the regulatory framework for the information and communications technology (ICT) and financial sectors has been overhauled. The Government is actively seeking foreign investments in the ICT sector by developing a package of incentives and through the creation of a Cyber City that is expected to be completed by September 2003.”

Ghana (2004)

“26. Information and communication technology (ICT), tourism, and manufacturing: other non-traditional sectors with potential. The potential crosscutting impact from a well-functioning ICT environment on growth and employment, improved government services, and accountability and empowerment, is high. For example, a dynamic ICT sector in Ghana has the potential to bring greater efficiencies to day-to-day operations of both government and private sector, as well as a platform for value-added services, such as outsourced data and call center services for overseas corporations. Strengthening the policy environment and regulatory capacity, and improving ICT infrastructure and access in both urban and rural communities, including resolving an investment dispute between the government and a shareholder of Ghana Telecom, are necessary preconditions to realizing this potential. Ghana’s ICT policy, developed in June 2003 following extensive consultation with stakeholders countrywide, seeks to engineer an ICT-led socio-economic development process with the potential of transforming Ghana into an infrastructure-rich, knowledge-based and technology-driven economy and society.”

the references are very brief. Two examples from the Uganda and Senegal CAS documents are given in Box 6.

Figure 3 compares the relative frequency of CAS discussions on different aspects of ICT sub-sectors with those in the PRSPs. The graph shows very clearly that telecom reform and infrastructure expansion are much more strongly emphasized in the CAS documents compared with PRSPs.

The graph also shows that while there is a high level of emphasis on information-technology applications in CASs, there is limited discussion on the potential role of radio in education and service-delivery efforts, and less emphasis on the Internet. The use of radio and the Internet are areas that could be more effectively explored and discussed during the PRSP and CAS consultations. These options could be of particular interest to the local private-sector and civil-society organizations that are more akin to the use of these tools for information dissemination and service delivery.

On the broader ICT applications, the CAS documents put more emphasis on the public-sector management applications. The development of management information systems and the computerization of budget, expenditure, tax, and customs operations are regularly discussed. IFMISs are often mentioned (43%) either as existing operations in need of improvement, or as new initiatives to improve public-sector management.

The provision of access to government information is an emerging area of policy reform in sub-Saharan Africa. A few countries (e.g., Ghana and Uganda) have taken the necessary steps in developing the policies and laws that will provide their citizens access to various government information. An example from the Ghana CAS highlighting this new trend is presented in Box 7.

Figure 4 provides an overview of the various ICT topics discussed in CAS documents as compared with the discussion of the same topics in PRSPs. The graph shows that with the exception of the treatment of telecom-sector reform

and private-sector development, almost all other aspects of ICTs are treated more emphatically and fully in PRSPs as compared to the CAS documents. This implies that the priorities of the actual development investment plans in the ICT area differ somewhat from those proposed in the broader poverty-reduction strategies, with a stronger emphasis on telecom liberalization and infrastructure expansion, and a somewhat weaker emphasis on public-sector investment in ICT-sector development and ICT applications in sectors.

The graph shows that there is a high level of demand from the countries for information-technology solutions, and the CAS documents also reflect a strong response. In financial terms, however, this response is much more limited in scope compared to the requirements of the demand. This aspect is treated in more detail in the PRSC section below. The results also reflect the strong support of the World Bank's country programs for the use of ICTs in public-sector management. This is not surprising since the findings of the bank's core fiduciary analyses of each country's capabilities in this area also confirm the need for different levels of computerization and other ICT-enabled interventions in the public sector.

About one fourth of the CAS documents mention local content development and information dissemination in various forms. Some CASs propose support for market information systems for small and medium enterprises, and the development of independent media, community, and commercial FM radio stations and private television stations.

The anecdotal examples sited in Box 8 offer a flavor of the evolving nature of ICT discussions in CAS documents between 2000 and 2004. These examples show that the ICT discussions in CAS documents have shifted from focusing on the development of ICT policies in 2000 to articulating the role of ICTs as enablers of development and growth in 2004. This is also partly a reflection of the fact that the level of awareness of the

Figure 5. ICTs in PRSPs, CASs, CASs, and PRSCs.

bank teams, as well as the governments and their domestic or external partners on the role of ICTs in development, has also changed considerably during this period.

ICTS IN POVERTY-REDUCTION SUPPORT CREDITS

The PRSC is a CAS-based development-assistance instrument that is often a multidonor basket fund to support the policy and institutional reform programs intended to help implement the country’s poverty-reduction strategy as described in the PRSP. This type of lending does not finance specific investments, but instead finances overall country budget execution. It is expected that the PRSP/PRSC framework will allow donors to combine their efforts behind a single program with consistent and harmonized monitoring and evaluation focusing on results at the project, program, and country levels within a short to midterm execution period.

As of mid-2005, 11 sub-Saharan countries had active (ongoing) PRSCs. Six of these countries (Benin, Cape Verde, Madagascar, Mozambique,

Rwanda, and Senegal) had their first PRSC in 2004 to 2005, while the other five countries (Burkina Faso, Ethiopia, Ghana, Tanzania, and Uganda) were in the second, third, or fourth cycle of their PRSCs. The rather limited number of countries with PRSCs poses a challenge in terms of any comparative analysis of the PRSC, CAS, and PRSP documents.

To address this challenge, the following approach was adopted for the purposes of this analysis. First, since PRSCs are instruments for the implementation of PRSPs, and each country has only one PRSP, the 21 PRSCs were grouped together by country, leading to 11 groups of PRSCs, and each group was then treated as a single integrated PRSC per country. Next, the ICT-related discussions in each country’s one or more PRSCs were tabulated per category and topic, and for each category and topic, all redundancies across a single country’s PRSCs were removed so that there would be no double counting of any category or topic per country. The results were then normalized with respect to the total number of countries that have PRSCs. This allowed for each country’s total number of PRSCs to be treated as a single document for a single operation in support of the corresponding PRSP.

Box 9. ICTs in poverty-reduction support credits (“Benin Poverty Reduction Support Credit”, 2004; “Burkina Faso Fourth Poverty Reduction Support Credit”, 2004; “Rwanda Poverty Reduction Support Credit and Grant”, 2004; “Senegal Poverty Reduction Support Credit”, 2004; “Uganda Third Poverty Reduction Support Credit”, 2004)

Benin: Government Accounting System. “Improvement of the reliability of government accounts is expected from the completion of full-fledge IFMIS [Integrated Financial Management Information System], in particular with: (i) the strengthening and comprehensiveness of the SIGFIP [integrated expenditure management system]; (ii) the installation of the computerized government accounting system (ASTER); and (iii) the development of a functional interface between SIGFIP and ASTER.”

Burkina Faso: Computerization of Customs. “...(iv) modernizing customs administration by strengthening customs offices 9 by the end of April 2004).”

Rwanda: Environmental management information system. “Enhance capacity of REMA to conduct environmental public awareness campaign. Design and installation of information and ICT systems in REMA. Training of staff to use, update and maintain these systems.”

Senegal: Computerization of the Courts. “49. The private sector operating in Senegal is demanding a better-functioning judicial system. This is also one of the Government’s major objectives, which will be supported by the World Bank Support Credit. Having developed a new sectorial strategy in collaboration with the community as a whole, the Government is now committed to allocating greater budgetary resources to this sector, to launching a human resource development program, and to proceeding with the computerization of courts in order to enhance the efficiency of Senegal’s judicial apparatus.”

Uganda: Integrated Financial Management System. “Completed a detailed study of the Government’s Fiscal Management Systems providing a detailed Information Technology Architecture and Plan, a common Chart of Accounts and User Requirements for an Integrated Financial Management System (IFMS); Contracted consultants to deliver and install an Integrated Financial Management System. The implementation is to be phased through selected Pilot Sites in the 2003/04 fiscal year with further rollout to selected sites commencing in the 2004/05 fiscal year; Established a financial management team of accounting professionals appointed to support the reforms to (a) strengthen the legal and regulatory framework for financial management; (b) enhance the capacity building activities amongst the accounting and auditing cadre in government; and (c) strengthen the budgeting and accounting systems in government (the IFMS); Twenty recent graduates were recruited to assist in the IFMS implementation; MOPS has authorized the recruitment of an additional 16 graduate accountants to strengthen the compliment of accounting staff. The recruitment has been completed and posting to the various ministries is being arranged; ...”

This approach may have skewed the PRSC results to some extent in favor of the countries with multiple PRSCs. Nevertheless, it does provide a means for the qualitative comparison of PRSCs with the corresponding CAS and PRSPs, as well as an overall comparison among all PRSP, CAS, and PRSC documents.

An overall comparison of the key categories of proposed ICT interventions in PRSCs and their corresponding treatment in CAS and PRSPs are presented in Figure 5. Since PRSCs provide the necessary funding for the implementation of any mutually agreed-upon proposed activities, it is reasonable to assume that the statements in these documents offer a more realistic picture

of the actual priorities of the governments and donors.

The results in Figure 5 indicate that with respect to telecom reform and the extension and expansion of communications infrastructure and services, the PRSPs (reflecting the countries’ priorities) and the PRSCs (reflecting the agreed-upon course of action and the corresponding financing by the donors for its implementation) treat these issues with a fairly high level of priority (47% and 45%, respectively). The CAS documents, however, show a much higher level of emphasis on telecom issues (84%). This may reflect the fact that CASs often emphasize the telecom reforms that are considered as important requirements to facilitate economic growth.

Figure 6. ICTs in PRSPs, CASs, and PRSCs of the 11 PRSC countries

Box 10. Uganda's Access to Government Information Law. ("Uganda Third Poverty Reduction Support Credit", 2004)

"48. Government plans to improve the right of access to public information, as one of the measures to improving accountability. First, we plan to revise the Official Secrets Acts, and replace it with a modern access to government information law. Consultations with stakeholders on access to government information have already started and in the next fiscal year, the plan is to assemble recommendations for enactment of the law."

The establishment of community radios and the use of radio, television, and the Internet as tools for awareness raising on development issues (e.g., in public-awareness campaigns on HIV/AIDS, community programs, etc.) is emphasized more strongly in PRSCs than the other documents.

The policy and strategy indicator used here reflects the cumulative references in the relevant documents to the national ICT policies, e-strategies, or specific policy discussions around the use of the new information and communication technologies for development.

It is worth noting that the discussion of ICT policy and e-strategies continues to decline from action planning (PRSPs) to financing envelopes

and programs (CASs) to implementation plans (PRSCs).

An interesting overall finding is that by far the strongest focus of the PRSCs is on the implementation of ICT-based solutions to improve public-sector management and public service delivery. This is significant because it demonstrates a strong consensus among donors and governments alike that ICTs do have a major role to play in improving the governments' fiscal management, accountability, and transparency. At the same time, this focus on ICTs is purely in the context of their use as appropriate tools to improve the efficiency of public-sector management activities only. There is very little emphasis on the significance of sharing

information with the general population through the use of appropriate technologies, or the impact of such applications on the broader objectives of poverty reduction and economic growth.

PRSC support for the introduction of new technologies in education is mostly focused on the introduction of education-management information systems, and in some cases on the introduction of new technologies in the higher education institutions. This does not necessarily imply that one of the broader objectives of PRSPs to mainstream ICTs in the education system is put on the back burner. Rather, it could mean that the sector reform activities and large-scale introduction of ICTs into the education system may require a different implementation support and funding mechanism such as a sector-focused project.

PRSCs also show a moderately strong trend toward increased support for small and medium enterprises; incubation programs; automation; new service-based, ICT-assisted businesses (e.g., call centers, etc.); and similar initiatives. This is encouraging since the trend could be further strengthened in the subsequent PRSCs. Compared to other priorities, the level of implementation support under PRSCs remains rather low.

The use of ICTs for rural development is an area that seems to need special attention. The indicators used in this category are for rural connectivity, the use of appropriate ICTs for rural development, agricultural information systems for farmers, and management information systems at various levels. Overall, this is the least discussed category in the reviewed documents with respect to the role of ICTs as enablers of development. Certainly, the endemic lack of reliable infrastructure and human resources, particularly in rural areas, may partly explain why this is not a priority area. However, successful examples of these types of initiatives could inform future policy discussions.

Another significant finding is that 45% of the PRSCs give high priority to the use of ICTs for poverty monitoring in the form of statistical capacity building, specific poverty indicator moni-

toring across sectors, environmental monitoring, and similar systems. This is a much stronger emphasis compared to CAS documents (12%) and PRSPs (37%), and indicates a growing shift toward focusing on results. References to local content development and information dissemination appear in four PRSCs.

Figure 6 provides an overview of the ICT discussions in the same set of documents for the 11 sub-Saharan countries that by mid-2005 had poverty-reduction support credits. The Figure shows that the salient features of the above comparison among the ICT discussions in all the PRSP, CAS, and PRSC documents for sub-Saharan Africa are also broadly applicable to the subset of documents for the 11 PRSC countries. See, for example, the emphasis on telecom in CASs, and the public-sector-management and service-delivery emphasis in PRSPs and PRSCs. The other trends are also generally consistent with the above findings, with minor variations.

In comparing the overall results among countries, it is interesting to note that Benin, Mozambique, Rwanda, and Senegal (from the group of countries with one PRSC each) all have fairly extensive discussions on the significance of ICTs for poverty reduction and economic development in their PRSPs. However, their respective PRSCs are almost exclusively focused on computerized applications in public-sector management, tax, and customs, and a variety of monitoring or management information systems in different sectors. In other words, major aspects of the role of ICTs in development have been left out of these PRSCs, probably with the expectation that such activities could be funded through other sources. This finding also suggests that the development organizations and donor agencies who are interested in the mainstreaming of ICTs in other aspects of the economy and service delivery to the poor, or as a sector, need to devise or utilize appropriate funding mechanisms beyond PRSCs.

CHALLENGES AND OPPORTUNITIES

The poverty-reduction strategy documents and MDGs provide the framework for country assistance strategies and poverty-reduction support credits in sub-Saharan Africa. The preparation of ICT policies is often carried out based on methodologies that incorporate the framing of the ICT policy in the context of the country's development priorities, the PRSP, and the MDGs. As a result, there is an increasing emphasis on the role of ICTs for economic growth and poverty reduction in the ICT policy documents.

Nevertheless, there is a persistent disconnection between the poverty-reduction strategy-development efforts and the ICT policy-development process. While many PRSPs refer to the role of ICTs in development, they are generally not informed by the ICT policy documents (where they exist), or by the discussions and the partnerships formed around their preparation. Consequently, the ICT policy papers often have little (if any) impact on the ICT priorities set forth in the PRSPs, CASs, or PRSCs. This has led to a strong focus on ICTs as tools for improved efficiency in public-sector operations rather than service delivery to the poor.

Reviewing the national ICT policies, PRSPs, CASs, and PRSCs, six trends stand out among the results.

1. Telecom reform, competition, and the expansion of infrastructure are much more strongly emphasized in country assistance strategies compared to PRSPs and PRSCs. This partly reflects the direction of the ongoing policy dialogue, and the significance that the World Bank Group ascribes to the implementation of telecom reform and the introduction of competition in the sector for economic growth and poverty reduction. The above finding notwithstanding, it is important to note that these issues are all prominently present in PRSPs and PRSCs as well, indicating at least a high level of ongoing dialogue on these themes.
2. Public-sector-management information systems in general and integrated financial-management information systems in particular are much more strongly emphasized in PRSCs than in CAS or PRSP documents. This is indicative of the fact that when it comes to improved public-service delivery, fiscal accountability, and transparency, both governments and the World Bank and donor community agree on the importance of these systems, hence the high level of emphasis on the actual implementation of these systems, and the corresponding appropriation of funds in PRSCs for that purpose.
3. Applications of information and communication technologies for development, particularly in education, the private sector, and rural development, are given low to moderate prominence in these documents. Since the private sector is expected to make most of the investments in the ICT-sector development initiatives, the references in these policy documents to ICT-sector development do not mean much if the private sector does not have the right enabling environment (whether for business at large or for the ICT sector in particular) to play an active role.
4. With very few exceptions, the actual support proposed in PRSCs is mostly focused on the monitoring and/or dissemination of information only rather than on the production and dissemination of relevant content based on local knowledge and/or the adaptation of relevant global experience. These and other areas could potentially benefit from more focused attention in future policy discussions, development strategies, and implementation-support programs.
5. The consultations and discussions during the ICT policy preparations are useful for

awareness raising and sensitizing the policy makers and the public toward the potential of ICTs for development. However, there is a noticeable disconnection in most countries between the ICT policy-development process on the one hand, and the poverty-reduction strategy development and the corresponding poverty-reduction efforts on the other hand.

6. Although the national ICT policies and e-strategies articulate many of the potential benefits of ICTs for development and propose potential applications, these documents also appear to be driven by, and follow, the proposed frameworks of the development agencies, donor organizations, and their local partners that have funded the process. Therefore, some of the policies seem more like a wish list rather than a road map for the use of ICTs in the development process consistent with the realities on the ground. This may partially explain the limited influence of the national ICT policies on the actual poverty-reduction strategies and programs developed by most African countries.

These findings confirm that for ICTs to become effective tools for economic development and poverty reduction, they need to be fully mainstreamed in the national development programs. This is to ensure that the necessary policy decisions as well as the required resources could be put in place for the holistic integration of ICTs in development efforts. The role of the private sector in all aspects of ICT-sector development also needs further emphasis both in poverty-reduction efforts as well as in the use of ICTs for development.

Applications of ICTs in development efforts need to have a clear focus on the use of appropriate technologies for targeted interventions aimed at improving the well-being of the citizens. Such applications of ICTs must be driven by the underlying development objectives and not by technologies. ICTs could play an important role

in poverty reduction only if they are properly adapted to the existing circumstances and used as tools that can help facilitate the achievement of development objectives in specific settings.

Additional work is needed in analyzing the effectiveness of the ICT investments that have been made by the public and private sectors alike in sub-Saharan countries and the impact of these investments on the ground. It is also necessary to assess whether the discussion of various ICT initiatives such as rural connectivity and other ICT programs in PRSP or CAS documents have actually translated into higher public-sector investments in these areas.

The integration of ICTs in development strategies is a necessary, but not sufficient, condition for ICTs to play an important role in the socio-economic development of sub-Saharan countries. The current realities on the ground in terms of low levels of infrastructure, human resources, policy environment, local-language content, and competitiveness are among the major factors that will define the scope of success in the use of ICTs for development in Africa. Therefore, the development of the appropriate ICT infrastructure, human resources, private enterprises, and institutional capacity to respond to these needs must become an integral part of the broader development strategies. In this context, many challenges as well as opportunities lay ahead for sub-Saharan Africa, requiring multifaceted and coordinated efforts to deal with them effectively.

NOTE

The findings, interpretations, and conclusions expressed in this chapter are entirely those of the author and do not necessarily represent the views of the World Bank Group, its executive directors, or the countries they represent, and should not be attributed to them.

Chapter 5.24

Poverty Reduction through Community–Compatible ICTs: Examples from Botswana and other African Countries

Rebecca Lekoko

University of Botswana, Botswana

Bantu Morolong

University of Botswana, Botswana

ABSTRACT

ICTs are an integral part of both scientific and lay cultures. However, scientific know-how, whose significant features are high expertise and highly trained personnel, is dominant while traditional cultures are gradually receding. The use of ICTs shows great potential for creating access boundaries between the rich and poor. Out of this awareness, this chapter invites readers to rethink basic questions: What are ICTs? What have been their benefits for the rich and poor? While these questions cannot be answered in detail here, few important points are presented emphasizing that ICTs do not function in a societal vacuum. The type of access to ICTs that the poor need is not

that which only enables them to be like others in using ICTs. They, much more than other sectors of society, have an increasing need to effectively manage their lives, and community-compatible ICTs can be employed for this purpose.

BACKGROUND

The key operational concepts in this chapter are poverty, information communication technologies, and community-compatible ICTs. Even though these are concepts in common usage in the various disciplines, for the purposes of elucidation, they are briefly defined in the discussion that follows. For each of the concepts, the

definition is expanded to highlight some of the fundamental issues that are relevant to the theme of this chapter.

Definitions and Fundamentals of Poverty and Information Communication Technologies

Poverty

Clearly, many definitions of the word poverty reflect the economic impact of being poor. In Botswana, for example, poverty is seen as a “consequence of a narrow economic base, which limits opportunities for gainful employment” (Republic of Botswana, 2004, p.17). To illustrate, in 1993, an estimated 47% of the population lived below the poverty datum line of approximately P100.00 (\$20) per person per month. Poverty here is simply viewed as a state in which a family’s income is too low to be able to buy the quantities of food, shelter, and clothing that are deemed necessary (<http://www.econ100.com/eu5e/open/glossary.html>). Perhaps it is this narrowness of focus that has led Botswana to develop a poverty line (PL) that considers only six categories of items as constituting the basic needs of a family in Botswana, namely, (a) food, (b) clothing, (c) personal items, (d) household goods, (e) shelter, and (f) miscellaneous (Central Statistic Office [CSO], 1991). Such an analysis may mislead because it oversimplifies the complex nature of being poor. It portrays a picture of poverty being measured in monetary and material possessions. Unfortunately, this type of understanding perpetuates a pervasive attitude of looking at the poor as the helpless and hopeless, hence giving those in power unprecedented capacity to determine how the poor should live their lives.

It is observed here that “most countries of the Sub-Saharan Africa are predominantly rural in character: roughly 70 percentage of the population live in the rural areas” (Bryceson, 1995, p.

8). It is in these rural areas where most of the poor people reside. According to the *Botswana Millennium Development Status Report 2004*, the “rates of poverty are higher in rural areas, mainly because of fewer opportunities for formal sector employment” (Republic of Botswana, 2004, p. 21). In these rural areas, the means of survival are relatively nonmonetized and predominantly agricultural. Agricultural production using a plough or hoe and livestock keeping are at a subsistence level. It can fairly be said that “animal and plants constitute human food and their importance is obviously great” in everyone’s life (Mbiti, 1988, p. 50); it is thus important to have them among the indicators of poverty, especially in Africa. It seems not right, therefore, to measure poverty solely in terms of money (mostly earned through employment in the formal sector).

A more complex picture may appear if we think and expand the definition of poverty to include poverty in the noneconomic sense, as is the case in this chapter. For purely analytical purposes, poverty in this chapter is understood as a state of lacking and/or being deprived of the essentials of life such as material and monetary possessions, employment, health services, education, and access to required social services and status, such as being responsible citizens who would participate meaningfully in their own development as well as the overall development of their country. It thus covers among others the lack of nontangible aspects of people’s lives such as power, exposure to different forms of violations, lack of access to information, as well as low levels of equality among social groups. These inequalities are mainly based on gender, class, and ethnicity. It should, however, be noted that poverty remains a very elusive concept. For example, in an attempt to accommodate the issue of the degree of poverty, there is always a desire to distinguish between poverty, absolute poverty, and relative poverty.

Generally, poverty is most noticeable in material deprivation and the psychological stigma

attached to being poor (Heeks, 1999). Wells (2000) contends that prolonged conditions of absolute poverty are associated with low levels of self-esteem, resulting in identity crisis. In some situations, the poor are described as “no-good”, “incompetent” and “stupid” such that they should expect failure of themselves just as the world expects it from them (Heeks, 1999). In simple terms, poverty is seen as being impoverished or underprivileged. Generally, “to be impoverished is to lack or be denied adequate resources to participate meaningfully in society” (<http://www.hsph.harvard.edu/thegeocodingproject/webpage/monograph/glossary.htm>). A bias in this chapter is toward analyzing and looking at poverty as it leads to exclusion in the economic, social, and political spheres of people’s lives, causing conditions of unemployment, and inadequate health and other social services.

Those critical of the definitions as given in the preceding discussion contend that these definitions have misled national leaders to aim at compensating for these deficiencies by setting up welfare systems. The welfare approach includes food handouts, nutrition, counseling, and family planning that merely aim at contributing to immediate relief of a needy situation. Such services continuously relegate the poor to a position of passive recipients of development projects. Whatever else is said and done for the poor opens the doors widely for a sympathetic attitude (Mtshali, 2000). People who are victims of this pity regard governments as power forces that have to change their situations. It is this status of the poor that the current development initiatives are aimed at addressing. This chapter reviews what the role of ICTs can be at the community level. Within the broad thematic area of ICTs and poverty alleviation, the concept of poverty is used here very broadly to refer to a lack of gainful access to and control over resources, with specific emphasis on ICTs as a socioeconomic resource.

Information Communication Technologies

The adoption of the millennium development goals (MDGs) in 2000 has meant that countries started looking for effective means of fighting the poverty scourge. In their search, the national leaders seem convinced that ICTs can be used to counter the crisis of poverty, especially if they are linked to the complex economic, educational, political, and other challenges facing the poor (Gerster & Zimmerman, 2003). Information communication technologies are generally defined as communication devices or applications encompassing radio, television, cell phones, computer networks, and hardware, as well as the services and applications associated with these (<http://searchsmb.teentarget.com>). According to Adeya (2002), it also includes electronic networks and services that embody hardware applied through networks, and services for information accumulation and flow in the public and private spheres. This encompasses Internet services, telecommunication equipment, libraries and documentation centers, and network-based information services. Some have referred to these as the group of technologies that have revolutionized the handling of information. A marked distinguishing feature for these in the current era is their capacity to be available (Gerster & Zimmerman, 2003). Other characteristics of these include (a) interactivity, (b) global reach, (c) reduced costs (cost effectiveness), and (d) usability. According to Gerster and Zimmerman, ICTs also refer to some artifacts, techniques, or knowledge used to create, store, manage, and disseminate information. Heeks (1999) sees them as electronic means of capturing, processing, storing, and communicating information. In discussing sustainable ICTs, Batchelor and Norrish (2002) say that the relevance of ICTs in long-term development goals cannot be realized, achieved, or adequately conceived without considering the three capital assets, which are finances, and physical and social capital.

The approach taken in this chapter in defining ICTs is to consider them in relation to the critical needs for countries to develop. Take, for example, information. In any developing country, one of the prime ingredients of development is information. ICTs provide a platform for information sharing and storage toward sustainable development. Information societies are those societies that have well-developed ICTs to share information for development and innovation (<http://cbdd.wsu.edu/kewlcontent/cdoutput/TR501/page59.htm>). In Africa, for example, information is disseminated for various purposes: information about new agriculture or land development, community building, public health (e.g., HIV/AIDS), and education information campaigns (<http://cbdd.wsu.edu/kewlcontent/cdoutput/TR501/page59.htm>). Thus, ICTs in this chapter are those artifacts that make it possible for people to share information in order to create a sustainable information society. In Botswana, for example, Vision 2016 states that to build an open, transparent, and accountable nation by the year 2016, “Botswana must improve the access of all its people to information and new technologies that are sweeping the world; it must introduce a freedom of information act to protect the rights of citizens to obtain and use information” (Republic of Botswana, 1997, p. 12). In terms of relevance and usability, Botswana intends to “introduce universal and national radio and television stations to bring information to all parts of the country” (p. 12). The use of the local media, for example, the newspaper and other print materials, are to be encouraged. In sum, information sharing and dissemination is a critical principle in defining the potential use of ICTs for the poor people.

Education is yet another critical platform on which ICTs can be defined. The process of education is basically related to information dissemination and ICTs because information educates (or information is education), and ICTs disseminate education or information. Through communication via ICTs, the world is a global village where

people from one country learn about happenings in many other countries as soon as the news breaks (<http://cbdd.wsu.edu/kewlcontent/cdoutput/TR501/page59.htm>).

When a country like Botswana invests in education in order to build an educated and informed nation, it does so with the knowledge that ICTs are critical tools in making it achieve this goal. Worldwide, ICTs are used to share educational information among people and countries for development purposes (<http://cbdd.wsu.edu/kewlcontent/cdoutput/TR501/page59.htm>).

Investment in education is a dynamic investment as the educated are creative enough to use available technology. In other words, education must improve all aspects of people’s lives, including their ability to create, invest in, and use ICTs for their development. A long-term vision for Botswana, Vision 2016, for example, states that “products of our educational systems must be independent, productive, innovative with cutting edge skills” (Republic of Botswana, 1997, p. 11). In this era, when cutting-edge skills are mentioned, skills for the effective use of ICTs are part of them. Botswana works hard to ensure that it maximizes the potentials of ICTs in its dream for an educated, informed, and productive nation. The executive summary of the Botswana ICT policy paper *Maitlamo* states that the ICT policy complements and builds upon Vision 2016, saying that Botswana will be a globally competitive, knowledgeable, and informed society where lasting improvements in social, economic, and cultural development will be achieved through the effective use of ICTs. Annual ICT expenditure is estimated at one billion Pula, demonstrating significant domestic demand for ICT products and services. Pula is Botswana’s currency. Currently, P5 (five pula) is the equivalent of \$1. Realizing this demand, the policy stresses the urgency for increased domestic skills to ensure that young graduates have an ICT career path.

It is in this broad usage of ICTs as information-sharing and dissemination tools for national

development that the concept of ICTs is presented in this chapter. Both the current and more traditional forms of ICTs are considered important.

The Concept of Community-Compatible ICTs

Developments in the area of information communication technologies have gone very far. What is equally true, however, is that “those areas of the world with the greatest access to new technologies have been privileged in their power to represent, to interpret and to influence development in ICTs and their use” (Johnson-Odim, 2002, p. 7). Their influences extended from determining what can be called an ICT to rules, standards, and even controls about access and the pace of development in this area. It is against this background that the concept of community-compatible ICTs has gained currency. This concept is used in this chapter to denote ICTs that are accessible to those living in both rural and urban community settings. It also refers to ICTs that are relevant, usable, responsive to communities’ needs, and accommodative of their existing ways of doing things as well as their ways of understanding, viewing, and interpreting the world.

The debate on community-compatible ICTs coincides with the thinking about sustainable development, which puts emphasis on people-centered, environmentally friendly, and participatory approaches to development. The basic argument is that with appropriate ICTs, the poor people stand a better chance of benefiting from the contributions of ICTs to development and poverty alleviation. In its general meaning, sustainability implies the capacity of something to continue for a long time (Batchelor & Norrish, 2002), with continued benefits or returns to those using it, in this case, ICTs. However, there is a strong critique on failure in most of the development initiatives to use the locally available resources, knowledge, and ideas. The relevance of ICTs in development initiatives is that they play a major

role in the transmission of information. Notable here is that information dissemination is a culturally based practice. It is, therefore, of utmost importance that those in the business of ICTs’ design and use take into account the close interaction between the contexts within which ICTs are introduced and the ICTs themselves. For those in the communities who adapt and adopt ICTs, it is suggested that being prepared to draw on the existing, indigenous knowledge technologies is a necessary condition for achieving community-compatible ICTs practices. This is meant to say that concern about community-compatible ICTs is, in a nutshell, a call for an understanding that there is potential for complementarity between the local environment and ICTs’ influences from elsewhere. This potential does not seem to have been adequately tapped, leaving ICTs to be seen as a modern invention that the indigenous people fail to understand and apply.

The literature reviewed for this chapter does push forward the distinction between “modern” ICTs and those that are traditional and have existed much longer. Experiences from many contexts of the world confirm this view by pointing to the fact that what are often referred to as simple technologies have been in existence for a long time. These include traditional musical instruments through which messages were transmitted, and tools and implements of art and painting from which we have learned so much about those societies. Among these are the most recent technologies upon which the new technologies have been built. In the African context, the radio is a good example here in its use of the airwaves just like the messengers of the chiefs who used to go to the top of the hill to announce to the community an important message. Both the radio and the messenger of the chiefs rely on the airwaves to transmit the messages. Dei (1999), for example, holds that different bodies of knowledge continually influence each other to show the dynamics of all knowledge systems (p. 111). This is meant to imply in this chapter that it should be expected that

some modern ICTs would have been informed by traditional technologies. New and old technologies can do well together.

There is evidence from research that indicates that many of the existing ICTs have their basis in traditional technologies. The radio has been given as an example. Consider the transition from AM radio to the technologically superior FM radio. After World War II, it was clear to industry participants that FM represented the future of radio. However, in spite of the victory of FM, AM radio has not vanished, operating alongside FM (Mendelson, 2001). Thus, many new technologies have some elements of compatibility with the old ones. Since traditional designs were responsive to community needs and environmental factors, we assume that both new and old technologies could be useful tools in addressing community problems such as the reduction of rural poverty. Some of the issues that are often pivotal and controversial when discussing issues of ICTs for poverty reduction are highlighted particularly in the context of the developing world.

KEY ISSUES IN ICTS AND POVERTY REDUCTION

The issues that can be termed key in the discussion of ICTs, particularly community-compatible ICTs, are many and diverse. One of the determining factors for an issue to be regarded as key in the discussion of ICTs is the context within which it is applied. In other words, one issue might be key in the context of Southeast Asia, but not be so much of an issue in the context of Southern Africa. This is simply because the needs and aspirations of people in the two contexts may not be exactly the same. In this chapter, the few issues selected for discussion are those that present themselves as general across regions of the world. Particular focus is made on the African context using Botswana as a point of reference. Among the issues are the following:

- General access to and use of ICTs
- The dilemma of devaluing African indigenous ICTs
- The expert-led belief in the use of ICTs
- The myths about ICT use and literacy
- Bureaucratic and political dimensions

There is a very close connection between the concept of community-compatible ICTs and the issue of the digital divide, which refers to the disparity in ICT diffusion and use between industrialized and developing countries, or indeed between the rich and poor, men and women, and urban and rural areas within individual countries (Souter, 2004). This divide has in “ironic ways put certain classes of people in touch with one another around the world and totally marginalized others” (p. 10). These digital divides are a reflection of deeper social, economic, and political divides. They have been part of a technological revolution (Gerster & Zimmerman, 2003). Thus, when a new innovation is introduced, the best way to assess its worth is to ask this crucial question: This is a revolution to whose benefit? Failure to answer this question is tantamount to defeating the very same benefits that ICTs are to bring to their users. A lack of compatibility of ICTs with community contexts is noted here as one of the contributing factors to the use of ICTs for social exclusion. The idea that is being advanced here is that ICTs have been applied in different parts of the world without due consideration of the importance of compatibility. Evidently, there has been limited reflection on how much impact ICTs would have on poverty if they were made compatible with community interests.

One of the main indicators for a lack of consideration of the issues of compatibility is the continuing lack of local content in the current application of ICTs at the community level. By local content of ICTs, it is meant “locally owned and adapted knowledge of a community, where a community is defined by its location, culture, history, language, interests and needs” (Gerster

& Zimmerman, 2003). For example, we need to consider the current move by the Botswana government to employ locally responsive ICTs. Botswana open-source software (BOSS), for instance, would be used by the Ministry of Education to determine the type of material to include in developing fully local educational software. To this end, financial estimates have been made through recommendations from *Maitlamo* (Mmegi, 2005). The concept of community-compatible ICTs is, therefore, viewed in this paper as an innovative idea through which improvements can not only be made on the types of technologies produced, but can also be made in the strategies for the effective application of these technologies. The next part of this chapter explores the relevance of this issue in the use of ICTs for poverty reduction.

General Access to and Use of ICTs

One of the reasons why the poor cannot reap the benefits that accrue from the use of ICTs is the problem of their limited access to these technologies. Access to ICTs for development is crucial because it is about access to information. In Botswana, for example, the rural and the remote-area dwellers do not have access to electricity and some of the infrastructure that is needed to support the use of new technologies. According to the Republic of Botswana's ICT policy document (2004), 37% of the households countrywide use electricity for lighting. Data also show that this number further falls to only 8% in rural and remote settlements. For computer ownership and Internet usage, the Botswana ICT policy reports a very low-level usage of 3 to 5%. This ownership is expected to be concentrated more in urban than rural areas, indicating that members of the remote communities are marginalized by ICTs to mainstream development efforts. Infrastructural limitations or inadequacies compound the problem of ICT access for the poor, most of whom are rural based. Their situation of poverty makes most sophisticated ICTs such as the Internet unaf-

fordable, with only few sections such as the mines and financial-service institutions making better use of ICTs. Thus, the use of ICTs, particularly in these communities, is sporadic. Just recently, in December 2005, the government of Botswana found it necessary to experiment with one of the deprived regions of Botswana, the Chobe district, by setting up a satellite dish for a radio station and the use of telephones. The number of people who responded to this was alarming, and many expressed disappointment at the end of the experiment. This is a case that indicates that many people who stay in the rural areas (mostly the poor) are deprived of basic things such as means for sharing information. Schilderman (n.d.) asserts that information enables the poor to increase their assets. Thus, when the poor are shut out of the world of information, they are put out of actions. The findings of research funded by Department for International Development (DIFD) and the World Bank and carried out in Peru, Sri Lanka, and Zimbabwe revealed the need to make information available for development by the poor. One of the key findings was that the poor do not seek information unless it is for a purpose: to meet a specific need, such as a need for social services, land, employment, and so forth (Schilderman, n.d.). Thus, they will use technology that addresses their life challenges and other needs.

While new challenges inevitably connect the poor to modern ICTs, generally, access to these new innovations is a farce for these people. It is their economic poverty that makes them great targets for using ICTs as economic boosters. Because rural communities lack certain necessary skills, technical and otherwise, and because they are on average less formally educated than urban communities, they miss out on the empowerment that comes with having information (Sebusang & Masupe, n.d.). When the Botswana government advocates for an informed and educated nation, as stated in its long-term vision, Vision 2016, the rural and the poor people are left out if nothing

is done to ensure that they reap the benefits of the ICTs for development. As of now, the rural communities in a number of African countries, Botswana included, do not have access to essential ICTs for development. Most ironically, 80% of the world's population has no access to reliable telecommunications, and the bulk of these are the poor peoples of the world. One third has no access to electricity, while there are more Internet account holders in London than there are in the whole of Africa (Heeks, 1999).

As a result of their limited access to modern ICTs, the poor continue to have gaps in information. Notably, the use of these ICTs is private-sector led and does not always focus on the needs of the poor. Where governments play a lead role in ICT provision, there are recorded cases of their reluctance to provide information that can empower the poor. For example, Schilderman (n.d.) reports that in Zimbabwe and Sri Lanka, ICT-based information is withheld from those living in informal settlements. As governments and the private sector fail to facilitate access to information for the poor through the use of ICTs, the poor have no choice but to continue to depend on traditional social networks for information, which are at times limiting.

It has been noted, however, that governments the world over have at least taken to acknowledging the role of ICTs as they give poverty reduction top priority as a challenge needing immediate attention. In the context of the Southern African Development Community (SADC), commitment to the use of ICTs to address development challenges was summarized by the executive secretary of the SADC. In his opening address at the conference of the International Telecommunication Union Economic Commission for Africa held in Botswana in the year 2004, he said that the harmonization of policies, the establishment of proper legal frameworks, and the development of predictable regulatory regimes are key to attracting private-sector participation in the development and expansion of networks to increase

access to ICTs. In addition to ICT policy, he said that infrastructure development and e-export are sine qua non for SADC to be transformed into an information-based region. As part of this context, Botswana is likely to be involved and be in step with regional and international ICT initiatives. It has hosted meetings and other activities of great importance, such as the Workshop on ICT Indicators for Africa in 2004 as well as the World Information Technology Forum in 2005. Botswana also participated in the World Summit on the Information Society (WSIS) meetings, particularly the second phase held in Geneva, Switzerland, in 2005. It is on the basis of these conventions that the president of Botswana, Mr. Festus Mogae, in his state-of-the-nation address at the first meeting of the fifth session of the eighth parliament (November 10, 2003), informed the nation that the top development priority for Botswana is the elimination of poverty. The country's Vision 2016 reflects this focus and goes further to indicate that ICT use is one of the core strategies for the reduction of poverty.

However, one cannot help but sympathize with the efforts that have been made so far in poverty reduction because they seem to be doing very little, leaving us with the fear that poverty is here to haunt the present and future generations. The recent *Botswana Millennium Development Status Report* (Republic of Botswana, 2004, p. 21) states clearly that "[d]espite its macroeconomic success, Botswana has a serious problem of poverty compared to countries of similar economic stature." Policies and program support for poverty reduction are reported to be strong in Botswana. The country alleges that 'a comprehensive system of social safety nets provides adequate welfare cover for the indigent,' yet poverty still lingers on. The 2004 *Millennium Development Status Report* acknowledges that all measures to reduce poverty 'translate in slow progress.' Perhaps Botswana needs to look critically at the ways in which it approaches its poverty-reduction campaigns. It is a well-known fact that in Botswana, ICTs are not

maximized like in other developing countries. In general, the current practices with the use of ICTs in a number of African countries have done very little to dispel the more subtle and yet influential attitudes that make access to ICTs difficult or impossible for the poor people. One issue worthy of attention that is closely connected to access to ICTs by the poor is discussed below: the dilemma of the devaluation of the indigenous ICTs in the context of Africa.

The Dilemma of Devaluing African Indigenous ICTs

Several decades have passed since a negative attitude swept across many countries: the devaluing of traditional African practices. In Botswana, the erosion of a traditional support mechanism as the economy modernizes perpetuates the situation of the poor as it is now. For example, there used to exist:

the Mafisa system, through which the poor family could get a small number of livestock, usually cattle from a better off family for the purposes of milking, draught power and possible seed...it is now difficult for poor families to barter their labor for draught power because cash is the dominant medium of exchange. (Republic of Botswana, 2004, p. 23)

The attitude described here also applies to the use of indigenous and locally based knowledge systems including the use of technology.

It is commonly known worldwide that people learn from their ways of living and common practices. They come up with unique indigenous technologies adapted and defined by their culture, environment, and needs. For example, Africans continue to use indigenous knowledge and techniques for food preservation, iron smelting, and the application of local medicines to humans and animals to cure diseases endemic to the community (Semali, 1999). Among terms used to refer

to these is the concept of indigenous technical knowledge. According to the National Research Foundation of South Africa, this is the complex set of knowledge systems and technologies existing and developed around specific conditions of indigenous communities and peoples of a particular area.

The African nations also continue to use community knowledge produced from local history and information. For example, “knowledge about flora and fauna” are important literacy skills that are critical to people’s survival (Semali, 1999, p.305). As Castle (cited in Semali, 1999) argues, whether the child’s habit is dominated by mountain, plain, river, or tropical forest, he or she learns new ways to control the environment, and its dangers, use, and fertility. Technological development in the context of traditional practices means that new knowledge and innovations are continuously developed by the local people as powerful driving forces for their survival. Thus, the richness of the poor should not be defined in terms of material possession or high education, but by their “capacity to generate new knowledge and by their ability to apply such knowledge successfully” (Walshok, 1995, p. 7). The type of knowledge referred to here is the one that derives its “origin or meaning not from an individual but a collective epistemological understanding and rationalization of the community” (Semali, 1999, p. 307). This demonstrates the fact that indigenous knowledge for Africans, like for people in other regions of the world, is about what local people know and do, and what local communities have known and done for generations. In the context of Botswana, indigenous technical knowledge has been applied in agro-pastoral activities to sustain livelihoods in natural resource management and in rural development as we see it today. These include tools and equipment to transmit information, to convey messages through music, and to ferry people from one part of their communities to others. It also includes the whole embodiment of indigenous lifestyles and practices of knowledge

and information transmission and management as well as its preservation. Thus, to understand people as knowledge producers is of inestimable value. National leaders should acknowledge the fact that the poor themselves are capable of coming up with innovations to address their priority needs (Chambers, 1993). The creative breakthroughs coming from the poor people are a sign that indeed ICTs are being used by these people, and they can play a vital role in poverty reduction. It is not good to devalue local knowledge, but a combination of modern ICTs and traditional ones can make profound impact in the lives of the poor. In this way, the benefits of ICTs can be felt in all sectors of nations rather than in the urban areas only. Thorough research should be carried out to determine how traditional and modern ICTs can be used concurrently to speed up poverty-reduction activities. The question to address here is what the goal in using ICTs should be. Should it be to join the global flow through their use, or to use technologies that are relevant and responsive as poverty-reduction strategies?

As alluded to earlier, the inequalities relating to decisions about which types of ICTs to use, the accessibility of these technologies, and their overall ranking seem to have immensely contributed to the evident notion of expert-led ICTs. This expert-led notion influences the imbalances in terms of decisions about the use of ICTs. The leaders in these decision-making processes are the experts on ICTs. This concept of expert-led belief in the use of ICT is further explored in the following part of this chapter.

The Expert-Led Adoption and Use of ICTs

The use of ICTs is influenced to a greater extent by the ways in which the “educated” or experts think about these innovations. Walshok (1995), for example, contends that the effective use of technology depends on the three critical elements of “new discoveries, highly trained personnel,

and expert knowledge” (p. 8). This implies that before national leaders think of using ICTs as one of the national development strategies for poverty alleviation, they should question whether ICTs can function effectively in the absence of highly skilled individuals. Although the concept of a skill may imply the ability to generate information and use it for social and economic progress, the Western idea is that a skilled person is one who has undergone formal training, especially in academic institutions. This type of understanding has deep and pervasive implications for how the ICTs can be incorporated as tools for national development, especially for poverty alleviation. First and foremost, this type of thinking automatically disqualifies the poor’s capacity and initiatives in using ICTs. Educationally, the poor people are generally known for having limited or no formal or school-based education.

Where expert-driven ICTs are the norm, the poor are deprived of access to ICTs by some of the factors mentioned earlier, and thus they are reflected as people who cannot think for themselves under those conditions. They are considered unable to help themselves and therefore are in need of experts to assist them (Kroeker, 1995). This happens even between nation states where the economically advanced who are also ahead in terms of highly skilled person power control decisions about ICT use for the less-developed countries. Those who can afford to buy high-priced ICTs are also in a good position to determine who these experts should be. They have the power to influence the types of ICTs for poor people without stopping to analyze the knowledge bases of the poor and to use these as springboards for ICT use in poverty reduction.

The current picture pertaining to the use of ICTs is that it has successfully created a kind of mandarin culture for the haves. With this, it is as if ICTs have not, in principle, always been available (Gerster & Zimmerman, 2003). What is different is the pace at which the modern ICTs advance and change, which is much faster than the

traditional systems. This culture of the privileged can be broken into and used to benefit the poor people, especially if indigenous technologies are recognized and used together with the modern technologies. This would be the concept of community-compatible ICTs as applied in this chapter. It is important that national leaders should have respect for the use of local knowledge, experiences, and interests (Bergdall, 1993; Dean, 1999) because it provides them with opportunities to learn from the local practices. If, for example, the poor people are helped to develop confidence and efficiency in using ICTs, such a move may reduce their dependency on the governments. High-priced and expert-driven technologies might not be the best for poverty reduction if they have no relevance to the needs of the community. Community-compatible ICTs are suggested here because the authors believe that the educational status of the poor should not be used to deprive them of the opportunities to use ICTs. The poor in this regard, like in many other development initiatives, have proved to be in a better position to decide on relevant technologies because they “know best their own needs” (<http://www.hc-sc.ca/hppb/wired/community.html>).

However, we cannot rule out the existence of a close relationship between literacy and use of ICTs. This suggests that changes have to be made in the educational systems of countries such as Botswana in order to lay foundations for the effective use of ICTs for poverty alleviation in communities. In the revised national education policy, Botswana realizes the need to acknowledge the benefits of ICT innovations in education. This follows recommendations as contained in the Botswana draft policy on ICTs. The recommendation being made is that ICTs be introduced to children at an early age and also be mainstreamed into the curriculum so that children can have the benefits of technologies throughout their entire lives (Mmegi, 2005). Also suggested in this context is an ICT-specific syllabus at all educational levels. Poor people need guided ac-

cess to ICTs. If well perceived and appropriately employed as priority tools in the development of communities, ICTs can play a significant role in ensuring good-quality lives of the rural poor. Also, government-sponsored breakthrough ICT courses for the poor can be developed to give them a broader understanding of ICTs, why we use ICTs, and how modern ICTs can be used for their own development. ICTs-based expanded community participation in policy analysis and the discourse of human development and poverty reduction needs special attention, too.

The Myths about ICT Use and Literacy

The relevance of literacy and numeracy in modern ICT use cannot be denied. The concept of literacy as applied here covers the idea of information literacy, which is sometimes interpreted as a type of literacy that is also a critical one in the 21st century. This type of literacy is associated with information practices. It is an ideal type of literacy in the context of rapid technological changes. This idea of literacy is associated with information practices. It denotes the capacity of those receiving information to use it for their development. This raises the issue that if information cannot be managed and used, then it is not beneficial. It is in this regard that this chapter holds a view that “learning the mechanism of reading and writing is the touchstone that could liberate the poor and uneducated people everywhere from the bonds of ignorance, disease and hunger” (Coombs, 1985, p. 265). For example, in Botswana, literacy has been identified as a “prerequisite if Botswana’s other developmental objectives are to be met” (Maruatona, 1998, p. 11). This step has been taken after it was observed that illiteracy stood to hamper any effective national development efforts. Thus, within the context of ICTs, literacy is functional to the extent that people can develop mechanisms to use ICTs in coping with challenges and opportunities in their local environments. This

type of literacy is required to transform today's information society into tomorrow's learning society (Bruce, 1999) since it provides learning opportunities that enable people to effectively take advantage of the ICTs.

Even though it is an established fact that there is a direct link between adult literacy and socio-economic development, there is also evidence to suggest that the ability to use ICTs does not require high education, but functional literacy. Take the cell phone, for example; basic numeracy and literacy skills enable one to use this piece of technology. There are many instances when people with the basic literacy skills (low or no formal education at all) use this device in their own successful way. The same thing applies to the ability to operate a telephone or a radio. The most amazing thing is to see illiterate people being able to watch TV. These could be illiterate children or even adults in Botswana who to a very reasonable extent can understand the language being used or relate to the pictures they are watching. The overt social benefits of employing these technologies need not be underestimated. They include an elevated social status just from owning the technology. This presumably goes with a sense of being empowered and better able to take up the challenges of development in one's own terms. This view marries well with one of the critical issues being raised in this chapter, which is the fact that illiteracy should not be used to keep the poor from using ICTs.

Bureaucratic and Political Dimensions of ICT Use

In many African countries, the rural poor are unable to take control of their lives because of the structural, economical, political, and cultural conditions that oppress them. Such oppression is articulated through centralized bureaucratic structures that make participation by the locals in decision making very difficult to implement. In the absence of participation in its ideal form, and

also as a key principle in classical thinking about democracy, the communities are represented by the bureaucrats. In this process, the services that are delivered to them are not always in line with their real needs as target groups. For scientific and technological advances, Brynard (1996) opines that these top-down approaches have contributed to the creation of new problems instead of solving existing ones, especially because of the top-down thrust of the use of these technologies. The same is true for ICT adoption processes, which have a top-down thrust that many governments use to address issues of poverty alleviation.

Instead, these welfare approaches do very little to alleviate poverty. A significant feature of this approach is that it makes it difficult for poor people to take responsibility for their lives. The Botswana government acknowledges that welfarism translates into slow progress in poverty reduction (Republic of Botswana, 2004). A study (Lekoko, 2002) also supports the government's contention. In this case, it was the participants of the study, the community-based extension workers, who alluded to the ineffectiveness of the welfare approach. They refer to it as a "spoon-feeding" approach. A significant feature of this approach is that it makes it difficult for poor people to take responsibility for their lives; it encourages dependency. There clearly needs to be some initiatives that challenge the needy people to realize that they have power to change their circumstances. This applies most strongly to the use of ICTs in which communities usually play the roles of passive recipients as governments spearhead all the pilots and more long-term programs, starting with ICT policies. Thus, when ICTs are considered economic resources, a more participatory framework should be worked out. One challenge for national leaders in the developing world is to look closely at the use of technologies in the context of the local economic and social relations and determine how these processes could be made inclusive, despite the unresolved issue of how and when ICT use could be made beneficial to all in an equitable

way. Even though there is much debate about how and when ICTs can work, a timely and relevant use can be beneficial. It is important for national leaders to assess how modern ICTs can be adapted to local innovations and new challenges of the local communities.

Within the top-down approaches, bureaucratic interests often can distort the government's choice of technologies. In many instances, the governments, whose key players are the bureaucrats and politicians, assume themselves to be the sole producers of information and knowledge that is vital for development or poverty reduction. As a result of this, they play the roles of a middle person between the poor and those providing the technologies. The governments usually provide the technology on the basis of free grants or subsidies unrelated to the poor's real needs. An example that readily comes to mind is the use of technologies such as radios, which were provided by the government of Botswana in the 1970s to help in agricultural initiatives and in the tribal land grazing policy initiative as a process of social and economic transformation. Because the poor were not as convinced as the government that such technologies would work, some of the program experiences confirmed the view that inadequate participation by recipients of technologies may lead to poor adoption. Radios were used for other purposes other than the program, thereby distorting the economic value of the technologies.

In general, bureaucratic entities are biased toward large-scale, modern, expensive, and usually imported technologies. In the context of countries of the developing world, governments have limited budgetary power to supply the technologies to the poor. Community-compatible ICTs can, therefore, be viable alternative tools to address this problem. This is not meant to suggest that the communities should not have access to the sophisticated technologies that come in as part of development. However, it is a call for a certain degree of realism about what the key principles of sustainable development embrace. While the

central thesis of community-compatible ICTs is being advanced here, we also acknowledge the fact that discrepancies can exist between what the governments think about ICTs and their potential role in poverty reduction and what the local people may think. Where the poor do not appear as convinced as national leaders that certain ICTs can play a vital role in their development, such ICTs should not be imposed on them. The locals need to be convinced of their worth, be listened to on their concerns about these technologies, and be adequately involved in the reformulation of what could work in their context. Furthermore, they should have their capacities tapped and properly aligned with what is required for these technologies to make a positive impact, while at the same time attempts should be made to help people understand the technologies and to make them affordable.

CURRENT POVERTY-REDUCTION STRATEGIES

Countries worldwide are committed to joining the fight against poverty. This is evidenced by their leaders being signatories to the MDGs, which among other things commit countries to reducing by half the number of people living in extreme poverty by the year 2015: that is, reducing the proportion of people living on less than \$1 a day (http://www.unmillenniumproject.org/reports/goals_targets.htm). In all, 189 United Nations member states pledged to meet this goal. This was a sign that indeed national leaders worldwide are committed to reducing poverty in their respective countries. The president of Botswana, for example, referred to poverty as the greatest threat of all to our future welfare (Republic of Botswana, 2004). He bemoans societies that are divided between extremes of wealth and poverty. The statistics indicate that about 27% of the sub-Saharan African population lives in poverty. Some other regions, for example, South Asia (47%), record a higher

proportion (http://www.marxist.com/Globalisation/growing_world_poverty.html). Pockets of abject poverty are also in existence in developed nations. Central and Eastern Europe, for instance, record 2% of people living on less than \$1 a day (http://www.marxist.com/Globalisation/growing_world_poverty.html). The situation of poverty is, no doubt, a key challenge for all nations.

In recent years, some African leaders have realized the fallacy of using the welfare approach to fight poverty. For these countries, poverty-reduction strategies that are now devised go beyond compensation and distribution of schemes for the poor. National leaders are aware that there is a need to instill in the poor the spirit of self-worth so that they become aware of taking care of their own situation. The fundamental tenets of the poverty-reduction strategy for Botswana (perhaps not the best but the most accessible to authors) are given below to illustrate the nature and content of such strategies that are said to aim at aggressively fighting poverty.

To deal critically and creatively with the problem of poverty, strategies for the reduction of poverty have to be conceived in terms of the poor's social well-being, as well as the economic and political dimensions. The legal aspect should be an issue of concern. Africa is caught up in situa-

tions in which resources are scarce, unemployment is rising, high levels of illiteracy are difficult to break through, and infirmity is increasing. These situations make Africa a great target for foreign aid. The present situation is that many African countries receive economic and technical aid from rich and/or developed countries, and "this aid is not given free, for there is no aid without bait" (Mbiti, 1988, p. 223). Some African countries thus fall victim to the dos and don'ts of some foreign countries. The consequences of this should not be overlooked. Offering some aid should not mean that the providers should undermine African potentialities to develop their own knowledge of addressing their plight.

THE ROLE OF ICTS IN POVERTY REDUCTION

The adoption of the MDGs in 2000 has meant that countries started looking for effective means of fighting the poverty scourge. The national leaders seem convinced that ICTs can be used to counter the crisis of poverty, especially if they are linked to the complex economic, educational, political, and other challenges facing the poor. Those who see ICTs as catalysts in poverty reduction make a

Table 1. Strategies for poverty reduction in Botswana (Source: Republic of Botswana, 2004).

The Instrument	Year	Objectives
National Poverty-Reduction Strategy	2003	<ul style="list-style-type: none"> • To link and harmonize antipoverty initiatives • To provide opportunities for people to have sustainable livelihoods through the expansion of employment opportunities and improved access to social investment • To monitor progress (regularly) against poverty
Revised National Policy for Rural Development	2002	<ul style="list-style-type: none"> • To reduce rural poverty • To promote sustainable livelihoods • To stimulate rural employment and income generation • To diversify the rural economy and reduce dependency on the government • To maintain and improve rural capital, increase agricultural productivity, and promote participation in development

connection between the absence of ICTs and the high levels of poverty in some parts of the world such as Africa, which is recorded as having less than 0.6% of Internet users (<http://www.icconnect-online.org>). The discussion on the role of ICTs in poverty reduction is entered into bearing in mind an observation made by Heeks (1999): Like any generic technology, ICTs lend themselves to sweeping statements about what they can do for development.

Programs have been put in place in different countries of the world to show that indeed ICTs can make a positive contribution to the reduction of poverty and the achievement of a better quality of life for the poorest and marginalized groups. Evidence for this in the African context can be drawn from a study that was undertaken covering three countries—Mali, Uganda, and Tanzania—conducted in 2003 under the Building Digital Opportunities Program. This study has demonstrated that ICTs can be important tools for achieving improvements in people's lives in the context of MDGs (iConnect.offline, 2003). In reporting this discovery, a strongly held point of view is that for ICTs to be effective in playing a pivotal role in poverty reduction, they should not be "set apart as a minor part of any development activity" (p. 2); instead, they have to be an integral part of the development process. From this study, the areas seen to have potential for increased benefits from ICT use were health, livelihood, and governance, with a special focus on HIV/AIDS.

In the broad area of improved livelihoods through ICTs, there is evidence to suggest that the overall empowerment of communities is achieved as they engage in agricultural processes using ICTs. Communities are empowered through capacity-building programs with emphasis on face-to-face contacts. An empowered community through access to information is better able to overcome most of the impediments to participation. This has to be noted here, bearing in mind the fact that participation is central

to good governance. Worth noting, too, is the interrelatedness between all the areas in which ICTs have a potential to contribute to poverty reduction as mentioned above. ICTs are reported to have given communities a voice in development and poverty-reduction debates. This has to a great extent made it possible for their ideas to be better integrated in development initiatives. It is on record also that being able to participate contributes first and foremost to the betterment of self in all the domains of human development. Even in the debate on sustainable development, people's participation is acclaimed as one of the cornerstones for achieving this ideal.

There are those who hold a view that ICTs per se do not contribute to poverty reduction. They should be valued in as far as their capacity to support civil society is concerned. Rykert (1999, p. 184) says, "Technology in and for itself, will not solve problems. Ethical choices challenge us at every turn as we work for the goals of civic society. Local knowledge has much to contribute to when, why and how ICTs can be applied."

The lesson learned from Rykert's (1999) contention is that technology should be applied for its potential to solve social problems. In his view, there are unanswered moral questions relating to effective ICT applications. Effective application, it is argued here, would be evidenced through combining old methods with new ones, sharing wisdoms, and learning from each other. It is the collective capacity, in the words of Rykert, that truly has impact.

Another factor that is likely to contribute to modern ICTs not making an impact on poverty reduction is the lack of the capacity by the poor to effectively apply ICTs to solve their poverty problems. Aside from knowledge and practical skills, it is argued by Heeks (1999) and others that even the trust and levels of confidence and security to use ICTs are lacking among the poor. This has been one of the major impediments for effective ICT use and for receipt of optimal benefits from the technologies by the poor. Incapacity here is used

in a very broad sense to include the poor people's lack of skills, trust, and ability to analyze risks and resources, and their lack of power to influence the direction of decisions. Those with this type of pessimism caution us as this chapter does about overoptimism toward ICTs as they are currently applied. In their view, the information that on the surface ICTs are said to effectively transmit... is a necessary resource for poverty alleviation but it is by no means a sufficient one.

The last impediment that this chapter will highlight relating to effective ICT use for poverty reduction is that of the capacity by the poor to manage the ICTs' generated information. No doubt, information generated by modern ICTs is immense in terms of volume and complexity, and therefore it is often also overwhelming not only for the poor but even for the most sophisticated users. It is most of the time context biased and not very organized, hence the general view that it should sometimes be used with caution, while applying special skills to decipher it for positive impact.

There is a generally held view that the poor do not have adequate skills to effectively manage this information (Rykert, 1999) and therefore they have not been able to adequately exploit the potential it holds for poverty reduction. This state of affairs, we would like to argue, will be significantly accentuated (to the disadvantage of the poor) by the rapid pace at which modern ICTs develop, change, and are redeveloped to suit the ever-changing trends and demands and challenges of development. This presentation questions the view held by those who "seem to behave as if it were possible to pluck ideas relating to ICTs, the types, uses, etc out of cultural contexts and treat them as independent technical facts" (Sillitoe, 1998, p. 228). For example, imported ICTs bring with them cultural biases that contribute to their being well received or not being well received. Sillitoe goes on to say, "we need to establish that it is dangerous to do this and demonstrate the importance of understanding environmen-

tal interactions and development opportunities within their socio-cultural contexts" (p. 228). We posit here that this is not possible because cultural influences are pervasive in every aspect of development.

CONCLUDING IDEAS AND RECOMMENDATIONS

Not too long ago, ICTs were considered marginal to the achievement of national economic growth. But a decade or so later, ICTs are considered a central part of development processes at the individual, national, regional, and international levels. There is evidence to suggest, however, that in the contexts of the developing world, more knowledge is still needed about the most effective ways of developing conducive environments for modern ICT use in poverty reduction.

There is a view that modern ICT use in general has, like development, fallen into a trap of trickle-down approaches with all their known limitations. Therefore, the poor and other disadvantaged groups have still not received the desired benefits. There are even those who argue that ICTs have increased the gaps, particularly in knowledge and information between the haves and have-nots. The viewpoint expressed in this chapter is that if modern ICTs have benefited the rich, there is no reason. They cannot benefit the poor but on one condition: that they are made compatible with community needs and environments.

Duly recognized is the fact that developing and less-developed countries are still less well equipped to exploit the potentials of ICTs for reduction of their poverty. One of the contributing factors to the ineffective use of ICTs in poverty reduction has been identified as the inability by these countries to effectively balance policies, and the evidently expensive investment options for ICTs against other socioeconomic objectives, for example, the MDGs. Suggested in this regard are policy priorities that aim to reduce factors

that inhibit the effective use of ICTs for poverty reduction. Some of the inhibiting factors as have been discussed in this chapter are inaccessibility to ICTs, limited capacities by the local communities to use the ICTs, and attitudes about modern ICTs as new inventions that the locals fail to understand. These have resulted in a failure to integrate traditional ICT systems into the new ones, and also inability to see ICTs and their use as part of a complex system of national development. Evidently, the relationship between ICTs and poverty reduction is not as clear cut a relationship as it is often assumed to be. It is suggested that a good starting point for the effective employment of ICTs in poverty reduction is to develop a full understanding of this relationship through multi-disciplinary research. This type of research will demonstrate the interactions between economic, social, political, and legal aspects of poverty.

Another critical issue raised in this chapter is that to assume that ICT use is of critical benefit when in fact it has had a similar marginalization effect as other developments is an oversimplification of issues. It is still very hard at this point to go into any convincing discussion of positive impact when the true relationships among all the factors have not been adequately ascertained, for example, through research (not even in the developed world). It is concluded, therefore, that many of the assumptions that underpin current thinking about the role of ICTs in development, in general, and poverty reduction in particular is based on intuition. There is only limited evidence from a narrow range of pilot projects to support these, and not from large-scale impact assessments carried out on a macroeconomic scale. Some authors have also argued that the benefits of ICTs are not in the short term, nor can they be easily isolated from the benefits derived from other factors in a given context.

For the developing world, a big issue is that of the affordability of ICTs by its evidently weak economies. The complicating factor in

this regard is that most of the ICTs that are used in this context are imported. They are not only imported, but they are accessed most of the time through foreign assistance. This has made it imperative for this presentation to argue for sustainable applications of ICTs in poverty reduction. For us, it is all the more reason why we believe community-compatible ICTs would be a better alternative because they would reduce the susceptibility of the business of accessing ICTs to all the factors of nonlocal production such as import duties, international market fluctuations, other types of taxes, and regulatory frameworks in the world of trade.

This chapter is concluded by affirming that consensus is growing on the potential positive contribution of ICTs to mainstream development. It has also been used to highlight the fact that the role of ICTs in poverty reduction cannot be limited to improvements in the state of economic deprivation. This is confirmed by Gerster and Zimmerman (2003), who hold that beyond economic benefits, ICTs increase levels of interactions between peoples of the world and therefore they are increasingly becoming a basic need.

Chapter 5.25

Interactions among Thai Culture, ICT, and IT Ethics

Pattarasinee Bhattarakosol
Chulalongkorn University, Thailand

ABSTRACT

Information is important to humans because without information, no task can be performed. Therefore, information and communication technology (ICT) was invented and implemented to serve the needs of people. This facility has both positive and negative impacts on Thai society. However, it is generally the information technology ethics of the user that determines the direction of use of the technology. This chapter presents the relations among Thai culture, ICT, and IT ethics, in which all impacts are considered and described. The discussion in this chapter indicates that there are various factors related to development of IT ethics, but the one main factor is family background. Thus, in order to increase the IT ethics of users in an ICT world, the proposed solution in this chapter is to create a strong family and instruct children in their religion. Although this method is long-term, the outcome is worth the wait.

INTRODUCTION

Information and communication technology (ICT) is a technology whose main activity is to make information accessible to communities using computer networks. ICT has experienced rapid growth and has become part of the human lifestyle all over the world, including Thailand. Since information is very important to people in many ways, computer scientists are trying to invent techniques to improve information transfer methodology to the point where people around the world can obtain information easily and quickly without boundaries. Consequently, most daily activities rely on ICT-based machines that perform quickly and perfectly.

Although computer scientists constantly are developing new technologies for ICT use, the results of using these technologies are still in the hands of people who use them. It is true that everything has two sides, as does ICT. If ICT is

applied to rights, or legal activities, the outcome can be expected to be positive to society; otherwise, its results may be negative.

Considering the fact that people are components of society and every society has a unique culture, one finds that culture in each society is what binds its members together. One significant part of the human culture is ethics. Although people in different communities have different cultures, what remains rather constant in each culture is that there is an ethical system that protects human rights.

As mentioned previously, human activities rely on information, but how the information is used depends on the IT ethics of the user. Since people have many chances to receive various kinds of information, some information may motivate users to violate their IT ethics in order to gain the highest benefits for themselves without being concerned with the negative outcome of these activities.

Thai culture and ethics have influenced Thai living styles for centuries, long before ICT was implemented. People carry on with their lives in accordance with what they have been taught by their ancestors. After ICT was implemented, Thai people had access to knowledge and information that were different from what they had been taught; this information is useful for their businesses and/or their lives. Moreover, ICT allows people to work anywhere, anytime, and whenever they want. Thus, the lifestyle of some Thais has started to change according to the information and convenience they have obtained through ICT.

The consequence of the changing life style of the Thai people may alter the ethics that they inherited from the past. Since Thai culture typically shows a significant connection with nature and since most activities belonging to Thai culture are related to religion, there is a possibility that the IT ethics of Thai people at the present time are influenced both by Thai culture and ICT. One might show this in a mathematical formula. If LE represents the level of IT ethics of a person, ETC

is the effects of Thai culture, $EICT$ is the effects of using ICT, and e is a small effect from environment, then the model of Thai IT Ethics can be formulated as $E = R(ETC, EICT, e)$, where $R()$ represents relation, which can be either function or nonfunction among parameters.

This chapter will focus on the impact of ICT on the IT ethics of the Thai people and their culture. Additionally, a solution to improve Thai IT Ethics in the cyberworld is suggested.

BACKGROUND

According to the Webster's dictionary, the word *culture* means the act of developing intellectual and moral facilities, especially through education, and it also can mean the integrated pattern of human knowledge, belief, and behavior that depends upon a person's capacity to learn and transmit knowledge to succeeding generations. Therefore, if the behavior of people in a society changes, it definitely will change the culture of that society.

Moor (1985) defines the meaning of computer ethics as follows: "Computer ethics identifies and analyzes the impacts of information technology upon human values like health, wealth, opportunity, freedom, democracy, knowledge, privacy, security, self-fulfillment, and so on." Considering the current roles of ICT, one finds that it has been implemented in every corner of human life. Although the original aim of developing ICT was for information transfer among organizations, this technology has been developed to support mankind in every activity everywhere. For example, people can communicate anywhere because of the development of mobile technology; people can exchange information because of the existing Internet. The ability to transfer and exchange information has enabled business units to improve their strength and increase their competitiveness.

Although ICT has been implemented all over the world, most people on the Internet expect that

other users will use the Internet under the same rules of ethics. Unfortunately, the consequences of using ICT are in the hands of the user. Thus, ICT usage can be classified both legal and illegal, depending on the objectives of the user. However, Mowshowitz (1978) said that the ethical judgment in using computers was based on the impacts through the organization. Additionally, searching for appropriate methods for ethical judgment and control in an organization must deal with the reality of the power of professionals.

In order to create a clear understanding of computer ethics, professional codes of ethics have been defined by various organizations. For example, a well-known code of ethics is the standard Ten Commandments based on Barquin (1992), which was announced by the Computer Ethics Institute. In 1998, the Association for Computing Machinery (ACM) also announced the ACM Code of Ethics and Professional Conduct, whose content is quite similar to the Ten Commandments by Barquin (1992). Moreover, another worldwide organization, the Institute of Electrical and Electronics Engineering (IEEE), announced the IEEE Code of Ethics for all engineers to follow, establishing a standard for ethical judgment.

Since information easily flows to all users, some users use it to commit crimes, while others use it for creating a good society. However, some users may use ICT without knowing that their actions are against the IT ethics rules, such as sending a tracking agent into other persons' computers or posting fake data on the Internet to cause confusion for others, and so forth. Therefore, in order to prevent unintentional crime, Solomon (1993) and Cappel and Windsor (1998) suggested that people should be provided knowledge about ethics in their professional training. However, the study of Cappel and Windsor (1998) has shown that ethical decision making is still dependent on professional experiences.

Since immoral uses of ICT have increased, the attitudes of people toward others have been altered. In the old days, people could live together

without guards or fences. Currently, we are living in an environment surrounded by high security systems, even though we are using the Internet at home. This indicates that people do not trust each other as in the old days.

Considering Thai culture in which people live with caring, sharing, and trust, we can see that the strength of community is bound up intimately with culture. Some influences upon Thai culture are from religion. According to their religion, people were taught to believe that causing harm to others is a sin, and consequently, they will go to hell after they die. However, has this culture been maintained, or has it been changed by the ICT world?

Since a part of Thai culture was established through the community's religion, and since the purpose of each religion is to teach people to be a good person for the society, rules in Thai culture are then consistent with the codes of ethics in IT. Thus, "What can Thai culture do for IT ethics?" is the next question that will be answered in this chapter. Nevertheless, if people use IT without ethics, serious damage will arise and will be hard to fix. Therefore, the next question to be answered is, "What would happen to ICT if there were no IT ethics?"

This chapter begins with a short description of Thai culture. The following sections then will discuss the relationship between Thai culture and IT ethics as well as how Thai culture can influence the actions of Thai users, or vice versa. Problems of using ICT without IT ethics will be stated, ending with a conclusion on the impact of ICT upon Thai culture. The last section will show the entire picture of interactions among Thai culture, ICT usage, and IT ethics.

THAI SOCIETY AND CULTURE

Thai culture has been around for more than 1,000 years. Hongladarom (1992) and Mahidol University (2002) referred that Thai culture can be

regarded as a combination of two great cultural systems: Chinese and Indian. Since religion is a significant part of Thai life, there is a high impact of religion upon Thai culture. In other words, religion in Thailand is the best representative of the culture of the Thai people. Figure 1 presents the relationship among Thai culture, society, and religion.

As mentioned by Phillips (1965), the Thai community is usually composed of a group of individualities bonded by their religion with small emotional commitment. Furthermore, Komin, (1990) stated, “The Thai social system is first and foremost a hierarchically structured society where individualism and interpersonal relationship are of utmost importance.”

Although Thai culture is based on religion, the Thai character is not the same as other countries that believe in the same doctrine. Komin (1990) concludes that Thai character is reflected in the nine value clusters as follows:

1. **Ego Orientation:** Thai people usually have the highest ego value of being independent and of self-esteem. The ego for the Thai is very important and is always a main factor in any decision making. Maintaining “face” in society is an automatic action of a Thai in any situation.
2. **Grateful Relationship Orientation:** Thailand has been called the Land of Smiles. In

general, Thai people are friendly, sincere, and helpful, with deep reciprocal relationships. This grateful relationship value also is based on gratitude toward others. Thus, reciprocity of kindness, particularly the value of being grateful, is a highly valued characteristic trait in Thai society.

3. **Smooth Interpersonal Relationship Orientation:** The values of Thai society are different from Europeans, whose focus is usually on personal achievement. In Thailand, society is based on many different values, such as care and consideration, responsiveness to situations and opportunity, and politeness and humbleness. Currently, these characteristics help bind the economic gap of society in Thailand.
4. **Flexibility and Adjustment Orientation:** For a Thai, there is nothing to be serious about. Thai people hardly hold on to anything. This might be the influence of the Buddha’s statement that everything on Earth is impermanent, or empty. Additionally, the feeling of care and consideration also may be a reason to adjust oneself to the situation in order not to hurt others.
5. **Religio-Psychical Orientation:** Owing to the fact that more than 90% of the population in Thailand believes in Theravada Buddhism, it is obvious that Buddhism has a significant role in the Thai lifestyle.
6. **Education and Competence Orientation:** Thai society puts a high value on education. People who achieve a high level of education always obtain high respect from others. Education can be compared to a social ladder on which people climb to success and a firm social position.
7. **Interdependence Orientation:** In the rural area of Thailand, people in villages always help each other in any task, such as rice harvesting, wedding ceremonies, or the ordination day of anyone’s son in the village. Apart from Thai ego and smooth

Figure 1. Relationship among Thai culture, society and religion

interpersonal relationship, this characteristic helps Thai society to facilitate coexistence of various ethnic groups in Thailand.

8. **Fun-Pleasure Orientation:** This value relates to many other values already mentioned. The value of grateful relationship is the creation of pleasure for others. Additionally, the value of religio-psychical is the belief of emptiness and impermanence. Therefore, Thai people never take anything seriously like the Japanese. Thus, Thai people always smile, whether facing troubles or participating in parties. Smiling is a method to relieve negative pressure in one's mind. Moreover, this action can comfort the actor for another positive side of life.
9. **Achievement-Task Orientation:** A part of the Thai educational system is to push children for hard work. Teachers always eulogize students who are smart and highly responsible for their assignments. Moreover, teachers usually set up these students to be class leaders. Thus, this attitude is embedded in children's minds and reflected when these children grow up to be adults. Unfortunately, the fact is that the winner in society is the person who has good relationships with others, not a person who performs good work.

Besides these characteristics, there are some characteristics of Thai that have not been stated by Komin (1990), but they are stated by Soopatra Soupap (1975) in the article, "Thai Society and Culture." For example, Thais love gambling and risk taking, Thais never show disagreement and easily believe in things, they don't like others to be as good as themselves, and so forth. These characteristics lead to changes in Thai society when information and communication technology moves into their lives. Unfortunately, these changes also affect the level of IT ethics.

Soupap (1975) mentions that Thais like to do things easily. This appreciation stimulates some Thai people to create tools to support their tasks.

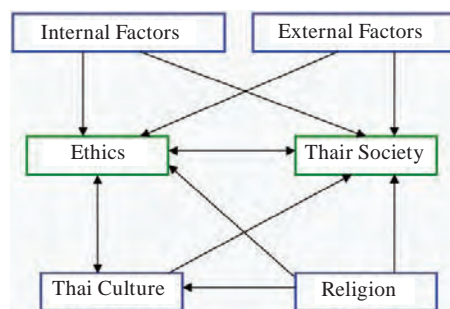

Thus, the need for making things easily can be counted as an internal factor for the change in Thai society. However, this change is a slow movement and, generally, does not turn over the normal lifestyle.

It is a fact that human life always changes, and external factors from different environments and different cultures can accelerate changes in society. Since Western people arrived in great numbers into Thailand, the rate of change has accelerated. Moreover, the direction of change also has been different from the past. At present, modern Thai society has been influenced by Western lifestyle in many areas, such as the education system, the economic system, commercialism, consumerism, arts, and entertainment.

Considering the model of Thai society, we find that the doctrine of every religion exerts a powerful influence on the behavior of the society. One worldwide acceptable behavior is ethics. This qualification of a human being usually is obtained from a strong belief in religious teachers. However, the ethics of a people also can be changed by both internal and external factors. Moreover, standards of ethics of the citizens can direct changes in society. A high standard of ethics leads to positive change; otherwise, the society will fall into trouble.

Referring to the details already mentioned, Thai society (*TS*) can be written as a model of

Figure 2. Relationships among Thai society, ethics (IT ethics), religion, culture, internal factors, and external factors

relations between ethics (E), religion (R), culture (C), internal factors ($IntF$), and external factors ($ExtF$); that is, $TS = R(E, R, C, IntF, ExtF)$. Since IT ethics is similar to general ethics in society, the model of Thai society in modern technology also is related to IT ethics and can be written as $=$, where E represents IT ethics.

Figure 2 represents the relationship among Thai society, ethics, religion, culture, internal factors, and external factors.

RELATIONSHIPS AMONG FACTORS

We learned from the previous section that there are links between IT ethics, Thai society, religion, culture, internal factors, and external factors. Since Thai society is a model of religion, Thai culture, internal factors, and external factors, the lines link between these parameters (boxes) have only one direction. Furthermore, there is a two-directional link between IT ethics and Thai society. This link means that when IT ethics of people change, the situation in the society, or the society, will change, or vice versa.

Due to the fact that IT ethics is highly related to religious belief and religious precepts that will never change, there is only one direction line link between IT ethics and religion. On the other hand, the edge between IT ethics and Thai culture is bidirectional, because when the culture changes, the level of ethics changes, and vice versa. The model of IT ethics is the reverse relation of Thai society, which can be represented as $E = R(TS, R, C, IntF, ExtF)$, where E is the level of IT ethics; TS represents Thai society; R and C represent religion and Thai culture, respectively; $IntF$ and $ExtF$ refer to internal and external factors. This relation is similar to the reverse relation of Thai society.

THE CHANGES

As society grows due to the increased activities of modern capitalism, every business also grows,

and human life becomes busier than normal. For example, shops have more customers to serve, schools have more students, and so forth. The daily lifestyle is not as easy as it used to be. Owing to the situation where a large amount of data must be computed in every organization in which manual calculation was the only method at the time, human error naturally occurred. Loss of benefits in the commercial world became a critical issue for business organizations. Frustrations in the working staff increased. Too much paper needed to be kept for reference, and so forth. Therefore, the computer system was invented to serve the fundamental needs of computation and data storing.

Some of the results of using a computer system in an organization are reduction in human error, increase in organization performance, and reduced space for paper storage. Additionally, the working staff is relieved of stress. Thus, the working environment is better. However, the data are still transferred manually.

Once the organization is well-organized by a computerized system, its service and productivity increase. Thus, an automatic data transferring system was another user requirement. Why is this so? Consider a system that has hundreds of documents to be distributed. If there is only one postal worker for this job, it would take many days to finish. A manual transferring system is not only slow, but it also may lose some documents along the way, or some receivers in the list may not receive the documents. These errors cause interruption in business processes and are not positive for the business organization.

As a means to reduce the errors mentioned, computer network technology was developed in order to link all computers together and to allow people on the network to transfer data freely. This system has a common name—information and communication technology (ICT). Thus, a revolution in data communication in society began.

At present, the modern Thai lifestyle relies on ICT to a large extent. Most of a Thai's daily life at work or at home depends on computers and

network facilities for information exchange and data communication. ICT provides facilities to its users until it seems like there is no boundary to its usage. Thus, ICT provides tools that were created by humans to support their tasks in the same way as other invented tools, except that the power of ICT is enormous and, hence, rather difficult to control.

Are all these changes the only changes in society? The answer is no. Another area of change that may not be obviously perceptible concerns human thought. In the early age, talks about works referred to functions to be performed but not to the question of who performed the functions. Now, talks about works do not consider functions to be processed, but people think first of the question, “Who will do the job? Then, functions to be performed will be assigned based on qualifications of the object that was assigned to perform those functions. This thought is the thought of objects.

This situation can be explained rather easily when we look at the development of computer language. Early programming languages, such as FORTRAN, COBOL, and PASCAL, are functional-oriented programming languages. The functional programming language supports the functional programming design; this means the design that concerns the functions to be performed by programs. Currently, functionally oriented technology is out-of-date, and organizations turn to use the object-oriented technology (OOT) instead.

The concept of OOT was based on things, which also can be called objects. The development process using OOT starts by defining objects in the developed system. These objects can be people, documents, equipments, and so forth. The second step is to define relationships among the objects, following the characteristics of each object, grouping objects under some constraints, and so forth. In the design process of OOT, the designers will start with the same process as the analysis process; that is, to define all necessary objects for the new system.

What does this change mean? The change from functionally oriented to object-oriented computer programming languages reflects the change of the human mind. But how? Usually, programming is a technique in which people pass on their thoughts into codes that force a computer to run jobs. The functionally oriented approach is not concerned with who will perform the tasks, while object-oriented programming does care about who must perform the tasks. Using a functionally oriented language, anyone can perform the tasks. This reflects a helping and sharing system. On the other hand, object-oriented languages reflect the different idea of independent and individual systems.

Thai society is an open one, and it has received ideas and influences from everyone with whom it comes into contact. Thai people love to follow others, especially now Europeans and Americans. Since one of the Thai characteristics is that they are people who love to do things easily (Soupap, 1975), using computers and ICT are, thus, favorite tools in modern Thai life. Many activities are performed by computers and ICT, such as e-banking, e-commerce, and e-learning.

According to the policy of the current Thai government, every task should be able to be transformed in the digital world, so all services will be fast and accurate with the right and completed documents in digital format (Bhattarakosol, 2003). Therefore, most government processes are transformed into the digital process under ICT facilities. This change makes Thai life more convenient; nonetheless, it is also a mirror reflecting that Thai society is also a busy society fully immersed in the cyberworld.

Once the digital system is applied in the Thai working environment, the concept of independent and individual system has been integrated into Thai society without awareness. Thai society is the same as other societies in the world. So, all businesses in Thailand, including government businesses, are expanding and changing their scales. Some Thais are struggling for survival in their work, having no time for their families.

A defect of working with computer applications is that every process must be in “right—authority,” “order,” and “rules.” Once a process is called without order or breaking a rule or without authority, then an error occurs. Thus, Thai staffs try to avoid these errors by not helping friends process their jobs.

Implementing ICT in Thai society, Thai citizens have chances to obtain knowledge from everywhere, anytime by themselves. Additionally, the chance to engage in discussions across countries is increasing. Thus, the Thai population has the opportunity to gain knowledge and experience different cultures via the Internet without having to attend classes.

In conclusion, Thai society has changed into a convenience society with a busy lifestyle. People are more independent, and, most importantly, family life has become looser.

IMPACT OF CHANGES—PROBLEMS

It is well known that human needs are unlimited; the desire of people is not limited only to necessary things, but they always want everything. These needs have pushed the development of ICT further and further with no end to serve these unending needs. Thus, ICT increases the power of mankind.

From the previous section, one can see that there have been many changes in society with ICT. These changes are as follows:

1. People are independent.
2. People are concerned with “object.”
3. People are smarter.
4. People have much freedom to exchange their thoughts through technology.
5. People’s lives depend on digital documents and equipments.
6. Human life is full of tools to support one’s work.
7. Family life is less important than work.

Consider the society model, $TS = R(E, R, C, IntF, ExtF)$, in which TS represents Thai society; E is the level of ethics; R and C represent religion and Thai culture, respectively; $IntF$ and $ExtF$ refer to internal and external factors. After ICT was implemented in Thai society, ICT become a new external factor in Thai society. Thus, the model of Thai society has been changed to be a convenience society with a busy lifestyle, independent, and most important, a looser family life.

Refer to the ethic model, $E = R(TS, R, C, IntF, ExtF)$, and Figure 2, in which E is the level of ethics, the relationships among parameters E , TS , and C are two-way relationships. Thus, when Thai society (TS) changes, the level of ethics (E) changes, and the culture (C) also is changed. Once these parameters are changed, problems may occur in the society. The impacts of changes are described next.

Impacts of Change in “Independence”

When society becomes a busy society, full of work and responsibilities, people have to concentrate on their lives more than others in order to survive. Although computers and ICT are fascinating tools for their work, there are some constraints of which users have to be aware.

Working with computers and ICT is not as simple as one might think. It requires “right,” “order,” and “rules.” “Right” means “authentication” and “authority.” A user cannot run applications without having the right to do so. Any computer applications usually authenticate their users before granting authority to run or use the program and data. Thus, each user must have the correct user name and password to log on to the system. These user names and passwords must be kept secret from other users, because whenever an error or any harm occurs in the system, the user name and password are used to identify the responsible person. For example, a student cannot use his or her login name and password to change

grades of the enrolled subjects, because students have no right to perform such a task. Therefore, the application will authenticate users before allowing them to enter any transactions.

“Order” means processes of applications that must be inputted in correct sequence; otherwise, the applications will not run properly or correctly. For example, users must enter the user name and password before pressing “Enter” to enter the system.

“Rules” are the constraints that are usually implemented under the requests of organizational managers. In order to perform some processes, some conditions must be validated and be true. For example, students cannot enroll in subjects without having taken prerequisites.

Looking back on Thai society, we find Thai people are always helpful to others. The normal situation in the past was that when a staff member (A) was sick, another staff member (B) would take care of A’s jobs. Unfortunately, according to “right,” “order,” and “rules,” people cannot help each other to perform the tasks because of fear of unexpected responsibility when errors occur. Therefore, when A gets sick, his or her job will be left for him or her until he or she returns. So, caring and sharing is wiped out from Thai society. This is an indicator that Thai culture has been changed in a negative way.

When computers are implemented and when most tasks are preformed by machines, quality management is applied to organizations in order to measure performance of working staff. Therefore, whenever evaluation indicates that the performance is lower than the expected investment cost, a reengineering and layoff process usually begins. Thus, people will do everything to maintain their positions; this includes corruption or being unfaithful to their responsibilities and their partners. Since ICT is an effective tool, performing fraud is easy, fast, and difficult to trace. Thus, using ICT to perform illegal tasks means that the ethics of IT users is decreasing.

Finally, the impacts of a change from dependence to independence can be concluded as negative in the change of culture and decreasing of ethics of IT users.

Impacts of Change in “Object Concerns”

According to the evaluation in the workplace, every task must be quantifiable in some way. This can be done, for example, by counting the number of papers to be printed or delivered, the number of hours to spend for a service, and so forth. These traditions create feelings of object concern more than mental concern.

The object concern strategy is the situation in which people focus only on the things or objects they need. The word *things* or *objects* refers to any tangible and intangible things, such as money, which is tangible; or sexual desire, which is intangible. The object concern is hardly aware of being right and wrong, but it focuses only on whether the demands were met properly or not.

The mental concern strategy is a situation in which people focus on the feelings of others, similar to Thai character in the past. The mental concern does not focus on objects or demands of a certain person, but it determines the right and wrong for the entire society. The defect of this strategy is that some requirements may not be served as needed, and the performance of the organization is lower than the expectation.

In the past, people usually worked with their hearts. Efficiency was measured by considering effort put on work, not the number of products. Therefore, forgiveness and understanding were the main mechanisms for organizational management. Unlike in the past, however, organizational management today is based on the number of benefits returned, which must be countable in some format, such as number of increased customers per year or number of girlfriends a man can have. Therefore, people are striving for objects to be counted.

Just like the previous issue, whenever people are concerned with objects or their needs more than with feelings of right and wrong, caring and sharing also decrease, because they are afraid of losing their objects to others, or they are afraid that their demands will not be met. Therefore, people may perform illegal actions in order to increase their objects or to serve their desires. An example of this is when the system of Orange prepaid mobile phones was hacked by a Thai teenager, who gained more than 100 million Baht (Thai Rath, 2005). Another case is that of a teenage girl who was raped by a man whom she had known only on the Internet (Kaosod, 2005). All of these actions indicate that IT ethics of people is missing, because they use ICT to serve their requirements without considering others or the law.

Impacts of Change in “Being Smart”

Every country wants its population to be smart, so an education system must be implemented in every corner of society. The Thai government also supports the implementation of an e-learning system to the entire country (Bhattarakosol, 2003). Information is distributed over the Internet, and people can access it via a modem at home or at the workplace. These channels support learning skills so that people can have much knowledge to perform their work without paying a fee.

One good thing about being smart is that people know how to serve their needs easily. However, this good point can be a big problem for society, because people might use their knowledge in the wrong way, to serve their desires. Thus, having good knowledge in technology is a double-edged sword that either can harm or support the society in which objectives are main factors for the outcome. The objective of using knowledge relies on the morality and ethics of a person. If a person is strong in ethics, the objective to apply the knowledge to society will be positive; on the other hand, it can cause negative results.

Impacts of Change in “Freedom to Exchange Their Thoughts”

The ability of ICT to expand the rate of distribution of information to the world means that various pieces of information are floating across societies. In the past, people usually stayed in their own communities and were taught the same model of life. Accepting different lifestyles is interesting and motivates change in society. These changes are both positive and negative. The positive changes are that people are able to find their roles or have an alternative lifestyle that supports their future and society. An example is the revolution in the Philippines in January 2001 caused by short message service (SMS), or text messaging. Citizens of the Philippines distributed SMS via mobile phones, allowing them to assemble and force President Joseph Marcelo Ejercito Estrada to resign and be arrested afterward (Ellis, 2001).

The facilities of ICT never have been limited. Thus, powerful ICT definitely increases human expectations. Therefore, the impact from ICT usage is very serious, as it could destroy an entire social or community system. Considering Thai culture, we find that Thai children usually are obedient to their parents. Thai society is a seniority society or hierarchical society in which older persons are given higher priority than the younger ones. Ethics and morality are taught to kids without question, and they usually believe what they have been taught. Once the new culture of freedom of mind spread into Thai society, children began bargaining with their parents. They acted against the normal culture and believed in equality without considering their responsibilities; they loved challenging their lives in abnormal ways. Therefore, teaching ethics to children is much more difficult because they will compare them to the actual world they see, and the question, “Why do we need ethics?” will always arise.

It is undeniable that the world is full of crime and that most of these crimes are uncontrollable,

especially digital crimes that are hardly detected and captured. These criminals can get away with their crimes, get rich, and be happy. This negative but true information is distributed throughout the Internet. Examples are used as models to be copied, because users on the Internet will feel that using ICT without ethics may bring about negative results to society, except to the person who used it. Once a person emulates the illegal process and gets away with it, others will follow the same path after knowing the technique.

In conclusion, if there is freedom for receiving information from the ICT world, a news filtering systems also should be used. Otherwise, the receivers can develop their behaviors in the opposite direction of the law. This indicates that the overload of information can cause a decrease in ethics.

Impacts of Change in “Digital and Equipments Dependencies”

According to the architecture of the ICT system, digital equipment is the most important part. Without this equipment, no communication can occur through the Internet. Since most information and functions of every organization are stored in digital systems called computers, the entire business functions rely on the completeness of the computers and their applications. Additionally, connections over the network also must be perfect; otherwise, the information transfer cannot be completed.

Considering the fact that a computer application is written by programmers and maintained by programmers and system administrators, the entire company actually is dependent on these groups. Since computers cannot work without coding, whether the program’s running codes are correct or incorrect depends on the correctness of codes. If programmers or system administrators are not faithful to their jobs, incorrect coding may exist and may cause critical loss for the company. Thus, the dependency of people on the

machine should be considered under the loyalty of persons.

Although there is no illegal function in the application, some fraudulent documents do exist. For example, a British man was captured by the Thai police because he created fake tickets for Scandinavian Airlines and sold them to tourists at half price (Matichon, 2005). These fake tickets were similar to the real tickets of Scandinavian Airlines, because he used the same technology to print them. Moreover, he used ICT to connect to the Scandinavian Airlines database and update the customer’s booking information.

So, the impacts of relying on digital documents and equipment may cause trouble in daily life when its functions are not performed correctly or when someone hacks into the system for his or her benefit. However, people remain in the digital world, while technicians are creating tools to protect all illegal processes. People cannot maintain trust or an easy mind, because they never know what will happen to their lives or their property.

What are the real effects of spending life in the digital world? As mentioned previously, people will be scared by the society around them because they will not be able to distinguish real or unreal documents, or they will not be able to trust the results from computer applications. Therefore, society is changed to an untrustworthy society.

Impacts of Change in “Tools”

In the modern world, organizations are computerized. Computers run applications to perform tasks for working staff. Since there are various kinds of demands, there are various applications invented for computers. The applications that people use to create their outputs and benefits are called *tools*.

Since computer technology is changing rapidly, various applications must be updated to suit the new invention and environment, such as the Microsoft operating system and its applications. These changes affect users because they need to

keep updating their knowledge in order to be able to run with the technological world. What will happen if the user's knowledge is obsolete? If the user's knowledge is out-of-date, it is possible that the user can be cheated by unfaithful technicians. Therefore, people must learn about tools and their technologies in order to protect themselves.

Consider the problems of computer viruses, which make it necessary to install virus detection systems on each machine. If the detection software is out-of-date, new viruses can attach themselves to the computer without protection, and serious damage can occur.

Generally, tools are good for users; they help users to perform tasks easily, accurately, and quickly with reliable results. Therefore, users count on these tools without worrying that someday the system may break down. Since applications perform all complicated tasks for the users such that they need not know how to solve it manually, when the system is down, officers may have problems. They cannot perform their jobs even with their knowledge.

Therefore, from the previous paragraphs, conclusions on the effects of using tools are: (1) people must update their IT system frequently; otherwise, they may not be able to perform some tasks; (2) without the knowledge of new technologies, people can be cheated easily; and (3) people do not know how to think or solve problems without tools.

How do these results affect society? It is quite obvious that a society of people with tools is lazy, as everything is dependent on tools; machine-dependent more than self-dependent or encouraging teamwork; and somehow extravagant in its spending money for new tools.

Impacts of Change in "Loose Family Life"

The last issue for impacts of change is about the situation of the family in modern society.

The family structure in Thailand or other Asian countries is that of close families; that is, family members (1) are close to each other, (2) respect elderly members, (3) are dependent, and (4) are considerate of others' feelings.

However, when ICT was implemented as a necessary tool, people became independent, self-centered, object-oriented, and careless. Therefore, most of the time, people spend time to serve their own needs more than sharing time with family members. Thus, relationships among family members are not as strong as the time without ICT.

In a new society in which technology leads the living styles, children in the big city usually are excessively self-confident; they receive too much information from the Internet, and their relationships with their parents are rather loose. Thus, these children have chances to make wrong choices for their lives. Additionally, these kids may not know what is right or wrong because (1) there is no one who teaches them at home, or (2) they believe in what they received from the real society or the Internet.

According to the previous paragraph, the level of ethics of children is decreasing because (1) children do not know the meaning of ethics, and (2) children do not see the importance of having ethics. When these children grow up to be adults, society will be full of adults with a low-level of ethics.

SOLUTIONS

When ICT is integrated into human life, many changes arise in society. These changes also affect the level of IT ethics of society members. It is hard to find the solution to solve problems of lack of IT ethics, because there are many causes of losing IT ethics.

Consider the model of the level of IT ethics, $E = R(TS, R, C, IntF, ExtF)$ in which E is the level of IT ethics; TS represents Thai society; R and C

represent religion and Thai culture, respectively; and *IntF* and *ExtF* refer to internal and external factors. To increase the level of IT ethics (*E*), parameters in the model must be changed in a positive direction. However, it is impossible to enforce every parameter to have a positive direction as needed. The obvious uncontrolled parameters are *IntF* and *ExtF*, which refer to internal and external factors. *IntF* is not able to be controlled because humans' needs usually are unbounded, while *ExtF* is obviously uncontrollable.

The remaining parameters are *TS* and *R* and *C*. Since *TS* is also dependent on *R* and *C*, the important factors are religion and Thai culture. According to the definition of Thai culture from Section 3, Thai culture is obtained or is a part of the religion of the people. Therefore, the only significant factor that can maintain a good level of IT ethics is to maintain the religion of the Thai citizen.

The belief of a child is a transferring process from the child's family. Thus, if society wants to maintain IT ethics in the ICT environment, the family in that society must be strong. The strength in the family maintains realizations of right and wrong of people. Children will trust and obey their parents or elderly members in the family. They will open their minds and learn about good and bad results from their guardians. Therefore, *IntF* and *ExtF* factors cannot lead these kids down on illegal path in the ICT environment.

Unfortunately, some children may not have parents and are brought up as orphans. Thus, they do not have a chance to learn from their parents about ethics or religion. Nevertheless, every child must go to school. Therefore, establishing a subject teaching about rules in religions is necessary in order to establish what is legal and illegal to kids. Once these kids grow up to be adults, society will consist of responsible adults, and society in the world of technology will develop in positive way.

WHAT WILL HAPPEN NEXT?

It is quite scary that the societies of the world are becoming societies of problems. Some examples from the statistical records of Fraud and Technology Crimes by 2002/03 British Crime Survey and 2003 Home Office Online Reports have classified technological crimes in various points, such as computer viruses, computer hacking, offensive messages and Web sites, and copyright theft. These crimes occur all over the world, and many techniques are invented to protect against those crimes.

The prevention methods can be classified in two categories: prevention by laws and prevention by technology. Prevention by laws is the announcement of codes of ethics from various institutes as well as statutes for property rights, e-commerce, and so forth. Applying codes of ethics and codified laws is one fundamental way to guide users in their actions. However, there is no social punishment. Unlike codes of ethics, laws are enacted by the government, and any breakers will be punished for their illegal actions. Unfortunately, in Thailand, these laws and codes still are not widely known, and many important laws concerning information technology ethics have yet to be drafted. In any case, the number of victims continues to increase.

The technological prevention method can be separated into two solutions. The first solution is to implement hardware to protect the system, such as implementing routers to filter the arriving packets before these packets enter the network of the organization. The second solution is to install software to protect the system from intruders, such as installing a firewall to protect the system from unauthorized users or installing virus protection software to protect and kill viruses on the system.

Consequently, the results of the changes and impacts of changes can be seen in the development of new laws and technologies. These developments

are performed to balance all changes and their effects. Thus, the society can be maintained on the object side.

Since society appears now to be full of crime, various patterns, and various approaches, people in the society usually do not maintain a peaceful life, because they have to be aware of things (visible and invisible) around them. Therefore, the mentality of mankind in the future may not be as happy as people in this age; this is a comment in the mental side.

In conclusion, there are possibilities that various developments in laws and technologies will arise to protect against technological crimes. Moreover, people in the future will live without trust and will be worried about being cheated. Therefore, satisfaction in life will be low. Furthermore, this trend is not suitable for living, because it is the same as the situation in business organizations in which the period of competition is 24 hours a day, seven days a week.

If the family system is altered, as recommended in the previous section, society slowly will turn back to be a pleasurable environment in which people can depend on others. However, adjustment in the family is not that simple, as there are many factors involved, and these factors mostly are uncontrollable. Therefore, the solution should be applied to a small community as a prototype and then should expand slowly to other communities. Additionally, the cooperation between families and schools must be well-maintained in order to support one another in creating good ethics. This process will take years to succeed, but starting now is better than not.

CONCLUSION

In this chapter, Thai culture is described, and factors related to it are also elaborated upon. Since Thai culture represents the religion of the people, and since ethics is related to Thai culture, ethics is also related to the religion. IT ethics is a part of

human ethics according to the use of ICT. Thus, there are interactions among IT ethics, ICT, and Thai culture. However, the belief in commandments of each religion relies on the family.

The consequences of implementing ICT into Thai society are both positive and negative. Unfortunately, the negative effects have caused problems for the entire world. These effects are caused by persons who ignore IT ethics. Even though new technologies, new methods, or codes of ethics are invented or installed to protect technological crime, it will not reduce crime. This indicates that the existing methods are not the right solutions to stop technological crime. Moreover, these methods are temptations for hackers and crackers to intrude upon the system.

In order to completely solve the problem of lack of IT ethics, the main reason for these effects must be solved. In this chapter, the main factor is family, and lack of IT ethics is the result of loose family life. Thus, IT ethics can be built up only when these family problems are solved.

Even though the proposed solution is not easy, it is not impossible. Starting in small communities is the first step to create a good society and ethics. As a result, people will have ethics, including IT ethics, no matter how much they are involved with ICT.

Chapter 5.26

The Use of Information and Communication Technology for the Preservation of Aboriginal Culture: The Badimaya People of Western Australia

Katina Michael

University of Wollongong, Australia

Leone Dunn

University of Wollongong, Australia

Information and communication technology (ICT) has been applied successfully to numerous remote indigenous communities around the world. The greatest gains have been made when requirements are first defined by indigenous members of the community then pattern matched to an ICT solution.

ADOPTION OF ICT BY INDIGENOUS PERSONS IN VERY REMOTE AREAS

In Australia ICT adoption by indigenous communities in very remote areas is very low; at home in

2001 only three percent used a computer and one percent used the Internet (ABS, 2001). The cost of foregoing online services such as e-government, e-banking, e-procurement and e-employment is still perceived to be relatively low by indigenous communities. One could hypothesise that, for the greater part, government agencies have taken on the servicing of indigenous needs rather than encouraging communities to participate themselves. An application of ICT that could have particular usefulness for indigenous peoples is a system for cultural preservation.

ICT SOLUTIONS FOR THE PRESERVATION OF THE BADIMAYA CULTURE

The discussion below shows the potential uses of ICT in key areas fundamental to the continuing presence of the Badimaya culture. The Badimaya people traditionally occupied a large area around Lake Moore in Western Australia. Their language is classified as a member of the Karlu sub-group, of the southwest group of Pama-Nyungan languages.

Geographical Information Systems: The Portal Framework

A vector-based map in a geographic information system (GIS) could be used to show where different generations of the Badimaya lived and what languages are spoken today by their descendents. The interactive map, which could also serve as the portal front-end, would identify that the Badimaya people traditionally occupied a large area around Lake Moore, Ninghan Station and Paynes Find. Various map layers could pinpoint important sites, streets/paths/trails and traditional locations and provide additional information on each upon querying. Graduated thematic maps could also show that the Badimaya today are scattered in towns throughout the Murchison Region in Mullewa, Cue, Mingenew, Mt. Magnet, Yalgoo, Carnarvon and Meekatharra. Hotspots on the maps would allow users to trigger the selection of photographs of people, places and things from the region. Theme maps could also show which languages are spoken by various communities today, such as Watjarri, otherwise known as the “Murchison” or “Yamaay” language. The GIS could also be used to provide evidence for native title land claims.

Multimedia Clips: Content Management

The Badimaya people interviewed by Dunn in the 1980s were all concerned about the potential for the Badimaya language to become extinct. They were pleased to hear that their language was being recorded, as many feared that over time it would be entirely lost. Joe Benjamin (now deceased), who was acknowledged at the time of recording the language to be one of the last speakers, was the principal source for the material gathered. While a Badimaya dictionary including phonetic pronunciation was documented by Dunn (1982, 1989), multimedia footage of Badimaya speakers conversing has not been captured. In 1982 there were only about 50 people claiming Badimaya descent. Apart from Dunn, Douglas (1981) and Gratte (1968) have documented a few Badimaya nouns.

The lexicon compiled from these authors would act as a directory source to corresponding multimedia clips of Badimaya culture. These clips could even show sacred locations, people participating in traditional rituals and live song and dance performances. Today, most of the Badimaya live in remote towns and non-traditional communities, so providing them with access to multimedia recordings is important in helping them maintain a link with their traditional culture.

Digital Document Archives: Knowledge Management

Although written historical accounts of the Badimaya are scarce, surviving documents could be digitally scanned and made available for access to the community. The majority of material that remains today dates back to the mid-19th century when Europeans first had contact with the Badimaya. There was the Badimaya experience

with the missionaries during the 1840s, the pastoralists/explorers during the 1850s and the gold prospectors during the 1890s. Without a doubt, there are mixed perspectives of the benefits and costs of these periods to the Badimaya people. The Badimaya culture was under pressure to change, especially the use of language for communicating with the Europeans. Some have favourable impressions, others do not. Some believe that the interplay between the two cultures caused the Badimaya to fragment as a people, forcing families onto stations and children into non-traditional schools. In other descriptions, the Badimaya are said to have worked in partnership with prospectors in the goldfields.

Digital photographs from these periods — showing artwork, artefacts, people interacting at work and Badimaya in their natural surroundings — could be used to inform future generations. In addition, recordings of members of the community talking about the changes that took place over time, and recordings of myths and stories that have only survived through oral transmission, would be enriching to modern-day Badimaya people.

PRESERVING CULTURE TAKES MORE THAN ICT

Culture encompasses such things as language, art, music, food, spirituality, craftsmanship, history, ancestry and geography. The inherent problem with ICT is that while it is good at preserving tangible knowledge, it has difficulty with how to treat tacit knowledge. ICT output, no matter how well represented, is usually one-dimensional. Digital archiving of information (encompassing text, audio, graphics and video) is only the first step to cultural preservation. The second is placing the information in a meaningful knowledge management system where it can be accessed via community technology centres (CTCs): These

centres can be re-used by educational institutions and maintained by the community itself. The third step is in defining relationships around that content through various collaborative tools relying on wireless or other networks, of which email and bulletin boards are only the beginning. Herein lies another problem for ICT, that of confidentiality: There are obvious “secrets” that belong to initiated males and females, and these are only passed down orally to other selected members of the community.

Cultural preservation cannot be achieved by ICT alone: It requires the spiritual element behind the history to be actively reinvigorated into a community to make its presence felt in a long-lasting manner. Culture is something that is alive and ever-changing. In brief, it is not machinery that reforms society, repairs institutions, builds social networks or produces democratic culture; it is people who make this happen. What has been presented in this paper is a way forward. By getting communities involved in the development of applications, ICT adoption by its members is likely to follow, bringing with it myriad benefits.

Chapter 5.27

ICT and the Orang Asli in Malaysia

Pauline Hui Ying Ooi
Intel Technology Penang, Malaysia

Orang Asli means the “Original People” in the Malay language. Nowadays, they are classified into three large groups: Senoi, Negrito and proto-Melayu, which further break down into various tribes. Although many still live in the rural areas, some youth have been fortunate enough to venture life in the city by pursuing higher education or seeking employment. A few information technology undergraduates from the Orang Asli community of Malaysia were interviewed via e-mail on the subject of information and communication technology (ICT) among the local indigenous peoples.

Senyeorita, Rubycca, Jeneta, Zue and Khairol were all born in Peninsular Malaysia. They came from different Orang Asli tribes, namely the Semelai, Temuan and Semai. The culture, lifestyle and beliefs of their communities had an impact in shaping their identities. Senyeorita described the Orang Asli people as shy due to limited exposure to the outside world. As for Khairol, having lived near the forests surrounded by nature, the Semelai

culture had shaped him to appreciate nature which gave him a feeling of harmony.

The Orang Asli in Malaysia are socio-economically and culturally marginalised, although most respondents felt that the development of indigenous peoples in Malaysia was fairly good considering Malaysia is one of the developing countries. Besides the digital divide, there are other issues which have led to an erosion of their cultural identity. The respondents stated that the land problem was one of the issues faced by the Orang Asli. Other major problems include the poor education system, health, poverty, sanitation and clean water supply. According to Khairol, some conservative Orang Asli were unwilling to accept development and disregard the significance of education for the younger generation. A high dropout rate also contributes to low participation in education among the Orang Asli children (Mokshein, 2004).

With regard to the digital divide, Jeneta explained that besides being computer illiterate,

the high cost of computer gadgets were among the technological issues faced by the Orang Asli. Rubycca also commented that it was impossible for the people to use the latest technology, as some of the villages do not even have basic necessities, including power supply and education. Khairol, Senyeorita and Zue agreed that the lack of exposure to ICT among the people could contribute to the wider technology gap.

ICT is a growing industry in Malaysia. Over the years, the industry has provided employment opportunities for its citizens, which also explicitly explains the increasing number of higher institutions offering ICT-related courses to encourage more students into this stream. While Zue, Senyeorita and Rubycca got involved in ICT because courses were offered at the university, Khairol and Jeneta chose ICT for other reasons. Jeneta was encouraged by her family and friends to get involved in ICT. Khairol was inspired by the rapid growth of technology globally, and he believed that ICT plays an important role in every aspect of life. In response to the opportunities offered by ICT to further the goals and interests of the Orang Asli community, the IT undergraduates were confident that it would improve the quality of life, knowledge and work performance of their people. ICT will also help to bridge the gap in education and economic status between Orang Asli and other ethnic races.

None of the respondents thought that ICT would pose a threat to their community. In fact, they were positive about the Orang Asli willingness to accept new technologies. However, Zue emphasized that the acceptance of technologies among the people without seeing it as a threat was greatly dependent on their exposure and the way technology was presented to them. Khairol said that some Orang Asli from the Semelai tribe were still unwilling to accept advancement in their lives because they assumed that it will threaten the chastity of Semelai people as well as the customs, culture, and beliefs of other com-

munities. All respondents said the potential ICT users among the Orang Asli community would possibly be the younger generations who received formal education.

The government, jointly with other organizations, has been organizing programmes to introduce ICT in rural areas. It is an ongoing process, which has ample room for development. Some of the suggestions given included giving workshops, presentations and seminars on ICT in Orang Asli villages as part of exposure measures, making ICT a core subject in school, supplying necessary equipment and a "One family one computer" campaign by introducing attractive packages. In 2003, it was reported that, with assistance from the United Nations Development Program and the Department of Orang Asli Affairs, Malaysia, the indigenous Temuan people in Pahang state were fortunate to have a solar power generator in their village. Although there was no school nearby, Temuan youngsters were learning how to read and write using solar powered computers. (Temuan take to technology transfer, 2003). Today, there are still several Orang Asli villages that are deprived of this privilege.

In conclusion, the indigenous peoples' involvement in information technology is still very small. Education is the primary factor that leads the community towards accepting information technology. However, other major problems such as poverty, a poor education system, health and sanitation should be overcome first before information technology is introduced to the indigenous community.

ACKNOWLEDGMENT

I would like to thank Senyeorita, Rubycca, Jeneta, Zue and Khairol for their participation and contribution to this case study. Special thanks to Dr. Laurel Dyson for her guidance and advice.

Chapter 5.28

Information and Communication Technology and Economic Development in Malaysia

Mohamed Aslam

University of Malaysia, Malaysia

ABSTRACT

Since the early 1990s, the government has emphasised the ICT sector as a new engine of growth and development. The Multimedia Super Corridor (MSC), which was developed in 1996, was regarded as a main vehicle and catalyst for ICT-sector development. Since there were many new institutions established by the government, it somehow had complicated and decreased efficiency in expanding the industry. ICT-related courses at public and private institutions were not developed well enough to meet the market demand. Consequently, the human factor, which was a major component for ICT development, was not fully utilised in research and development, therefore reliance on foreign technology remained

a critical issue. These have slowed the progress of ICT development. This chapter will discuss the ICT-sector development policy in a broad view and try to analyse critically to what extent the development of the ICT sector has contributed to economic development in Malaysia.

INTRODUCTION

In 1991, the Malaysian government launched Vision 2020, with one of its main goals for Malaysia to become a fully developed nation by the year 2020. En route to achieving this goal, the information and communication technologies had been identified as one of the key sectors to realize this goal. This sector has been regarded and empha-

sized as a new sector of future economic growth and development. The sector had been included in the *Sixth Malaysia Plan* (6MP) for development within 5 years from 1991 to 1995. However, a bold policy and the necessary infrastructure and environment for the development of ICT was developed during the *Seventh Malaysia Plan* (7MP, development period from 1996-2000). Under the *Ninth Malaysia Plan* (9MP, development period from 2006-2010), the government has almost doubled its allocation for the ICT sector to RM13 billion compared to RM7.8 billion in the *Eighth Malaysia Plan* (8MP, development period from 2001-2005)(Table 1). Part of the allocation, about RM3.7 billion (in 8MP, the amount was RM2.4 billion), will be used to boost ICT capacity in government agencies and bridge the digital divide between urban and rural agencies.

To strengthen ICT development, in 1996 the government had initiated and established the Multimedia Super Corridor (MSC) managed by the Multimedia Development Corporation (MDC). Since then, the MSC has grown into a thriving dynamic ICT hub, hosting more than 900 multinational foreign-owned and homegrown Malaysian companies focused on multimedia and communications products, solutions, services, and research and development (R&D). The government has planned for the second phase of MSC and four new cybercities, which will be developed under 9MP. The number of MSC-status companies is projected to grow from 1,421 as of 2004 to some 4,000 by 2010, and these are expected to create some 100,000 new jobs and generate about 1,400 new intellectual properties.

In order to support the country's ICT development plan and fulfill Vision 2020, the education system is in the process of being transformed to create a new generation of more creative and innovative Malaysians who are adept with new technologies and able to access and manage the information explosion. ICT-enabled smart schools act as a catalyst within this process. The first phase of implementation began in 1999 with 90 schools.

Also, to foster the ICT industry in the short term, tertiary education, particularly computer science and engineering faculties, has been restructured by not only focusing on hardware matters but also focusing on software development. This is to ensure human capital for the ICT industry in various specialities adequate to meet the demand.

In fact, the ICT sector has been a main industry and a main component of economic growth since the early 1970s. The introduction of export-oriented industries with emphasis on electrical and electronics (E&E) industries and supported by the heavy inflow of foreign direct investment (FDI) in the sector has expanded it. The expansion of the foreign-owned E&E industries has spilled over into the domestic economy, whereby many local support industries and IT-related firms have been developed. Consequently, the demand on labour for both skilled and unskilled workers has increased very significantly. The ICT industry's export performance has been increasing steadily over the years from RM35.3 billion in 1998 to about RM61 billion in 2005 (about 50% of the total manufacturing goods). Major export destinations were the traditional markets such as the USA, Japan, Singapore, and Hong Kong. On the other hand, domestic spending on ICT material reached RM36 billion in 2004. To enhance trade in the ICT sector, e-commerce trading has been promoted and developed.

With respect to the ICT industry, there are many issues that have emerged and worry policy makers. Too much emphasis on the ICT sector, particularly by the government and by the market, has created and increased unemployment for ICT graduates either at the first degree or certificate level, including diploma holders. This has somehow retarded the smooth development and progress of the ICT sector. The economic crisis from 1997 to 1999 has also slowed the ICT industry's development. Many companies that are ICT related, foreign as well as local, have closed operations and moved to China in particular. This is a cost to the economy. The government

has revised and further liberalized the investment incentives for the ICT industry to reattract old firms and attract new ones to be established in the country. The Third Industrial Master Plan, which was launched in August 2006, gave greater concentration on the ICT sector besides services related to the manufacturing sector.

Government Policies on ICT-Sector Development

The government has been committed to developing the ICT sector since the 6MP. It has established various agencies related to ICT, and each agency has introduced policies promoting ICT development within the jurisdiction of the particular agency, such as the Malaysian Institute of Microelectronic Systems (MIMOS), the National Information Technology Agenda (NITA), the National Information Technology Council (NITC), and the Ministry of Energy, Communications, and Multimedia (MECM; Table 2). Too many policies

were formulated by the federal government, and the agencies have somehow increased in redundancy and created inefficiencies in developing the ICT sector.

The seriousness of the government in promoting the ICT sector can be seen from the government's allocation for the sector. The government has increased allocation from RM2.125 billion under the 8MP to RM5.734 billion under the 9MP. The large amount of allocations is invested in the computerisation of ministries and government agencies. This huge amount of funds is in line with the government's plan to increase paperless transactions, reduce operating costs in the future, and speed up the processing of applications and any matters related to government. To meet the aims, the government has increased allocation to the e-government subarea of the MSC multimedia application from RM537.7 million in the 8MP to RM572.7 million under the 9MP, (Table 1). Another vital project is Bridging the Digital Divide, which also received a huge amount of

Table 1. Development expenditure and allocation for ICT-related programmes, 1996-2010 (RM million; Source: Government of Malaysia, 2001, p. 388; Government of Malaysia, 2006, p. 154)

Programmes	7MP	8MP	9MP
Computerisation of Government Agencies	1,641.8	2125.0	5,734.2
Bridging the Digital Divide	1,098	2,433.1	3,710.2
Schools	945	2,145.1	3,279.2
Communications Infrastructure Service Provision Programme	119.8	254.0	150.0
Telecenters	33.2	18.1	101.0
ICT Training/Services	-	15.9	180.0
ICT Funding		1,125.6	1,493.0
MSC Multimedia Applications	1,824.9	1,153.1	1,100.5
E-Government	434.8	537.7	572.7
Smart Schools	401.1	363.9	169.8
Telehealth	400.0	91.8	60.0
Government Multipurpose Card, etc.	589	159.7	298.0
MSC Development	-	320.8	377.0
ICT Research and Development	300.0	727.5	474.0
Other	294.4	-	-
Total	5,159.1	7,885.1	12,888.9

government allocation. The allocation of the project has been increased from RM1.1 billion in the 7MP to RM3.7 billion in the 9MP. Even though the federal government allocation to ICT has increased over the years, the government's spending is about 6% compared to the global average government ICT spending of 15%.

Government Agencies and Policies on ICT Development

As mentioned, there are many agencies that have been developed by the government that have established a law related to ICT. Also, a trade association was formed among ICT firms (Table 2). In this section we will focus on the govern-

ment think tank on ICT, the National Information Technology Council, which was established in 1994. The NITC was responsible for formulating the National Information Technology Agenda, which was launched in 1996. NITA provides a comprehensive framework for ICT development. The primary objective of NITA is to ensure a coordinated and integrated approach in developing the ICT industry more systematically and also to transform the Malaysian society into a value-based knowledge society. The government has adopted NITA as a major strategy for national development and nation building through the ICT sector. NITA proposed a trisectoral smart partnership between the public, private, and community-interest sectors, where all parties win. A two-prong strategy of combining top-down and bottom-up approaches

Table 2. ICT sector: Institutional development (Source: MDC, 2003)

Agencies	Function/Role
Malaysian Institute of Microelectronic Systems (MIMOS Berhad)	Established on January 1, 1985, then corporatised on November 1, 1996. Deals with research and development (wafer and chip technology). Plays a crucial role in developing ICT. An Internet service provider (Jaring).
National Information Technology Council (NITC)	Established in 1994. A government think tank. Advising and recommending policy on ICT development.
Ministry of Energy, Communications, and Multimedia (MECM)	Established on November 1, 1998. To develop the communications and multimedia industry based on the concept of the convergence of the telecommunications, broadcasting, and computing services.
Malaysian Communications and Multimedia Commission (MCMC)	Established on November 1, 1998. Responsible for regulating the broadcasting industries, ICT, and telecommunications in accordance to the Communications and Multimedia Act of 1998. A sole regulating authority for all communication and multimedia industries.
Multimedia Developed Corporation (MDC)	MDC was established to assist the government in developing and managing the MSC. A one-stop shop for investors.
Association of the Computer and Multimedia Industry Malaysia (PIKOM)	A voluntary self-funding trade association representing the ICT industry. The number of members is about 370 companies. Members control about 400 firms and represent about 80% of the total ICT trade in the country.
Legislation Supports	The Digital Signature Act of 1997, which governs electronic signatures. The Computer Crimes Act of 1997, which outlaws the fraudulent use of computers and other related cybercrime. The Electronic Government Act of 1997, which regulates communication within the public sector. The Multimedia Convergence Act of 1997, which streamlines communication, information, and broadcasting services. The Telemedicine Act of 1997, which allows for the promotion of medical services. The Communications and Multimedia Act of 1998, which facilitates the orderly development of the multimedia industries, in particular the contents industry, and replaces existing inadequate legislation. The Intellectual Property Protection Act of 1998, which protects copyright laws.

for planning and implementation is recommended (refer to subsection on MSC).

The National ICT Framework under NITA is combining people (human resource), infrastructure (both hard and soft infrastructure), and applications and content (product) development. NITA places the human factor as the main element; all citizens need access to information in an equitable manner. The second element of infrastructure is seen in terms of both the hard and soft infrastructure. The hard infrastructure is the computer hardware and the relevant telecommunication components. The soft infrastructure includes databases, networks, laws, and regulations. The applications and content element emphasises the importance of developing applications in IT and encouraging local product development.

Under the 7MP, the government indirectly based its policy on ICT development on NITA. The policy formulated by the federal government under the 7MP was regarded as a concrete policy in promoting, developing, and expanding the ICT infrastructure, and to promote the extensive application of ICT and accelerate ICT usage in the various sectors of the economy. The document elucidates several national strategies on ICT as listed below:

- Develop a national plan to ensure a more systematic approach to manage the development of ICT through NITA and the Multimedia Super Corridor.
- Increase and enhance IT education and training.
- Expand and upgrade the communications infrastructure to increase accessibility.
- review laws and regulations to promote the growth of electronic communities and the development of a continuous learning environment.
- Promote the development of e-commerce, indigenous contents, and the local IT industry, especially the software and knowledge

products industries, to generate new growth opportunities.

- Review and improve the national innovation systems to generate R&D output capable of driving the knowledge economy.

Multimedia Super Corridor

Under the 7MP, the government established the Multimedia Super Corridor on August 1, 1996. The development of the MSC was the main outcome of NITA and the government policy in developing the ICT sector. The initiative of MSC came with a two-prong strategy. The strategies are to transform the Malaysian economy from one of manufacturing and primary commodities to software and services, and to create an ideal environment for global ICT companies to use as their regional hub and test bed, becoming a catalyst for a highly competitive cluster of homegrown ICT companies that can become world-class over time.

Development of the MSC is a government long-term project that was initiated to run from 1996 up to 2020. This long-term period is divided into three phases. The first phase covers 1996 to 2004, during which the government would develop the MSC area. The second phase covers 2004 to 2010. This phase will link the MSC to other cybercities in Malaysia. Finally, the third phase covers 2010 to 2020, during which the government hopes to realise the objective of transforming Malaysia into a knowledge society.

In the first phase, the government developed the MSC center, which is located south of the Kuala Lumpur City Center. Two smart cities, namely Putrajaya and Cyberjaya, were developed in the MSC. Putrajaya is the new seat of the federal government and administrative capital of Malaysia, where the concept of electronic government is introduced. Cyberjaya was planned as an intelligent city with multimedia industries, R&D centers, a multimedia university, and operational headquarters for multinationals using multimedia

technology for their worldwide manufacturing and trading activities. The MSC was built upon a 2.5- to 10-gigabit digital optical fibre backbone enabling direct high-capacity links to Japan, the USA, and Europe (MDC, 1996). The MSC was developed to attract world-class technology-led companies to Malaysia and to develop local industries; to create a multimedia utopia that offers a productive, intelligent environment within the multimedia value chain of goods and services that will be produced and delivered across the globe; to offer a place of excellence with multimedia-specific capabilities, technologies, infrastructure, legislation, policies, and systems for competitive advantage; to establish a center for invention, research, and other multimedia developments; and to create a global community living on the leading edge of the information society, and a world of smart homes, smart cities, smart schools, smart cards, and smart partnerships (MDC, 1996).

To ensure the realisation of the MSC, the government introduced the MSC Bill of Guarantees. Under the Bill of Guarantees, the Malaysian government commits the following to companies with MSC status:

- Provide a world-class physical and information infrastructure.
- Allow unrestricted employment of local and foreign knowledge workers.
- Ensure freedom of ownership by exempting companies with MSC status from local ownership requirements.
- Give the freedom to source capital globally for MSC infrastructure and the right to borrow funds globally.
- Provide competitive financial incentives (no income tax up to 10 years or an investment tax allowance of up to 5 years will be granted).
- Become a regional leader in intellectual property protection and cyberlaws.
- Ensure no Internet censorship.

- Provide globally competitive telecommunication tariffs.
- Tender key MSC infrastructure contracts to leading companies willing to use the MSC as their regional hub.
- Provide a high-powered implementation agency to act as an effective one-stop supershop.

The Multimedia Development Corporation, the agency that manages the MSC, is the one-stop shop for Malaysian and international companies that are prepared to set up operations within the MSC or otherwise contribute significantly and strategically to the MSC's development. A company seeking MSC status must fulfill three criteria. The company must (a) be a provider or a heavy user of multimedia products and services, (b) employ a substantial number of knowledge workers, and (c) be able to transfer technology and knowledge to Malaysia, or otherwise contribute to the development of the MSC and the Malaysian economy.

Since the development of the MSC in 1996 until 2000, there have been 326 companies that have received MSC status, and 192 of these companies are fully owned by Malaysians. In 2005, the number increased to 1,421 companies, of which 1,033 firms were fully locally owned and 349 firms were fully foreign owned. Since the early phase of the MSC produced remarkable results, the government plans to develop MSC's second phase (MSC II) under the 9MP. Under the second phase, the government plans to build new MSC cybercities in the states of Perak, Melaka, Johor, and Sarawak. The proposed development is expected to bring in 250 additional multinational companies (Government of Malaysia, 2006). The number of MSC-status companies is projected to increase from 1,421 in 2005 to 4,000 by 2010, generating 100,000 jobs nationwide and 1,400 intellectual properties.

Progress and an Assessment of ICT Development since the 1990s

Since the government introduced the national development and expansion of the ICT industry in 1996, it has been very committed and serious on the matter, and this can be seen by looking at the government expenditure, which has increased quite tremendously (Table 3). In terms of spending on ICT usage, the government expenditure has increased from RM159 million in 1990 to RM2.2 billion in 2005 (Table 3). The government policy and expenditure allocation has in turn accelerated private-sector expenditure on ICT. In 1995,

the total expenditure on ICT was RM1.3 billion. The figure increased to RM3.8 billion in 1995, to RM25.6 billion in 2000, and to about RM32.2 billion in 2005. The main industry that has increased expenditure significantly is the manufacturing sector; its expenditure has increased from 6% of the total economy expenditure in 1990 to about 45% in 2005. Other sectors that have increased the usage of ICT are wholesale and retail trade, transport and communications, finance and business services, and consumer spending on ICT products (Table 3).

Figures in parentheses are the percentage of expenditure of each sector of the total expenditure of the period.

Table 3. ICT expenditure by sector, 1990-2005 (RM million; Source: Government of Malaysia, 1996, p. 479; Government of Malaysia, 2001, p. 365; Government of Malaysia, 2006, p. 136)

Sector	1990	1995	2000	2004	2005
Agriculture	26 (2.0)	76 (2.0)	200 (0.8)	128 (0.4)	138 (0.4)
Mining	234 (18.0)	380 (10.1)	222 (0.9)	224 (0.7)	234 (0.7)
Manufacturing	78 (6.0)	494 (13.1)	12,188 (47.5)	13,652 (45.6)	14,367 (44.6)
Utilities	39 (3.0)	266 (7.0)	378 (1.5)	430 (1.4)	470 (1.5)
Construction	-	-	112 (0.4)	126 (0.4)	135 (1.5)
Wholesale and Retail Trade	91 (4.0)	304 (8.1)	1,585 (6.2)	1,735 (5.8)	1,870 (5.8)
Transport and Communications ¹	39 (3.0)	114 (3.0)	1,221 (4.8)	1,581 (5.3)	1,770 (5.5)
Finance and Business Services	507 (39.0)	1,026 (27.2)	1,894 (7.4)	2,563 (8.6)	2,845 (8.8)
Government	156 (12.0)	380 (10.1)	1,389 (5.4)	1,981 (6.6)	2,245 (7.0)
Consumers	-	76 (2.0)	6,314 (24.6)	7,440 (24.9)	8,104 (25.1)
Other Services ²	130 (10.0)	657 (17.4)	140 (0.5)	62 (0.2)	70 (0.2)
Total	1,300	3,773	25,643	29,922	32,248

Notes: ¹ Includes telecommunications services

² Includes businesses providing personal, repair, cultural, recreation and entertainment, health care, legal, educational, social, and professional services

Expenditure on ICT by consumers (society) has increased. Since 1995, it has increased by more than 7,000%. In 2005, consumers spent about RM8.1 billion on ICT-related products. The expansion of consumer expenditure on ICT-related products is clearly indicated in Table 4. The number of people who bought computers has increased from 0.8 million people in 1996 to about 5.7 million in 2005. Indicators of IT usage in society have increased from 50 per 1,000 people in 1996 to 218 per 1,000 people in 2005. In line with IT usage, Internet subscription by society has increased quite remarkably. Internet dial-up subscription also increased from 64,000 people to 3.7 million people in 2005 (Table 4). The Internet was first introduced in Malaysia in the mid-1990s with MIMOS as the sole provider of Internet service. In the late 1990s, the government liberalized the sector by allowing more network-based companies to provide Internet service. At present, there are six network-based companies that have been licensed to provide Internet service in the country, namely, MAXIS, DIGI, TT.DOT.COM, CELCOM, TELEKOM, and PRISMANET. However, only three network-based companies provide Internet service, namely, JARING (under MIMOS), TMNet (under TELEKOM), and

MaxisNet (under MAXIS). In terms of subscribers registered with JARING and TMNet, the number increased 10 times from 42,000 in 1995 to 425,320 in 1998, and reached about 1.68 million in 2002 (Yusuf & Radzi, 2003). In terms of users of the Internet, the number has increased from 30,000 in 1995 to 4.8 million in 2001 (Minges & Gray, 2002). The penetration rate has increased from 0.1% in 1991 to 20.2% in 2001 (Minges & Gray, 2002). A survey by the International Data Corporation in 1999 indicated that households constituted the largest group using the Internet, comprising 64% of total users, followed by users in the education and business sectors who comprised 24% and 12%, respectively (MDC, 2003). The survey also showed that subscribers were concentrated in the urban areas, particularly in the Federal Territory of Kuala Lumpur, Johor Bahru, Petaling Jaya, and Penang. The growing market of ICT in the country provides incentives for local firms to invest further in telecommunication. Currently, there are six licensed telecommunication companies in Malaysia, but only five in operation, providing telephony services. During 1996 to 1999, telecommunications operators upgraded and improved their services through investments in telecommunication infrastructure, comprising

Table 4. Selected ICT indicators (Source: Ministry of Finance, 2001, 2002, 2006)

Indicator	1996	1998	2000	2001	2002	2003	2004	2005
Telecommunications								
Number of cellular phone subscribers (thousands)	1,363	2,149	5,122	7,385	9,053	11,124	14,611	19,545
Number of Internet dial-up subscribers (thousands)	64	405	1,659	2,113	2,614	2,881	3,293	3,672
Information Technology								
Personal computers actively installed (millions)	0.8	1.4	2.2	3.0	3.6	4.2	4.9	5.7
Number of computers per 1,000 people	50	60	94	125	145	166	192	218
Broadband subscribers (thousands)	-	-	-	-	19.3	110.4	252.5	490.6

fibre optics, satellites, and wireless technology. As a result, the backbone of the information superhighway was formed, which was capable of supporting extensive public, educational, and business applications. In addition, the country also registered a market penetration rate of 10 cellular phones for every 1,000 people, which was one of the highest in the developing world (MDC, 2003). The number of mobile phone customers is expected to break the 6 million mark or 250 for every 1,000 people by 2005 (MDC, 2003).

Investment and Export

The investment incentives such as tax breaks, MSC status, and capital allowance that have been provided by the government have managed to attract local and foreign capital into the ICT sector. In the broad category of the ICT sector, that is, the E&E sector, investment has increased from 39% of the total investment in 1996 to 40% in 2005. The electronics goods exported in 1996 was 62% of the total export of manufactured goods, with 34.1% coming from the semiconductor industry followed by electronics equipment and parts. In

2005, exports of E&E goods increased to 73.4% and semiconductor industries contributed about 32%, while 42% came from firms producing electronics equipment and parts (Table 5). Major export destinations were the traditional markets such as the USA, Japan, Singapore, and Hong Kong. Malaysia was a net exporter of ICT products worth RM28.3 billion in 2002 and RM33.8 billion in 2003 (Malaysian Industrial Development Authority [MIDA], 2005). Imports of ICT products, which consist of computers, servers, mainframes, and telecommunication equipment, totaled RM18.6 billion in 2002 and RM18.0 billion in 2003 (MIDA, 2005). Major imports for computers and computer peripherals were sourced from China, Singapore, and the USA, while telecommunications products were imported mainly from China, Japan, and Korea. Major import items were thermionic valves and tubes, parts for office machines, electrical apparatuses, and measuring, checking, and controlling instruments. The items most imported were thermionic valves and tubes, whose worth has increased from RM45.8 billion in 1997 to RM105.7 billion in 2005 (Ministry of Finance, 2006). The presence of foreign firms

Table 5. Exports of ICT-related products (percentages; Source: Bank Negara Malaysia, 2006)

Products	1996	2000	2003	2005
Electronics	62.0	72.4	75.1	73.4
Semiconductors	34.1	30.9	38.2	31.8
Electronics equipment & parts	27.9	41.5	36.9	41.6
Electrical machinery & appliances	38.0	27.6	24.9	26.6
Consumer products	19.1	11.5	8.8	8.1
Industrial & commercial products	10.1	10.3	9.1	10.2
Industrial machinery & equipment	8.2	5.5	6.1	7.3
Household electrical appliances	0.6	0.3	0.9	1.0
Total E&E exports (RM billion)	104.3	230.4	222.9	282.8
Percentage of total exports	65.8	72.5	67.9	65.8

made Malaysia a net exporter of computers and computer peripherals valued at RM22.1 billion in 2002 and RM22.6 billion in 2003. Malaysia currently ranks third in the world for the production of HDD for desktop computers (MIDA, 2005).

In the case of investment in the MSC zone, the value increased from RM3.16 billion in 2001 to RM5.11 billion in 2005 (Table 6). As mentioned in the previous section, in 2005, the number of firms that were ICT related was 1,421; about 1,033

Table 6. MSC indicators, 2001-2010 (Source: Government of Malaysia, 2006, p. 145)

Category	2001	2005	2010
MSC-status company (number)	621	1,421	4,000
Locally owned	410	1,033	-
Foreign owned	198	349	-
Joint venture (50/50)	13	39	-
Job creation (number)	14,438	27,288	100,000
Knowledge workers	12,169	24,252	-
Others	2,269	3,036	-
Investment (RM billion)	3.16	5.11	12
Revenue (RM billion)	-	7.21	69
Exports (RM billion)	-	1.57	2.5
R&D expenditure (RM million)	-	670	1,000
IPs registered (number)	-	119	1,400

were fully locally owned while about 349 were fully foreign owned. There were more than 50 international world-class companies that received MSC status such as NTT, Fujitsu, IBM, Sun Microsystems, Microsoft, Oracle, Ericsson, Nokia, Siemens, and Dell. Until 2003, the activities of MSC-status firms range from software development, Internet-based business, and hardware and electronics design to education and training, as shown in Figure 1. The exports of the MSC-status firms were about RM1.57 billion in 2005. The revenue of the firms in the same year was about RM7.21 billion (Table 6). The firms involved in the research and development area had spent about RM680 million. The expansion of the industry has created jobs, from 14,438 in 2001 to 27,288 in 2005. The majority of workers that have been employed by the firms are knowledge workers (ICT).

Human Resource Development

The expansion of the ICT sector has increased demand on skilled and semiskilled workers or

knowledge workers. There are about 12 public institutions of higher learning, 7 polytechnics, and 154 private institutions offering courses on ICT and multimedia at the certificate, diploma, and degree levels. From 1995 to 2004, the total enrollment at these institutions was more than 80,000 students. In addition, industrial training institutes conduct ICT-related courses such as architectural computer-aided design (CAD), mechanical CAD, CAM (computer-aided manufacturing), and computer maintenance.

In a broad view, the employment of electrical and electronics engineers from 1995 to 2005 on average was about 4% of total employment. The employment of assistant engineers in the same field on average was about 10% of total employment (Table 7). According to statistics from the MDC, the estimated net demand for ICT manpower between 1998 and 2005 in five occupations (technical support, programmers, business/system analysts, software engineers, and systems/hardware engineers) was 108,000 while the supply was 104,000 (<http://www.mdc.com.my>). The total number of ICT workers was about 87,000 by the

Table 7. Employment of engineers (Source: Government of Malaysia, 1996, p. 121; Government of Malaysia, 2001, p. 95)

Occupation	1995	2000	2005
Engineers	55,254 ¹ (12.1)	61,034 (10.4)	108,400 (12.6)
Civil	16,695 (3.6)	20,711 (3.5)	27,500 (3.2)
Electrical & Electronics	15,759 (3.4)	21,064 (3.6)	38,600 (4.5)
Mechanical	12,583 (2.7)	16,082 (2.7)	29,800 (3.5)
Chemical	1,037 (0.2)	3,177 (0.5)	12,500 (1.5)
Engineering Assistants	92,082 ² (20.1)	143,220 (24.4)	247,739 (28.9)
Civil	25,971 (5.7)	25,973 (4.4)	71,401 (8.3)
Electrical & Electronics	40,023 (8.7)	65,353 (11.1)	103,856 (12.1)
Mechanical	18,706 (4.1)	50,020 (8.5)	67,073 (7.8)
Chemical	1,425 (0.3)	1,874 (0.3)	5,409 (0.6)

Notes: ¹ including unspecified engineers (8,509)

² including unspecified assistants (5,957)

end of 1998. The largest group was technical support with about 28,000 personnel or 32.2% of the total workforce, while the smallest group was software engineers with about 8,000 workers or 9.6%. Among the expertise and skills in demand are systems development and integration, operations management, R&D, software development, database management, and telecommunications networking. MDC notes that there is a labour shortage for technical support, programmers, and software engineers, but a surplus of business and systems analysts and systems and hardware engineers. On the other hand, the supply of ICT skilled and semiskilled workers from local higher learning education institutions from 1995 to 2005 was about 9,500 workers a year. By 2006, the total number of workers should exceed 104,500 workers. Therefore, the figures produced by the MDC are overestimated. With the total ICT graduates that are produced by public and private higher learning institutions, more than 30% of the graduates were unemployed by 2006.

The government realised that there is an increasing demand and shortage of certain skills in the ICT sector due to new developments in the ICT industry. However, the public and private institutions are slow in improving and developing new courses to meet the current demand. In general, the institutions offer a basic curriculum in ICT courses. To overcome the situation, the government, particularly the Ministry of Human Resource and the Ministry of Education, is trying to match the supply of skilled human resources with the needs of the ICT sector. Moreover, the government has encouraged more training courses provided by employers, as well as encouraging local higher learning institutions to embark on more courses related to ICT. The government set up the Human Resource Development Fund (HRDF) to provide reimbursements for ICT-based training (offered by ICT-related firms and private colleges) to ensure that there is continuous upgrading of

ICT knowledge and skills among the working population. During the period of 1996 to 1998, a sum of RM64.8 million or 14.6% of the total HRDF disbursements were utilised for ICT-based courses. In May 1998, the HRDF introduced the Training Scheme for Retrenched Workers. Under this scheme, a sum of RM846,000 was provided to finance 203 courses or 36% of the ICT courses approved at the certificate and diploma levels.

Figures in parentheses are the percentage of engineers (and assistants) of total employment.

CONCLUSION

ICT development, which was planned under the 6MP and embarked on since the 7MP, has produced overwhelming results. The impetus of the plan and policies were somehow retarded from 1997 to 1999 due to the impact of the financial crisis that hit in July 1997; however, the crisis has not stopped the federal government from achieving the ICT development plan. Since the 6MP, the development budget for the ICT-related sector has increased dramatically. The eagerness and seriousness of the government is evident in the national development report in terms of the increase of ICT usage in government services and in school. Furthermore, the government has received support from foreign firms. The investment by foreign firms that are ICT related has increased significantly. In fact, the overwhelming response from the local and foreign firms has encouraged the government to proceed to the second phase of MSC development and to develop a few more cybercities in selected states in Malaysia.

We do not deny that the development of the ICT sector, particularly through the development of the MSC, has induced the sector development in terms of investment, exports, and labour absorption. However, there are a few shortcomings in the development. First, the development of the

ICT sector has established many institutions with different policies and roles, and there were more than seven main rules and regulations related to ICT. In certain circumstances, roles of the agencies were overlapping each other, for instance, the roles of the MECM, MDC, and MCMC. Which agency has the right to approve and issue telecommunications licenses? Which agency handles rules and regulations, and which agency has the right to enforce rules that have been established? The government should streamline and provide clear guidelines, roles, and functions of the agencies that have been established to avoid any redundancy, attract more investors, and become more private-sector friendly. The second shortcoming is related to human resource development. The development of the ICT industry, for instance, in the software and hardware areas (Figure 1), requires high-skilled workers. Public and private institutions have produced an ample workforce for the sector; however, most of the MSC-status firms have employed foreign workers, subsequently creating unemployment for local ICT graduates, of which more than 30% were unemployed. The oversupply of ICT graduates is attributed to weak planning by the education ministry; furthermore, the curriculum of the ICT courses that are offered by the higher education learning institutions do not meet the market demand. Most institutions produced a workforce knowledgeable in how to handle and manage ICT rather than in how to create, invent, and develop a product. In other words, institutions produce a workforce with very low skills in producing products. This weakness in the education institutions has forced foreign firms to employ high-skilled labour from abroad.

Currently, there is a lack of research related to MSC and economic development. Most of the studies conducted produced a report rather than empirical data. Two of the main crucial issues with respect to MDC development are the market demand for ICT graduates and the ICT course

curriculum in public and private universities and colleges. The role played by foreign MSC-status firms in helping and developing the ICT industry in the country remains very much unclear. These issues should be explored further to gauge relevant indicators for future development.

Chapter 5.29

Urban Information Systems in Turkish Local Governments

Koray Velibeyoglu

Izmir Institute of Technology, Turkey

INTRODUCTION

Since the end of 1980s, different sectors have implemented geographical information systems (GIS) in Turkey. A study on GIS market in Turkey indicates that municipalities are the primary customers (Gülersoy & Yigiter, 1999). One of the earliest GIS projects in Turkey began with the production of digital maps covering the boundaries of Istanbul Metropolitan Municipality in 1987. Since 1994, a rapid development process has occurred with the widespread diffusion of GIS especially in universities and large public sector organizations respectively. However, the early city-wide municipal GIS projects were initiated only after 1996 (Ucuzal, 1999). In recent years, a major change has occurred in the context of GIS projects from small-scale infrastructure projects to city-wide municipal GIS projects for three reasons:

1. After the devastating earthquake in Marmara region in 1999, people suffered from the lack of vitally important information, because

such information never existed or was never kept in a systematic way. The importance of accumulation and distribution of up-to-date and accurate data among city-wide organizations was recognized (Tecim, 2001);

2. Rapid development of Internet in Turkey in recent years encouraged the communication efforts within and among the organizations, and among people and organizations, and this triggered the need for inter-organizational GIS (Karas, 2001);
3. Initiatives supporting e-municipality and e-government, and transition from government to governance raised the importance of transparency, communication, and public accountability (Tüzün & Sezer, 2002). In this sense, the concept of “urban information system” (UIS) began to be popular in the context of local governments. At the time of publication, UIS was used as an umbrella term encapsulating all the efforts for an information system—whether GIS or LIS—or information technologies like the Internet within an integrated system that

is supposed to be performed in municipal operations in order to support organizational rationality.

Although so-called urban information systems were being marketed by vendors as the panacea for all problems, the implementation of large-scale information systems generally ended up with failure because information systems (IS) require large changes in the organization's existing structure. In the Turkish case, no municipality has been able to complete establishing a city-wide urban information system so far. Ankara, Istanbul, and Bursa are the cities, where implementation processes are still underway (Celik, 2002). Therefore, there needs to be case studies to address implementation problems of UIS and to evaluate the reasons behind the failures.

In this article, the emphasis will be given upon organizational and political aspects of UIS implementation that is critical for the success and failure of such systems. For this purpose, the approach adopted rests on the assumption that "the success or failure of IS projects is dependent on the degree of mismatch between the conceptions of these systems and the organizational realities into which it is introduced" (Heeks, 1999). In the rest of the article, based on Heeks's argument, the assessment of these gaps is evidenced in the case of Turkish metropolitan municipalities, and further evaluations are made guiding further projects and studies.

ORGANIZATIONAL CONTEXT OF INFORMATION SYSTEMS

Information systems today play a vital role in businesses, governments, and other organizations. Because they are so closely tied to organizations, it is necessary to closely understand the nature of organizational realities. Public sector organizations like municipalities are the single largest collector, user, holder and producer of informa-

tion. The work of these organizations is thus very information-intensive.

Municipalities are responsible for providing the basic urban services (i.e., infrastructure development, fire department operations, garbage collection, planning services, etc.) to the public that requires collecting accurate information about environment and efficient use of this data to perform municipal tasks. The capability for planning, programming and decision making in the municipalities is largely dependent on the collecting, storing, preserving and managing of the spatial information. Municipalities collect and manage both spatial data (i.e., district plan, base maps and cadastre maps) and non-spatial data (i.e., water-system revenues, environmental taxation and building permissions) in their operations. Almost 80% of total data exploited by municipalities are "spatial data". Thanks to advancing technology municipalities are increasingly using geographic information systems (GIS), management information systems (MIS), and the Internet to carry out municipal tasks and services more efficiently. By combining many of the municipal services into an urban information system, the aim is to obtain service unity, reduce service costs and increase revenues.

Information systems differ from information technologies in that they involve people and their actions. Further, they incorporate a set of rational structures, processes and even culture and strategies for the operation (Campbell & McGrath, 2003). Thus, changes in the organizational context are required for information systems to operate rationally.

Considerable declines in the price of information technologies and the increased capacities of technological innovations in supporting municipal tasks and services have increased the implementation of urban information systems (UIS) in Turkish municipalities. Although considerable resources were allocated for UIS projects, a great many "implementation failures" are experienced due to the lack of required interest during the implemen-

tation process. Despite the promise of supporting the organizational rationality, the aim of many UIS projects is to get prestige. Municipalities tend to favor large, complex UIS projects supported by generous funding. But the continually changing political context brings an end to the projects started because of prestige, but not supported by organizational rationality.

In this context, Heeks's ITPOSMO model, based on conception-reality gap assessment, allows a suitable framework to reveal the mismatch between the concept of hard-rational design of information systems and soft political realities of organizations.

ITPOSMO DIMENSIONS OF INFORMATION SYSTEM

Richard Heeks's (1999) model of conception-reality gap assessment is an effective technique, which helps to illuminate the causes of an implementation outcome in organizations (Kouroubali, 2002). According to Heeks, there are conception-reality gaps in implementation process of urban information systems. Successful adoption depends on the size of these gaps: "the larger the gap, the greater the risk of failure" (Heeks, 1999, p. 59). After a review of a number of case studies, he concludes that gaps between conceptions and reality can be classified into seven categories summarized by the I-T-P-O-S-M-O acronym:

- **Information:** Provided by the system versus actual information needs, and the extent to which the organization can access the information.
- **Technology:** Technological capacity required for participation and actual technology capacity of target organizations.
- **Process:** Technology features in relation to existing processes.
- **Objectives and values:** In accordance with the objectives and values incorporated in the

system in relation to objectives and values of users.

- **Staffing and skills:** How well the system fits with human capability requirements.
- **Management and structures:** How well the system fits within existing organizational structures.
- **Other resources:** How available resources such as time and money match with required ones (Heeks, 2001).

Heeks's model of conception-reality gap based on ITPOSMO dimensions has a great value for the following case study section for three reasons:

1. Conception-reality gap assessment is derived from world-wide examples of IS implementations particularly from the public sector organizations and those of many developing countries;
2. ITPOSMO model has the value to being able to examine the reasons why the introduction of information system projects in similar organizational settings results in a various degrees of success or failure;
3. A knowledge base consisting of ITPOSMO dimensions creates opportunities to share and communicate the reasons of success and failure of different cases systematically.

Further clarifications on the pros and cons of the technique are discussed by Heeks elsewhere (Heeks, 2003).

BURSA URBAN INFORMATION SYSTEM (BUIS)

As mentioned in the previous section, efforts to implement Urban Information Systems (UIS) in Turkish municipalities are in infant stages so there is value in carefully documenting implementation process. The Bursa Urban Information System

(BUIS) was selected for study for three specific reasons:

1. the relatively longer experience of urban information systems (since 1996) in this situation creates a greater chance to observe changes through time based on ITPOSMO dimensions;
2. the availability of more financial resources, and municipality's ready acceptance of the wider implementation of various technological systems;
3. the funding obtained through an international donation-loan, professional consultancy and feasibility study provided a significant impetus for a detailed investigation.

Development of BUIS Project

With automotive and major textile plants, and foodstuff industry, Bursa is one of the prime industrial centers in Turkey. With its current population of 1.6 million, the city is the fifth largest in Turkey. In 1987, Bursa was granted the status of a "metropolitan municipality", encompassing three district municipalities under its jurisdiction.

Bursa Metropolitan Municipality wanted to use UIS for the planning and management of this rapidly flourishing city. With such a motivation, they began BUIS project with a GIS feasibility study conducted by U.S.-based firm "Psomas and Associates" between 1994-1996. Funding for the feasibility study was through "Trade and Development Agency" (TDA), an arm of the United States Department of State. The study had four major steps: needs assessment, study tour, pilot project and feasibility study/implementation plan (Henstridge, 1999). Meanwhile, an international fund provided Bursa Metropolitan Municipality with a loan from the World Bank for the planning, reconstructing, improving and managing the water and sewerage system of the city. After the completion of feasibility study, Intergraph won

the bidding to design and to begin implementing Phase-1 of the project in 1996. In order to provide an interactive system management, Intergraph established a branch in Bursa for the implementation process. Permanent staff members from the Metropolitan municipality and district municipalities of Bursa were assigned for the control of the implementation process from 1996 to 1998. Aside from Intergraph, three different companies that specialize in different categories of data collection and processing signed a contract within the same period. Since 1999, BUIS had been fully operated by local "urban information system division", which was responsible for operating the system, supporting other departments in the organization, and coordinating inter-organizational data sharing among respected local organizations.

ITPOSMO Dimensions of BUIS

Based on the results of field study, interviews, and corresponding materials, Richard Heeks's ITPOSMO model was examined for BUIS.

Information

As a rapidly urbanizing metropolitan region, Bursa is undergoing tremendous infrastructure expansion with associated land titling, land registration and environmental projects. In the implementation phase-1 (1996-1998), the information needs of BUIS were projected and four different firms were commissioned to produce spatial data (i.e., base maps, cadastre maps, etc.) and attribute data (i.e., building details, household data) through surveys and digitization of maps. Then, an inter-organizational network was established. Covering three metropolitan-district municipalities in Bursa, The Cadastre and Title Deed Office, Turkish Telecom, Bursa Natural Gas Company, the BUIS implementation succeeded in the coordination of data management (BUIS, 2003). It also provided a software application

developed for 182 “muhtars” (selected headmen of the villages), connecting them to the main system by wide-area network.

The conception-reality gaps for were as follows:

1. there was an absolute need for accurate and up-to-date data in the heart of all information systems. There were some serious problems in the currency of the data that threatened the sustainability of the project: e.g., since the international funding options were not available after 1999 the heavy costs of information maintenance (46% of total BUIS expenditures) became more prone to the political choices of decision-makers;
2. there were serious inefficiencies in the provision of attribute data by respected local bodies: e.g., muhtars were expected to update the database once in a week. In reality, only 20% of them succeeded in operating properly (Erarslan, 1997); and
3. information systems require a clear information management strategy to fulfill the organizational needs and objectives rationally. Yet, the fact that the needs assessments could not be completed by each municipal unit, meant that features of the information systems largely fail to address to the needs and objectives of the organization.

Technology

The hardware and associated GIS software was provided in the implementation phase of the project with the support of international donors. Both software and hardware are currently operational to perform municipal tasks and services. There is also a fiber-optic network connection between all municipal divisions and corresponding district municipalities.

The conception-reality gap was relatively low for the technology dimension but some issues still need to be improved. These include the coordina-

tion of municipal tasks and inter-organizational communication between local bodies, and better provision of municipal services which were the major aims of the BUIS. The telecommunications infrastructure in Turkey, however, is somewhat limited, therefore there some problems occurred in the provision of Web-based services. There was not a fully established network system in and between local public sector organizations and this made the sharing of data more challenging.

Processes

As proposed in the feasibility study, “Urban Information System Division” was founded under the Directorate of Public Works to support functioning of municipal services, in-house production and maintenance of information. Many municipal units adjusted their working processes according to BUIS. For example, citizens’ demand for fixing and maintaining of infrastructure system via telephone service was converted into a “task sheet” by local system operator and transmitted to maintenance crews working in the field.

Conception-reality gap was also low for this dimension. Yet, the absence of office automation reduced the opportunity of fully integrated work process that BUIS may have offered.

Objectives and Values

The feasibility report assumed objectives of greater efficiency through increased revenue generated from property tax collection, effective provision of utility services, control of urban development, and delivery of emergency health, safety and police services with BUIS project.

Some of the system objectives mentioned earlier were achieved. On the other hand, there were some problems increasing the size of this gap:

1. an urban information system is a costly investment and may only be profitable in the long run. It requires a strong political

and individual commitment to fulfill the objectives of the organization. In this respect, such factors as the international consultants, project contractors leaving at the end of the phase-1 of the project with the expiration of their contracts, international donors withdrawing their support, and the mayor, the founder of the BUIS, not being re-elected, reduced the chance of wide spread adoption of the system;

2. In terms of values, there was a “communications gap” between politicians and BUIS administrators in the determination of current and future needs of BUIS.

Staffing and Skills

Feasibility study paid great attention to training of the staff for the successful system implementation. In this context, consultants provided a comprehensive training program included hardware, software, and training of system administrators, chief managers and system operators.

Staffing and skill gap was not important for the BUIS. Sufficient attention was given to continuous training of the staff in information technology. But innovative use of software packages and re-inventing them for specific operations remained relatively small. This was largely because of the problem of public sector employment policy that neither computer skills nor individual productivity was encouraged and rewarded by the administrative system.

Management System and Structures

The design of BUIS proposed strategy to develop an appropriate structure aiming to increase the effectiveness of the organization and its service to its clients or public.

Since BUIS had a city-wide basis, some obstacles were encountered in the sharing and pro-

duction of the data originating from the country’s legal and administrative system:

1. the majority of applications in the GIS market were insufficient to fully perform the responsibilities and coordination role of Metropolitan Municipalities to the digital environment (BUIS, 2003);
2. there was an ongoing challenge between local bodies of central administration and Metropolitan Municipality in the sharing of information. As vital source of BUIS, for instance, cadastre maps were not available free of charge for Municipal organizations; and
3. there was also a conflict between Metropolitan Municipality and associated district municipalities in conjunction with their political stances. In some cases, district municipalities may establish completely different software packages or operating systems that interrupt the city-wide coordination efforts and cause economic loss due to the incompatible data production and exchange. BUIS suffers largely from these issues and the gap was higher for this dimension.

Other Resources

For the BUIS case, donor-aid made the money available for the feasibility studies and phase-1 of the project. The time schedule for training and implementation of basic features of the system worked for the first stage as envisaged in feasibility study. Also, some revenues were gained through the marketing of spatial data and digital maps prepared by the BUIS staff (BUIS, 2003).

But significant budget cut-offs were experienced in the second phase due to the lack of political support and wider economic recession in the country. Therefore, the conception-reality gap was gradually increased.

CONCLUSION

The result of the study indicates that several ITPOSMO dimensions namely “information”, “objectives and values”, and “management structures and systems” seem critical and may lead to “sustainability failure” for BUIS. Broadly, 15 years of GIS experience in Turkish Municipalities confirms that urban information system (UIS) implementation was neither based on a well-designed information management strategy nor utilized in long-run due to the ever-changing political context. A UIS generally incorporates a significant set of rational structures, process, culture, professional strategies and involvement. For this reason, almost all of the implementations realized that failure to complete the pre-requisite conditions and careful management of implementation process may face failure (Pick, 2004).

There is no recipe for success that might be advised to other institutions. But, freezing some ITPOSMO dimensions, getting them smaller and simpler and finding solutions by bringing them closer to organizational realities may open the way leading to a more successful implementation (Heeks, 1999). In this sense, the approach of incrementalism can be applied to avoid over-ambitious UIS projects, which carry high risks of failure. This approach recommends organizations to concentrate on limited applications, which directly meet perceived organizational needs. Such an approach is less vulnerable to organizational and environmental changes and political instability which are very important in developing country context.

Studies in GIS implementation problems especially in developing countries should become a priority issue (Ramasubramanian, 1999). Yet, currently few studies focusing on the institutional dimension of the technology are demonstrated in recorded case studies. In the research pyramid of GIS studies (Obermeyer & Pinto, 1994), institutional issues should be given more attention.

As a result, the evidence obtained from Heeks’s ITPOSMO model could be suitably extended and updated. This study will hopefully lead to further studies which address the soft organizational realities (cultural, structural, political, people factors) of urban information systems.

KEY TERMS

Communications Gap: Relates to that part of the knowledge gap which can be attributed to miscommunications between the parties involved (i.e., IT designers understand technology but not the realities of governance. Officials and politicians understand the realities of governance but not the technology).

Geographic Information System (GIS): A GIS is a computerized system for the collection, storage, manipulation, and output of information that is spatially referenced (Obermeyer & Pinto, 1994).

Land Information System (LIS): A GIS specially designed for use with land information. Land rights, ownership, boundaries, utility, land cover, and zoning data are common layers and attributes in a LIS.

Non-Spatial (attribute) Data: Data that relate to a specific, precisely defined location. The data are often statistical but may be text, images or multi-media. These are linked in the GIS to spatial data that define the location.

Spatial Data: Any information about the location and shape of, and relationships among, geographic features, usually stored as coordinates and topology.

Sustainability Failure: An initiative that succeeds initially but then fails after a year or so.

Wide-Area Network (WAN): A computer network that spans a relatively large geographical area. Typically, a WAN consists of two or more Local-Area Networks (LANs). Computers con-

Urban Information Systems in Turkish Local Governments

nected to a WAN are often connected through public networks, such as the telephone system.

They can also be connected through leased lines or satellites.

ABSTRACT

This chapter looks at the impact of the Internet on the worldwide human rights movement, and examines the opportunities and pitfalls of the technology and its applications for human rights organisations. It argues that the technology is a useful tool in nongovernmental efforts toward worldwide compliance with human rights norms despite the new challenges it presents for human rights defenders and activists, particularly in the South. Conceptualising the movement as a collection of issue-based social submovements, it draws on social movement literature and examples from Africa to describe how the technology and its ap-

plications benefit the movement in six key areas of activity. The promises, pitfalls, and difficulties of Internet usage are discussed, with particular emphasis on censorship, surveillance and privacy, and the challenges they pose for human rights activists operating in a digital environment.

INTRODUCTION

The worldwide human rights regime has been growing in legal, political, and moral strength ever since the adoption of the Universal Declaration of Human Rights in 1948. But it was only after the end of the Cold War that human rights law and discourse became prominent in local, national,

and international agendas, and a growing array of professionalised, nongovernmental organisations (NGOs) began to appear (Rosenblum, 2000). Human rights defenders and local activist groups can now look to these for moral and material support, and they in turn can mobilise advocates around the world to act on behalf of victims of abuse and oppression. Through the collective efforts of these individuals and organisations, states and other actors have been forced toward greater accountability, institutional structures have been set up, and a vocabulary of liberation has been provided for people all over the globe.

Human rights activists everywhere share a commitment to compliance with human rights norms that transcend nationality and particular cultural values (Shelton, 2002). Granted, the origins of human rights discourse in a Western, liberal tradition is often seen as either undermining its universal value (Kennedy, 2002) or contributing to its ongoing manipulation (Abdul-Raheem, 2005). But antiuniversalism is refuted by arguments against genocide, slavery, racial discrimination, and other grave forms of abuse (Li, 1996), and by the widespread support that the major international human rights documents enjoy among the states of the world today (Perry, 1997). Certainly, particularities of context are important, and it is only when asserted within each country's tradition and history that human rights can become a reality (Tharoor, 1999). Thus, instead of allowing Western actors to set the agenda, local human rights movements in Africa and elsewhere need to "build sustainable legitimacy through local presence and work" (Abdul-Raheem, 2005).

Today, the international human rights regime encompasses institutional actors such as the United Nations (UN); national legal systems and human rights bodies; national and international criminal tribunals; quasi-governmental truth commissions; international, regional, national, and local (grassroots) NGOs; and academics,

lawyers, educators, and activists all over the world (Ball, Girouard, & Chapman, 1997). It is becoming increasingly diverse not only because of the worldwide heterogeneity of cultures, subcultures, and contexts in which it operates, but also because the initial preference given to civil and political rights in the "western doctrine of human rights" (Cassese, 1986, p. 297) has waned. Equal attention is now given to economic, social, and cultural rights, and efforts are being made to place these on national and international agendas. There are also new global challenges to contend with: the integration of markets, the shrinking of states, increased transnational flows of information and people, the spread of cultures of intolerance, the decision-making processes of global institutions like the World Bank and multinational corporations (Brysk, 2002), and international terrorism. In response to these, the human rights movement—the worldwide community of advocates and activists working for the promotion and protection of human rights—has extended, evolved, and diversified. The lines between it and other civil society movements have become blurred, and human rights discourse now permeates, and often underpins, peace, conflict resolution, development, environmental protection, gender, health, and many other areas of civic concern.

The human rights movement has been described as "one of the most potent of contemporary social movements" (Cohen & Rai, 2000, p. 7) based on its implied universal logic. As with other international movements to which similar logic can be applied (such as the environmental movement and the women's movement), subnational, national, and regional struggles are often considered tactical, not strategic, interventions. But while individuals and groups may share an intellectual or moral commitment to the abstract ideal of human rights, Charlesworth (2002) notes that the interests of particular groups and individuals can differ dramatically. The diversity of the actors involved, ranging from a UN high

commissioner to grassroots activists, renders attempts to analyse it as a single monolithic entity fraught with difficulty.

States are the primary accountable parties in cases of human rights abuses, and violator states rarely change their behaviour without serious, consistent pressure from other states (Burgerman, 1998). The role that transnational networks of human rights groups and activists play in applying this pressure is an important one. Globalisation creates new opportunities to challenge states “from above and below” (Brysk, 1993), and one way in which human rights networks do this is through the use of information and communication technologies.¹ Indeed, at the 2003 World Summit on the Information Society (WSIS), the UN commissioner for human rights noted that ICTs are crucial to improving the enjoyment of human rights such as freedom of expression, access to information, privacy, the right to an adequate standard of living, education, health, and development (Jorgensen, Lindholt, & Lindholt, 2004). The Internet is one of the most important of these tools.² Just as the fax machine became a key tool for the human rights movement in the 1980s (Hick, Halpin, & Hoskins, 2000), e-mail and the World Wide Web became important in the 1990s. Similarly in the early 21st century, blogging (the continuous posting of information to a Web site)³ created an enormous opportunity for the worldwide dissemination of information about human rights abuses.

This chapter looks at the impact of the Internet on the human rights movement as a whole, and examines the opportunities and pitfalls of the technology and its applications. We conceptualise the movement as a collection of issue-based social submovements, and draw on social movement literature to outline the advantages and disadvantages of Internet usage by component networks and organisations. We then examine how the technology and its applications benefit the human rights movement in six key areas of activity. Examples of products and ICT initiatives are included, with

an emphasis on work being undertaken in Africa and less developed countries.

While ICTs like the Internet have an important functional role in human rights movements, as many of the examples in this chapter show, their value can easily be overjudged and is frequently overhyped. Technology is only a tool, and ICTs are simply a means to an end for human rights organisations. Since one of the most important considerations is the way in which human rights organisations use these tools to manage information, we look at how the Internet helps organisations to manage this most valuable of resources.

The promises, pitfalls, and difficulties of Internet usage for the human rights movement are numerous and varied. While we discuss these in general, the related themes of censorship, surveillance, and privacy deserve particular attention. In the context of the ever-increasing counterterror measures being adopted by states, these represent particular challenges to human rights activists and freedom of expression.

In conclusion, we identify a number of key issues that will impact on how the human rights movement can reap the potential benefits of the Internet and other ICTs. It is particularly important to ensure that the technology is used to amplify the voices of the victims of human rights abuse and oppression, and it is in this context that new policies and initiatives should be viewed.

UNDERSTANDING THE HUMAN RIGHTS MOVEMENT

The most common approach to dealing with the diversity that exists within the human rights movement is to conceptualise it as a collection of issue-based social submovements that seek political and/or social transformation (Cohen & Rai, 2000). The child rights movement, indigenous peoples’ movements, and antitorture movement are all examples of how a particular category of rights has been internationalised by the estab-

ishment of a global regime seeking to regulate behaviour on an issue. Like all social movements (as defined by Diani, 1992), they are made up of networks of individuals, groups, and organisations who are formally independent, who understand themselves to have common interests, and who assume a common identity for at least some significant part of their social existence.

The study of social movements has benefited greatly from the application of a network perspective (Diani & McAdam, 2003; Friedman & McAdam, 1992; Gould, 1993). This is the approach taken by Burgerman (1998), who uses the concept of transnational issue networks developed in Keck and Sikkink (1998) to analyse human rights advocacy. She sees networks as single interconnected entities, operating at both international and domestic levels, and made up of individuals and agencies that are connected to each other by shared values, a common discourse, and dense exchanges of information and services. Transnational human rights networks can influence state practice through these exchanges, but for this to happen, domestic human rights activists and the “micro-sites of resistance to practices of power, often disarticulated with reference to the global” (Baxi, 2000, p. 35) must somehow keep their cause on the international agenda and provide information to their international allies (Burgerman, 1998).

While the big emancipatory human rights movements like the women’s rights movement and the gay rights movement are still in existence, there has been a greater tendency in recent years toward the formation of networks and movements around a single campaign, or with a specific objective. The international network that built up in support of the Ogoni people of Nigeria in the 1990s is a good example of this. The Ogoni, an ethnic minority living in the Niger River Delta region, were demanding increased political power, economic justice, and control over natural resources. The Movement for the Survival of the Ogoni People (MOSOP) organised the Ogoni

and brought world attention to their conflict with the Nigerian government and the international oil company Shell. MOSOP and international organisations such as Amnesty International, Human Rights Watch, Greenpeace, and Friends of the Earth worked together to support the Ogoni efforts and to provide support to human rights defenders inside the country (Bob, 2005).

In Africa, there are a number of understandings of the term social movement (Clarke Brill, 2005), all of which are in evidence in this example. The term is used to refer to broad movements like the human rights movement that work for change on an issue. It is also used to refer to a grouping of people who are not heavily involved with an organisation and who may not see themselves as activists; they are often people like the Ogoni who are faced with oppression in their own everyday lives. Finally, it is used to refer to particular organisations that have a strong representation of people who are oppressed, poor, or experiencing human rights violations first hand. MOSOP and the Treatment Action Campaign (TAC), a postapartheid South African organisation that campaigns for greater access to AIDS treatment by raising public awareness of the issues involved, are good examples of these.

Within the global human rights movement, all of these movement types exist and interact in increasingly complex webs of movements within movements and networks within networks. For example, the child rights movement contains issue-related movements that focus on child labour, children in armed conflict, the sexual exploitation of children, and so on. It also contains global organisational movements like the Child Rights Information Network (CRIN; <http://www.crin.org>), which covers the broad issue of child rights but with a strategically limited scope of activities. CRIN disseminates information about the Convention on the Rights of the Child⁴ and child rights in general amongst NGOs, United Nations agencies, and other institutions. It has a membership of 1,550 organisations in over 125 countries

(Yates, 2005), amongst which there are divergent, and occasionally incompatible, information needs (Halpin, 2003a, 2003b). In this respect, it is typical of a growing number of organisations that service the information needs of the ever-expanding human rights community.

The number of international NGOs active in the area of human rights has increased substantially since the early 1990s (Ishay, 2005; Keck & Sikkink, 1998; Smith, 1997). Organisations like the membership-based Amnesty International (<http://www.amnesty.org>) mobilise transnational resources to act on a wide range of human rights abuses, and often set up their own internal issue-based networks. Others like OMCT, the World Organisation against Torture (<http://www.omct.org>) coordinate and support global networks of local, national, and regional NGOs fighting against specific forms of abuse.⁵ These international NGOs play a role in international policy networks and work with other like-minded NGOs to ensure their campaigns reach the widest possible audiences. There has been a trend toward increased connectedness of these international NGOs through the 1990s (Kaldor, Anheier, & Glasius, 2003), but formal collaboration between them is a relatively new development. For example, it was as recently as 1997 that the Association for the Prevention of Torture (APT) began organising meetings at its headquarters in Geneva to bring together international NGOs to improve the coordination of torture prevention, direct action, and rehabilitation. The broadest antitorture “coalition network” (Diani, 2003, p. 10) in existence today, CINAT (Coalition of International NGOs Against Torture), was only formed in 1999.

The international NGOs strive to bring international pressure to bear on states and to exert influence at the intergovernmental level. Because of the closer relationship that is developing between these NGOs and the United Nations, they are in a position to undertake research on issues under consideration by the Commission on Human Rights and other bodies; to assist in the drafting of

its decisions and resolutions; to supply verified, up-to-date data; and to act as intermediaries between the larger NGO community and the United Nations (Maran, 1998). They have a broad constituency and can impact directly and indirectly on national and international legislators, diplomats and officials, and the public at large. They also fulfill another important function, which is to reinforce grassroots NGOs and to support the development of domestic human rights movements. These tend to work locally and are less concerned with the potential of UN accreditation and lobbying than with the plight of people in their own area. They collect, record, and report information about what is happening in their own country. They also ensure that their societies are working toward long-term human rights protection by building and motivating local actors and networks to advocate for change, and they press governments to live up to their formal commitments. This is often done at great personal risk as human rights defenders draw unwanted attention to the illicit actions of the state or its agents, and seek to bring about unwelcome reforms.

THE IMPACT OF THE INTERNET ON SOCIAL MOVEMENTS

ICTs and especially the Internet have transformed the capacity of social movements to build coalitions and networks and to advocate for causes, principles, and other people (Hick & McNutt, 2002). They help to share information and place it within contexts while retaining editorial control over information content and external communication (Scott & Street, 2001). They also allow groups and organisations to mobilise beyond their constituency and to precipitate real-world activities. They can be cost efficient, and they allow for high impact without the need for major resources.

The Internet reduces the need for central communication and top-down information flows

within social movements, making it suited to a nonhierarchical structure (Selian, 2002; Wasserman, 2005). Using the Internet, action can be organised in a decentralised way, even across borders. This opens up opportunities for local organisations, giving them national, regional, or global reach and impact. The Internet also facilitates the convergence of divergent organisations with different goals and strategies (Cammaerts & Van Audenhove, 2003), something that is important in human rights movements. It also allows the creation of new network organisations in which smaller organisations pool their information, thus greatly increasing participants' access to information resources and outlets. News of crises can be spread very quickly to highly interested and energetic people, and there can be equally speedy support for the movement. This can create opportunities for spontaneous global, collective action to supplement planned activities on the ground.

The frequent underestimation of the importance of ICT-based networks by governments has made them excellent tools for undermining efforts at censoring information entering or leaving a country. One of the best examples of how movements can successfully bypass state control and communicate in a secure environment using ICTs are the ongoing efforts of Falun Gong practitioners to highlight human rights abuses in China. According to the Falun Dafa Information Centre in New York,⁶ more than 28,000 cases of serious human rights violations were reported up to March 2004.⁷ The majority of these were sent by e-mail or fax despite China's all-encompassing surveillance network (Garden Networks, 2004), and the media and information blockade imposed by the Chinese government in all cases relating to Falun Gong (Amnesty International, 2000; Srinivasan, 2004). Practitioners outside of mainland China have also been using the Internet to break through the country's great firewall and to communicate with practitioners inside the country; the tools and technologies used include

e-mail, chat rooms, peer-to-peer technologies,⁸ and proxy servers.⁹

However, despite the great promise they hold for social movements and networks, ICTs are no more than an "opportunity structure" (Cammaerts & Van Audenhove, 2003, pp. 8-9). As a means of communication, the Internet can assist activists to mobilise participation by augmenting existing communication methods and overcoming their limitations (Wasserman, 2005). However, the notion that it will bring about radical changes in the way social movements and organisations are ordered is questionable. Agre (2002) and other proponents of the amplification theory contend that the Internet changes nothing on its own, but that it can amplify existing forces, which may, in turn, bring about change. The Internet serves to enlarge and accelerate processes already in place in societies and organisations rather than create entirely new forces. Even Selian (2002), who presents a more utopian view of the power of new communication technologies to bring about social change (which she defines as the enhanced awareness and protection of human rights in the international system), concedes that the way in which power is governed and managed by those who control and regulate various communications apparatus is a decisive factor.

According to Manji, Jaffer, and Njuguna (2000), all technologies have a natural proclivity to amplify inequalities, and the Internet is no exception. By the middle of 2005, only 14.6% of the world's 6.4 billion people had access to the World Wide Web (Internet Usage Statistics, 2005). The global divide in access to information technology is currently widening, but Norris (2001) suggests that over time the gap is likely to shrink as in the case of older communication technologies like the telephone, radio, and television. However, she goes on to say that in relation to the worldwide social divide, which is about income, education, class, gender, and race, the Internet reflects and thereby reinforces, rather than transforms, society.

While ICTs are important for the global participation and visibility of marginalised groups such as resource-poor communities, indigenous peoples, immigrants, and refugees (Sassen, 2004), there are two necessary preconditions. One is the preexistence of social networks built through cross-border communities of activism and practice, academic sharing, migration, organisational links, and so on. The other is the availability of adequate technical infrastructure, applications, and expertise to make it happen. In fact, the latter is a three-stage problem (Surman & Reilly, 2003). First there is the fundamental problem of access: Adequate and reliable bandwidth is necessary, as is a computer with an Internet connection, an Internet café in which one is free from surveillance, or a cell phone with SMS (short-message service). Then there is the adoption and development of basic skills needed to use the technology. Finally there is appropriation or strategic use, where a movement turns the technology to its own purposes, making it its own.

Online networks promise and can deliver inclusion, but there is a need for more conscious and concerted attempts to develop online spaces that are interesting, informative, and inclusive. Web sites like Kubatana.net (<http://www.kubatana.net>), which allows Zimbabwean activists to provide information resources and perspectives on the current social and political situation in the country, are a valuable public space for civil society in general and human rights movements in particular. Described by Bev Clark (2005) as a “one stop shop for information,” it aims to improve access to human rights and civic information in Zimbabwe at a time of great political unrest. Global Voices Online (<http://cyber.law.harvard.edu/globalvoices/>) is another example; it is a nonprofit global citizens’ media project that uses a wide variety of technologies including Weblogs, wikis,¹⁰ podcasts,¹¹ online chats, and other techniques to bring attention to points of view from around the world.

Social movements have been making effective use of electronic mailing lists since the early

1990s. They have been used to promote causes and campaigns, to keep in touch with networks, to collaborate on projects, and to share information and experiences. They were also used, and continue to be used, to create a sense of solidarity and community. The Womenslink mailing list that linked women’s organisations in Northern Ireland and the Republic of Ireland (O’Donnell, 2001) was a case in point. But for many organisations, the time and costs involved in hosting and maintaining a list is still not feasible. For this reason, organisations that have the skills and capacity to host and maintain mailing lists and listservs¹² do so on behalf of smaller, less resourced groups. National and regional organisations like Kabissa (<http://www.kabissa.org>), which provides African organisations with accessible, affordable, and secure Internet services (including Website hosting and discussion groups) enable civil society organisations in less developed regions to use ICTs effectively. They host network mailing lists for organisations that want to facilitate and encourage information sharing or coalition building, and newsletter mailing lists for member organisations that simply want to send regular or irregular mailings to interested parties.

While e-mail, mailing lists, virtual communities, and other forms of computer-mediated communications can create new links, strengthen existing links within networks, and sometimes even facilitate the formation of new activist networks and discussion groups, they can also change the rules, the physical context, and the content of communication, and make cooperation agreements extremely fragile. Many of the success stories of online networks have happened when the primary focus was on sharing tactics, information, or other resources. For example, African gender groups have used ICTs very effectively to establish links and to share resources across geographical and cultural borders (Wasserman, 2005). This is helped by the efforts of regional networks like WOUNET, the Women of Uganda Network (<http://www.wougnnet.org>),

which promotes the use of ICTs as a tool to help groups address gender issues collectively. But for long-term, close collaboration where building togetherness and confidence is important, face-to-face communication systems are still superior to computer-based alternatives. Nonetheless, the WOUGNET experiences show that building capacities in ICTs can help expand the reach and activities of a network.

HOW HUMAN RIGHTS MOVEMENTS BENEFIT FROM THE INTERNET

Notwithstanding the limitations to its effectiveness within social movements, Hick et al. (2000) state and demonstrate in their book, *Human Rights and the Internet*, that “[t]he Internet is changing the operation of human rights organisations, their use of information, and the relationships between them” (p. 8).

Organisations are using it as a tool for their professional activities, but individual human rights activists and advocates are also using it to fight directly against abuse. The uses are numerous, varied, and often innovative as access to technology and training grows.

Information Dissemination

There are a number of identifiable and overlapping areas in which human rights movements can benefit from Internet usage. The first is information dissemination. Human rights workers and domestic grassroots groups use the Internet to supply rapid, accurate, and cheap information about human rights violations to as wide an audience as possible. The traditional media, especially radio and television, may be most effective in informing local communities of a human rights violation, but any mention of it in the traditional foreign media is likely to be in newspapers that appear several days after the event (Katz-Lacabe & Lacabe, 2000). The Internet, on the other hand,

can provide an almost instantaneous dissemination of news to a wide audience, thus helping the chances of attracting global attention and getting a faster international response to a human rights abuse. While human rights organisations continue to use the traditional media, the Internet also allows human rights activists to publish more of their information.

Shahjahan Siraj, a former online editor of *Banglarights.net* (<http://www.banglarights.net>), an independent Web portal that exposes and challenges discriminations and violations of human rights in Bangladesh, wrote that “ICT, [e]specially [the] Internet, used in collaboration with human rights activism, creates virtual alternative tunnels for the free flow of uncensored information within and out of [a] country” (Siraj, 2005, p. 26). In recent times, blogging has made it easier for human rights activists to disseminate information about abuses and to reach a potential audience of millions. Organisations like Human Rights Watch (<http://www.hrw.org>) and Global Voices Online provide numerous RSS feeds¹³ on human rights issues, usually classified according to theme and region, and updated several times daily.

All around the world, journalists and activists document and blog human rights abuses on a daily basis. Blogs like *Realidades Colombianas* (<http://lacoctelera.com/realidades>), which covers the guerrilla war, working conditions, freedom of the press, poverty, child labour, and other issues in Colombia, provide well-researched, critical reports on the happenings in the writer’s country. Others like *Sudan: The Passion of the Present* (<http://platform.blogs.com/passionofthepresent/>) are a resource for communities like those in Darfur who are experiencing daily suffering and oppression.

Blogs are particularly important in countries where the traditional press is under the control of the authorities. Human rights activists are using them to combat censorship and circulate independent news and information, and they have become a powerful tool for freedom of expres-

sion. They are easier to set up than a normal Web site, and can be adapted, configured, and altered without special expertise (although installation can be a little tricky). While organising content is not a problem, engaging the audience it reaches can be. To gain an international audience, the choice of blog community is important, as is the frequency and quality of posts, and the technology used to ensure the blog gets picked up by the main search engines. Nonetheless, content syndication, where a blog's author makes all or part of its contents available for posting on other Web sites, is becoming a far more efficient way of disseminating information than e-mail lists and electronic newsletters.

Locally, the Internet also assists in the distribution of information. For some grassroots human rights activists who find it difficult or dangerous to receive hard-copy reports, accessing them in electronic format can be an effective solution (Whaley, 2000), despite the fact that filtering and blocking techniques used by state authorities often make it difficult for human rights organisations to download or even display online information.¹⁴ Civil society information portals like Kubatana.net, which contains information that is accessible and relevant to local individuals and groups and is actively promoted, can increase the flow of information and news within a country where it is often difficult to access diverse views and opinions.

Taking Action

Disseminating information about human rights violations is the first step in human rights activism; the second and most essential step is action. The Internet is a good place for human rights organisations to encourage action, but it depends on timely and reliable information. Jamie Metzl highlighted this in the 1990s: "...accurate and timely information is an indispensable tool to human rights and an essential precondition for effective responsive action and the promotion of

human rights, whether by organisations, individuals, governments or international institutions" (Metzl, 1996, p. 706).

The Internet helps make the responsive action of human rights activists more effective in three ways. First, it is used to promote traditional forms of off-line action such as letter writing, home government lobbying, and so forth. Second, it has provided opportunities to develop new forms of online action. Third, it is an ideal medium for the sharing of tactics.

Electronic urgent-action mailing lists have been operated by organisations such as Derechos (<http://www.derechos.org>) and Amnesty International for many years. Their objective is to encourage people to send letters and faxes, and to make telephone calls to those responsible for human rights violations. As well as facilitating faster and cheaper distribution, these allow organisations to reach a wider range of international supporters and to issue targeted action appeals. They also allow recipients to take advantage of computer applications to draft letters and to send faxes.

Nowadays, Internet-based activism is becoming more popular than the traditional forms of action. E-mail is taking over as the preferred mode of response for human rights activists to urgent-action appeals. In a survey of key South African Amnesty International activists, conducted at a meeting in July 2004, 64% of the 28 respondents said they were most likely to respond to an urgent-action alert by e-mail, 23% said they would post a letter, and 9% said they would send a fax (Lannon & Halpin, 2005). Organisations like Amnesty, whose main support base is amongst those with access to new technologies, have had to take cognizance of this trend.

Legitimate human rights organisations also engage in other forms of cyberactivism¹⁵ or "normal, non-disruptive use of the Internet in support of an agenda or cause" (Arquilla & Ronfeldt, 2001, p. 241). They do this primarily by organising online petitions and e-mail actions targeting government authorities. Other more disruptive tactics, gener-

ally referred to as “hactivism” or electronic civil disobedience (Wray, 1999), are sometimes used by independent human rights activists or groups acting alone; these include tactics like the July 2005 virtual sit-in organised by the Electronic Disturbance Theater against anti-immigrant Web sites.¹⁶ However, these tactics raise questions about ethics and the limits of freedom of expression on the Internet, just as civil disobedience tactics like blocking a road do in the real world (Katz-Lacabe & Lacabe, 2000).

The Internet is also used by human rights organisations to share information on tactics. A good example is the online database set up by the New Tactics in Human Rights project (<http://www.newtactics.org/>). The project, led by a diverse group of international organisations and human rights practitioners, aims to promote tactical innovation and strategic thinking within the international human rights community. As well as the tactics database, they also provide an electronic newsletter for periodic updates and an online discussion forum in which human rights advocates can discuss their experiences.

Organising, Supporting, and Protecting Human Rights Defenders

A third benefit of the Internet in human rights work is that it helps to organise, support, and protect human rights defenders. It does this by providing a means of communication between human rights workers and NGOs that is cheap, instant, and easy to use. Front Line, an international foundation for the protection of human rights defenders (<http://www.frontlinedefenders.org/>), claim that people have been able to contact them from hiding using e-mail, and that the Internet has enabled them to get fast lobbying done in cases where people were imprisoned and in danger of being tortured. Indeed, part of their work is to provide technical assistance to human rights defenders in countries like Tunisia, where access to technology and freedom of association and expression

are scarce, so that they can record human rights violations and provide information quickly and directly when they are at risk (Lannon, 2002).

Human rights defenders face the same computer risks as other users, including virus attacks, equipment breakdown, difficult physical environments, spamming, and hacking. During a workshop on information technology, electronic communications, and security at Front Line’s 2003 Platform for Human Rights Defenders conference, participants highlighted the need for simple solutions to day-to-day problems like these. They also discussed how governments and other actors that are determined to undermine their work create problems for human rights defenders through surveillance, interception of e-mails, reading of computer files, deletion or distortion of information on Web sites, and identifying them as spammers to service providers (Front Line, 2003; Guerra, 2003).

One of the solutions developed to counteract these problems is the Martus human rights bulletin system (<http://www.martus.org/>). This is a free and open source technology tool that allows grassroots human rights defenders and activists to document human rights abuses quickly and securely. Anyone with basic experience of e-mail can record incidents; these are stored and replicated in multiple locations to safeguard against possible loss and attacks. Human rights groups can even decide what to make public and what should be kept private as they monitor and strive to reduce incidents of human rights abuse (Paik, 2005).

In Guatemala, where the widespread impunity for past human rights abuses has been seen as a major factor in a wave of new abuses, a number of NGOs have used Martus to help secure and protect information relating to events that took place during the pre-1996 civil war. Other projects include the Arizona Coalition against Domestic Violence’s compilation of reports of murder-suicides in domestic-violence disputes, and ongoing efforts by the Human Rights Commission in Sri

Lanka to monitor human rights violations in the north and east of the country.

Ultimately, what human rights defenders need is the ability to perform routine monitoring as this is more reliable than recording after a human rights crisis has exploded. New convergent technologies like mobile blogging and audio blogging (posting audio to a blog from a phone) have great potential in this area. Mobile blogs or “moblogs” that can be updated remotely from anywhere using a mobile phone or digital assistant can provide human rights defenders with the ability to record and disseminate information about human rights violations as they occur.

Finally, the importance of testimonies given or recorded by human rights defenders in advocacy work (McLagan, 2003) provides another basis for ICT usage. The use of testimonies grew in the 1990s, and with the advent of ICTs came new opportunities for recording and archiving. One of the more recent forms is video; footage has been used in courts, tribunals, legislative and executive bodies, and human rights commissions, as well as by the media and transnational organisations and solidarity networks. The online Witness archive (<http://www.witness.org/>) is one of the best sources of video advocacy material; it now consists of more than 1,000 hours of raw footage documenting a vast range of human rights abuses. Local human rights defenders in nearly 50 countries shot these, and they feature first-hand testimonies, interviews, and imagery about rights violations and conflict sites around the world.

Research and Analysis

The Internet is also a valuable research tool for human rights workers. Researchers now use it to retrieve information published by other organisations, to cross-check information with other research groups, and to make their own work available to the human rights community. Even for the general public, Web portals like Human Rights Internet (<http://www.hri.ca/>)

and Banglarights.net can be efficient sources of information on a region, country, or specific human rights issue.

The Web has also become a valuable source of information from local newspapers about background data on legal or economic questions, and about intergovernmental and governmental reports (Whaley, 2000). There is also a growing number of online repositories of human rights information, including databases and documentation centres¹⁶ that provide details of human rights treaties and conventions, case law collections, human rights impact assessment reports, and so on. Some, but not all, recognise that those wishing to access online resources may have limited technology and expertise; they may have unreliable or low bandwidth, or be working with old tools (such as an old version of a Web browser). Even still, attempts to survey what is available over the Internet can be a daunting task for human rights practitioners, given the amount of information and the breadth of online sources. Search engines and Web portals are now making the task of finding required information easier; dedicated human rights search engines like HURISEARCH (<http://www.hurisearch.org/>), which is hosted by the Swiss-based Human Rights Information and Documentation System International (HURIDOCS),¹⁷ provide a single access point to all human rights information published by organisations worldwide.

While search engines and Web portals have greatly improved the retrieval of published human rights information, the electronic exchange of data and information¹⁸ within the human rights community is less clear cut. In some cases there are nontechnical issues like confidentiality, privacy, and the safety of human rights defenders to keep in mind. In other cases there are tactical reasons why organisations are not willing to share information; it may form the basis for a report that is due for release at a later date, or there may be donor-driven demands to keep in mind. Sharing can sometimes be of great benefit; however, if

organisations telling the same story pool their information, they can build a more complete picture of an event and ultimately a more forceful case against the perpetrators.

The key to the successful sharing of data and information within the human rights community is the use of standards. Clarity and meaning is important when human rights information is being shared (Halpin & Hick, 2000); even the inconsistent use of terminology like *inhuman treatment* and *persecution* can be a problem. Language is the most obvious reason for inconsistency, but quite often the difficulty is that the information is not sensitive or relevant to the local culture. HURIDOCS and other organisations have done a lot of work to address this through the development of event reporting standards (Dueck, Guzman, & Verstappen, 2001a) and thesauri (Dueck, Guzman, & Verstappen, 2001b). As more and more of the available information is stored as digital resources, the use of embedded metadata¹⁹ with information about victims, types of abuse, places, and so forth becomes an important consideration.

Human Rights Education and Training

A fifth benefit of the Internet is in human rights education and training. Claude and Hick (2000) explain that human rights education is about more than information dissemination; it is helping people “to analyse the world around them, understand that human rights are a way to improve their lives and the lives of others, and to take action to prevent human rights violations” (p. 226). There has been a growing need and demand for training human rights organisations over the past number of years. As a result, there are now many examples of formal online human rights education programs where documents and lessons are provided online. Planned learning processes, centred around or supplemented by these, are designed to develop awareness of human rights

and the capacity to act to further human rights aspirations (CEDAL, 1996).

Human rights education is defined by Flowers (2000, p. 35) as “all learning that contributes to the knowledge, skills, and values of human rights.” It includes information dissemination, but it is a much more complex process that requires cognitive, emotional, and active learning (Mihir, 2004). Human rights education resource centres like the Human Rights Education Associates (HREA) Web site (<http://www.hrea.org/>) now go beyond the provision of teaching material for formal education and training of professional groups like the armed forces, human rights monitors, and health professionals. They also include online forums and links to other organisations and resources, and are designed to address the needs of nontraditional education sectors like community leaders and NGOs.

A collection of Web-based visual aids for human rights learning published online by HREA presents an interesting example of how the Internet can contribute to emotional learning.²⁰ It consists of an annotated compilation of photographs, paintings, drawings, prints, sculptures, and mixed media on human rights themes (Jawad, 2003), and was put together in order to further human rights learning through the viewing of such images and the environments in which violations take place. The images depict a variety of topics including war, genocide, child labour, and torture, and were created by people of all ages and nationalities.

Human rights education involves analysis through reflection on one’s own situation. The mere gathering of knowledge is not enough for this; there also needs to be an awareness-building process, day-to-day examples, experience, and reflection (Freire, 1995).²¹ A good example of how the Internet and other ICTs can be used to meet this challenge is Pambazuka News (<http://www.pambazuka.org/>), a weekly newsletter and platform for social justice in Africa. According to its editor, Firoze Manji of Fahamu (<http://www.fahamu.org/>), it is a response to the social divi-

sion “that prevents the experiences of the greater part of humanity from being heard, and which, therefore, under-nourishes the discourse of those who do not have access to the technology” (Manji, 2005, p. 13). It helps organisations to find information and to disseminate their own material online by organising it into categories that reflect the subjects of concern to the constituency (these include human rights, refugees and forced migration, women and gender, health and HIV/AIDS, and education). But, in keeping with the need for emotional and active learning, Pambazuka News has also become a tool for advocacy in Africa. As part of the campaign for the ratification of the protocol on the Rights of Women in Africa, for example, two special issues were produced profiling important aspects of the protocol. In 2004, it also exploited the potential of the growing mobile phone market for social change; a system was developed to enable mobile phone users to sign an online petition, and an SMS service was developed to send information on the protocol to people who wanted to subscribe to the service (Manji, 2005).

The informal human rights education that was traditionally supplied by the media is also being greatly enhanced by participation in online news-groups, chat groups, and various forms of civic journalism, including blogging. Marginalised and disadvantaged communities are now being supplied with human rights education materials from centralised online sources like Kubatana.net in Zimbabwe, or the Peoples Movement for Human Rights Education (<http://www.pdhre.org/>). The latter has even developed an innovative Human Rights Cities initiative to examine traditional beliefs, collective memory, and aspirations as related to the Universal Declaration of Human Rights.

Networking and Connectivity

Another very important benefit of the Internet for human rights movements is in networking.

Formally constituted networks can have their own Web site, giving members the opportunity to discuss and share information. Even mailing lists and newsletters like Pambazuka News can help create a sense of community with other human rights activists and facilitate joint projects with other like-minded individuals and organisations (Katz-Lacabe & Lacabe, 2000). They also provide the opportunity for discussion with experts or people in the human rights field who may have specific expertise or knowledge.

Human Rights Internet claims that it communicates by phone, fax, mail, and the Internet with more than 5,000 organisations and individuals around the world working for the advancement of human rights.²² While most of these will probably never engage in direct online communication with each other (not least because of the cost involved), there are plenty of international, regional, and national networks where online information flows between members are important. Networks like the Human Rights Network in Uganda (<http://www.hurinet.or.ug/>), whose mission is to build stronger linkages and cooperation between human rights groups, use the Internet as one of the mechanisms to achieve this. Interorganisational networks like these are nonhierarchical, and collectively and individually the members benefit from the increased exposure that a Web presence gives them.

Another aspect of the Internet that is proving to be of great benefit to some human rights activists and workers is Internet telephony or voice over IP (Internet protocol). One of the best-known service providers, Skype (<http://www.skype.org/>), provides a free program for making free calls over the Internet to anyone who also has Skype. This is a cheap and convenient way for activists to communicate, providing they have the bandwidth to support it. Without broadband access, however, its value is severely limited. Because the majority of the world’s population does not have broadband access, they do not get to make free calls (Burnett, 2005).

THE IMPORTANCE OF INFORMATION

While ICTs like the Internet have an important functional role in human rights movements, their value can easily be overjudged and is frequently overhyped. Technology is only a tool, and ICTs are just a means to an end for human rights organisations (Ball et al., 1997; Fleming, 2002; Manji, 2005). One of the most important considerations is the way in which these tools are used to manage information, since this is at the heart of what they do (Weyker, 2002). Coupled with the need to communicate, collaborate, and organise, it should provide the basis for ICT investment within human rights organisations.

The ability to access background information, training material, and other documentation online is an important asset to human rights organisations. From a network or movement perspective, being able to share information is equally important. Gauthier (2000) notes that in parts of the world where there is a lack of resources to set up and access traditional documentation centres, being able to feed data into online documentation centres where it can be analysed, classified, and redistributed means organisations are not working in isolation. To be usable, these centres must be well organised, of course, and ideally they should use standard formats to store and present information. HURIDOCS guidelines for recording information about human rights violations (Noval, 1993) are now being used by human rights and like-minded organisations all over the world, including large organisations like the UN High Commissioner for Refugees and the Council of Europe, NGOs like Amnesty International, and smaller groups. However, a lot more needs to be done to ensure consistent and effective management of human rights information throughout the movement.

While the Internet facilitates the gathering and dissemination of information, it does not help in its analysis. In fact, its use can contribute to another problem if the information is not managed properly: that of information overload. There is now more information available through which to build a campaign than ever before (Stoecker, 2000), but finding it, sifting it, evaluating it, and using it can be a time-consuming distraction. Search engines, Web portals, well-organised databases, and RSS aggregators all help, but for human rights organisations that have floods of electronic information pushed toward them, it is becoming increasingly necessary to “weed out or edit lower quality documents, ensure that action is coordinated, that the source is accurate, that follow-up is completed, and that processing is done effectively” (Sottas & Schonveld, 2000, p. 79).

When dealing with information online, reliability can also be a problem for human rights activists and organisations. The Internet environment lends itself particularly well to fabrication and distortion of information, anonymous information, and plagiarism (Chabanov, 2004; Dahlberg, 2001; Warnick, 1998). Some organisations might even be tempted to exaggerate the extent of human rights violations because of the competition for grants. There is even a concern that human rights data are viewed by some organisations as a private, commercial commodity to be used primarily for raising the organisations’ own fundraising potential (European Co-ordination Committee on Human Rights Documentation [ECCHRD], 2001). Because of this, the circulation of information in open networks is in some cases diminishing rather than growing.

A lack of objectivity can also be a problem with many online information sources. Blogs, for example, generally represent one person’s views, and while they often offer valuable commentary and insight into denials of human rights, their content cannot always be viewed as independent or impartial.

AUDIENCE BUILDING AND THE INTERNET: PROMISES AND PITFALLS

In Africa, the average cost of a local dial-up Internet account for 20 hours a month in 2005 was about \$60 (including call charges). This is higher than the average African monthly salary (Manji, 2005). Nonetheless, despite the high initial costs necessary for the purchase of equipment and the price of connecting to the telecommunications network, Gauthier (2000) saw the Internet as providing African human rights organisations with a new method for working under very difficult conditions.

There are a variety of service-provision options and alternatives for human rights NGOs seeking to take advantage of ICTs. One is e-riders (<http://www.eriders.net/>), an ICT consultancy solution for small, mission-focused NGOs that cannot afford a full-time technology support person.^x There are also projects that provide recommendations and software distribution based on a grassroots approach, such as NGO-in-a-Box (<http://www.ngoinabox.org>). This provides CD box sets of tools and materials based on the experiences of informed practitioners and field experts, and aims to tackle two primary issues: appropriate software selection, and access to such software and related documentation (Tactical Technology Collective, 2005).

One of the primary goals of NGO-in-a-Box is the promotion and distribution of free and open source software (FOSS) to the nonprofit sector. The free software concept, which refers to the user's freedom to run, copy, distribute, study, change, and improve the software (Lutfy, 2004), is based on the notion of adding to what others have done before. Like the human rights movement, it strives to remove restrictions on freedom, cooperation, and information sharing.

While ICTs, and in particular the Internet, are unrelated and irrelevant to the daily struggles of many poor and oppressed communities, they can

still be useful for representative NGOs. Wasserman (2005) indicates that for the TAC, an organisation that appeals to the middle class despite its roots in the poor communities, the Internet has been instrumental in establishing and maintaining an important support base. Using the Internet to reach elites means it can build capacity, even beyond activist circles. However, in giving some groups increased access to elites, transnational human rights networks, funding agencies, and other key players, the Internet can sometimes create a greater disparity between the ICT haves and the have-nots. Unlike their counterparts in the North who benefit greatly from the instantaneous flow of information over the Internet, the majority of the Southern hemisphere, and in particular sub-Saharan Africa, lags behind in terms of technological development. There, NGOs often have extremely limited access to telephone lines, let alone computers or international connections. Out of necessity, therefore, Southern NGOs often allow their larger Northern counterparts to set the agenda and make key decisions. Thus, while ICTs like the Internet aid collective decision making, they also serve to concentrate power within a few organisations that collect human rights information and transmit it between the local groups and the transnational community.

Another difficulty faced by human rights movements and organisations is information protection. According to the Benetech Institute (2001), which developed Martus, much of the data collected by human rights groups never reaches its full potential or intended audience because a large part of it is lost. Reasons for loss include confiscation or destruction, neglect, passage of time, and lack of resources within grassroots groups to document and communicate violations systematically and securely. Computers eliminate some of these but introduce other risks like equipment failure, user errors, computer viruses, power surges, and arson attacks. While training and support for grassroots groups is part of the solution, other measures such as off-site storage

must also be considered. Here again, the Internet becomes useful by providing the basis for software tools like Martus, which allows users to back up human rights data over the Internet to a secure server located in a different part of the world.

CENSORSHIP, SUIVEILLANCE, AND SECURITY

Given the sensitivity of much of what they possess and the threat it could pose to the authorities, human rights organisations in many parts of the world are vulnerable to deliberate external attack. These attacks can take the form of communications interception, monitoring of activities, or physical raids by state agents or others opposed to the organisation's work (Mobbs, 2002)

In a February 2002 *New York Times* article, the human rights writer Michael Ignatieff (2002) observed that since September 11, 2001, the strength and relevance of the human rights movement has been under threat. In the post-September 11 reshaping of international order, human rights has been disconnected from questions of national security (Wilson, 2005), and their protection has been demoted by states all over the world in the interests of a worldwide "war on terror." Freedom of expression has also suffered; while it was not in an ideal state before September 11, there has been a vast increase in detentions and domestic spying powers over the past 5 years, justified as a part of the war on terror (Bhagwat, 2005). In Syria, Iran, Zimbabwe, China, Uganda, Tunisia (which hosted the second phase of the World Summit on the Information Society in 2005), and scores of other countries, the authorities censor the media and impose restrictions curtailing freedom of access to information, freedom of association, and freedom of movement of human rights defenders. Even in countries of the democratised West, including the United Kingdom, Australia, and the United States (where it is now permissible for the authorities to request all kinds of personal

and private information), antiterrorism legislation severely restricts the freedom of speech of those who question or oppose government policy.

The expansion of counterterrorist activities has also accelerated the rise of a more bureaucratic cybercontrolled society (Ishay, 2005). Most authoritarian regimes now have the technical means to censor the Internet. Material deemed to be illegal or subversive is automatically blocked by filters in countries like Vietnam, where it is not possible to access Web sites that criticise the government, expose corruption, or talk about human rights abuses (Reporters Without Borders, 2005). While activists and bloggers are increasingly making use of the Internet, e-mail, and text messages to publicize human rights abuses, organise protests, and exchange political information and ideas, Human Rights Watch (2005) reports that in many countries like Iran, the government regularly detains and imprisons online journalists, bloggers, and Web-site administrators.

In environments like these, human rights organisations need to be particularly vigilant about their information security. As Mobbs (2002) notes, those seeking covert access to an organisation's information repositories will be often deterred by good access barriers because of the additional time required to circumvent them. However, when the state acts, it does not have this problem. It works openly and generally has the staff and specialist tools to gain access. Still, while securing an organisation's premises, computer room, storage devices, and data files does not provide protection, these access barriers can provide vulnerable NGOs with time to take other action, like calling legal assistance or alerting international solidarity networks.

Governments can also easily intercept electronic communications. They can do this by trapping transmitted information packets at publicly accessible Internet nodes through line tapping or disclosure by Internet service providers, or by intercepting the main lines that connect their country to the rest of the world. To protect

transmitted information and messages from being read or altered, encryption, a means of encoding information so that it cannot be decoded without a “key,” has become a necessary and seamless part of e-mail usage and Web browsing.^y However, there is now a real danger that the use of difficult-to-crack encryption technologies for the electronic transmission of information may be outlawed. Criminalizing the unauthorised use of these strong encryption products is a threat to the work of human rights organisations as the Internet becomes a more integral part of how they operate (Lane, 2000; Marthoz, 2002).

New tools and techniques are being developed and deployed to address the security needs of human rights defenders and groups. These include Web-based services to allow sending and receiving secure e-mails (Hushmail at <http://www.hushmail.com> is one example), proxy servers and anonymous Internet communication systems that protect Web browsers against Internet surveillance (such as Tor, <http://www.tor.eff.org>),^z and firewall tools to protect against unauthenticated access from the outside world.^{aa} Without these, activists working hard to secure human rights might actually be jeopardizing their cause as well as the safety of individuals they are trying to protect (Mladen, Guerra, & Young, 2002). Within the human rights movement, the cost of leaving information unprotected, or of transmitting communications without privacy and security, can often be very high.

CONCLUSION

Despite globalisation, ICTs, and the tremendous expansion of the human rights regime, international attention to human rights issues remain “spotty” (Bob, 2002). On the one hand, the Internet offers the potential to address this imbalance by providing grassroots organisations with the opportunity to create global awareness and strengthen their own efforts. On the other, the ability to exploit its

potential is linked to the infrastructure, resources, and skills at the organisation’s disposal, and the freedom they are allowed to exercise their own rights to organise and communicate.

Efforts to reduce the gap between communities who can make effective use of ICTs and those who cannot is seen as essential for development (United Nations Development Program [UNDP], 2002). In this context it can also be viewed as essential for the enjoyment of human rights, particularly economic and social rights. As these rights are inextricably linked to all other rights, including civil and political rights, the use of ICTs to increase civic engagement and to challenge oppressive and discriminatory state practices is also a fundamental component of development for all.

Internationally, the human rights movement has always been quick to explore new opportunities presented by ICTs. Human rights NGOs that enjoy widespread moral and financial support have, over the decades, used fax machines, e-mail, Web sites, and aggregated news feeds to disseminate targeted information, rally popular outrage, and bring pressure to bear on norm-violating governments. In open societies, human rights initiatives have benefited from the increased visibility provided by ICTs (Ishay, 2005). The fast, global spread of images of abuse in Abu Ghraib prison, Iraq, in April 2004 showed how new forms of information dissemination lead to international outrage and ultimately to effective pressure on the perpetrators of the abuse.

International network movements like CRIN and OMCT offer grassroots organisations online information, expertise, and solidarity. But for domestic movements of people living in poverty and experiencing human rights violations first hand, accessing these resources is not always easy. While ICTs make it possible to maintain links and share resources across geographical and cultural borders, NGOs need to be skillful at using limited bandwidth effectively. The difficulties are compounded by restrictions imposed on democratic social movements, and in particular

human rights movements, which have increased since September 11, 2001. Even when human rights defenders do manage to get online (often at great risk to themselves and those whose rights they are defending), it can be hard for them to be heard amongst all the “noise” in cyberspace. Knowing what to do with sensitive data, who to send communiqués to, and how and where to post information are all critically important. For groups who are working to build their cases, being able to access online information efficiently can be a major factor in how successful they are. Without the training and support that enable them to do all these effectively, attempting to use the Internet can be like walking into a marketplace blindfolded.

The international intergovernmental and non-governmental organisations have a role to play in helping grassroots human rights activists use the Internet effectively. They need to be cognizant of the resources that are at the disposal of their partners in developing countries: in their Website design and e-mail transmissions, as well as in their content management. They need to avoid crowding out the weaker participants in the online human rights networks, and to provide a space for everyone to contribute to the human rights discourse. The use of ICTs to communicate and inform implicitly favours the dominant voices of the North. For this reason alone the global human rights movement needs policies and initiatives that promote a more egalitarian use of ICT resources so that grassroots organisations and activists can ensure the movement remains relevant to their struggles.

Overall, the Internet helps human rights movements to bring greater pressure to bear on norm-violating actors. It does this through targeted information flows, and new and increased levels of activism. It allows more data to be gathered and recorded securely, and it provides access to background reports and information. It also presents greater opportunity for organisations to pool resources and to benefit from the experiences and

expertise of others in the movement. But organisations in the South need help in overcoming access, adoption, and appropriation problems. Developing expertise within local and regional NGOs on how to gather human rights data in a secure environment, analyse the data themselves, build their own databases, and exchange information if and when they wish to is crucial. It is also important that everyone in the human rights movement uses a common language to exchange human rights information; if everyone is using the same words, then data can be collected more efficiently, and information can be accessed more easily.

Organisations like HURIDOCs started working on standards for human rights event reporting in the 1990s. It now needs to be taken a step further by looking at new Internet technologies and opportunities for data gathering and information exchange. This includes the use of metadata to embed usable data into normal Web pages in order to link human rights information from sources all over the world. Using the right technologies, human rights organisations telling the same story with different information can potentially pool together their information and build a more complete picture of what is happening in any part of the world.

Ultimately, one of the keys to the effective use of the Internet by human rights organisations is the development of the necessary information management and research skills within the movement. What is important is not the technology; it is being able to define relevant information, to know how and where to seek it, and to have the capacities and skills to use it. Organisations should not base strategies on technology, but rather they should identify their information needs based on an understanding of what they can manage. The processes they put in place in support of strategic objectives should allow them to take advantage of technologies like the Internet, but the tools should not dictate the strategy.

Further research is required into whether or not technologies like the Internet have made a

difference to information and communications flows within human rights movements. One way to do this might be to look at new advocacy movements such as those working on rights issues surrounding HIV/AIDS and compare them to the pre-Internet movements like antitorture. Without question, there are other factors at play in determining the strategies and tactics adopted by these newer movements, but the role of the Internet is one that cannot be discounted.

ENDNOTES

¹ Information and communication technologies is a broad term, usually understood to encompass all the technologies that facilitate the processing and transfer of information and communication services.

² The Internet refers to both the technical infrastructure of worldwide digital networks, and the use to which this infrastructure is put. Current uses include, but are not limited to, sharing computer resources independently of location, distributing and accessing information via the World Wide Web, and communicating using electronic mail, distribution lists, and newsgroups.

³ A Weblog or blog is a personal Web site on which information is posted by an individual, as in a diary. Postings in a blog are typically arranged in chronological order, with the most recent additions at the top of the page. The activity of updating a blog is known as blogging.

⁴ The Convention on the Rights of the Child was adopted by the United Nations General Assembly Resolution 44/25 on November 20, 1989.

⁵ OMCT is the world's largest coalition of nongovernmental organisations fighting against arbitrary detention, torture, extrajudicial executions, forced disappearances, and other forms of violence. Its global network includes almost 300 local, national, and regional organisations.

⁶ Falun Gong is also known as Falun Dafa.
⁷ S. Chinn, Falun Dafa Information Centre, New York, personal communication, March 24, 2004

⁸ Peer-to-peer technologies refer to networks in which computers can share information without having to go through a third computer (server).

⁹ A proxy server is an intermediary between a Web user and the Internet. One of its main functions is to keep the user's local area network secure through the use of firewall software. It is also useful in cases where anonymity is needed since it hides the local network and user's identity.

¹⁰ A wiki is a collection of Web pages that can be created and edited by anyone through a browser. The term comes from the Hawaiian term *wiki wiki*, meaning rapidly.

¹¹ The term podcasting comes from an amalgam of Apple's *iPod* and *broadcasting*. It is a method of publishing files to the Internet and allowing the receipt of new files automatically using an iPod device. It is used mostly for audio files.

¹² A listserv is a communication tool that

offers its members the opportunity to post information, comments, or questions on predetermined topics and discussions to a large number of people at the same time. When something is posted to the listserv, it is distributed to all of the other people on the list.

¹³ RSS (really simple syndication) is a family of file formats for Web syndication of information links that is used by news Web sites and blogs. Internet users or other Web sites can subscribe to Web sites that provide RSS feeds of information of interest to them instead of browsing to find the information.

¹⁴ For a comprehensive description of censorship and how to circumvent it, see *Reporters Without Borders* (2005).

¹⁵ Alternatively called electronic advocacy, netactivism, and e-advocacy (Hick & McNutt, 2002)

¹⁶ A virtual sit-in consists of people using software that automatically requests a Web page over and over in an attempt to make the Web page unavailable to other users. According to the Electronic Disturbance Theater, over 27,000 people took part in the July 2005 action. See <http://www.thing.net/~rdom/ecd/ecd.html> (retrieved February 24, 2006).

¹⁷ A database is a collection of records held on a computer. It contains structured information organised in a consistent manner. A documentation centre, which may or may not be computer based, contains free-form text information. Databases are organised in such a manner as to facilitate searching for a particular record or set of records, whereas documentation centres rely on cataloguing and/or classification of documents to make information retrieval possible.

¹⁸ HURIDOCS is a global network that facilitates the handling, dissemination, and exchange of information by other human rights organisations. It functions as a decentralised

network in which human rights organisations can handle information according to their own requirements. It also develops tools and techniques for information handling and provides support for the establishment and maintenance of information systems and documentation centres by other organisations (<http://www.huridocs.org/>).

¹⁹ Data are raw materials that are used to produce information; information is data that has been organised, processed, and interpreted so one can draw conclusions and understand implications.

²⁰ Metadata are data about data. They describe how, when, by whom, and in what format data were recorded. Metadata are added in a Web page or stored in a database; they are available for searching but are not displayed.

²¹ See http://www.hrea.org/erc/Library/display.php?doc_id=1257&category_id=18&category_type=3 (retrieved February 13, 2006)

²² Cited in Mihr (2004)

²³ See <http://www.hri.ca/about/intro.shtml> (retrieved December 20, 2005)

²⁴ Ungana-Afrika, a South African service provider, is one example of an organisation providing e-rider solutions (<http://www.ungana-afrika.org/>).

²⁵ While the integrated use of encryption techniques such as pretty good privacy (PGP) can successfully hide the content of a message transmission, they do not always guarantee complete anonymity or protection. For example, most e-mail programs that use PGP will encrypt the message contents but not the details of the sender or recipient that are contained in the message header.

²⁶ Tor uses a concept known as “onion routing,” which takes the idea of proxy servers to an additional level of complexity. Each request made through an onion-routing network goes through 2 to 20 additional randomly selected

Human Rights Movements and the Internet

computers, making it difficult to discover what computer originated a request (taken from Reporters Without Borders, 2005).

²⁷ The security edition of NGO-in-a-Box (<http://security.ngoinabox.org>), prepared by Front Line Defenders and the Tactical

Technology Collective, includes most of these tools. This project provides a variety of FOSS to help organisations and individuals improve their computer and information management operations, stability, costs, and security.

Chapter 5.31

Learning IT: Where do Lectures Fit?

Tanya McGill

Murdoch University, Australia

Samantha Bax

Murdoch University, Australia

ABSTRACT

Lectures are the traditional method of content delivery in undergraduate information technology degrees, yet concerns have been raised about their effectiveness. This chapter addresses the role of lectures within information technology (IT) degree programs from a student perspective; it examines the factors that influence lecture attendance, and student perceptions of the usefulness of a variety of possible lecture activities. Overall, the results suggest that students see the lecturer as contributing significant value to their learning experience through the lecture setting. Students appear to value the expertise of the lecturer and find activities that can best make use of the lecturer's expertise the most useful. The results also suggest that students recognize the impor-

tance of active learning within the constraints of traditional learning settings.

INTRODUCTION

The traditional lecture is one of the most common forms of teaching, and has long been the primary method of formally introducing subject material to the student population (Kumar, Kumar, & Basu, 2002), as well as providing opportunities for lecturers to guide students on how to study the courses' content (Khan, 1997). Yet the lecture is also considered to be one of the least effective forms of instruction for students (Bligh, 1972; Felder, 1992; Johnston, Moffat, Sondergaard, & Stuckey, 1996). Some problems reported with the lecturing approach include that lectures can

promote passivity, feelings of isolation (Isaacs, 1994; Rosenthal, 1995) and boredom (Mukherjee, 2000). This could make them ineffectual as an approach to learning.

Despite these concerns and the increasing availability and popularity of online education (McCormick, 2000; Peffers & Bloom, 1999), the lecture is the traditional method of learning in undergraduate IT degrees and is still the standard for IT courses (Griffiths & Oates, 2003; Lynch & Markham, 2003). This raises the question of what the role of lectures can and should be within an IT degree program. The study described in this chapter meets Khan's (1997) call for more research on students' perceptions of the importance and benefits of attending lectures and explores the opinions of a group of IT students; examining the factors that influence their lecture attendance, and their perceptions of the usefulness of a variety of possible lecture activities.

BACKGROUND

The majority of on-campus IT students today are assumed to attend lectures, which provide the main method of introducing IT content to students. However, lecture attendance is rarely mandatory and varies from course to course, with anecdotal evidence suggesting that there is a trend towards lower attendance. This lower attendance may reflect students' dissatisfaction with lectures as a tool for learning, but may also reflect the changing nature of student life, with students facing many competing demands on their time and requiring flexibility in learning.

Many lecture sessions take the format of traditional 'talking head' lectures. One concern associated with the passivity a lecture can encourage is that students who are not actively participating (whether physically or mentally) have a reduced level of concentration after the first 10 to 15 minutes of a lecture (Stuart & Rutherford, 1978), after which the amount of information retained by the

student declines (Bligh, 1972). McKeachie (1986) reports that after a lecture, a student recalls 70% of the information presented in the first 10 minutes, but only 20% of the information presented within the last 10 minutes of lecture time.

Schank (1998) asserts that it is a difficult task to listen while someone else (i.e., the lecturer) talks, with the best case scenario being that a student will think about what has just been said, and then miss the points that follow in the lecture. What is required for learning to take place is for the student to stop listening and process what they have just heard before continuing with further points in the instruction (Rodger, 1995; Schank, 1998). Schank (1998, pg 23) goes so far as to state that, "lecturing is antithetical to learning."

In addition to problems with concentration and information retention, traditional lectures do not easily accommodate discussion, yet dialog and discussion are considered to be important elements in the promotion of higher-level cognitive processing (Mannison, Patton, & Lemon, 1994). Levels of effectiveness in learning are believed to be directly related to the participation of the student, with students tending to retain much more of the material when their engagement with it is high—that is, when they are active learners rather than passive members of an audience (Dale, 1969).

Not all lecture sessions are alike. Lecture sessions may be utilized in a number of ways. In addition to the traditional 'talking head' session, today's IT lecture can involve multimedia demonstrations (e.g., Fagin, 1994; Makkonen, 1998; Robling & Freiseben, 2000), interactive case study analysis (Mukherjee, 2000), role playing exercises (Lynch & Markham, 2003; McConnell, 1996) and in-class problem solving (Rodger, 1995), as well as more unorthodox lecturing approaches, such as class singing as suggested by Siegel (1999). What these approaches have in common is an attempt to introduce active learning to the lecture situation.

One of the most common modifications to the traditional lecture format has been online availability of lecture notes. To reduce the amount of time students spend taking notes and hence make time available for more active learning, many academics have advocated making lecture slides available online prior to the lecture (e.g., Wirth, 2003). However, concerns have been expressed that online availability of lecture notes promotes lower attendance to the detriment of students concerned (Hunter & Tetley, 1999; Khan, 1997; Roosenburg, 2002).

While ideas for teaching innovations abound, very little empirical evidence is available to support them. This chapter addresses the role of lectures within IT degree programs from a student perspective. It explores the opinions of a group of IT students, examining the factors that influence their lecture attendance, and their perceptions of the usefulness of a variety of possible lecture activities.

THE STUDY

This study was conducted by survey. Participants in the study were students enrolled in a second-year IT course at an Australian university. They had experienced at least 1 year of IT lectures already, and these lectures would have been in classes of various sizes with a wide variety of lecturers. Participants were recruited during the first lecture of the semester and completed a questionnaire on the spot. It was stressed that completion of the questionnaire was voluntary and that it formed no part of their assessment in the course.

The first part of the questionnaire collected background information about participants and information about their lecture attendance. The participants in the study were 113 students (78.8% male, 21.2% female), with an average age of 24 (minimum age of 18 and maximum age of 49). The students were from two campuses of the univer-

sity; 73.5% attended the larger main campus and 26.5% attended a smaller regional campus.

Students believed that they had attended around 80% of lectures during the previous semester, with a range from 5% to 100% attendance. Given anecdotal reports from academic staff who had previously taught this cohort of students, this average attendance figure might be an overestimate; however, it is consistent with figures reported by Hunter and Tetley (1999).

The second part of the questionnaire included questions that sought to determine the factors that influence whether students attend lectures. A list of factors that have been proposed to influence lecture attendance was provided and participants were asked to indicate if each factor influenced whether they attended lectures. The list of factors that have been proposed to influence lecture attendance was drawn from the literature (e.g., Hunter & Tetley, 1999; Isaacs, 1994; Khan, 1997; Roosenburg, 2002). Table 1 includes the list of factors.

The questionnaire also asked about student perceptions of the role of lecturers. The final questions asked students to rate the usefulness, in terms of their learning, of each of a list of possible lecture activities. This list was also drawn from the literature (e.g., Mannison et al., 1994; Mukherjee, 2000; Rodrigues & Atchison, 1996; Rosenthal, 1995; Wirth, 2003). The lecture activities were rated on a 5-point scale, where 1 was 'not useful' and 5 corresponded to the activity being 'extremely useful.' The Appendix contains a copy of the questions asked.

RESULTS AND DISCUSSION

Factors Influencing Lecture Attendance

Various factors have been proposed to influence lecture attendance. Clashes with other classes are an obvious one, because if a student has more

than one class scheduled for a particular timeslot, clearly they can be present only at one of them. The time of day in which a lecture is scheduled has been cited as a factor affecting lecture attendance by Khan (1997), who states that lectures timetabled for early morning or late afternoon appear to have a lower level of attendance. As discussed earlier, online availability of lecture notes is another factor that appears to affect lecture attendance, leading to a decrease in attendance as students have an alternative means of accessing at least some of the information provided in lectures (Hunter & Tetley, 1999; Khan, 1997; Roosenburg, 2002). The lecturer’s style of teaching has also been suggested as a factor influencing lecture attendance, with approximately 50% of students citing poor-quality lecturing as a reason for non attendance in Khan’s (1997) survey. The quality and accessibility of textbooks is another factor that has been suggested as a factor influencing attendance. It is considered that students will attend lectures to gain additional explanation and illustration of concepts presented within the text, especially if the textbook is difficult to understand or presents new or complex material.

Table 1 shows each of these factors ranked from most influential to least influential. Surprisingly, the style of the lecturer’s teaching was the most commonly cited determinant of lecture attendance (57.4%). This result is consistent with Khan’s (1997) comment that students will be attracted to well-prepared and delivered lectures that are engaging, easy to follow and relevant to

their studies. However, this result also implies that while the student may consider that a lecture adds value to his or her learning experience, if the style of the lecturer is not one that suits the student, attendance will fall.

The time of day at which the lecture is scheduled was ranked second (40.7%) among the five factors influencing lecture attendance. This appears to be consistent with Khan (1997), who noted that students prefer classes that are not scheduled during late afternoon or early morning.

Online availability of lecture notes was ranked third among the factors (32.4%) influencing lecture attendance. While not the most influential factor, online availability of lecture notes played a major role in influencing whether or not approximately one-third of the students attended lectures. This is consistent with the results of Hunter and Tetley’s (1999) study of the reasons for nonattendance of lectures. Nevertheless, a substantial proportion of students (67.6%) were not influenced by availability of online lecture notes and presumably believe that attending lectures can add further value to their learning experience.

Clashes with other classes were ranked fourth (30.6%). This relatively low ranking may result from careful lecture scheduling in the past, ensuring that a minimal number of classes are timetabled for the same timeslot for this cohort of students. However, a lecture at which some of this data was gathered was inadvertently scheduled to clash with two other classes during the semester, and this fact was noted by a number of students within the comments section of the survey.

Table 1. Ranked list of factors influencing lecture attendance

Rank	Factor	No. responses citing factor	Percentage of responses
1	Lecturer’s style of teaching	62	57.4
2	Time of day lecture scheduled	44	40.7
3	Online availability of lecture notes	35	32.4
4	Clashes with other classes	33	30.6
5	Quality and accessibility of the textbook	22	20.4

The quality and accessibility of the textbook was the least-cited determinant of lecture attendance (20.4%). This may indicate that many students believe that the lecturer adds substantial value to the material available to them, regardless of the quality of the textbook. It may also be that attendance is influenced by a number of these factors in combination. For example, the quality of the textbook might not be such an influential factor if the related lecture notes are available online.

The results were further examined to determine whether gender, age or the campus a student attended had an influence on the factors determining lecture attendance. Possible differences due to gender, age or campus were explored using chi-square tests, as the variables were all measured on nominal scales. Significantly more male students than female students identified teaching style as an influence on their attendance ($\chi^2(1) = 5.004$, $p = 0.025$). One explanation for this is that female students are more likely to view lectures as adding value to their learning regardless of teaching style. However, an alternative explanation might be that lecture attendance meets other needs of female students, such as face-to-face interaction before and after the lecture presentation. No other gender differences were found.

Age appeared to have a significant effect on whether the time of day the lecture was scheduled influenced lecture attendance. Approximately 31% of the sample was at least 24 years old and these students were less influenced by the time of day at which the lecture took place ($\chi^2(1) = 10.137$, $p = 0.001$). It may be that older students, having made the decision to return to study, are more dedicated to completing the course than younger students, and so they will attend the lectures regardless of the time at which they are scheduled. Further research is required to confirm this possibility. No other age differences were observed, nor were any differences noted between the two campuses regarding factors that influenced students' attendance.

Students also identified other factors that might influence lecture attendance. These included the length of the lecture (the lecture for the course in which the survey was administered was at this time scheduled for a 3-hour block, and the majority of students were noted as being opposed to this) and the students' work commitments. However, several students noted that they would always attend lectures both as a preparation for the tutorial work and as an aid in staying up to date within the class, while others claimed laziness and lack of motivation as other factors influencing their attendance at lectures.

Role of the Lecturer

Students were asked to indicate whether they consider the role of lecturers to be 'to teach you' or 'to help you learn.' Despite being asked to select the statement that most accurately reflected their perceptions, a number of students selected both statements. Thus, 19.4% considered the role of lecturers to be to teach students, 51.9% considered it to be to help students learn and 28.7% considered the role of the lecturer to be that of both teaching and helping the student to learn. The results indicate that lecturers are increasingly considered to be guidance or learning support personnel, indicating that students at university have a heightened sense of responsibility for their own scholarship. Thus, student-centered learning appears to be a goal being accepted by university staff and students alike (e.g., Griffiths & Oates, 2003; Lynch & Markham, 2003; McConnell, 1996; Mukherjee, 2000; Rodger, 1995).

Possible differences in perceptions of the role of the lecturer due to gender, age and the campus attended were examined using the chi-square test. While the majority of students saw the role of lecturers to be primarily to help students learn, significantly more male students than female students ($\chi^2(2) = 7.507$, $p = 0.023$) still believed the role of lecturers is to teach students (25% of male students compared to 0% of female students).

Thus, female students appear to have accepted the responsibility for their learning more readily than male students. This is consistent with the gender difference in response to teaching style discussed above. That is, the lecture attendance of female students is less likely to be affected by their perception of the lecturer’s teaching style.

No significant differences were noted between age groups for the perceived role of the lecturer. It thus appears that a student’s view of the role of the lecturer does not significantly change as they mature. This result is surprising, given that older students might be expected to take a more mature and self-motivated approach to learning (Piccoli, Ahmad, & Ives, 2001).

A significant difference did exist however, between the two campuses of the university ($\chi^2(2) = 6.433, p = 0.040$). A much larger percentage of students attending the smaller regional campus (35.7%) considered that the role of the lecturer was to teach them, compared to 13.8% of the students at the main university campus. This result was surprising, as we had anticipated that students attending the larger, more anonymous lectures at the main campus would be predisposed to seeing their own role as a more passive one. However, the difference may be due to the students at the regional campus having a more traditional working class background, and hence being less familiar and comfortable with the technological innovations that tend to support student-centered learning.

Lecture Activity Usefulness

The final part of the questionnaire asked students to rate the usefulness, in terms of their learning, of each of a list of possible lecture activities. All suggested activities were ranked relatively high, indicating that students want more than just the traditional style of lectures. Table 2 shows each of the activities ranked by perceived usefulness.

The lecture activity identified as most useful to learning was practical demonstration. The fact that a number of students also specifically commented that they would like to see practical or ‘real-life’ applications of the theory covered within lectures provides further evidence of this. The importance of the use of real-world illustrations of course material has also been highlighted by Orngreen and Bielli (2002), Mukherjee (2000), and Rodrigues and Atchison (1996).

Reviewing of exam questions was ranked second in terms of usefulness as a lecture activity. This result may be related to the students’ recognition that reviewing exam questions is a useful revision aid for the current lecture topic, particularly when having access to the knowledge of the lecturer while the revision activity is occurring. This result highlights how focused students are on passing courses. With increases in education costs, this is to be expected.

Coverage of the topic material was listed as the third most useful lecture activity. Despite the increased flexibility in approaches to study available to students, many appear to still consider the

Table 2. Perceived usefulness of lecture activities

Rank	Lecture activity	Mean	SD	Min.	Max.
1	Practical demonstrations	4.47	0.74	1	5
2	Reviewing previous exam questions	4.29	0.90	1	5
3	Coverage of topic material	4.12	0.88	1	5
4	Questioning the lecturer	3.78	1.04	1	5
5	Class discussion	3.64	1.06	1	5
6	Videos/Multimedia	3.58	1.04	1	5
7	Small group activities/exercises	3.49	1.05	1	5

lecture, and its related additional explanations and clarifications, as a valuable addition to their learning.

Questioning the lecturer was considered fourth in usefulness as a lecture activity. This is further evidence that students view the lecture as an opportunity to add value to their learning experience, and that the expertise of the lecturer is considered to be a significant addition to both their lecture time as well as to their education.

Class discussion was ranked fifth. This relatively low ranking of class discussion as a lecture activity can be explained by the fact that many IT classes are large (Johnston et al., 1996), and group discussion is impractical for large groups. Many students feel uncomfortable expressing themselves in a large public setting, and it is difficult to hear individual contributions within a large lecture theatre. In addition, in Australian universities, class discussion is traditionally an activity performed during tutorial classes. Thus, undertaking an activity already being completed within other learning sessions may not be considered by students to be a useful activity during lecture time. Despite this, Rodger (1995) reported on the value of class discussion in IT lectures, stating that, "Although less material is covered during class, students obtain a deeper understanding of this material and can expand on this understanding outside of class" (p. 278).

Use of videos and multimedia was ranked second lowest. Computer-based activities are perhaps perceived as activities that students can undertake on their own time. Thus, time during lectures could be better spent in activities that are less flexible time-wise and that can take advantage of the expertise of the lecturer while he or she is present. The lowest-ranked lecture activity was that of small group activities and exercises. This result might be explained by small group activities also being prevalent within tutorial classes, and thus the students may not consider this to be a useful addition to the lecture timeslot.

Overall, it appears that activities that provide access to the knowledge and expertise of the lecturer are those most valued during the lecture timeslot. However, it also appears that the students wish to have a greater control of these activities to ensure that the activities undertaken during lecture time suit their perceived needs.

The responses were further examined to determine if differences occurred in perceptions of the usefulness of the suggested lecture activities based on gender, age or the campus surveyed. This analysis was undertaken using independent sample t-tests. The results indicated that on average females overall ranked most of the activities as more useful than males (except for practical demonstrations). However, the only significant differences existed for small group activities/exercises ($t = 0.276$, $p = 0.007$) and questioning the lecturer ($t = 2.35$, $p = 0.021$). This may be an indication that females desire a more personalized approach to learning, relative to their male counterparts. However, more research is required to further explore this finding.

Videos and multimedia were seen as significantly more useful additions by students who were younger (younger than 24 years of age) ($t = 2.35$, $p = 0.021$). One explanation for this finding may be that younger students are more comfortable with the use of technology in education and, hence, perceive it to be more useful. However, future research is required to better clarify this finding.

The only significant difference in preference for lecture activities between campuses was that of class discussion ($t = -0.201$, $p = 0.047$), where the students attending the smaller regional campus indicated this as a more useful lecture activity. This difference can be explained by the fact that class discussion during lecture times is more feasible with the smaller class sizes of the regional campus.

CONCLUSION

The results of this research suggest that students can see the importance of attending lectures, and that they see the lecturer as contributing significant value to their learning experience through the lecture setting. Students appear to value the expertise of the lecturer, and wish to take advantage of this knowledge during lecture time. Thus, despite the influence of the lecturer's teaching style on attendance, the activities that can best make use of the lecturer's expertise are those most preferred to be undertaken during the lecture timeslot.

It also appears that the role of the lecturer is perceived as more than just that of a teacher. Many students have adopted a student-centered view of education and perceive the role of the lecturer as facilitating their learning. The results of the study also suggest recognition of the importance of active learning within the constraints of traditional learning settings. Active learning has received attention among both trainers and academics for its role in aiding learning (Mukherjee, 2000) and encouraging students to become self-directed learners throughout their lifetimes (Meyers & Jones, 1993). Therefore, it should be a goal of all lecturers to involve active learning in their lectures.

This chapter attempted to explore the role of lectures within IT education. As discussed above, many students do see the importance of attending lectures, and see the lecturer as contributing significant value to their learning experience through the lecture setting. However, if lectures are to continue to play a role in IT education, they must facilitate active learning in ways that are appropriate for the size and nature of the course. Given the prevalence of online availability of lecture notes, and the flexibility this provides to students, lecturers must ensure that lecture sessions provide added value. They must provide varied opportunities for students to take advantage of the lecturer's expertise, and

also encourage students to become active and self-directed learners.

Chapter 5.32

Information Technology Certification: A Student Perspective

Tanya McGill

Murdoch University, Australia

Michael Dixon

Murdoch University, Australia

ABSTRACT

Certification has become a popular adjunct to traditional means of acquiring information technology (IT) skills, and employers increasingly specify a preference for those holding certifications. This chapter reports on a study designed to investigate student perceptions of both the benefits and risks of certification and its importance in obtaining employment. Certification was perceived as an important factor in achieving employment and students undertaking it anticipate that it will lead to substantial financial benefits. Yet, higher salaries are not seen as the most important benefit of certification. The potential benefits that students believe are most important relate to 'real-world' experience. The respondents were aware of the possible risks of certification but did not appear to be overly concerned about them.

INTRODUCTION

Certification has become a popular adjunct to traditional means of acquiring IT skills, and increasing numbers of job advertisements specify a preference for those holding certifications. Certification intends to establish a standard of competency in defined areas. Unlike traditional academic degrees, certifications tend to be specific to narrow fields or even to individual products. They are designed to provide targeted skills that have immediate applicability in the workplace.

Vendors such as Microsoft and Cisco Systems dominate the vendor-specific certification market worldwide, with qualifications such as the Microsoft Certified Systems Engineer (MCSE), Cisco Certified Network Associate (CCNA) and Cisco Certified Internetwork Expert (CCIE). Vendor-neutral certifications, such as those provided

Information Technology Certification

by the Institute for Certification of Computing Professionals (ICCP), the Computer Technology Industry Association and the Disaster Recovery Institute, also play a role. It has been reported that there are more than 300 IT certifications available and that approximately 1.6 million people have earned approximately 2.4 million certifications (Nelson & Rice, 2001), and no doubt these figures have already increased dramatically. Gabelhouse (2000) quoted an IDC Inc. report that found that the IT training and testing industries had revenues of \$2.5 billion in 1999 and were expected to reach \$4.1 billion by 2003.

Vendors create certifications as a way of promoting widespread adoption of their products and technologies, but they have also become important for educational institutions in attracting students and placing graduates (Brookshire, 2000). This chapter explores the perceptions of students who are undertaking courses of study that can lead to certification. It reports on a study designed to investigate student perceptions of both the benefits and risks of certification and its importance in obtaining employment.

Benefits of Certification

Numerous benefits have been proposed to result from IT certification. As Nelson and Rice (2001) note, many of the claims of benefits have originated in the brochures and Web sites of certification agencies; however, there also seems to be a wider recognition of their importance. The major benefits that have been claimed can be categorized as relating to employers, educational institutions and students (i.e., potential employees). The major benefit for employers is believed to be the provision of more capable employees (Ray & McCoy, 2000), and one in eight IT job advertisements have been found to mention certifications (Clyne, 2001; Nelson & Rice, 2001). Some support for the benefit of employee certification to employers is provided in a study by IDC Inc. (1999), which found that 92% of managers surveyed said they

realized all or some of the benefits they expected from their certified employees. The major benefits to employers accruing from certified employees were:

- Greater knowledge and increased productivity;
- A certain level of expertise and skill;
- Improved support quality;
- Reduced training costs; and
- Higher morale and commitment.

The major benefit proposed for educational institutions is the opportunity to extend program content and to have an increased assessment capability (Ray & McCoy, 2000). Institutions that successfully offer certifications can become known for their expertise in these areas and attract more students and employers for their graduates (Brookshire, 2000). Student performance on certification exams also provides additional and generalizable measures of student competencies.

The greatest benefits of certification are believed to exist for students (Ray & McCoy, 2000). Marketability is proposed as a major benefit. Students are marketable if their programs of study contain content considered valuable by employers. For example, holders of Cisco certifications should have substantial experience as network administrators, designers and troubleshooters on real networks. Higher salaries are also commonly cited as a benefit, and there is evidence to support this. A survey conducted by *Certification Magazine* (Gabelhouse, 2000) reported that on average certification resulted in a 12% increase in income. This study also reported varying values for different certifications. For example, an MCSE led to an average increase in income of 12.6%, a Cisco CCNA to a 16.7% increase and a Novell CNA to a 13.3% increase. However, Alexander (1999) speculates that increased supply of people with the most popular certifications (such as MCSE) means diminished value in the marketplace. Other proposed benefits associated with increases in

marketability and salary include increased self-confidence and credibility (Karr, 2001).

Risks Associated with IT Certification

Despite these benefits, various concerns have been expressed about the current popularity of IT certification. Ray and McCoy (2000) identify the heavy involvement of vendors as an issue for concern, citing the absence of unbiased neutral groups for determining content, creating exams and authorizing examiners. They also recognize that the rapidly changing knowledge base might mean that certification is not of lasting value. Wilde (2000) also highlights the fact that some certifications do not require practical or real-world experience, thus limiting the claims of usefulness.

As IT certifications are increasingly offered by universities and colleges, concerns have been raised that academics might be uncomfortable with the loss of control over content that arises when certification exams determine the content of courses and academic programs (Nelson & Rice, 2001; Ray & McCoy, 2000). Academics might also be uncomfortable with the pressure to maintain their own proficiency levels and certification status.

Given the increasing pervasiveness of certification in the IT profession, more research is needed to verify the benefits of IT certification and to determine the importance of the proposed risks.

THE RESEARCH PROJECT

The exploratory study reported on in this chapter contributes to the need for further research on the risks and benefits of IT certification by investigating student perceptions of both the benefits and risks of certification, focusing particularly on Cisco certification. This research was con-

ducted by survey. Participants in the study were students enrolled in several electronic commerce, telecommunications management and IT courses at an Australian university. Students who have successfully completed these particular courses can also pursue Cisco certification as the courses make use of the Cisco curriculum. Participants were recruited during class and completed a questionnaire on the spot. It was stressed that the completion of the questionnaire was voluntary and that it formed no part of their assessment in the course.

The questionnaire was designed to be easy to read and understand, and to require no more than 10 minutes to complete. The questionnaire contained four main groups of items. The first section asked about:

- Age;
- Gender;
- Amount of previous work experience (both total and IT experience); and
- Whether the skills provided by their degree are those employers require.

The second group of questions related to the perceptions of the participants about the importance of industry certification for employment. Those participants who were not currently working in the IT industry were first asked to rate the importance of industry certification for obtaining their initial IT employment. This item was measured on a 5-point scale, ranging from (1) 'Not Important' to (5) 'Vital.' They were then asked to indicate how much higher (as a percentage) than the average graduate starting salary they believed their starting salary would be if they obtained various certifications. The list of certifications included those currently available to participants and several other popular certifications (see Table 2 for the list).

Those participants who were currently working in the IT industry were instead asked to rate the importance of industry certification for getting

ahead in their current employment. This question also used a 5-point scale, ranging from (1) ‘Not Important’ to (5) ‘Vital.’ They were then asked to indicate how much they thought their salary (as a percentage) would increase if they obtained the various IT certifications.

The third group of questions related to participants’ perceptions of the importance of various proposed benefits of seeking certification. A list of 11 benefits proposed for IT certification was developed from the literature on IT certification (e.g., Alexander, 1999; IDC Inc., 1999; Karr, 2001; Nelson & Rice, 2001; Otterbourg, 1999). Each potential benefit was rated for importance on a 5point scale, ranging from (1) ‘Not Important’ to (5) ‘Very Important’ (see Table 3 for the list).

The fourth group of questions related to participants’ perceptions of the importance of various concerns about certification. A list of potential risks of reliance on IT certification was drawn from the literature on certification (e.g., Nelson & Rice, 2001; Ray & McCoy, 2000; Wilde, 2000). Participants rated each potential risk for importance on a 5-point scale, ranging from (1) ‘Not Important’ to (5) ‘Very Important’ (see Table 5 for the list).

There were 145 participants in the study, with an average age of 23.4 years (with a range from 18 to 48). Twenty-one (14.5%) were female and 124 (85.5%) were male. The gender proportions in

this study are consistent with the low representation of females in IT courses around the world (Downes & Hobbs, 2000; Fitzsimmons, 2000; Klawe & Leveson, 1995). The majority of participants were at the undergraduate level (89.7%), with approximately 10% at post-graduate level. Participants who had previously been employed had on average 5.8 years’ work experience, of which 3.4 years were in the IT industry. Table 1 summarizes some of the background information about the participants.

RESULTS AND DISCUSSION

Benefits

IT certification was perceived as very important both for obtaining initial IT employment and for getting ahead if currently employed in the IT industry. The average importance rating given to IT certification by those not currently employed in IT was 4.09 (out of 5) and 3.75 (out of 5) for those currently employed in the IT industry (see Table 2 below). These perceptions of students who were not yet certified are consistent with results of a survey of 470 IT contractors described by Alexander (1999). In that study, 83% of the contractors believed that IT certifications were

Table 1. Background information about participants

	Number	Percentage
Gender		
Male	124	85.5
Female	21	14.5
Degree level		
Undergraduate	130	89.7
Postgraduate	15	10.3
Work experience* (mean = 5.8 years)		
No	75	51.7
Yes	70	48.3
* Work experience includes both IT and non-IT experience		
IT work experience (mean = 3.4 years)		
No	97	66.9
Yes	48	33.1

either ‘very important’ or ‘somewhat important’ to their prospects for career advancement. Thus, student perceptions of the importance of certification appear to be consistent with industry perceptions. The majority of student participants in the current study also believed that the studies they were undertaking would provide the skills required by employers (yes: 64.5%, not sure: 32.4%, no: 2.8%).

In general, participants perceived that obtaining IT certification would lead to clear financial benefits. The average increases that students

who were not currently working in the IT industry believed they would receive from obtaining certification ranged from a high of 25.27% for CCNP certification down to 18.87% for CCNA certification (see Table 2). The range of increases anticipated by participants was very large, with some suggesting that no increase would result, up to a maximum of 100% for all of the certifications. This wide range of responses suggests that this group of participants did not have a good sense of the value of these certifications in the marketplace. It would be reasonable to expect

Table 2. Perceived importance of certification

	N	Mean	SD	Min.	Max.
Importance of certification for initial job	119	4.09	1.00	1	5
Importance of certification for current job	24	3.75	1.26	1	5
Anticipated percentage increase in starting salary (if not currently in IT employment)					
CCNA certification	99	18.87	21.46	0	100
CCNP certification	97	25.27	23.85	0	100
Security certification	96	22.88	21.61	0	100

Rank	Benefits	N	Mean	SD	Min.	Max.
1	Practical experience with real networking tasks	143	4.57	0.60	2	5
2	Experience with real equipment	143	4.55	0.62	2	5
3	Widely recognized qualification	142	4.39	0.71	1	5
4	Greater knowledge/skill	143	4.29	0.64	2	5
5	Able to apply for the increasing number of jobs that require certification	143	4.19	0.75	1	5
6	Obtaining a formal marketable qualification	143	4.11	0.85	1	5
7	Academics that teach certifications must be certified, so you can be confident of their knowledge	143	4.08	0.84	1	5
8	Higher salaries	143	4.00	0.88	1	5
9	Increased credibility	143	3.99	0.77	1	5
10	Increased self-confidence	143	3.89	0.97	1	5
11	Flexibility of study because of online curriculum	142	3.62	0.97	1	5

this result for those certifications not currently available to participants as part of their program of study. But more surprising for the CCNA and CCNP, these certifications are readily available to the participants, and the potential financial benefit resulting from them could be assumed to have influenced their decisions to undertake the courses being surveyed. This lack of knowledge about the financial value of certification is also reflected in the large number of participants who did not provide answers to these items (approximately 20% did not respond to at least one of the questions about salary). Instructors have a major role to play in providing up-to-date information about employers' needs and likely outcomes of obtaining certification. The instructors need to be highly accessible and ensure that their knowledge of the marketplace that graduates will enter remains current so they can help guide students (McGill & Dixon, 2003).

Those participants who were currently working in the IT industry also anticipated financial gains from certification, but the average percentage gains they suggested were lower than those anticipated by students not working in the IT industry. The percentage increases anticipated by those who were currently employed were consistent with the figures available from surveys, such as the one conducted by *Certification Magazine* (Gabelhouse, 2000), suggesting that employed students have realistic expectations. There was also a narrower range of responses provided, suggesting less confusion about likely financial outcomes resulting from certification. Presumably, those working in the IT industry would have received better-quality information, as they would have access to IT work colleagues; whereas those without IT work experience might have been receiving information from a pool of people with perhaps limited direct IT industry experience (McGill & Dixon, 2003).

Table 3 presents the average perceived importance of each potential benefit of IT certification. The ratings of benefits are ranked by perceived

importance. All benefits were ranked relatively highly, with averages above the midpoint of the scale. The two most highly ranked benefits were practical experience with real networking tasks, and experience with real equipment. Almost 97% of the respondents considered practical experience with real networking tasks to be important or very important. This finding reflects that the participants were primarily undertaking Cisco certifications. Wilde (2000) comments that Cisco Systems has the most 'realistic' certification program, requiring those undertaking certification to perform real tasks, using real equipment. Wilde also raises concerns that some certifications do not emphasize practical skills.

The third-ranked perceived benefit in terms of importance was having a widely recognized qualification. IT certifications are global and enable those who have them great flexibility in terms of obtaining employment around the world. The fourth-ranked benefit was greater knowledge and skill. It appears that the intrinsic value of the knowledge and skill obtained during certification is perceived as important beyond the job-related benefits that can result.

The fifth- and sixth-ranked proposed benefits relate to the role of certification in improving opportunities to obtain jobs. The ability to apply for the increasing number of jobs that require certification was ranked fifth, and obtaining a formal marketable qualification was ranked sixth. Improving employment opportunities is clearly important to those who undertake certification, but the higher rankings of practical experience and improving knowledge and skill suggest that employment is not the sole motivation for undertaking certification. The perceived importance of practical experience obtained goes beyond just improving marketability.

Confidence in the knowledge of those who teach certification programs was ranked as the seventh most important benefit. While having knowledgeable instructors is clearly important (with an average of 4.08 out of 5), the relative

ranking perhaps suggests that students perceive those who teach them to be well qualified for the job regardless of whether the unit of study involves a certification and hence requires instructor certification.

Higher salaries were ranked eighth in terms of importance. While potential salaries perhaps receive the most publicity in terms of benefits to holders of certifications, this ranking suggests that salary is not the major driving factor for students. The ninth- and tenth-ranked benefits relate to the importance of certification for how students see themselves. Increased credibility and self-confidence did not appear to be major reasons for undertaking certification. The lowest ranked of the proposed benefits was the flexibility of study enabled because of online curriculums. While certification providers, such as the Cisco Networking Academies, pioneered delivery of quality e-learning material, online materials are now routinely available to IT students whether or not they are attempting certifications (McCormick, 2000; Peffers & Bloom, 1999), thus reducing the perceived importance of this benefit.

Several themes appear to emerge from the examples of benefits that have been proposed. To determine the number and nature of factors underlying the various benefits identified from the

literature, a principal components factor analysis with varimax rotation was performed in SPSS 11.5 using the data from the 145 respondents. Three factors with eigenvalues of greater than one emerged, indicating the existence of three underlying dimensions (see Table 4 for factor loadings).

Examination of the benefits associated with each factor led to naming the factors as follows:

- **Marketability benefits:** Which relate to desirability in the eyes of employers
- **Personal benefits:** Which relate to the impact of the certification on the way in which students perceive themselves and to the ease of their study
- **Learning benefits:** Which relate to intrinsic fulfillment from the type of learning.

These factors summarize the major types of benefits that students anticipate will accrue from certification

Risks

Table 5 presents the average perceived importance of each of the potential risks of or concerns about

Table 4. Factor loadings of benefits

	Marketability Benefits	Personal Benefits	Learning Benefits
Experience with real equipment	0.10	0.18	0.90
Practical experience with real networking tasks	0.21	0.18	0.89
Obtaining a formal marketable qualification	0.75	0.13	0.26
Greater knowledge/skill	0.48	0.13	0.52
Higher salaries	0.76	0.28	0.06
Widely recognized qualification	0.71	0.27	0.20
Flexibility of study because of online curriculum	0.12	0.78	0.16
Increased credibility	0.34	0.78	0.16
Increased self-confidence	0.17	0.80	0.19
Able to apply for the increasing number of jobs that require certification	0.60	0.46	0.11
Academics that teach the Cisco curriculum must be certified, so you can be confident of their knowledge	0.43	0.53	0.06
Percent of variance explained	24.04%	23.20%	18.99%

Table 5. Risks of certification

Rank	Risks	N	Mean	SD	Min.	Max.
1	The rapidly changing knowledge base might mean that the certification is not of lasting value	138	3.91	0.82	1	5
2	The absence of an unbiased neutral group for creating exams and approving examiners	139	3.58	0.78	1	5
3	The absence of an unbiased neutral group for determining content	140	3.49	0.81	1	5
4	Heavy involvement of vendors	139	3.47	0.81	1	5
5	Academics might be uncomfortable with the pressure to maintain their own proficiency levels and certification status	138	3.34	0.79	1	5
6	Academics might be uncomfortable with the thought that certification exams determine content of courses and academic programs	138	3.30	0.79	1	5

IT certification. The ratings of risks are ranked by perceived importance. The average importance ratings for the risks are mostly well below those of the benefits discussed above. So while the participants were conscious of the potential risks, they did not appear to be overly concerned about them.

The highest-ranked risk was that the rapidly changing knowledge base might mean that certification is not of lasting value. IT has been changing rapidly over a long period, and this rate of change is likely to continue or increase (Benamati & Lederer, 2001; Fordham, 2001). Organizations find it difficult to obtain personnel with the appropriate knowledge and skills to meet the growing demands for IT services (Doke, 1999), and this has contributed to the desirability of certified employees, as they provide a way for employers to obtain a pool of employees with up-to-date skills. However, the rapidly changing knowledge base also means that certification may not be of enduring value, and means that recertification is necessary. Gabelhouse (2000) found that 75% of certification holders shoulder some of the costs of certification, with 45% paying for everything themselves. If regular recertification is required, the costs and investments of time can become prohibitive.

The middle-ranked group of risks relate to the potential for bias in certification. The second-

ranked risk was the absence of an unbiased neutral group for creating exams and approving examiners, and the third-ranked risk was the absence of an unbiased neutral group for determining content. The fourth-ranked risk was heavy involvement of vendors. While vendor-neutral certifications do exist, most certifications are linked to vendors, and this has been raised as an issue of concern (Ray & McCoy, 2000). Again, students appear to be aware of the issue, but not overly concerned about it. They appear to accept the central role of vendors in the IT industry.

Concerns have been raised by several authors (Nelson & Rice, 2001; Ray & McCoy, 2000) that academics might not be comfortable with the loss of control over content that occurs because of the role of certification exams. They might also be uncomfortable with the pressure to maintain their own proficiency levels and certification status. Not surprisingly, these are the two lowest-ranked concerns of the students surveyed in this study.

CONCLUSION

IT certifications are a popular adjunct to traditional means of preparing for a career in IT. Many educational institutions offer a range of IT certifications. This study explored the perceptions of

students currently undertaking courses of study that could lead to IT certification. Certification was perceived as an important factor in achieving employment, and students undertaking it anticipate that it will lead to substantial financial benefits. Yet, higher salaries are not seen as the most important benefit of certification. The potential benefits that students believe are most important relate to the 'real-world' experience that is part of some certifications. They also value the potential improvements in knowledge and skill to which certification should lead.

Those respondents who were currently working in the IT industry had realistic perceptions of the likely salary increases available once certification was obtained, but those students with no IT experience appeared to overestimate the potential financial benefits. Instructors should ensure they have current information about salaries and employers' skill requirements so they can help guide students.

The respondents were aware of the possible risks of certification, but did not appear to be overly concerned about them. The issue considered most important was the potential for the rapidly changing knowledge base to mean that certification is not of enduring value.

Obtaining IT certification has become an important consideration for the IT profession. More research is needed to understand the benefits of IT certification and to determine the importance of the proposed risks. The study reported on in this chapter has provided a starting point, but future research should extend it to holders of IT certifications and to employers.

Chapter 5.33

The Effects of Human Factors on the Use of Web-Based Instruction

Sherry Y. Chen

Brunel University, Middlesex, UK

ABSTRACT

Web-based instruction is prevalent in educational settings. However, many issues still remain to be investigated. In particular, it is still open about how human factors influence learners' performance and perception in Web-based instruction. In this vein, the study presented in this chapter investigates this issue in a Web-based instructional program, which was applied to teach students how to use HyperText Markup Language (HTML) in a United Kingdom (UK) university. Sixty-one master's degree students participated in this study. There were a number of interesting findings. Students' task achievements were affected by the levels of their previous system experience. On the other hand, the Post-Test and

Gain scores were positively influenced by their perceptions and attitudes toward the Web-based instructional program. The implications of these findings are discussed.

INTRODUCTION

Web-based instruction is prevalent in educational settings. The value of Web-based instruction lies in the capabilities of hypermedia, which permit significant flexibility in the delivery of non-linear course material (Khalifa & Lam, 2002). Students are allowed to learn in their own way—to determine their own path through the material available (Barua, 2001)—and to learn things at their own pace (Chen, 2002). However, the freedom offered

by Web-based instructional programs may come with a problem, because flexibility increases complexity (Ellis & Kurniawan, 2000). Learners are forced to determine their own learning strategies and, therefore, will differ in their perceptions and approaches to learning. In particular, some learners who lack the skills of independent learning may find this difficult and become confused (Last, O'Donnell, & Kelly, 2001), so they may forget what they have already covered, and miss important information (McDonald, Stodel, Farres, Breithaupt, & Gabriel, 2001). This suggests that not all students will appreciate the flexibility and freedom offered by the Web and that human factors, therefore, are important issues to be considered in the development of Web-based instruction programs.

In this vein, the study reported in this chapter aims to investigate how human factors influence students' reactions to a Web-based instruction program. The chapter begins by building a theoretical framework to present the relationships between Web-based instructional programs and individual differences. It then describes an empirical study of students' learning experiences in a Web-based instructional program. Subsequently, the design implications are discussed based on the findings of this empirical study.

THEORETICAL FRAMEWORK

Web-Based Instruction

Over recent years, the World Wide Web (Web) has been becoming a useful tool for information distribution (Sridharan, 2004). In particular, there is an increase in use of the Web for instruction (Evans, 2004). Web-based instruction provides a number of advantages, among which dynamic interaction and flexible schedule are two key items. In terms of dynamic interaction, Web-based instruction presents an enormous amount of information through various interconnections

that offer students a rich exploration environment. The development of Web-based instruction provides learners with many opportunities to explore, discover and learn in theory according to their individual needs. Students can create individualized learning paths to reach the desired goals, move at their own speed and retrieve additional information as needed (Hui & Cheung, 1999). There is a shift away from didactic instruction to discovery of information (Smaldino, 1999). This approach is in line with the constructivist philosophy of learning, where the learner is encouraged to interact with the environment to construct individual knowledge structure (McDonald et al., 2001).

With regard to flexible schedule, Web-based instruction allows learners to read course content through a computer network at any time and at different places (Chang, Henriquez, Honey, Light, Moeller, & Ross, 1998). Burton and Goldsmith (2002) found that such a flexible schedule makes Web-based instruction appealing to students, including the convenience of not having to be on campus during the week, to easily arrange personal commitments and to take courses around work schedules. This type of learning may be particularly beneficial to individuals who live in remote places (Daugherty, 1998). Individuals living in remote areas can have access to the same course content as those living in big cities. This is why many educators have tried to develop a distance learning program on the Web. As pointed out by Clark and Lyon (1999), Web-based instruction has been predicted to be the future of all types of distance learning programs.

However, these advantages may come with a price. Power and Roth (1999) reported that Web-based instruction is more dynamic and flexible than other learning material, but it creates new challenges related to the effect on learners' comprehension. Ng and Gunstrone (2002) indicated that although students had positive perceptions to self-based learning provided by Web-based instruction, the unstructured nature of the Web

made some students need more time to search information. Quintana (1996) stated that while students gained the advantage of flexibility in time, pace and distance with Web-based instruction, many students, on the other hand, felt isolated, lack of motivation, or lack of support and feedback consequently to drop out of the course. Hedberg, Harper, and Corrent-Agostinho (1998) indicated that some students are still working to come to grips with a new and difficult way of learning. They exemplify the concern by asking for more incentive, more time, more structure and more guidance. These studies provide evidence that not all types of students appreciate being given freedom in their learning processes. In particular, students who need more guidance through the learning process may meet an increased number of problems in using Web-based instructional programs. To address this limitation, Web-based instruction should be developed to support the unique needs of each individual learner (Carter, 2002). Only when their needs are identified can developers of programs effectively enhance functionality and increase learners' satisfaction (Ke, Kwakkelaar, Taic, & Chenc, 2002). Therefore, understanding of learners' individual differences arguably becomes an important consideration in the development of Web-based instruction programs.

Human Factors

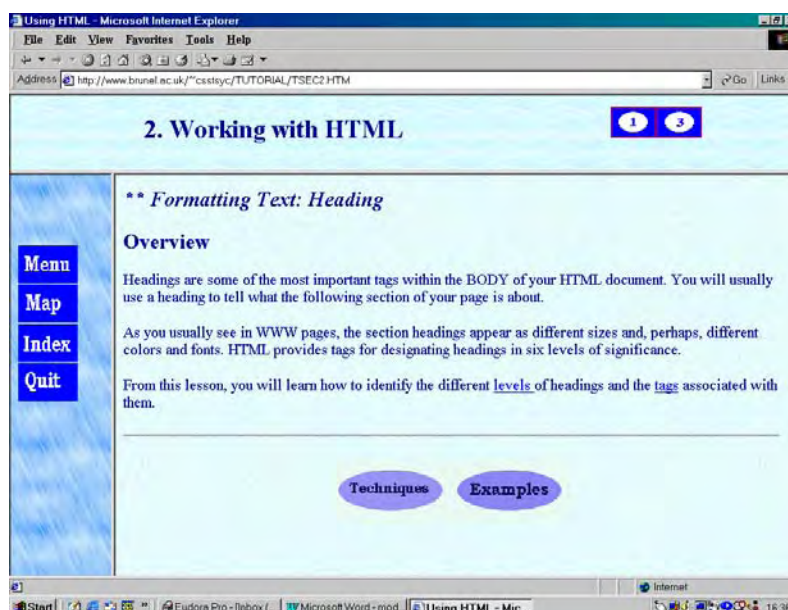

Human factors play an important role in learning. Individuals differ in traits such as skills, aptitudes and preferences for processing information, constructing meaning from information and applying it to real-world situations (Jonassen & Grabowski, 1993). The effects of human factors on students' task performance in a computer-based learning environment have been a growing research area (Wang & Jonassen, 1993; Ke et al., 2002). Among all human factors, gender differences (Ford & Miller 1996), domain knowledge (Mitchell, Chen, & Macredie, 2005) and system experience (Reed

& Oughton, 1997; Chen & Ford, 1998) have been recognized as especially relevant factors to users' interaction with the Web. In terms of gender differences, previous research indicates that gender differences influence users' navigation strategies in Web-based instruction. Schwarz (2001) found that females and males request different kinds of support when locating particular information. Male users need a larger frame of reference, while female users ask procedural directions. The other study by Roy and Chi (2003) indicated that males tended to navigate in a broader way than females. They also found that males tended to perform more page jumps per minute, which indicates that they navigate the information space in a nonlinear way.

In respect of domain knowledge, research suggested that less knowledgeable users experienced more disorientation problems in Web-based instruction (Last et al., 2001). This may be due to the fact that they are unfamiliar with the subject matter of the text, so they cannot rely on prior knowledge to help them structure it. On the other hand, more knowledgeable users may experience fewer navigation problems because their greater grasp of the conceptual structure of the subject matter can enable them to impose structure on the Web (McDonald et al., 2001). In regard to system experience, novices and experts demonstrate different attitudes toward the use of Web-based instruction. Liaw (2002) found students' experience using the Internet to be a good predictor of their computer and Web attitudes. Furthermore, Torkzadeh and Van Dyke (2002) found the transition from low experience to high experience could improve Internet self-efficacy.

Results from these studies suggest that human factors play an important role in the use of Web-based instruction programs. These studies also indicate that further empirical works are needed to identify the learners' different preferences, and their results may help to guide the development and evaluation of Web-based instructional programs. This chapter presents such a study, which

Figure 1. Screen design of the HTML tutorial

aims to examine how human factors influence students' reactions to a Web-based instructional program.

RESEARCH DESIGN

Web-Based Instruction Program

The Web-based instructional program, which was used to give an HTML tutorial, began by giving an introduction to the learning objectives and explaining the available navigation approaches provided in the instructional program. The contents were divided into three sections: (1) What is HTML? (2) Working with HTML, and (3) Relations with Standard Generalized Markup Language (SGML) and the Web. Section 2 is the key element of the Web-based instructional program, which covers 12 sub-topics of HTML authoring. Each sub-topic was further split into

five parts, comprising (a) overview, (b) detailed techniques, (c) examples, (d) related skills, and (e) references. Information was presented in 82 pages using texts, tables, an index and maps.

As shown in Figure 1, the screen was divided using frames. In the top frame was a title bar showing the section name being viewed and the other available section buttons. In the left frame were the Main Menu, Index, Map and Quit buttons. The right frame displayed the main content for each section, including topic buttons and text-based hypertext links.

In terms of navigation control, the Web-based instruction program took advantage of the features of non-linear learning and provided students with freedom of navigation. Topics and sub-topics could be studied in any order. In other words, students were allowed to decide their own navigational routes through the subject matter. Three types of navigation control were available in this tutorial, as shown in Table 1.

Table 1. Three types of navigation control

Control	Purposes	Tools
Sequence Control	To allow students to decide the sequence of subjects to be learned	<ul style="list-style-type: none"> • <i>Subject Maps</i>: to show all topics and sub-topics in a hierarchical way • <i>Keyword Index</i>: to list keywords in an alphabetical way • <i>Back/Forward</i>: to see the page previously visited
Content Control	To allow students to control the selection of the contents they wish to learn	<ul style="list-style-type: none"> • <i>Section Buttons</i>: to choose three sections of the main content • <i>Main Menu</i>: to present main topics • <i>Hypertext Links</i>: to connect relevant concepts
Display Control	To allow students to choose one of several display options that cover the same concept	<ul style="list-style-type: none"> • <i>Display Options</i>: to include overview, examples and detailed techniques, and so forth

Pre-Test and Post-Test

Examining students’ learning outcome in theoretical knowledge was conducted by using a Pre-Test and Post-Test methodology. The students were evaluated with the Pre-Test to examine their levels of prior HTML knowledge, and with the Post-Test for assessing learning achievement. Both tests were presented in paper-based formats and included 20 multiple-choice questions. Only one correct answer was provided among the multiple choices provided in each question. The formats of the questions were similar, with only the specific subject of the question being modified. The questions covered all three sections of the Web-based instruction program, from basic concepts to advance topics.

Students were allotted 20 minutes to answer each test and were not allowed to examine the content presented in the program at the same time. Students’ learning outcome was assessed by:

- **Post-Test score:** Each student’s score on the Post-Test, ranging from 0 to 20 to identify general learning performance
- **Gain score:** Score difference between the Pre-Test and Post-Test, to measure improved learning performance by taking the HTML tutorial.

Task Sheet

Students were assigned to do a practical task, which involved constructing a Web page using Notepad to measure learning outcome on the real skills that they had learned. The practical task entailed 10 key areas (e.g., creating hypertext links, changing background colors, formatting text, etc.). A printed task sheet was given to the students that described the detailed features of the Web page to be completed. The students were allowed to decide the order in which they attempted to complete the task activities on the sheet, and could look at the content of the HTML tutorial simultaneously.

One and a half hours were allocated for each student to complete the task. The starting and end times for each student were recorded. Students’ task achievement was evaluated by:

- **Task score:** A score consisting of summing items successfully completed, on a 0-10 scale
- **Task time:** The total time spent for completing the tasks.

Exit Questionnaire

The questionnaire was divided into two parts. The first part sought information regarding bio-

The Effects of Human Factors on the Use of Web-Based Instruction

graphical data relating to the student and his or her experience of using computers, the Internet and HTML. The second, which was the main focus, consisted of three open-ended questions and 47 closed statements to collect students' responses to the Web-based instructional program. It took students approximately 20 minutes to respond to all questions.

The open-ended questions were related to students' opinions about the strengths and weaknesses of the HTML tutorial and the barriers that they met. Students were requested to express their opinions in their own words. Enough space was provided for them to write down their opinions. The closed statements were designed to collect information about students' comprehension, preferences, and satisfaction or dissatisfaction with the Web-based instructional program. It included five sections: (1) level of understanding; (2) content presentation; (3) interaction styles; (4) functionality and usability; and (5) difficulties and problems.

Each closed statement could be classed as either "in favor" or "not in favor" of the program. The number of 'favored' statements was almost equal to the 'not-favored' statements (20 favored statements and 27 not-favored statements), in an attempt to reduce bias in the questionnaire. All statements used a five-point Likert Scale consisting of: 'strongly agree'; 'agree'; 'neutral'; 'disagree'; and 'strongly disagree.' Students were required to indicate agreement or disagreement with each statement by placing a check mark at the response alternative that most closely reflected their opinion. Their perceptions and attitudes were measured by:

- **Positive perceptions:** the total score for all favored statements of the Exit Questionnaire with the same Likert Scale
- **Negative attitudes:** The total score for all not-favored statements of the Exit Questionnaire with the same Likert Scale.

<i>Little</i>	9	11	20
<i>Average</i>	6	7	13
<i>Good</i>	8	5	13
<i>Excellent</i>	0	0	0

Procedure

All participants took part in the study in the same room at the same time, and they all interacted with the Web-based instructional program accessed using Microsoft's Internet Explorer. The participants were asked to do the following activities:

1. Take the Pre-Test to ascertain levels of prior knowledge of HTML
2. Interact with the Web-based instructional program (i.e., HTML Tutorial)
3. Do a practical task, which involved constructing a Web page using HTML
4. Complete the Post-Test to identify learning performance
5. Fill out a paper-based exit questionnaire to describe their personal details and reflect on their opinions of the Web-based instructional program.

Data Analyses

To investigate how human factors influence student learning in the Web-based instructional program, the data obtained from Pre- and Post-Tests, practical tasks and the exit questionnaire were used to conduct statistical analyses to identify students' learning experience. T-test was applied to examine the gender differences, and ANOVA was used to identify the differences among different levels of prior knowledge. In addition, Pearson's correlation was employed to find the relationships between students' learning performance and their perceptions and attitude. A significance level of $P < .05$ was adopted for the study. In addition, the

mean scores are employed to describe the learning outcome for each individual group.

DISCUSSION RESULTS

The participants (N=61) consisted of master's students at Brunel University's Department of Information Systems and Computing. Despite the fact that the participants volunteered to take part in the experiment, the sample is evenly distributed in terms of gender and system experience. There were 32 males and 29 females. The computer experience and Internet experience reported by the participants ranged from average to excellent on a five-point scale. Their familiarity with the subject content, *HTML authoring*, ranged from none to good. As shown in Table 2, there is the similar proportion of computer and Internet experience and HTML authoring in both male and female groups.

Table 3 describes the students' overall learning performance. In terms of perceptions and attitudes, a majority of students (78%) felt that the Web-based instruction program was useful and they liked the Web treatment of the content.

Tasks vs. Tests

As indicated in Section 3, students needed to be assessed by both practical task and paper-based tests. It is important to note that both task and tests were markedly different. The distinctions between them are similar to those between open-book examination and closed-book examination. The practical task was completed in "open-book"

Table 3. Overall learning outcomes

	Post Test	Gain Score	Task Score	Task Time
Mean	10.4	7.7	6.5	46.5
SD	1.8	0.9	1.6	6.8

The Effects of Human Factors on the Use of Web-Based Instruction

examination style, with the students building their Web pages while being guided by the task sheet. The practical task could be completed successfully without recourse to memory by applying knowledge read from the screen at the particular time it was needed. On the other hand, the Post-Test looked like a closed-book examination, as it was a multiple-choice factual test that entailed recalling knowledge from memory and was completed after learning using the Web-based instructional program. These differences can also be associated with those between *procedural knowledge* and *declarative knowledge*. Derry (1990) distinguishes between these two, procedural being “knowledge how,” and declarative being “knowledge that.” Procedural refers to knowledge of how to do things, while declarative refers to knowledge about the world and its properties (McGilly, 1994). Practical tasks refer to procedure knowledge of how to use HTML, while paper-based tests refer to declarative knowledge about the properties of HTML.

Another interesting finding is that the students’ task scores were affected by the levels of their previous Internet experience and HTML authoring (Table 4). On the other hand, there were positive relationships between the students’ perceptions and attitudes and their Post-Test ($P<.05$) and Gain scores ($P<.01$). In other words, the students who had more positive perceptions toward the Web-based instructional program could obtain better Post-Test and Gain scores than those who had more negative attitudes toward the program.

This implied that performance on the practical task of applying procedural knowledge could be promoted by prior system experience in using the Internet and HTML authoring, but it would not be affected by the matching or mismatching of instruction with students’ preferences. Conversely, the ability to recall declarative knowledge appears to have been facilitated mainly by matching instructional presentation with learners’ preferences, but it is not influenced by

Table 4. Task score and prior knowledge

prior system experience of using the Internet and HTML authoring.

Gender Differences

There were interesting correlations between the students' learning performance and their gender differences. Female students performed better than male students in the Post-Test. Conversely, the male students outperformed the female students in the practical task (Table 5). As indicated earlier, the differences between the Post-Test and practical task can be related with those between *declarative knowledge* and *procedural knowledge*. It implies that female students are better at acquiring declarative knowledge rather than procedural knowledge. Conversely, male students are skilled at gaining procedural knowledge instead of declarative knowledge.

For learning attitudes, the male students were patient in completing the task. On the other hand, the female students felt nervous doing the tasks, and some of them (N = 10) gave up doing the tasks within 15 minutes. In addition, the female students needed more guidance than the male students did. The female students tended to ask for instruction from the tutor, instead of trying to correct errors by themselves. These findings are in line with some previous studies, which found that males showed more interest in using and learning about computers while females reported fear of using computers and feeling helpless around them (Shashaani, 1994; Koch,

1994). For this phenomenon, educators should help female students build their confidence in facing the challenge of using computers, instead of giving too detailed instructions. In addition, educational settings should ensure that instructional programs should not place any students at a disadvantage due to their gender differences (Owen & Liles, 1998).

Prior Knowledge

Through analyzing students' prior knowledge, one thing seems evident: For doing practical task, students who had greater experience of using the Internet or HTML authoring seemed able to look for relevant information in an efficient way. Conversely, students who were lacking prior knowledge of the subject content needed more time to decide the learning paths for completing the task (Table 6). It seemed that students' existing knowledge did influence their interaction with the Web-based instructional program. These findings arguably supported results from previous studies (Shih & Gamon, 1999; Gay, 1986), which found there was a positive relationship between learner control and prior knowledge.

Expert learners who had an adequate amount of prior knowledge on the subject felt familiar with the interface and the contents of the Web-based instructional program, so they were confident about being more active when navigating the Web-based instructional system. On the other hand, novice learners might not be aware of the

Table 6. Prior knowledge and task time

Task Time					
Internet Experience	Excellent	Good	Average	Little	None
Mean	39.2	44.5	54.4	N/A	N/A
SD	5.5	6.1	8.1	N/A	N/A
Significance	P<.05				
HTML Authoring	Excellent	Good	Average	Little	None
Mean	N/A	31.4	41.9	50.5	61.2
SD	N/A	3.2	4.3	5.9	7.3
Significance	P<.05				

best order to read the material or what the most important information was. Therefore, it is important to provide novice learners with an initial phase of orientation relating to both interface and domain contents (Linard & Zeillger, 1995). One way to do this is by providing visual paths, which can be displayed by means of cues to indicate how far students are along a path or by giving some conceptual description for the possible sequences. An alternative method is to provide good labels for the pages. Labels that clearly indicate the role of a particular page may help novices successfully decide the appropriate coherent path (Lewis & Polson, 1990).

Learning by Doing

In this Web-based instruction program, students were asked to do a practical task (i.e., designing a Web page with HTML). A significant number of students (44%) reported that doing the task was a useful way of helping them to set a focus in the Web-based instructional program. From this 44% of students, 52% of them obtained Post-Test scores above the average (=10.4) and 63% of them demonstrated more positive perceptions to the Web-based instructional program. These results implied that “learning by doing” could assist some students to set their effective learning strategies. As indicated by Smith and Parks (1997), tasks serve to simulate “goal directed” browsing in such a way that learning performance can be enhanced.

On the other hand, a few students (30%) reported that doing the task hindered their learning. They found that they lost other important information they needed to learn because they were concentrating on doing the task. From these 30% of students, 58% of them obtained Post-Test scores below the average and 54% of them showed more negative attitudes toward the Web-based instructional program. This raises some interesting questions for further studies: (a) whether task activities can facilitate promoting students’

learning performance in a Web-based instructional program; and (b) what the relationships are between students’ attitudes and their learning patterns as reflected in a Web-based instructional program with and/or without setting tasks.

CONCLUSION

The aforementioned findings provide evidence that Web-based instructional programs may not be suitable for all learners as an instructional methodology. Instructors must be aware of individual differences, such as gender and levels of prior knowledge possessed. Some learners—for example, novice learners—may need greater support and guidance from instructors, while others may be able to follow Web-based instructional programs relatively independently. Thus, instructors should not assume that every student would benefit equally from Web-based instructional programs in educational settings. There remains the need for guidance to ensure that all learners attain their learning potential.

Implementing Web-based instructional programs is a complex process composed of interactions among students, instructional content and the features of Web-based instructional programs. It is important for educational settings to have a good plan in advance. Instructors should remain cautious about making a sweeping decision to convert entire curricula onto Web-based instructional programs. The goals of such a process should be weighed against potential problems (e.g., alienating certain learners). To avoid alienating a certain group, instructors should continue to incorporate a number of different teaching strategies into their lectures. In addition, this transition requires time for the student and time in the classroom to acquaint students with Web-based instructional programs. This is especially the case for students who have difficulties in independent learning; there is a need to let them have a longer time for this shift. With this issue in mind, such innovation

in teaching and learning will be more meaningful and valuable.

This study has shown the importance of understanding individual differences in the development of Web-based instructional programs, but it was only a small-scale study. Further studies need to be undertaken with a larger sample to provide additional evidence. The other limitation is that this study adopted self-developed Pre- and Post-Tests, so the reliability and validity of these tests are questionable. Therefore, testing and modification of the tests are needed in the future. There is a need to conduct future research that would examine the impact of other individual differences, such as cognitive styles, cultural background or domain knowledge. Such research should also be conducted within a more sophisticated multimedia Web-based instructional program, including the presentation of animation and video. It would be interesting to see how individual differences influence student learning in multimedia Web-based instructional programs. The findings of such studies could be integrated to build robust user models for the development of personalized Web-based instructional programs that can accommodate individual differences.

Chapter 5.34

Exploring the Rhetoric on Representing the User: Discourses on User Involvement in Academia and the IT Artifact Product Development Industry

Netta Iivari

University of Oulu, Finland

ABSTRACT

Users should be involved in information technology (IT) artifact development, but it is often difficult and rare, especially in the development of commercial IT artifacts for external use. This paper critically examines discursive construction of user involvement in academia and in the IT artifact product development industry. First, three academic discourses on user involvement are identified. Then, discursive construction of user involvement is explored in four IT artifact product development organizations, in which user involvement is indirect and labeled as usability work. Five discourses on usability work are identified. They are related to the academic discourses on user involvement, and some of them are criticized (Asaro, 2000) as “forms of technological colonialism,” merely “silencing the users” instead

of “giving them a voice.” It is recommended that especially the human-computer interaction (HCI) community should carefully reflect on what kinds of discourses on user involvement it advocates and deems as legitimate.

INTRODUCTION

This paper critically examines discursive construction of user involvement¹ both in academia and in industry; more specifically, in IT artifact² product development organizations, developing commercial IT artifacts for external use. Therefore, the focus is on the development context, a central research area in both information systems (IS) (Lyytinen, 1987) and HCI literature (Grudin, 1996). The focus is limited to the product development context (as contrasted with custom IS

development), which is a less studied context in IS research, but is the context in which the field of HCI emerged. In product development, commercial IT artifacts are typically developed for a large user population in a situation in which the users might be not known until the product is in market (Grudin, 1991a, 1991b; Keil & Carmel, 1995; Symon, 1998).

However, the product development context should also be considered a critical, even though a very challenging, context for user involvement. IT artefacts, whether developed in a custom IS or product development context, always condition, enable, facilitate and shape social practices. Altogether, they constitute the rules and resources available for human action (Grint & Woolgar, 1997; Orlikowski & Robey, 1991; Suchman & Trigg, 1991). Also, HCI literature highlights that IT artifacts impose new ways to work, which may be only implicitly designed, but anyhow delivered through the solution. However, an explicit redesign should always be carried out (Beyer & Holtzblatt, 1998; Cooper, 1999; Rosson & Carroll, 2002). Also in the product development context, development—explicitly or implicitly—constitutes the boundaries for the users' work practices, and in constituting the boundaries, an interest in the users seems critical.

Indeed, it has been widely accepted in both IS and HCI literature that users should be involved while developing IT artifacts. Participatory Design (PD) especially has been influential in emphasizing active user participation (Greenbaum & Kyng, 1991; Schuler & Namioka, 1993). In IS research, user participation has been a central topic for decades, currently legitimately labeled as an “old, tired concept,” which, however, needs revisiting (Markus & Mao, 2004). The field of HCI has addressed the importance of user involvement in approaches such as usability engineering (UE) and user-centered design (UCD) (Bannon, 1991; Cooper & Bowers, 1995; Gould & Lewis, 1985; Karat, 1997). However, in HCI, user involvement has traditionally been accomplished by “rep-

resenting the user” in development (Cooper & Bowers, 1995). This paper focuses on the rhetoric on “representing the user” in IT artifact product development organizations. The responsibility to “represent the users” is assigned to a group of specialists called, for example, usability/human factors/UE/UCD specialists in the literature (e.g., Aucella, 1997; Bias & Reitmeyer, 1995; Bødker & Buur, 2002; Borgholm & Madsen, 1999; Fellenz, 1997; Grønbaek et al., 1993; Mayhew, 1999b; Mrazek & Rafeld, 1992; Tudor, 1998; Vredenburg, 1999). The “representation work” carried out by the “user surrogates” is labeled usability work, in which user involvement is informative or consultative (Damodaran, 1996) at the most. Users comment on predefined design solutions or act as providers of information and objects of observation, but they do not actively participate in the design process nor do they have decision-making power regarding the design solution (Carroll, 1996; Damodaran, 1996).

I adopted a critical poststructuralist approach informed by Foucaultian tradition³ for the analysis of discourses on user involvement in IT artifact development. I critically examine discourses on usability work, referring to the ways usability work is constructed in practice—in the case organizations involved in this study, but also in academia—in the literature addressing usability work and, more generally, user involvement. Regarding the construction of user involvement in academia, it has been argued that user involvement is a very vague concept and there is a variety of views of what user involvement is and how it should be accomplished (Asaro, 2000; Carroll, 1996; Kujala, 2003). Furthermore, the influential role of academic communities in imposing meanings and particular “truths” to the social world has been emphasized (Clarke, 2001; Cooper & Bowers, 1995; Bloomfield & Vurdubakis, 1997; Finken, 2003; Foucault, 1972; Weedon, 1987). Some studies (Cooper & Bowers, 1995; Finken, 2003) have already examined HCI and PD in the Foucaultian spirit as discourses constructing

their objects of study (e.g., the users and the user interface) in particular ways and at the same time legitimizing their existence. This paper continues their work, but adds new insights by reviewing more recent literature and incorporating a product development perspective in the analysis.

Regarding user involvement in practice, existing literature has already warned that user involvement may be used only as a buzzword or weapon for achieving surprising or even paradoxical ends (Beath & Orlikowski, 1994; Catarci et al., 2002; Hirschheim & Newman, 1991; Howcroft & Wilson, 2003; Kirsch & Beath, 1996; Newman & Noble, 1990; Nielsen, 1999; O'Connor 1995, Robey & Markus, 1984; Symon, 1998). Some studies on discourses (e.g., Alvarez, 2002; Bloomfield & Vurdubakis, 1997; Nielsen, 1999; Sarkkinen & Karsten, 2005) have already analyzed discourses in IT artifact development, criticizing them for mainly reinforcing management agendas and goals. However, these studies have been carried out in the custom IS development context. There is a clear lack of both empirical studies and studies on discourses on user involvement in the challenging product development context. Therefore, this paper takes a step towards filling that gap by utilizing a poststructuralist approach informed by Foucauldian tradition. This approach has also gained increasing attention in IS research during recent years (Brooke, 2002; Clarke, 2001; Stahl, 2004), and empirical studies on discourses relying on Foucaultian tradition have proliferated (e.g., Doolin, 1999; Edenius, 2003; Sayer & Harvey, 1997; Thompson, 2003), even though none of them address discourses on user involvement in the challenging IT artifact product development context.

The paper is organized as follows: The next section outlines the poststructuralist approach utilized in this research effort. The third section identifies academic discourses on user involvement in both IS and HCI literature. The fourth section outlines the interpretive research approach utilized in the empirical part of this research

effort, the cases involved in this study, and the procedures of data gathering and analysis. The fifth section presents the discourses on usability work identified in the empirical material. The discourses are related to particular organizational settings, but also to the wider discursive field in which the academic IS and HCI communities participate and contribute. The final section discloses the central observations of the paper, discusses their implications and outlines paths for future work.

POSTSTRUCTURALIST APPROACH

I rely on a critical poststructuralist approach informed by Foucaultian tradition⁴ in the analysis of discourses on user involvement. Within this approach language, subjectivity and power are central notions. Language is in a critical position: It is assumed that language does not represent reality, but produces it. It is maintained that all prevalent definitions are constructed in language. Furthermore, different languages and different discourses using the same language produce different kinds of realities (Weedon, 1987, 2004). Discourses are “certain ways of speaking” that “systematically form the objects of which they speak” (Foucault, 1972, p. 49). Foucault highlights the importance of power in the analysis of discourses. Knowledge and power are both articulated in discourses (Foucault, 1972; Weedon, 2004). Discourses also compete with each other and struggle over meanings in language. There is a quest to disseminate the preferred understandings of the world (Fairclough & Wodak, 1997; Foucault, 1972, Weedon, 1987).

Discourses are both socially constructed and socially constructive. Discourses construct our identities and our objects of knowledge (Fairclough & Wodak, 1997; Weedon, 2004). Poststructuralism assumes subjectivity to be fragile, contradictory and constantly constituted

in discourses (Weedon, 1987, 2004). Discourses offer individuals subject positions that must be occupied if participating in the discourses (Foucault, 1972, pp. 118-119; Foucault, 1980). People are continuously persuaded as subjects in the discourses that constitute individuals as “subjects of a certain kind.” However, people do not only adopt the discourses and the subject positions offered to them, but the discourses can also be questioned and challenged (Weedon, 1987, 2004). Nevertheless, some discourses are more available and influential than others. On the other hand, one needs to acknowledge also that access to the discourses might be limited, and not all individuals have the right to participate in a discourse (Foucault, 1972; Weedon, 1987).

Based on this discussion, guidelines for the analysis of discourses on user involvement are outlined. First, it is important to analyze the formation of objects. One needs to analyze the statements that constitute the objects (e.g., users and the practice of involving them) in discourses. One needs to focus on “certain ways of speaking” that exclude other ways. Foucault maintains that “everything is never said” and “few things are said of the totality.” Therefore, one needs to concentrate on statements that have emerged excluding others. Second, one needs to analyze the subject positions individuals must occupy to take part in a discourse—both as speakers and as listeners (i.e., subject positions offered to and adopted by the researchers and practitioners advocating user involvement, involving the users or being involved as users). Discourses invite people as subjects into the discourses. However, it is also important to acknowledge that access might be limited and only a limited amount of individuals may be allowed to adopt the subject position and consequently participate in the discourse. The analyst needs to ask: Who has the right to speak, the ability to understand, access to the discourses and the capacity to invest the discourse in decisions, institutions, practices? (Foucault, 1972, 1980).

DISCOURSES ON USER INVOLVEMENT IN ACADEMIA

As mentioned, it is widely accepted that users should be involved while developing IT artifacts, but there is considerable confusion about the concept of user involvement, which can range from active user participation to the involvement of users as only providers of information and objects of observation (Asaro, 2000; Barki & Hartwick, 1994; Carroll, 1996; Cavaye, 1995; Karat, 1997; Kujala, 2003). First, HCI literature on user involvement that addresses the challenging product development context is reviewed.

The Practical HCI Discourse

Cooper and Bowers (1995) have analyzed HCI literature as a discourse, and show how HCI legitimizes its existence by constructing its objects—users and the user interface—in particular ways. They separate a first wave and a second wave of HCI discourses. The first wave of HCI discourse used a “compassionate rhetoric to advocate user-centered design”: HCI was needed since it “represents the users,” who form an ignored group in systems design and computer science. In some texts, even a “political and war discourse” was used—HCI was needed to fight for the users. However, “crisis rhetoric” emerged in the beginning of the 1990s. This second wave of HCI discourse did not criticize the designers⁵ or the computer scientists, but the first wave of HCI discourse (Cooper & Bowers, 1995, pp. 48-57). HCI was accused of not producing useful results. Furthermore, HCI was criticized of postulating users only as “human factors,” not as ‘human actors’; that is, as active agents working and using the computer systems in particular settings (Bannon, 1991). It was criticized that HCI should involve the users, not only represent them. Claims for more user involvement and for contextual inquiries were expressed (Bannon, 1991; Cooper & Bowers, 1995; Rosson & Carroll, 2002). Interest

also emerged related to the place of HCI in the design process and to the relationship between HCI and designers. Cooper and Bowers (1995) argue that currently there is a trend in HCI to empower the designers who are postulated as users of HCI. They claim HCI is always empowering someone, but there has been a shift from users to designers (Cooper & Bowers, 1995).

Next, recent HCI literature addressing user involvement in organizations is reviewed. This literature consists of very practical HCI textbooks and articles addressing issues such as how to “design quality HCI” and “make your organization user-centric.” This discourse is labeled as a *practical HCI discourse*. The speaker is positioned as a *consultant* and a *change agent*, offering advice on this quest. This discourse constitutes usability work, in which user involvement is indirect⁶. There are to be “user surrogates” (called usability specialists from now on) “representing the users in development” (Aucella, 1997; Bias & Reitmeyer, 1995; Cooper 1999, Fellenz, 1997; Grønbaek et al., 1993; Mrazek & Rafeld, 1992; Nielsen 1993, Tudor, 1998; Vredenburg, 1999); that is, direct user involvement is not within the scope of this discourse. Usability specialists are offered a subject position of *a user surrogate representing (if not fighting for) the user in development*. However, this has proven to be very challenging—the position of the usability specialists is articulated as problematic (Aucella, 1997; Bias & Reitmeyer, 1995; Borgholm & Madsen, 1999; Gould & Lewis, 1985; Mayhew, 1999a, 1999b; Rosenbaum et al., 2000). Some even label their work as a “battle” (e.g., Bloomer & Croft, 1997; Mulligan et al., 1991) to highlight the challenge. All said, the legitimacy of this discourse is established this way.

Another position assigned to usability specialists is that of *a user surrogate involving the designers*, by manipulating and seducing them to “buy into usability work.” The designers are postulated as a very important target group (Aucella, 1997; Bloomer & Croft, 1997; Bekker

& Vermeeren, 1996; Boivie et al., 2003; Cooper, 1999; Grudin, 1991b; Fellenz, 1997; Mayhew, 1999a, 1999b; Mrazek & Rafeld, 1992; Muller & Carey, 2002; Nielsen, 1993; Seffah & Andreevskaia, 2003; Tudor, 1998; Vredenburg, 1999) who should be involved in usability work (Aucella, 1997; Billingsley, 1995; Bloomer & Croft, 1997; Fellenz, 1997; Gardner, 1999; Tudor, 1998). They should be involved early so the activities affect the design (Aucella, 1997; Gardner, 1999; Grudin, 1991a, 1991b; Muller & Czerwinski, 1999). Altogether, project teams should “buy into usability” (Aucella, 1997; Mrazek & Rafeld, 1992) and the teams should perceive usability specialists as team members and allies (Bias & Reitmeyer, 1995; Fellenz, 1997; Mayhew, 1999a, 1999b; Muller & Carey, 2002; Rosenbaum et al., 2000). As one can see, Cooper and Bowers (1995) succeeded in predicting this trend of “HCI empowering the designers instead of the users.”

In addition, usability specialists are to act as *user surrogates, producing guidelines, tools, methods and processes that prescribe usability work*. The literature highlights creation of documentation of best practices, methods and techniques for usability work (Aucella, 1997; Bekker & Vermeeren, 1996; Fellenz, 1997; Mayhew, 1999b; Muller & Czerwinski, 1999) and integration of usability work into the formal development process (Boivie et al., 2003; Butler, 1996; Fellenz, 1997; Mayhew, 1999a, 1999b; Nielsen, 1993; Vredenburg, 1999) as important. Furthermore, usability specialists are positioned as *change agents that address many different target groups*—management, documentation, training, marketing, different kinds of change and improvement efforts—in their organization. Management’s commitment is postulated as an important criterion for success (Beyer & Holtzblatt, 1998; Bias & Reitmeyer, 1995; Billingsley, 1995; Boivie et al., 2003; Cooper, 1999; Grudin, 1991b; Fellenz, 1997; Mayhew, 1999b; Mrazek & Rafeld, 1992, Nielsen, 1993). A high-level champion allows usability work to have authority, autonomy and access to develop-

ment (Beyer & Holtzblatt, 1998; Billingsley, 1995; Boivie et al., 2003; Nielsen, 1993). Furthermore, usability specialists should be perceived as allies of different kinds of improvement initiatives in organizations (Bloomer & Croft, 1997; Mayhew, 1999a). In addition, marketing, training and documentation should be addressed and cooperation initiated. In all, usability specialists should be able to tailor their message and present their results in languages that each target group understands (Beyer & Holtzblatt, 1998; Billingsley, 1995; Bloomer & Croft, 1997; Cooper, 1999; Hutchings & Knox, 1995; Grudin, 1991b; Mayhew, 1999a, 1999b; Rosenbaum et al., 2000; Seffah & Andreevskaia, 2003).

In all, usability specialists are supposed to seduce and manipulate a multitude of stakeholder groups to “buy into usability.” The literature argues that usability work should be “sold” into organizations (Mayhew, 1999a, 1999b). Presentation of the things done and the results achieved is recommended (Aucella, 1997; Beyer & Holtzblatt, 1998; Cooper, 1999; Mayhew, 1999b; Muller & Czerwinski, 1999; Rosenbaum et al., 2000; Tudor, 1998). One should also be able to show the benefits achieved (Cooper, 1999; Mayhew, 1999a, 1999b; Rosenbaum et al., 2000). The business perspective is highlighted (Beyer & Holtzblatt, 1998; Bloomer & Croft, 1997; Cooper, 1999; Fellenz, 1997; Mayhew, 1999a, 1999b; Rosenbaum et al., 2000)—usability work should make sense from the business perspective and be related to key business goals (Beyer & Holtzblatt, 1998; Bloomer & Croft, 1997; Cooper, 1999; Fellenz, 1997). Consideration of costs and benefits is also recommended, since cost-benefit tradeoffs may play a major role in the adoption of usability work (Mayhew, 1999b; Nielsen, 1993; Vredenburg et al., 2002). Resources should be well planned and budgeted (Aucella, 1997; Mayhew, 1999b; Nielsen, 1993) to assure that usability work does not increase development costs and time (Bloomer & Croft, 1997; Nielsen, 1993).

Altogether, a competitive advantage and competitiveness in the marketplace achievable through usability work are emphasized. “Selling usability work into organizations” by highlighting the business point of view and cost benefit analyses, and by using the language that sales, marketing and management understand, is advocated. Within this discourse, an ideology of managerialism is evident; management goals are constructed as the main motivator for usability work. The discourse emphasizes profit maximization, work intensification and successful implementation achievable through usability work (c.f., Asaro, 2000; Hirschheim & Klein, 1989; Spinuzzi, 2002).

The Reflective PD Discourse

However, the practical HCI discourse on usability work is by no means the only discourse advocating user involvement in IT artifact development. There is literature in proximity to HCI, but clearly separating itself from “mainstream HCI.” In this literature, critique is addressed to “traditional HCI methods,” especially usability testing. It is criticized for restricting understanding of problems, limiting dialog, inhibiting cooperation between designers and users, having a weak impact on design, and advocating neutrality and objectivity (Bannon, 1991; Beyer & Holtzblatt, 1998; Borgholm & Madsen, 1999; Buur & Bagger, 1999; Bødker & Buur, 2002; Carroll, 1996; Cooper, 1999; Gardner, 1999; Kyng, 1994; Löwgren, 1995). Therefore, this literature separates itself from non-reflective, objectivist HCI and positions itself within the PD tradition, even though acknowledging there might be a need for some kind of “facilitators” (usability specialists, researcher designers) between users and designers.

This literature argues for more cooperative work and reflection related to design practice. The literature maintains that design should be seen as cooperative work, in which people with different competencies appreciate each other and

jointly create new work practices. Design needs to be seen as a creative and communicative process involving “mutual reciprocal learning” and “design by doing.” Usability specialists need to support everyone’s participation and make everyone comfortable in participating (Anderson & Crocca, 1993; Beyer & Holtzblatt, 1998; Blomberg & Henderson, 1990; Brun-Cottan & Wall, 1995; Buur & Bagger, 1999; Bødker & Buur, 2002; Bødker & Iversen, 2002; Bødker et al., 2000; Gadner, 1999; Kyng, 1994, 1998; Löwgren, 1995; Rosson & Carroll, 2002). Furthermore, emphasis should be on reflection and improvisation. It is argued that PD should not consist of applying decontextualized methods. Instead, professionalism, reflection and creativity are important. One should reflect on methods and challenge their assumptions. One should ask: Why do we do PD and where do we want to take it? (Anderson & Crocca, 1993; Bansler & Bødker, 1993; Beyer & Holtzblatt, 1998; Bødker & Buur, 2002; Bødker & Iversen, 2002; Clement & Van den Besselaar, 1993; Cooper, 1999; Löwgren, 1995; Löwgren & Stolterman, 1999; Thoresen, 1993).

This discourse is labeled as *reflective PD discourse* in which the participatory and cooperative nature of the design process is highlighted. Furthermore, the focus is on creation of new work practices—a term that makes a distinction with HCI, which mainly aims at developing *usability*. The speakers within this discourse have adopted the subject position of a *reflective research designer*. This discourse legitimizes its existence by differentiating itself from objectivist, non-reflective HCI (and IS). In this discourse, users are positioned as skillful partners in the design process. The usability specialists, if needed at all, are positioned as “*reflective facilitators of cooperation and reflection among users and designers*.”

This discourse has a clear background in the tradition labeled as the PD or cooperative design tradition (i.e., Greenbaum & Kyng, 1991; Schuler & Namioka, 1993). Finken has analyzed this coop-

erative design tradition as a discourse constructing its objects of study in particular ways and at the same time legitimizing its existence. Finken shows that this discourse constitutes IT artifact development, users and (researcher) designers in a specific way divergent from other traditions. The tradition constructs itself as empowering and other traditions (functional, socio-technical) as hegemonizing—serving the needs of the management. The cooperative design tradition postulates organizations and IT artifact development as conflict-laden, and researcher designers on the side of the oppressed. They should act as advocates of democracy. Design, on the other hand, is postulated as cooperative work that necessitates mutual reciprocal learning. Reality is postulated as socially constructed. Users and researcher designers are positioned as experts whose cooperation as equal partners is needed (Finken, 2003). However, cooperative design in Finken’s article includes both developments during the 1990s (i.e., Greenbaum & Kyng, 1991) and the Scandinavian trade unionist tradition (term derived from Hirschheim et al., 1997; Iivari & Hirschheim, 1996), on which cooperative design tradition is based. However, clear differences can be revealed between the Scandinavian trade unionist and cooperative design traditions, even though the latter is an outgrowth of the former. These differences are discussed next.

The Critical IS Discourse

The Scandinavian trade unionist tradition has been postulated as a very critical and management-hostile tradition in IT artifact development. This tradition focused on workplace democracy and trade union involvement in the development of IT artifacts. The tradition had a strong Marxist flavor and relied on the notion of conflict between capital and labor (Asaro, 2000; Bjerknes & Bratteteig, 1995; Bansler, 1989; Bansler & Kraft, 1994; Clement & Van den Besselaar, 1993; Hirschheim et al., 1997; Iivari & Hirschheim, 1996; Kraft

& Bansler, 1994; Kyng, 1998; Spinuzzi, 2002). The goal of user involvement was democratic empowerment of the users, which maintains that workers should be able to participate in decision-making in their workplace (Clement, 1994). However, in recent years, political issues have decreased in importance and the current outgrowth of this tradition has been labeled as PD or cooperative design. During this trajectory, the focus has shifted from industrial democracy to the cooperative design process, from political to ethical and from structured institutions (trade unions) to situated, local action, even though the ethical responsibilities of the designer still remain as important (Asaro, 2000; Bansler & Kraft, 1994; Beck, 2002; Bjerknes & Bratteteig, 1995; Blomberg & Henderson, 1990; Bødker, 1996; Clement & Van den Besselaar, 1993; Gärtner & Wagner, 1996; Kraft & Bansler, 1994; Hirschheim et al., 1997; Iivari & Hirschheim, 1996; Kyng, 1998; Robertson, 1998; Spinuzzi, 2002).

Related to this discussion, one can argue that the *reflective PD discourse* in which the participatory and cooperative nature of the design process is highlighted clearly bases its argument on the current cooperative design tradition, and in this discourse political issues have decreased importance. On the other hand, in some studies in IS literature, the political issue clearly endures. First, studies criticizing user involvement only as a buzzword or a weapon (Beath & Orlikowski, 1994; Hirschheim & Newman, 1991; Howcroft & Wilson, 2003; Kirsch & Beath, 1996; Newman & Noble, 1990; Nielsen, 1999; Robey & Markus, 1984; Symon, 1998) can be interpreted to employ a critical stance. Many studies also highlight the influence of politics and conflicts in IT artifact development (Alvarez, 2002; Bansler & Bødker, 1993; Beck, 2002; Bjerknes & Bratteteig, 1995; Bødker, 1996; Gärtner & Wagner, 1996; Hirschheim & Klein, 1994; Howcroft & Wilson, 2003; Kirsch & Beath, 1996; Newman & Noble, 1990; Nielsen, 1999; Sarkkinen & Karsten, 2005;

Symon, 1998). Of these studies, some have adopted a clearly trade unionist, management-hostile position (Bjerknes & Bratteteig, 1995; Gärtner & Wagner, 1996; Howcroft & Wilson, 2003). Related to this, it is also argued that IS researchers, instead of defining better IT artifact development methodologies and accepting the managerialist agendas of IT artifact development, should carefully analyze this conflictual and political context and question the agendas (Howcroft & Wilson, 2003). One should focus on dominance, power, marginality and exclusions both in IT artifact development and use (Beck, 2002).

This discourse is labeled as a *critical IS discourse*, in which the speaker is positioned as a *warrior, partisan or emancipator* (Hirschheim & Klein, 1989) fighting on the side of the oppressed against the oppressors. Workers are viewed as oppressed and in need of emancipation. Usability specialists are offered no position within this discourse, since users need to be active agents in the design process, having power to make decisions regarding the design solution (Damodaran, 1996). They are not to be “represented.” Altogether, this discourse clearly relies on a critical tradition; conflict between capital and labor and emancipation of the workers is emphasized (c.f., Asaro, 2000; Hirschheim & Klein, 1989; Spinuzzi, 2002).

However, in this literature, the target of criticism is not HCI, but IS literature (as well as apolitical PD); traditional systems development methodologies (“prescriptive IS literature”) relying on functionalist paradigm (Hirschheim & Klein, 1989; Kirsch & Beath, 1996) as well as capitalist approaches and methods claiming to involve or empower users/workers popular especially in North America (Asaro, 2000; Bansler & Craft, 1994; Beck, 2002; Beath & Orlikowski, 1994; Carmel et al., 1993; Hirschheim & Newman, 1991; Kraft & Bansler, 1994; Kyng, 1998; Robertson, 1998; Spinuzzi, 2002) are under attack. They are accused of being apolitical, neglecting the role of conflict and only serving management

goals (Asaro, 2000; Bansler & Bødker, 1993; Beck, 2002; Beath & Orlikowski, 1994; Bjercknes & Bratteteig, 1995; Hirschheim & Newman, 1991; Howcroft & Wilson, 2003; Finken, 2003; Kirsch & Beath, 1996; Newman & Noble, 1990; Spinuzzi, 2002).

This section identified three academic discourses on user involvement: a practical HCI discourse, reflective PD discourse and critical IS discourse. The practical HCI discourse is discussed in detail, since the empirical part of this paper focuses on user involvement in the product development context, and user involvement in this context is “mainstream HCI usability work.” The critical IS discourse, on the other hand, provides an interesting contrast to the practical HCI discourse identified. Finally, the reflective PD discourse can be argued as “building a bridge” between the academic communities of IS and HCI, since in both communities extensive interest in PD emerged during the 1990s and abundant references to PD have been made. However, the list of discourses on user involvement is by no means exhaustive; there is a multitude of discourses on user involvement to be identified in both HCI and IS literature. Nevertheless, these discourses all construct user involvement in coherent and yet divergent manners—there is a set of rules defining what is legitimate to say about user involvement within each discourse. Furthermore, the discourses offer distinct subject positions for the speakers (HCI and IS researchers) and the listeners (users, usability specialists and designers). However, it needs to be remembered that discourses are always fluid—“their edges are not demarcated and the researchers do not cluster around a prototype, but instead gather at the crossroads” (Deetz, 1996, p. 199).

Next, while discourses on user involvement are reviewed in a set of IT artifact product development organizations, they are also contrasted with the discourse on user involvement identified in this section.

RESEARCH DESIGN

Research Approach

In the empirical part, a case study method is utilized to examine “a phenomenon in its natural setting, employing multiple methods of data collection to gather information from one or a few entities (people, groups or organizations). The boundaries of the phenomenon are not clearly evident at the outset of the research and no experimental control or manipulation is used” (Benbasat et al., 1987, p. 370). This method is recommended if little is known about the investigated phenomenon or current perspectives have little empirical evidence, conflict with each other or with common sense (Eisenhardt, 1989). Related to user involvement in the product development context, the challenging nature and the lack of empirical studies have already been brought up.

More specifically, this research effort is an interpretive case study in which we assume that our knowledge of the world is gained through social constructions, and we attempt to understand and make sense, not explain in the predictive sense. The focus is on meanings attached to the studied phenomenon. Theories are used only as sensitizing devices (Denzin & Lincoln, 2000; Klein & Myers, 1999; Walsham, 1995). An interpretive case study method, thus, is suitable for studying how user involvement is constructed in the challenging and currently empirically weakly explored product development context. This is needed also since it has been shown that a variety of meanings can be associated with user involvement in practice. Therefore, in focus are the meanings attached to user involvement in the discourses, in which the organizational members participate and contribute.

Furthermore, the focus on discourses emphasizes that this research is not about “true facts” about what user involvement is, how it is carried out and why it is carried out, but about critically

analyzing and revealing how “truths” are constructed in the cases. The adopted epistemological stance is labeled as “weak social constructivism.” Social constructivism rejects a naive realist view of representation “that assumes meanings” are fixed entities that can be discovered. “A weak version assumes that there might still be better and worse interpretations, but a strong version rejects even that, maintaining that “truth” is always produced by particular interpreters and should always be analyzed with suspicion (Schwandt, 2000, pp. 197-200). I view the empirical material to represent a process of reality construction. Then, the material is not assumed to “tell the truth,” but it tells how the “natives” are trying and willing to represent “their truth.” However, I don’t go far in reflecting on my role as a producer of these results (truths) and as an interpreter with particular biases. Therefore, the label “weak” is needed.

Case Description

The cases are four product development units (case units A-D) from four IT artifact development companies. Units A and D are organizational units of large global corporations, units B and C of small- to medium-size enterprises (SMEs). Access to the units was gained through a research project about facilitating usability work in IT artifact development organizations in which the units participated. The units all had a strong background in usability work and/or an interest in facilitating it.

Unit A has “a few years” background in usability work. There are four usability specialists in the unit. Usability work in unit B has been part of development for more than 10 years. There was a group of usability specialists in the unit, but only one was left at the time of the study. Unit C has very little background in usability work. There is one usability specialist in the unit. She has carried out usability work mainly as student work. Finally, usability work in unit D has been in a central position since the establishment of the

unit. There is a group of professional, experienced usability specialists in the unit.

The cases were chosen for theoretical reasons to provide examples of polar types in the sense that units A and D are parts of large, global corporations, while units B and C are parts of small IT artifact development companies. In addition, the units’ backgrounds in usability work clearly differed, from more than 10 years (B) to only a couple of years (A) to almost no experience at all (C).

The practical ways of involving the users resembled the consultative and informative types in all the case units. The users did not participate nor did they have decision-making power in the design process. The usability specialists “represented them in development.” The usability specialists had carried out customer visits (interviewed and observed the users) and evaluated design solutions by using methods such as laboratory usability testing, paper prototyping and different kinds of usability inspection methods. Users were involved as providers of information and objects of observation (c.f., Bannon, 1991).

Data Gathering

The research material was gathered over a period of 3 years. Process data related to usability work was continuously gathered. Process data refers to the “stories about what happened and who did what when—that is, events, activities and choices ordered over time” (Langley, 1999, p. 692). The material was gathered while conducting process assessments in the units and while supporting the units in the facilitation of usability work by offering workshops and training. In the process assessments, units’ personnel were interviewed about their ways of working in a selected project, and it was examined whether usability work was carried out in the projects. The research team also had regular meetings with the personnel. The minutes of the meetings, assessment reports and all e-mail correspondence were saved for the

Exploring the Rhetoric on Representing the User

purposes of research. The research team also kept field notes after each joint event.

In addition, contextual data was gathered from the units. We experimented with multiple methods for data gathering to gain grounded insights and to clarify the meanings attached to the phenomenon studied (Benbasat et al., 1987; Denzin & Lincoln, 2000; Eisenhardt, 1989). First, we experimented with organizational culture surveys and gathered quantitative data from the units. Afterwards, we interviewed personnel and gathered feedback from survey results. We interviewed both the usability specialists and people whose work is directly related to the units' core mission. In the interviews, we discussed the context for and the process of usability work. An interview results report was produced. Afterwards, we organized workshop sessions in which we discussed and evaluated the interview results. The results report was updated after the sessions. Finally, we organized additional workshop sessions in which the results gained through the different techniques for data gathering were compared and contrasted with the results of the other units. In addition, before the workshop sessions, we went

through all the memos, e-mails, field notes and assessment reports produced. From this material we listed all usability activities carried out in the units, all reported problems related to the activities and all preferences expressed for future actions. We presented this material to allow the participants to also comment on that material. Therefore, the technique of member checking was utilized extensively. Data gathering related to the case units is summarized in Table 1.

Data Analysis

Analysis of qualitative data is a difficult and not much codified phase in interpretive research. Qualitative research that imitates the positivist tradition aims to make qualitative research rigorous; and formalized, rigorous qualitative methodologies have been defined. However, interpretive research seeks for emic meanings held by the people within the cases studied. Researchers typically have a large amount of qualitative data that is not mechanically manipulable. In addition, analysis is always a creative process: The insights and imagination of the researcher

Table 1. Summary of data gathering and case units

Unit	Process Data	Contextual Data	Description of the Unit
A	Process assessment documentation, unit's internal documentation, memos and e-mails, field notes, interviews	Organizational culture surveys, interviews, workshop 1, workshop 2	IT artifact product development unit of a large global corporation, a few years' background in usability work
B	Process assessment documentation, unit's internal documentation, memos and e-mails, field notes, interviews	Organizational culture surveys, interviews, workshop 1, workshop 2	IT artifact product development unit of a SME, background in usability work for more than 10 years
C	Process assessment documentation, unit's internal documentation, memos and e-mails, field notes, interviews	Organizational culture surveys	IT artifact product development unit of a SME, very little background in usability work
D	Process assessment documentation, unit's internal documentation, memos and e-mails, field notes	Organizational culture surveys, interviews, workshop 1, workshop 2	IT artifact product development unit of a large global corporation, many years' background in usability work

are always needed (Denzin & Lincoln, 2000; Eisenhardt, 1989; Klein & Myers, 1999; Langley, 1999; Walsham, 1995). Altogether, interpretive practice is always artistic, political and creative (Denzin & Lincoln, 2000). However, interpretive research also aims at generalizations and abstractions. It is argued that the particularities in empirical data should be related to more abstract categories and concepts (Klein & Myers, 1999). Generalizations in interpretive research can be of different types, but generally one can state that they are “explanations of particular phenomena derived from empirical interpretive research in specific ... settings, which may be valuable in the future in other organizations and settings” (Walsham, 1995, p. 79).

Regarding data analysis in this research effort, I viewed the material as discourses adopted, adapted, produced and reproduced by the personnel of the case units. I searched for recurrent themes in the material—on the level of language use—related to usability work, paying special attention to who says what, why and when. We critically examined the material over and over again to reveal the construction of meanings related to the usability work in each unit. The focus was on systematic ways of language use related to usability work, as well as on subject positions occupied by the speakers that constitute the speakers as subjects “of a certain kind” in relation to usability work. Afterwards, similarities and differences in language use were identified between the cases. Altogether, the systematic ways of language use and the associated subject positions emerged from the empirical material after several rounds of reading through the material.

DISCOURSES ON USER INVOLVEMENT: IN INDUSTRY

Usability Work as a Tradition

First of all, it was evident that all the case units emphasized that “taking the users into account”

is important. In unit A, the manager has strongly emphasized this, as in other units, also:

When 2 years ago I went to (another) unit to present myself, they asked me how many usability people there is in our unit. I said 20; the whole team. (Laughing) They started crying in the (other) team. ... I don't even doubt; I'm sure our group has a positive attitude towards this job. (Manager, A)

The path has been smoothed a lot probably because management has had such a positive attitude and has marketed this thing (usability work). (Usability specialist, A)

Unit B is positioned as a “pioneer” in usability work by the management:

From the viewpoint of the image of the company, one of our goals is to be a pioneer. (Executive, B)

This is visible also in the way the usability issues have been acknowledged. We were the first ones who started it. It's not only related to the technology. (Manager, B)

Also unit C is argued as having “this kind of culture”:

Our products are easy to use from the point of view of the users. So it (user-centeredness) has been there, even though not systematically. ... We have tested, not usability, but similar kinds of things. We have had these; representatives of customers have gone through these and thought about these issues. And ergonomics and things like that have been a starting point for industrial design. It is a kind of culture in this firm. (Manager, C)

Finally, usability work is positioned as “our bread and butter” in unit D:

Exploring the Rhetoric on Representing the User

We have this general rule that the specification is to be carried out by using user-centered methods. ... This should be our bread and butter, user-centered design methods and usability. (Usability specialist, D)

The whole unit should have it as a kind of guiding light (usability as our bread and butter) that directs all our efforts. (Project manager, D)

Management in all the case units highlights the importance of usability work; that is, they are positioned as friendly allies that appreciate usability work. This discourse illustrates that in the case units, the importance of “usable products” and user orientation have been acknowledged—as is the case also in HCI literature, in which “the rhetoric on representing the user,” as mentioned, has been crucial as a whole for the legitimacy and identity of the field (Cooper & Bowers, 1995). However, the critical IS discourse warns us that user involvement might be used only as a slogan or buzzword (e.g., Catarci et al., 2002; Hirschheim & Newman, 1991; Kirsch & Beath, 1996; Nielsen, 1999; Symon, 1998; Tudor, 1998). From this viewpoint, this discourse can be suspected of being only rhetoric without any aim to actually involve the users. However, next we will review arguments that offer motives for assigning usability work such a central position.

Usability Work as an Image Factor and a Selling Argument

Within the second discourse, meanings influenced by a clearly business-oriented viewpoint are assigned to usability work. Usability work is deemed useful since it can be used as an image factor and a selling argument—it can be used to address and manipulate the customer. In unit B, both the usability specialists and managers acknowledge this:

I think [user-centeredness] has been a selling argument and a thing that we have had, but not

necessarily the competitors. We have been most progressive in this respect. (Team leader, B)

If we talk about our strengths as a company, we don't talk only about customer-centeredness, but we say we have this competence; we have behavioral scientists, research and cooperation with universities. ... Because this is quite exceptional. (Executive, B)

This applies also in unit C:

Eric (manager) told me the basic reasons why we would participate [in the facilitation of usability work]. We need to be more convincing in the eyes of the customer. That way, we could dictate some things, for example UI (user interface) issues. The project would offer facts which could enable us to do that. ... Improvement of our company's image is one of the main reasons why we participate in this project. (Usability specialist, C)

Customers do not know what is good for them. The company has to convince the customers that the company knows better. One way to do that is to appeal to the fact that the company participates in the university project dealing with usability issues. This might give authority to the company in relation to the customer. (Field notes, C)

Also in IS literature, user involvement has been constructed as useful in overcoming resistance and ensuring acceptance (Nandhakumar & Jones, 1997)—the customers as well as the users need to be convinced that the “company knows better.” Within this discourse, the capitalist management orientation is evident: Profit maximization and a competitive advantage achievable through user involvement (Asaro, 2000; Spinuzzi, 2002) are highlighted. Related to this, this discourse can be criticized as a “realization of Scandinavians' worst fears” (Spinuzzi, 2002), since the original aim of user involvement—democratic empowerment of the oppressed worker (Clement, 1994)—is totally missing. On the other hand, the practical HCI

discourse clearly advocates this kind of discourse while emphasizing the business benefits achievable through usability work (Beyer & Holtzblatt, 1998; Bloomer & Croft, 1997; Cooper, 1999; Feltenz, 1997; Mayhew, 1999a, 1999b; Rosenbaum et al., 2000).

From the managerial point of view, this seems to be a tempting discourse on usability work, positioning the speaker as a “business and profit-oriented utilizer of usability work.” From the usability specialists’ viewpoint, on the other hand, this can be seen as a discourse to utilize as a change agent, “selling usability work into the development organization” (Bloomer & Croft, 1997; Mayhew, 1999a; Rosenbaum et al., 2000).

However, one can also criticize this discourse as being mere rhetoric without any aim to actually involve the users. The usability specialists of unit B acknowledge this risk:

I admit that it is valued here—my and Ellen’s (both former usability specialists) work is valued in this firm—but it is like: ‘it’s enough that you are here (laugh).’ It is like mere talk was enough. (Team leader, B)

The fact that the team (of usability specialists and graphical designers) existed created an illusion that usability issues are taken care of. There were people who took care of these issues and had knowledge about these issues, but the knowledge didn’t necessarily have any contact with the end product or how it was developed. (Graphical designer, B)

Also, the usability specialists of unit D discuss the risk of usability work becoming only a useful managerial buzzword:

We have been wondering about this, about this bragging related to user-centeredness, because it isn’t realized in every project. (Usability specialist, D)

“Total user experience” or other fancy keywords like that are used, but the question is: How are we going to achieve them? How do we prove that the outputs are like that? ... There is no monitoring of whether we produce quality designs or fancy total user experiences (laugh), whatever that means. (Usability specialist, D)

Usability Work as a Waste of Time and Money

The discourses do not necessarily glorify usability work. In some case units, some personnel have adopted a very negative standpoint related to usability work. In unit A, usability work is positioned as contributing merely to the “finishing touch,” involving “useless speculation”:

Projects always have limited resources and one must decide whether to invest in the finishing touch [usability] or in bugs and functionality. (Designer, A)

Yes, sure, sometimes it feels like the usability issues become kind of useless speculation. ... Sometimes usability work is overemphasized. If we are in a hurry, it might be that we don’t have time for these speculations. (Designer, A)

Also, in unit C usability work has been criticized as useless, since it is time-consuming and incapable of producing concrete, visible results:

Of the cooperation, Pete [designer] mentions that as a result something concrete and visible needs to appear. Usability activities have not resulted in that so far. (Field Notes, C)

Our designers considered usability work as useless. (Usability specialist, C)

Rick [manager] again suspects the suitability of user-centered design. Last time he raised doubts about whether the requirement specifications

Exploring the Rhetoric on Representing the User

(produced by a usability team) are complete: Have all exceptions and requirements been taken into account? Now he argues that paper prototyping seems to have too many loops and users; when can you stop? (Field Notes, C)

Finally, in unit D, usability work has been condemned “burdensome, delaying and dull”:

There is some unwillingness to carry out usability tests, because usability activities are perceived to be burdensome and dull. (Usability specialist, D)

[Usability specialists are perceived as] kind of delayers. (Graphic designer, D)

Yes, delayers who fuss over minor issues and pay attention to irrelevant issues. (Project manager, D)

Altogether, within this discourse usability work is condemned to be inefficient and time-consuming. This is quite alarming, and apparently a problem acknowledged also by the HCI community, since the practical HCI discourse warns that one should assure that usability work does not increase development costs and time (Bloomer & Croft, 1997; Nielsen, 1993), and cost-benefit tradeoffs may play a major role in the adoption of usability work (Mayhew, 1999b; Nielsen, 1993; Vredenburg et al., 2002).

Financial issues, particularly, are brought up as hindering usability work:

It is problematic to get money and the permission from the projects to do this, it's not easy to get permission to spend money on doing usability. (Manager, A)

Another important issue is that one should be able to show the benefits achieved (Cooper, 1999; Mayhew, 1999a, 1999b; Rosenbaum et al., 2000). Unit C especially has placed strong emphasis on

concrete results and on money spent in achieving them:

The company is expecting some concrete advantages [from usability work] to appear. ... The product should be more usable, and there should be clear savings in money and an increase in sales. (Manager, C)

When we were making the budget for this year, the question was, 'why spend resources on this [usability work]?' It costs money when people participate in this; they spend time on that. What can you get out of this? ... This type of questioning exists and it is good, because it all comes down to money and resources. We have limited resources and must have clear arguments. (Manager, C)

In this particular case, the financial reasons eventually led the organization to even abandon usability work:

When compared to the costs, one can raise a question that what has been received? The company has spent much more money on UI design than what was planned. ... Eric [manager] says the company has moved backwards: In the beginning, this [usability work] was a big thing, but now the situation is that soon nothing is done. Eric asks Rick [manager]: Has usability become a curse word? (Field Notes, C)

According to Eric, Rick has decided that no user-centered design activities will be carried out in the new product development project. ... Due to the bad reputation it currently has, the term 'usability' will not be mentioned for a while. (Field Notes, C)

The personnel responsible for IT artifact development—the designers and their managers—position themselves as sceptics in relation to usability work, condemning it as useless unless proven otherwise. The arguments of the practi-

cal HCI discourse highlighting the importance of designers' and managers' "buy in" (Aucella, 1997; Bloomer & Croft, 1997; Fellenz, 1997; Mayhew, 1999a; Rosenbaum et al., 2000) can also be read as an implicit fear of the existence of this discourse.

Usability Work as a Controllable and Measurable Quality Improvement

However, insofar as usability work is viewed as useful, it can still be constructed by relying on different kinds of discourses. One possibility is to adopt a discourse that constructs usability work as a controllable, measurable quality improvement effort that should and could be treated like other large-scale quality improvement efforts in organizations. This was the case in unit A, in which it is assumed that usability work should be carried out by "controlling projects to do quality work." As mentioned, in unit A, "it is problematic to get money and permission from the projects to spend money on doing usability." The discussion proceeded as follows:

Yes, if we think of these things separately. But if we think of it from the viewpoint of our everyday job, the question is that do we get permission to do quality work (laugh)? (Usability specialist, A)

Yes, do they allow us to stop the projects from wasting their time and effort (laughing)? ... I don't think that in the long run usability work costs a lot in the projects. (Manager, A)

"Doing usability" refers to "doing quality work" that stops projects from "wasting their time and effort." This discourse postulates usability work as improving the design process (Nandhakumar & Jones, 1997)—as improving the quality of the process and the product. Furthermore, it is assumed that controlling and monitoring is needed:

When you bring usability orientation into an organization, you have to be a police in the beginning. The designers don't have the knowledge needed in their head, and you have to act as a police. (Usability specialist, A)

Here we have a quality organization which perceives quality within a rules-oriented approach. Numerical things are highlighted; bugs and stuff like that. We have quality plans and we report the bugs and follow the projects. ... We have these control mechanisms, and they are very powerful. If you try to compete with them, and you are not in the control mechanisms, then you are left out. Because these control mechanisms set the pressures. (Usability specialist, A)

Controlling, constant controlling and monitoring, it's part of normal project work. Maybe it comes from there, the monitoring. I don't know whether you think this way, but if the usability work can be measured and controlled, then it's more natural, then it's just part of your job. (Team leader, A)

The usability specialists have labeled themselves as a "mommy mob"⁷ (Usability specialist, A) reflecting their will to control "the projects to do quality work."

Also in unit D, the usability specialists position usability work as "doing quality work" and, more specifically, "real research":

We should have more research orientation and quality. Related to quality, the workers and the [usability] specialists have started demanding that it should be monitored and there should be orderliness. We have also made proposals with other specialists, related to the ways we should work here. (Usability specialist, D)

If we design, we should do it in some rational way. ... I think we should be able to produce something rational, carry out relevant research through which we could say: 'Yes, this is how it

Exploring the Rhetoric on Representing the User

goes.' *We should produce something new and verifiable.* (Usability specialist, D)

A project manager states that the projects should always be able to state that “we had real users involved in this, there is real research in the background, these relations are correct” (Project manager, D). Related to this, controlling and monitoring are necessary, since:

If [usability work] is not demanded, guess what happens? People don't do it, because it is too burdensome. Why would people do things in a difficult, burdensome way if they can do it more easily? (Usability specialist, D)

Our managers should say that it is stated in our strategies that in the future we will carry out these kinds of initiatives and our competence in usability should be on a high level. And now we will together to start to fix it. (Project manager, D)

Within this discourse, written work descriptions are seen as useful, as is also suggested by the practical HCI discourse: Documentation of best practices (Aucella, 1997), a description of the methods and techniques for usability work (Fellenz, 1997) and a formal development process with usability work included (Fellenz, 1997; Mayhew, 1999a) are recommended. In unit A, a software process model with usability work included has been produced and is deemed helpful in integrating usability work into “normal project work”:

Now, when the new process is being implemented, now those [usability activities] are planned, and then you have permission to do them and time to do them. They are included in the schedules. (Team leader, A)

Also in unit D, the specialists, as mentioned, have produced “proposals related to ways of working in the unit.”

This discourse was evident in units A and D.

These units are parts of large, global corporations. In unit A, not only the usability specialists, but also the designers and managers, participated in it. However, in unit D the situation is different. The usability specialists were the only ones postulating usability work this way. Furthermore, they seemed to utilize this discourse in positioning the other stakeholder groups—designers and managers—in a morally subordinate position; managers are postulated as “not demanding enough,” designers as “careless” and “having no arguments behind their decisions”:

Management has not understood to demand quality which, together with the lowering of the competence level, has resulted in degradation of usability. (Usability specialist, D)

In some [projects] there are 'staid researchers,' research-oriented people, and in some other projects there are these 'careless designers.' ... This 'research gang' questions existing things and wants to examine things. On the other hand, these designers like to do things that are fun. They don't have, like, arguments, behind their decisions. (Usability specialist, D)

Usability Work Through Persuading, Marketing and Manipulating

Finally, this discourse on usability work is distinctive in its view of usability work as a phenomenon that should be sold to the IT artifact development preferably by “sneaking in, in secret.” This discourse, as well as the previous one, positions usability specialists as the ones “empowering the designers,” but these discourses attach clearly divergent meanings to this “empowering.” In the former discourse, usability work was constructed as “controlling and monitoring,” while in the latter discourse usability work means “sneaking in, in secret.” This can be accomplished, for example, through the usability specialists employing influential positions:

I think it is very important from the point of view of user-centeredness that our manager is a usability specialist, that there is this kind of competence. We can avoid a lot of unnecessary work, because our manager makes the decisions. We can trust her; we don't have to question her decisions. ... This user-centered viewpoint kind of affects other things in secret. I think it is strategically very important that a usability specialist was nominated as a manager who can make the decisions regarding the product. (Team leader, B)

Within this discourse, usability specialists act as change agents who address many different target groups and tailor their message to languages that each target audience understands (Bloomer & Croft, 1997; Mayhew, 1999a; Rosenbaum et al., 2000):

[Knowledge of user-centeredness] spreads through my and Ellen's [both former usability specialists] personalities, what we are able to tell about it. We forcefully talk about user-centeredness when [sales and marketing] want to hear what we do. (Team leader, B)

Here the discussions between development and marketing, they happen through me [former usability specialist]. The designers don't discuss directly with marketing and marketing doesn't contact the designers directly. I function as a mediator. (Manager, B)

However, designers are postulated as the most important target group (Aucella, 1997; Bloomer & Croft, 1997; Fellenz, 1997; Mayhew, 1999a) who should buy in to usability and perceive usability specialists as allies (Aucella, 1997; Fellenz, 1997; Mayhew, 1999a; Rosenbaum et al., 2000):

This is not only a few people's job, but everyone should understand what user-centeredness means and how much should I apply those principles

and in which part of my job. ... I think it is better that everyone knows a little about it rather than us having a dozen usability specialists and rest of the personnel know nothing about it; because this situation is a battlefield. Or, there should be a designer and a usability specialist doing things together all the time. But in this situation, the designer becomes a usability specialist almost naturally. (Team leader, B)

Doing things together is the most effective way to teach. It is much more efficient than to produce fancy guidelines for how things ought to be done, at least for part of our personnel. Some people might be good in following written work descriptions, but they are quite rare here. (Manager, B)

It is argued that “representing the user” is accomplished through the usability specialists actively cooperating with the designers, who otherwise might ignore the results of usability work. In this quest, the controlling and monitoring strategy is condemned as ineffective.

Only the personnel from case unit B participated in this discourse, and even in this unit it was only the usability specialists who participated in it. This is quite natural, since the aim is to “sneak in, in secret.” However, personnel from units A and D are familiar with this discourse, but they could not offer a success story related to it. In unit A, there is a “long way to go”: “If we aim at all our designers actively carrying out usability work in projects, we still have a long way to go” (Manager, A). Regarding addressing other organizational units, short lectures have been given by the usability specialists, but it is maintained that “this work is extremely painful and a persevering job. You must proceed slowly and take small steps. You can't change the direction of a ship of this size very fast” (Manager, A).

In unit D it is maintained that if “usability is everybody's responsibility, then it's nobody's responsibility:

Our boss wants us all to be usability people, that there lives inside us all a small usability specialist. ... But then it is nobody's responsibility. It is everybody's responsibility and, therefore, nobody's responsibility. (Usability specialist, D)

Furthermore, the usability specialists are not keen on the idea of selling their work inside their organization:

All work we do should be marketable inside our company. ... Management says: Go and sell your work. But they are sitting in the ivory tower, from which it is much easier to see where to sell it. ... In practice, when you present your work to [other units in the company], they don't care whether you have used [a UCD method] or just invented everything. ... It is a big effort to sell this work to people who don't understand it. Very rare people even bother to find out what [a UCD method] means in practice. (Project manager, D)

Therefore, this discourse was adopted only in unit B. Nevertheless, this discourse has a clear resemblance to the practical HCI discourse. The manipulative, seductive strategy has already been recommended—the ones introducing usability work should act as change agents and seduce and manipulate other people to “buy into usability” (Billingsley, 1995; Beyer & Holtzblatt, 1998; Bloomer & Croft, 1997; Cooper, 1999; Hutchings

& Knox, 1995; Mayhew, 1999a, 1999b; Rosenbaum et al., 2000; Rosson & Carroll, 2002). However, only in unit B do the usability specialists maintain having succeeded in this quest.

DISCUSSION

Summary of the Results

This paper has examined discourses on usability work in IT artifact product development organizations. Through analysis of empirical, qualitative material, five discourses on usability work were identified. The discourses construct usability work and the position of usability specialists in different ways in the case units. The differences are summarized by mapping the discourses on usability work identified with the particular units in which they emerged, as illustrated in Table 2.

The usability specialists in unit A employ the position of a controlling “mommy mob” “fighting for the user”; the designers have condemned usability work as a waste of time and money, but at the same time, the controlling, monitoring, measuring approach to usability work is accepted as a working solution. The usability specialists in unit B are positioned as seductive change agents “sneaking in, in secret.” The uses of usability work as an image factor and a selling argument

Table 2. Summary of the discourses on usability work in the case units

Usability work as...	Unit A	Unit B	Unit C	Unit D
Tradition	x	x	x	x
Selling argument and image factor		x	x	x
Waste of time and money	x		x	x
Controllable and measurable quality improvement program	x			x
Persuading, marketing, manipulating		x		
Usability specialists as ...	Controlling mommy mob	Seductive change agents	—	Demanding staid researchers

are acknowledged, granting usability work some legitimacy—especially at the executive level. However, subtle ways of working are needed in this unit to influence and manipulate a multitude of stakeholder groups to “buy into usability”. Also in unit C, usability work is appreciated as a selling argument and an image factor, but the discourse of the personnel responsible for technical development overrode in this context, and “usability became a curse word”. Therefore, usability specialists currently employ no position in this unit. Finally, the usability specialists in unit D are positioned as “staid researchers demanding more quality and control.” Also in this unit, usability work is utilized as a managerial tool for improving the image of the unit. In addition, designers are a hindering stakeholder group condemning usability work as a waste of time and money. In unit D, however, the usability specialists offer the “careless designers” and “not demanding enough managers” a morally subordinate position.

This observation may be related to the notion of power, a prominent theme in Foucault’s writings. The designers in case units A, C and D utilize a discourse constituting usability work as a waste of time and money. In unit A, a controlling and monitoring strategy is, nevertheless, accepted as a working solution, but in unit C, the usability specialists clearly have “lost the battle.” All in all, one could argue that the discourses the usability specialists utilize are typically submissive, figuring out ways and strategies for involving (empowering) the designers, who do the “real work here” (Manager, A) and whose contribution is “always needed” (Team leader, B).

If you think of the personnel of our unit, we have SW (software) developers who think that the SW development is the only real job in here. Even our respected usability specialist thinks this way, not to speak of our manager. (Manager, A)

In unit D, however, the usability specialists offer the “careless designers” and “not demanding

enough managers” a morally subordinate position. The notion of “usability work as bread and butter” grants the usability specialists an influential position in this unit. Nevertheless, except for unit D, one could argue that the usability specialists do not seem to employ very influential positions in the IT artifact development and are, due to this, also in desperate need of “rhetoric on representing the user that legitimizes their existence.”

Relationship to Academic Discourses

It was argued that these discourses can be related to wider discursive fields in which both the HCI and IS communities participate and contribute. As mentioned, existing literature has made us aware that user involvement might be used only as a buzzword and a slogan (e.g., Catarci et al., 2002; Hirschheim & Newman, 1991; Kirsch & Beath, 1996; Nielsen, 1999; O’Connor 1995). The first discourse assigning usability work a central position in every case unit might be viewed as relating to the same phenomenon. Furthermore, the other identified discourses indicate that this important position has not been fully realized. Especially the second discourse—which constructs usability work as useful, since it can be used as an image factor and a selling argument—warns us that within this discourse the management goals may be the main (sole?) motivator for usability work. Usability work is useful for the company in making more profit and improving the image of the company. Furthermore, the third discourse that condemns usability work as a mere waste of time and money implies that this “tradition of user-centeredness”—even though highlighted by the management—is not very strong. The designers are unwilling to accept usability work, and the benefits of usability work must be realized before it will be accepted. The financial reasons had led one unit to even abandon usability work.

The fourth and fifth discourses, however, illustrate that in the other three case units usability

work has survived further. These discourses show, nevertheless, that it can be postulated in different ways. Usability can be constructed as a measurable, controllable quality criterion that should be aimed at through the usability specialists—acting as policemen—controlling and monitoring the projects “to do quality work.” In this case, the focus is on the quality of both the process and the product. On the other hand, usability work can also be viewed as a phenomenon to be sneaked in, in secret. The designers are seen as an important target group and they are supposed to become “usability specialists” “in secret,” by “doing things together” with the usability specialists. The usability specialists should also aim at employing influential positions in their units for their competence to also be “sneaked in, in secret” and so they can “sell usability” to a multitude of target groups in their company.

Altogether, these discourses on usability work bear a clear resemblance to the *practical HCI discourse* identified earlier. Within the discourses, user involvement is constituted as indirect, and usability specialists are offered a subject position of a user surrogate representing (if not fighting for) the users in development. However, the case units differ in terms of other subject positions offered to these user surrogates. They might also be positioned as change agents involving a multitude of other stakeholder groups (designers, managers, marketing, sales ...) by seducing and manipulating them to “buy into usability” or as controlling and monitoring “prescribers” impos-

ing guidelines and processes on development. In either case, the resemblance to the existing HCI discourse is still evident. The empirical findings are summarized next in relation to the subject positions offered to usability specialists in the practical HCI discourse (see Table 3).

The *reflective PD discourse*, on the other hand, was argued as “building a bridge” between the academic communities of IS and HCI. In both communities, extensive interest in PD has emerged during the 1990s. Recent HCI textbooks advocating user involvement (e.g., Beyer & Holtzblatt, 1998; Mayhew, 1999b; Rosson & Carroll, 2002) refer directly to PD literature and suggest more participative design. This reference to PD literature, however, has been criticized, since either PD is only mentioned, not actually expected (e.g., in Mayhew, 1999b), it is interpreted only as a technical method improving the design process (Carroll, 1996) or it is interpreted to refer merely to prototyping and, all in all, suggested merely to achieve management goals (especially Beyer & Holtzblatt, 1998, according to Spinuzzi, 2002). Regarding this discourse in practice, the empirical results do not support the notion that “participative design” has been realized in industrial settings. Participative user involvement was not articulated in the discourses that the members of the case units participated in and contributed to.

Next, the *critical IS discourse*, relying on an ideal of democratic empowerment of the skilled worker and on the view of them as active agents in the design process, which is political and full

Table 3. Subject positions of the practical HCI discourse in the case units

Usability specialist as ...	Unit A	Unit B	Unit D
User surrogate representing the user	x	x	x
User surrogate involving the designer • Controlling and monitoring the designer • Seducing the designer	x	x	x
User surrogate as change agent targeting, manipulating and involving marketing, sales, management and so forth		x	

of conflicts that need to be acknowledged, is contrasted with the discourses on usability work identified from empiria. In doing so, the results achieved within this study can be seen as very alarming. From the viewpoint of the critical IS discourse, some of the discourses on usability work can be interpreted to be in stark contrast with the original aim of user involvement. Within these discourses, the goal of usability work is expressed in terms that appeal to management; they highlight the money-making and money-saving aspects of usability work. Usability work is seen as helping the projects to “do quality work” and “get it right the first time”—usability work is constructed as useful for money-saving purposes. On the other hand, usability work is highlighted as a selling argument and image factor for making more profit. This discourse especially can be criticized for being overtly capitalist, and even labeled as a “misuse of user involvement.” The management goal of “convincing the customer” by appealing to usability work might even be viewed as a way of “silencing the users” (Asaro, 2000), instead of “giving them a voice.”

Altogether, this type of capitalist orientation related to usability work identified in the product development context might be viewed as a “realization of Scandinavians” (trade unionists) worst fears (Spinuzzi, 2002), totally neglecting the original aim of user involvement; that is, democratic empowerment of oppressed workers. Related to this, it is also acknowledged that “empowerment” and “involvement” can be used only as rhetorical tools that try to conceal that IT artifacts are always developed to serve management goals. “Involvement” may actually mean exclusion and marginalization rather than empowerment of the ones who are oppressed (Howcroft & Wilson 2003, O’Connor 1995). Particularly when user “involvement” is only indirect, it is a question mark whether and how users could be “emancipated” or empowered in the democratic sense, even though these user surrogates are “representing them in the development.”

User involvement can also be criticized of only serving technological colonialism (Asaro, 2000). Just like anthropologists—who served the interests of colonial control while producing representations of other exotic, primitive cultures who were not able to contribute or argue against these authoritative representations (Clifford & Markus, 1986)—the designers (and the usability specialists) produce representations of users and at the same time serve the interests of technological colonialism: They represent the users for the sake of management goals—for the purposes of money making and money saving in the IT artifact development companies (c.f., Asaro, 2000). Furthermore, if users participate in the process, they are contributing to the production of these texts—the representations of themselves. From this viewpoint, user involvement can be seen as a way of silencing the users—users cannot reject the system anymore, since they have participated in the process. However, users are never equally equipped to produce these texts or to participate in the development, due to which the “technological elites”—like the anthropologists—ultimately have the authority to produce the representations of the technologically illiterate, “primitive,” “exotic” other (c.f., Asaro, 2000). In the case units, the users were not active participants who produced representations of themselves, due to which they were not “silenced” in this sense. However, in one case unit, the designers were not producing representations of the users either and even refused to take into account the representations produced by the usability specialists. Management, nevertheless, was “silencing the users” (and the customers) by appealing to usability work.

Relevance to Practice

This type of critical studies can be argued to lack relevance to practice, which seems to be a very important goal in both IS and HCI research. However, as a defense for this type of studies, one might argue that relevance can be achieved

in many ways. For example, researchers can act as the conscience of society (Lee, 1999), and they can reshape the practitioners' thinking and actions in the longer perspective (Lyytinen, 1999)—also, these issues have been interpreted to be relevant to practice. Therefore, critical examinations of user involvement in IT artifact development should be considered useful in the sense of highlighting the risk of user involvement becoming only a buzzword and a slogan whose acceptance and utilization is totally dependant on short-term financial motivators. Related to this, the influential role of academic communities is also emphasized (Cooper & Bowers, 1995; Finken, 2003; Foucault, 1972; Weedon, 1987). It is recommended that the HCI community especially should carefully reflect on what kinds of discourses on user involvement it advocates and deems as legitimate.

All in all, this paper provides help in answering questions such as, “What kind of animal is this (and should it be)?” related to research on “user involvement,” and “What kind of animal are you (and should you be)?,” which addresses both the researchers analyzing, advocating and prescribing user involvement in IT artifact development, and the practitioners developing IT artifacts, involving the users in development or being involved as users in development. The practitioners especially, who assume a subject position of a “user surrogate” “representing the user” in IT artifact development can reflect on the other subject positions offered to them. In the practical HCI discourse, these practitioners have also been positioned as “user surrogates,” monitoring and controlling or seducing and manipulating the designers, or as change agents selling usability work to a multitude of stakeholder groups in their organization. As an addition to these subject positions, the critical IS and reflective PD discourses provide alternative subject positions that, nevertheless, could be occupied by these “user surrogates,” those being a “warrior, partisan or emancipator fighting on the side of the users against the oppressors,” or a “reflective facilitator of cooperation among users and designers.”

Paths for Future Work

Altogether, it has been argued that especially in the IT artifact product development context, the ethical issues should eventually be acknowledged (Adam & Light, 2004). Therefore, regarding paths for future work, I would recommend studies that critically analyze literature on user involvement from the viewpoint of the ethical assumptions they advocate. In addition, studies that analyze our representational practices and articulations of our authority (c.f., Clifford & Markus, 1986) in the studies on user involvement are recommended. In this study, I have not reflected on these issues; that is, the reflection on my representational practices is lacking. This type of study could ask: Who has the authority to interpret user involvement in organizations? How is this authority articulated in the text? How does the writer's voice situate and pervade the accounts? What is excluded, and are voices silenced? And finally: Why are these stories produced in the first place? On a more practical level, empirical studies on user involvement in the product development context are also recommended. Contextual factors affecting user involvement (and more particularly, usability work) should be examined. In addition, the voice of the users, a voice clearly silenced in this paper, should be heard also in the IT artifact product development context. Finally, studies that critically examine power, politics, marginality and exclusion (c.f., Beck 2002) in the IT artifact product development context are warmly recommended.

ENDNOTES

- ¹ The term involvement is preferred over participation, since participation is interpreted to refer exclusively to actual, direct participative activities (c.f., Hirschheim, 1985), while in the product development context user involvement is mainly indirect.
- ² IT artifacts are defined (Orlikowski & Iacano, 2001) as “bundles of material and

cultural properties packaged in some socially recognizable form, such as hardware and/or software” (p. 121).

³ Another widely used tradition would have been the Habermasian tradition, but it has been argued that Foucauldian tradition focuses on “real discourses” and on critical examination of the formation of objects and “truths,” revealing hidden and tacit assumptions (Stahl, 2004), which is also the aim of this paper. The Habermasian tradition is well suited for “normative explication of the validity and acceptability of discourses” (Stahl, 2004, p. 4331) through the construct of “ideal speech situation.” The aim of this paper is not to identify the shortcoming of real speech situations in relation to “an ideal speech situation.”

⁴ This description relies on the description of “feminist poststructuralism” outlined by Weedon (1987).

⁵ Designer refers to the “legion of technical and analytical specialists who put together computer systems” (Greenbaum & Kyng, 1991, p. 20).

⁶ In HCI, the traditional goal of this work has been the development and ensuring of “usability,” but a recent trend has been to extend this work to cover also the development and ensuring of “usefulness” (e.g., Beyer & Holtzblatt, 1998; Cooper, 1999; Rosson & Carroll, 2002).

⁷ A “mommy mob” is a label the usability specialists in unit A use of themselves, referring to a (largely) female group of usability specialists trying to control and monitor the designers.

This work was previously published in International Journal of Technology and Human Interaction, Vol. 2, Issue 4, edited by B.C. Stahl, pp. 54-83, copyright 2006 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 5.35

E–Government Practices in Regional Context: Turkish Case

Derya Altunbas

Canakkale Onsekiz Mart University, Turkey

Elif Karakurt Tosun

Uludag University, Turkey

ABSTRACT

This chapter introduces the importance of the Information and Communication Technologies on the regional development in Turkey. Socio-economic transformation can be done with the efficient service opportunities in regions that have different growth rates. Specially, some regions have migration problems for economic and employment reasons in Turkey. Growth poles are a typical development style for Turkey. Therefore, less developed regions should have more advantage from national economic programs. In this chapter, included in Regional development programs of Turkey in the context of Information and Communication Technologies. The objective of this chapter is to point out importance of

improvements of Information and Communication Technologies and e-government programs in Turkey. At this time, it is defined the role of e-government programs on social, economic and political structures of the regions in Turkey.

INTRODUCTION

Network economies which arise with the development of Information and Communication Technologies (ICTs) have caused unavoidable transformation of the paradigm in the social dimension. This is the transformation that has harmonized the information revolution and Information Society. This socioeconomic transformation effects directly the shape of the administration,

the working mechanisms of the state, the level of economic development, and the relationships of the citizen.

The transformation of ICTs offers different alternatives to countries that are efficient and produces service opportunities for their citizens on social, economic, political, and cultural platforms. Specially with this transformation, underdeveloped countries and developing countries could find opportunities of supply by using their resources efficiently, similar to the developed countries.

Beside the potential of minimization of differentiations at development among the countries, regional differentiations are also removed in a country which is another function of ICTs. At the same time, it has given opportunities that are distributed equally among the citizens of a country. In this study, the basic hypothesis is depending on the idea that ICTs can act as instruments for governments to remove the differentiations of development either among different countries or within each country. However, efficient use of this instrument depend directly on the current socioeconomic conditions of the country. This study examined a few cases on efficient use of the e-government system in Turkey. In this framework; first of all, government decisions are analyzed that were used in the regional policy, including development planning decisions about underdeveloped areas or the regions with priority of development. Secondly, it has tried to assess the level of ICTs in Turkey. Finally, it analyzed the effects of ICTs on the socioeconomic life in the regions that have priority for development.

REGIONAL DEVELOPMENT: DEFINITION AND TERMINOLOGY

Differentiations of development can be based on differentiations of capital and skilled labor investment in certain regions that accumulate imbalances apart from the different geographical conditions in a country (Ozturk, 2001). So, re-

gional planning must include social and economic needs of the citizens when making settlements for inhabitants. Therefore, the aim of the regional planning should be to increase the social and economic welfare of people and at the same time improve the condition of physical living place or working place.

It has been observed that the interregional balanced development in industrialized countries is decreasing the income inequalities, source spending, and harmful effects of the industrialization in more developed regions. But, underdeveloped or developing countries are mostly determining which strategical point is suitable as the starting point of development and deciding whether strategical public investments will make it possible or not (Gurbuz, 2001).

There are two functions to perform in regional planning. First, regional planning must be efficient to increase the country's economic development. In this view, when the settlement system is establishing and decision of infrastructure is taking place, each decision must be efficient enough for betterment of the economy or at least able to create additional positive effects. Second, the function of regional planning is a tool for preventing regional differentiations. In this context, regional planning seems like a mechanism of use to reverse the unequal development in the country (Tekeli, 1981). The aims of the regional development should ensure that (Gurbuz, 2001):

- Regional imbalance is decreased.
- Each source and economic activity must be compatible in delivering within the geographical regions.
- Source of the region must be properly evaluated.
- Regional development must be dispersed in the country.
- Healthy growth in the region must be promoted.
- Interregional distribution of the industry must be balanced.

- Less developed regions should have more advantage from the national economic development programs.

Furthermore, there are three principles in development policies. They are social revenues, growth poles, and citizen participation. Each of them complement each other (Akder, 2003; Gurbuz, 2001; Kurt, 2003; Tavgac, 2001). The social revenue principle is a short term process and is not economical, but at the same time long term application gives economic benefit to underdeveloped regions. This type of investment must be made by governments (Dinler, 1998). The Growth Poles principle is applicable to the industries that have motor effects in the regions in one or more points of the country. With this investment in the region, the importance of the region is increased and differentiation emerges. This type of development has poles effect on the country's economy. The principle of citizen participation in development policies suggests that if a region's inhabitants have effective participation in policy making, the country will experience success in regional economic and social development.

REGIONAL DEVELOPMENT PROGRAMS IN TURKEY

For regional development programs in Turkey this study has covered two periods of time: before planning and after planning periods. From 1923-1963 is the "before planning" time period. In this period there were not many systematical programs for regional development because the country's overall regions had underdeveloped characteristics. After 1960, the State Planning Organization (SPO) was established for preparing regional planning making (Regional Development Specialization Commission Report, 2002). There are Eight National Development Plans and each of them was prepared to each five years until today. In the regional context, there are some chosen

pilot regions for development at the beginning of the first National Development Planning period. Several different development plans were completed during these periods, such as Eastern Marmara Planning Project, Zonguldak Project, Antalya Project and Çukurova Projects. At the beginning of seventh National Development Plan, some larger regional scale projects were planned in Turkey. They are Eastern Anatolian Project, South-Eastern Anatolian Project, Eastern Black Sea Regional Growth Planning, Zonguldak Bartın Karabük Regional Growth Project and Yeşilirmak Sphere Growth Project. The aim of Regional Development Projects in Turkey is to minimize the regional differentiation, to encourage private sector, to develop infrastructure of the transportation, to increase the facilities of health and education, to increase productivity of agriculture, and to increase employment rate. During this period, there were no recommendations about the development of information and knowledge technologies that relate to the regional context. The reason is that they were taken before the 7th Five Years Development Plan. Most of the regional development projects were in a preparatory stage from 1996-2000. In fact, since October 4, 2001, the E-Turkey Action Plan was integrated with the Europe+ Action Plan. However, in Turkey, programs on the knowledge and Information Technologies develop faster than adoption of regional development application. Thereby, it has been realized that, development rate of knowledge and Information Technologies must be in sequence to the development rate of the investments for these technologies to reach each region in Turkey. A few of the cases are discussed here.

Eastern Anatolian Project (State Planning Organization, 2000)

This project includes 16 cities in the east region of Turkey, covering 158.972 km.² The population of the region is 6,147,603 as per the 2000 census.

Table 1. Cities of Eastern Anatolian Regional Project

Cities	Population	Annual population increase rate (%)	Gross Domestic Product per person (Dollar)	Socio-economic Development of cities (81 inside in Turkey)	Socioeconomic Development Index

E-Government Practices in Regional Context

The regional area is 20.4% of the total area of Turkey and the population is 11.03% of the total of Turkey. The 16 cities that fall in this region are ranked in comparison to Turkey's 81 cities (see Table 1), according to socioeconomic factors.

South Eastern Anatolian Project (<http://www.dpt.gov.tr/bgyu/bkp/gap.html>)

This project has components comprising the development of agricultural infrastructure, industrialization, education, health, and other sectors. Beside the transportation opportunities, in this project dams were built on the Dicle and Firat rivers, and hydroelectric power plants were installed, including some irrigation facilities. In this context it can be seen as a multi dimensional project. Table 2 shows its ranking.

Eastern Black Sea Regional Growth Planning

This project is third of the regional development projects. This region's people have the least portion of income in Turkey. Because of low income and fewer employment opportunities there was

a migration problem in this region. Cities in the region and their socioeconomic ranking can be seen in Table 3.

Zonguldak Bartın Karabük Regional Growth Project

The economy is especially dependent on agriculture and the coal mining establishment in this region. Population was 1.024879 million in 2000 and the population was 0.015 % of Turkey's population. The annual increase rate of this region's population is -8.416 % (2.17 % is for all of Turkey). This region has annual migration of 1.7% in comparison to other parts of the Turkey. Table 4 shows this region's socioeconomic ranking.

Yeşilirmak Sphere Growth Project (<http://www.dpt.gov.tr/bgyu/bkp/ye-silirmak.html>)

In the Sphere River, there is erosion and environmental pollution. Some problems were there due to the overflowing and water pollution, too. With the project of Yeşilirmak Sphere Growth Project the most suitable land use and economic benefits were searched. Ecological equilibrium

is the base issue in this project, and by making economic land use planning management of the natural resources and following the nature accurately it has tried to decrease the differentiation of development within the other regions. This project has contributed to the country's economy, and the population's welfare has improved in the region (see Table 5 for ranking).

E-GOVERNMENT CONCEPTUAL EVALUATION

In the 21st century, the transformation of Information Technologies plays an important role

for the transformation of relationships between government and society. The public management process runs more efficiently through effective participation of citizens using Information Technologies. Within this context it has emerged as the e-government model at the management level. In this model, citizens are able to express their opinions about the administration to public clearly and easily to impact the local or national administration processes in their country. Electronic government can be defined as the government services and duties that belong to the government and must be made available without cutting; and they should be carried out with the mutual participation of citizens in a safe atmosphere within

the electronic Information Technologies (State Planning Organization, 2005c). At the same time, it is important to perform the services, rather than technologies. The government should not only perform electronic shape of services to citizens, but also prepare to use them (Yıldırım & Karakurt, 2004). In another view, e-government system is used to process the public institutions, support the public services, and develop the capacity of citizens. However, some academicians reject the definition of the easiest way to reach to deliver services because it seems too narrow and simple. As a matter of fact, the use of ICTs is not only limited within the Internet or Web sites, but at the same time there are geographical knowledge systems, the tools that are used institutional efficiency and helps public decision makers (Yıldız, 2003; Uckan, 2003).

E-Government Objectives and Practice Areas

In e-government processes, all the services and duties to citizens given by the government must be equal, fast, safe, and efficient. In this process not only does technological renewal happen, but at the same time renewal of the government structure for citizens occurs. Public institutions, local administrations, and other institutions in the public sector, private institutions, and citizens benefit from this opportunity (State Planning Organization, 2005c). Targets of the e-government practices are:

- Visual clarity in the state.
- Fastest process for citizens and government relationship.
- More participation at each level of public administration.
- Citizens lives must be easier when the government gives public services to them.
- More effective working atmosphere in the units of public services.

- Information entirety must be provided and prevented to abuse it.
- Data and work repetition must be prevented and knowledge flow must be provided among the institutions.
- Bureaucracy must be decreased.
- Citizens must have the opportunities by benefiting from public services in all day.
- Public services must be accessible and widespread.
- In public service production and the consumption process, participating citizens must be supported, and their desires or tendencies must be evaluated efficiently.
- Institutions of the state must work to be productive and rational.

The Role of E-Government on Social, Economic, and Political Development

Renewal of the social, economic, and political platforms by utilizing the development of ICTs is most important for developing countries like Turkey. The development process will be faster and easier at each economic platform and, therefore, economic productivity will increase and costs of processes will decrease. However, it is more important to decrease the costs and increase the productivity in the context of the global economy to protect countries' competition power. Specially, if a country has scarce sources as developing countries, thereby using the existing sources more efficiently, the production sector can find more important place in global competitive conditions. Using the ICTs intensively, acceleration will also be created in the social platform. It can be possible with these technologies to increase the quality of life of each person's isochronal throughout the country. However, to achieve this aim, the education program needs to be reframed, at first. Thus, social development should be considered initially, so that underdeveloped regions

and people living in those regions are able to find opportunities for establishing a higher level of standard in their work. By using ICTs the political arena can benefit, too. In this way, perception of the government and citizenship is changed, and participation of the citizens to administration process acts efficiently. Thus, democracy is also realized. Therefore, reliance of the government and citizen is constructed (Turkey Information Foundation Association of Turkey Information Industrialists and Businessmen, 2004). A few of the benefits of the information and communication technologies in the social structure are given below:

- Behavior of public services is changed.
- Brings transformation in perceptiveness about administration.
- Bureaucracy is decreased.
- Cost of management is decreased due to the decreased use of files.
- Productivity increases.
- Effective and efficient services are given.
- E-democracy moves into the country.
- Tax revenues are increased.
- Accessibility to the information will be easier for people.
- Each person will be responsive to the world and participate in the country's development processes.
- Administrative participation process for citizens increases.
- Shorter time is needed to reach information at grass roots.
- Service costs will be minimized at all level for the citizens.
- Quality of education will be increased.
- Employment possibilities will increase.
- E-commerce will create new tools for innovative projects with least cost and fast dissemination.
- Connectivity among the establishments and business houses will be renewed.

E-Government Programs in Turkey

Objectives

After realizing that Europe needs benefit from the opportunities of the new economy, and especially what the Internet brings, the European Council prepared an Action Plan that was decided to be supported and developed by the European Commission in December 1999, not only to decrease the distance between Europe and the U.S., but also to decrease the imbalance among regions of Europe (European Commission, 1998, 2000). Within the European Union, the Middle and East European Countries' high level Committee on Information Society was given responsibility to compose an Action Plan similar to E-Europe, at the Information Society European Ministers International Conference organized in Varshova during in May 2000. This enterprise was primarily called an "E-Europe-like Action Plan" and afterward named "E-Europe+." Later on, the European Council assembled in Lizbon in March 2000 and determined an objective to make Europe the most competitive and dynamic information based economy of the world (Cayhan, 2002). Main objectives of these initiatives are to:

- Provide faster, cheaper, and secured Internet infrastructure
- Cheaper and faster Internet for everybody
- Faster Internet for students and researchers
- Secured nets and intelligent cards
- Increased investment for people and their capacity development
- Prepare European youth for digital age
- Labour power for information economy
- Participation of everybody in the information economy

Encourage the use of Internet to speed up:

E-Government Practices in Regional Context

- E-Trade
- E-Government: Communication for public services
- Online health
- European digital contents for global nets
- Intelligent transportation system

After achieving the objectives determined by the 2002 Action Plan for E-Europe, European Union Countries determined long term objectives for themselves and prepared the continuation of the previous “E-Europe 2005 Action Plan.” The aim of this new plan is to provide contemporary public service for private investigators, to increase productivity, to create suitable conditions for new jobs, and to give the opportunity for everyone to participate in the global Information Society. Furthermore, the goals of E-Europe 2005 (Communication From The Commission To The Council of The European Parliament, 2002) are to provide contemporary online public services, such as:

- E-Government
- E-Knowledge
- E-Health

However, it has been found that, dynamic e-work conditions provide the following benefits, such as:

- Competitive price
- Secured information infrastructure

While using E-Europe 2002 Action Plan for themselves, EU countries prepared E-Europe+ Action Plan for nominees in order to provide them an opportunity to achieve the same social transformation. It has been planned for the candidate countries to achieve these objectives till the end of the year 2003. By the E-Europe+ Action Plan, it is aimed for candidate countries to speed up their economic renewal, to support their institutional development, to develop their power for

general competition and prepare plans for those deserving special conditions. According to this plan, the candidate countries agreed on political determination for four main objectives until the end of 2003. These four objectives are:

- To speed up the formation of the basis of information.
- To provide cheaper, faster, and a more-secured Internet.
- To provide investment for human research.
- To inspire Internet usage.

Before proceeding to discuss an e-government practice in Turkey, authors would like to focus on Turkey’s transformation processes, which are structurally illustrated in Table 6.

E-TURKEY TRANSFORMATION PROCESS

Turkey as a candidate country of the European Union, after agreement with the E-Europe+ Action plan, started working towards formation of an e-Turkey Action Plan parallel to the E-Europe+ Action Plan under the coordination of the Prime Ministry Counselorship since October 2001. For this purpose, 13 different working groups have been assembled comprised of private and civil social establishment representatives. At the end of an 18 month study of these groups, an Action Plan has been prepared and presented to the European Union with a situation determining First Midreport in May 2002. Furthermore, it has been decided that the preliminary conditions determined as the objectives of Turkish e-transformation programs have to be achieved. This preliminary determination is to speed up the main procedures of the Information Society:

- To provide appropriate priced communication services for everybody.

Table 6. Work phases that Turkey performed

Related Institutions	Work	Year
ULAKBIM	Research net will be priority: National research nets will be developed in order to provide appropriate data for researchers and students in candidate countries by using MED foundations over more powerful nets.	Till the end of 2002
MEB, YOK, DTM, TUBITAK, TSE, private sector	General security of online processes will be increased: Cooperation among public/private sector on information basis and dependence to each other will be formed, partners will be educated about technological criminology and security, basic specifications for intelligent cards to be developed and security will be established. Common strategies for expanding the usage of intelligent cards will be developed and put into practise.	
UBAK, TELECOMMUNICATION INSTITUTION (TK), RTUK	Telecommunication sector will be liberated: Internet service will be appropriate for everybody, and arrangements will be completed.	Till the end of 2003
DPT, GAP Management, National treasury, Private sector, TK	Increasing support will be given on development of projects and Information Society; primarily in less developed regions.	
DTM, ETKK, Nongovernmental Organizations KOSGEB	Usage and recognition of electronic signature and studies for basis of e-trade will be accelerated.	
Ministry of Health, TT, Private sector	European Public health nets and databases will be established, infrastructure for health thematic will be developed.	
MEB, YOK, TBD	Expanded usage of a European certificate about basic Information Technologies will be promoted	Till the end of 2004
Ministry of Justice, DTM, ETKK, organizations of consumers, private sector, nongovernmental organizations	Reliance for e-trade among consumer groups and industry cooperation will be increased Appropriate attempts will be formed and efficient codes will be supported.	
UBAK, Ministry of Public Works, KGM, TT, TK	Development Plans, especially for highway infrastructure and intelligent transportation services, will be prepared.	
MEB, UBAK, TK, TT, TISSAD	Every school, student, and teacher will be able to use Internet: Support services and educational sources will be established. Educational curriculum and methods of teaching will be made dependent on ICTs.	Till the end of 2006
Ministry of Working and Social Security, working institution, Chambers of occupation, Nongovernmental Organizations	Appropriate education for finding jobs for people unemployed for a long time will be given	
Ministry of Working and Social Security, UBAK, TK, Management of the defectives, YOK, Private sector	Design of standards for the handicapped ones will be improved for access of Information Technologies. For excellence on this issue, national centers nets will be formed.	
Prime Ministry	Online data will be provided about legal, cultural, environmental, and traffic information. Online access to basic public services, easy online administrative procedure for commercial sector e-signature among public will be supported, and e-market for bids for the public contracts will be formed.	

E-Government Practices in Regional Context

- To attract European Union about the Information Society.

At this level the agreement dates for adaptation criteria will be given to the European Union that have been determined by meetings under the Turkish Scientific Research Institute (TUBITAK) secretaryship and in coordination with the European Union General Secretaryship and Ministry of Foreign Affairs (TUBITAK, 2002). According to the determined outline, Turkey has to meet all these criteria in 2006. Depending on this date of agreement, the European Mediterranean Partnership (MEDA) projects will end in 2006 (Cetin, Aydogan & Ertugrul, 2002).

To enhance the processes further, the Turkish Telecommunication Company has been given responsibility to develop the e-government portal in coordination with the State Planning Organization under guidance of the Council of Ministers on January 25, 2005 (State Planning Organization, 2005b). Previous to this, the State Planning Organization Counselorship was responsible for coordination, observation, evaluation, and direction of the E-Transformation Turkey Project as the Chairmanship of Information Society.

The goals, institutional structure, and application principles of the E-Transformation Turkey Project were delivered by a printed notice on February 27, 2003 (State Planning Organisation, 2005b). The Emergency Action Plan, E-Transformation Turkey Project is being held in three phases. These are (Ilter, 2000; State Planning Organisation Information Society Department, 2004):

- Phase one is comprised of preparation and review of the existing situation, especially for e-Turkey; and similar efforts will be evaluated. In this phase, report on recommendations based on applications of good examples in Turkey will be prepared.
- E-Transformation National Action Plan will be prepared in the second phase.

- In the third phase, the Action Plan will be put into practise. Report on observation of applications of the plan will be delivered to State Planning Organization Counselorship (State Planning Organization, 2002; Ulusoy & Karakurt, 2003).

As per the project under Turkish National Information Main Plan (TUENA), the cost price for the infrastructure is calculated to be \$35 billion and under this project each of the citizen could reach national information infrastructure by 2010. It is foreseen that 14 billion of this amount will be spent for infrastructure, and \$21 billion for output units like computers, Web, TV, and so forth.

It has been observed that among macroeconomic policies, e-government investments have a priority as far as the E-Transformation Turkey Project is concerned. However, it is stated that among the projects in practice, the ones which can be adopted to the E-Transformation Turkey Project will have priority parallel to sectoral and regional priorities (State Planning Organization, 2005c). Moreover, about e-government studies, it is stated that e-government services will be established holistically instead of individual institutional approaches. In this manner, it is mentioned that bureaucracy and other problems emerging from recessive connection among institutions will be decreased.

E-GOVERNMENT PRACTICES IN TURKEY

With the Primeministry circular on December 4, 2003 (State Planning Organisation, 2005b), the application of the E-Transformation Turkey Project Short Term Action Plan had started an organizational structure. The Ministries of Industry and Commerce, Transportation, Education, Health, Justice and State Planning Organization, Institute of Turkey Standardization, Association of

Turkey Information and Communication worked together in coordination for the Short Term Action Plan during 2003-2004. From a legal perspective, "Having Knowledge Law" on 24th April 24, 2004 and "Electronic Signature Law" on July 23, 2004 came into effect and rules and regulations on electronic signatures were in operation beginning January 6, 2005 (State Planning Organisation, 2005b).

In addition to these, there is an important tool for transformation of Information Society working in Turkey, that is, "The Project of E-Transformation in Turkey." Targets of this project are development of social welfare, efficient use of investments, effective use of information to decrease the cost of services, and increased international competition. In this context, policies and strategies are being taken. Technical infrastructure and safety of information, education, human resource, legal infrastructure, standardization, e-management, e-health, and e-commerce are taken as a base for the process of transformation. The Board of Directors of "E-Transformation of Turkey" has prepared the Document of Transformation Policy for Information Society. In that document, it is recommended that public institutions and civil society institutions should work together. Furthermore, in the document the most important thing which has been raised is e-government. In this context, studies have already started and important steps have been achieved by the state. For example, literacy rates and Internet use have increased. In this framework, the Ministry of Education and Turkish Telecommunication Company has developed a protocol. According to the protocol, 42,534 schools throughout the country could have Asymmetric Digital Subscriber Lines by the end of 2005. At the same time, 58,900 schools are to have computers and Internet connections. By this time, 578,800 teachers were educated by using the computer as an educational tool. Another project has been launched in the e-government context that aims to increase numerical illiterate people that exist in the public institution.

In the framework of the E-Transformation Turkey Project, the tendency of investment in public institution for ICTs has increased. In 2002, under the National Investment Program, 203 projects were taken with 286,013 billion TL (158.8 million US\$); in 2003 for 204 projects 369,321 billion TL (208.6 million US\$) were allocated; in 2004 for 211 project 451,181 billion TL (281.3 million US\$) budget was given; and in 2005 for 200 projects 626, 253 YTL (388.4 million US\$) was disbursed. It has been observed that, in this area investment for public services increased by 16.6% from 2002 to 2003, by 8.4% from 2003 to 2004 and in 2005 special investment was made in education. At the Investment Program about ICTs cost of the project investments was 2,088,708,000 YTL (1,295,725 US\$) in 2005. The rates of it inside the total public investment is 2.9% in 2002; 3.0% in 2003; 3.8% in 2004; and 3.9% in 2005 (Odabas, 2005; State Planning Organization, 2005a).

In August 25, 2005, there were 6,722 Internet hosts in Turkey that belonged to institutions providing public services. Distribution of them, especially belong to the central administration. These are 3,029 for central administration (gov.tr), 1,001 for local administration (bel.tr), 2,372 for primary and secondary schools (k12.tr), 186 for university or institute (edu.tr), 8 for military service (mil.tr), and 126 for security (pol.tr) (State Planning Organization, 2003; TUBITAK, 2002). Figure 1 shows the distribution of subdomains of .tr and it can be observed that .com remains at the top with 48,136 hosts.

Usually, land phone, mobile phone and Internet penetration are being accepted as the basic indicators of ICT. Surprisingly, it was found that in Turkey, only in 2002, 10,000 people had new subscriptions for phones, but it was decreased in 2003. Mobile phone subscription growth was fast especially in recent years, that is, looking at the period of 1994 until today. In 2003, it had reached to approximately 27.9 million subscribers in Turkey. In this ranking, Turkey has ranked as sixth among the European Union member countries. Internet

use is also increasing year by year in Turkey. In 2003, the Internet users in Turkey increased by 5.8% in comparison to 31.1% in the European Union; in 2002, Internet users increased to 7.1% in Turkey, while there was a 35.7% increase in the European Union; and in 2003 Turkey's Internet user growth rate was 8.48%, while the European Union rate was 38.50% (Oruc & Arslan, 2002). Table 7 shows a few ICT indicators and they have been compared with other countries.

Furthermore, in the report on "Global Information Technology," prepared by the World Economic Forum, there are ranked countries related to transformation of information technology. In this ranking, technical infrastructure remains an important indicator as compared to service performance and development. Technical production ability and legal regulations criteria are also taken into account. Turkey's placement in this ranking within the countries is given in Table 8. Table 9

Table 8. Basic indicators related to the ICTs in Turkey

	2003	2004	2005
Capacity phone switchboard (thousand people)	21.163	21.006	21.106
Phone subscribers (thousand people)	18.917	19.125	19.000

E-Government Practices in Regional Context

provides an e-readiness comparison, Table 10 gives an overview on computer ownership since 1994 with a target indicator in 2015, and Table 11 gives an overview on Internet users from 1999 with a target of 20,000 in 2005.

E-GOVERNMENT APPLICATION STUDIES IN THE CONTEXT OF REGIONAL DEVELOPMENT IN TURKEY

The searching of following a definite policy in the field of science and technology and the formation of this matter started with a planned period and TUBITAK was founded in 1963 during the first Five Year Development Plan (1963-67); the Second Five Years Plan (1968-1973); the Third Five Years Plan (1973-1977); and the Fourth Five Years Plan (1979-1983) were successfully implemented. Thus, Five Five Year of Development Plans were prepared and the technological improvements and the

technology transfer regions were included in this plan. The fourth Five Year Development process dealt with the policies of technology, and it was foreseen that the policies of technology should be considered as a whole structure with employment and investment policies. The same subjects are also mentioned in the latest, the eighth Five Year Development Plan in 2004 (State Planning Organization, 2002).

In the context of the European Union Adaptation process, the studies about Turkey's communication and information fields are also increased. On October 4, 2001, the studies on formation of E-Turkey Action Plan were started in coordination with the E-Europe Action Plan under the Prime Ministry's Councillor. By January 25, 2005, the responsibility was given to the Turkish Telecommunication Company e-government portal under the coordination of the State Planning Organization. In this way, the projects of information and communication of Turkey have been carried out rapidly. These projects are carried out in such a

way that entails the whole country. In other words, none of the existing projects could avoid the digital division in socioeconomically less developed regions (Cetin, Aydogan & Ertugrul, 2002).

However, in accordance with the aims of regional development, no special work regarding the communication and information was confirmed in the projects which were started during the period of the Seventh Five Year Development Plan. These projects are Eastern Anatolian Project, South-Eastern Anatolian Project, Eastern Black Sea Regional Development Project, Zonguldak Bartın Karabük Regional Growth Project, and Yeşilirmak Sphere Growth Project; and they are working with the following objectives to:

- Increase the income and the employment per person.
- Reform the income distribution inside the regional areas.
- Widen the activities which will speed up the developments.
- Acquire the long term continuing development by protecting the natural resources and the capacity of the region.
- Provide the continuation of development.
- Improve (develop) the subregional centers as industrial and service centers.
- Improve the private sector.
- Increase the opportunities of employment.
- Increase the agricultural productivity.
- Develop the manufacturing sector related with agriculture.
- Increase the indicators of health and education up to the level of country's average.
- Increase the inside-region and outside-region connectivity.
- Prepare the practice devoted to human improvement.
- Form a filter against the East-West immigration.

In Turkey, related to ICTs projects, it is seen that the required infrastructure projects are be-

ing planned by choosing pilot regions which are developed socioeconomically throughout the country, instead of preparing special projects for undeveloped or underdeveloped regions. The reason for this is, when compared to various countries worldwide, the infrastructure of data processing in Turkey is quite insufficient. And what is more the Turkey prefers; by applying all these projects initially in order to use those experiences in socioeconomically developed regions. After realization for these regions then transmit them to the underdeveloped regions of the country. By using this method, implementation will be less expensive and, at the same time, the results will be reached in a short period in terms of ICTs. However, these may be applicable for government run initiatives.

In Turkey, the relationship between information and knowledge technologies and regional development was weak until 2000. After the E-Turkey Action Plan that is related to the E-Europe+ Action Plan to constitute e-transformation, Turkey has been trying to complete faster organizational, legislation and infrastructure works. In this period of time Turkey has moved forward working about knowledge society importantly, in order to decrease the knowledge disparities within the society. The primary target of Turkey is to transform to an Information Society in the next five years (San, 2005).

In the Preliminary National Development Plan (2004-2006), long term knowledge society strategies have been included that will be completed by 2023 (State Planning Organization, 2003). Turkey will also update the programs of the institutions according to the 2006-2008 program that included regional, national, and international improvements and demands. Besides this, it is implied that the development of the information in the areas of transportation, education, health, agriculture, industry, mining, and manufacturer sectors have been taken into account in the framework of knowledge and information technologies, and infrastructures will be developed throughout

the country (State Planning Organization, 2005a). According to the report on the e-transformation in Turkey 2006, it is determined that knowledge and information technologies have focused primarily on investment in e-government. These investments will be distributed with balance among the regions. To realize this, apart from the central administration, local administrations, non-governmental organizations, universities, private sector entrepreneurs, and local unions will be included in some projects. This will be done firstly, to realize regional development and secondly, to achieve a high rate of welfare succession on the global platform. However, within the perspective of these targets, it is important to have e-strategy. Turkey has the aim to complete the infrastructure in relation to the e-strategy to be included in the first 15th rank on knowledge economy in the world by 2015 (State Planning Organization, 2005c). It is also important to realize governance along with this aim. Nongovernmental organizations, local administrations, and professional institutions will be included to work to achieve this aim. At the same time, to increase qualified people and to widen remote education, programs will be applied in the e-strategy. Specifically, this will create new employment facilities in underdeveloped regions, income levels will be increased, competition power will be strengthened, necessary technical infrastructure systems will be established all over the country, and legislation will be accomplished.

RESULT AND EVALUATION

In this document, it is analyzed that Turkey has used the ICTs in the undeveloped areas in order to provide the socioeconomic escalation as summarized as follows:

- According to the Census 2000, Turkey, having the population of 67,844,903, with a rate of 18.34% population increase, and national

income of US\$4,744 per person (according to the 2005 data), is included as one of the developing countries. However, there are regions differing from each other in the concept of socioeconomic development.

- In Turkey, various policies have been produced since 1963 (the planned period) in order to develop the socioeconomically backward regions. State Planning Organisation has been responsible for this to provide the coordination and to activate the projects.
- In Turkey, the targets of the regional development policies are to minimize the socioeconomic differences among regions, to improve the private sector, to complete the infrastructure of transportation, to increase the education and health services, to increase the productivity of agriculture, to increase employment, and to increase the income per person.
- Recently, Turkey has accelerated the programs in the field of ICTs in order to compete with the other countries in the global aspect and to get benefit from the positive values resulting from the differences in the ICTs. As Turkey is a candidate country for the European Union membership and as the European Union is giving importance to the projects on ICTs, it is important for Turkey to carry out similar projects.
- On October 4, 2001, the project on formation of an E-Turkey Action Plan was started in coordination with the E-Europe Action Plan under guidance of the Prime Ministry's Councillor. On January 25, 2005, Turkish Telecommunication Company started implementing the E-government Portal under the coordination of the State Planning Organisation. Similarly, the Information Society Department Presidency was founded in the structure of SPO which is responsible for the coordination, observation, evaluation, and the orientation of the E-Transformation Turkey Project.

- When compared to various other countries of the world the infrastructure of data processing in Turkey is at the bottom levels. It has been found that, one of the most important problems about the usage of ICTs is the digital division. This is due to low income status of each individual in the country.
- The programs regarding the ICTs in the country are applied in the pilot regions where the results of the projects are supplied with a lower cost and in a shorter time.
- In a developing country like Turkey, use of ICTs in socioeconomic and social development is a great opportunity, but regarding the use, in terms of time and funding, it is quite insufficient. Turkey cannot properly take this opportunity as an advantage, unless every kind of project has been practiced in educational, legal, political, economical, and social aspects in order to increase the ability to compete with other countries in the global aspect and to use the ICTs effectively within the country.

Turkey has a young and dynamic population and this is an advantage to e-transformation. If there is an integration between the regional development projects and knowledge and information technologies development, regional migration tendencies will be decreased and the population will be employed in the regions. In conclusion, with knowledge and information technologies, differentiation or polarization of the regions will be prevented and certain socioeconomic levels will be reached in all the regions of Turkey.

Chapter 5.36

Information Security in Small Businesses

Kishore Singh

University of KwaZulu-Natal, South Africa

ABSTRACT

This chapter discusses the impact of security in small and medium enterprises. It views the development of a security policy in serious light and come up with some recommendations on how this can be handled.

INTRODUCTION

The management of information security and security related events has become an issue commanding ever-increasing attention from the various professions attending to the information needs of organisations using ICT¹ (Von Solms, 2001). The basic need of developing secure information systems (IS), however, continues to remain unfulfilled. This is because the focus continues to remain on the means of delivery

of information (i.e., the technology (Galliers, 1993)). Management continues to believe that information security and related problems can be solved by technical means (Vermeulen & Von Solms, 2002). The responsibility of information security is entrusted to the technical department without proper, direct, and continuous support from executive management. The net result is that technology is used to solve the information security problem without a total, comprehensive solution (Von Solms & Von Solms, 2004).

This chapter describes the contribution made by small businesses² to the South African economy, reviews some of the current literature in information security, and examines some of the more recent (2002 to 2004) survey statistics describing the state of information security in organisations. This chapter is aimed at academics, information security researchers, information security practitioners, and owners of small

businesses that make use of computer-based information systems. Additionally, any student of information security that needs to understand the fundamentals of effective information security implementation in small businesses will find this chapter useful.

SMALL BUSINESS PROFILE

South Africa has a thriving small business sector supported by a network of financial and non-financial service providers. By enabling people to meet their basic needs for survival, small businesses play an important role in economic development. It has been proven in many parts of the world that the small business sector stimulates economic growth, redistributes wealth, and creates jobs. The latter being particularly important within the context of the reality that large corporations' demand for labour does not increase in proportion to their growth (Ntsika, 2002).

According to Ntsika (2002), some of the reasons why small businesses in South Africa have become an important target for policy makers are: (1) they can easily absorb excess labour capacity as compared to other sectors, (2) the cost of creating a job is lower than in the large

businesses, (3) they create more competitive markets, (4) they can easily and quickly adapt to changing consumer tastes and trends, (5) they often use local recycled resources, (6) they provide opportunities for entrepreneurs, and those who are unemployed, under-employed, or retrenched, (7) they allow workers with limited or no skills or training to learn these on the job, (8) they are often sub-contracting by large enterprises thereby providing flexibility to production processes, and (9) they play an important role in innovation.

Classification and Distribution of Small Businesses

For the purpose of this chapter, enterprises in South Africa have been categorized according to the definitions provided in the National Small Business Act (NSBA, 1996). Table 1 summarises the NSBA (1996) classification of small businesses.

The National Small Business Act (NSBA, 1996, p. 34) additionally distinguishes a small business using the following three criteria: (1) total full-time equivalent employees (<100, with the exception of mining and quarrying; and manufacturing (<200), (2) total annual paid turnover (figures vary according to sector), and (3) total gross asset value (figures vary according to sector).

Table 1. Classification of small businesses source (Adapted from the National Small Business Act 1996)

Category	Characteristic
1. Survivalist	income generated is less than the poverty line, there are no paid employees and the asset value is minimal
2. Micro	turnover is less than the VAT registration limit, they are not formally registered and employ between 1- 4 people, excluding the entrepreneur
3. Very small	operate in the formal market and have access to modern technology
4. Small	a secondary co-ordinating management structure is in place with some form of managerial level coordination
5. Medium	further decentralization of decision-making, a more complex management structure and further division of labour are evident

Growth of Small Business Sector

During his State of the Nation Address (2004), the South African president stated that South Africa would continue to focus on the growth and development of a modern “first economy” in order to generate resources to meet the challenges of its underdeveloped “second economy.” He added that further expansion of small and medium enterprise will be a contributing factor and promised to help increase the market share of small businesses (Mbeki, 2004).

Prior to the official launch of the Small Enterprise Development Agency (SEDA), the Deputy Minister of Trade and Industry commented that small businesses have an important role to play in the economy. The minister added that further development of the small business sector will assist in economic growth, job creation, and reduction of poverty in South Africa (SEDA, 2004).

Contribution to Economy

South Africa’s small business sector is the backbone of the national economy and currently employs over 50% of the workforce and accounts for over 35% of the GDP (Ntsika, 2004). According to Ntsika (2002), the contribution of small businesses in 2001 to GDP was 36.1%, up from 32.7% in 1995. Small businesses accounted for at least half of GDP in the agricultural and construction sectors and more than 40% of GDP in the trade, catering, and accommodation, as well as the transport, storage, and communication sectors.

In 2002, small businesses employed 68.2% of people employed in the private sector, as opposed to 44% in 1995 and 53.9% in 2001. Small enterprises constituted the most significant small business employer, (accounting for 21% of total small business employment), followed by medium-sized (18% of total small business employment) enterprises and micro enterprises (17% of total small business employment).

The largest provinces in economic terms are Gauteng, Kwazulu-Natal, and Western Cape, which jointly account for 69% of South Africa’s GDP. Some 60% of all enterprises and 70% of all small businesses are concentrated in these three provinces. Small business distribution in these three provinces is Gauteng (38.4%), Kwazulu-Natal (18.4%), and the Western Cape (13.4%) (Ntsika, 2002).

Small Businesses and Technology

According to Pratt (2002), small businesses have benefited from new technologies that have decentralized computing and telecommunications. In the past only large corporations could acquire the sizable capital required for commerce that depended upon mainframe computers and other costly business equipment. However, since the 1980s, the advent of inexpensive personal computers have enabled small firms to compete with larger businesses. First, the cost of equipping a home office has dropped significantly and the capabilities of business tools have improved. Second, the Internet, is transforming the way people work, live, and conduct business. E-mail, the Internet, and the cell phone offer connections that extend globally from any location--an office building, a home office, a car, or boat (e.g., Amazon.com, initially started out in a home basement, has since taken over the online book market from Barnes and Noble). Individuals now have access to information and to markets on a 24x7 basis (Pratt, 2002).

Small businesses, by their very nature, are able to adapt to change faster than large businesses. Small businesses are the fastest changing sector of business (SBA, 1999a). Small businesses are embracing the use of Internet technologies and e-commerce as a way to leverage their limited resources and to reach an expanded customer base. According to SBA (1999b), small home-based businesses represent more than 18% of

all homes with personal computers, and of all home-based businesses in the United States, 60% use personal computers to conduct their business activities (Pratt, 2002).

According to SBA (1999b), the rate of Internet connectivity among small businesses rose from 21.5% in 1996 to 41.2% in 1998 to 61% in 1999. The percentage of small businesses with a World Wide Web (WWW) presence was 35% in 1999. Of those small businesses with a Web site, 78% were motivated to develop one in order to reach new and potential customers. One third of small businesses currently perform business transactions using their Web site. Small businesses that use the WWW have higher annual revenues than those that do not, averaging about one million U.S. dollars per year more (SBA, 1999b).

Small businesses often initiate technological innovation, the use of business applications, the use of personal computers, and the Internet (Oliver, 2000). The personal computer and Internet support smaller businesses and allow them to match big-business efficiencies, thereby enhancing their ability to communicate with suppliers and customers, lower costs, and expand markets (Oliver, 2000). Innovative entrepreneurs (early adopters) use technology and the Internet as a way to market niche products and reach distant customers in ways that were not available in the past. As a result, of this adoption of technology, structural changes are required industrial organization.

Petkov, Fry, Petkova, and D'Onofrio (2003) state that small businesses need technology in order to succeed. Some of these technologies could be used to solve the problems of smaller businesses and to accumulate knowledge for improvement of their services. Lubbe (2004) states that investment in IT has an impact on the competitiveness of small and medium organisations. As a result, small businesses are beginning to spend a higher percentage of their turnover on IT; however Lubbe (2004) goes on to state that the biggest limitation to ICT implementation in small businesses was that 80% of them did not know how to use ICT

correctly. Additionally, the biggest mistake that small businesses made in implementing ICT was that they did not understand that they cannot do everything themselves.

From the discussion in the preceding paragraphs, the author concludes that ICT adoption and an Internet presence are emerging as powerful tools for business success. As more small businesses show successful use of ICT, other small businesses will be motivated to adopt these technologies and practices. Embracing ICT and the Internet are critical factors that will determine a small businesses market share in the future. Those small businesses that ignore or hesitate to implement new technologies will be doing so at their own risk (Pratt, 2002).

Small Businesses and Crime

Berger (1981) affirms that security, in general, is a problem for small businesses. A small business does not have the business base across which to spread the cost of security personnel or technologies. Additionally, he concludes that businesses with more than 100 employees are better able to afford a security officer or manager on staff. Chelimsky, Jordan, Russell, and Strack (1981) recognize that small businesses suffer more from crime than larger businesses and bear a greater proportion of loss as a result of crime than other businesses. The author therefore concludes that those least able to protect themselves—the small business sector—are targeted more often, and the consequences are often more serious.

According to Chelimsky et al. (1981), insurance companies attribute approximately 30% of business failures to internal theft. A 20-year old analysis of white collar crime conducted by Berger (1981) confirms that internal theft by employees surpasses the incidents of shoplifting, hold-ups, and burglary collectively.

Small businesses continue to embrace new technologies resulting in the computerization of many business processes (Pratt, 2002). As a

result, they have become potentially more vulnerable to internal theft. This is particularly true with regards to theft of money, which is the most threatening crime to small business (Doney, 1998). Most small businesses aren't large enough to have security experts on staff (Keogh, 1981), yet the potential result of computer-based crime can be catastrophic (e.g., business failure, financial, and personal liability). Studies described in Doney (1998) indicate that the average loss experienced by a business is about ten times higher when a crime is committed with the assistance of a computer as compared to when committed without it.

According to Pratt (2002), the issues that arise in the move of small businesses to electronic commerce include the cost of establishing and maintaining an Internet presence and security issues associated with online transactions. Of the security-related concerns, the predominant one is that of fraud. The concern over fraud is expected to be amplified by security concerns related to digital cash, as that medium becomes common.

Most small businesses are managed by the owner with only basic management structures (if any) in place (NSBA, 1996). A survey conducted by Lubbe (2004) established that one-half of small business owners do not have any idea of what ICT entails nor how it should be used. It is therefore a reasonable conclusion that by embracing new technologies without correct investigation, implementation, or incomplete understanding of the technology itself, small business owners are exposing themselves to a risk environment and are unable to set up and maintain a suitable level of information security without expert assistance. Additionally, a survey conducted by PriceWaterHouse Coopers (ISBS, 2004) determined that, more than 50% of businesses in the United Kingdom think that information security incidents will continue to increase in the future, despite their high confidence in existing security controls. How then can small business

practitioners deal with the ever-increasing threat to information security?

Initial attacks of computer-based information systems were aimed at specific organisations, primarily large corporate enterprises. Although smaller firms were attacked, most small firms could somewhat depend on "security through obscurity" (Panko, 2004, p. 10). Today, most attacks are equivalent of firing guns into the crowds. This implies that every computer attached to a telecommunications network has an equal opportunity of being compromised (Panko, 2004).

Lubbe (2004) verifies that a security gap exists between current and required security practices in small businesses. This gap did not appear as a result of the absence of a shared vision. Instead, according to Lubbe (2004), there was an agreement between big business and small business respondents about the importance of certain security tasks and security skills. Many of these security tasks, however, received low importance scores from small business practitioners.

REVIEW OF INFORMATION SECURITY LITERATURE

This section reviews some of the current literature in the subject of information security and provides a background to the problem of information security in small businesses.

Definition of Information Security

Security relates to the protection of valuable assets against loss, misuse, disclosure, or damage (ITGI, 2001). Security related problems occur because of the need to balance two important yet conflicting goals viz. (1) the goal of providing access to resources and (2) the goal of preserving confidentiality, integrity, and availability (Mehta & George, 2001).

Tsujii (2004) defines information security as a process for establishing a complete system of

social fundamentals that links and coordinates technologies, administration, and management techniques, legal and social systems, and information morals. This, he states, will improve usability and efficiency, enhance security and privacy, and lead to a reduction in monitoring and surveillance over system users. Finne (1998) suggests that when information is misused, lost, or threatened it is as a result of insufficient information security.

The United States National Institute of Standards and Technology (NIST, 1995, p. 5) offers the following definition of information security

“The protection of information system assets (including hardware, software, firmware, information/data and telecommunications) against various threats and attacks in order to preserve the integrity, availability, and confidentiality of these systems.”

A desirable outcome of security is thus the reliability and preservation of system conditions and functions. Confidentiality, integrity, and availability (CIA) are regarded as the three components of information security (Tsuji, 2004). These concepts are summarized in Table 2.

Williams (2001) states that the concept of security relates to the protection of valuable information assets. The data or information must be protected against harm from threats leading to its loss, inaccessibility, alteration, or wrongful disclosure. The main objective of information

security is to protect the interests of those relying on information, and the systems that deliver the information, from damage resulting from failures of availability, confidentiality, and integrity (Williams, 2001).

The IT Governance Institute (ITGI, 2001) confirms that information security objectives are met when: (1) information is observed by or disclosed to only those who have a right to know (confidentiality), (2) information is protected against unauthorised modification (integrity), and (3) information is available and usable when required, and the systems that provide it can appropriately resist attacks and recover from failures (availability).

The COBIT security baseline (COBIT, 2004) ascertains that the relative priorities and significance attached to confidentiality, integrity, and availability varies according to the value and type of information and the context in which it is being used. For example, integrity of management information is important to a business relying on critical strategy-related decisions, and integrity of online shopping is very important to a home user. Furthermore, the amount of protection afforded to a system depends on the likelihood of a security incident occurring and the level of impact the incident will have should it occur (COBIT, 2004).

The definition of information security adopted in this chapter is as specified in NIST (1995), for example:

Table 2. Confidentiality, integrity, and availability (Adapted from Tsujii, 2004)

Component	Description
1. Confidentiality	Only a person who has permission to access particular information can access it.
2. Integrity	Information and its associated processing methods are authentic and complete.
3. Availability	The ability of authorised users to access information and related assets reliably whenever necessary is preserved.

Information security is the protection of information system assets³ against various threats and attacks in order to preserve the confidentiality, integrity, and availability of these systems.

Importance of Information Security

COBIT (2004) establishes that ICT has become an integral part of everyday business and private life, and dependency on information systems is constantly growing. New technologies have emerged that allow unprecedented functionality but introduce new risks and environments that are harder to control (e.g., wireless technology, mobile computing, and integration of technologies (i.e., multimedia). Increased dependency on ICT by individuals and organisations alike implies that the impact of system failures is magnified. Whether the incident happens to a home user (e.g., relying on online banking) or an enterprise (e.g., relying on online customers), security incidents have a real impact. With the proliferation of communication networks, individuals are justified in being concerned about the privacy of their personal information and organisations need to protect the confidentiality of corporate data, while promoting electronic business (COBIT, 2004).

According to ITGI (2001), ICT can generate many direct and indirect benefits, and as many direct and indirect risks. These risks have led to a gap between the need to protect systems and the degree of protection applied. The gap is caused by (1) extensive use of technology, (2) increased interconnectivity of systems, (3) elimination of distance, time, and space as constraints, (4) rapid technological change, (5) decentralized management and control, (6) increase in unconventional electronic attacks against organisations, and (7) external factors such as legislative, legal, and regulatory requirements, or technological developments.

New risk areas that could have a significant impact on critical business operations, have emerged. These include: (1) increasing require-

ments for availability and robustness, (2) growing potential for misuse and abuse of ICT affecting privacy and ethical values, and (3) external dangers from hackers, leading to denial-of-service and virus attacks, extortion and leakage of corporate information (ITGI, 2001).

New technology provides the potential for dramatically enhanced business performance hence, improved and demonstrated information security can add real value to any organisation (small or large) by contributing to interaction with trading partners, closer customer relationships, improved competitive advantage, and protected reputation (ITGI, 2001). Technology can also enable new and easier ways to process electronic transactions and generate trust (ITGI, 2001). However, the ensuing increase in technical complexity has led to new and more complex risks (COBIT, 2004).

Von Solms (1998) notes that in the early days (pre-personal computer period), securing computing environments required few technical and physical mechanisms. With the advent of the personal computer (PC) and multi-processors, a number of additional technical security measures became necessary (e.g., user identification, authentication, authorization, and access control to data). Nevertheless, a precise information security policy ensured that the entire environment was controlled and secured, to an acceptable level, by the organisations personnel (Von Solms, 1998).

As organizations connect their communication networks to the Internet or to the networks of their business partners, it is no longer possible to maintain precise control over their ICT systems and users, and consequently information security in general. The information security policy, which dictates the behaviour of users within an organization, has no influence on any users outside the organization. Therefore, it is imperative for individual organizations to protect their own ICT environments satisfactorily since technologies such as EDI,⁴ the Internet, and EFTPoS⁵ enable organizations to exchange information electronically, and inadequate protection on one side may

have negative consequences on the other side (Von Solms, 1998). It can be potentially harmful to any organisations reputation if business partners or potential business partners label the organisation as having inadequate information security.

Blatchford (1998) notes that severe business uncertainty can result from systems that are vulnerable and that poor information security can have adverse economic impacts on individuals, organizations, and society in general. Von Solms (1996) suggests that a stage is being reached where an organisations potential business partners will require proof of adequate information security. Failure to provide such evidence may result in the inability to attract new business and the potential loss of some existing business partners. Mitchell, Marcella, and Baxter (1999) confirm this by stating that information security breaches can have a devastating effect on an organisation. He notes that the loss of confidential information (proprietary product information, client data, and business plans) can result in the loss of customers and credibility and eventually reduced profitability. He goes on to say that while management processes, policies and technologies exist to protect corporate information, evidence continues to suggest that companies are either unaware of the scale of the threats, or are not taking steps to protect information.

As businesses begin to increasingly adopt and depend on the Internet and ICT to increase their bottom lines, concerns over security and related issues will continue to be listed as top challenges hindering increased earnings potential and expansion of market shares (Garg, Curtis, & Halper, 2003). In addition to the growth of e-commerce, laws such as the Electronic Communications and Transactions Act (ECT, 2002) stipulate that comprehensive safeguards must be deployed in order to protect the security, privacy, and confidentiality of personal and corporate information.

Thomson and von Solms (1998) claim that even though technological progression has contributed to the development of information security

management, an emerging issue in information security is the change in the profile of the end-user. End-user tasks are no longer limited to simple data capture. Due to increasing competition from rival businesses, managerial end-users require access to information on a “must have now” basis. Additionally, these end-users often develop their own small systems to interpret and manipulate data. This increase in sophistication of the end-user combined with the need to grant them access to the information they require means that it is no longer possible to maintain effective information security with physical and technical controls only (Thompson et al., 1998).

A partial review of information security survey statistics (AusCERT, 2004; BCMS, 2003; E-Crime, 2004; ISBS, 2004) was conducted next in order to offer evidence to support (1) the importance of ensuring effective information security and (2) the increasing incidence of information security breaches in organisations. The results of the review are stated in the following paragraphs.

The 2004 E-Crime Watch Survey (E-Crime, 2004), conducted by *Carnegie Mellon University Software Engineering Institute's CERT® Coordination Centre*, showed a significant number of organizations reporting an increase in electronic crimes (e-crimes) and network, system or data intrusions. Forty-three percent of respondents reported an increase in e-crimes and intrusions when compared to the previous year (2003) and 70% reported that at least one e-crime or intrusion was committed against their organization. Respondents declared that e-crime cost their organizations approximately US\$666 million in 2003. This increase in electronic crimes over the previous year demonstrates the need for organizations to develop coordinated efforts between their ICT and information security departments to maximize defence and minimize e-crime impact.

The Australian Computer Crime and Security Survey (AusCERT, 2004) conducted by the *Aus-*

tralian High Tech Crime Centre and the *Australian Federal Police* showed a definite increase in the number of organisations experiencing electronic attacks (49%) in the last 12 months, when compared to the previous year (42% in 2003). The survey also indicated that a considerably higher percentage of organisations experienced harmful externally sourced attacks (88%) than harmful internally sourced attacks (36%). This trend continues to demonstrate that organisations connected to the Internet are at a higher risk than those that are not and these organisations appear to be finding it more difficult to prevent externally sourced attacks.

The Information Security Breaches Survey (ISBS, 2004) conducted by the *UK Department of Trade and Industry* and *PriceWaterHouse Coopers* highlighted the continuing increase in the number of UK businesses suffering a security breach. Seventy-five percent of all companies and almost all large companies had at least one security incident in the last year (2004). Overall, 33% of all UK businesses and 66% of large businesses had a serious security breach. This was an increase from just under 50% in 2002. The survey results also suggested that large businesses were more successful at repelling attacks. For the smaller businesses, 1 probe in 50 resulted in a breach of their defences as compared to less than one probe in a hundred for the larger businesses.

No comparable survey data exists that uniquely profiles the entire spectrum of South African businesses. However, in the first ever Business Continuity Management Survey ZA (BCMS, 2003) conducted by *KMPG* and *BMI-TechKnowledge*, 74% of the respondents indicated that their biggest concern was information security breaches. It must, however, be noted that this survey only sampled South African businesses with an annual turnover of between R100 million to R30 billion.

In the preceding paragraphs, a partial review of information security survey statistics was conducted. The year-on-year figures provide

substantial evidence that information security breaches are on the increase. These figures provide conclusive evidence that (1) provision of effective information security is essential for an organisations continued existence, and (2) information security continues to remain a problem for many organisations. Witman (2004) supports this conclusion when he states that information security is a difficult task that requires complex interdependencies between organisations and work units in order to establish and maintain a systems security.

The foregoing discussions have offered evidence that reiterates the importance of information security. The benefits accruing from providing adequate and effective information security include (but are not limited to) increased profitability, larger market share and, most importantly, trust amongst business partners.

Definition of Threats and Vulnerabilities

An overview of the risk environment in which information systems operate is presented next. Information systems are susceptible to many threats and vulnerabilities that can cause various types of damage resulting in significant losses. The effects of these threats vary considerably: some affect the confidentiality or integrity of information while others affect the availability of a system (NIST, 1995).

A threat is the potential for a particular threat-source to successfully exercise a particular vulnerability. A threat-source is defined as any circumstance or event with the potential to cause harm to an ICT system. A vulnerability is a weakness that can be accidentally triggered or intentionally exploited. A threat-source does not present a risk when there is no vulnerability that can be exercised. In determining the likelihood of a threat, one must consider threat-sources, potential vulnerabilities, and existing controls (Stoneburner, Goguen, & Feringa, 2002). It is

the author's conclusion that protection should be against threats that can exploit vulnerabilities. If vulnerabilities exist but there are no threats to exploit them, then little or nothing is gained by providing the protection.

Cisco (2001) identifies several threat-sources and provides some motivations why security crimes are committed. According to this white paper, sources of threats to information security include; organized criminals, cyber terrorists, industrial spies, foreign countries in conflict with targeted nations, disgruntled employees, and amateur hackers. Each of these groups has different motivations and poses a different type of threat and the damage caused can range from simple file integrity errors to total destruction of entire information systems. Some of the reasons why hacking and intrusions occur are: (1) organized criminals are economically motivated and seek information that can be sold or used to extort money from victims, (2) terrorists are politically and/or religiously motivated, (3) industrial spies are seeking competitive information, (4) disgruntled employees want to do damage to systems or obtain information to embarrass their

employer or former employer, and (5) amateur hackers are attempting to prove their abilities (Cisco, 2001). Figure 1 gives a typical list of the threats experienced and the cost (US\$) incurred by each type of threat in 2004 (CSI, 2004).

According to Figure 2, virus infections accounted for the largest portion of losses (approx. \$55.05 million). In ISBS (2004), 70% of organizations surveyed suffered a virus infection, thus confirming the CSI (2004) finding. These results are further confirmed by MessageLabs (2005) where the finding is that at least one in every 34.95 email messages (during January 2005) contained a virus and this number continues to rise. This number is disturbing as 99% of all firms surveyed by CSI (2004) implement antivirus software.

Other incidents identified by CSI (2004) were denial-of-service (approx. \$26.06 million); theft of proprietary information (approx. \$11.46 million); insider net abuse (approx. \$10.6 million); abuse of wireless network (approx. \$10.16 million); financial fraud (approx. \$7.67 million); laptop theft (approx. \$6.74 million); unauthorized access (approx. \$4.28 million); telecom fraud (approx. \$3.98 million); misuse of public Web application (approx. \$2.74 million); web site defacement (approx. \$958,100); system penetration (approx. \$901,500); and sabotage (approx. \$871,000).

Figure 1. Categories of security threats and associated costs (U.S. dollars) (Adapted from CSI, 2004)

\$2.75 million); Web site defacement (\$958,100); system penetration (\$901,500); and sabotage (\$871,000). Although these statistics pertain to U.S.-based organisations, it is a reasonable conclusion that worldwide trends will follow similar patterns. A review of some information security survey statistics (AusCERT, 2004; BCMS, 2003; E-Crime, 2004; ISBS, 2004) was undertaken and this confirmed the author's conclusion.

Protecting ICT systems has never before been more important. Organisations today are facing a wide range of threats to their information assets. Any organisation that suffers an information security incident must be able to identify *who* did *what* and *when* they did it. By better understanding the potential threats and vulnerabilities, an organisation can implement a number of procedures in order to raise the level of its information security and reduce the likelihood of security related incidents.

Information Security Investment

The concept of investment has one purpose and that is to generate a return. This return is seen in the form of capital, time, and both tangible and intangible benefits (Tsiakis & Stephanides, 2005).

In support of Tsiakis et al. (2005), in 1995, Murray, (cited in Anttila, Kajava, & Varonen, 2004, p. 1), declared that "*information security should pay, it should not cost*"; as the common belief at the time was that information security was unproductive and only incurred an extra financial burden on organisations.

Prior to making information security investment decisions, facts about assets (i.e., information, software, hardware, and systems), vulnerabilities, and the probability of breaches (and damages) need to be analysed. An evaluation needs to be done in order to find the best possible security solution (Tsiakis et al., 2005). Lubbe (1997) supports this conclusion by declaring that the evaluation of technology investments is

imperative due the increasingly strategic nature of the impact of technology on organisational performance.

A key factor in getting value from security is to ensure that technology investments protect the right assets. The financial returns gained from a successful implementation of security should justify the cost of security in terms of enabling the business. An organisation needs to assess security investment against the probability that a loss producing security incident will occur and multiply that by the impact that the problem will create (Tsiakis et al., 2005). Pipkin (2000) notes that the costs of implementing information security measures must be compared to the value of the information being protected and the consequences of incurring a security breach due to non-implementation of adequate security measures.

Investment decisions regarding information security should consider (1) the frequency of security breaches, (2) the cost of security breaches, and (3) investment in information security measures. Gordon and Loeb (2002) proposed a model to determine the optimal amount an organisation should invest in information security mechanisms. In their model, the amount to invest in security is taken as an increasing function of the level of vulnerability of the information being protected. The results of their research are summarised next:

- The optimal amount to invest in information security depends on the specific form of the security breach but should not exceed 37% of the expected loss due to the breach.
- There are no simple procedures to determine the probabilities of threat and their associated vulnerabilities.
- There are no simple procedures to determine the potential loss from information security breaches.

Cavusoglu, Mishra, and Raghunathan (2004) suggested the following additional approaches to

determine the optimal investment in information security:

- The fear, uncertainty, and doubt (FUD) strategy. This approach is used by information security vendors to sell security solutions.
- The cost of deploying security. This approach asks the question, “What is the most I can get for \$X,⁶ given that I am going to spend \$X?”
- Indirect estimation of dollar value costs associated with security breach announcements, such as the loss in market value (e.g., share price).
- Traditional risk or decision analysis framework. In this approach, the expected loss is computed once risks, potential risks and their likelihood of occurrence are identified.

Managers responsible for information security are increasingly required to justify their budget requests in purely economic terms. There has been considerable interest in using financial metrics used to justify and evaluate investments in information security (CSI, 2004). Figure 2 confirms this assumption.

Figure 2 illustrates that 55% of organizations use return on investment (ROI)⁷ as a metric, 28% use internal rate of return (IRR) and 25% use net present value (NPV). Although numerous metrics are available, ROI has emerged as the method preferred by most organisations.

Return on security investment (ROSI) is the most recent catchphrase that economists are using to characterize the value of security investments. Despite the fact that defining ROSI is difficult, security practitioners need to understand the variables that define ROSI and assign dollar values to quantities that are inadequately defined (SBQ, 2001).

It is apparent that information security management is a demanding task; however assessing the value of security technologies is an essential requirement in effectively managing information security. Various techniques and tools are available to the practitioner of information security. However, the economic perspective stresses that, while some investment in information security is good; more security is not always worth the cost. Hence, it is the author’s belief that, the amount that an organisation spends on information security

Figure 2. Percentage of organisations using financial metrics to quantify information security investments (Adapted from CSI, 2004)

will typically be far less than the expected loss from a security incident.

Impact of Information Security Breaches

No information security breach is good, but the impact of some incidents is considerably worse and more difficult to measure than that of others. There's always some financial aspect to security related incidents and organisations intent on not being victimised must pay a price as information security measures come at a price (Gordon & Richardson, 2004).

Every organisation (small or large) must understand the costs associated when information security is breached. Farahmand, Navathe, Sharp, and Enslow (2003) notes that the cost of an information security incident must be measured in terms of the impact on the business and, identical incidents in different organisations of the same industry could have different costs. The impact may be financial, in the form of immediate costs and losses, but the more serious incidents are those that have hidden costs associated with them. Furthermore, they (Farahmand et al., 2003) associate the following losses with information security breaches: (1) the brand image, public reputation, and the goodwill in the market place, (2) the financial value of business transactions, (3) public and customer confidence in the accuracy and fraud-resistance of business transactions, (4) the ability to maintain revenue cash flow in a timely manner, (5) the ability to resolve disputes beyond reasonable doubt, and (6) the ability to meet the requirements of regulators.

Cavusoglu (2002) states that public announcement of information security breaches are negatively associated with the market value of the affected organisations. He notes that compromised organisations lose approximately 2.1% of their market value within two days of the security incident and smaller organisations appear to be penalised more than larger ones when a

security breach occurs. This means that smaller organisations must keep in mind the importance of information security for their survivability.

Campbell, Gordon, Loeb, and Zhou (2003) examined the market reaction to newspaper reports of information security breaches at publicly traded U.S. corporations. Potential costs identified with security breaches were (1) lost business (immediate and long term as a consequence of negative reputation effects), (2) activities associated with detecting and correcting breaches, and (3) potential legal liability. They observed that survey data on the cost of information security breaches was limited since many organisations are unwilling or unable to quantify their losses. They concluded that there is some evidence of an overall negative stock market reaction to announcements of information security breaches and these announcements affect the future economic performance of the affected organisations. They also found that all types of information security breaches did not have similar economic impacts. There was no significant market reaction to breaches not relating to confidentiality (e.g., denial-of-service attacks); however, a significant reaction to violations of confidentiality (e.g., breaching a customer database) was noted. It was also noted that many of the non-confidential incidents (e.g., virus attacks) received more publicity and affected more organisations than the confidential incidents. Nevertheless, stock market reaction was not determined by the level of media publicity.

Garg et al. (2003), conducted a study that extended to include investor reactions to information security incidents on security vendors. They concluded that the share price of security vendors responded positively to information security breaches, with increases of 0.9% to 3.3% on average for all incidents. The reason given for this situation was the perception of investors that attacks would result in an overall increase in security spending by all organisations (and not just the affected ones).

Many information security surveys (e.g., AusCERT, 2004; BCMS, 2003; CSI, 2004; E-Crime, 2004; ISBS, 2004) also use the cost of a security incident as a measure of its overall impact. However, it is evident that this is a difficult question to answer (e.g., Campbell et al., 2003; Garg et al., 2003; Farahmand et al., 2003; Cavusoglu, 2002). It has been shown that security breaches can have many different impacts. Direct cash expenditure is only one of these. Other costs, such as time spent investigating and responding, also need to be included. Some, such as the cost of business disruption or damage to reputation, are hard to quantify. The author concludes that every organisation (small or large) must understand the costs associated when their information security is breached and that breaking down the cost of security breaches into its component parts can assist in this process.

Information Security Management

A fundamental issue that arises in discussions about information security is that of responsibility. A reasonable answer is that information security ought to be the responsibility of anyone who can affect the security of the system although specific duties and responsibilities of individuals and business units may vary (NIST, 1995).

Birman (2000) states that information security is more than a technical issue, and could even have strategic as well as legal implications. It is therefore important that information security is evaluated at management level and is integrated into the processes of the business. An organisations' executive management must be involved in and be constantly informed of the effectiveness of the information security strategies implemented as they (management) are ultimately responsible (1) to the shareholders and (2) for compliance with applicable laws and regulations (Posthumus & von Solms, 2004; Von Solms, 1996). Entrust (2004) encourages the implementation and acceptance of an information security management framework.

These actions, according to Entrust (2004), protect business information, improve the efficiency of the business and ensure that the business meets its legal requirements. Hong, Chi, Chao, and Tang (2003) state that an organisation should establish and maintain a documented information security management system. Organisations should examine the environment, familiarise themselves with security standards, define the scope of information security and assess the risk and control in order to develop an information security management system.

Straub and Welke (1998) declare that information security continues to be ignored by executive management and despite the seriousness of risk from security breaches; many organisations are either completely or insufficiently protected. If the threat is so clear then why is this so? Information security needs executive management support in order to succeed and to create a security-oriented culture in any organisation (Kankanhalli, Teo, Tan, & Wei, 2003; Siponen, 2001; Whitman & Matford cited in Witman, 2004; Williams, 2001). Goodhue and Straub (1991) note that managerial concern about information security is a function of (1) risk inherent in the industry, (2) the extent of the effort already taken to control these risks, and (3) individual factors such as awareness of previous system breaches.

In a study conducted by Mitchell et al. (1999), in 50% of the companies' surveyed, responsibility for information management was placed with the IT department while in only 25% responsibility was with senior management. Only 5% had a dedicated information security manager responsible for corporate information and most (57.5%) had the same person responsible for information security and information management. This study highlights the fact that in most organisations the management of information security continues to be placed within the IT function. IT managers continue to be responsible for managing and securing electronic information and it appears that information security is viewed as a technology

problem to be dealt by the technology people. It is this attitude that is responsible for gaps in an organisations information security chain of defences.

In most organisations information security is the result of an evolutionary process and although a proliferation of technology has been implemented to provide security, the approach used does not appear to have been systematic (Anttila et al., 2004). If an organisation does not have clear guiding principles or ideas for information security, the measures applied are very likely followed mechanically, leading to an ineffective implementation of security. Information security must be related to business performance and the final responsibility lies directly with the organisations' executive management.

Philosophy for Developing Information Security

NIST (1995) describes eight principles that are essential to developing an effective information security program in any organisation (small or large). These principles (see below) assist the information security practitioner in understanding how information security supports the mission of the organisation. Support for the NIST (1995) principles is provided in (e.g., DTI, 2004; OECD, 2002; Posthumus & Von Solms, 2004; Swanson & Guttman, 1996).

The eight principles that are essential to the development of an effective information security program are (NIST, 1995):

- **Information security must support the mission of the organization:** By selecting and applying appropriate techniques, information security aids the organization's mission by protecting its physical and financial resources, reputation, legal position, employees, and other tangible and intangible assets. Occasionally, information security may be seen as counter productive due to
- **Information security must support the business:** Information security is not an end in itself, but a means to an end. Rules and procedures imposed on users, however, it must be emphasized that these (rules and procedures) do not exist for their own sake but to protect important assets. Information security should, therefore, be viewed as a means to an end and not the end itself.
- **Information security is an integral element of business management:** ICT assets are often crucial to supporting the mission of an organization (refer to the previous) and protecting them can be as critical as protecting other organizational resources, however, including security considerations in the management of ICT does not completely eliminate the possibility that these assets will be harmed. Ultimately, business managers must decide on the level of risk they are willing to accept (taking into account factors such as the cost of security controls and whether an organisations ICT assets are linked to an external partner).
- **Information security must be cost effective:** The costs and benefits of security should be carefully examined in both monetary and non-monetary terms to ensure that the cost of controls does not exceed expected benefits. Security should be appropriate and proportionate to the value of and degree of reliance on the information systems and to the severity, probability, and extent of potential harm. Security must be seen as *smart business practice* and by investing in security measures; an organization can reduce the frequency and severity of information security-related losses.
- **Information security responsibilities and accountability must be made explicit:** Depending on the size of the organisation, assignment of responsibilities may be internal or may extend across organisational boundaries. However, every organisation (small or large) can prepare a document that states organisational policy and makes

explicit information security responsibilities.

- **System owners have information security responsibilities outside their own organizations:** If a system has external users, its owners have a responsibility to share appropriate knowledge about the existence and general extent of security measures so that other users can be confident that the system is adequately secure.
- **Information security requires a comprehensive and integrated approach:** Providing effective information security requires a comprehensive approach that considers a variety of areas both within and outside of the information security field. This comprehensive approach extends throughout the entire information life cycle.
- **Information security must be periodically reassessed:** Computers and the environments they operate in are dynamic. Security is *never* perfect when a system is implemented, procedures become outdated over time, new ways are constantly being discovered to intentionally or unintentionally bypass or subvert security, and changes in the system or the environment can create new vulnerabilities. All of these issues make it necessary to periodically reassess an organisations information security.
- **Information security is constrained by societal factors:** Security measures should be selected and implemented with recognition of the rights and legitimate interests of system users. This many involve balancing the security needs of information owners and users with societal goals. However, rules and expectations change with regard to the appropriate use of security controls. These changes may either increase or decrease security.

As more organizations share information electronically, a common understanding of what

is needed and expected in securing information assets is required. The principles discussed in the preceding paragraphs address information security from a high-level viewpoint. These principles are intended to guide security practitioners in developing effective information security programs for organisations (small & large).

Designing and Implementing Information Security

As organisations develop, previous methods of communication can become less effective. Informal understandings and discussions can prove insufficient. Legal and regulatory pressures increase as companies expand. Providing the entire company with clear, concise, internal governance can bring real benefits in terms of efficiency as well as a means of reducing information risk (DTI, 2004b).

A policy is an expression of intent. An information security policy must provide clear direction and be supported by management for the implementation and maintenance of information security. To be effective the policy must be relevant, accessible, and understandable to all intended users throughout the organisation (DTI, 2004b).

According to DTI(2004b), Lichtenstein(1997), Microsoft (2005), and WatchGuard (2004), an information security policy is an important document to develop while designing an information system. The security policy begins with the organization's basic commitment to information security formulated as a general policy statement. The policy is then applied to all aspects of the system design or security solution. The policy identifies security goals (e.g., confidentiality, integrity, availability) that the system should support and these goals guide the procedures, standards and controls used in the design of the information security architecture. The policy must also define critical assets, perceived threats, and security-related roles and responsibilities.

Although each organization's security needs are unique, most security policies address common elements. Due to the dynamic nature of the ICT environment an information security policy is never set in stone, rather it is a living document. The SANS Institute (SANS, 2005) recommends that the following elements be included in a security policy:

- **Objectives:** Clearly states the reason the security policy exists
- **Scope:** Identifies the people and systems affected by the policy
- **Protected Assets:** identifies the assets that the policy protects (e.g., e-mail servers, databases, and Web sites)
- **Responsibilities:** Identifies the groups or individuals responsible for implementing the conditions of the policy
- **Enforcement:** Discusses the consequences of violating the policy
- **Remote access policy:** Outlines acceptable methods for remotely connecting to the internal network (e.g., whether employees are allowed to connect to the network from their home computers)
- **Information protection policy:** Provides guidelines to users on the processing, storage, and transmission of sensitive information
- **Virus protection policy:** Provides requirements for the use of antivirus software as well as guidelines for reporting and containing virus infections
- **Password policy:** Provides guidelines for how user-level and system-level passwords are managed and changed
- **Firewall security policy:** Describes, in general, how firewalls are configured and maintained, and by whom

Once the organisational security policy has been created, the next step is to establish the information security plan. While the policy defines

the goals, the plan determines the steps that need to be taken to implement information security. Information security is not a separate task but an overlapping association of technologies, people, policies, and processes. The plan coordinates the whole security effort to match the organisations' security policy and ensures that there are no gaps (Microsoft, 2005).

The four steps in developing an information security plan (Lichtenstein, 1997; Microsoft, 2005; WatchGuard, 2004) are:

- **Assess:** The current state of security, identify critical assets, predict threats, and determine exposure for each asset
- **Plan:** For risks, noting that the objective is not to eliminate all risk regardless of cost but to minimise risks
- **Execute:** Check for adequacy, obtain participant feedback, modify plan if required and implement the plan
- **Monitor:** Research new threats as they become evident, modify the plan when changes occur (e.g., personnel changes) and perform ongoing maintenance (e.g., antivirus definition updates)

There is no silver bullet to the information security problem. Modern information systems are complex and dynamic and no simple solutions exist to completely protect organisational information assets. To be effective, security solutions must work together, and in harmony, to secure the critical assets of the organisation. Implemented solutions should be powerful, scalable and adaptable in order to effortlessly incorporate new functionality to meet emerging threats.

REVIEW OF INFORMATION SECURITY SURVEY STATISTICS

Kabay (2001) notes that no one can be expected to give reliable answers pertaining to questions

on information security. He adds that the two fundamental difficulties preventing the development of accurate statistics are: (1) the problem of detection and (2) the problem of reporting. The first problem is that an unknown number of crimes (of all kinds) are undetected because some frauds are discovered long after they have occurred. The second problem deals with reporting of security related crimes. Even if crimes are detected, few are reported in a way that allows systematic data

collection. This belief is based in part on the unquantified experience of information security professionals who have conducted interviews of their clients, and it turns out that only about ten percent of the attacks against computer systems revealed in such interviews were ever reported to any kind of authority or to the public.

On the basis of Kabay (2001), it follows that, even though the methodology used by information security surveys (e.g., AusCERT, 2004; BCMS,

Table 3. Summary of respondents from small and large businesses

Survey	Respondents	Small Businesses (aggregate % employees)	Large Businesses (aggregate ¹ % employees)
1. CSI 2004	494	19%	81%
2. ISBS 2004	1001	52%	48%
3. AusCERT 2004	240	15%	85%
4. E-Crime 2004	500	15%	85%
5. CSI 2003	530	18%	82%
6. AusCERT 2003	214	52%	48%
7. Deloitte 2003	175	none	100%
8. CSI 2002	503	16%	84%
9. ISBS 2002	1000	80%	20%
10. AusCERT 2002	95	39%	61%

Table 4. Survey comparison: Summary of security breaches experienced (Source: Compiled from each of the listed surveys)

Survey	Security Breach Experienced
1. CSI 2004	53% experienced a security incident in the past 12 months.
2. ISBS 2004	74% experienced a security incident in the past 12 months.
3. AusCERT 2004	49% experienced a security incident in the past 12 months.
4. E-Crime 2004	70% experienced a security incident in the past 12 months.
5. CSI 2003	56% experienced a security incident in the past 12 months.
6. AusCERT 2003	42% experienced a security incident in the past 12 months.
7. Deloitte 2003	39% experienced a security incident in the past 12 months.
8. CSI 2002	60% experienced a security incident in the past 12 months.
9. ISBS 2002	44% experienced a security incident in the past 12 months.
10. AusCERT 2002	67% experienced a security incident in the past 12 months.

2003; CSI, 2004; E-Crime, 2004; ISBS, 2004) may be imperfect and should not be taken as the absolute representation of the state of information security; they do however provide valuable data on the relative frequencies and severities of various security threats.

This section reviews ten of the more recent (2002 to 2004) information security surveys in order to determine the state of information security in organisations (small and large). Performing a meta-analysis of the surveys would be difficult because the questions asked differ both in content and method from survey to survey and because the results were developed and reported in different ways. Nevertheless, it was apparent that there were several common findings, which form the basis of this review.

The size of the organizations represented in each of the surveys, as measured by the number of employees, is given in Table 3. The table gives the total respondents for each survey and divides the organisations into small and large businesses as per the definition of small businesses adopted for this research.

Each of the surveys specifically asked if the respondents had experienced any security breaches in the previous year. Table 4 shows the specific survey data, with the numbers ranging from 39% to 74%. When examined chronologically, the overall trend is that security breaches are increasing.

Another frequently asked question related to the monetary loss resulting from information security breaches. Nine of the ten surveys provided some quantification of the monetary losses associated with information security incidents. Table 5 shows the survey results.

As can be seen by the reported data, the ability or willingness of the respondents to quantify losses is limited at best. Most of the surveys approached this area of questioning from the point of view of how much damage had been done in aggregate. As a result, the losses reported include average costs per serious incident (ISBS, 2004) to total losses per annum (CSI, 2004).

Nine of the surveys asked respondents what their most important security concerns were. These concerns are viruses, denial-of-service,

Table 5. Survey comparison: Financial loss

Survey	Amount of Loss Reported
1. CSI 2004	Total losses for the 54% able to quantify: \$141,496,560
2. ISBS 2004	The average cost of a serious security incident was approximately £7,000 to £14,000. For large companies, the equivalent cost was approximately £65,000 to £190,000.
3. AusCERT 2004	Total losses for the 57% able to quantify: AU\$15,921,064
4. E-Crime 2004	Of the 68% that tracked monetary losses the following breakdown was given: 3% - \$10 million 5% - \$1 million to \$9.9 million 5% - \$500,000 to \$999,999 11% - \$100,000 to \$499,999 26% - Less than \$100,000 50% - Don't know amount
5. CSI 2003	Total losses for the 48% able to quantify: \$201,797,340
6. AusCERT 2003	Total losses for the 58% able to quantify: AU\$11,800,783
7. CSI 2002	Total losses for the 44% able to quantify: \$455,848,000
8. ISBS 2002	The average cost of a serious security incident was approximately £30,000
9. AusCERT 2002	Total losses for the 80% able to quantify: AU\$5,781,300

some form of theft (ranging from data to equipment), misuse of systems and unauthorised access (hacking) appear in almost all of the top five rankings.

The statistics confirm that information security breaches continue to rise annually. The data examined provides evidence that: (1) information security continues to remain a problem for many organisations and (2) the provision of effective information security is essential for an organisations continued existence. As more organisations continue to suffer from information security incidents and the associated financial losses, understanding the information security problem becomes essential in security planning and development of effective information security, especially for small businesses.

CHAPTER SUMMARY

Information security is defined as the protection of information system assets against various threats and attacks in order to preserve the confidentiality, integrity, and availability of these systems. Modern society is significantly dependent on IT and there is little likelihood that this will change in the future. As globalization continues to advance and electronic civil disobedience increases in volume and efficacy, the implementation of effective information security continues to become an area of concern for academics, information security researchers, information security practitioners and management of organisations (small and large). It is essential that all stakeholders are aware of security threats and trends and take appropriate steps to provide adequate protection of information system assets.

Early research in information security (1970s and 1980s) treated information security as something tangible and concrete. Security was seen as a means to protect tangible assets and consisted purely of providing a security fence around information processing activities. However, security

cannot be viewed as a disjoint sequence of activities nor is it just a sequence of “locks and keys” in the prevention of adverse events. As organisations have evolved and organisational structures are becoming more flat and decentralised in nature, a new vision for addressing information security concerns has emerged. This vision, which is the key to effective information security in the new millennium, must be aligned with social groupings and behaviour and include a substantial human component. This paradigm shift provides an excellent motivation and platform for holistic research into the information security crisis.

Information security research has predominantly been positivist in its approach. Phenomenological or interpretivist research is almost entirely absent. Historically, much of the analysis into the problems of, and solutions to, information security has been quantified against highly structured questionnaires. This method has bounded the discussion and preconditioned the answers and the resulting metrics are often given a factual status that they do not deserve. The fundamental limitation on the applicability of these findings is that generalisations in the field of information technology and security are difficult to justify due to the diversity of systems installed in organisations. A phenomenological approach to information security research would certainly be advantageous as it would attempt to bridge a gap between man and machine and in doing so would provide a holistic view of the problem domain, rather than a simplistic and one-dimensional explanation.

Studies conducted by Kotulic and Clark (2004) involving diverse organisations (small and large) indicate that information security research is one of the most intrusive types of organisational research, and that there is a general mistrust of anyone attempting to gain data about information security practices in organisations. It is nearly impossible to extract information of this nature from businesses without a major supporter.

A critique of several non-academic surveys on information security was done in order to create some baseline of data from which to perform this research. The findings of the critique were that: (1) information security breaches continue to rise annually, (2) the surveys were entirely quantitative in their approach, (3) the targeted audience were primarily large businesses with only a small percentage (if any) of small businesses participating, (4) information security continues to remain a problem for many organisations, and (5) the provision of effective information security is an essential aspect of a organisations (small and large) success and continued existence. Historically, some small businesses have been included in surveys on information security (see Table 2-3) however; South African small businesses are noticeably absent. Even though this is the case, the researcher believes that the reported findings are also applicable to small businesses in South Africa. Support for this belief is provided by Kabay (2002) who states that the basic reasons why we care about information security remain the same in every organisation (small or large).

Some concerns uncovered by the author during the literature search are: (1) small businesses are trying to do everything by themselves (without enlisting expert assistance) and (2) small businesses are frequently exposed to crime, (especially technology related crimes). The rationale is that they (small businesses) do not have the base across which to spread the costs of hiring security experts or implementing expensive security-related technologies. Additionally, the researcher has discovered that academic and non-academic studies in information security have concentrated primarily on large organisations. Possible reasons for this state of affairs are that: (1) large businesses can make a greater contribution to the economy and (2) that large businesses have bigger budgets and therefore can spend more on information security and security research. Many researchers are of the opinion that what

is good for large businesses is also applicable to small businesses. This view is based on the incorrect assumption that research conducted in large businesses can be applied directly to small businesses. Consequently, this biased viewpoint has resulted in small businesses being excluded from information security research. Although information security attacks and breaches make no distinction in the size of the organisation (small and large are equally at risk), the small business practitioner has to recognise and manage information security risks without the resources available to larger businesses. Throughout this literature search, however, it has been found that models of information security developed for large businesses are simply forced onto small businesses without recognising the fact that small businesses are not just little big businesses.

With regard to small businesses, the findings reveal that this sector is rapidly growing and is making significant contributions to the economy. Furthermore, small businesses are embracing ICT and the Internet to gain competitive advantage, market share, and access to new markets, solve business problems, and to accumulate knowledge for improvement of services. Innovative entrepreneurs are also using technology and the Internet as a means to market niche products and to reach distant customers. The above-mentioned reasons provide excellent justification for developing and building capacity regarding academic research into the information security crises facing small businesses.

There is no silver bullet to the information security problem in small businesses. Information security requires a firm grounding in academic theory in order to be effective. Security cannot be gained by installing a gadget, no matter how good it is. Security is a process that must be woven into the corporate culture of every organisation (small or large), with due attention to the ever-changing landscape of threats, vulnerabilities and risks. Any models or guidelines developed must

be relevant and take cognisance of the fact that small businesses are unique and that they have their own focus and drivers when dealing with the information security problem.

CONCLUSION

The contribution of this chapter is twofold. First, it presents the current research directions in information security. It identifies the trend that information security research is moving away from a narrow technical viewpoint to a broader managerial perspective. Although a multitude of research and data exists in the field of information security, the literature indicates that information security research is restricted to large organisations. While academic research has investigated different perspectives of information security, it has been found that most of the studies looked at specific issues with little or no attempt being made to obtain a complete view of information security. Additionally, academic researchers have concentrated on information security in large organisations and presume that these findings are compatible with small businesses. Most researchers also rely on standards bodies (e.g., ISO,⁸ BSI,⁹ NIST¹⁰) to develop frameworks on which information security research is based.

Second, this chapter recognises the fact that the use of a phenomenological approach for understanding information security is still at a theory building stage. The literature search found practically no case studies that used a qualitative approach for evaluating information security. Almost all the studies on information security were based on the positivist paradigm. This highlights the need for interpretivist empirical research to develop a set of management guidelines for investigating and implementing effective information security practices in small businesses.

Chapter 5.37

Impact of Organisational Intranets on Profitability in Organisations

Udo Richard Averweg

eThekweni Municipality and University of KwaZulu-Natal, Durban, South Africa

ABSTRACT

Organisations are being forced to invest heavily in the deployment of information systems (IS) to obtain value and benefit in the new knowledge-based environment. Organisational intranets are being used as the platform for developing and deploying critical business applications to support business operations and managerial decision-making across the Internet-worked enterprise. Executive Information Systems (EIS) grew out of the information needs of executives. Web-based technologies are causing a revisit to existing information technology (IT) implementation models, including those for EIS. Some technologies include intranet, Internet, extranet, e-commerce business-to-business (B2B), e-commerce business-to-consumer (B2C), wireless application protocol (WAP), including other mobile technologies. The author conducted a survey of 31 well-established

organisations in KwaZulu-Natal, South Africa, which successfully implemented EIS. A validated survey instrument was administered to an EIS stakeholder in each organisation surveyed to rank Web-based technologies in order of their perceived impact on EIS implementation in organisations surveyed. The author reports that an organisational intranet has the highest level of impact on EIS implementation in organisations surveyed in KwaZulu-Natal, South Africa. Given this impact, justifying investment in such IS and IT should be carefully evaluated and quantified.

INTRODUCTION

Organisations are being forced to invest heavily in the deployment of information systems (IS) to obtain value and benefit and to stay competitive in the new knowledge-based environment. Manage-

rial tasks in organisations typically require more collaborative work than day-to-day operational tasks (Abraham & Seal, 2001). Abraham and Seal (2001) report that an intranet facilitates the communication behaviour between individuals who have to accomplish a task together. Giesecke (2001) foresees that creating information will become a team process. Communication is facilitated because the intranet provides the platform to integrate communication tools (e.g., electronic mail) as well as information sharing mechanisms (e.g., databases and file servers). Information technology (IT) investment uses certain of an organisation's resources. It makes it easier for people in managerial roles to make use of IT to carry out their work. Users in organisations are demanding that the IS used by the organisation should be more efficient and effective (Wessels, 2003). The use of the intranet becomes integral to the success of the managerial functions in the organisation.

Intranets are being used as the platform for developing and deploying critical business applications to support business operations and managerial decision-making across the Internet-worked enterprise (O'Brien, 2000). Many applications are designed to interface with and access existing organisation databases and legacy systems so that employees (within the organisation) can access and run such applications using Web browsers from anywhere on the network whenever needed. O'Brien (2000) reports that some intranet-using organisations are in the process of Web-enabling operational and managerial support applications including executive information and decision support. One theme in information communication technology (ICT) management theory is the effect of IT investment on the risk of managers in the IT-using industry and this serves as a backdrop. Although IS expenditure is regarded as risky and costly, many IS investments appear to go ahead without the use of formal investment appraisal and risk management techniques (Ward, 1996). The impact of organisational intranets on executive information

systems (EIS) implementation in organisations is a focus of this chapter.

ORGANISATIONAL INTRANETS

An intranet (or internal Web) is a network architecture designed to serve the internal information needs of an organisation using Web (Internet) concepts and tools (see, for example, Cortese, 1996). Turban, Rainer, and Potter (2005) indicate that an intranet is a private network that uses Internet software and TCP/IP protocols. Defined technically, intranets are the application of Internet technology (and specifically the World Wide Web service) for a prescribed community of users (Scheepers & Rose, 2001). An intranet is a network designed to serve the internal informational needs of an organisation, using Internet concepts and tools (Turban, McLean, & Wetherbe, 2004).

Organisations can use Internet networking standards and Web technology to create intranets (Laudon & Laudon, 2000). It provides similar capabilities, namely inexpensive and easy browsing, communication, and collaboration (Turban & Aronson, 1998) and are used solely for intraorganisational communication activities and information flow (Abraham et al., 2001).

Intranets can create networked applications that can run on many different kinds of computers throughout an organisation (Laudon et al., 2000). Typical intranet applications include:

- Publishing corporate documents
- Providing access to searchable directories (e.g., telephone and address lists)
- Publishing corporate, departmental and individual pages
- Providing access to groupware applications
- Distributing software
- Providing electronic mail
- Transacting with other organisational computer-based IS
- Organisation-wide information searches

- Providing a consistent user interface
- Data warehousing and decision support access

Turban et al. (1998) and Turban et al. (2004) note that intranets have the power to change decision-making processes, organisational structure, and procedures and help re-engineer organisations. Strom (1996) reports that much information on intranets is available directly on the Web. The use of intranets is increasing rapidly not only as an internal communication system, but also as a facilitator of e-commerce (Turban, McLean, & Wetherbe, 1999). Robinson (1996) suggests that intranets can be applied to enhanced knowledge sharing and group decision and business processes. Information that is most frequently included in intranets *inter alia* includes data warehouse and decision support access (Chabrow, 1998). Many organisations have benefited from use of the intranet Web-based technology and have made their organisations more efficient (Sprout, 1995). KPMG Consulting (2002) reports that organisations are focusing strongly on internal communications projects (such as intranets). It is the differences in governance and communication that enables some organisations to success and flourish where others fail.

EXECUTIVE INFORMATION SYSTEMS

EIS grew out of the development of IS to be used directly by executives and used to augment the supply of information by subordinates (Srivihok, 1998). An EIS is a computer-based system that serves the information needs of top executives (Turban et al., 2004). For the purposes of this chapter, EIS is defined as “a computerized system that provides executives with easy access to internal and external information that is relevant to their critical success factors” (Watson, Houdeshel, & Rainer, 1997). EIS are an important element of the information architecture of an organisa-

tion. EIS is a computer-based technology that is designed in response to executives’ specific decision-making needs (Turban et al., 2005). Turban (2001) suggests that EIS capabilities are being “embedded in BI.” All major EIS and information product vendors now offer Web versions of the tools designed to function with Web servers and browsers (PricewaterhouseCoopers, 2002). Business intelligence is a broad category of application and techniques for gathering, storing, analysing, and providing access to data to help users in organisations make better decisions and strategic decisions (Oguz, 2003).

With the increasing amount of IT investment and substantial evidence of failures (Remenyi & Lubbe, 1998), many managers and researchers feel that IS justification and evaluation has become a key management issue. The old argument that it is not necessary to justify the investment in IS because they are strategically important to stay “in business” is being questioned (Wessels, 2003). EIS has become a significant area of business computing and there are increasing amounts of money invested by organisations in EIS development projects (Kaniclides & Kimble, 1995) and the subsequent operation (use) of these systems (Belcher & Watson, 1993; Millet, Mawhinney, & Kallman, 1991). For example, in October 1997 the largest water utility in South Africa, Rand Water, took a decision to build an EIS (based on Oracle products) and invested ZAR4,5 million in revamping its IT infrastructure to support that deployment (Harris, 2000). In the current business environment where senior managers and decision-makers are held more accountable to their shareholders and investors for their investment decisions, there is a need for using generally accepted techniques and methods to justify IS investment decisions. For a survey of the state of EIS implementations in organisations in South Africa, see, for example, Averweg, Erwin, and Petkov (2004).

Web-based technologies are causing a revisit to existing IT implementation models, including EIS (Averweg, Petkov, Erwin, & Moolman,

2003). Web-based tools “are very much suited” to executives key activities of communicating and informing (Pijpers, 2001). With the emergence of global IT, existing paradigms are being altered which are spawning new considerations for successful IT implementation (Averweg & Erwin, 2000).

BACKGROUND AND GOAL OF THE RESEARCH

Intranet technology is essentially a pull technology and intranet use is largely voluntary (Lyytinen, Rose, & Welke, 1998). Computer or IS usage has been identified as the key indicator of the adoption of IT by organisations (Suradi, 2001). Igbaria and Tan (1997) report that system usage is an important variable in IT acceptance since it appears to be a good surrogate measure for the effective deployment of IS resources in organisations. Lu and Gustafson (1994) report that people use computers because they believe that computers will increase their problem solving performance (usefulness) and they are relatively effort free to use (ease of use). From the available literature, there is little evidence to suggest that the impact of Web-based technologies on EIS implementations has previously been investigated. This creates a platform for conducting such research. User acceptance of IT has been a primary focus in IT implementation research (Al-Gahtani, 2001). Researchers in the field rely on the theories of innovation diffusion to study implementation problems. Davis’ (Davis, 1989; Davis, Bagozzi, & Warshaw, 1989) technology acceptance model (TAM) is based on the diffusion of innovation model. TAM is a well-respected model of IT adoption and use (Al-Gahtani, 2001).

As the usage of IT increases, Web-enabled information technologies can provide the means for greater access to information from disparate computer applications and other information resources (Eder, 2000). These Web-based technologies

include intranet, Internet, extranet, e-commerce business-to-business (B2B), e-commerce business-to-consumer (B2C), wireless application protocol (WAP), and other mobile technologies. The focus of this chapter is on organisational intranets. There exists a high degree of similarity between the characteristics of a “good EIS” and Web-based technologies (Tang, Lee, & Yen, 1997).

The technology for EIS is evolving rapidly and future systems are likely to be different (Sprague & Watson, 1996). EIS is now clearly in a state of flux. As Turban (2001) notes, “EIS is going through a major change.” There is therefore both scope and need for research in the particular area of future EIS implementations being impacted by organisational intranets as executives and business end-users need systems that provide access to diverse types of information that form part of information age economies. Emerging (Web-based) technologies can redefine the utility, desirability, and economic viability of EIS technology (Volonino, Watson, & Robinson, 1995). Damsgaard and Scheepers (1999) describe intranet technology as a multi-purpose, rich networked, and malleable in terms of its application. As with all other investments, management must make a conscious decision to invest in a particular IS. Decisions to invest (or not invest) will influence the future of the organisation. With the absence of research efforts on the impact of organisational intranets on EIS implementation in South Africa, this research begins to fill the gap with a study of selected organisations in KwaZulu-Natal, South Africa, which have implemented EIS.

RESEARCH METHOD AND DATA GATHERING

The questionnaire was validated using expert opinion. It was based on previous instruments used in published research papers. Particular attention was given to Straub’s (1989) guideline of a

pre-test for the technical validation of the research instrument. This validation included the use of “previously validated instruments wherever possible” (Straub, 1989). Watson and Frolick (1993) note that numerical information comes from the questionnaire. The findings of the author’s survey will be based on the survey instrument.

As a preamble to the interview, the classification of the various types of IS and the distinguishing characteristics of EIS were discussed with each interviewee. A working definition of EIS (as used earlier in this chapter) was also given. This preamble to the actual interview meant that the interviewee was properly focused on the EIS in the organisation. The author’s survey instrument consists of three parts:

- **Section 1** deals with an organisation’s demographics. Questions were extracted from the Roldán (2000) EIS questionnaire, translated from Spanish to English and adapted for the author’s survey. The measurement of demographic variables of interest is consistent with prior research in sociology and organisational behaviour (Venkatesh & Morris, 2000).
- **Section 2** deals with the attributes of the organisation’s EIS. Questions were extracted from the Roldán (2000) EIS questionnaire, translated from Spanish to English and adapted for the author’s survey.
- **Section 3** deals with how an interviewee perceives specific Web-based technologies impacts the organisation’s EIS implementation. The selected Web-based technologies are (1) intranet; (2) Internet; (3) extranet; (4) e-commerce: business-to-business (B2B); (5) e-commerce: business-to-consumer (B2C); (6) wireless application protocol (WAP) and other mobile technologies; and (7) any other Web-based technologies.

Pre-testing a survey instrument is common practice. Roldán and Leal (2003) report that their

“instrument was pre-tested with consultants and business and IS professors.” A similar process was undertaken and experienced by the author who solicited expert opinion for additions, modifications, and/or deletions to the survey instrument. A pilot study was conducted to ensure that the interview schedule was clear, intelligible, and unambiguous. In order to evaluate the initial questionnaire design, an executive who uses EIS and four academics participated in separate field tests. One Spanish academic with EIS research interests commented “Very interesting.” Their comments led to a refinement of the questionnaire instrument. Their contributions are gratefully acknowledged. The survey instrument was submitted to three EIS software vendors (Cognos, JD Edwards (amalgamated with PeopleSoft, which is now part of Oracle) and ProClarity) in South Africa. A senior employee (e.g., managing director) from each vendor independently furnished some suggestions regarding the survey instrument. Some appropriate suggestions were adopted by the author and incorporated in the survey instrument.

There are six major metropolitan Councils in South Africa. Ethekwini Municipality Area (EMA) is the most populous municipality in South Africa (SA2002-2003, 2002). EMA’s geographic area size is 2,300 km² with a population of 3.09 million citizens (Statistics South Africa, 2001). During 2004, eThekwin Municipality was voted the best performing municipality in South Africa (Makhanya, 2004; Mthembu, 2004). The author’s survey of organisations in KwaZulu-Natal, which have implemented EIS, is confined to organisations in the EMA. It is acknowledged that some organisations may have implemented more than one EIS. In those cases and for this study, only the latest EIS implementation is used in the author’s survey.

Some studies suggest that EIS should not only be accessed by executive users (see, for example, Rai & Bajwa, 1997; Volonino et al., 1995). Salmeron (2001) notes EIS as the technology for

information delivery for all business end-users. Kennedy (1995) and Messina and Sanjay (1995) report that EIS have spread throughout organisations. It is evident that EIS requires continuous input from three different stakeholder groups (known as constituencies):

- EIS executives/business end-users
- EIS providers (i.e., persons responsible for developing and maintaining the EIS)
- EIS vendors or consultants

All constituencies are surveyed in the author's data sampling. The sample was selected using the unbiased "snowball" sampling technique. Cooper and Emory (1995) state that this technique has found a niche in applications where respondents are difficult to identify and are best located through referral networks. A formal extensive interview schedule was compiled and used for the semi-structured interviews. Interviews were conducted during May-June 2002 at the interviewee's organisation.

DATA ANALYSIS AND INTERPRETATION OF THE RESULTS

From the 31 interviews conducted using the author's survey instrument, 31 completed questionnaires were analysed. A tally of the responses to question 1.1-1.5 (Section 1) and question 2.1, 2.3, and 2.5-2.13 (Section 2) was made. Where there was a null (or blank) response recorded, this null (or blank) response was excluded from the respective tally. Frequency tables were constructed for each tally. For the responses to question 2.2 and 2.4, the data was arranged, sorted and frequency tables constructed. Such approaches are common in EIS research (see, for example, Kaniçlides & Kimble, 1997; Meneely & Pervan, 1994; Roldán & Leal, 2003; Salmeron, Luna, & Martinez, 2001). As Meneely and Pervan (1994)

report, the questionnaire data was analysed using basic statistical methods including frequencies. The author adopted a similar descriptive statistical process.

Demographics of Organisations Participating in Study

From a tally of interviewees' responses to question 1.1, the organisations participating in the study belongs primarily to the manufacturing (22.6%) and financial services (19.5%) sectors. (See Table 1) The prominence of these two sectors is reported in the Spanish EIS survey by Roldán and Leal (2003). The corresponding Spanish activity sector percentages are manufacturing (37.1%) and banking/financial services (24.3%).

From a tally of interviewees' responses to question 1.2, the gross annual turnover in South African Rands of organisations surveyed is given in Table 2. One respondent was unsure of his organisation's turnover and was not able to give a response to question 1.2. This null response was not included in Table 2. From Table 2, 27 (90.0%) of the organisations surveyed were large enterprises in the EMA. One organisation surveyed had an annual "sales for the year exceeding R12 bn" (Butcher, 2002).

From a tally of interviewees' responses to question 1.3, the number of permanent employees in organisations surveyed is given in Table 3. From Table 3, 20 (64.5%) of these organisations had more than 500 employees. This percentage compares favourably with the Spanish EIS survey percentage of 71% (Roldán et al., 2003).

From a tally of interviewees' responses to question 1.4, the number of years of existence of organisations surveyed is given in Table 4. From Table 4, 28 (90.3%) of organisations surveyed have existed for more than a decade. This suggests that these organisations are well-established in the EMA. The surveyed organisation which existed for less than five years was from the Information Technology Services sector (see Table 1).

Impact of Organisational Intranets on Profitability in Organisations

Table 1. Activity sector list of organisations surveyed which have implemented EIS

Activity Sector	Number of Activity Sectors in survey sample and associated percentage of total sample surveyed (N=31)
Agriculture	1 (3.2%)
Catering	1 (3.2%)
Construction and Automotive	1 (3.2%)
Education	1 (3.2%)
Electrical Power Distribution	1 (3.2%)

Table 2. Gross annual turnover of organisations participating in study

Gross annual turnover (in South African Rands)	Number of organisations in survey sample and associated percentage of total sample surveyed (N=30)
More than 500 Million	16 (53.3%)
Between 100 and 500 Million	8 (26.7%)
Between 20 and 100 Million	3 (10.0%)
Between 5 and 20 Million	0 (0.0%)
Between 1 and 5 Million	3 (10.0%)
Less than 1 Million	0 (0.0%)
TOTAL	30 (100.0%)

From a tally of interviewees' responses to question 1.5 the classification of organisations surveyed is given in Table 5. Table 5 suggests that the existence of EIS in organisations is not

limited to a single organisational classification. As EIS differ considerably in scope and purpose "the primary purpose of the system will change from one organization to another" (Roldán et al.,

2003). In the case of the Foreign enterprise classification, both organisations were locally based (South African) but wholly owned by their respective overseas (based in Germany and Switzerland) parent organisations.

Interviewee names and their corresponding organisation names were recorded against question 1.6. These are not reported in this chapter. From the recorded responses to question 1.7, an inventory of interviewee’s job titles was compiled. These are also not reported in this chapter. Some interviewees had identical job titles (director, managing director, regional manager, and systems analyst). Twelve (38.7%) interviewees held IT positions in organisations surveyed. Earl (1996) suggests that if IS implementation is left to IS professionals and users alone, the investment is rarely recouped.

From an interviewee’s response to question 1.8, the author objectively classified respondents into one of three stakeholder groups: EIS executive/business end-users, EIS providers and EIS vendors or consultants. The three EIS constituencies and number of surveyed respondents and associated percentages per constituency are given in Table 6. Most research of IT acceptance and use does not distinguish senior executives as a separate group (Pijpers, 2001).

From an analysis of interviewee’s responses to question 1.8, 29 respondents indicated that they were EIS users in their organisations. Two respondents reported that they were EIS implementers.

This concludes the analysis and findings of the interviewee’s responses to Section 1 of the author’s survey instrument. Interviewees’ responses to

Table 3. Number of permanent employees in organisations participating in study

Number of permanent employees in organisation	Number of organisations in survey sample and associated percentage of total sample surveyed (N=31)
More than 5,001 employees	6 (19.5%)
Between 2,001 and 5,000 employees	5 (16.1%)
Between 501 and 2,000 employees	9 (29.0%)
Between 251 and 500 employees	5 (16.1%)
Between 51 and 250 employees	5 (16.1%)

EIS failure (where the latest EIS implementation has been successful)	1 (3.2%)
TOTAL	31 (100.0%)

question in Section 2 of the survey instrument are now analysed and discussed.

EIS in Respondent’s Organisation Participating in Study

Roldán et al. (2003) surveyed organisations whose EIS were “operative or in an implementation stage sufficiently advanced.” From a tally of interviewees’ responses to question 2.1, the current (i.e., during the interview period) EIS situation in the respondent’s organisation is given in Table 7. From Table 7, one EIS implementation failure was reported by a respondent. This failure was ascribed to the most *recent* EIS implementation. In the Pervan and Phau (1997) EIS survey of organisations in Australia a similar experience

was reported—“only one of the organisations had experienced complete failure, in which the system had fallen into disuse.”

From the 27 operational EIS and in use by executives/business end-users (see Table 7) in organisations surveyed, a tally of interviewees’ responses to question 2.2 is given in Table 8. Two respondents were not able to report the time taken before the EIS was in use by executives/business end-users. They stated “EIS in use before I joined the company.” Their null responses are not included in Table 8.

From Table 8, the average time taken before the EIS was in use by executives and business end-users is 9.01 months. This compares favourably with the Roldán et al. (2003) average time of 8.53 months. Salmeron et al. (2001) report that

Table 8. Time taken before EIS was in use by executives/business end-users

For operational EIS, time taken before EIS was in use by executives/business end-users	Tally and associated percentage of the time taken as reported by respondents in sample surveyed (N=25)
3 days	1 (4.0%)
10-15 days	1 (4.0%)
14 days	1 (4.0%)
1 month	2 (8.0%)

24 months	2 (8.0%)
36 months	1 (4.0%)
TOTAL	25 (100.0%)

Impact of Organisational Intranets on Profitability in Organisations

the development of an EIS (in Spain) usually takes 6-12 months. These average times should be considered long term when compared with previous studies (Watson, Rainer, & Koh, 1991; Watson, Rainer, & Frolick, 1992; Park, Min, Lim, & Chun, 1997), which could negatively affect the users' acceptance of the system (Young & Watson, 1995).

From a tally of interviewees' responses to question 2.3 (more than one answer could be given), the applications for which the EIS is used in organisations surveyed is given in Table 9.

Research has found that the accessibility of information is more important than its quality in predicting use (O'Reilly, 1982). Access to updated online information is a basic characteristic of EIS (Houdeshel & Watson, 1987; Martin, Brown, DeHayes, Hoffer, & Perkins, 1999). Pervan and Phua (1997) report that the ability to access current

status information, such as performance reports, is the main feature most highly used by executives in obtaining the day-to-day information needed for their decision-making. From Table 9, the two highest scoring (see shaded areas) EIS applications used in respondents' organisations confirms the Australian EIS survey findings. Jones (2002) notes, "Executives need to be able to draw upon corporate knowledge and make decisions based on hard facts, not assumptions." The value of an intranet for managing knowledge is largely dependent on the calibre of the content and tools it provides to its users and their ultimate application in the organisation's business operations (Hall, 2001). An IS investment can either have a negative effect, a positive effect or no effect on the objectives of an organisation and these effects can be of a long-term duration.

Table 9. Applications for which EIS is used in organisations surveyed

EIS applications used in respondent's organisation	Tally and associated percentage of the number of applications reported by respondents in total sample surveyed (N=31)
Office automation activities	5 (16.1%)
Access to current status information	22 (71.0%)
Access to projected trends of the organisation	23 (74.2%)
Querying corporate and external databases	16 (51.6%)
Performing personal analysis	16 (51.6%)
Measuring key performance indicators	1 (3.2%)

Table 10. EIS users in organisations surveyed

EIS user statistics in organisations (N=27)	
Minimum number of EIS users reported	6
Maximum number of EIS users reported	700
Mode	20
Mean	54
Standard deviation	134

From the 27 operational EIS and in use by executives/business end-users (see Table 7) in organisations surveyed, the EIS user statistics of interviewees' responses to question 2.4 is given in Table 10.

The EIS user statistics for *all* interviewee's responses (31 organisations surveyed) to question 2.4 is given in Table 11. The mean number of EIS users per organisation in both samples (see shaded areas in Tables 10 and 11) is similar.

Roldán et al. (2003) report that "the average number of users in all organisations studied is 75.93 persons." This figure is significantly higher than the author's means of 54 (N=27) and 50 (N=31) in Tables 10 and 11 respectively. A possible explanation for this is that in the Spanish survey, three organisations surveyed each had more than

400 users. One of these three organisations had a total of 1,800 EIS users. In the author's research, the largest number of reported EIS users in one organisation was 700. Roldán et al. (2003) suggest that it would therefore be more appropriate to take into account the mode values. They report "the number of 20 users as a measure of the central trend." This mode corresponds exactly to the author's survey results given in Tables 10 and 11.

From a tally of interviewees' responses (more than one answer could be given) to question 2.5, the hierarchical employee levels where EIS is used in organisations surveyed is given in Table 12. Liang and Hung (1997) report that in their survey of organisations in Taiwan, middle-level managers are primary EIS users (78.94%) "but lower-level managers (24.58%) are also popular." From Table

Table 11. EIS users in organisations surveyed

EIS user statistics in organisations (N=31)	
Minimum number of EIS users reported	2
Maximum number of EIS users reported	700
Mode	20
Mean	50
Standard deviation	126

Table 12. Hierarchical employee levels where EIS is used in organisations

Hierarchical employee level where EIS is used in organisation	Tally and associated percentage of the number of employee levels reported by respondents in total sample surveyed (N=31)
Managing director/ chief executive officer	14 (45.2%)
Director (or delegated)	18 (58.1%)
General manager	20 (64.5%)
Senior operations manager	19 (61.3%)
Middle manager	24 (77.4%)
Line manager	14 (45.2%)
Business end-user	12 (38.7%)
Financial consultants	1 (3.2%)

Impact of Organisational Intranets on Profitability in Organisations

12, middle managers show significant higher EIS use levels (77.4%) than top managers (managing director/chief executive officer (45.2%) and director (58.1%)). This middle manager use level (77.4%) corresponds with the Liang et al. (1997) survey but is higher than the Roldán et al. (2003) middle manager survey result of 68,6%. While Roldán et al. (2003) report a “close similarity” between EIS use by middle managers (68.6%)

and EIS use by managing directors (70.0%), this similarity is not evidenced by the author’s findings in Table 12. There is a significant use difference between these two hierarchical levels. Furthermore Roldán et al. (2003) report that “21.4% of organizations declare that they have other users’ below the line manager hierarchical level.”

From Table 12 there are 12 (38.7%) business end-users and one (3.2%) financial consultant

Table 13. Functional areas where EIS is used in organisations

Functional area where EIS is used in organisation	Tally and associated percentage of the number of functional areas reported by respondents in total sample surveyed (N=31)
Finance	20 (64.5%)
Planning	10 (32.3%)
Marketing	20 (64.5%)
Sales	16 (51.6%)
Personnel	5 (16.1%)
Production/ Operations	12 (38.7%)
Entire Organisation	7 (22.6%)

Table 14. Functional areas where EIS is used in organisations

Types of information held by EIS in organisation	Tally and associated percentage of the number of types of information as reported by respondents in total sample surveyed (N=31)
Strategic planning	11 (35.5%)
Inventory management/suppliers	10 (32.3%)
“Soft” information	4 (12.9%)
Finance	28 (90.3%)
Business/Sales	23 (74.2%)
Trade/Industry	4 (12.9%)
Human resources	9 (29.0%)
Quality	7 (22.6%)
External news services	1 (3.2%)
Production	8 (25.8%)
Competitors	3 (9.7%)
Stock exchange prices	1 (3.2%)

below the line manager hierarchical level. The total percentage (41.9%) of these EIS users is significantly higher than the Roldán et al. (2003) survey. This tends to suggest that the degree of EIS diffusion to lower organisational hierarchical levels and use by these levels in organisations surveyed in South Africa, is on par with organisations surveyed in Taiwan but is significantly higher than experienced by organisations in Spain. As Liang et al. (1997) note, a “reason for this may be the extension of EIS to everybody information systems.” EIS are becoming less strictly defined to support professional decision-makers throughout the organisation (Turban et al., 1998). Turban et al. (1998) state that “there is now increasing number of tools designed to help functional managers (finance, marketing); these tools are integrated with EIS.”

From a tally of interviewees’ responses to question 2.6 (more than one answer could be given), the functional areas where EIS are used in organisations is given in Table 13. The highest scoring functional areas are Finance (64.5%) and Marketing (64.5%). The lowest scoring functional area is Personnel (16.1%). Table 13 shows that the functional areas where EIS are used in organisations surveyed are quite broad. Similar broad findings are reported by Liang et al. (1997) in organisations surveyed in Taiwan. One must ensure that the cost of the technology is able to justify its usage (Agarwal, Higgins, & Tanniru, 1991).

From a tally of interviewees’ responses to question 2.7 (more than one answer could be given), the different types of information held by an EIS in an organisation is given in Table 14. From Table 14, Financial information (90.3%) appears as the most important item followed by Business/Sales (74.2%) and then Strategic Planning (35.5%). In the Roldán et al. (2003) survey, the three highest ranking types of information held by an EIS in an organisation were commercial and sales information (89.2%), financial information (65.7%) and production information

(55.7%). While previous research studies agree in presenting these three types of information (sales, financial, and production) as the most relevant ones (Allison, 1996; Kirlidog, 1997; Thodenius, 1995) the author’s findings partially support these findings with business/sales (74.2%) and finance (90.3%) types of information. Holding strategic planning information in EIS in organisations in South Africa appears to have a higher importance than holding production information. Wessels (2003) conducted a survey about IS investment decisions in organisations in South Africa and found that 66.0% of respondents stated that they justified their investment on strategic reasons.

Watson et al. (1996) recognise that executives require “soft” information (often provided informally) for decision-making. Soft information is “fuzzy, unofficial, intuitive, subjective, nebulous, implied, and vague.” Watson et al. (1996) found that soft information was used in most EIS but the author’s findings (12.9%) do not support this. One possible explanation is that it is often policy not to allow unsubstantiated rumours into IS without a reference to a source and tagged by the individual entering the information (Turban et al., 1998). In the justification of investing in IS and the process of making decisions (whether to invest in a new IS or not), “soft” factors also need to be incorporated (Hinton & Kaye, 1994).

From Table 14 it can be observed that the information that appears predominantly in EIS has an internal characteristic (Preedy, 1990). External information obtains low response levels: trade/industry (12.9%), external news services (3.2%), competitors (9.7%) and stock exchange prices (3.2%). Roldán et al. (2003) report similar low response levels. Salmeron et al. (2001) note that “it is surprising that external information is so seldom included in Spain.” Intranets and knowledge sharing can assist to “capture, organise, store, and transmit” source material from which an individual may acquire knowledge (Gundry & Metes, 1996). An IT investment decision is a process of filtering and distilling often com-

Impact of Organisational Intranets on Profitability in Organisations

plex data, information, and knowledge to levels manageable to the human mind (Bannister & Remenyi, 2000).

From a tally of interviewees' responses to question 2.8 (more than one answer could be given), how information is held by EIS in an organisation is given in Table 15. From Table 15, information is generally presented by products (71.0%), operational areas (64.5%) and geographical areas (58.1%). Roldán et al. (2003) report similar findings for operational/functional areas (62.9%), products (61.4%), and geographic areas (52.9%). Roldán et al. (2003) note that "information according to processes ranks quite low, existing in only 20%

of participating entities." From Table 15, there is a striking commonality with the author's finding of 19.4%. This situation was highlighted by Wetherbe (1991) as one of the traditional IS problems for top managers (i.e., these systems are considered as functional systems rather than being considered as systems crossing functions).

From a tally of interviewees' responses to question 2.9 (more than one answer could be given), the different types of sources of information that support an EIS in an organisation are given in Table 16. One of the capabilities or characteristics of EIS is the filtering, organisation, and consolidation of multiple data sources. This quantitative data stems

Table 15. How information is held by an EIS in an organisation

How information is held by EIS in organisation	Tally and associated percentage of how information is held as reported by respondents in total sample surveyed (N=31)
By products	22 (71.0%)
By projects	5 (16.1 %)
By operational areas	20 (64.5%)
By geographic areas	18 (58.1%)
By strategic business units	10 (32.3%)
By processes	6 (19.4%)
By key performance areas	14 (45.2%)
By company	11 (35.5%)
By customers	1 (3.2%)

Table 16. Sources of information that support EIS in an organisation

Sources of information that support EIS in organisation	Tally and associated percentage of sources of information as reported by respondents in total sample surveyed (N=31)
Corporate databases	25 (80.6%)
Individuals	12 (38.7%)
Operational databases	20 (64.5%)
External databases	8 (25.8%)
Documents or reports	7 (22.6%)
Internet, intranet or extranet	5 (16.1%)

Table 17. Approaches taken for EIS development in organisations

Approach taken for EIS development in organisation	Tally and associated percentage of approach taken for EIS development as reported by respondents in total sample surveyed (N=31)
In-house development using existing software tools	6 (19.4%)
In-house development with critical EIS features developed initially and optional features added over time, using existing or commercially purchased software tools	9 (29.0%)
Fully developed by vendor	7 (22.6%)
In-house development with assistance from vendor	12 (38.7%)

from corporate databases (80.6%) and operational databases (64.5%). Data aggregation is to integrate data from various sources to provide critical information requested by decision-makers (Liang et al., 1997). A significant advantage of using an intranet involves its facilitation of decentralised decision-making (Van der Merwe, 2001). This occurs because everyone has access to information and there is no reliance on a limited number of employees who have access to different types of information from different departments within the organisation.

As previously discussed, Table 14 reflects that the information that appears predominantly in EIS has an internal characteristic. Table 16 reflects that a significant majority of the information came from internal sources. External sources have a low presence: external databases (25.8%) and Internet, intranet, or extranet (16.1%). This trend towards internal sources supports the results obtained in previous research studies (Basu, Poindexter, Drosen, & Addo, 2000; Kirlidog, 1997; Roldán et al., 2003; Watson et al., 1991; Watson et al., 1992). In the opinion of Salmeron et al. (2001) “the extent to which information coming from the environment is included in the EIS of Spanish big businesses should reach higher figures, due

to the fact that all elements that currently form economy are interrelated”. Given the presence of Web-based technologies and from Table 16 it is therefore somewhat surprising that the Internet, intranet and extranet rank as the lowest source of information which support an EIS in the organisations surveyed in the EMA. One of the contributions of the Web has been streamlining and co-coordinating the internal communication structure of organisations by using the Web as a standard (Abraham and Seal, 2001).

System justification implies first an evaluation and then the activity of justification, showing that the IS is appropriate for the particular business context (Remenyi, Money, & Twite, 1995). From a tally of interviewees’ responses to question 2.10, the approach taken for EIS development is given in Table 17. In-house development with assistance from the vendor (38.7%) was the most common approach taken. A “piece meal” strategy where in-house EIS development with critical features was conducted initially then operational features added over time using existing or purchased software tools was most preferred (33%) by organisations surveyed in Australia (Pervan et al., 1997). From Table 17, a similar pattern (29.0%) was evidenced in organisations surveyed in South Africa.

Impact of Organisational Intranets on Profitability in Organisations

Roldán et al. (2003) report a “low number of cases in which the systems have been developed with software produced by the organization itself (5.7%).” In the author’s survey, in-house development using existing software tools is somewhat higher (19.4%). A possible explanation is that some organisations surveyed may not yet have migrated from their first (in-house developed) EIS.

Pervan et al. (1997) report that for organisations surveyed in Australia, only 17% of EIS were developed in-house with assistance from a vendor/consultant. Roldán et al. (2003) report in-house development with assistance from the vendor (47.1%) as the most common approach taken in organisations surveyed in Spain. From Table 17, it can be seen that while this approach is taken by organisations surveyed in South Africa, the occurrence is slightly less. Many organisations do not perform evaluations or cost benefit analysis on there is and those who do sometimes report mixed or confused results (Remenyi et al., 1995).

From a tally of interviewees’ responses to question 2.11 (more than one answer could be given), the distribution of the market amongst vendors of EIS tools used in organisations surveyed is reflected in Table 18.

One respondent indicated that his organisation *only* used in-house developed software. This response was therefore not included in Table 18. From Table 18, Cognos is the most frequently (60.0%) reported commercially packaged EIS software tool. Cognos has 2.5 million users at 18,000 customers in 120 countries and its business intelligence solutions are available from more than 3,000 worldwide partners and resellers. See <http://www.cognos.com>

Pervan et al. (1997) report that “Pilot was the most popular choice with 26%, followed by Powerplay with 16%” in organisations surveyed in Australia. Roldán et al. (2003) found that “Commander from Comshare (39.1%), DSS Agents from MicroStrategy (21,9%), Forest & Trees from

Table 18. Distribution of market amongst vendors of EIS tools according to responses

Name of commercially purchased EIS software tools and/or ERP software with EIS features	Tally and associated percentage of commercially purchased EIS software tools and/or ERP software with EIS features as reported by respondents in total sample surveyed (N=30)
Business Objects	2 (6.7%)
Cognos	18 (60.0%)
Crystal Enterprise	1 (3.3%)
Holos	1 (3.3%)
Hyperion	3 (10.0%)
JDEdwards BI	4 (13.3%)
Lotus Notes	3 (10.0%)
Oracle	4 (13.3%)
Pilot	2 (6.7%)
ProClarity	1 (3.3%)

MISYS	1 (3.3%)
BI Query	1 (3.3%)

Table 19. Frequencies of EIS use in organisations

Frequency of EIS use in organisation	Tally and associated percentage of EIS use in organisation as reported by respondents in total sample surveyed (N=31)
Very rarely or not at all	1 (3.2%)
Rarely (a few times per month)	1 (3.2%)
Occasionally (a few times per week)	1 (3.2%)
Sometimes (about once per weeks)	1 (3.2%)
Fairly regularly (several times per week)	4 (12.9%)
Regularly (once a day)	12 (38.7%)
Frequently (several times per day)	13 (41.9%)

Platinum Technology (15.6%), and Focus/EIS from Information Builders (10.9%)” were the popular EIS software tools in organisations surveyed in Spain. From Table 17 and the Australian and Spanish survey findings, it appears that little use is made of ERP software with EIS features. EIS products “tend to be included in larger software systems, becoming a module integrated in quite a few ERP systems such as SAP” (Roldán et al., 2003). However, the author’s findings suggest that there is a strong *usage* preference for commercially purchased EIS software tools (as opposed to ERP software with EIS features) by organisations surveyed in South Africa. Usage of ERP software with EIS features appears to be minimal in organisations surveyed in South Africa.

From a tally of interviewees’ responses to question 2.12 (more than one answer could be given), the frequency of EIS use in organisations surveyed is given in Table 19. This EIS use measure was self-reported by respondents. Although previous research suggests that self-reported frequency measures are appropriate as relative measures (Blair & Burton, 1987), they should not be regarded as precise measures of actual use frequency (Davis et al., 1989).

From Table 19, frequent (several times per day) and regular use of the EIS were reported by a total of 25 (80.6%) respondents (see shaded area

in Table 19). In the survey of EIS applications in Taiwan, Liang et al. (1997) state that “over half of the respondents reported using their systems every day. Twenty-two percent used the system very often.” Liang et al. (1997) report that organisations with EIS “rely heavily on their systems for support decision making.” In the author’s survey, some respondents reported different EIS use frequencies during the month (e.g., higher EIS use during month end). One respondent stated, “First week of month is a lot busier. Towards end of the month not more than an hour.” An EIS has the effect of multiplying the frequency of use (Palvia, Kumar, Kumar, & Hendon, 1996).

The low EIS use frequencies can be ascribed to the fact that three EIS implementations in organisations are currently under development and implementation (see Table 7). Despite this, Davis (1989) notes that users are often willing to cope with some difficulty of use in a system that provides critically needed functionality. System use is the most crucial aspect of EIS operation.

From the responses to question 2.14, a smorgasbord of some interviewee’s comments is now given. Twenty-nine interviewees expressed a positive personal expectation to the success of the EIS implementation in their organisations. Some interviewee comments recorded were “Positive,” “Very optimistic,” “We knew it would be a suc-

cess from our previous history,” “I though the guys would really go for it,” “Had a very high expectation of success,” “We had nothing. We believed it would sort out all our problems,” “I knew it would be successful because we had done a lot of research,” and “I knew it would work as we were reliant on the mainframe.”

One interviewee’s response was neutral with a reply “Can’t comment. Before my time.” Another interviewee “thought it would fail...had old style managers who were not into new kinds of things... things have now changed.” Perlman (1986) notes that overcoming inherent human conservatism associated with any change is crucial. The right determination is seen as a key to EIS success (Salmeron, 2001).

From a synthesis of interviewees’ responses to question 2.15, the first author identified that 27 interviewees reported the most recent EIS implementation in their organisation as successful, three interviewees reported partially success, and one interviewee reported failure with his organisation’s most recent EIS implementation.

For the 27 successful organisations, some interviewee comments recorded were “Yes, definitely growing now,” “Yes, it was successful due to the ease of implementing the Cognos product. It is very scalable. We staged the implementation,” “Absolutely, yes!” “Oh, yes. Without a doubt,” “To a large degree it achieved what we had originally set out to achieved,” “Successfully implemented but not widely used,” and “Yes, once up and running.”

For the partially successful EIS implementations some interviewee comments recorded were “It has not yet been completed...serious mindset to get rid of” and “thought it would be successful but needed executive team buy-in.” Support from senior management is considered to be the most critical issue affecting EIS operation (Kaniclides et al., 1997).

For the not successful (i.e., failure) EIS implementation in response to question 2.16, the interviewee stated for the latest EIS implementation

his organisation had “tried to pilot a project ... but there were some political reasons for its failure.” Politically motivated resistance from executives is a highly rated factor affecting the success of EIS development (Kaniclides et al., 1997). Kaniclides et al. (1997) note that politically driven tactics can originate from both executives designated as initial users of the system and those regarded as potential future users of the system. This scenario appears to be present in the organisation, which the interviewee reported that the latest EIS implementation had not been successful. Furthermore, there seemed to exist an interest in letting the EIS system fail rather than a lack of interest in system success. A similar finding was reported by Poon and Wagner (2001) in organisations surveyed in Hong Kong.

There is little information available to assist practitioners regarding the question of how to minimise the risk of EIS failure (Watson et al., 1991). Watson and Glover (1989) carried out a study of 21 EIS failures. From their findings, they identified the following factors that contribute to the EIS failure: inadequate or appropriate technology, failure of the system to meet user needs, lack of executive commitment and executive resistance to technology. In the Pervan et al. (1997) study of EIS failures in organisations surveyed in Australia, inadequate or appropriate technology was reported as being the major EIS failure factor. During the author’s interview of the respondent who reported his most recent EIS implementation as not successful, the interviewee cited that “there were some political reasons for its failure.” At first glance this finding appears to be inconsistent with the Watson et al. (1989) and the more recent Pervan et al. (1997) studies.

A further investigation reveals that in the Pervan et al. (1997) study, “with only 16% of organisations having EIS that are in full operation, this may be the reason for political problems being rated the least important.” Pervan et al. (1997) note that “this issue may increase in significance as more organisations progress from the evaluation

stage to the operational stage in the near future.” During the author’s survey, the respondent who reported his most recent EIS implementation as not successful *had* progressed from an EIS evaluation stage to the operational stage. Consequently, the author’s findings do not appear to be inconsistent with the Pervan et al. (1997) study. Willcocks (1996) suggest that the high failure rates of new IS in organisations stems from the fact that there is a wide gap between the level of investments in IS and an organisation’s ability to achieve the necessary benefits from such investments. Most organisations do not formally evaluate their investment in IS (Wessels, 2003).

From the responses to question 2.15 for successful and partially successful EIS implementations in organisations surveyed, some interviewee’s comments are now given. “Software had to be user friendly...the way that we had done our reporting did not display well...our MD wants to look at something more visual,” “a very clear understanding of user requirements is necessary because they don’t know what they want,” “the ease of extracting the data...must be very easy and flexible,” “...the buy-in was already there,” “that we can use our data for analysis,” “management support,” “the immediate access to data, drill down, KPIs to customers and products,” “presents answers in a presentable way...user-friendly,” “reliable, timeliness, and flexibility,” “accurate, timeous, relevant to what’s happening in business at moment...also ease of use,” “needed to be backed by management to be successful,” “needed an executive sponsor,” “stable technology,” and “data integrity.”

Rockart and Delong (1988) observed several factors in organisations which appear to be the most important for effective EIS implementation. Some factors which Rockart et al. (1988) report as critical to a successful EIS implementation, are a committed and informed executive sponsor, an operating sponsor, appropriate IS staff, appropriate technology, management of data, clear link to business objectives, management

of organisational resistance, and management of system evolution spread. Pervan et al. (1997) report that these factors will be refined by other researchers as the EIS field evolves. While there is no consensus on the “ingredients for EIS success” (Paller & Laska, 1990) there appears to be a strong degree of commonality between the identified factors and interviewee’s comments. The process of evaluating IT is the application and absorption of a range of input information which includes data, evaluation techniques, personal experience, personal knowledge, corporate or departmental politics, personal decisions and intuition (Wessels, 2003). This concludes the analysis and findings of the interviewee’s responses to Section 2 of the author’s survey instrument. Interviewees’ responses to questions in Section 3 of the survey instrument are now analysed and discussed.

LEVEL OF IMPACT OF WEB-BASED TECHNOLOGIES ON EIS IMPLEMENTATION

From Section 3 of the author’s survey instrument, a tally, and associated percentage of the perceived degree to which specific Web-based technologies impacted a respondent’s EIS implementation is given in Table 20. The shaded area in Table 20 suggests that there is little (if any) perceived impact by Web-based technologies on EIS implementation in organisations surveyed in KwaZulu-Natal.

Table 20 shows that only seven (22.5%) of organisations surveyed reported that the organisational intranet significantly impacted their EIS implementation. From a managerial perspective, intranet technology’s cost, flexibility, and wide spectrum of uses does render it an attractive IT in the organisational environment (Scheepers et al., 2001). The level of impact by the Internet on EIS implementation is slightly lower with six (19.4%) of organisations surveyed reporting that the Internet had significantly impacted their EIS

Impact of Organisational Intranets on Profitability in Organisations

Table 20. Tally and associated percentage of the expected degree to which specific Web-based technologies impacted respondent's EIS implementation

Web-based technology	The degree to which Web-based technologies impacted respondent's EIS implementation (N=31)						EIS implementation
	Not at all	Very little	Somewhat little	Uncertain	Somewhat much	Very much	
Intranet	17 (54.8%)	2 (6.5%)	2 (6.5%)	0 (0.0%)	3 (9.7%)	4 (12.9%)	3 (9.6%)
Internet	21 (67.7%)	1 (3.2%)	1 (3.2%)	0 (0.0%)	2 (6.5%)	3 (9.7%)	3 (9.7%)
Extranet	24 (77.4%)	1 (3.2%)	2 (6.5%)	1 (3.2%)	1 (3.2%)	2 (6.5%)	0 (0.0%)
E-commerce (B2B)	28 (90.4%)	1 (3.2%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	1 (3.2%)	1 (3.2%)
E-commerce (B2C)	26 (83.9%)	1 (3.2%)	1 (3.2%)	0 (0.0%)	2 (6.5%)	0 (0.0%)	1 (3.2%)
WAP and other mobile technologies	29 (93.6%)	1 (3.2%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	1 (3.2%)
Portal	26 (83.8%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	2 (6.5%)	2 (6.5%)	1 (3.2%)

implementation. While 24 (77.4%) of the organisations surveyed reported the extranet had no impact on their organisation's EIS implementation, the balance of the data sample (22.6%) reported different degrees of impact. Turban et al. (2004) note that the use of extranets is rapidly increasing due to the large savings in communication costs that can materialise. The author reported relatively low-level impact by the extranet on EIS implementations in organisations surveyed, and this may be an avenue for further investigation. The Internet, intranet, and extranets can be used in various ways in a corporate environment in order to gain competitive advantage (Turban et al., 2004). As a mission critical corporate tool, Internet technology has to support all the core business functions and it must do this more effectively and economically than is possible using other concepts and tools (Van der Merwe, 2001). The Internet provides global access and is the conceptual start of both intranets and extranets (Askelson, 1998).

The results show that the vast majority (90.4%) of respondents reported that e-commerce (B2B) had not impacted EIS implementation in organisation surveyed. A slightly lower result (83.9%) was reported for e-commerce (B2C). One possible explanation for e-commerce (B2B) and (B2C) low impact levels is that the software development tools are still evolving and changing rapidly. E-commerce is a rapidly evolving area that is continuing to penetrate into new application areas (Hawryszkiewicz, 1999). Another possible reason is it is difficult to integrate the Internet and e-commerce software with some existing applications and databases. However, Ciborra and Hanseth (1998) suggest that intranet technology may even emerge without a grand plan in the organisation.

WAP and other mobile technologies have no (93.6%) or very little (3.2%) impact on EIS implementations. Of the seven Web-based technologies given in Table 20, WAP and other mobile

technologies have the *least* impact (combining “Somewhat much,” “Very much,” and “Extensively”) on EIS implementation in organisations surveyed. Only one respondent (3.2%) reported that WAP and other technologies had extensively impacted the EIS implementation in her organisation. A possible explanation for this result is that the EIS consultant was technically proficient in WAP technologies.

From Table 20, three interviewees reported that their organisation’s EIS implementations were significantly impacted (“Very much” and “Extensively”) by portal technologies. This is noteworthy as the portal technology impact on EIS implementations (9.7%) is higher than the extranet (6.5%), e-commerce (B2B) (6.4%), e-commerce: (B2C) (6.4%) and WAP and other technologies (3.2%) impacts. For a discussion of the impact of portal technologies on EIS implementation in organisations, see Averweg et al. (2004).

Combining the results (“Somewhat much,” “Very much,” and “Extensively”) for each of the seven Web-based technologies, Table 21 gives a descending ranking order of the levels of impact on EIS implementations. From the selected Web-based technologies, intranets have the highest level of impact on EIS implementation in organisations surveyed in KwaZulu-Natal. Organisational intranets are envisioned as platforms for organisational knowledge management (Davenport & Pruzak, 1998). This information is particularly

useful for IT practitioners in the planning of future EIS implementations. The key point is that an organisational intranet utilizes Internet and Web-based technologies to conduct internal communication and collaboration activities within an organisation and provides a level of integration and access.

This concludes the analysis and findings of the interviewee’s responses to Section 3 of the author’s survey instrument. Some concluding remarks will now be given.

CONCLUDING REMARKS

Ezingard et al. (1998) report that in their survey, more than half of the respondents did not formally list the benefits expected of their IT and IS investment but justified the investment as an “act of faith.” Intranet technology calls into question some of our traditional IT implementation wisdom and presents new challenges for seeking to implement the technology (Balasubramanian & Bashian, 1998; Scheepers, 1999). Consequently, approaching an EIS implementation with a traditional mindset or using existing implementation models may be short-sighted. Emergent processes require new modelling methods and technologies to build successful systems that support them. The advent of the organisational application of Internet-based technologies (especially intranets),

Table 21. Descending rank order of impact levels of Web-based technologies on EIS implementation

Rank	Web-based technology	Tally and level of impact on EIS implementations
1	Intranet	10 (32.2%)
2	Internet	8 (25.9%)
3	Portal	5 (16.2%)
4	Extranet	3 (9.7%)
5	E-commerce (B2C)	3 (9.7%)
6	E-commerce (B2B)	2 (6.4%)
7	WAP and other mobile technologies	1 (3.2%)

now marks the ubiquitous computing paradigm that weaves together a complex array of existing ICT into one rich medium (Dahlbom, 1996).

There is a need to identify crucial differences in existing IT implementation models that enable some organisations to success with their IT investment where others have failed. Developers must be aware of emerging trends in the organisational intranet market to create systems that will be able to incorporate the latest technological developments and new methods of information delivery and presentation. Organisations need to build connections between information and organise it in ways that most individuals can navigate through choices for themselves. As the use of Web-based technologies in the distribution of internal information in organisations in KwaZulu-Natal, South Africa becomes more widespread, it is envisaged that future EIS implementations will be further impacted by organisational intranets. Given this impact, justifying investment in such IS and IT should be carefully evaluated and quantified.

Chapter 5.38

Training Sequences and their Effects on Task Performance and User Outcomes

Clive Sanford

Aalborg University, Denmark

Anol Bhattacharjee

University of South Florida, USA

ABSTRACT

This chapter introduces the concept of information technology (IT) training sequences and examines how sequencing of conceptual and procedural training impact IT task performance, user satisfaction and users' self-efficacy. Using assimilation theory, we develop four hypotheses related to training sequences. These hypotheses were then tested in a database design context using a quasi-experimental study involving student subjects. Empirical results demonstrate improved far-transfer and near-transfer task performance and higher self-efficacy for subjects trained in the conceptual-procedural sequence

vs. the reverse sequence, though user satisfaction was not significantly different between the two sequences. Implications for IT training research are discussed.

INTRODUCTION

As IT has been widely adopted by firms as a potent means of improving task performance and user productivity in today's IT-dominated workplace, such adoption has also imposed substantial pressure on firms to continuously train internal users in the knowledge and skills needed to use these systems effectively. Despite innovations

in the training domain, such as computer-based, CD-based and online training, the core issue still remains how training programs should be structured to improve IT users' knowledge retention and task performance given predefined technologies, tasks and potential users (Davis & Bostrom, 1993).

Several approaches to IT training have been proposed in the literature, such as instruction-based vs. exploration-based training (Davis & Bostrom, 1993), applications-based vs. construct-based training (Olfman & Bostrom, 1991), and conceptual vs. procedural training (e.g., Olfman & Mandviwalla, 1994; Santhanam & Sein, 1994). Of these, the last taxonomy seems to have gained the broadest acceptance. *Conceptual training* is a "top-down" approach where IT users are trained in the nature and associations of semantic objects required for comprehending and solving a problem, while *procedural training* is a "bottom-up" approach focusing on action-plan sequences that users should learn to complete specific tasks. Because of the direct and immediate applicability of procedural knowledge in specific task situations, procedural training has emerged as the approach of choice for many corporate IT training programs (Atlas, Cornett, Lane, & Napier, 1997).

Prior research on conceptual and procedural training has compared the relative effects of these approaches on IT task performance, reporting mixed results (e.g., Olfman & Mandviwalla, 1994; Santhanam & Sein, 1994). However, researchers tend to agree on the importance of both forms of training. Santhanam and Sein (1994) note that procedural training is more useful when the target system is easy to operate; however, these users tend to perform poorly on novel tasks. They also note, "conceptual training is likely to provide a better opportunity for a user to form a coherent mental model compared to procedural training" (p. 382). Elaborating the gaps in extant IT training research, Olfman and Mandviwalla (1994, p. 407) state, "some *combination* of concepts and procedures is needed ... It is the relative quantity

and *sequencing* of the two kinds of content that has not been fully established" (emphasis added).

Defining *training sequence* as the ordering of conceptual and procedural training, the objective of this study is to examine whether the conceptual-procedural sequence improves IT task performance and user outcomes, such as satisfaction and self-efficacy, compared to the reverse sequence. Though the importance of training sequences was noted by Olfman and Mandviwalla (1994), to date, empirical analysis of such sequences has remained unexplored in the IT training literature. The idea of training sequences, however, has some support in learning theory (Glaser, 1990) and instructional design theory (Reiguluth & Stein, 1983), where leading proponents have long advocated that user training be conducted in a holistic manner to include both conceptual and procedural components. The rationale is that this strategy integrates two complementary forms of knowledge (concepts and procedures) that are both required for the performance of many complex organizational tasks.

To examine the above research objective, we draw on Ausubel's (1978) assimilation theory in the educational psychology literature to develop four research hypotheses relating training sequences to near- and far-transfer IT task performance (defined later), user satisfaction and user self-efficacy. These hypotheses are then tested empirically via a quasi-experimental laboratory study in a database design context. Results of the analysis confirm that the conceptual-procedural training sequence improves task performance and self-efficacy more than the reverse sequence, though user satisfaction is not significantly different between the two sequences.

The rest of this chapter proceeds as follows: The next section formulates research hypotheses by drawing on assimilation theory and prior IT training research. The third section describes experimental research design, subjects, treatments and measurement. The fourth section describes statistical data analysis techniques and results.

The fifth section discusses the study's key findings, limitations and implications for research and practice.

THEORY AND RESEARCH HYPOTHESIS

Assimilation Theory

The individual learning process is presumed to proceed in three stages (Mayer, 1981). In the reception stage, learners acquire new information from the external environment and store it in their short-term memory. The short-term memory is a temporary and limited-capacity storage space where information is stored as distinct entities (instead of integrated knowledge structures). Next, in the availability stage, learners search their long-term memory for knowledge structures (or "schemas") potentially related to the new information. The long-term memory is a permanent and virtually unlimited storage space for classifying, organizing and archiving information using preexisting or new schemas. Finally, in the activation stage, the new information is transferred from the short-term memory to appropriate knowledge structures or "anchors" in the long-term memory, where it is mapped and integrated with prior schemas and preserved for future use.

Assimilation theory defines two types of human learning: meaningful learning and rote learning (Ausubel, 1978). *Meaningful learning* (or assimilation) occurs when learners relate, connect and integrate new information with that already stored in existing knowledge structures or schemas in their long-term memory. In contrast, *rote learning* (or memorization) occurs when learners store new information in their short-term memory in a disjointed manner, without integrating that information within schemas in their long-term memory. While rote learning requires the completion of only the reception stage in Mayer's (1981) three-stage learning process,

meaningful learning occurs only when all three stages are completed.

Rote learned information, such as procedural rules, is often useful in performing tasks that are simple, routine or structurally similar to that of the learning context (termed *near-transfer tasks*), but provides little assistance in performing novel, creative or structurally dissimilar tasks (*far-transfer tasks*). Further, this information is difficult to retain over the long term because of its lack of organizing structure. Being stored in the short-term memory, it is also susceptible to interference from new information. However, meaningfully learned information residing in the long-term memory is often useful in performing novel, dissimilar or far-transfer tasks, is temporally stable and is retained for a longer period of time (Davis & Bostrom, 1993). Moreover, meaningful learning takes advantage of the knowledge already possessed by the learner, which is purportedly the single most important driver of individual learning (Ausubel, 1978).

Many organizational IT tasks, such as transaction processing and electronic mail (e-mail) usage, are of the near-transfer type, requiring users to learn procedural know-hows, such as event sequences and screen layouts. However, other tasks, such as decision-making and executive planning, are of far-transfer type, requiring conceptual know-whats, such as what-if analysis and ad hoc data mining. Complex knowledge work, such as system development, often involve both components, in that the designers should not only learn near-transfer details such as program coding, application program interfaces and integrated development environment (IDE) features that are easily transferable across projects, but also less transferable far-transfer knowledge, such as requirements planning, systems analysis and integration test planning. Hence, successful comprehension and performance of such tasks are best supported by a combination of conceptual and procedural approaches, which we call a "training sequence."

Prior research have compared conceptual vs. procedural training for Windows accessories (Write and Paintbrush) (Olfman & Mandviwalla, 1994) and the VAX e-mail system (Santhanam & Sein, 1994), and found no significant difference in effects between the two approaches. Though these studies contrasted training *approaches*, no studies to date have empirically studied training *sequences*. Further, prior research has mostly focused on relatively simple IT tasks, such as e-mail or spreadsheet usage, where training sequence may have marginal impact. As described next, training sequences are likely have a greater impact on more complex tasks of the type examined in this study (database design).

IT Training Sequences

In complex IT tasks requiring both conceptual and procedural knowledge, do users perform better if they are trained conceptually first, then procedurally, vs. the reverse sequence? Assimilation theory suggests that training sequences are not commutative and that the two sequences have differential effects on users' ability to retain and apply knowledge (Ausubel, 1978). In the conceptual-procedural sequence, the knowledge structures or schemas developed during initial conceptual training provide a meaningful context or "ideational scaffolding" (Ausubel, 1978) for interpreting and assimilating action-plan details acquired later, aiding near-transfer task performance. In contrast, in a procedural-conceptual sequence, lack of mental schemas during initial procedural training may hinder appropriate "anchoring" of concepts during subsequent conceptual training, hurting far-transfer task performance. Anderson (1995) noted that some users may be able to infer conceptual knowledge from procedural details learned earlier. However, we argue that such inference is more likely for simple (primarily procedural) IT tasks/technologies, such as e-mail or word processor usage, but less so for

more complex tasks, such as database design or system development, requiring substantial levels of both conceptual and procedural knowledge. Training sequences, therefore, are expected to be more relevant in the performance of complex IT tasks (i.e., IT-based knowledge work).

In the conceptual-procedural sequence, the need for assimilative schemas or "advance organizers" (e.g., high-level ideas, diagrams, abstracts) was highlighted by Ausubel (1978), who found that learners' recall of ambiguous textual content improved significantly when an organizing title was provided prior to the actual textual material, while the organizing title had no effect on subjects' learning or retention if presented after the learner had read the text. Likewise, Reigeluth and Stein (1983) recommended designing instructional content as "elaborative sequences," where the general concepts are presented first, followed progressively by differentiated levels of procedural details and specificity. Hence, we hypothesize:

- H1: IT users trained in a conceptual-procedural sequence perform *near-transfer* IT tasks better than those trained in a procedural-conceptual sequence.
- H2: IT users trained in a conceptual-procedural sequence perform *far-transfer* IT tasks better than those trained in a procedural-conceptual sequence.

Though task performance is the primary dependent variable of interest to corporate IT trainers and managers, we also examine two user-related outcomes – user satisfaction and self-efficacy—that are increasingly being viewed as key motivators of user learning/training circumstances. *Satisfaction* refers to users' affective evaluation of their own task performance, and *self-efficacy* is the cognitive belief in their ability to perform similar tasks in the future. Bandura's (1986) social cognitive theory provides theoretical support for

the self-efficacy construct, which is theorized to be directly related to satisfaction and future task performance. Empirically, Yi and Davis (2003) demonstrate that post-training software self-efficacy is related to intermediate-term and long-term task performance; Compeau and Higgins (1995) justify the linkage between IT training and self-efficacy; and Compeau, Higgins and Huff (1999) validate the association between self-efficacy and affect (e.g., satisfaction). Following a meta-analysis of the training literature, Colquitt, LePine and Noe (2000) show that pre-training self-efficacy positively impacts motivation to learn, which in turn affects post-training self-efficacy and task performance.

Most users tend to favor procedural training because of its technology-focused and hands-on nature and its ability to quickly initiate a user to a specific task at hand. Carroll and Rosson (1987) contend that users prefer learning quick procedures that can help them get started with system usage and thereby minimize the “IT productivity paradox,” rather than “waste” their time understanding concepts. Since procedural-conceptual sequence initiates users to procedural training faster, users are more likely to be satisfied with this sequence than with the reverse sequence. In contrast, self-efficacy should be higher for the conceptual-procedural sequence, because as these users perform near-transfer and far-transfer tasks better (per assimilation theory); they gain confidence in their ability to perform similar tasks in the future. Hence, we hypothesize:

- H3: IT users trained in a conceptual-procedural sequence experience *lower* satisfaction with IT task performance than those trained in a procedural-conceptual sequence.
- H4: IT users trained in a conceptual-procedural sequence experience *higher* self-efficacy regarding their IT task performance than those trained in a procedural-conceptual sequence.

Control Variables

Extraneous variables that can potentially confound the above hypotheses can be grouped into four categories: (1) technology attributes, (2) training context (e.g., trainer, setting), (3) task attributes, and (4) trainee attributes (individual differences). The first three categories can be partially controlled via appropriate research designs; for example, by employing a single IT (technology attributes); a common training approach, duration and trainer for all sessions (training context); and common IT tasks (task attributes). We control for individual differences by adding prior IT experience and attitude toward IT as control variables in our study, for reasons described below.

Users’ prior IT experience may be an alternative source of assimilative schemas (as opposed to conceptual training) driving the meaningful learning process (Santhanam & Sein, 1994). Ex ante availability of such schemas in long-term memory (from prior experience) can help more experienced IT users anchor and assimilate new procedural information without additional conceptual training. Programmers already familiar with one programming language often find it easier to learn a second similar language, because they can assimilate the procedural details (e.g., syntax) of the second language within schemas (e.g., branching, iteration, arrays) acquired from the first. In contrast, lack of such schemas may force relatively novice or inexperienced users to rely on rote learning for retaining procedural details for near-transfer task performance. Prior IT experience, therefore, can confound the impact of training sequence on near-transfer task performance and is included in this study as a control variable.

IT users’ task performance may also be confounded by their attitude (affect) toward IT tasks (Bostrom, Olfman, & Sein, 1990; Olfman & Pitsatorn, 2000). Users with positive attitudes (e.g., enthusiastic users) often put in more effort

in task performance, irrespective of their prior conceptual and/or procedural training, resulting in improved task performance. In contrast, users with negative attitudes (e.g., less motivated users) may be reticent to put forth their best effort despite extensive prior training, leading to poor performance. In order to tease out the effect of IT training sequences on task performance, we include attitude as a second control variable.

RESEARCH METHODOLOGY

Experimental Design, Subjects and Treatments

A quasi-experimental laboratory study (see Figure 1) using student subjects was conducted in a database design context to empirically test our four research hypotheses. Entire class sections were randomly assigned to one of the two treatment groups (conceptual-procedural or procedural-conceptual training sequence); hence the quasi-experimental design. A mixed-model research design was employed, where (1) different subjects experience different treatments, and (2) all subjects experience each treatment (Myers, 1977). An explicit control group (with no treatment) was not required, since each group acted as a control for the other group. All treatments were administered by the same instructor, using a combination of lectures, discussions, in-class exercises and graded assignments.

Subjects for this study were drawn from undergraduate and graduate students (approximately 50% in each category) enrolled in four sections of a database management class at a large public university. The subject pool had a mean age of 26 years, full-time work experience of 3.7 years, computer-related work experience of 2.8 years, and database usage (but not design) experience of 0.9 years. Forty-one percent of these subjects were previously or currently employed in the IT industry, being somewhat representative of the

target population of IT professionals. Though student and non-student subjects may differ in their intrinsic motivation toward learning database design, we attempted to control for this difference by including subjects' attitude as a covariate in our research design. Further, our use of student subjects was consistent with much prior IT training research (e.g., Ahrens & Sankar, 1993; Davis & Bostrom, 1993; Santhanam & Sein, 1994).

The database design task was selected because this is a typical example of a complex IT task that included elements of both conceptual and procedural knowledge, which rendered it well to the research objectives of this study. Though this particular task has seen very limited use in prior IT training research (one exception being Ahrens and Sankar, 1993), it is a fairly common task domain for real-life IT professionals and hence, was deemed appropriate.

Prior to the experimental treatments, subjects were administered a short pre-treatment questionnaire soliciting demographic information, prior work experience (general and IT related) and attitude toward learning database design. For the next 3 weeks, about half of the subject pool (Group A in Figure 1) received conceptual training on database design, while the other half (Group B) received procedural training. The conceptual training focused on abstracting a conceptual data model from a textual narrative of users' data needs, documented in the form of an entity-relationship diagram (ERD). This training included: (1) identifying data objects (entities), (2) specifying relationships between entities, (3) identifying attributes for each entity, and (4) establishing relationship cardinalities (e.g., one-to-many, subtype-supertype, mandatory-optional). Procedural training focused on converting an existing ERD into a logical data model (LDM) (a set of third normal form relations or tables for relational implementation) using procedural rules. Specific activities included: (1) mapping entities into relations, (2) specifying primary keys, (3) normalizing relations into third normal form, and

Figure 1. Research design

	Week 0	Weeks 1-3	Weeks 4-6	Week 7	
Group A	O _{PRE}	X _{CT}	X _{PT}	O _{FT+NT}	O _{POST}
Group B	O _{PRE}	X _{PT}	X _{CT}	O _{FT+NT}	O _{POST}

Legend: O_i = Observations (questionnaires: PRE, POST;
tasks: near transfer [NT], far transfer [FT])
X_i = Training (conceptual [CT], procedural [PT])

(4) specifying relationships using foreign keys or associative relations.¹ For weeks 4-6, the training approach (and content) was reversed for the two groups, so that Group A subjects received procedural training and Group B received conceptual training. Each 3-week training period ended with an in-class database design exercise intended to help subjects internalize their recent learning experience, which was graded and returned to the subjects. On the 7th week, subjects were asked to complete an in-class database design task that involved both far- and near-transfer components (i.e., design an ERD and LDM from a given user narrative), following which, they recorded their post-training satisfaction and self-efficacy in a post-treatment questionnaire.

Construct Measurement

Training sequence (independent variable) was manipulated via treatment assignment. Prior IT experience and attitude (control variables) were measured via the pre-treatment questionnaire. Among dependent variables, IT task performance was assessed by three independent judges, and IT user satisfaction and self-efficacy were assessed perceptually using the post-treatment questionnaire. A combination of fill-in, Likert-scale, semantic differential and externally evaluated measures were employed to reduce common methods bias. Scale items were adapted from pre-validated measures, appropriately modified

for the database design context, and are listed in Appendix A.

Prior IT experience was assessed using three fill-in questions that asked subjects the number of years they had worked with (1) computers, (2) databases, and (3) programming (item means were 2.8, 0.9 and 1.2 years, respectively). Databases and programming are two typical functional domains of IT tasks, and thus were considered appropriate for this scale. The overall experience measure was computed as the average of these three items.

Attitude was measured using three seven-point semantic differential items anchored between adjective pairs: (1) extremely bad ... extremely good, (2) extremely desirable ... extremely undesirable, and 3) strongly dislike ... strongly like. These items were adapted from Mathieson (1991) and reworded to relate specifically to the database design context.

Near-transfer and far-transfer task performances were evaluated by a panel of three independent judges. The panel consisted of one teaching faculty, one research faculty and one graduate assistant experienced in database design. A diverse panel was purposely chosen to reduce potential judgment biases among judges. However, to ensure consistency in judges' performance assessment, assessment rules were discussed and agreed upon prior to actual grading.² Each judge assigned a score of 1 (completely incorrect), 2 (mostly incorrect), 3 (about half-correct), 4 (mostly correct) and 5 (completely correct) for each task,

which were later averaged across judges for an overall score for that task. External assessment helped avoid subjectivity often inherent in self-reported performance measures.

Satisfaction, referring to subjects' overall emotional state following IT task experience, was assessed using three seven-point semantic differential items from Bhattacharjee (2001). These items were anchored between adjective pairs: (1) extremely dissatisfied ... extremely satisfied, (2) extremely frustrated ... extremely contented, and (3) extremely terrible ... extremely delighted. A fourth item in the original scale (extremely displeased ... extremely pleased) was dropped because of its semantic proximity with the first item.

Self-efficacy was measured using five seven-point Likert-scaled items (anchored between "strongly disagree" and "strongly agree") taken from Compeau et al.'s (1999) computer self-efficacy scale. These items examined subjects' confidence in their ability to design databases (1) without help from anyone, (2) using only database manuals for reference, (3) using only an online help facility for assistance, (4) if adequate time is available to complete the tasks, and (5) if someone can be reached for assistance. Compeau's scale had five additional items that were not applicable to our study, given that we were measuring post-usage self-efficacy (while Compeau et al. measured pre-usage self-efficacy), and thus were dropped from our scale.³

DATA ANALYSIS AND RESULTS

Pilot Study

Since IT experimental studies are often plagued with inadequate treatments, unreasonable tasks (for target subjects) and unclear instrumentation (Jarvenpaa, Dickson & DeSanctis, 1985), a pilot study was conducted prior to the actual empirical study to examine these issues. This study in-

involved 19 undergraduate subjects, 10 of whom were trained using the conceptual-procedural sequence, while the remaining nine were trained in the reverse sequence. Subjects completed the near-transfer and far-transfer tasks and the pre- and post-questionnaires as shown in Figure 1. In addition, they were asked to comment on the reasonableness of tasks, the adequacy of the preceding training, and the clarity and understandability of scale items.

Subjects confirmed that the assigned far-transfer and near-transfer tasks were indeed reasonable (most scores ranged between 3.5 and 4.5 on a 5-point task performance scale) and that a 3-week training duration for each task type was adequate for acquiring the necessary database design skills for performing these tasks. However, based on their inputs, some of the scale items and task descriptions were slightly reworded to improve understandability. Since IT task performance was a key dependent variable in this study, we also examined correspondence between judges' ratings of this variable using Pearson's correlation coefficients. This statistic ranged between 0.61 and 0.72 for pairs of judges, with a mean correlation of 0.67. All correlations were significant at $p < 0.01$, indicating a high level of agreement between judges.

Finally, effect size estimates (means and standard deviations) obtained from the pilot study was used to estimate optimal sample sizes required to detect the hypothesized effects in the main study. Power calculations based on a two-sample, normal, equal variance distribution, desired statistical power of 0.80 and significance level of 0.05 yielded a minimum sample size of 52 to detect the hypothesized far- and near-transfer task performance effects. To be on the safe side, we decided to target a desired sample size of 100.

Instrument Validation

The final empirical study consisted of a total of 121 subjects. This subject pool consisted of 59

Training Sequences and their Effects on Task Performance and User Outcomes

graduate and 62 undergraduate students. Sixty subjects were trained using the conceptual-procedural sequence and 61 subjects were trained in the reverse sequence. Comparison of means tests revealed that the two treatment groups were not significantly different with respect to age (means 25.35 and 25.94 years, $t=0.88$, $df=138$), prior work experience (means 3.41 and 3.82 years, $t=0.77$), prior computer-related work experience (means 2.61 and 2.71 years, $t=0.21$) and prior database usage experience (means 0.70 and 0.99 years,

$t=1.09$), assuring equivalency between groups. Approximately equal-sized treatment groups also improved the statistical power of our analysis (described later).

The first step in our statistical data analysis was to examine the psychometric properties (validity and reliability) of scale items. For this purpose, the three perceptual scales in this study—IT user attitude, satisfaction and self-efficacy—were factor analyzed using the principal components technique with direct oblimin rotation (oblique

Table 1. Scale reliabilities and validities

Scale Item	Mean	Std. Dev.	Factor Loadings (Direct Oblimin Rotation)		
			Factor 1 (Self-Efficacy)	Factor 2 (Attitude)	Factor 3 (Satisfaction)
ATT1	5.78	1.30	0.07	0.90	-0.08

ATT3	5.93	1.11	0.02	0.90	-0.01
SAT1	5.22	1.45	0.23	-0.01	0.84
SAT2	5.31	1.58	0.19	-0.04	0.94
SAT3	5.11	1.58	0.21	0.06	0.92
SE1	4.94	1.67	0.94	0.10	0.14
SE2	4.90	1.69	0.93	0.07	0.15
SE3	5.14	1.60	0.87	0.10	0.02
SE4	4.98	1.71	0.86	-0.03	0.27
SE5	5.02	1.47	0.33	0.10	0.58
Eigenvalue			4.51	2.43	1.97
Variance extracted			40.95%	22.10%	17.86%
Cronbach alpha (reduced scales)			0.92	0.88	0.91

Table 2. Group means and standard deviations

	Means (Standard Deviations)		
	Conceptual-Procedural (N=60)	Procedural-Conceptual (N=61)	Overall (N=121)
Near-transfer task performance	4.57 (0.46)	4.09 (0.54)	4.33 (0.55)
Far-transfer task performance	4.31 (0.37)	3.79 (0.45)	4.04 (0.49)
Satisfaction	5.13 (1.41)	5.29 (1.42)	5.21 (1.41)
Self-efficacy	5.30 (1.40)	4.68 (1.56)	4.99 (1.51)

Note: Far- and near-transfer task performance was assessed on 5-point scales (by external judges); satisfaction and self-efficacy was assessed on 7-point Likert scales (by subjects).

rotation was chosen because the scales were expected to be correlated). Prior IT work experience was excluded from this analysis since it consisted of three self-reported fill-in items. Three factors were identified based on a visual examination of the scree plot and a minimum eigenvalue criterion of 1.0, which respectively extracted 41%, 22%, and 18% of the total variance (cumulative variance of 81%). Item factor loadings, along with item means and standard deviations, are listed in Table 1.

For convergent validity, hypothesized scale items should have factor loadings exceeding 0.60 on their underlying scales (SAS Institute, 1990). This condition was met by all items in the attitude and satisfaction scales, and four out of five self-efficacy items, except SE5 (“... if I can call someone for help”). For discriminant validity, cross-factor loadings (on other scales) should be less than 0.30 (SAS Institute, 1990). This condition was also met by all items except SE5. In light of the above problems, item SE5 was dropped from the self-efficacy scale. Cronbach alpha for the remaining scales were 0.88 for attitude, 0.91 for satisfaction and 0.92 for self-efficacy—all exceeding the minimum of 0.80 required for confirmatory research.

Inter-rater reliability for IT task performance (rated by three judges) was assessed by pooling

together the near-transfer and far-transfer task performance scores and examining Pearson correlations between pairs of judge ratings. All correlations were significant at $p < 0.01$ (two-tailed), and the mean correlation was 0.713. High agreement between judges was proof of the quality of this measure.

Hypotheses Testing

Means and standard deviations of aggregated dependent variables for the overall sample and for each treatment group are listed in Table 2. Group A (conceptual-procedural sequence) experienced higher far- and near-transfer task performance means on Week 7 (4.31 and 4.57, respectively, on 5-point scales) than Group B (procedural-conceptual sequence) (3.79 and 4.09, respectively), as expected from Hypotheses H1 and H2. Satisfaction was lower and self-efficacy was higher for Group A (5.13 and 5.30, respectively, on 7-point scales) compared to that of Group B (5.29 and 4.68, respectively), in accordance with Hypotheses H3 and H4. Hence, the directionality of empirically observed effects is consistent with theory.

The multiple analysis of covariance (MANCOVA) technique, followed by univariate analysis of covariance (ANCOVA) for each dependent

Table 3. MANCOVA results

Error	260.23	117			
Design: Dependent variable = Intercept + Treatment group + Prior IT experience + Attitude					
*Power estimated using $\alpha=0.05$.					

variable, was used to examine whether the above differences were significant. This approach was appropriate, since our independent variable (training sequence) was categorical, the four dependent variables (far- and near-transfer task performance, self-efficacy and satisfaction) were interval-scaled, and covariates (prior IT experience and pre-training attitude) were also interval-scaled. Per the multivariate central limit theorem, two-group comparison analysis is robust to violations of the multivariate normality and equality of variance/covariance assumptions for

large samples (> 20 per group), as was the case in our study.⁴

MANCOVA was performed using the general linear model approach; the results are presented in Table 3. Four multivariate significance tests were performed: Hotelling's Trace, Wilks' Lambda, Pillai's Trace and Roy's Largest Root test.⁵ Each test reported a significant treatment effect (training sequence), with an F-statistic of 11.59 ($p<0.01$) and statistical power close to 1.00, confirming a multivariate treatment effect of training sequence on four dependent variables: far-transfer task

performance, near-transfer task performance, satisfaction and self-efficacy. The covariates, prior IT experience and attitude, had non-significant effects (p -values of 0.14 and 0.75, respectively) on the dependent variables; however, these lack of effects may have been masked by low power (presumably due to small effect sizes).

Results of follow-up univariate ANCOVAs (tests for individual hypotheses) are reported in Table 4. These results indicate that the treatment effect was significant for near-transfer task performance ($F=26.89$, $p<0.01$) when controlled for users' pre-treatment IT experience and attitude. Coupled with the higher mean for Group A (4.57) than for Group B (4.09) (see Table 2), this indicates that the conceptual-procedural training sequence resulted in significantly better near-transfer task performance than the procedural-conceptual sequence. Likewise, the significant treatment effect for far-transfer task performance at time T_3 ($F=45.88$, $p<0.01$) combined with the higher mean for Group A (4.31) than that of Group B (3.79), demonstrates the superiority of the conceptual-procedural training sequence in far-transfer task performance. Hence, Hypotheses H1 and H2 were both supported. Note that the statistical power of both effects equaled or exceeded 0.99, providing high confidence in our empirical findings.

Post-training satisfaction was expected to be significantly lower for Group A than for Group B (Hypothesis H3), while the reverse effect was expected for self-efficacy (Hypothesis H4). In conjunction with the self-efficacy means (5.30 and 4.58 for Groups A and B, respectively), ANCOVA results supported H4 ($F=4.84$, $p=0.03$), though the statistical power of this test was lower than desired (0.59). However, H3 was not supported ($F=0.36$, $p=0.55$), despite the group means for satisfaction being in accordance with the stated hypothesis (5.13 and 5.29 for Groups A and B, respectively), indicating that satisfaction may not differ significantly across training sequences. Even if users value procedural training more than conceptual training, the above results indicate that

they may be indifferent to whether the procedural training is received earlier or later in the training sequence. Implications of these findings are discussed in the next section.

DISCUSSIONS AND CONCLUSION

Key Findings and Implications

The goal of this study was to examine whether conceptual-procedural or procedural-conceptual training sequence was most effective in achieving the best IT task and user outcomes. Drawing from assimilation theory (Ausubel, 1978), we postulated that a conceptual-procedural training sequence can provide better near-transfer task performance, far-transfer task performance and user self-efficacy but lower user satisfaction than a procedural-conceptual sequence. These hypotheses were empirically tested using a quasi-experimental study of 121 subjects in a database design context, while controlling for subjects' pre-treatment attitude and IT experience.

Assimilation theory predicted that the conceptual-procedural sequence is better for near-transfer and far-transfer task performance because prior conceptual training creates mental schemas that help assimilate procedural details during subsequent procedural training. Since IT users trained in the conceptual-procedural sequence experience better task performance, they gained confidence in their ability to perform similar tasks and, hence, increased their self-efficacy. In contrast, the reverse sequence was expected to be more satisfying, because users can directly relate to action-plan knowledge gained during the procedural training but not necessarily to the abstract schemas acquired during conceptual training.

Our empirical findings supported the predicted effects for far- and near-transfer task performances and user self-efficacy, but not for user satisfaction. The satisfaction mean was slightly higher for procedural-conceptual sequence as expected, but

this difference was non-significant. Hence, procedure-first IT training programs, often employed to maximize user satisfaction, are marginally useful in enhancing satisfaction while adversely impacting near-transfer and far-transfer task performance and self-efficacy. Instead, scarce training resources are best utilized in designing training programs where conceptual training precedes (rather than follows) procedural training, especially for complex IT tasks involving both conceptual and procedural knowledge.

Limitations of the Study

Like most experimental studies, this study is not without limitations. First, one may question whether the study's findings, inferred using student subjects, are generalizable to the general population of IT users because of differences in intrinsic motivation between the sample and the population. However, the mean work experience of 3.7 years and mean computer-related work experience of 2.8 years make our sample somewhat representative of the target population. Further, many of our subjects were also employed in the local IT industry at the time of the study. The key difference between student subjects and the IT workforce at large is often prior IT experience, which was controlled for in this study.

Second, though our post-test-only design alleviated several threats to internal validity—such as pre-test/post-test sensitization, statistical regression (toward the mean), and subject mortality—it may still have been susceptible to novelty effect (subjects' newness of database design task), Hawthorne effect (subjects' awareness that they were participating in an experiment) and Rosenthal effect (the researcher's physical proximity to subjects during task performance) (see Huck, Cormier, & Bounds, 1974).

Third, since we used both undergraduate and graduate students in our sample, one may argue whether these two groups were systematically different in their response patterns. Graduate

students tend to be older and have more work experience than undergraduate students, and may even demonstrate a more positive attitude toward IT learning. We eliminated these concerns by controlling for prior IT experience and pre-training attitude in our research design. The F-statistics and p-values of these effects (see Table 4) suggest that even if undergraduates differed from graduate students on these dimensions, such differences did not significantly influence their task performance or personal outcomes.

Finally, it may be questioned whether our findings, based on a database design task, can be generalized to other types of IT tasks. A database task was chosen in this study because of its combination of conceptual and procedural content typical of most complex IT tasks. While this is different from simpler and more procedurally oriented tasks examined in prior training research (e.g., e-mail or spreadsheet usage), we expect our findings to be generalizable to other complex tasks, though this assertion cannot be validated without additional studies. Further, we expect task complexity to moderate the effects of training sequences on task and user outcomes, which is also left open for future research.

Contributions for Research and Practice

The study makes several important contributions for IT training research and practice. First, it introduces the concept of IT training sequences and describes how training sequences should be structured for optimal task and user outcomes. For IT tasks that require both conceptual and procedural knowledge, we demonstrate that conceptual training should precede procedural training, so that IT users can form conceptual schemas prior to assimilating action plan sequences using these schemas. Even if the conceptual-procedural training sequence marginally decreases user satisfaction, it is still preferable by virtue of its positive impacts on near-transfer and far-transfer task

performance and user self-efficacy. For practitioners, this finding offers some guidelines on how to allocate scarce training resources for the best outcomes. For researchers, this study empirically validates the expectation from prior research that conceptual training prior to procedural training helps form better mental models (e.g., Santhanam & Sein, 1994) and extended this logic to demonstrate its effects on task performance and user outcomes.

Second, this study was one of the earliest to examine multiple types of training outcomes. Specifically, we examine two task outcomes (near-transfer and far-transfer task performances) and two user outcomes (self-efficacy and satisfaction), and demonstrate that these constructs do not necessarily covary. We did not fully explore the theoretical linkages between these outcomes, but this presents an opportunity for future researchers to extend the current study.

Finally, while prior studies examined training involving simple IT tasks/technologies such as e-mail, spreadsheet or word processing usage, this study was one of the earliest focusing on complex IT tasks, such as database design, typical of today's knowledge-based work. Appropriate training sequence is more critical in the latter context, given its higher conceptual and procedural knowledge requirements. As IT tasks/technologies become more complex, it will be important to broaden our range of training contexts to examine areas such as database design. Further, consideration of task complexity may help reconcile some of the mixed empirical findings reported in prior training research and build a cumulative body of knowledge in this area.

ENDNOTES

- ¹ To conserve space, the training script is not provided here, but is available from the authors on request.
- ² To avoid possible confounding between near-transfer (LDM) and far-transfer (ERD) task performance, since the former followed the latter, LDM was evaluated based on subjects' depiction of ERD, even if the ERD was incorrect.
- ³ The five dropped items were: (1) "if I have never used a software package [performed similar tasks] like it before," (2) "if I had only seen someone else using it before trying it myself," (3) "if someone else had helped me get started," (4) "if someone showed me how to do it first," (5) "if I had used similar packages before this one to do the same job." These were not relevant in our context since subjects have already seen the instructor perform similar tasks during the

training process, had been shown how to perform such tasks by the trainer, and had gotten started on (and completed) similar tasks during the training process.

⁴ Multivariate central limit theorem states that test statistics in two-group analysis can be assumed to be normally distributed if: (1) the samples are drawn randomly, (2) the groups are independent, and (3) the groups are large (> 20) (Johnson & Wichern 2002, p. 282-283). Tests of multivariate normal-

ity and equality of variance/covariance of sample data are required to assure normal distribution of test statistics only if the samples are small or more than two groups are being considered, or the independent variable is continuous or interval-scaled.

⁵ Results from Pillai's and Roy's tests were similar to that from Hotelling's and Wilks' tests and, hence, are not reported in Table 3.

APPENDIX A: MEASUREMENT ITEMS

Training Sequence:

Manipulated via experimental treatment (conceptual-procedural versus procedural-conceptual).

Prior IT Experience (fill-in):

EXP1. Number of years of experience working with computers: _____ years

EXP2. Number of years of experience working with databases: _____ years

EXP3. Number of years of programming experience: _____ years

Attitude (seven-point semantic differential scale):

ATT1. I strongly (dislike...like) the idea of learning about database design.

ATT2. Learning about database design is an extremely (bad...good) idea.

ATT3. Learning how to design databases is an extremely (undesirable...desirable) idea.

Task Performance (five-point assessment scale):

Assessed independently by three judges.

Satisfaction (seven-point semantic differential scale):

SAT1.I am extremely (dissatisfied...satisfied) with my overall performance in this assignment.

SAT2.I am extremely (frustrated...contented) with my overall performance in this assignment.

SAT3.I feel extremely (terrible...delighted) with my overall performance in this assignment.

Self-Efficacy (seven-point Likert scale):

SE1. I can now design databases even if there is no one around to help me.

SE2. I can now design databases using only database manuals for reference.

SE3. I can now design databases using only online help facility for assistance.

SE4. I can now design databases if I have enough time to complete the task.

SE5. I can now design databases if I can call someone for help if needed

(dropped).

APPENDIX B: FINAL DATABASE DESIGN TASK

Prepare (1) an entity-relationship diagram (ERD), (2) a logical data model as a set of third normal form (3NF) relations reflecting the data and relationships of the following narrative. Your ERD should contain appropriate cardinality and mandatory/optional symbols. Your logical data model should have appropriate primary (identifier) and foreign keys, referential integrity constraints, and associative relations.

A cable television (CTV) company desires a database to manage customer data. CTV offers three services (monthly charges in parentheses): (1) Basic (\$30), (2) Movie Channels A, B, or C (\$15 per channel), and (3) Children's Channel (\$10). In addition, it rents two types of equipment (serial numbers and monthly charges in parentheses): (1) Decoder (1237810, 484965, 319542; \$5 per decoder), and (2) Remote (432, 947, 376; \$4 per remote). Two typical customers are:

Training Sequences and their Effects on Task Performance and User Outcomes

Account Number: 101
John Lamb
123 Lanai Court
Gotham City, NY 10023
Phone: 203-247-5195
Service: Basic, Movie Channel B
Equipment: Decoder(1237810), remote
control(947)

Account Number: 102
Mary Jones
4443 8th Ave
Gotham City, NY 10043
Phone: 203-232-6243
Service: Basic, Children's Channel
Equipment: Decoder (319542)

The following business rules apply to this company:

- Each customer is assigned one account number only, which can be used for multiple services.
- The company can have a service that has no assigned customers.
- The company maintains an inventory of equipment, which may or may not be used.
- It is possible for a customer to have established service without any assigned equipment.

Chapter 5.39

CareerQuesting: Evaluating Web-Based Resources for Interesting Girls in STEM Careers

Karen F. White
Purdue University, USA

Mara H. Wasburn
Purdue University, USA

ABSTRACT

This paper develops an educational strategy to foster the interest and persistence of middle school girls in science, technology, engineering, and mathematics (STEM) careers using existing Web sites. Criteria are specified that enable middle school teachers to evaluate Web sites that can serve as supplemental learning activities within prescribed curricula. In particular, these criteria help evaluate sites that provide materials appealing to both boys and girls. This allows teachers to adopt them without concern that they are providing an unfair advantage to girls.

INTRODUCTION

In September 2001, the Council on Competitiveness, a group of industrial, university, and labor leaders whose mission is elevating national competitiveness to the forefront of national consciousness, launched the Building Engineering and Science Talent (BEST) initiative. It is described on the Council Web site as a public-private partnership “to identify the most effective strategies for building a more diverse science, engineering, and technical workforce and to bring best practices to communities nationwide” (Council on Competitiveness, 2004). One of the first reports to emerge from the BEST program begins:

There is a quiet crisis building in the United States — a crisis that could jeopardize the nation’s pre-eminence and well-being. The crisis has been mounting gradually, but inexorably, over several decades. If permitted to continue unmitigated, it could reverse the global leadership Americans currently enjoy. (Jackson, 2004)

This report goes on to cite “the gap between the nation’s growing need for scientists, engineers, and other technically skilled workers, and its production of them.”

The literature refers to a “leaky” pipeline of female talent, leading to “under-representation” of women in the STEM professions. Much research documents this problem, tracing attitudes and behaviors of girls from elementary school through graduate studies and employment. The studies reflect a clear gender distinction at all ages (Freeman, 2004; Jones, Howe, & Rua, 2000), showing that as girls grow older, there is steady decline in the number expressing interest in STEM subjects, and a corresponding decline in the numbers of women entering higher levels of study. Numerous programs proposed, and implemented over the past decade to improve gender equity in STEM education and workforce. These programs aim to provide information and other support for women and girls, allowing them to make better informed decisions with respect to their educational activities and career planning (AAUW, 2004; National Science Foundation, 2003). Given the proliferation of such efforts, some measurable effect on “entry and persistence” of women into these professions should be expected. However, data do not indicate substantial gains (Freeman, 2004; Huang, Tadese, & Walter, 2000).

The apparent failure of these programs may be due to a failure to implement or adopt them broadly. In light of recent political pressure to improve standardized testing scores, teachers must devote most of their time to the specific curriculum requirements. They may lack the time to locate and evaluate additional resources to ad-

dress such gender equity issues, or may lack the budget to adopt commercially available resources. Even when appropriate materials are available for little or no cost, such as those on Web sites for many gender-equity programs, teachers may not understand how or when to use them (Furuta et al., 1999; March, 1997).

Web site-based resources are often developed as part of informal experience to be used as a supplement to regular classroom activities. However, it is unlikely that students will seek out these resources on their own. Additionally, research suggests that only a small percentage of teachers believe it is appropriate to address gender-equity concerns in the typical classroom (Bullock, 1997). Those who do may not have support of the school administration to adopt programs perceived to benefit only girls (Posnick-Goodwin, 2005).

The goal of this paper is to identify a set of criteria for use by teachers in evaluating existing Web sites with the potential for increasing interest and persistence of middle school girls in STEM fields. In particular, the criteria emphasize materials that might appeal to both boys and girls, allowing teachers to adopt them without concern that they are providing an unfair advantage to girls.

REVIEW OF THE LITERATURE

There are many alternative explanations for why women continue to avoid STEM professions. Early studies cited difficulties in mathematics and science, or avoidance of these subjects by girls as the main concern. Girls entered college level studies without adequate preparation for STEM fields, and so avoided them. Programs designed to stimulate interest in mathematics and science (GirlTech.org, 2004), to make them entertaining and appealing to girls, were offered as a means of addressing this problem. Some recent research has indicated that skills development programs have, in fact, been successful, and that girls are

participating equally in middle school and high school studies in science, mathematics, and technology, then entering college studies without the skill gap observed in the early 1990's (Clewell & Campbell, 2002; Freeman, 2004). If this is true, then other influences must be responsible for the continued absence of females involved in college degree programs, or seeking employment in STEM fields.

Often, studies report that girls' and women are choosing other fields of study because they are "not interested" in STEM subjects (Morgan, Isaac, & Sansone, 2001). The problem may be explained as being linked to gender stereotypes, (Seymour, 1998) leading girls and young women to dismiss certain jobs as too "masculine." Educational materials, books, and Web sites, typically address such stereotypical thinking by providing "virtual" role models for girls through biographies of female scientists and engineers. Alternately, there are Web sites devoted to increasing interest in, or raising awareness of, STEM careers as exciting and challenging, with the intention that young girls will then aspire to these in spite of the stereotypes. These resources highlight scientific and engineering specialties thought to appeal more strongly to females. Many such programs include a substantial Web site component, providing a mechanism for distribution of educational resources for use by students, teachers, and even parents.

Informal vs. Formal Educational Strategies for Gender Equity in STEM

While Web sites may have some beneficial effects, some research indicates that girls would benefit more from increased *curricular integration* of science, technology, and math (BEST, 2004). For Web-based materials to be effective, the target audience must be directed toward to the resources, or alternatively, exhibit a strong interest in the subject in order to seek them out (Millar & Shevlin,

2003). Given that one goal shared by most of the Web sites is to "develop" interest, it follows that the target audience in this case is not inclined to find these sites independently. The medium itself has connotations of being too technical, and girls are assumed to have no interest in computers (Hanson, 2002).

The Gender & Science Digital Library (GSDL) project has addressed the needs of teachers seeking to provide an "interactive collection of high-quality, gender-equitable science, technology, engineering and mathematics (STEM) resources for K-12, higher education (community college and university), women's studies, teacher preparation programs, and informal learning environments" (EDC, 2004). Materials accessed on the GSDL Web site have been reviewed for quality, providing the user with confidence in their use. The site serves as a clearinghouse for materials, providing a description referencing the basic content and aims of the material, appropriate age groups, and other relevant information (Hanson, 2002). However, the primary goal of the GSDL project is to make available this type of resource. The site does not clearly provide guidance as to how or when to access these resources, or in what context, except to the extent that the referenced materials do so.

Also, the GSDL project attempts to learn more specifics regarding what teachers are looking for in Web-based resources, as part of their *Digital Libraries: Effective Access* project for STEM educators. A preliminary report available online (Sucher, 2003) describes survey results showing that a significant number of the STEM educators surveyed (86 percent) had not received training in equity in STEM education. Further, one-half of the teachers surveyed had not received training and were not interested in such training (Sucher, 2003, p. 38).

The overwhelming number of projects and Web sites available produces some confusion concerning which would be best for a particular need. Teachers noted that they relied on some of

their regular professional reading (educational journals or newsletters) or colleagues to reference good Web sites (Sucher, 2003). The GDSL study focused on “effective access,” and participants were asked to “select the top three challenges faced in seeking and using Web-based resources.” Seventy-one percent responded that the time it takes to locate resources was the primary concern. When participants were asked, “How long do you typically spend looking for educational resources on the Web?” Sucher (2003) reports slightly more than two-thirds replied, with some amounts up to 10 hours per month.

PROCEDURES

The AAUW (2004) report provided a key insight with respect to the development of this project, in terms of how Web sites and electronic resources might retain the advantages of “informal” education, yet maintain the accessibility and structure afforded by the classroom. The report summarized 416 projects in terms of subject content (science, technology, engineering, or math related, or some combined subject elements).

Of the four “STEM subjects,” science received the greatest attention, with 196 of the 416 programs citing science content as a primary subject matter. The lowest representation was for engineering programs, with only 64 programs claiming engineering as a focus. In addition, in spite of the funded programs’ fundamental commitment to gender equity, a significant number of programs (approximately 40 percent) served both boys and girls

The AAUW report further highlighted the characteristics of each subject emphasis. In this, technology focused programs were singled out for three unique characteristics. First, every technology-focused program specified at least some kind of goal for the program, while some programs in science, engineering, and mathematics omitted this. More than two-thirds of these had a goal to

“increase student engagement with technology” and one-third including goals of career awareness or gender equity awareness. Second, one-third of these were school-based (which was the highest percentage of school-based programs of all the STEM subjects). Finally, in comparison to the other STEM subjects, technology projects seemingly provided a unique opportunity for interdisciplinary focus, with 71 percent combining technology activities with science, engineering, or mathematics content.

Taken together, these findings indicate that “technology” as the focus of program subject matter provides a vehicle compatible with achievement of other learning goals. Further, 10 of the 17 Web-based programs were in the subject area of technology. Thus, technology was selected as a subject focus uniquely suitable to the purpose of the directed project, to facilitate the use of existing Web-based resources in the classroom setting

In moving forward with the second stage of the project, and the final analysis to identify appropriate Web sites or Internet tools for inclusion in the Web site, it was necessary to provide some criteria for evaluation of the candidates in terms of the potential learning experience and ease of incorporation into the regular curriculum. A review and analysis of three previous studies on evaluation of gender-equitable software and programs, each focusing on a different aspect of “assessment issues” with respect to gender equity programs, was undertaken:

- Gender & Science Digital Library (GSDL)
- Building Engineering & Science Talent (BEST)
- GirlsTech (from The Douglass Project)

The Gender & Science Digital Library (GSDL) project addressed the needs of teachers seeking to provide an “interactive collection of high-quality, gender-equitable science, technology, engineering and mathematics (STEM) resources for K-12, higher education (community college and

university), women's studies, teacher preparation programs, and informal learning environments" (EDC, 2004). Materials accessed on the GSDL Web site have been reviewed for quality, providing the user with confidence in their use. The site serves as a clearinghouse for materials, providing a description referencing the basic content and aims of the material, appropriate age groups, and other relevant information (Hanson, 2002). However, it does not clearly provide guidance as to how, when, or in what context to access these resources.

The Web site for the BEST initiative specifically notes its emphasis on programmatic results: "BEST sought to convene the nation's respected practitioners, researchers and policymakers and identify 'what's working' across the country to develop the technical talent of under-represented groups in pre-K through 12, higher education, and the workplace" (BEST, 2004). The BEST program goal is to encourage adoption of programs that have extensive research studies supporting effectiveness. However, the end list of resources did not provide any that would be readily accessible to a teacher involved in preparing lesson plans.

The GirlsTech investigators created a framework for evaluating the appeal of Web sites, CD-ROMs, and other electronic information resources to young women. This framework, called "The GirlsTech Model," was developed by analyzing library and information science and gender studies research, and through original theoretical work. Consequently, resources selected using the GirlsTech Model can encourage young women to increase their use of Web sites and related technology, thereby increasing their computer experience and confidence and making computer and technology professions more appealing career options (The Douglas Project, 2003). This template addresses how to interact with technology, and is more concerned with "attractiveness" and improving attitudes of girls toward the STEM subject by making the experience more enjoyable.

Given budgetary constraints of most schools, it is necessary to focus on Web site resources that are free of charge, and yet provide high quality materials. Therefore, some of the government-funded projects were considered as primary candidates for inclusion (AAUW, 2004; National Science Foundation, 2003). These sites will provide free or low cost materials, with associated government financial support to ensure continued access and maintenance.

Evaluation of CareerQuesting Resources

None of the three evaluation protocols reviewed actually would serve the purpose of this project as originally designed. The GSDL tool is perhaps the most useful, but it is overly detailed to facilitate curriculum development. The GirlsTech approach to "gender specific" criteria attempts to generalize "female" preferences in a categorical manner to enhance "enjoyment" or engagement but does not necessarily address the effectiveness of resources. In practice, the GirlsTech tool also failed to identify a substantial pool of resources that were more than "average" with respect to some of the key "female friendly" factors. Finally, the BEST template is the only one that strongly emphasizes programmatic effectiveness, and attempts to impose a strict definition of success (using rigorous investigative assessment of student outcomes). However, this approach fails to provide a sufficient pool of accessible (and affordable) materials, unlike the GSDL, for which one criterion of any resource selected for inclusion is that it be readily available via the Internet at no cost to users.

The literature review on gender-specific issues in career selection also identified four key elements that the chosen resources or activities should emphasize:

1. Career Information and Exploration — career specific information offered at a point

Table 1. Summary of CareerQuesting evaluation elements

<p>General Content and Media Criteria Pre-Screen</p> <p>Domain: Contains subject matter in the domains of natural sciences, pure or applied, mathematics, engineering, or technology.</p> <p>Grade level: Middle school students, appropriate for classroom use.</p> <p>Access/ Availability: Readily available, via the Internet, at no cost, with clear means of ongoing support and funding. Minimal use of advertising (may acknowledge corporate sponsors) Easy to use, clear directions and functionality, utilizes only content and tools available on the site or commonly available and accessible to the public.</p> <p>Functionality: Must meet minimum design and technical support criteria commonly expected of Websites and multimedia, including good page layout and navigational design.</p> <p>Final Evaluation elements</p> <p>Gender Equity Criteria *</p> <ol style="list-style-type: none"> 1. Pedagogical Criteria	20	-20												

Table 3. Web site and WebQuest scoring sheet

Resource: _____ URL: _____

Criteria	Description	SCORE
Gender Equity Criteria		
Gender equity/ Inclusivity	Content and activities suitable for both boys and girls. Resources should portray balanced images and content with respect to the participation of men and women, boys and girls in related activities, and be inclusive of other “underrepresented” groups.	
Programmatic goals for STEM diversity	No strict requirement for explicit gender equity focus, but the materials or Web sites should conform to best practices for engagement of student interest and building enthusiasm for understanding and application of STEM skills.	
Gender-Specific Criteria for Media and Software		
Career Information and/or “Real world” application	Content linked to inspirational content on related careers, specific career exploration component that addresses issues relevant to student interests, or which highlights the real-world applications of the technology or subject matter.	
Relevance/ Personal Identification	Web site should provide students with a chance to experiment and apply technology in ways that relate to their own interests or allow them to leverage additional talents and interests.	
Social Connectivity/ Collaboration	Will provide elements allowing for collaborative interactions between students, or can be integrated with other sources add opportunities for students working together.	
Contextuality	Content is provided along with background or history, supplemental information on application is provided. If this is not provided, within the site or resource, can the material be integrated with other content to frame and present the activity or experience?	
Pedagogical Criteria		
Technology use	Interactive content, increases student engagement with technology, development of fundamental technology use skills.	
Standards and credibility	Content will meet highest standards of scientific and technical credibility, and will be endorsed/produced by a reputable source.	
Versatile Use	Materials or tools allow for customization of the activity or applications Can be adapted or customized for use in different class setting or curriculum content.	
Flexibility	Preferences will be given to sites that provide a general purpose experience, where skills can be applied in a variety of other contexts, including general application of technology to problem solving, etc. Provide opportunity for students to exercise basic skills and processes creatively.	
Interdisciplinary	Preference will be given to technology related activities that integrate other STEM related content, including mathematics, physical sciences, and engineering.

- where the girls have not internalized a negative perception of STEM subjects
2. **Personal Identification and Relevance** — students may perceive that technology is not something that they need to learn more about because they have no personal need to do so. If they can find ways to use technology that benefit them directly in their daily lives, they are more motivated to learn and master the basic skills necessary to use it.
 3. **Real World Application and Context** — allowing girls to acquire basic technical skills or a knowledge base to enhance their sense of competence in STEM-related activities.
 4. **Social Interaction and Teamwork** — STEM or technology education should emphasize the potential for working with others to solve problems, including application of technology to further communication and social relations.

Together, these should provide a foundation for students to exercise their talents and creativity in a scientific or technical outlet, and find the experience to be both enjoyable and rewarding.

It is important to emphasize that each of these elements will also benefit all students, not just girls, providing an opportunity to encourage less technically inclined boys to develop these same competencies, and further broaden the pool of skilled workers in technology and related fields. Levine argues that the classroom must focus more on work-life readiness, giving students the tools they need to be productive and effective in their careers (Levine, 2005, pp. 10-11).

The emphasis of the *CareerQuesting* resources is upon providing the students with the learning experiences that will engage them in the process of career exploration and selection. Unlike resources explicitly targeted to girls, teachers and administrators have a clear and compelling motivation to provide students with this kind of career preparation experience.

The final section of the tool included a two-stage review, with a preliminary screen that focused on the key elements of accessibility and content suitable for general classroom use. Each of the resources identified was evaluated using the pre-screening questions. In particular, the Web sites should be easy to use without excessive adaptation of materials, available at no cost, and the materials should be appropriate for a diverse student population. A summary of the evaluation criteria appears in Table 1.

The highest possible pre-screen score is 22, with a preferred score of 15 or above. If an electronic resource met the pre-screening criteria, it was further evaluated. The resource must have met at least "Average" standards with respect to the listed criteria, with preference given to with highest scores. A template for evaluation of the *CareerQuesting* Web sites is presented in Table 2.

Web Sites and WebQuests

The search results were divided into two broad resource categories, Web sites and WebQuests. WebQuests are Web-based constructivist lesson formats that present a problem or series of tasks to be addressed by students using suggested Web-based resources for research (Dodge, 2005). If a site passed the initial pre-screening, it was subjected to the final review process using the Web site and WebQuest Scoring Sheet presented in Table 3.

The search results were divided into two broad resource categories, Web sites and WebQuests. The final selection of recommended resources proceeded to identify the "top 10." The rankings of those Web sites and WebQuests are shown in Table 4.

Best Overall Web Site

- **Kidz Online - Tech Training** (<http://www.kidzonline.org/TechTraining/>) — Best met the criteria specified. It includes extensive technical education resources on subjects ranging from animation to Web page creation. There are lesson plans for nearly every subject from English and Language Arts to Science and Technology Education. The materials are intended for students from 6th to 12th grade. Technology skills are highlighted in nearly every area.

Best Career Planning Web Sites

Three Web sites were chosen to provide alternatives for career exploration tools (these Web sites are explicitly devoted to career exploration or planning activities).

- **USA TODAY Education Career Quest** (<http://www.usatoday.com/educate/careers/>)

CareerQuesting

careers.htm)—A general career exploration resource.

- **Career Voyages – Welcome** (<http://www.usatoday.com/educate/careertech/index.html>) — Contains valuable content, but may be more suitable for slightly older students.
- **Projects CyberCareers Home** (<http://www.nwcet.org/projects/cybercareers/default.asp>) — A general career exploration resource.

Best Technical Sites

Three Web sites were chosen as the best sources of in-class technical assignments to foster interest in STEM subject matter. These Web sites are primarily considered as resources for technical assignments and application of technology, building of technical skills, but in some cases included elements of career exploration as well.

- **Ohio Math Works** (<http://www.ohiomathworks.org/>) — A high-quality resource focusing on development of quantitative skills and real-world application of mathematics, with elements of career exploration.
- **GM - GMability Education 5-8** (<http://www.ohiomathworks.org/>) — Emphasizes technical subjects and engineering related careers.
- **Welcome to NASA Quest!** (<http://quest.arc.nasa.gov/index.html>) — Significant classroom and educational resource support.

Best General Education Resources

Three Web sites were chosen as general-purpose Web sites for teachers to find lesson plans or ideas for class assignments. These sites have interac-

tive content or game-like activities for students. Resources focus on more involved, longer-term activities.

- **Lemelson Center Presents Invention at Play** (<http://inventionatplay.org/>)—Focuses on creativity and having fun with technology and basic science or engineering skills.
- **GetTech.org (also Getsmarter.org Home)** (<http://www.getsmarter.org/index.cfm>) — Provides online game-like activities, along with tutorial or quiz-applications.
- **Welcome to eCYBERMISSION** (<http://www.ecybermission.com/index.cfm>) — A resource for a team-competition activity with more than average involvement and lesson plan development. Other competitions often focus on “math drills” or robot building, or similar activities that are either more like trivia contests or are somewhat remote from daily life. Projects focus on “working to solve problems in your community.” Also, the competition is directed toward for teams of 6th to 9th grade students, making it more likely that students will find the projects more interesting and relevant.

WebQuests were the subject of a separate search and evaluation process, to find specific examples that embody key elements of the *CareerQuesting* functionality. Since these are designed by teachers for their own use, they provide a very flexible resource for classroom use.

Best for Career Exploration

Each of the following is a well-developed career exploration activity. The FutureQuest activity includes a group task to allow for student collaboration on the project. There are links to several good interactive resources for career interest testing and assessment as well:

- **Who Am I? Career WebQuest** (<http://home.sullivan.k12.il.us/teachers/lawson/webcareers.htm>)
- **Martin Willams's Career WebQuest** (<http://home.sullivan.k12.il.us/teachers/lawson/webcareers.htm>)
- **FutureQuest** (<http://www.pvpusd.k12.ca.us/teachweb/twidwell/FutureQuest.html>)

Best for Technical Skills

Each of the following WebQuests focuses on assignments to learn Web page construction skills or use of the Internet for research.

- **Cyber Science Mag** (<http://projects.edtech.sandi.net/kearny/cybermag/index.html>) — Suitable for use in general English/composition courses and journalism, or as part of science and technical education classes.
- **NetForce** (http://www.geocities.com/lukasaurus_smith/) — Group assignment structure makes this useful for teamwork and collaboration activities.
- **Dr. B's Internet Research Guide: Atlantis Quest** (<http://drb.lifestreamcenter.net/Lessons/Atlantis/index.htm>) — Group assignment structure makes this useful for teamwork and collaboration activities.

RECOMMENDATIONS AND CONCLUSIONS

The purpose of this paper was to identify criteria for use by teachers in evaluating Web site resources with potential for increasing interest and persistence of middle school girls in STEM fields. The tool is not intended to be understood as a model of psychometric rigor. Rather, it offers a framework for evaluation based on the research literature, and can be modified and weighted according to classroom need. In particular, the tool

was used to identify general-purpose materials that might appeal to both boys and girls, allowing teachers to adopt them without concerns that they are providing an unfair advantage to girls.

Resource selection should be validated using an independent review process to establish quality standards for all resources. It may be necessary to make some modification of the tool, since in finalizing the list of Web sites for inclusion as recommended resources, it was apparent that the final selection process remained difficult. This was especially true in the decisions as to whether or not a particular Web site met the requirement that a resource be from a reputable source with evident means of funding or support. It is possible to argue that some of the resources selected as recommended resources did not fully meet this standard.

This was particularly the case with government and non-profit sources. Generally, both met the reputation requirement but the funding element was difficult to evaluate. Most of the non-profits, such as universities, were dependent on money from federal grants. Some of the resources selected were part of government initiated educational reform, and thus were subject to policy changes that would eliminate a particular program or Web site. For corporate resources, funding was not seen as an issue, but corporate outreach and community involvement policies could shift dramatically, and a particular Web site might be eliminated.

It is important that the *CareerQuesting* resources be established as effective in encouraging girls and boys to identify and seriously consider challenging, rewarding, and enjoyable career opportunities in technical fields. To that end, the outcomes of using each of the selected resources in the classroom should be systematically evaluated. The goal is to prepare students for what Levine (2005) terms “work-life readiness”:

A sizable hunk of a child's success is measured by her ability to comply, to learn what she is expected to learn, and to do what she's told to do. An adult

must be able to chart her own road maps. *The odyssey leading into adulthood can be a lonely and harsh voyage, especially if a startup adult is naive and uninformed, if he's never learned to be a mapmaker.* (Levine, 2005, p. 10)

While the resources do focus on attracting girls to technical or STEM subjects, career exploration remains as the central concern. The intent of the *CareerQuesting* model is that students will be taught to be “mapmakers” as part of the regular curriculum. A quest usually refers to a long journey of discovery and learning, with a person seeking an important goal or treasure at the end. Students need a map for this inevitable “career” quest each must embark upon. They need to know how to make such a map, and how to use the map. The goal of evaluating Web sites is to provide teachers with better access to some of the best tools and resources to help create a generation of mapmakers that includes girls as well as boys.

Chapter 5.40

Feeling Welcome: Internet Tourism Marketing Across Cultures

Wolfgang George Arlt
University of Applied Sciences, Germany

ABSTRACT

If used in a proper way, the Internet can be a powerful cross-cultural incoming tourism communication tool. This chapter examines to what extent the opportunities are utilized which are offered in the virtual sphere to extend across physical and cultural distances a welcoming hand to potential visitors from far-away source markets. The discussion is based on the results of a study about the non-german language Web sites of Central European DMOs, conducted in 2002 and updated in 2006, and the results of a study of German-language Web sites of non-European NTOs and DMOs, conducted in 2005. It can be shown that an increase in multilingual Web sites within the period under review can be

recognized, but that an increase in cross-cultural awareness of the providers of such Web sites is still lacking.

INTRODUCTION

“Tourism destinations are probably one of the most difficult “products” to market, involving large numbers of stakeholders and a brand image over which a destination marketing manager typically has very little control.” (Palmer, 2004, p. 128) In the 21st century, both the expectations as well as the actual experiences are informed by all kind of communication received via media beforehand and by interpretation through different kinds of “cultural mediators” (Ooi, 2002), which influ-

ence and shape the “tourists gaze” (Urry, 2002), especially in international tourism.

These complex processes are only accessible for the tourism industry in a very limited way, as images are not simply the result of promotions put forward by companies or destinations (Goodall & Ashworth, 1988). The brand image for example of Arab countries for European tourists can be traced back to the Orientalism (Said, 1978) fortified by Flaubert and French painters like Delacroix, Decamps, and Fromentin (Lemaire, 2000). The way these countries are portrayed in the news in a situation of increased fears of terrorism also will influence the image. Peer-group information and the travellers own experiences play an often even more important role here, forming the image according to the descriptions by friends and colleagues who have actually been there and on the background of own former visits to foreign countries.

Nevertheless, some degree of influence of the brand building based on “image” by the responsible destination marketing organization is possible and in fact an important part of the marketing strategy for a given destination (Chon, 1991). This influence is growing with the “otherness” of the destination (Bieger, 2002). The degree of otherness is perceived in the same way as distances are perceived in tourism—not in kilometres, but in accessibility, including accessibility in a cultural and lingual sense. The less well-known, the more exotic a destination is, the greater the chance to influence the image through tourism marketing activities. One important tool for such long-range marketing activities in the 21st century is undoubtedly the Internet.

If used in a proper way, the Internet can be a powerful cross-cultural incoming tourism communication tool. This chapter examines to what extent the opportunities are utilized which are offered in the virtual sphere to extend across physical and cultural distances a welcoming hand to potential visitors from far-away source markets. The discussion is based on the results

of a study about the non-german language Web sites of Central European destination marketing organizations (DMOs), conducted in 2002 and updated in 2006, and the results of a study of German-language Web sites of non-European national tourism organizations (NTOs) and DMOs, conducted in 2005. It will be found that an increase in multilingual Web sites within the period under review can be recognized, but that an increase in cross-cultural awareness of the providers of such Web sites is still lacking.

TOURISM AND INTERNET MARKETING

Within a single decade, the Internet has developed from an obscure network for scientists into an indispensable daily tool for about 16% of the world population. The number of Internet users, doubling from approximately 500 million in 2001 (Globalreach, 2005), to more than a billion in 2005 (Internet World Statistics, 2006), has surpassed the number of international travels, which grew from 684 million to 808 million border-crossings in the same period (WTO, 2006).

Not counting the 2% of Internet users both in Africa and in Oceania, roughly one third each of the global Internet users are located in the USA, in Asia and in the Europe respectively. In 2000, English was still the mother tongue of 50% of all Internet users. By 2006, the user community can be divided by languages into three almost equal parts, having English, another European or an Asian language as their respective mother tongues. Comparing the situation in 2001 and in 2006, English lost ground dramatically especially to Chinese and to “smaller” languages, documenting the fact that the Internet has outgrown its mainly North American beginnings.

Travel and tourism is one of the major fields of Internet usage. In terms of sales, tourism products like air tickets, hotel rooms and last-minute packages for domestic and short-haul tourism are

Feeling Welcome

the most common products sold via the Internet except books. Here the Internet's main function is to act as a booking machine. In 2002 online travel sales reached US\$27 billion in the North American and 8 billion € in the European mar-

ket, capturing 14% and 5% of the total market respectively (Marcussen, 2003). For 2005, the European market expanded to 25 billion € (10%) (Marcussen, 2006). The total value of online travel sales worldwide reached US\$49 billion

Table 1. World Internet users by mother tongue 2001-2006 in % (Sources: September 2001 data: GlobalReach, 2001; November 2004 and March 2006 data: Internet World Statistics, 2006)

Language	2001	2004	2006
English	43	35	31
Spanish	7	7	8
German	7	7	6
Italian	4	4	3
French	3	5	4
Portuguese	3	3	3
Dutch	2	2	2
Chinese	9	13	13
Japanese	9	8	9
Korean	4	4	3
Others	9	12	18
Total users	505 million	801 million	1022 million

Figure 1. World Internet users by mother tongue 2001-2006 in % (Sources: September 2001 data: GlobalReach, 2001; November 2004 and March 2006 data: Internet World Statistics, 2006)

in 2005 and climbed further to US\$65 billion in 2005 (eMarketer, 2005), not the least fuelled by no-frill airline ticket sales.

Internet marketing has, as has been recognized by the industry, a number of advantages against other media:

- Reduced costs compared to advertisement and promotional activities
- Easier to update than brochures and pamphlets
- Easier and cheaper to handle compared to telephone hotlines
- 24-hour availability of information (Douglas & Mills, 2004; Mills & Morrison, 2002)

For Incoming tourism, especially for long-haul leisure travel, the dominant usage and the main advantage of Internet Web sites is quite different. Decision-making for travel requires qualified information and confidence, making the Internet first of all an image-building tool, important to help deciding whether to go to a specific new destination, to stay for a shorter or longer period, or to use specific services of a company at the destination. Incoming tourists, especially when not travelling to neighbouring countries, are by necessity less spontaneous. Perceived images will therefore play a more important role in their decision for or against travelling to certain destinations or using certain services, whereas online booking will be less relevant in a situation of unfamiliarity with the destination.

New incoming tourists are not easy to target. Established, major markets can be reached via sending information to known customers, by traditional public relations work, fair attendance, advertisements, and so on. These measures are however costly, time- and effort consuming and typically do not reach minor—or underestimated—markets. Potential visitors from new source markets can be more easily targeted by a dedicated Web site, which can be found by the customer wherever he or she lives. No other medium can

beat the Internet as the cheapest, most convenient and most efficient way to address these potential customers in distant countries, belonging to different cultures.

What culture and cultural differences mean, especially for tourism, is a topic of hot debate (Reisinger & Turner, 2003; Trompenaars & Hampden-Turner, 1998). Hofstede (2001) defines culture as “collective programming of the mind which distinguishes the members of one group or category of people from those of another” (p. 9). and, according to Paul A. Herbig, “over 450 definitions of the word culture exist” (Herbig, 1998, p. 11). However, this is not the place to enter the “relevance of culture” debate, as at least the existence of cultural differences is not disputed in the tourism literature.

A differentiation of the classical “guest-host” interrelation scheme (Smith, 1989) should be introduced here. Marion Thiem (1994) developed the thinking tool of four different tourism cultures. Extending the well-known distinction of Goffman (1959) of the front stage and the backstage of a destination, she points out the difference between the daily-life cultures of the travellers home region and the specific culture of travellers away from home, which differs considerably from the daily-life culture in factual behaviour as in self-perception. Similarly the inhabitant of the destination also has a daily-life culture as well as another culture which is the one shown to the tourists purposely, being it as a “genuine fake” (Brown, 1996) or a “mediated authenticity” (Ooi, 2002). The form of this presented culture might also be different for different target markets.

For cross-culture tourism marketing—online as well as offline—this communicated culture has to be adapted to each source market culture accordingly, stressing common points or explaining local culture in terms which relate to the source culture and are therefore easier to understand and probably more sympathetic to the receiver. In international business the seller is expected to adapt to the buyer, this is the “Iron Rule #1” for

Feeling Welcome

cross-culture marketing, according to Gesteland (2002, p. 15).

For the cross-culture Internet marketing of destinations and attractions this author proposed in an earlier study an expansion of this “Iron Rule” to three “Golden Rules,” namely that the potential customer/visitor has to be able to:

- **Find the online information**
- **Understand the online information**
- **Feel comfortable about the way it is presented** (Arlt, 2005)

The technical problem of finding has become smaller with the availability of better global search engines. Still a domain address which is neither a .com-address nor a top-level domain of the targeted market (for instance .de, .at., .ch in the case of German-speaking customers) and/or a non-intuitive address like “www.aspureasitsgets.com” or “www.fac.de” will make it harder for the user to locate the Web site. Keywords in the language of the target markets and links from other, local Web sites will enhance the visibility of the Web site.

Understanding starts with language. As stated above, only a third of all Internet users share a common mother tongue, English, even though many Internet users are able to understand English to different degrees. However, information given on a Web site conveys not just the facts, it also shows respect and attention paid to the speakers of other languages—or the lack of it. To make visitors feel welcome, to make them feel that “they thought about me,” providing information in the mother tongue of the visitors will make a huge difference in supporting a positive bonding beyond the mere availability of useful facts. According to Forrester Research, Web site visitors stay twice as long on a local language Web site compared to an English Web site (De Palma, 1998). “Even customers who speak English prefer sites that offer their local language as well as local product selections, relevant payment options, and

localized versions of customer service” (Torris, 1999). Toru (1998) and Auh (1998) underline the importance of multilingual sites for Japan and Korea. Kralisch and Mandl (2006) point out that even for bilingual speakers of a ‘smaller’ language “the use of their native tongue can represent an additional service that discriminates a product from others by enhancing its value/perception” (p. 2). This statement is supported by their research which shows clear preferences by users for native language Web sites if given a choice.

Besides the question of the usage of different languages, would-be visitors from afar will in many cases request information that is much too obvious for local users to be mentioned. Few Chinese will need to be informed about the fact that the shops are open seven days a week in China; for a German this might be a useful reminder helping to shape their travel plans. Illustrations and webcams can provide additional useful non-verbal information, providing information like the dressing style of the locals, architectural features, daily life behaviour etc. which will elude the attention of members of the local culture but provide useful insights for viewers with different cultural backgrounds.

To make potential visitors feel comfortable is the most complicated but also most rewarding part of cross-culture internet marketing. To provide the address of a German-speaking dentist for potential German visitors may need a bit of extra research, but to provide this information will put to rest one of the many worries of potential German visitors to an overseas destination and will help to turn anxiety into pleasant anticipation. Colours and symbols have different meanings in different cultures. Web sites overflowing with colours and moving graphic objects may look interesting and cute to some visitors but confusing, kitschy or even offending (Becker, 2002) to others. An Asian Web site which uses colours perceived as “typical Caribbean” will mystify the European Web site visitor. The expected carriers of trustworthy information will vary—they will have to

be “authorities” for visitors from more hierarchical orientated societies and peer group members for individualistically moulded visitors.

“You cannot not communicate, especially across cultures,” Paul Watzlawick stated 40 years ago (Watzlawick, Beavin, & Jackson, 1967). While such a comment probably overstates the communication problem, destination Web sites that obviously do not care about foreign, especially non-English speaking tourists by not providing useful information, or providing static or outdated pages for them are in danger of sending a signal to such potential visitors that suggests: “You are not welcome here.”

MEASURING THE CROSS-CULTURAL SERVICE QUALITY OF TOURISM WEB SITES

Many tourism sites, especially of NTOs and DMOs, cannot use online sales as a measurement, as they typically do generate little or no revenue of their own (Tierney, 2000). Nevertheless, the evaluation of the effectiveness of their Web sites is needed to learn about the relation between cost and effect, to facilitate continuous improvements and to compare the performance of the site with its competitors and industry peers (Morrison, Taylor, & Douglas, 2004).

Studies on Web site evaluation have been conducted for a decade with the emergence of agreed methods for Web site evaluation. Murphy, Forrest, Wotring, and Bryner (1996); Murphy, Forrest, and Wotring (1996); and Kasavana, Knutson, and Polonowski (1997) can be counted among the pioneers of Web site evaluation, concentrating on hotels and restaurants. Among the first evaluations for tourism Web sites are the studies of Hanna and Millar (1997) and of Cano and Prentice (1998). A list of major Web site evaluation studies is provided in Morrison et al. (2004, p. 241). All these studies rely on different forms of content analysis with

different features and characteristics evaluated, mostly executed by just one expert.

With a few exceptions (e.g., Donthu, & Yoo, 1998; Furrer, Liu, & Sudharshan, 2000; Okazaki, 2004; Tsiriktsis, 2002), most surveys have given little attention to the special requirements of Web sites crossing linguistic and—more importantly—cultural borders. However, Sigala and Sakellariadis (2004) have tried to use Hofstede’s cultural dimensions to developed global rules for culturally aware Web site design. Schegg, Steiner, Frey, and Murphy (2002) include language use as part of a “value-added service” within their five dimensions, the other four being service processes, customer relationships, creating trust and cybermarketing. Douglas and Mills (2004) mention “glocalisation” and the need “... to communicate in the language of the visitor thus opening the international gateway to the local products and services.” (p. 277). The appeal that “the results of studies focusing on the cross-cultural differences in online search behavior ... should be incorporated into Web site designing process to capture every cultural market segment since the Internet targets are worldwide” (Jang, 2004, p. 45) is seldom translated into criteria for Web site evaluation. Even so, implicit cultural values are part of any evaluation when for instance “uncluttered” Web pages are seen as an asset of any Web site regardless of the targeted audience (Morrison et al., 2004, p. 250).

THE PRESENT RESEARCH: RESULTS OF TWO STUDIES

The two studies presented here are based on earlier research of the author in cross-culture Internet marketing, starting originally outside the field of tourism. Through a series of studies on cross-culture Internet marketing in tourism, for instance about the multilingual and multicultural content of the regional British Tourist Board Visitor Web

Feeling Welcome

sites, eight groups of criteria were developed and refined, taking into account different research approaches found in the literature (Arlt, 2001, 2002a, 2000b, 2003, 2005).

Points were given for 65 weighted criteria under the headings of “accessibility,” “languages,” “technical quality,” “design quality,” “international content,” “target group specific content,” “topicality,” and “interactivity.”

Visibility, technical quality, design quality and target group specific content made up the first cluster, each evaluated with a maximum of 100 achievable points awarded. The other four criteria, that is, language, specific content, topicality and interactivity were awarded a 50% higher weighting, as these aspects have been found in earlier studies to be especially responsible for the evaluation of the usage of the opportunities of virtual cross-cultural communication. Each criterion was evaluated with a maximum of 150 achievable points. Altogether a maximum of 1,000 points could be achieved.

Even though the main topic of the research was cross-cultural marketing, visibility, technical, and design quality were included as “[i]t seems imperative that any holistic Web site evaluation approach must have at its foundation an assessment of the technical details of the site design. Insufficient attention to site design and search engine positioning greatly reduce the value of good content and sound marketing.” (Morrison et al., 2004, p. 246)

For each criterion 80% of all possible points (80 and 120 points respectively) were awarded according to five to eight sub-criteria each (see Appendix A). The other 20% of each criterion were awarded for special outstanding offers, making it possible to award single achievements not included in the sub-criteria. For each sub-criterion the full points or a fraction could be awarded.

The first study using the methods described above was conducted in March 2002, with an update done in April 2006. It analysed the internationality of the official tourism Web sites of

60 DMOs in Germany, Austria and the German-speaking part of Switzerland. The selection was done in the following way: For Germany, the 30 cities and communities with the highest numbers of foreign overnight stays according to the German national statistics (Statistisches Bundesamt, 2001) were selected, provided that they offered any foreign language content on their tourism Web sites. Accordingly, twelve destinations could not be evaluated, including three out of the dozen of most foreign-visited destinations (Düsseldorf, Medebach, and Gunderath), and destinations down to the No. 43 on the list, Boppard, entered the evaluation process. Similarly, for Austria the 15 communities with the highest number of foreign overnight stays were selected according to the national statistics (Statistik Austria, 2002). In Austria only one destination (Mittelberg) had to be dropped because it did not offer any foreign language content. For Switzerland, only destinations in the German-speaking part of the Swiss Confederation were used, excluding ski resorts like St. Moritz and Klosters and cities like Berne and Geneva. As no ranking for foreign overnight stays is provided, all destinations being named on www.myswitzerland.com as important international destinations were chosen, provided that they had more than 20,000 inhabitants, were located in the German speaking Cantons of Switzerland and offered foreign language content. Many of these destinations failed on the last criterion, offering content only in German even though they are visited by many Swiss and foreign guests speaking other languages. In the end, 15 destinations could be evaluated for German-speaking Switzerland.

The Austrian capital Vienna emerged as overall winner and the only destination that reached very good marks (890/1000) in this study. Five other destinations could claim a good result with more than two thirds of the points available, namely Zurich, Saalbach-Hinterglemm, Berlin, Innsbruck, and Sölden. Four out of the six best Web sites were provided by Austrian communities,

whereas in Germany and Switzerland only the respective biggest city could achieve a satisfactory score. Three Swiss, five Austrian, and 11 German destinations were awarded more than half of the maximum number of points, nine other destinations achieving more than 400 points and a “passed” mark.

No less than 26 mainly German and Swiss destinations, almost half of all Web sites evaluated, failed to reach even 40% of the possible points and must be regarded as providing a rather negative brand image to non-German speaking potential visitors (for the list of all 60 cities see Appendix B).

The main problems could be summarized as follows:

- Many important destinations did not provide any non-German content at all, ignoring the information needs of the 98% of mankind not speaking German.
- Foreign language content was offered in most cases in English only. Online content in other languages was rare, even when printed information was available in other languages.
- Almost all Web sites showed a lack of consistency. Positive or original solutions in one part contrasted with erroneous or lacking offers in other parts. Coincidence or arbitrariness played a big role: for example, links often led to German language content without warning or explanation.
- The major advantages of Internet communication, topicality and interactivity were seldom used. Especially information about upcoming events, which is less easy to find for potential visitors in other countries, was not translated. Foreign language content was often outdated, even when the German content was up-to-date.
- Very rarely non-German pages of the Web sites evaluated used interactive elements like newsletters, guestbooks, or instantly downloadable information. The opportunities to get information about the visitors to the Web site were almost totally ignored, as were the chances to get in contact with foreign media or travel company representatives in international source markets. Offering pictorial current information by using webcams to show daily life in a destination in real-time was seldom used.
- A check of the quality of the foreign language content at regular intervals is obviously almost never done. Broken links and very outdated information were found much more often on the non-German than on the German content pages.
- An adaptation to special source markets and their interest and culture was seldom found. Special navigation, different colours, additional content, and so on were lacking. Information was not offered with a customer orientation. For example maps showing the location of the destination within Europe, information about foreign language church services, addresses of mosques, and so on were almost never provided. Target-group specific content proved to be the least developed part, with just eleven out of the 60 evaluated Web sites reaching more than half of the total points awarded.
- The fact that tourism and holidays should be connected to fun and happiness was communicated only by some of the Austrian Web sites. On the German and Swiss-German pages old buildings instead of smiling visitors, art historians lectures instead of specific ambience and complicated feedback forms instead of photographs of the contact person clearly dominated.
- Especially negative impressions were given by English-language parts of Web sites which seemed to have been abandoned long ago. In addition, some DMOs openly refused to send out information material to addresses outside the home country. Visitors

Feeling Welcome

were further angered on many Web sites by sentences like “For more information please consult the German pages” or very bad translations obviously done by a non-native speaker.

After four years, the Web sites were revisited. Out of the top 10 Web sites of 2002, Vienna still remained clearly the best international DMO Web site in German-speaking Europe, with now 14 languages and adapted content for most of them. The second-placed Zurich still offers a technically excellent Web site, however with only English content and little interactivity. Saalbach-Hinterglemm, Sölden, and Lech kept their lively style, by creating the infrastructure for a foreign language community, by taking care to provide foreign language texts also for webcam explanations, and so on. Berlin and Bremen now offer 10 languages each, with special content added especially for the FIFA World Cup 2006, whereas Innsbruck and Baden-Baden in April 2006 still included content on their Web sites about the possibility to visit the Christmas markets of 2005. Trier offered an up-to-date international Web site with different content versions for different target groups, putting for example information about the Karl Marx museum on the Chinese language homepage only. Leipzig, the number 11 of the 2002 study as best East German city also added content for the FIFA World Cup 2006 and even provides as a rare treat links to the homepages of its sister cities.

Out of the four German and Austrian cities among the top 12 international destinations, which did not provide any foreign language content on their Web sites in 2002, only Düsseldorf had improved its offer by 2006. However, even though Düsseldorf is still the no. 6 of the international destinations in Germany, only a partial English Web site is offered. Current events are still only provided in German and some links, leading for instance to the important Caravaggio exhibition to be held later in 2006, are not working.

The bottom 10 destinations of 2002 continued to show many shortcomings. Bonn still expected visitors to understand “*Zur englischen Startseite*” (to the English homepage) as the description of the button to click to get to some English—non-current—content. St. Gallen, Schaffhausen, Rudesheim, Solothurn, and Brunnen showed no improvement with information up to two years old and no information on events in foreign languages. “If you understand a little German you might find some useful information on our site” the Schaffhausen site states rather frankly.

Neustift provides information in seven languages but on a Web site done in a rather amateurish way. Real improvements were shown only by the two big German city Web sites of Frankfurt and Köln. Both include more languages now, Köln even offers a Chinese-German language guide and multi-language news provided by Deutsche Welle (German International Radio). However, both Web sites showed still a limited interactivity, a confusing embedding of international into German content (Köln) and a German sense of humour (Frankfurt): “Please note that we only offer this service (events calendar) in German due to the large amount of topical information available.”

To summarise, after four years more languages are used, but almost no improvement in intercultural skills are displayed. The big German cities are getting a push from the FIFA World Cup 2006. Some small destinations keep their advantage in international customer orientation, many others still do not give much thought to their international visitors and provide English language content only out of a sense of duty but without any enthusiasm or professionalism or even insight into the gains that can result from it.

For the second study presented here, which was conducted in August/September 2005, the opposite approach was used. This time German-speaking tourists were chosen as the target group to answer the question: how are non-European destinations using targeted Web sites to lure Ger-

man-speaking tourists to their shores? The choice of German was based—besides the background of the researcher—on the fact that German-speaking people are both prolific Internet users and ardent international travellers.

In the three mainly German-speaking countries Germany, Austria and Switzerland, Internet usage is above 55%, resulting in 62 million Internet users, representing almost 7% of the world Internet population against the fact that only 2% of the world population speaks German (Globalreach, 2005). At the same time, German-speaking tourists are responsible for no less than 15% of all international tourism expenditure. Germany, as the number one tourism spending nation in 2004 was the source of US\$71 billion tourism spending outside Germany. Austrian and Swiss travellers added another 11 and US\$9 billion respectively in their international spending (UNWTO, 2006). If segmented by languages, German-speaking tourists with US\$91 billion expenditures represent by far the biggest purchasing power in international tourism after tourists from English-speaking countries. Even if taking into consideration that about 80% of the German-speaking outbound travellers stay within Europe, US\$18 billion for the remaining 20% inter-continental travellers still represent an out-of-continent tourism purchasing power equalled only by US citizens.

The culture of German-speaking people can briefly be described in Hofstede terms as showing very high uncertainty avoidance levels, very low power distance levels, medium high individuality and masculinity levels, and rather short-term orientation. This results, speaking very generally, in a pronounced interest in planning on the basis of clear and extensive information, the wish to find out by themselves rather following advice, to see “behind the curtain,” and a rather high wish for security as well as education. These characteristics are more pronounced in long-haul leisure tourists who tend to be better educated and/or older than the average German-speaking traveller (Hofstede, 2001).

For the 2005 study, 500 Web sites of NTOs and DMOs of national and regional destinations as well as important cities and well-known attractions, relevant for German outbound tourism, were visited. The destinations and attractions were selected by using statistics from the German National Tourism Board and through analysis of major German tour operators’ catalogues. To mirror the search behaviour of German tourists, only Web sites recognisable as the “official” Web sites of the destinations and attractions were considered, not Web sites of third parties or private partner companies in Central Europe. Geographically all areas outside Europe were considered, including the Americas, Asia, Africa and Oceania. As the whole world minus Europe was taken as the chosen research area, obviously no comprehensive study was possible. The 500 Web sites chosen do, however, reflect an important part of the information interests of German-speaking intercontinental tourists.

The content analysis of the Web sites was conducted in two steps. In a first step, all Web sites were checked for possible German-language content. A minimum of two pages German-language content was set as a minimum level, to eliminate Web sites that offer no more than a few welcoming sentences. Out of the total sample, 50 Web sites could be identified which offer more than one page of German-language content. In a second step, the remaining 50 Web sites were analysed twice by a group of students of the University of Applied Sciences in Stralsund and by the author in August/September 2005, using a standardized evaluation form. Results were compared and discussed in a panel meeting.

The study revealed again a widespread disregard of cross-culture Internet marketing. Many major non-European tourist destination and almost all major non-European tourist attractions do not have any German-language content at all. Within the 50 analysed Web sites with German-language content, practically all major mistakes possible in cross-cultural Internet marketing could be found.

Feeling Welcome

Accordingly even the Web site with the most favourable evaluation for its German-language content, www.australia.com, could secure only 67% of the maximal points possible. Only seven Web sites returned results above 60% of the possible points, with another 13 above 50%. 30 out of 50 Web sites (60%) did not reach half of the achievable points, risking to rather annoy visitors to the Web site than to inspire them to visit their destination or attraction (all results can be found in Appendix C).

The strengths of the Web site could be found mainly in those criteria that are relatively independent from cultural differences: visibility, technical quality and overall design quality. The weaknesses were found in the core cross-culture criteria, showing a lack of knowledge of and/or a disregard in cross-cultural Internet marketing.

Some common mistakes and omissions, ordered according to the criteria evaluated are as follows:

- **Visibility:** Without an intuitive and/or local URL, German language metatags and extensive linkage, many Web sites failed to show up in Google.de or Google.com searches. Offers to bookmark the Web site or to list the page as the user's homepage were almost never made.
- **Language:** Many Web sites were done by professional agencies, using native German speakers as translators. Some however obviously used their own personnel to create rather funny, if unassuring texts. Only the top performers offered all information in translation, most giving only a partial translation, often with German-labelled links, which lead without warning to pages in English or other languages. Opportunities to create bonding and empathy by comparing proverbs in German and in the local language, relating descriptions of sights to German fairy tales, poems, and so on were not used at all.
- **Technical quality:** Technically most Web sites were of a quite good standard. Even so, sitemaps were often missing and search functions frequently not working. Generally speaking, functionality is the area with the least problems, here the Web agencies producing the Web sites have their core competence.
- **Design quality:** Most Web sites had a professional-looking design. However, a customization towards preferences of different user groups was nowhere to be found. For German preferences many Web sites appear to be too overloaded with information, not well enough ordered in the presentation of the information and simply too kitschy. The top performers offered not only automatic language recognition but also a function to change to other languages, important for German speaking users entering the Internet from a computer whilst already in the destination or in a third country.
- **Specific content:** Specific content is the area where most omissions were found. Information was generally simply translated without taking into account the target group's specific interests. Frequently information, which is self-evident for locals, was not provided for visitors who may not have known about it. Specifically, access information and maps showing the location within the greater region were often missing, as were webcams. More specifically, information about German language services in the country, from guided tours to bakeries to doctors to libraries with German newspapers was almost never provided. Such information is not only of factual value—indeed many such facts are only needed after arrival—but also serve to reassure visitors that such services are available when they are needed. The German obsession with planning and predictability is not catered for.

- **Target group specific content:** One of the strengths of Internet information provision is the possibility to include many extra areas for special interest. A certain amount of information was provided by most Web sites on outdoor activities and local food. However, information for business travellers or students looking for internships, press releases, and so on was seldom to be found. Many countries or cities have twinning or other spartnership arrangements with German localities. Sometimes also associations of destination-born persons now living in Germany exist. These existing connections could be used to support the arising bonding possibilities; however, this opportunity is missed in most cases.
- **Topicality:** The second-most important difference between a guidebook and a Web site is the possibility to include up-to-date information on the Web site. Potential visitors can be guided towards specific events, festivals, and so on which might strengthen their decision to travel to the destination or to stay longer than otherwise planned. As many long-haul travellers have fixed return-date flights, such information needs to be communicated well before departure to the destination. Web sites which do not show the date of the last update, sometimes giving an event for “November” without mentioning the year, can annoy visitors. Some Web sites had German-language versions that seemed to be never updated, showing event calendars several years old.
- **Interactivity:** The most important difference between a guidebook and a Web site is the possibility to interact with the visitors and potential customers. Brochures can be offered as .pdf-files for instant download, newsletters give the opportunity to communicate on a regular base, ePostcards help

to spread the URL of the Web site, games give reasons for repeat-visits to the Web site. Providing the opportunity for users who have already been to the destination to put peer information on the Web site themselves, to report about their best experiences, or to upload their favoured snapshots, are readily used when offered. Likewise a “matching tool” to find potential fellow travellers, peer-group ratings for specific services and attractions or links to customers’ blogs make all the difference between “advertisement” and real information, especially for users from Hofstedian low power-distance societies like Germany, Austria or Switzerland. Unfortunately, in the field of interactivity only very few of the analyzed Web sites showed any creativity.

CONCLUSION

The results of the two studies discussed here show the prevailing problems of adequate use of the Internet as a communication and marketing tool for inbound tourism. Most German, Austrian and Swiss-German DMOs are offering no more than a slimmed English version of their Web sites without the crucial elements of topicality and interactivity. Likewise, designers of non-European Web sites for German-language speaking potential customers fail to understand the importance of communicating to the customer and potential visitor in his or her own language, in his own way and style, taking into account specific interests and characteristics. The importance of facilitating communication with and among customers from a specific culture in their own terms is still clearly underestimated, even though this could be used as a crucial brand image building tool. As a result even most of the Web sites that are providing German language content are technically working well but fail to transfer a positive specific image

to such a large and affluent source market as the German-speaking countries.

Effective Internet communication across cultures is about much more than having a static Web site with some pages translated word by word into another language or simply betting on the language abilities and cultural adaptability of potential visitors. To improve the communication quality is not mainly a financial question but rather a question of customer orientation. By allowing customers to voice their wishes and ideas about the style and content of the Web site both online and while they are staying in the destination can provide the customers' point of view needed to customize the Web site successfully.

Cross-cultural Internet tourism marketing is a powerful instrument to support inbound tourism. In 2006, NTOs and DMOs spend more time and money on providing multi-language static information on their Web sites than they did a few years earlier, but the missing topicality, interactivity and content customization that often occurs is however endangering the positive brand image building effect for potential visitors with different cultural backgrounds. More efforts are needed to convey the message that visitors from all source market can feel truly welcome.

APPENDIX A: CRITERIA AND SUB-CRITERIA WITH MAXIMUM ACHIEVABLE POINTS

1. Visibility	100
URL intuitive	10
Links to other Web sites	10
Recognizable as official page	10
Google.de Rank 1-20 („x Tourismus“)	10
In Google.de under URL-Name	10
.de/at/ch address	10
Metatags in source code	10
Metatags in German	10
Special Visibility (e.g., bookmarking)	20

2. Language	150
Level of German translation quality	30
Additional other language 1	10
Additional other language 2	10
Additional other language 3+	10
German version easy to find	10
German version full translation	10
First page German	10
Quality of German language used	30
Special Language (e.g., proverbs)	30

3. Technical quality	100
Loading time short	20
Screen size optimized	10
Functioning Sitemap	10
No special browser needed	10
Functioning Search function	10
Functioning Quickfind/Shortcut	10
Functioning Flash w/ Skip function	10
Special technical quality (e.g., downloads for software)	20

continued on following page

4. Design quality	100
Design quality according to German taste and expectations	30
Navigation simple	15
Design adapted for diff. versions	15
Design meeting regional style image	10
Links easy recognizable	10
Special design quality (e.g., automatic language recognition changeable)	20

5. Specific content	150
Extent of information in German	15
German language further information	15
German language guiding offered	15
Map with location in the country/region	15
Map with location in the continent	15
Access information from Germany	15
Working Webcam	15
Working weather report	15

Chapter 5.41

ICT and the Travel Industry: Opportunities and Challenges for New Zealand Travel Agents

Vladimir Garkavenko

Waiariki Institute of Technology, New Zealand

Simon Milne

Auckland University of Technology, New Zealand

ABSTRACT

This chapter focuses on the impact of the ICT on the travel industry with a focus on the New Zealand travel agent (TA) sector. We present key findings from a longitudinal study of TA businesses conducted during 2000-2004. These findings are compared and contrasted with information gathered from in-depth interviews with consumers. The study explores major pressure factors on TA businesses: direct airline-consumers sale, introduction of the Internet, and the emergence of the well-informed consumer. The research also establishes that there is great variation in the extent to which travel agents use the advantages associated with new technology

and how New Zealand travel agents perceive ICT. We argue that in such a crucial moment of disintermediation and the fight for the consumer, TA will need to implement more aggressive advertising policies with a strong emphasis on their professional advice, personal financial reliability, and time-saving attributes for clients.

INTRODUCTION

The evolution and impact of information and communication technologies (ICT) is a dominant issue in the tourism business today. Tourism is an information intensive industry. There are three main waves of technological development

that have characterised ICT influence in tourism enterprises: computer reservation systems (CRS), global distribution systems (GDS), and the Internet. The Internet makes information accessible to consumers, and therefore establishes a direct link between the consumer and the supplier. As a result, the traditional travel distribution channel is changing rapidly. A major feature of this change is described as disintermediation: when the principal bypasses intermediaries such as travel agents. A lot of researchers and business experts suggest that the threat of disintermediation is imminent and that the trend is irreversible (Bloch & Segev, 1996; Harrington & Power, 2001; O'Brien, 1999; Prideaux, 2001).

Travel agents (TAs) are considered to be particularly vulnerable to disintermediation. ICT replaces the core competencies of the intermediaries which include transaction processing (ticketing and settlement) and information provision (raw product information as provided by suppliers). The disintermediation phenomenon is particularly pronounced in the relationship between airlines and travel agents. To minimize the risk of disintermediation and to improve business performance, travel agents need to reposition themselves and review their core strategies to compete efficiently in the changing business environment. It is argued that an intermediary will only survive in a distribution channel to which it adds value. The overall tendency can be described as a shift towards consumers rather than the principals. Some newly created travel agencies act purely in cyberspace while others try to act as the new intermediaries—infomediaries—aiming to help consumers to analyse and integrate information. Research into the travel agency sector by academics has focused on the need for travel agents to adopt strategies that enable them to compete in an ever-changing technological environment. There has, however, been little research outside European and North American settings.

The main objective of the chapter is to analyze the impact (challenges and opportunities) of ICT

and the Internet in particular on the New Zealand travel agent sector as an example. The specific foci of the chapter are:

- What do New Zealand travel agents (TAs) perceive to be major impacts on their businesses?
- An analysis of the disintermediation process as a result of ICT introduction and adoption using the example of travel agents relationships with airlines
- How do TAs perceive ICT?
- How does the consumer perceive the role of a travel agent in the Internet era?
- How should New Zealand travel agents reposition themselves to compete successfully?

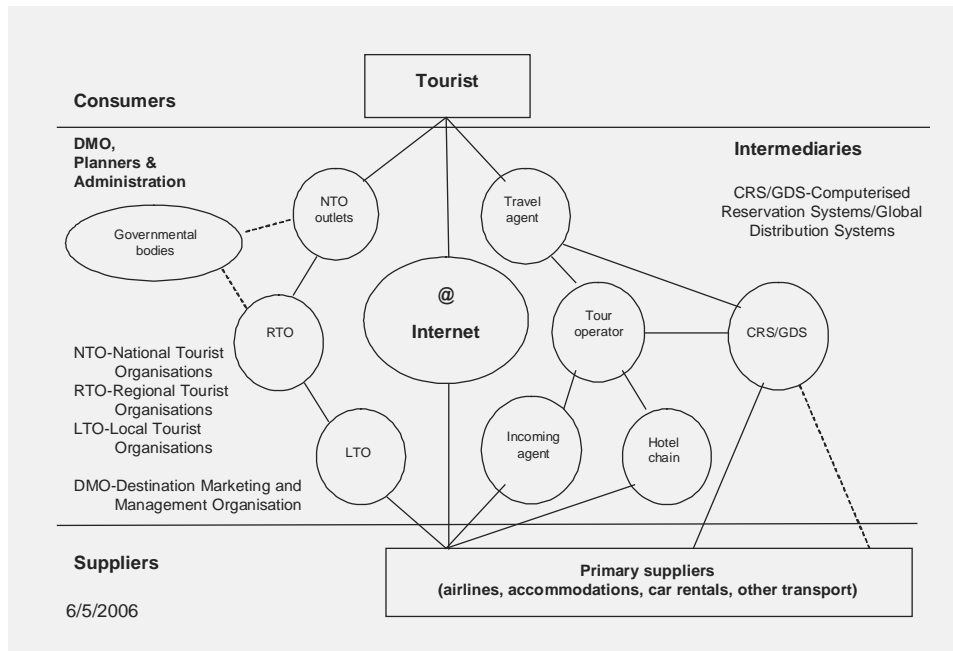

We present the results of a five year study of the New Zealand TA market. Consecutive in-depth interviews were held with TAs from the Auckland region in 2000 and then in 2003. The main issues and problems of the modern TA business environment were identified and conceptualised. The theoretical assumptions formulated on the basis of the received data were tested in a national online survey of TA businesses in 2004. To verify the congruency of the TA and consumer perception of the TA role in the modern environment, in-depth interviews were held with consumers.

BACKGROUND

Tourism is an information-intensive industry. For each traveler there are numerous messages and pieces of information to be exchanged: itineraries, schedules, payment data, destination and product details, and passenger information. Fast, efficient exchange of information between the players in the industry is essential for efficient distribution, sales and customer service (Figure 1).

This information dependence has placed the industry at the forefront of ICT adoption (Mason

Figure 1. Model of tourism information flows (Source: Werthner & Klein, 1999, p. 8)

& Milne, 2002). A most dramatic change for the tourism industry came in the 1980s with the introduction of central reservation systems (CRS). CRS increased the power of the airlines in the distribution channel and dramatically altered the balance of power in the wholesale travel market (Poon, 1993). The Internet and electronic commerce is the next major wave of technological change which is influencing the industry.

Tourism Industry: Changes in Distribution Channels

The Internet and electronic commerce developments in the late 1990s, and the adoption by tourism of the prime business to business (B2B) and business to consumer (B2C) applications, has changed the industry and has shifted the traditional way tourism and travel products are distributed (Buhalis, 1998; O'Connor, 1999; O'Connor and

Frew, 2002). Increasingly, consumers can undertake their entire tourism product search and booking online and, therefore, the role of intermediaries has been changing dramatically. The Internet is widely used as a means to deliver up-to-date content. As a result, it has created the conditions for the emergence of a wide range of new tourism eMediaries. Tourism suppliers (particularly airlines, car rentals, and hotel chains) have taken advantage of the new opportunities and developed e-commerce applications by allowing users to directly access their reservation systems. This includes single supplier provisions, such as British Airways, Marriott Hotels, and Avis, as well as multi-supplier Web pages that have emerged to support airlines in their efforts to reach the consumer directly (e.g., www.orbitz.com).

In addition, several destinations have developed destination management systems to distribute their smaller properties and to present

the destination as a holistic entity. A number of Web-based TAs also have emerged (Expedia.com, Travelocity.com) whilst off-line agencies have developed their online provision. Internet portals (Yahoo, Altavista, Excite) and vertical portals (or vortals) also have developed online travel distribution, often by sourcing their travel contents from external online agents and suppliers. Media companies, including newspapers and television networks, have gradually integrated their off-line with their online provision and have expanded to include e-commerce capabilities on their sites. Online last minute agencies have emerged to enable distressed inventory to be distributed efficiently.

According to Palmer and McCole (1999), the “most important structural change that could be brought about by the Internet is disintermediation wherein principals bypass the intermediary and sell directly to end-users” (p. 37). This phenomenon is especially pronounced in the relationship between airlines and travel agents. Travel agencies have always played a key role in the outsourcing of airline sales. The passage of the Airline Deregulation Act of 1978, accompanied by liberalization of many of the bilateral aviation agreements between the U.S. and other countries during the 1980s, brought about more competition and increasingly complex fare structures (Trethewey & Oum, 1992). Both of these changes favored the use of travel agents by prospective passengers. In 1976, 40% of the airline tickets issued in the USA were written by travel agents; by 1985 this proportion had increased to more than 80% (Trethewey & Oum, 1992).

Traditionally, the travel distribution role has been performed by outbound travel agencies, tour operators (TOs) and inbound travel agents or handling agencies (Buhalis & Laws, 2001) (Figure 1). They have been supported by computer reservation systems, global distribution systems or tour operators’ videotext systems (leisure travel networks (Bordat, 1999; Karcher, 1997). These traditional electronic intermediaries, particularly

GDSs, progressively consolidated their position to four major systems, namely SABRE, AMADEUS, GALILEO, and WORLDSPAN (Karcher, 1996; WTO, 1995).

ICT Adoption by Airlines

The development of the World Wide Web represents a major opportunity for airlines (American Airlines, 2000; Buhalis, 2000a, b; Smith & Jenner, 1998). Airlines quickly have adapted to the potential opportunities associated with e-commerce (both B2B and B2C). Since the mid-1990s most airlines have offered Web sites, which not only inform consumers about basic fare and schedule information, but also enable itinerary building, fare construction, and reservations. This enables the development of marketing strategies focused on building direct relationships with customers (Buhalis, 2000b; French, 1998).

The Internet has revolutionised the airline business. Online booking revenue is forecast to rise to over 11% of the total in Europe by 2008 from just over 4% in 2003, according to Jupiter Research (*The New Zealand Herald*, 2004).

As a result of airlines ability to communicate directly with consumers, several structural changes in the industry have emerged. Airlines have reduced their commission rates significantly (i.e., from 10-12% to 7%), while they also have introduced “commission capping” (e.g., \$10 per ticket). In addition, electronic ticketing and ticketless travel have gradually reduced both distribution and labour costs.

Airlines are increasingly dealing directly with their corporate customers, bypassing the agency entirely. For example, Continental, which derives over 50% of its revenues from business travellers, has established net fares for its corporate customers. Such fares, which are widespread in the USA, involve major discounts on published tariffs paid directly to the corporate customer. In these arrangements, carriers bypass the corporation’s agency entirely, paying it no commissions. The

agency is then left to derive its income from travel management service fees it charges the corporation.

There is also a rapid increase in Internet-generated bookings amongst U.S. and European low cost carriers. The majority of low cost carriers' online sales are on their own Web site whereas the full-service carriers' rely more heavily on online travel agents such as Travelocity and Expedia (Alamdari, 2002).

ICT Impact on the Travel Agent Sector: Challenges and Opportunities

ICT have enabled travel agencies to build complicated itineraries in minutes, while they provide up-to-date schedules, prices and availability data. The proliferation of CRSs and GDSs has also provided an effective reservation mechanism which supports travel agencies in obtaining information, making reservations and issuing travel documents for the entire range of tourism products efficiently and at a fraction of the cost if these processes were undertaken manually (Vasudavan & Standing, 1999; Wardell, 1998).

It has been noted by some researchers that despite having used ICT for some time now, the vast majority of travel agents have not yet managed to take full advantage of ICT capabilities (Buhalis, 1999, 2000b). This is the result of a certain shortage of strategic vision in ICT usage as well as a reluctance to invest in new technology. Low profit margins and a traditional reluctance to invest in assets have deprived agencies of a wide range of critical tools that have prevented them from taking full advantage of emerging ICT. This results in a relatively low level of technology integration, and thus less information is available to support strategic and tactical decision-making. In addition, it results in a low level of management and operational integration, which does not allow agents to capitalise on information for efficient operations, integrated customer service

and development of partnerships with suppliers and institutional buyers (Buhalis, 1999, 2000b).

The Internet has introduced challenges for travel agencies. Agents not only have to match the availability of information and reservation capabilities of the Internet, but they also need to provide great value when serving consumers who have access to available information. In addition, traditional travel agencies need to compete with several ICT-based newcomers, such as Expedia, Travelocity and the Internet Tourism Network, which enable consumers to have access to information and make online bookings (Buhalis, 1999, 2000b; Modahl, 2000; O'Connor, 1999).

The high dependence of travel agencies on information and communication in order to perform their role, in combination with their reluctance to take advantage of emerging technology, places traditional agencies in an extremely vulnerable position (Bloch & Segev, 1996; Garkavenko, Bremner, & Milne, 2003; Garkavenko & Milne, 2004; Poon, 1993; Richards, 1995). A "threatened intermediaries (or disintermediation) hypothesis" was introduced by Malone, Yates, and Benjamin (1987) who used the term "electronic brokerage effect" for the phenomenon. The hypothesis essentially describes the reduction or elimination of the role of retailers, distributors, brokers and other middlemen in transactions between the producer and the customer (Atkinson, 2001). One common vision of the electronic marketplace is an ideal electronic market in which consumers interact directly with producers, as manufacturers internalize activities that traditionally have been performed by intermediaries (Sarkar, Butler, & Steinfield, 1995, 1998). Although entire channel layers may not be eliminated, there could be significant shifts in power from one channel layer to another (Vassos, 1996). According to Porter (1999), the Internet is going to lead to the demise of a lot of intermediaries.

There also is a threat to travel agents' "standard products": the processing of transactions (ticketing and settlement) and the supply of raw

product information from suppliers (O'Brien, 1999). These roles will increasingly be replaced by technology as suppliers provide standard product information, electronic ticketing, and electronic funds transfer services directly to the customer. For instance, some traditional travel agents in the U.S. have reported a 10 to 20% decline in business as customers switch to online ticket purchasing (Taylor, 1998).

There are different opinions regarding the plausibility of disintermediation in the context of the travel industry. Most commentators would probably agree that the pre-Internet position of TAs is unsustainable (UNCTAD, 2000), and that TAs who fail to take advantage of the Internet are faced with a real threat. Yet, it has been pointed out that there is little empirical evidence to support any arguments and predictions relating to the future role of middlemen in the travel distribution channel (Anckar, 2003; Palvia & Vemuri 1999).

Drawing on data from surveys of managers and travel consultants of Australian travel agencies, Standing, Borberly, and Vasudavan (1998) and Vasudavan and Standing (1999) forecast that many high street retail TAs will be eliminated over the next few years. However, in a series of exploratory studies using survey data it was found that even experienced Internet users have trouble producing satisfactory travel arrangements through self-booking services (Anckar & Walden, 2000, 2002), so there may be a delayed effect in the take-up of alternatives to high street retailers.

Based on an exploratory survey among industry experts, Licata (2001) presented findings indicating that more conventional forms of distribution, such as global distribution systems (GDS) and high street shops, are likely to be bypassed or that their roles will change dramatically: Nearly all (97%) of the respondents in Licata's study agreed or strongly agreed with the statement that the Internet will be the most prominent distribution channel in five years; the corresponding figures being 20% for high street shops and 27% for GDS. Yet, the majority (70%) of the respondents

also agreed that the disintermediation of the traditional distribution channel is avoidable, and that reintermediation is a more probable outcome (Licata, 2001).

Schmitz (2000) also pointed out that the disintermediation hypothesis is too simplistic, seeing its interpretation of intermediation as a single service rather than a number of different services. Sarkar et al. (1995, 1998) argue that the case for the elimination of intermediaries as a result of e-commerce is based on a questionable assumption, concluding that more, rather than fewer intermediaries (mainly new players, cybermediaries) will be involved in electronic markets (Giaglis, 1999).

Chircu and Kauffman (1999) propose an "IDR cycle," a recurrent pattern of intermediation, disintermediation, and reintermediation, arguing that traditional non-technological middlemen will be able to reintermediate in the long run. Werthner and Klein (1999) argue that evidence of a reintermediation process can already be seen as traditional intermediaries adjust their services offering to the needs and opportunities of an electronic sales channel. Giaglis (1999) envisaged three major scenarios for electronic intermediaries: disintermediation, reintermediation (the emergence of online subsidiaries of traditional intermediaries), and cybermediation (the emergence of new entrants with intermediary functions). The authors call attention to the fact that electronic markets are still far from reaching a state of maturity, and maintain that it is extremely difficult to predict the market structure of the future and the type of intermediation that will dominate in any given market.

Internet booking is not a panacea for the whole tourism industry (WTOBC, 2001). By retaining the human touch and specialising wisely, smaller offline travel agencies can reach a reasonable level of profitability. In the agents favour are a number of unique services that dot.com travel companies and airline Internet portals have difficulty offering. These include:

- The person-to-person nature of retail travel agency businesses
- The ability of agents to offer and explain complex fare options to clients
- Agents are able to discuss the advantages and disadvantages of destination selection.
- Clients have the option of developing long-term personal relationship with agents.
- Agents can develop specialist knowledge of specific destinations. (Prideaux, 2001, p. 224)

TAs must analyse what strategies they can follow to sustain their role as middlemen. There are two directions that agents can take in this quest (Tse, 2003). The first is to improve their efficiency by repositioning themselves as low-cost agents through the Internet. Another alternative is to develop a different business model that adds value to a travel experience. Providing travel advice, enhancing customer satisfaction, and building bookings with other related services are just some of the many options travel agents need to consider to fight this trend of disintermediation. To survive, the agents should reintermediate themselves as being able to provide personal services. TAs must invest in deep learning about their target customers' preferences to find out what would most satisfy them (Tse, 2003).

The New Zealand Travel Market

The New Zealand tourism market is certainly not immune to the changes outlined above. The Travel Agents' Association of New Zealand has stated that never before has the industry experienced a period of such turbulence and change (TAANZ, 2001b). In addition to the growth of the Internet, shifts in airline ownership, the disappearance of some carriers from the New Zealand market, commission cuts, and evolving consumer demand and expectations are fundamentally altering the ways in which NZ TAs conduct business (TAANZ, 2001b).

Tension between travel agents and Air New Zealand has been growing. The airline has poured large sums of money into creating a new Web site which was designed to increase the number of Internet based bookings and sales (www.airnz.co.nz). The airline has adopted the concept of paperless travel throughout its domestic network (Kennedy, 1997). In July 2002, Air New Zealand cut its fares by up to 28% for its one-class, no-meal Air NZ Express. The price to the consumer is lower if booked over the Internet. Air New Zealand has removed a 4% commission for each domestic ticket sale (Aronson, 2002a). Travel agents have responded by launching a campaign against Air New Zealand commission cuts (Aronson, 2002b; *The New Zealand Herald*, 2002).

The impact of these changes is not hard to see. According to TAANZ, 60% of processing by New Zealand TAs is airfare related (TAANZ, 2001a) and the bulk of this involves Air New Zealand. Over the past four years, the number of travel agents in New Zealand has plummeted. TAANZ noted that the number of travel agents within their organisation dropped to 470 by 2004 from the 1999 figure of 626 (*The New Zealand Herald*, 2000). By some estimates, around two agencies were closing their door each week in 2000 (Scherer, 2001).

New Zealand agents also face challenges from principals other than Air New Zealand. In a move similar to the North American Orbitz initiative, Zuji.com launched its Web site in the Asia Pacific region in 2001. Zuji.com has 16 members, including Japan Airlines, Qantas, Singapore Airlines, United, and China Airlines. Utilising the technology of the major GDS, SABRE, the portal allows the consumer direct access to systems that were previously the domain of travel agents alone. It also should be noted that there are, like the Orbitz case, serious legal challenges to the operation (Griffin, 2002).

With very high use of Eftpos and ATM technology, as well as with high Internet connection and Hi-Tech electronic ownership, New Zealand

seems to have all the advantages for successful online business development. However, according to Deloitte Touche Tohmatsu (2000), New Zealand businesses, including those in the travel industry, are laggards in ICT adoption.

Although there are no firm figures on the total number of establishments in the NZ TA sector the total number of current TA employees can be estimated at 4800 with approximately 800-900 shops around New Zealand. TAANZ members employ 3610 staff in 533 locations. The biggest NZ travel agencies are TAANZ members except for Flight Center (approx. 1000 employees), Travel Centers (22 shops, 120 staff), Harvey World Travel (53 shops, 150 staff), STA travel (15 branches, 70 employees).

Research on the NZ Travel Agent Sector

The investigation of the New Zealand TA sector and its changes in response to ICT introduction are identified as the purpose of this study. Primary data collection started with semi-structured interviews with TA and industry specialists to identify the main issues facing the New Zealand TA sector. The research then proceeded with a follow-up of semi-structured interviews to refine the findings regarding the main issues and to investigate the evolution of TA perceptions, attitudes and relationships. This allows us to formulate theoretical assumptions regarding the TA business environment in the information era. A fully-structured online questionnaire was designed and implemented to verify the assumptions made on the basis of the in-depth interviews.

The presented study adopts qualitative methods. Qualitative analysis is part of the naturalistic method of inquiry, which assumes that reality is continually changing and that human social phenomena are so complex that it is impossible to discover anything approximating a scientific law (Oppenheim, 1992; Silverman, 2004). A goal of qualitative research is to locate the understand-

ing of a phenomenon within the context of other phenomena.

In-depth interviews with TA and industry specialists were adopted as a means of collecting data. It is well accepted that in-depth interviews are applied to enhance the knowledge of just-emerging, under-researched phenomenon (Oppenheim, 1992). Until the researcher is relatively clear on what is to be studied and how, the objective of the interview should be discovery and enhanced understanding of the phenomena. Such an understanding is derived from data grounded in the informants' experience—what they say about what they did, how they felt, or what they thought. Such a theory development objective demands an emergent design for the research process—one that is fluid and adaptable as concepts and relationships are revealed in the course of data collection, analysis, and interpretation. Unlike survey or experimental research that demands the investigator's intervention prior to data collection through the precise creation of a questionnaire, qualitative methods such as in-depth interviews involve the researcher as an interpreter mostly during and after data collection (Oppenheim, 1992).

In-Depth Interviews 2000-2001

Interviews were held with 20 senior management or owners of TA in the Auckland region by the New Zealand Tourism Research Institute during 2000-2001. A sampling method was adopted that enabled the researchers to include a cross-section of travel agent operations, including corporate/business, leisure specialists, franchise/chain retail operations, small independent enterprises, and wholesalers. The Auckland region was chosen because the city is New Zealand's major entry and departure point for tourists. Interviews with TAs were designed to elicit information on an agent's particular market, key competitive pressures, evolving relationships with airlines, the use of ICT, relationships with consumers, and main survival

strategies. Interviewees were asked whether they thought that their customers have changed with time, and if they believe consumers are ready to buy travel products online.

Research conducted in 2000 on New Zealand TA revealed that processes of disintermediation, especially driven by the national carrier Air New Zealand, were a major concern (Garkavenko et al., 2003; Garkavenko & Milne, 2004). Commission cuts by the national carrier Air New Zealand were a major focus of attention for most of those interviewed along with direct sales through the airline's upgraded Web site. The major pressure factors were identified by TAs as commission cuts and direct sale of principals to consumers (Figure 2).

In-Depth Interviews 2003-2004

The aim of the follow-up interviews was to refine the formulation of the main issues of the New Zealand travel agent market and formulate theoretical assumptions regarding the changes and main pressure factors facing this sector. In common with the 20 interviews held in 2000, a sampling method was adopted in 2003-2004 that included a cross-section of travel agent operations.

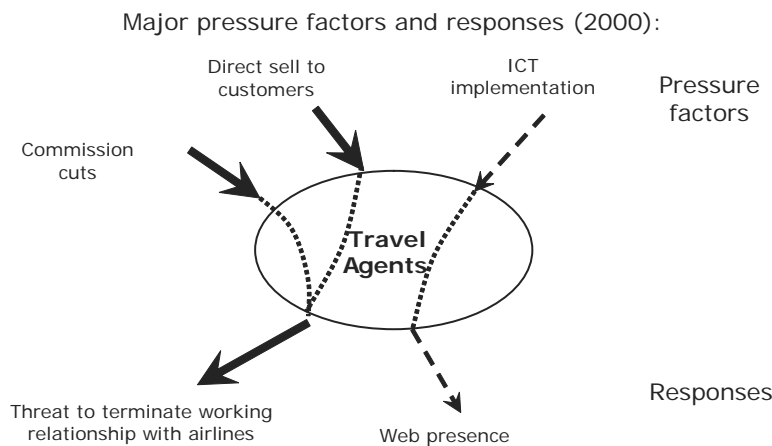

Interviews were carried out with 25 retail travel agents, owners, wholesalers, senior management, and travel sector experts in the greater Auckland region to investigate their perceptions of the effects of the changing business environment.

Interestingly, neither commission cuts, nor direct Web-based sales by airlines, were on the list of major threats in the 2003 follow-up in-depth interviews with Auckland region TAs. Given that 60-85% of profits of those interviewed are still air-fare related it appears that New Zealand TAs have begun to find ways to build a healthier relationship with the majority of airlines.

Although no single concept underpinned respondents' views of ICT importance, there were a number of recurrent themes. The Internet and other ICT are considered as commodities rather than strategic means for survival. Only one interviewee mentioned the Internet and intelligent agent software in particular as tools for adding value. No other respondents mentioned ICT as an enabling factor. Further discussion identified that interviewees don't particularly know how ICT can add value to their product, or how specialised software can make their work more efficient.

The 2003 interviews with New Zealand TA also revealed that ICT in general and the Internet

Figure 2. Major pressure factors on TA businesses and TA responses (Source: 2000 survey interviews by authors)

in particular are not perceived as a major threat to TA businesses. One of the interviewees said: “Consumers research on the Internet, and then they come to us to do bookings. It will come that they will be confident to book, but not at this stage. At this stage it is not a huge impact on what we do.” Indeed, a Travel Agents Association of New Zealand representative recently said that travellers who book through the Internet are a different clientele from those who use an agent (*Newstalk ZB News*, 2004).

National Online Survey 2004

When main issues of the TA sector and their evolution were identified and refined, a fully-structured national online questionnaire was designed and implemented. Over 120 TA businesses participated in the survey, the main aim of which was to check the following assumptions that were formulated from the analysis of in-depth interviews with New Zealand TAs:

- Commission cuts by airlines, suppliers selling directly to the consumer, the Internet and emergence of the more knowledgeable

consumer have a great impact on the TA market in NZ

- ICT and the Internet in particular are not perceived as a strategic tool by NZ TAs
- Main survival strategies are: alliances, shift to consumers, niche marketing

The national online survey of TA businesses in 2004 refined the notion of how TAs perceive major pressure factors and ICT impact on the industry (Figure 3). The findings showed that TAs perceive commission cuts, direct principal sales to consumers, the Internet, and the emergence of a new more informed consumers, as well as terrorism and health threats as major pressure factors on their businesses. In general there is much more recognition of ICT as a pressure factor after 2003.

These data reveal that there is great variation in the extent to which TAs exploit the advantages of new technologies. As has been pointed out by Gamble, Chalder, and Stone (2001) and other researchers, the major barrier in relation to new technologies seems not to be technological capacity, but uncertainty surrounding the demand for online travel and the possible resultant disinter-

Figure 3. Major pressure factors on the TA businesses and TA responses (Source: National Survey by authors)

mediation effects on the traditional travel agent. The national online survey established that TAs in big cities, especially Auckland, perceive ICT as a strategic tool. They invest in ICT earlier and that is why they do not perceive the emergence of the informed customer as a threat to their businesses.

As with Tse's work (2003), two key tendencies in TA survival strategies are identified. One tendency is a low-budget orientation, especially pronounced in franchises with high turnover (called by one interviewee "the McDonalds of travel") and small TAs catering for specific ethnic and social groups. One interviewee noted that the latter sell tickets with as little as a 2% margin to establish themselves on the market. A second business model is to focus on adding value to travellers' experiences. For example, some businesses add value to the travel product by providing expert advice regarding destinations, bundling airfare bookings with other related services such as visa support and organizing overseas working experience. One of the interviewees noted: "We will become smarter. The days of sitting in your agency and waiting for people to come in are gone."

Perhaps most importantly, the national survey revealed a greater emphasis on the competitive problems associated with the emergence of better-informed and more ICT savvy consumers. It is interesting to follow the evolution of TA perceptions of consumers during the 2000-2001 and 2003-2004 studies. This evolution can be described as a progression from a perception of the consumer as "non-skilled," "not ready to buy online" to "more informed," "more sophisticated." A lot of TAs now find that consumers come to them with a solid knowledge of their destination and ticket/hotel prices retrieved from the Internet.

The general feeling remains that the consumer is still not quite ready to buy travel products through the Internet (especially those which involve long-haul/complex itineraries). It was acknowledged that the majority of arrangements for

domestic and one-point trips will be done online in the near future. However, it was emphasised that there will be still some categories of travellers that will use TAs even for simple itineraries. Online services and information searching are still perceived as very complex, chaotic and time-consuming.

In simple terms these findings reveal that the consumers themselves are, in many respects, becoming the main 'competitors' with TAs, in terms of gathering information and searching for destination-related knowledge. One of the interviewees noted that to survive "TA have to be able to have access information 'cleverer' and 'quicker' than they [*consumers*] do. Then we will be able to charge for this." There is a general understanding that TAs should be orientated to consumers. However, customer-relationship management strategies vary considerably. None of the respondents reported being 100% satisfied with the quality of their current customer management data. Only one TA that works with several niche markets has a well-developed customer relationship strategy and an established customer database. This particular TA looks after individual customers' post-trip follow-up, as well as sending newsletters plus providing personalised services and detailed knowledge of specific destinations.

For one TA who specializes in Eastern Europeans living in NZ, success has been based on an intimate knowledge of his clients' psychology and language, and thus of their specific needs and demands. The specific product for such a group includes not just tickets, but visa support and other immigration services. In this case the TA does not have any functional customer database, relying on word of mouth in a small, relatively tight-knit, community.

TAs continue to play a vital role in the tourism distribution system. Research shows that TA are a more frequently utilised external information source by international travellers from almost all EU member states (Gursoy & Umbreit, 2004). The success of TAs relies on their ability to provide

products that suits clients' needs and wants. An understanding of those needs and wants, coupled with deep product knowledge are implicit in this assertion.

Consumer expectations and perceptions of the modern travel agent are an important element in the complex TA business environment. This is a reality that often determines the success of a TA in the disintermediation context. Gursoy and Chen (2000) and Gursoy and Umbreit (2004) state that there are national-culture differences in consumer's search and booking of travel products. These authors established that the European Union consists of distinctive segments of consumers that prefer brochures and TAs in search and booking, or the Internet, TV/radio and minitel. It therefore is relevant to find some specific characteristics of the New Zealand travel product consumer to determine if this is so in the local market.

The Pacific Asia Travel Association (PATA, 2004) reported that TAs were the most popular information source for overseas-bound New Zealand travellers. The Internet is becoming more popular in information searching with 11% of respondents using this tool. TAs were the most popular booking channel for outbound tourists in New Zealand. Only 9% of travellers booked their trips online. Nevertheless New Zealanders are frequent and skilled computer users. The Computer Industry Almanac estimates that there were 2.34 million Internet users in New Zealand in 2004 (European Travel Commission-New Media Review, 2004). In August 2001, Nua reported that 44% of New Zealand's Internet users went online to plan or book overseas holidays, up from 23% in 1999. The percentage was lower for online planning of domestic holidays, however 28% of online New Zealanders did go online to plan or book domestic holidays, up from only 10% in 1999.

Subsequent Research

While there have been some studies on the demand side of the New Zealand TAs market (Gamble et al.,

2001; Oppermann, 1998) these have not adopted an in-depth approach to understanding consumer perspectives. To embrace the complexity of the multifaceted characteristics of the TA business environment, the present research adopted a qualitative approach based on a "double-sided" analysis of TA services that included both TA and consumer's in-depth interviews. Twenty in-depth interviews with consumers were conducted.

A convenience sample was used for the consumer interviews. Rather than following a random selection routine, professionals and white-collar workers who travel regularly (two to three times a year) were approached. When selecting consumers, respondents were pre-screened and only those who use the Internet on a regular basis were asked to participate. The argument for pre-screening is that those customers who are familiar with the Internet and use it on the regular basis would have a choice between using the Internet or a travel agent in their trip preparation. The interviews mainly focused on the use of the Internet in trip planning and preparation, the (dis)advantages of using a TA for trip preparation, and the consumer's perceived role of TAs in the modern era.

The aim of the in-depth interviews with consumers was to identify their attitude towards TAs in the modern Internet era. It was found that travellers are pragmatic in choosing which channel to book through—looking for where they can get the best deal (Tse, 2003). This reflects previous findings on service attributes of travel agencies in New Zealand (Oppermann, 1998). Oppermann pointed out that differences in perceptions of the importance attached to service vary between TAs and clients/potential clients. Attributes rated highly by consumers were not considered in the same light by travel agents. The most highly rated service attribute for consumers was that the "agents give clients the best deal" and for travel agents it was "agent is courteous and friendly." Similarly, in our study there was a discrepancy between TA and consumer perceptions of quality service: during in-depth interviews TAs men-

tioned more “personalised service,” “specific product catering,” and consumers were talking more about a “better deal,” and “flexibility,” or “financial responsibility.”

The research findings also reveal that there is a gap between customer expectations and customer perceptions of the services provided by travel agents. The ideal travel agent is expected to be a professional who gives the best deal in term of prices, and has intimate destination-related knowledge. The perceived role of TAs is as a transaction facilitator and not as an information source or adviser. There is a tendency among consumers to look for information online and use a TA only for bookings and financial transactions.

The findings further show that consumers perceive competitive pricing, flexibility in arrangements and personal financial responsibility as being crucial factors when choosing/using a TA. If TAs are to survive—and thrive—in the years to come, it is important that they address the issue of what matters most to consumers. Interestingly, another study regarding online relationships examined the importance of trust in accommodation bookings in New Zealand (Fam, Foscht, & Collins, 2004).

Perceptions of the main service attributes by TA and by consumers are compared and summarized in Table 1.

It appears that considerably improved computer and Internet skills are expected by consumers from TA, and at the same time the national survey revealed that most TA respondents realise

that these factors are very important for their business progress and survival. Similarly, both consumers and TA recognise that consumers are often very knowledgeable about the travel product. On the other hand, consumers named “personal financial responsibility,” “finding a better deal” and “flexibility” as the main service attributes they look for in a TA. TAs however were talking more about “personalised service,” and “added value” as the main attributes. Consumers also see the role of TAs in the Internet era almost exclusively as “transaction facilitators.” They also were quite suspicious regarding the professionalism of TAs. While many TAs are ready to charge their customers for the services they provide there, was a great deal of hesitation regarding TAs fees among interviewed consumers.

It appears that the mainstream consumer is hesitating and can be convinced by aggressive marketing to buy travel products either online or through TAs. These findings have very important implications for TAs. If the Internet becomes more user-friendly there is no doubt that more and more consumers will purchase online. TAs will need to implement more aggressive advertising policies with a strong emphasis on their professional advice, personal financial responsibility (including the bond system), time-saving attributes, and intimate knowledge of destination. TAs also need to develop their Internet skills to compete with their customers when searching for information/best deals.

Coincidences	Discrepancies
<ul style="list-style-type: none"> • TA should be more skillful in computer usage • Consumer is the main TA competitor for the travel information 	<ul style="list-style-type: none"> • Main attributes of the quality service • Role of TA • Fees for TA services

THE “SUCCESS MIX” FOR NEW ZEALAND TRAVEL AGENT BUSINESSES

The New Zealand travel agent sector is represented mainly by SMEs; almost half of them are independent or family operated. It appears that ICT adoption by New Zealand TAs is less advanced than in the USA or Europe. There is a great deal of hesitation regarding the use of ICT as a strategic tool. While the Web presence of New Zealand TAs increased considerably from 2001-2004, many are still more interested in using cyberspace for marketing rather than as a core component of overall business strategy. There are no giants in New Zealand cyberspace like Expedia or Travelocity. Indeed, online travel has proved a difficult business for local operators venturing on the Web. Local provider Travel.co.nz lost more than \$2 million in revenue of \$20 million in the year 2003.

Overall, it appears that the reintermediation process is the reality for the average New Zealand travel agency. First of all, the national survey of 2004 revealed the considerable heterogeneity of NZ TA businesses in perceived pressure factors, attitudes towards technology, relationship with the consumer, and business success. The major differences were found not between franchises and independent TAs as was expected, but between TAs from Auckland and other major cities, and those from small towns. Early recognition of the ICT impact on their businesses, and recognition of the fact of emergence of the “new” consumer gave some TA business, especially in Auckland a market advantage.

TAs that perceive their business situation as better or much better compared with three years ago point out that excellent customer service is a big part of their advantage. They recognised reasonably early that with ICT accessibility to all parties in the distribution channel the way to survive is to become a customer representative and to add value to services. TAs recognise that

there is a need to improve their computer/Internet skills to deliver a service. Successful TAs are catering to specific niche markets trying to deliver a personalised service with added value. These findings allowed the formulation of a “success mix” for TAs in New Zealand (Figure 4). The research has established that businesses which recognised the emergence of a new, more sophisticated consumer, embraced ICT as a strategic tool, and/or began to cater for niche markets are better off now than three years ago. At the same time there is another feature specific to the New Zealand TA market—all outbound travel is long haul, and much of this is complex with several stop-overs and costs a considerable amount of money. Interviews with consumers show that although they largely perceive TAs as simple transaction facilitators, they still hesitate to trust the Internet with their money and are still not quite confident to complete complex travel arrangements online in this situation. In simple terms this means that New Zealand consumers still need TAs, results replicated elsewhere (Anckar, 2003).

Nevertheless, the data reveal an intention by a growing number of consumers to abandon high street travel agencies when booking travel. Approximately half of the existing and prospective Internet bookers intend to use direct distribution approaches, whereas half intend to use the Internet merely as a communication channel to human travel agents, thereby primarily fostering reintermediation.

Although the Internet undoubtedly has the potential to revolutionize the travel distribution chain, it should be noted that many hindrances to the mass adoption of online services in travel still exist. The lack of travel agent expertise and advice is one of the greatest consumer disadvantages of electronic travel distribution. “Buy direct from the factory and save money” may be good advice for some types of products, but is generally not true for travel products. Anckar (2003) has pointed out that there are several categories of barriers for consumers booking and purchasing

online. These barriers are: lack of knowledge or experience with the Internet, technical problems, system limitations, and poor Web services, as well as difficulties in locating Web sites. Furthermore, making price comparisons is time-consuming.

Although the demand for online arrangements exists, the supply side has to be more mature and offer easy-to-use reliable ways of travel booking. It can be hypothesized that the next step in the evolution of distribution in the travel industry will be the development of special software that assists consumers in online bookings of their trips. TA will again be put in the position of adding value to their services, repeating once again the disintermediation-re-intermediation cycle.

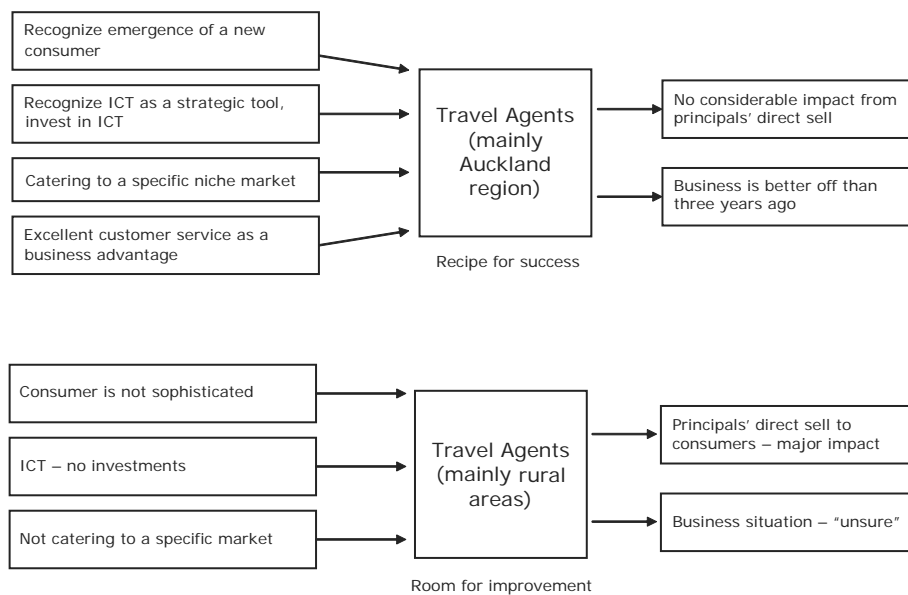

CONCLUSION

ICT has changed the competitive environment for travel agents in the New Zealand travel market. Tourism industry principals and technology providers in New Zealand are entering

the market—bypassing TAs and selling directly to consumers. This study on the New Zealand travel agent market revealed that commission cuts, suppliers selling direct to the consumer, the Internet, and the emergence of a new more informed consumer are the main pressure factors on travel agent businesses in New Zealand.

This research has also established that there is great variation in the extent to which travel agents use the advantages associated with new technology and how New Zealand travel agents perceive ICT. It seems that the major barrier in relation to new technologies is not the technological capacity of TAs, but the uncertainty surrounding the demand for online travel. The research also reveals great variability in attitudes towards ICT as a basis for sustained competitive advantage. The majority of the study participants have decided not to invest in ICT and do not perceive ICT as a strategic tool. So, while it appears that the level of ICT adoption among New Zealand travel agents is high, the use of ICT is limited to e-mailing and

Figure 4. “Success mix” for New Zealand TA businesses

information searching. The majority of NZ travel agents have Web sites, but the role of these Web sites is mainly for information and marketing rather than for e-business.

The Internet has provided several challenges for travel agents. Agents not only have to match the availability of information from off the Internet, but they also need to provide great value when servicing consumers who already have access to most of the available information.

It has been established in this chapter that the New Zealand consumer perceives travel agents mainly as “transaction facilitators” rather than a source of information or a person who intimately knows a destination or provides an unbiased deal for an airfare. At the same time, consumers pointed out that “flexibility” and “financial responsibility” are definite advantages in using travel agents. Consumers also pointed out the often chaotic nature of online information.

The New Zealand consumer is currently “hesitating” in their preference to use the Internet or a travel agent in purchasing travel products. Travel agents can use this critical time to promote their businesses more assertively, putting the emphasis on their personal financial responsibility and skills in the construction of complex itineraries as well as flexibility in changing travel arrangements to suit their clients.

Section 6

Managerial Impact of Information Communication Technologies

This section presents contemporary coverage of the more formal implications of ICT, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be facilitated within organizations. Core ideas such as IT-related training and continuing education as well as the efficiency and effectiveness of ICT in modern organizations are discussed throughout these chapters. Contributions within this section seek to answer the fundamental question of ICT implementation in organizations—how can particular technologies best be integrated into businesses and at what cost? Particular chapters provide methods for integrating ICT into the workforce and offer feedback from employees and employers regarding the future of ICT in the modern organizations.

Chapter 6.1

Holistic Approach to Align ICT Capabilities with Business Integration

ABSTRACT

In this ever faster changing world, organizations have to adapt quickly to changes in the market or its environment. Business integration, within one or between multiple organizations, is one of these changes imposed on organizations. In some cases, information and communication technology (ICT) is an enabler of an effective and efficient integration, but in other cases, ICT is one of the reasons of failure to this integration. In this chapter, a holistic approach to align ICT capabilities with business integration is proposed. In this proposal, a broader perspective is taken in which not only ICT, but also cultural and social aspects, are taken into account.

INTRODUCTION

Business integration is becoming more and more important in the current business landscape due to changing market dynamics, changing legislation, mergers and acquisitions. Business integration, however, does not stand on its own. The need for integration is a demand from the business, emerging from the business strategy of a company, itself derived from the grand strategy of that enterprise.

On the other hand, the need for business integration implies challenges on an enterprise's ICT department and the ICT **capabilities** it puts to the disposition of the business to assist in realizing the business strategy.

In this chapter, a holistic approach for the alignment of **business integration** with the necessary ICT capabilities is described. This holistic approach encompasses the set-up of an interdisciplinary forum (**IF**) whose task is to align the business strategy with the resource strategy and whose output consists of Service Level Agreements (SLAs) for human resources (HR), finance, ICT. The IF is the implementation of the holistic approach and, therefore, it cannot solely be a collection of technocrats. The IF takes into account the mission statement, the vision and the values of an enterprise. Values especially are a differentiating factor between organizations and define the organization's culture, a typical social phenomenon.

For every SLA, a steering plan and steering group is formed, guarding the negotiated SLA. In the holistic approach, the IF further delegates the SLA for ICT to the Enterprise Architecture, which serves as guardian of the ICT capabilities and ICT assets.

In the remainder of this chapter we will discuss the IF in general. Then, we discuss our view on Enterprise Architecture and how it relates to the IF. Following, it is time to tackle business integration's impact on Enterprise Architecture. The theoretical foundations as laid down in this chapter are evaluated against a case. Finally, we conclude with a summary.

THE INTERDISCIPLINARY FORUM

Context

Business integration, be it within the boundaries of one enterprise or between enterprises, is about the business value expected to be obtained through exchanging services and information between **business processes**. How to exchange the information is a technical challenge whose solution depends on the technology portfolio and the ICT capabilities of the ICT departments

responsible for implementation of the business integration. Why and what information should be exchanged are answered by analyzing the business needs. Hence, the information to be exchanged is dependent on the business strategy which, in turn, is an outcome of the grand strategy of the enterprise.

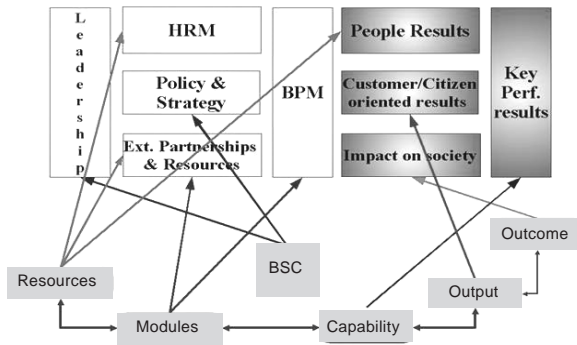

Rabaey, Hoffman, and Vandendorre (2004) argue, through a mapping of military strategy to civilian organizations, that for each resource a resource strategy has to be developed in function of the core business and, in doing so, it will maximize the achievement of the enterprise's main objectives. This resource strategy is, in contrast with the business strategy, not a direct derivative of the grand strategy, but it is aligned with this grand strategy.

Therefore, considering the differences in defining business and resource strategies, an alignment between these two has to be put in place. This is done through setting up an IF, which consists of experts in the field of the business strategy as well as experts from each resource field. The output of this IF is descriptions of services (through SLAs) and Resource Allocation Agreements (**RAA**) delivered by the different resource fields to the core business processes. For that reason, the supportive business units are made accountable for realizing the business strategy.

The discussion framework is based on a self-assessment technique of Malcolm Baldrige, European Foundation of Quality Management (EFQM) and Common Assessment Framework (CAF). These frameworks take topics as strategy, process management, leadership, partners and personnel into account. In the results, indicators are defined to check the critical issues.

The advantage of choosing a self-assessment technique as foundation for the working of the IF is that in doing so, the social and cultural characteristics of an enterprise or network of enterprises are taken into account. Considering **business integration**, the **IF** brings a consensus on (enterprise) cultural differences and establishes

Figure 1. Relationship CAF, BSC, and BPM

an appropriate culture (values) for the particular business processes.

Figure 1 shows the upper part the CAF model, in which Business Process Management (BPM) is a separate criterion. Much attention is given to BPM because **business processes** deliver the **capabilities** to attain the goals set by the business strategy. These capabilities in turn deliver the output to achieve the desired effects (outcome). To be able to compare the effects resulting from a business process with its desired effects, performance management should be integrated.

Regarding performance management, Kaplan and Norton (1996) have proposed the Balanced Scorecard (BSC). The four perspectives in their original work are “financial,” “clients,” “internal processes” and “learning and growth.” The main advantages of this model are its balancing of long-term with short-term objectives, its balancing of financial with non-financial objectives, but above all, the strategy map (cause-and-effect diagram).

Self-assessment techniques, however, overlap a lot with the BSC: ‘BPM’ with ‘internal processes,’ ‘customer’ with ‘clients’; and indicators and initiatives often tend to be the same. Therefore, the BSC should focus on the performance of an organization; however, still balanced: the generation of capabilities and the (operational) use of

these capabilities. This leads to an adaptation of the BSC as introduced on the Second European CAF Event (Rabaey, 2005) and here illustrated in the lower part of Figure 1. That the BSC and CAF complement each other is also illustrated in Figure 1.

The business unit wishes to have effects (*outcome*) in the society (CAF criterion (crit) 8) by giving a good service or product (*output*) to the citizens and organizations (Crit 6). Therefore, it needs *capabilities* (measured by Crit 9), which are generated by *modules* (processes, Crit 5), using resources (Crit 3, 6, 4). The mission statement, vision and values are defined by the managers of the operational strategy (Crit 1, 2). This leads to the following five perspectives in the adapted BSC: outcome—output—capabilities—module—resources. Regarding investments and evaluation of the business unit, this type of BSC is an extension of the CAF implemented in the IF, the IF serving as the global framework.

To avoid the sub-optimal deployment of all resources in the whole organization, a global IF session has to be held at corporate level. The same type of BSC for the business units may be used to guide the strategic leadership of the organization.

Business Architecture as Input for the IF

Business processes are dependent on changes in the internal or external environment. These changes may force the organization to adapt its business processes. A description of the adaptation of the business process, taking the former as well as the new situation into account, must include the process’ desired effect, the SLAs the process provides, the SLAs the process is dependent on and the current **RAA** for that process. This kind of description of a business process is part of the business architecture of that process and will be discussed in depth by Enterprise Architecture.

The description of the changes needed in the business process and the impact of these changes serves as input to the IF.

Decision Process

The IF evaluates the proposals it receives based on the pros and cons of the suggested **business process** adaptation, the cost involved, the **SLAs** the business process delivers, the SLAs the process is dependent on and the RAAs. The evaluation is based on a self-assessment technique; for instance, Malcolm Balridge. The last step in the evaluation of proposals for changes in business processes is prioritization, and from this prioritization choices are made. Once the choices are approved by the decision-maker, elaboration of the changes can be started.

For every resource involved in the change, the steering plan needs to be adapted, the SLAs are refined starting from the embryonic description of the SLAs in the proposal for the change to the business process and new RAAs must be negotiated. This decision process is illustrated in Figure 2.

Worthy to note is that SLAs can be provided by external partners.

Although it is clear that the IF is not an ICT-specific forum, it also deals with finance, HR ..., we limit ourselves in the remainder of this chapter to discussing the cooperation between the IF and ICT.

ENTERPRISE ARCHITECTURE

Enterprise Architecture's Role

Many different interpretations of the term **Enterprise Architecture** exist. These interpretations studied in the **IF** range from, at one end of the spectrum, the list of technological choices made in an organization concerning infrastructure and application design, to the other end of the spectrum, wherein Enterprise Architecture encompasses these technological decisions but also sets guidelines to information architecture and business architecture.

From observations and day-to-day practice in large-scale organizations, we learned that it is a necessity to consider Enterprise Architecture broader than merely infrastructure architecture and application architecture. This necessity stems from the fact that applications are built to support business processes and operate on information gathered through these business processes. Hence, architecture only concerned with infrastructure and application design is insufficient to support a business, because such an Enterprise Architecture has no view on the business and its dynamics and, hence, it cannot take precautions for changing business requirements or the reuse of certain artefacts in other business domains.

For these reasons, we always consider an Enterprise Architecture as consisting of distinguished levels. The naming of the distinguished levels may be different, but at least the general ideas as described hereunder should be part of the **Enterprise Architecture**:

Figure 2. IF: decision process

- Business Architecture
- Information Architecture
- Application Architecture
- Infrastructure Architecture

Business Architecture is about the description of the **business processes** as viewed from a business perspective and not, as is often misinterpreted, an ICT perspective. This description must certainly include how the business process is operated, which tasks or sub-processes are done by people, which tasks or sub-processes are automated, which **SLAs** the business process delivers to other processes, which SLAs from other business processes it is dependent on and what the RAAs involved are.

Information Architecture describes the information on which the business is dependent. This description must pay attention to where information enters the **business processes**, how this information enters the process (electronically or by other means), who is the owner of the information and by whom it is used. A very important artefact in Information Architecture is a matrix describing which information entities play a role in which business processes, which information entities are implemented in which applications and which applications serve which business processes. This matrix is often called the city map. State-of-the-art information architecture is an invaluable asset for Decision Support Systems (DSS) as described by Rabaey, Leclercq, Vandijck, Hoffman and Timmerman (2005b).

Application Architecture is about how to implement the applications or IT systems, the programming paradigms and languages, the development environment, software documentation guidelines, release to production procedures and so forth.

Infrastructure Architecture deals with guidelines concerning hardware platforms, network infrastructure, operating systems and so forth.

A definition for **Enterprise Architecture** taking into account the above requirements is given

by Ross (2003, p. 5): “An Enterprise Architecture is the organizing logic for applications, data and infrastructure technologies, as captured in a set of policies and technical choices, intended to enable the firm’s business strategy.”

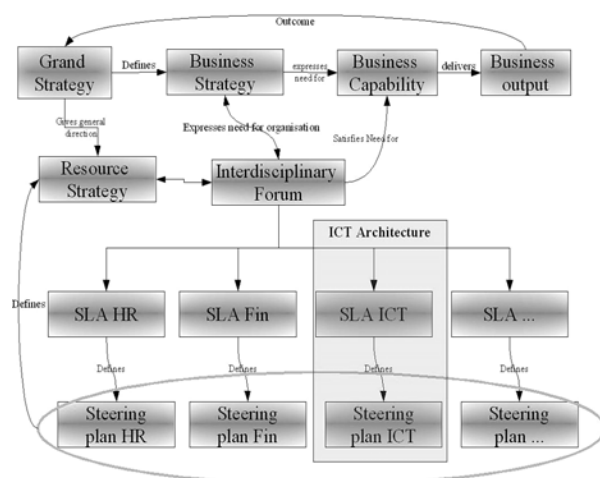

As a consequence of taking the above definition of Enterprise Architecture, the negotiation, implementation and maintenance of the ICT-related SLAs, following from the IF is the task of the Enterprise Architecture.

Schematically this can be depicted, as in Figure 3.

Prerequisites for a Successful Enterprise Architecture

Identifying the need for an **Enterprise Architecture** as a business-supportive entity and giving it the responsibilities to realize its specific **SLAs** as defined in the IF is a major step. But, by itself, that is not sufficient to have a successful Enterprise Architecture. Many other considerations play a role. For Enterprise Architecture to accomplish a successful realization of strategic business benefits, it must satisfy three major characteristics as described by Ross (2004): senior management involvement, project methodology and the level of architecture maturity.

Figure 3. IF and Enterprise Architecture’s role

Holistic Approach to Align ICT Capabilities with Business Integration

First, senior management involvement stretches in time further than the initial planning phase, with active involvement and having knowledge about ICT architectural principles and implementation.

Second, Enterprise Architecture must be built into the project methodology. Every business supporting project formulated through a business case can no longer, as was often the case in the past, be built as a silo application without taking into account past implementations and future directions. This, however, has a repercussion on the way people are used to working, and from change management, it is known that people are quite resistant to changes in the way they work. This again implies that long-time senior management involvement, combined with a change management track, is an inevitable stage to attain a successful Enterprise Architecture. Furthermore, the project methodology should be extended with stages in which enterprise architects validate a proposed solution to an implementation against the set of policies forming the Enterprise Architecture. Again, this is a change in the way of working and is often considered to be a delay for the project at hand.

Third is the level of Architecture maturity, as described by Ross (2003). An organization cannot decide from one day to another to install an Enterprise Architecture. This is a process that

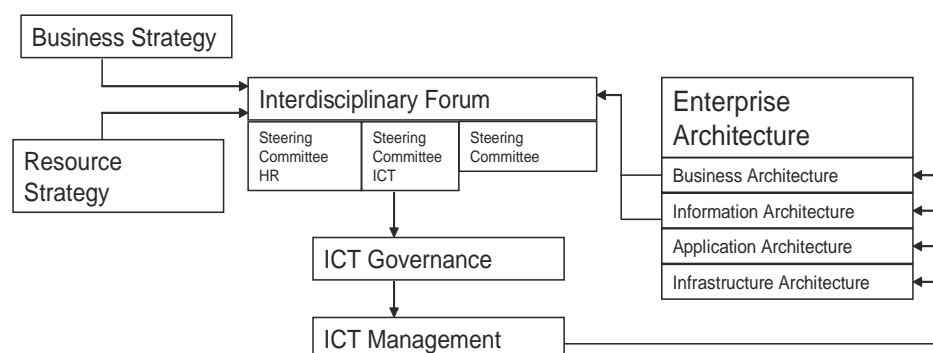

takes quite some time, depending on the size of the organization and the organization's implicit ability to react agilely and flexibly to new conditions. The four stages identified by Ross (2003) are:

Application Silo Stage in which the Enterprise Architecture is just the collection of the architectures of isolated applications, often implemented in different technologies. Integration and information exchange efforts are characterized by being point to point and ad hoc. In this stage, resources are focused on delivering individual applications through own development or vendor package installation. A typical characteristic of this phase is that each application defines its own transactional data.

Technology Standardization Stage as the first step towards an enterprise wide Enterprise Architecture in which technology gets standardized and often centralization is put in place. The deployment of resources shifts from application development into the development of a shared infrastructure. This phase is further often characterized by the introduction of data warehouses and sporadic and not institutionalized business management participation.

Data Rationalization Stage characterized by an expansion of the enterprise architecture to include process and data standardization. The deployment of resources shifts from application development into data management and infra-

Figure 4. ICT Governance in relation to the Interdisciplinary Forum

structure development. The involvement of senior business managers becomes institutionalized and a dialog between business managers and IT becomes common practice. Very important in this phase is the shift of data ownership from IT towards the business. This phase is further often supported by tools like ERP, CRM...

A Modular Architecture characterized by enterprise wide global standards with loosely coupled applications and data and technology components to preserve the global standards while enabling local differences through modules extending the core processes.

How to set up an Enterprise Architecture in practice within an enterprise is described in great detail by Heinckens (2004), based on experiences gathered in the actual set up of an Enterprise Architecture department within a multinational organisation.

ICT Governance

Since the concept of ICT Governance is becoming more and more important in larger organizations concerned with ICT technology, it is relevant to map the suggestions made in this chapter to notions of ICT Governance in industry.

Broadbent et al. state that IT Governance is about who is entitled to make major decisions, who has input and who is accountable for implementing those decisions. IT Governance is therefore not synonymous with IT Management, but is about decision rights, whereas IT Management is about making and implementing specific IT decisions (Broadbent, 2003).

Therefore, the IT Governance processes put in place must be aligned with the Interdisciplinary Forum and will have repercussions on the ICT SLAs and the ICT Steering Plan. Broadbent and Weill (2003) argue that IT Governance combines three components:

IT Domains being the areas where decisions need to be made at the intersection of business and information technology. Five main IT domains

are distinguished: IT Principles, IT infrastructure strategies, IT Architecture, Business application needs and IT investment and prioritisation.

IT Governance styles specifying who delivers input for the decisions and who makes the decisions. Six different governance styles are distinguished, involving different combinations of business and IT executives at different organization levels.

ICT governance mechanisms, which are used to make and enact the decisions. Amongst the frequently used mechanisms Broadbent and Weill (2003) refer to the executive committee, IT councils, the IT leadership group, business/IT relationship managers and service-level agreements.

Combining the observations from Broadbent and Weill (2003) with the principles leading to the Interdisciplinary Forum leads to Figure 3.

The ICT Steering Committee is responsible for the definition of the SLAs and RAAs concerning ICT. In the adapted BSC, as introduced in paragraph "The interdisciplinary Forum: Context", this is the output level. Taking the steering plan as input, ICT Governance defines the tasks for the ICT Management which in turn is responsible for the implementation of the decisions made on ICT level. The day to day follow up of these activities in the four defined architectural areas is the responsibility of the ICT Management.

Service Level Agreements for ICT

Rabaey et al. (2004) define a matrix leading to as well plans for the different business processes in an organisation as for the SLA plans for the different business and business supportive domains. This matrix contains in one dimension the service providers and in the other dimension the service clients. Note that a business process or a supportive domain can act at the same time as service provider and as service client. The SLA plan for ICT is the union of the SLAs ICT has to deliver towards its clients. Figure 5 illustrates this graphically.

Figure 5. SLA Plan for ICT

		Service Providers						
		Business Process 1	Business Process 2	...	HR	ICT	...	External Processes
Service Clients	Business Process 1					SLA		
	Business Process 2					SLA		
	...							
	HR					SLA		
	ICT					SLA		
	...							
						ICT SLA Plan		

As stated in the previous paragraph on ICT Governance the SLA plan is the outcome in the adapted BSC. How the investment or disinvestments in resources and modules should generate the capabilities to be able to come to this output is part of the steering plan for ICT.

Limitations on ICT

Despite the ubiquitous presence of information technology tools, ranging from Business Process management and modelling tools, workflows, programming languages, database management systems... organizations and business users are still confronted with lots of difficulties in automating their processes, just think about the number of projects failing to stay within time and/or budget.

Lots of effort has been put in trying to capture the richness of the business landscape into ICT artefacts, we mention for instance ERP packages, IBM’s San Francisco project, EDI, XML... and still business users are confronted with very limited reuse of very expensive ICT artefacts. This leads us to the question why ICT is still not able to fulfil business needs.

Crucial to the correct working of the automated processes is the correctness, the availability and the quality of the information these processes operate on. This information is fetched and

stored in databases, which get accessed through programs developed aligned with the application architecture and which are stored on the hardware platforms as defined in the infrastructure architecture. From this point of view, it is the database that contains the information the processes rely on. Hence, the database, enriched with programming logic, dictates how information is stored and what the semantics of the information are.

Semantics of information are deduced from business requirements gathering and are for instance described through the use of “Use Cases”. Afterwards these requirements are translated into programming language and database artefacts. This means that the full richness of the business problem at hand has to be written down in programming language and database constructs. The expressiveness of programming languages and databases however is much lower than the expressiveness of natural languages. Furthermore, the relations between software artefacts, be it objects in an object oriented language, tables in a database or the relations to map the objects to the database are not flexible. So it takes a lot of development and testing effort to change relations between software artefacts. This has as a consequence that if for instance a relation between software artefacts is misconceived in the gathering of the requirements, or the relation has to change due to a change in the business process or due to external circumstances (for instance a changing legislation) the database, the access logic to the database and possibly the presentation logic has (partially) to be redeveloped and retested.

As an example we describe what happened in a rather small but business wise significant project. The original project was estimated to be two hundred man-days and was to be delivered within 3 months. In the requirements gathering it was stated and confirmed by the business user that there was “one national representative organisation per country”. In ICT terminology this means that there was a one to one relation between the national representative and a country.

The application was built according to this requirement. During development of the questionnaire, an essential part of the application, where the requirements stated that next to a general list of questions, each national representative organisation had to be able to add specific questions it was discovered that the relation between the national representative organisations and countries was many to many, meaning that one national representative organisation could be responsible for more than one country and that in one country there could be more than one national representative organisation.

The impact on the application was enormous; the total effort due to the misconception of this relation was approximately 20 man-days, being 10% of the initial estimated effort. Even more unfortunately, there was no time to do the necessary changes and an emergency solution was put in place. This emergency solution solved the problem technically but ruined the possible reuse of parts of the application due to the application specific interpretation that was given to certain data in the database.

BUSINESS INTEGRATION’S IMPACT ON ENTERPRISE ARCHITECTURE

Figure 6 gives an overview of the relationships between the different levels of strategy. The Grand Strategy determines the Business Strategy and defines the principles of the Resources Strategy. ICT is part of the Resources strategy. If the Grand Strategy states that synergy with other companies has to be sought, then a principle for ICT may be to conceive an architecture based on open standards or a Service Oriented Architecture.

Business people and Resources delegates meet each other in the Interdisciplinary Forum, where the Operational Strategy is defined. Business processes are designed to achieve the goals (effectiveness) with the most optimal use of resources (efficiency).

Figure 6. Relationship between different strategy levels

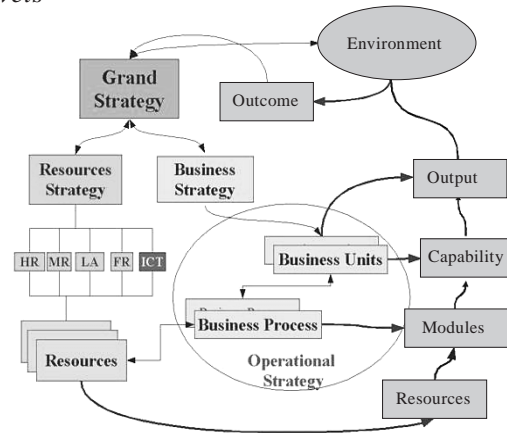

Figure 7. Strategy Integration

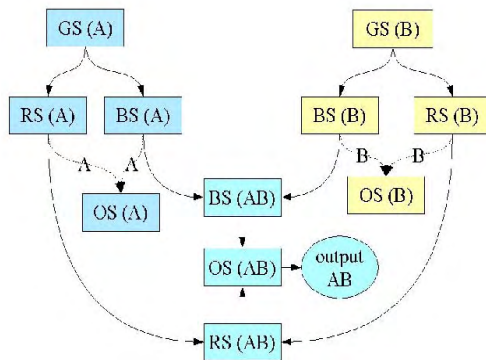

Business integration is about the cooperation of two or more entities acting as a single unit to obtain a certain goal. If for each involved entity the model, as described in the previous paragraph is used, decisions must be taken on the level of integration of business strategy, resource strategy and Enterprise Architecture. The possible levels of integration, looked upon from a strategy perspective, are described in the following paragraphs.

Strategy Integration

By the term “Strategy Integration” is meant the deduction of a common Business Strategy BS(AB) based on the Grand Strategy of two participants A

Figure 8. Strategic Integration

and B together with a common Resource Strategy RS(AB).

We do not further consider the case for Strategy Integration for it means that everything is integrated. The impact on the Enterprise Architecture in this case is that the respective individual Enterprise Architectures cease to exist and merge into a common Enterprise Architecture AB.

Strategic Integration

If the common interest of two or more parties is of such a strategic importance that one or more business processes are integrated and possibly business units are integrated, the term Strategic Integration is used. Its main characteristics are the set up of a common Business and Resource Strategy, next to the individual Business and Resource Strategies of the involved parties. The impact of this kind of integration on Enterprise Architecture is that for the integration purposes a common SLA and Steering Committee is formed which will exist for the duration of the integration effort. Parts of the Business Strategy and Resource Strategy of as well A as B are separated from A and B and put in the common Business and Resource Strategy of A and B. This has as implication that also part of the SLAs of A and B are split of in a common SLA for A and B.

Figure 9. Operational Integration

Figure 10. Operative Integration

Operational Integration

Within Operational Integration, no common Business and Resource Strategy is set up. From the respective individual Business and Resource Strategies of A and B, a common Operational Strategy is deduced. For the Enterprise Architecture this means that again the respective individual Enterprise Architectures of the individual involved parties are conserved, however, in contrast to the case of Strategic Integration, no common SLAs are defined and no common Steering Committee is formed. This has as implication that part of the SLAs for as well A as B contains SLAs for A and B. The same goes for the Steering Plan.

OPERATIVE INTEGRATION

Operative Integration is, looked upon from a strategic point of view, the weakest of the possible

Figure 11. Balanced Scorecard Extension: Capability Generation

forms of integration. In this case, no common Business Strategy, no common Resource Strategy and even no common Operational Strategy are formed. The impact on Enterprise Architecture is that for the realisation of the integration merely interaction standards between business processes have to be defined. For these purposes, no SLA or Steering Plan has to be defined, a merely commercial contract between two or more parties is sufficient.

It is very useful to take another view (see Figure 11 on these different possible forms of integration, based on the adaptation of the Balanced Scorecard of Kaplan and Norton (1996) to non-commercial organisations as described by Rabaey (2005).

For what concerns the set up of the resource strategy for Enterprise Architecture, 5 key management mechanisms have been defined by Ross (2004):

- Clear Statement of ICT Architecture guiding principles
- The writing of business cases for architecture investments (see the case description for BIRB in the next paragraph)

- The forming of an IT Steering Committee
- A one page graphic depicting the high-level architecture
- A technology research and adoption process enabling project architects to align with the Enterprise Architecture

CASE: BIRB

The Company

Within the framework of the agriculture policy of the European Union, the Belgian Office of Intervention and Refunds (BIRB) is a federal agency, which is charged with Interventions, Refunds and Support Measures payments of financial subsidies to economic organisations that are not producers. The tasks of BIRB are:

- **Payment of Refunds:** A refund is a subsidy when agricultural products are exported outside the European Union (EU).
- **Issue of certificates:** A certificate is a document needed for import and export of agricultural products.
- **Management of intervention measures:** An intervention can be a direct purchase or direct support of storage of surpluses
- **Management of support measures:** Support for production, treatment and market promotion of agricultural products

BIRB's business partners are manifold and have very heterogeneous ICT-systems. Regarding business integration, at the strategic integration level, BIRB hosts common applications. Next to these strategic integrations, BIRB has a case for operational integration; however most of the cases are based on operative integration. It is BIRB's strategy to integrate its processes with its partners' processes in order to provide a better service.

Free Food Distribution

Free Food Distribution (FFD) is an instrument of social aid of the European Union. The surplus of agricultural raw produce is transformed into food, which is freely distributed to people in (social) distress.

The policy of BIRB is make every process as paperless as possible (Grand Strategy) and as a consequence to make every process web-based (Resources Strategy). The Free Food Distribution (FFD) has been chosen to be the pilot project to implement the e-Government policy of the BIRB, because it is quite independent from other processes but has the greatest amount of clients.

The first interdisciplinary forum session had as result that to change the manual FFD processes into an “e-government process” (as paperless and Web-based as possible), a Business Process Re-engineering (BPR) (Hammer et al. 1993) had to be performed. A list of possible solutions was presented to the Director-general, who decided on the scenario to be implemented.

Since the process should be almost paperless and web-based, a further business analysis is being performed together with the ICT department and using CAF, before the next interdisciplinary forum session. The chosen solution is based on Service-Oriented Architecture (SOA) and Business Process Execution Language for Web Services (BPEL or BPEL4WS). In what follows, the used evaluation technique is discussed.

Cross Border Business Collaboration

Cross Border Business Collaboration (XBC) is an extension of an Enterprise Application Integration (EAI) evaluation framework as is discussed in detail in Rabaey et al. (2005a).

The integration of processes may also affect other processes. All the processes are catalogued in the Process-Process Matrix (PP-matrix in Figure 12) where the relationships between the

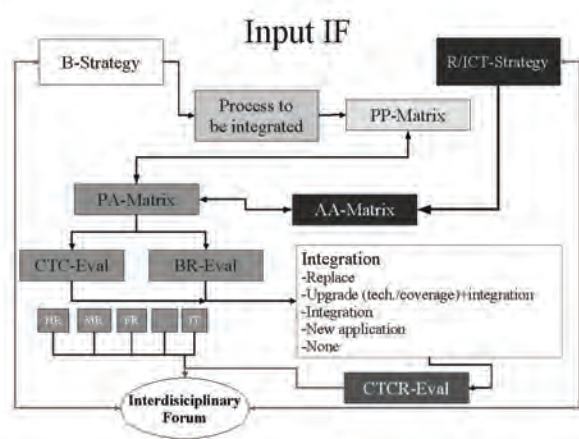

processes are described (supporting, collaborative, etc.). Most of the processes are supported by ICT-applications (noted in Process-Application Matrix (PA-Matrix). The interconnection of applications is mapped in the Application-Application

Matrix (AA-Matrix: file transfer, web services, API, and so on). The PP, PA and AA matrices are an implementation of the city map as discussed in the paragraph on Enterprise Architecture’s role.

When the consequences of the business integration or EAI are known, three evaluations take place. The first two evaluations are a CTC-Eval (Cost-Technical-Coverage Evaluation) and a BR-Eval (Business-Resources Evaluation: detection of Core Business Processes and/or Resources processes). The result of both evaluations indicates which actions should be undertaken. Possible actions are the replacement or upgrade of an application, the integration of one or more applications, the deployment of new applications or no action has to be undertaken. During the third evaluation (CTCR-Eval: Cost-Technical-Coverage-Risk Evaluation) all possible solutions are discussed. The Interdisciplinary Forum in turn evaluates these alternatives in a broader context.

In the case of the BIRB, the introduction of SOA to enable a BPEL implementation of the

Figure 12. Cross Border Business Collaboration

Free Food Distribution had a lot of impact on the existing architecture and on the culture at BIRB. Since the investment decision making process is characterised by uncertainty and incomplete knowledge, the real options approach was used.

The need for EAI rises from the technical side or from the business side of the organisation, which is also the case for Cross Border Business Collaboration. Until now we have discussed the business approach to EAI. The business needs find their origin in a change in the business or grand strategy, in business integration or in business process reengineering (BPR).

Resource-strategy driven EAI/XBC may be due to a change in the resources or grand strategy, efficiency issues (better use of resources), systems that may be technically obsolete or the introduction of new technology. In many cases, ICT is at the base of resource-strategy driven EAI/XBC.

In the latter approach, the evaluation will start with the Application-Application matrix. Via the Process-Application matrix the involved processes are detected. Then the influence on other processes is determined through the Process-Process matrix. It may occur that the business strategy has to be reviewed because of new, possible business op-

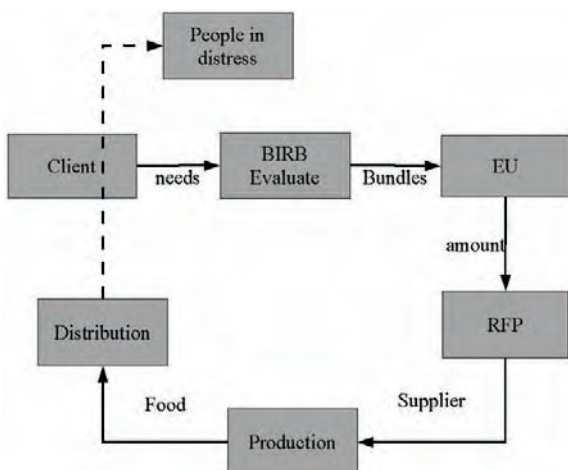

portunities due to the new technology or due to another use of technology.

Once approved by the people responsible for the business (or even grand) strategy, the evaluation of EAI/XBC will follow the same path as the business-driven EAI/XBC. With both approaches a Business/Resources evaluation is guaranteed. The case of FFD was a business-driven XBC. The kind of integration is mentioned between brackets. Figure 13 shows a summary of the phases in the FFD process.

The clients (social aid organisations) express their needs via the portal (operational). These needs are evaluated and bundled in a global demand of Belgium to the European Commission. The official amount of exchange is sent back to FFD. An external party handles (operative) the requests for proposal (RFP). As a result, the list of the suppliers with their respective orders is returned.

In the production phase, FFD collaborates with the suppliers, controllers (operative) and silo-managers (operational). The produced food is delivered to depots of Defence (Strategic), where the clients get the food (operational) and distribute it to the people in distress. So, all types of integration were present and were evaluated with the XBC-method.

Figure 13. Process Flow Free Food Distribution

Steering Plan ICT

In the proposal of Rabaey et al. (2004) the aggregation of all ICT-SLAs formed the steering plan. However by performing the IF with the Free Food Distribution, the impact of Service Oriented Architecture (SOA) on ICT-infrastructure could not be evaluated. Therefore two more plans were added: SLA-plan and RAA-plan. The optimization of the use of ICT-resources in the additional plans enabled the creation of business cases for ICT-infrastructure or global ICT-services.

Other Issues

Before the Business process re-engineering (BPR), only the activities inside BIRB were automated. Due to its interdisciplinary nature, the Interdisciplinary Forum proposed that all processes of FFD should be assessed and supported from the beginning the process (the expression of the needs) until the end (satisfaction of the needs) and not only the own BIRB-activities.

The result of this statement was that each actor in the process was consulted and that his or her environment (social and cultural) was taken into account. In this way, no hostile intrusion in the way of working (integration) of the external partners or actors was felt.

Originally three directors were concerned with FFD. After the BPR, one process-owner was dedicated to manage the processes of FFD (horizontally). The concerned directors give input from their domain (vertically) to the process-owner. Before the BPR, the introduction of a matrix-organisation was never accepted. Due to the Interdisciplinary Forum, every problem of FFD was discussed in a transparent way, which brought the “common sense” at the surface.

SUMMARY

In this chapter a holistic approach for business integration has been introduced with a strong emphasis on the alignment of ICT capabilities with the required business integration. The impact of business integration on Enterprise architecture was discussed along various integration scenarios. An extended and adapted version of the Balanced Scorecard for non-commercial organisations was introduced to define a general integration framework. The set up of the Interdisciplinary Forum, key to successful business integration, has been thoroughly tested in a real life case

within the Belgian Intervention and Restitution Bureau (BIRB) a case which has led to improvements in our original view of the working of the Interdisciplinary Forum.

Chapter 6.2

A Framework for Business Performance Management

Marco van der Kooij

Hyperion Solutions, The Netherlands

ABSTRACT

To manage their performance in a dynamic and complex environment, organizations need forward-looking intelligence. Forward-looking intelligence is the ability to make reliable predictions about where the business is going to and what is driving the business. To produce forward-looking intelligence, an organization should have an insight into its business drivers, an adequate management process, and skilled people able to collaborate and share knowledge. To support the production of forward-looking intelligence, the role of information technology is crucial. However, the existing decision-support infrastructures in companies often fail to support this production. In this chapter, a framework is presented that can be used to structure and organize the production of forward-looking intelligence. This framework also serves as a background for the evaluation and implementation of a supportive ICT infrastructure.

INTRODUCTION

What do airliners and companies in the food industry have in common? An abrupt crisis (9/11 and the BSE crisis) in their respective industries forced them to change their strategy dramatically. For instance, the beef sales of Dutch company Royal Wessanen suddenly decreased to zero in Germany due to the BSE crisis and the media attention about this crisis¹. Another recent crisis—the Enron and WorldCom affair - taught us that integrity, transparency in financial figures and accountability for these figures by top management is vital. As a result of this affair, the creditability of many companies was and still is at stake. Relevant questions are whether organizations could have foreseen such crises and how they should deal with them. The ability of organizations to anticipate events and developments in their business environment and to deal with these events is the main topic of this chapter.

When business volatility increases and market conditions become more aggressive and stakeholders more demanding, organizations should optimize their resources efficiently to meet changing goals and gain or maintain competitive advantage. To do this, relevant information about the business processes and the environment is imperative. Suppose a product manager of mobile phones is introducing a new range of mobile phones that should bring his/her company back into a market-leading role within six months. In order to provide a reliable estimate about the number of phones sold and their revenue, a lot of information is required. How much of the current range of phones has been sold and during which conditions, to whom and when? What is the estimated delivery time? What is in stock and what needs to be produced? Does this have an impact on the production and introduction of the new range? What is the impact of marketing activities for the current and new product range? What is the competition doing? What is the impact of the competitor's activities? What is the impact of introducing the new product range earlier or later? To make the right decisions, forward-looking intelligence is required. Forward-looking intelligence is the ability to make reliable predictions about where the business is going to and what is driving the business. Forward-looking intelligence entails having an insight into business drivers, a management process and skilled people able to collaborate and share knowledge with the systems and organization to support this.

The existing decision-support infrastructures in companies often inhibit, rather than enable, an organization from producing forward-looking intelligence. The underlying systems are departmental in scope, focus on single business functions, fail to integrate in any meaningful business sense, lack process support and are expensive to maintain and modify. In my daily practice I have noticed that the financial consolidation process is used to collect data from the last quarter for financial and management reporting about the

past, with a forecast that has a limited outlook to the future. The data from the consolidation process are of limited use in anticipating the future. These figures are meant for the statutory and financial reporting for some internal and external stakeholders. These figures explain too little about what is really going on in the business itself. Therefore, a forecast is needed, but the currently used forecasting method consists of a limited set of metrics which only grasp at the developments in sales and expenses for the remainder of the year or, if you are lucky, some quarters ahead in a rolling forecast. Just like the yearly exercise of putting a budget together, the value of this forecast is limited, as it is often completed only by the financial department and not by the people who are involved in the business on a day-to-day basis such as account, product and production managers.

Over the last couple of years many companies have invested a lot of money in enterprise resource planning (ERP), supply chain management (SCM) and customer relationship management (CRM) systems to improve operational processes. However, many systems did not meet expectations and some even failed. Next, data warehouses were built to collect data from all these operational systems in order to use the data for management information. Most data warehouses are either not able or not designed to deliver forward-looking intelligence to managers. Information technology (IT) is a core component to produce forward-looking intelligence and to support collaboration between people. The important role of IT is extensively described in this chapter.

To plan and control their organization, managers need timely, accurate and relevant intelligence. To obtain this intelligence, the following questions should be answered:

1. What are the "business drivers" and how well does the organization perform based on these drivers?

2. What are the most important uniform metrics to measure the performance of the company?
3. What does the management process look like for the entire organization?
4. How do people collaborate across all functional areas in the organization and/or outside the organization whenever necessary?
5. Which intelligence systems are used to support the management process and collaboration?
6. Who is responsible for and how is the support of the management process and systems arranged?

These questions enable organizations to manage their business performance. In this chapter each question is described in a separate paragraph. There is also a separate paragraph with guidelines for their practical implementation. This chapter can also be used as a checklist for business performance management and intelligence projects, as the most important aspects are described for initiating and implementing these types of projects.

BUSINESS DRIVERS

Southwest Airlines is the only airliner in the United States making a profit since 9/11. How is this possible? The reason for this is that Southwest Airlines knows exactly what the drivers in its industry are and knows what to do to remain profitable. For instance, the company knows exactly what the utilization is of each route by type of aircraft; which routes by type of aircraft are making or losing money; what the most important cost components are; what its customers' preferred service level is; what the level of customer satisfaction is, etc. The company also compares this information to the industry in general and its main competitors. Based on assumptions about

developments in flight behavior and the number of passengers, Southwest Airlines was able to create reliable scenarios and predictions. These scenarios prompted immediate action to terminate routes, to decide which type of aircraft should be used to control expenses for a certain route and to determine what the effect of these actions is to the profitability of the company. Another reason why Southwest Airlines outperforms its competitors is that it was able to test assumptions, identify bottlenecks and constraints and to solve these using different "what-if" scenarios better than the competition.

An example of a business driver for a company developing and selling software is license revenue. Based on this driver, the company can evaluate its performance compared to the market. License revenue also drives revenues from services to implement the software and maintenance fees for support to assure future investments in development. License revenue is also relevant for the evaluation conducted by shareholders, business partners and (potential) customers to judge whether it's worthwhile investing in this company. Together with the metric days sales outstanding, the business driver license revenue is revealing something about customer satisfaction and the quality of the software. Customers will not pay their bills when the software is not working as expected.

UNIFORM METRICS

Many organizations define and use indicators for monitoring their performance. However, several problems have been found with these indicators. For instance, a lot of companies use too many metrics. This results in an unclear and unrealistic view on what is going on in the business. In addition, when a set of indicators is used, some of them contradict others. An example of this is merged or acquired companies that combine different sets of metrics for performance measurement

without closer attention to the metrics actually required. This can also be the case in companies that changed their strategies (e.g., from operational excellence to customer intimacy) and the metrics associated with the new strategy are not aligned, company-wide, with the new strategy.

To identify the most important metrics, the information matrix can be used. The information matrix is a tool to outline goals, business drivers (BD), critical success factors (CSF), key performance indicators (KPI) and other common metrics. It explains, for each metric, where the data is coming from and which information it provides to whom, how often and by which means. The information matrix is also a tool for collaboration between the business and the IT department. The business users define the metrics and how they want to use them, while the people in the IT department can ensure that the right data is used to calculate the metrics and the appropriate tools are used to present the metrics to the business users in a format they prefer.

The column headings are explained below:

Metrics: In this column, the name of the metric is stated. The name must be unambiguous, common and understandable for every user. For example, the company’s goal is to increase license revenue growth by 10% each year. The business driver license revenue was described

in the paragraph Business Drivers. A critical success factor is what must be accomplished to achieve 10% growth each year. A key performance indicator is the metric to measure performance of an activity to achieve 10% growth each year (Oakland, 1993).

Definition: How is the metric calculated and accounted, e.g., with a formula, a number or a percentage? For example, license revenue is the net sales of all software products in U.S. dollars (thus without discounts). With this definition the metrics are guaranteed to be clear, concise and therefore, can be interpreted by everyone throughout the entire organization and also by other stakeholders when used for benchmarking. The data source(s) from which the metric is calculated must also be defined. This is the so-called mapping of the data.

Dimensions: For which dimensions does the metric have to be calculated? This also defines which slices of the data must be calculated by the metric. A slice is, for example, license revenue by product, by customer, by country or by month.

Level of Detail: At which levels must the metric be calculated? This is also the drill-down path for the metric. For example, license revenue by geographical area drills down from Europe to The

Table 1. The Information Matrix

Metrics	Definition and Mapping	Dimensions	Level of Detail	Domain	Frequency	Means	Scenario
Goal		Time	Year/Quarter/Month	Function	Hour	Paper	Actual
BD		Customer	Customer Group	Person	Day	Report	Budget
CSF		Country	Customer		Week	Dashboard	Forecast
KPI		Product	Product Group		Month	Intranet	MTP
		Supplier	SKU		Quarter		What-if
					Year		

Netherlands, to North Holland, to Amsterdam.

Domain: In which functional areas will the metric be used and for whom is it important? As an example, is it important for the entire organization and all managers or just for the directors and account managers in the sales department?

Frequency: How often is the metric measured? This is relevant to the requirements set for the systems, especially when the frequency is higher (e.g., data delivery and calculation by hour).

Means: How do the users want the information to be delivered and presented? Do they want a reporting tool with figures and graphs in one view, accessible over the Internet or hard copies of the reports? This is also relevant to the requirements of the systems used.

Scenario: For which data categories does the metric have to be calculated and used for variance analysis? For the current (actual) year, this is derived from the operational systems. For budget and forecast, the calculation may vary. For example, the budget is submitted bottom-up by a departmental manager based on top-down targets. Some of the costs such as the total IT costs are allocated to departments based on the number of computers in that department. The forecast is entered and modified over time by account, product or production managers based on their ongoing foresight in the business. Moreover, the budget data can be very specific for each product by customer, while the forecast is entered by customer group and product type. These differences set the requirements for the intelligence systems to use.

There are different methods to get the most important metrics, for example, with the help of a computerized brainstorm. With this method, different people can brainstorm anonymously using computers. Following this, the metrics are categorized into groups and duplicates are eliminated.

Next, they can complete the information matrix together. The selection of the uniform metrics used in the corporation may consist of a combination of different methods used; for example, value-based management, balanced scorecard or activity-based management (Geishecker, 2002). The use of these methods for the company's strategy is described in the paragraph Intelligence Systems.

To satisfy managers' constant need for intelligence, the information matrix can be used. It enables the definition of a set of uniform and common metrics and supports their utilization to measure the performance of the company over time. However, for this purpose, it is vital to keep the information matrix updated. The use of and the responsibility for the information matrix should be incorporated into the organization. This will be described in the paragraph Responsibility of this chapter.

THE MANAGEMENT PROCESS

At any level in the organization—top-management, departments or teams—management processes are essentially the same, no matter what aspect of the organization is being addressed. Management can be seen as a cycle consisting of six sub-processes (see Figure 1) (Hyperion, 2002). This cycle is not necessarily unidirectional, since interaction and collaboration are required at every step of the process to ensure success. Common, consistent information (the “shared information” hub in the middle) is required to ensure that all decision makers are working with the same information. The six fundamental processes are:

- **Goal-setting:** defining and confirming the criteria and measures for successful performance of the management process that bring together long-term business strategies and day-to-day business operations.
- **Modeling:** identifying the business drivers and determining the relationship between drivers and predicted results.

- **Planning:** establishing a set of actions or targets that are designed to meet the business goals.
- **Monitoring:** acquiring and normalizing internal results, key performance indicators and external influencing factors (e.g., market or economic events), triggering alerts and responding to exceptions at any given point in time.
- **Analysis:** gaining insight from results and variations in predicted outcomes and using this information to improve the process.
- **Reporting:** providing information in an expected, predefined format.

It is critical that this approach of the business management process is fully supported by the intelligence systems, as described in that paragraph. It is important that realistic goals and objectives are set and that business models are used to test different scenarios and to validate plans. As plans are executed, it's necessary to

constantly monitor the progress and not just the outcomes. If there are variances in the metrics used to measure performance, plans need to be adjusted to ensure that goals are met. End results need to be analyzed and compared to the original goals to discover deviations and variances. All information can be used to explain the reported results and to adjust models for future success. By using this approach, continuous business improvements can be applied to an organization. For example, based on the strategic target of 10% growth in license revenue, the marketing department has a goal for the number of leads to provide to the sales department. Based on the assumptions and constraints (budget, employees, etc.) modeling is conducted to determine how many campaigns by which media can be executed and what the potential results will be. After that, the best and most likely scenario is transformed into an operational plan. The outcome of the plan is monitored against the actual results. If differences are detected, they are analyzed to find out their

Figure 1. Management Process

causes and these are reported in order to make adjustments and improvements.

In the financial domain this process is known as the planning and control cycle (Mintzberg, 1994). Here it is called the management process, as this cycle applies to every manager in the entire organization. Managers secure the control aspect (monitor, analyze and report) through procedures and systems with internal checks from the financial domain and external checks from the auditor. The planning function is gaining importance, as previously mentioned, with the rolling forecast. Operational managers, who are close to the business, complete the rolling forecast. In this way, a more frequent and reliable picture of what is going on in the business and the company's own position in the marketplace can be provided. A change is expected from the annual budgeting process to a monthly or even more frequent rolling forecast process. Eventually, the creation and completion of the budget will be obsolete and completely replaced by the strategic planning process and the rolling forecast.

The need for an increase in speed within the management process is an additional issue. The entire management process needs to be performed faster, especially when certain events happen and thus render the current budget and forecast irrelevant. Corrective actions must be taken quickly to avoid the company from being outperformed by the competition. This means that the planning function should be closer to the business and outside the financial domain where it often is today. The financial domain facilitates the planning process with models and systems, at most.

COLLABORATION FOR ALIGNMENT

The definition, testing and translation of strategic goals into daily operations usually start with mid-term planning for several years. In today's business environment, looking forward several years is hardly possible, with the exception of scenario

analyses (Vijverberg, 1993), and has even been mentioned in press releases detailing the financial results of various companies. Moreover, increasing numbers of managers are becoming involved in the whole process at the same level and also in other levels of the organization (see Figure 2). In the planning process the output of the operational plan from one unit is the strategic plan for another unit. The same applies for control. The reporting from one unit is part of the monitoring of another. Information must be shared in the whole process and between processes to anticipate and take actions whenever events happen. This means that the process must be faster, more iterative and more interactive to ensure better collaboration between managers. The targets of the sales department mean that marketing has to supply them with enough leads. When this doesn't happen, the sales department needs to act in order to still realize its sales target. The sooner the sales department knows something is not going as planned, the faster it can act accordingly.

Shared information for collaboration is the reason why the use of uniform definitions for metrics is essential; for example, what is the definition of a lead and do sales and marketing use the same definition. Otherwise it is very difficult to share information and experiences. Subsequently, process management is also important. When hundreds or thousands of managers are involved in the rolling forecast and managers depend on the outcome of another unit, then the workflow of the process must be supported and managed. This sets requirements for the systems used.

Any business manager has five fundamental responsibilities which make up the management environment:

- Strategy setting and leadership (goals, targets, direction);
- Finances (budgets, expenses, capital requests);
- The people who make up a business (teams, business units);

- Products and services that are provided to customers;
- Customers.

The top management (leaders) of the company establishes the goals and objectives. Divisional and local management teams need to work together to make sure those goals and objectives are realistic and obtainable. Enterprise-wide collaboration is required to optimize all aspects of the business for success. This means that managers must work across domains and alignment is essential, both between domains and from top to bottom and vice versa (see Figure 3). For instance, the sales forecast from the commercial domain determines the demand planning for production in the production domain. Consequently, the production determines headcount planning and/or recruitment and the budget for hiring new employees or investments in equipment when the workload becomes too high. Obtaining insight into business issues across

domains sets requirements for the systems used and for the use of uniform definitions of common metrics (Oakland, 1993).

INTELLIGENCE SYSTEMS

Information technology plays a very important role in today's business and in managing the business. The first part of this section describes the developments in IT for supporting the management process. In the second part, the components of a framework for business performance management are described.

As shown in Figure 3, applications in the management environment use data coming from operational systems. These systems are used to store transactions such as sales orders, flight reservations, payments, etc. In many companies these transactions are also stored in a data warehouse to be used by managers to make informed decisions

Figure 2. Collaboration is Essential

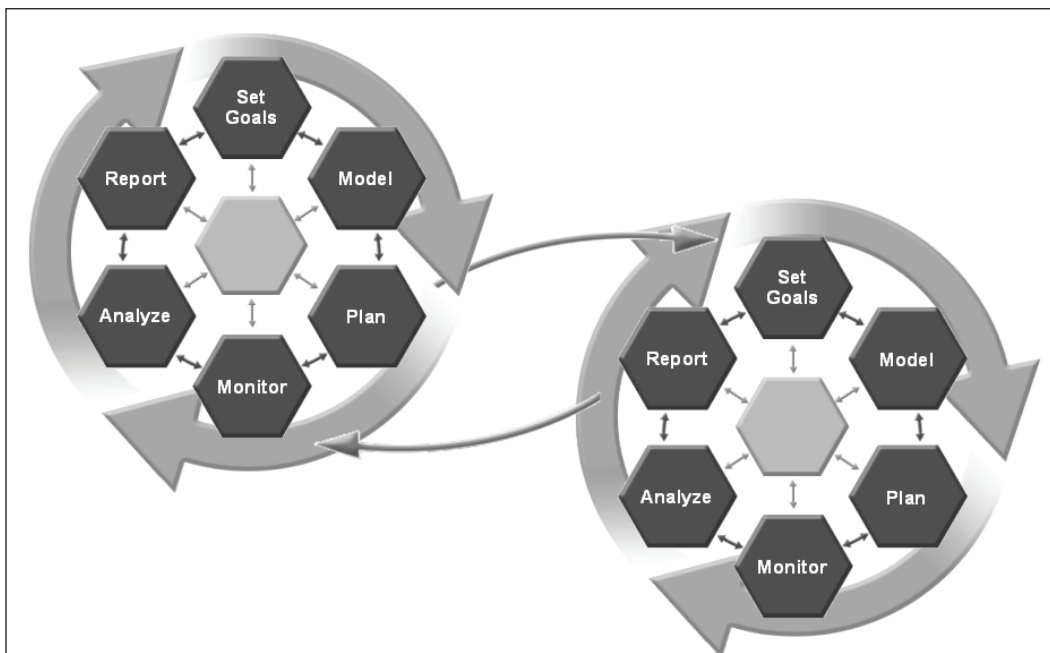

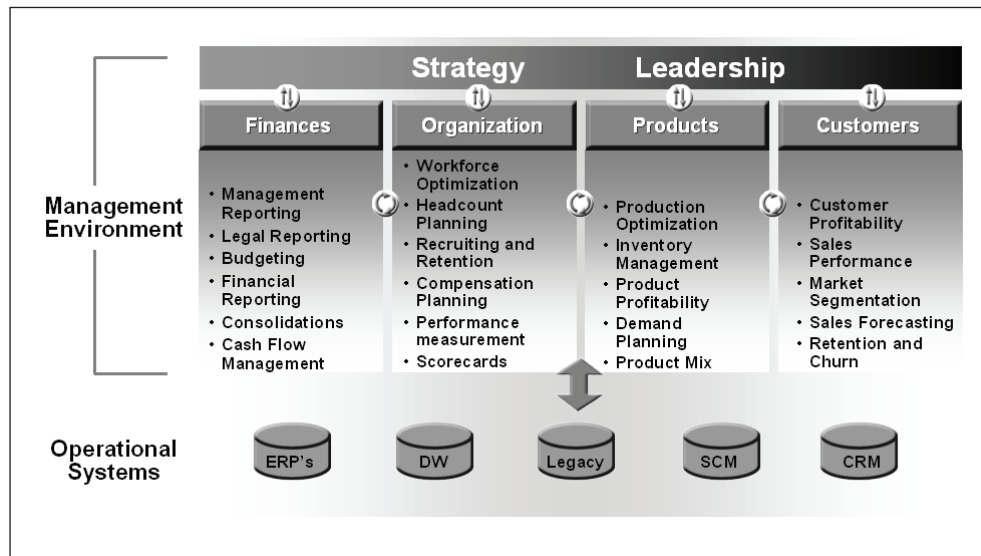

Figure 3. Collaboration Supports Management Responsibility and Alignment

and set actions. Often external data about market shares, competitors, the weather, etc., are added. Managers need this information to do a better job, achieve unprecedented, better results and to surpass the competition (Porter, 1985).

Business changes every day. Managers need information to anticipate changes no matter where this information comes from, as long as it is reliable. This information must support the management process and collaboration (Vijverberg, 1993). Today, in many companies, data are stored in separate systems for each domain or even in totally different and unintegrated applications in a specific domain. Spreadsheets and PowerPoint presentations are also widely used to store strategic information used in the management process. This software is not designed to assure uniformity in metrics (formulas can easily be changed) or to be used simultaneously with other users. When data warehouses and/or OLAP tools (OnLine Analytical Processing) are used, these systems are often only used in a specific domain or in a certain unit, consisting of historic data to report and analyze what happened.

Companies such as Southwest Airlines and Royal Wessanen are transforming from business intelligence to business performance management. Business performance management² describes the methods, metrics, processes and systems used in organizations to translate strategies into plans, monitor execution, and provide insight to improve financial and operational performance. It represents the strategic, integrated evolution of business intelligence (BI) to support the management process. To support management decisions there must be (see Figure 4):

- A proactive approach to decision-making;
- Collaboration between peers;
- The use of information to support management decisions;
- General use for all decisions;
- An enterprise-wide approach for managing a business;
- A unified approach to the business and its information.

Business performance management is beyond historical data delivery; it is about managing the

Figure 4. The Evolution to Business Performance Management

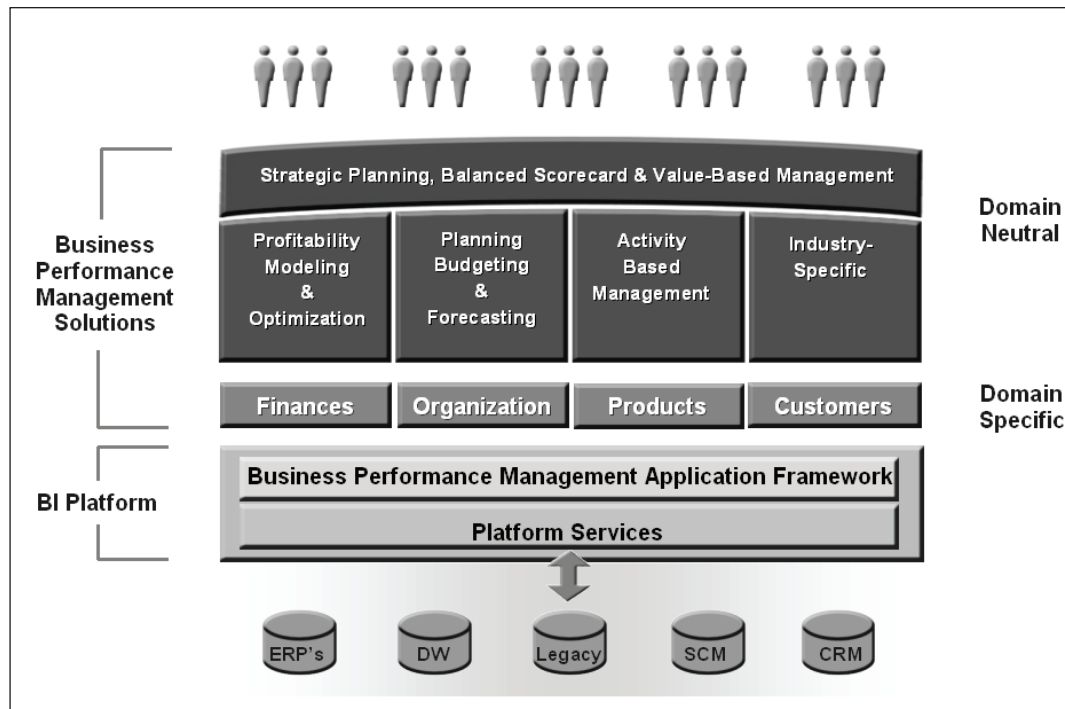

business with information. It automates and supports the workflow and decision-making involved in management. This is marrying intelligence and the management process in order to measure performance and drive profitability. The goal of business performance management is to drive business performance by supporting organizational goals to:

- Identify and exploit opportunities for investment, growth and profitability;
- Optimize deployment of organizational resources for maximum impact on the bottom line;
- Simplify the execution challenges of organizational strategy.

This means that a question such as: “How to increase profitability by 10% every year?” has huge consequences for almost every manager’s business. The impact of such a question is enormous. Answers to such questions do not come from operational systems or data warehouses. To fulfill managers’ ever-changing demand for information, requirements are set for the intelligence systems to be used.

As mentioned earlier, requirements are set for the intelligence systems to be used. These requirements are determined by the use of forward-looking intelligence based on uniform metrics in order to fulfill the ever-changing demand for management information, to have access to data and information no matter where it comes from, to provide all stakeholders such as customers,

Figure 5. Framework for Business Performance Management

suppliers and partners with access to required areas of the system, to support the management process with workflow and to support and manage the collaboration between people. The net result of this is to stay ahead of the competition in a very dynamic market. To achieve this, a business performance management framework must be in place to support strategic and operational decision-making (see Figure 5).

How can systems help to dominate the business instead of being dominated by others in the marketplace and to understand what really drives the business? Also, how can they help test scenarios based on trends and business drivers in order to be prepared and to adjust the company’s strategy when unexpected events happen? As previously stated, it all starts with the need for forward-looking intelligence. This intelligence is not available in operational systems and data warehouses. That

explains the need for an additional business intelligence platform (BI platform), in which values are calculated based on assumptions, bottlenecks, constraints and the collective experience available in present and historic data.

The business performance management framework consists of different layers and these are described below.

Platform Services

These consist of a number of components for the integration of data from operational systems, the administration of users, applications (dimensions and metrics), distribution of information and enterprise-wide collaboration of the company’s internal and external users. In brief, this is the technical fundament of the platform. The most important services are explained below.

Interoperability Services

Interoperability services are the most critical part of the framework in order to apply business performance management enterprise-wide. These services enable the collaboration between the different applications used for the sharing and mapping of uniform definitions (metadata). They offer version control: who changed what, when and why? Furthermore, these services enable the promotion of changes to applications from development to testing and production.

Applications do not have to be from the same supplier for collaboration to work between them. Open standards, such as XML (eXtended Markup Language), XMLA (for Analysis) and XBRL3 (eXtensible Business Reporting Language) are used to exchange metadata and data. Therefore, it is important that the applications can support these open standards to ensure the use of uniform definitions, metrics and information enterprise-wide.

Analytic Services

This component deals with the analytic power and the applied technique to offer an enterprise-wide scalable solution. Analytic power is required for calculations and business rules to calculate the derived values used as management information, which is not available in operational systems; for instance, derived values such as market shares for individual products or services by group of customers, profitability by customer and product or complex statistical calculations for scenario testing. Therefore, it is essential to enter assumptions into the BI platform to calculate results quickly. To have write-back capabilities to the BI platform is also important for the rolling forecast. The rolling forecast is often entered on a different level of detail than the data in the operational systems or for top-down targets, or other amounts are allocated based on predefined drivers. It is

even better to automatically process data from reports of industry analysts, news agencies or even competitors for a new forecast to see what the impact on the business will be, and in addition to that with proposed actions to take in different what-if scenarios with the impact of these proposed actions. In this case managers can decide very quickly about what to do and communicate with the people involved.

The applied technique is relevant for the storage of mass data. Is the data stored in the OLAP environment or can this be done in combination with relational database technology (Hybrid OLAP)? This is of great importance for analyzing millions of customers. The storage of data also has an impact on the platform to be used. Next to Windows, are Unix, Linux or a mainframe computer also viable options to store and calculate data and metadata? Is the use of multi-processors supported in order to achieve acceptable performance of complex calculations? Any failure resulting from the use of software and systems is often caused by the lack of using them. If users have to wait too long for answers to questions then they look for other ways to get answers.

Query and Reporting Services

End-users do not care where their information is coming from. They want acceptable performance and the software must be easy to use. Therefore, the use of Internet technology is crucial, as information must be disseminated worldwide in a reliable, secure way, internally in the company and also externally to stakeholders such as shareholders, customers, suppliers or business partners. In addition to all types of graphical features for presentation purposes, three things are critical to the end-user:

1. The information must be provided proactively based on triggers such as an alert on the screen or by e-mail. Users have access to Internet or e-mail everywhere, even with

their mobile phone. An example of a trigger is when net working capital increases due to the submitted forecasts and exceeds the acceptable bandwidth;

2. The information must, preferably, be presented in a single and central place for the end-user via a so-called “portal.” In this way, the developments in the manager’s area of responsibility are instantly clear. From there on, quick and easy drill-down should be performed to find the cause of the increase of net working capital. After that, actions must be taken to solve the issue before it actually occurs;
3. Both quantitative and qualitative information must be available. When the net working capital indicator increases due to the introduction of a competitive product and damages the sales of your products, then, for example, the press release information from the competitor is also available as an explanation. The beauty of Internet technology is that different types of information are easy to present together, regardless of where the information is stored.

The information matrix can be used to determine which users need which information delivered and presented and in what way. This should be taken into consideration when disseminating the information.

Integration Services

In the case of huge amounts of data, it is common, for integration purposes, to load this data from operational systems to data warehouses and between applications automatically. When a data warehouse and an ETL tool (Extraction, Transformation and Load) are used it is an advantage to incorporate this into the BI platform. Before data is loaded into a data warehouse it is cleansed, unduplicated and validated to improve and assure the quality of the data. For example, in

the case of a mobile telecommunications company all connections must be unique and all data must be associated correctly with each connection, such as personal, billing, payment and contract data. Part of this data will be used in the BI platform and domain-specific applications. This data has to be integrated easily and maintained from the source system or from a central repository. Additionally, if more detail is required in the BI platform this must be readily available to the end-user. For instance, when a number of customers withdraw and defect to the competition: what are their demographic characteristics and in what way are they the same? Action has to be taken before other customers with similar characteristics defect as well.

The openness and integration facilities of the BI platform are very important for setting up new applications. A lot of data is stored in all types of different systems, from “small” databases and spreadsheets to massive, inaccessible (proprietary) databases of ERP systems. As data from different source systems becomes easier to load automatically, the shorter the time for implementation will be and results will be shown quickly to the end-users.

Administrative Services

Maintenance of the BI platform and applications is another relevant component in order to run a complex system used worldwide. Here too, open standards are recommended, as these standards are already being used a lot in the company. The advantage of this is that knowledge is available and it is fairly easy to acquire new employees to assure continuity. Administrative services also include the workflow and control of the management process. This needs to be aligned with the current working method of the organization and not the other way around (i.e., business process redesign in the 80s and 90s in order to use certain ERP systems).

Application Framework

The application framework offers the option to develop applications based on building blocks so that rapid development is possible. These building blocks contain preprogrammed intelligence necessary for an analytic environment. In this way, developing applications from scratch is prevented and applications can be delivered on time and not when the original specifications have become obsolete. Critical business information must easily be available. Examples of applications are mentioned in Figure 4; however, some other examples are: inventory turnover analysis, route profitability, product sales analysis and employee compensation analysis. An application framework is useful for company or industry-specific applications which are not ready-made available or which require a very large investment.

On top of the application framework, different, ready-made applications are available. These can be divided into domain-specific and domain neutral applications.

Domain-Specific

There are, for every domain, applications available in the market such as the ones for financial consolidation or churn analysis. The major advantage of a domain-specific application is the ready-made availability of the accumulated knowledge and experience in it. This shortens the implementation of these applications considerably. Consequently, the danger of separate domain-specific applications is that each has its own definitions; for example, the marketing and sales departments use a different definition of net sales than the people in the finance domain. These applications must be aligned and integrated within the whole framework in order to make management decisions and to set actions. As mentioned earlier, the result of the sales forecast has an impact on the demand planning for the production process, etc.

Domain Neutral

The strategic management of the organization involves the methods used and the management process (Geishecker, 2002). Value-based management has an impact on the entire organization, as all activities must add value to the company. Companies are increasingly focused on profitability by customer and product or service. That is one of the reasons why activity-based management is also used in marketing and supply chain management. As stated earlier, the forecasting process has an impact on all managers with revenue and expenses responsibilities. The readily available, relevant information from people who are close to the business is crucial in order to act fast and stay ahead of the competition. These aspects and automating them are the responsibility of top management, so they increase transparency and their accountability for their activities to all stakeholders.

RESPONSIBILITY

Previous paragraphs have described the use of uniform metrics, a management process and the intelligence systems within a framework. To ensure that users are enabled to work with this framework a company requires organization and procedures to accommodate this. Furthermore, one person should be given ownership and responsibility for the framework. Where that role fits into the company is difficult to answer, as every company is different. From my experience at a number of multinational companies in The Netherlands I saw that the domain neutral applications were initiated and facilitated functionally by the finance domain. Employees from the IT department were available or even added for technical support. The advantage of the financial domain is its broad experience with automation of financial management information and that most

A Framework for Business Performance Management

applications in the management environment are financially driven. Also, a lot of the methods used, such as value-based management and balanced scorecard, originate from the financial area. The finance domain consists of an internal network within the organization, with local controllers and accountants who are accustomed to working together in the financial reporting process. However, this could not succeed without the support of the IT department. Firstly, this is because current standards (technical and procedural) applied in the organization must be used as much as possible to assure continuity. Secondly, the use of Internet technology and the related security issues is work for specialists. Thirdly, technical people are needed for the development of domain-specific applications, together with people from the domain concerned, based on the company's framework.

Ideally, a separate, organized group of people in a department should be available for the following activities:

- Control of the framework's content based on the information matrix (not to determine the content, as this is done in cooperation with the business users and senior management);
- And to translate this into improvements for current and new solutions;
- To monitor the alignment of the systems used with the management process;
- To accelerate and facilitate the use of applications;
- To take charge with new initiatives;
- To deploy and test scenarios and to conduct complex ad hoc analyses for strategic planning;
- To manage the technical realization and technical control of the BI platform and applications based on company standards;
- To monitor the quality of the metadata, data and performance of the systems used;
- To have a liaison role between business users

and the IT department for the management environment.

The following rule of thumb can be applied to this department's reporting within the organization and in the following order: in a business driven commercial company, to the Marketing and Sales Director. If another domain is very important for the business, like manufacturing, and there is a collaborative environment then place it there. In a financially managed company with also a focus on management reporting it is wise to report to the Chief Financial Officer. If IT is the only department with an overview in the whole organization then place it there with a reporting line to the Chief Information Officer (Buytendijk, 2001).

GUIDELINES

From experience and research, I have discovered some useful guidelines on how to start and implement a business performance management framework. These guidelines are as follows:

1. Bring together a limited number (eight to 12) of key users of management information in a workshop and use the described management process to make the following clear:
 - How well is the current process compared to the process described in the paragraph The Management Process?
 - Which reports and analyses are used in the different steps of the management process?
 - What is the content of these reports and analyses and how relevant are they? This is used to gain insight into business drivers and metrics.
 - Which methods are used enterprise-wide and per domain? Check these according to relevance for business drivers and the most critical metrics.

- Which forward-looking information and metrics are missing?
- How are reports and analyses made and with which systems?
- How is information shared and how do managers collaborate?
- How are the metadata, definitions and data integrated?
- Who is responsible for which systems and which activities are associated?
- What are the company's standards for business intelligence and which of them meet the requirements for the business performance management framework?

It is important to have people participating who are able to look further than their own domain and to realize that the impact of their daily business activities also has an impact on others within the company. If participants are only focused on their own needs then a company-wide view and the creation of alignment is hardly possible. It is advisable to facilitate this workshop with experts in order to prevent people from going into too much detail. By staying focused on the main topics the company's current position becomes clear very quickly. Document this carefully and use this document to find a sponsor from top management: someone who believes in forward-looking intelligence and wants to be able to respond faster in case of events (and feels that this is lacking). This step is also necessary for financing the program and supporting an enterprise-wide implementation.

2. Determine the ultimate goal of the program and then determine the gap with the current situation from Step 1. Construct, with the help of experienced people, the roadmap to execute the program. Divide the program into separately manageable projects and prioritize based on the biggest problems in the organization. For instance, by missing the

forecast due to myopia, insufficient insight into the company's own market position and market trends, a lot of companies are afraid to make announcements regarding future results. Therefore, companies themselves do not know how to proceed and are punished by the stock market. This causes problems for financing future growth to sustain or improve their competitive positioning.

3. Ensure the provision of quick and visible results. Start with the 10 to 15 most important metrics for the company. Make sure that the source data is available and use cleansed data so there is no doubt about the quality of the data. Present the metrics to a larger group of key users with a professional tool. Then broaden the scope by number of metrics, end-users and further into all domains. Make use of external experts wherever necessary to acquire knowledge and experience for future projects. I was the external expert for a company due to the people in the company having hardly any experience with a BI platform and business performance management applications. By using a framework and a roadmap it was clear for them (business users, IT department and the external software implementation partner) on how to proceed step-by-step with minimal risks.
4. Have guts and perseverance. The management process is more flexible than the primary process. It is a challenge to support the management process with systems. Operational systems are strict because of the unambiguous primary process, whereas intelligence systems must be very flexible. It is unknown, beforehand, to which questions answers must be given. Use this as a fact when exploring the management process, developing applications and implementing systems. The support of the IT department is key for the technical infrastructure of the framework. The more the framework fits into the current standards and procedures of the

A Framework for Business Performance Management

IT department the better it is. Nevertheless, flexibility from the IT department is also important because the needs of managers change every day. It is better to be equipped for that than to fight change every day. So make sure that the IT department is aligned as well.

5. Establish a separate department within the organization to secure the maintenance and the use of the framework, as stated in the previous paragraph Responsibility.

CONCLUSION

How bright is an organization in anticipating and specifically responding to events which have an immediate impact on profitability and competitive positioning? In this chapter, an approach to this issue is formulated: a business performance management framework. This framework contains methods to derive real insight into the business (drivers) and to get a grip on giant and complex organizations by means of a specific management process. In this process, it is imperative to use uniformly defined metrics and IT systems to supply forward-looking intelligence so people can collaborate for the success of the company. It is essential to root this firmly within the organization in terms of people and procedures to assure alignment and to gain and maintain the required knowledge. There are guidelines provided to start and implement a business performance management framework. With these guidelines, it is possible to start smart and provide results.

Chapter 6.3

Neural Data Mining System for Trust-Based Evaluation in Smart Organizations

T.T. Wong

The Hong Kong Polytechnic University, Hong Kong

ABSTRACT

Nowadays, many enterprises manufacture and distribute their products or services globally, and quite a number of smart organizations are formed on the Internet and are expected to evolve to a strategically important e-business model. Although information and communication technologies (ICT) and knowledge management plays an important role in linking the core and partner companies, it remains subservient to the humans that form the smart organizations. This chapter identifies two instances in which trust-based evaluations of partners in the smart organizations are applicable. A review of the literature indicates that neither researchers nor practitioners agree on a single model of interfirm trust that applies to all partner evaluation contexts. A decision-support system based on neural network and data mining technologies is proposed. A case example is given to illustrate a trust-based evaluation in real situation.

INTRODUCTION

Fostered by the rapid and ever-increasing pace of development of information and communications technologies (ICT), a new digital economy is emerging around the globe. In this new digital economy, small and medium enterprises will have more chances than ever before to play a role alongside the big players. Since the Internet is being adopted as the most important global communications infrastructure, and because global knowledge is becoming accessible by everyone with Internet access, the digital economy will be characterized by radically new forms of business relationships and will have a profound effect on the way we work and live.

The current business environment can be typified by continuous pressures to change and the shortening of product development times and product life cycles. Markets are fickle and strongly customer-led, with unrelenting pressures to bring down costs and to take advantage

of innovative technologies. Many organizations look to new organizational structures such as the smart organization to enable them to cope with these changed conditions. As computers rapidly shrink in size, ICT are becoming ubiquitous and invisible. Organizations preparing to go digital need to recognize the implications this transition will have on their business processes and organizations as a whole. Besides setting up the digital infrastructure, organizations need to be able to:

- enter into virtual global internetworked collaborations
- manage transition and adapt quickly
- leverage human capital to optimize performance

In other words, organizations need to get “smart.” The characteristics of a smart organization (Filos & Banahan, 2000) adopted in the present context are:

- internetworked
- dynamically adaptive to new organizational forms and practices
- knowledge and learning-driven
- hierarchically flattened where the individual’s skills, intellect, and knowledge, are recognized, valued, and leveraged

In the past, it was more cost-effective to own all aspects of the value chain—vertical integration was the business model of choice. In today’s global market, focus is critical. Owning the value chain may actually put an organization at a competitive disadvantage due to the lack of flexibility and financial commitment true vertical integration represents. Selecting the right partners and nurturing these relationships can help a company focus on what creates the most value for customers and concentrate on its core activities. Smart organizations also offer versatility. They create new, viable market options and allow companies to deal more effectively with the uncertainties

and complexities of today’s highly competitive global market.

Following Jarvenpaa and Leidner (1998), a global smart organization can be defined as a temporary, culturally diverse, geographically dispersed, electronically communicating work group. The notion of temporary in the definition describes teams on which members may have never worked together before and who may not expect to work together again as a group (Lipnack & Stamps, 1997). The characterization of smart organizations as global implies culturally diverse and globally spanning members that can think and act in concert with the diversity of the global environment (DeSanctis & Poole, 1997). Finally, it is a heavy reliance on the integration of information and communication technologies (ICT), knowledge and organizational networks that allows members separated by time and space to engage in collaborative work. The reasons that smart organizations are becoming so prevalent nowadays include low overhead, flexibility, minimum investment, and high productivity. By owning few resources and focusing on the organization’s expertise, the company can keep high levels of productivity while allowing its partners to do the same. Both the partners in a smart organization and the individuals who work for the partners are allotted greater flexibility. The partners can focus on core competencies, while individual workers may have the ability to telecommute from their homes. In a smart organization, companies are linked by the free flow of information. There is no hierarchy, no central office, and no vertical integration: just the skills and resources needed to do the job. Each participating company contributes what it is best at. It can be seen that since no single company will have all the skills necessary to compete in the global electronic market, these arrangements will become the norm. One of the keys to the success of the smart organization is the use of ICT to facilitate these alliances.

Creating a smart organization takes more than just the ICT. A recent study on issues of information technology and knowledge management concluded that there is no evidence that ICT provides options with long-term sustainable competitive advantage. The real benefits of ICT derive from the constructive combination of ICT with organization culture for learning and innovation, supporting the trend toward more flexible forms of organization. Information technology's power is not in how it changes the organization, but in the potential it provides for allowing people to change themselves. Creating these changes, however, presents a whole new set of human issues. Among the biggest of these challenges is the issue of trust in system security and trust among partners in the smart organization. It has been reported that the lack of trustworthy security services is a major obstacle to the use of information systems in private business (B2B) as well as in public services, and trust is closely linked to consumers' rights, such as security, identification, authentication, privacy, and confidentiality (Mezgar & Kincses, 2003).

In the following sections the importance of trust in the operation of a smart organization will be described, and suggestions on trust building and discussion of the trust problems associated with ICT system security and smart organization partnering will follow. A trust-based evaluation of smart organization partners using the neural network and data mining technologies will be given.

IMPORTANCE OF TRUST IN SMART ORGANIZATIONS

While technology seems to provide sufficient safeguards, such as digital signatures, encryption, web seal assurances, and standards that provide technology-based security and trust mechanisms at present, there seems to be a perception by businesses that transactions conducted specifi-

cally via the Internet are insecure and unreliable (Bhimani, 1996; Raman, 1996). The findings of a recent electronic commerce survey that examined the adoption of electronic commerce in Australia and New Zealand indicated that there is still an initial slow growth of Internet business to business electronic commerce within the Asia Pacific region as compared to United States. This is due to perceived risks in the security of business to business electronic commerce transactions and trust of the trading parties (KPMG, 1999). It seems as if despite the technical assurances, trading partners in business to business electronic commerce do not trust the "people side" of the transactions. Parkhe (1998) suggests that this is due to two types of uncertainties: uncertainty regarding unknown future events, and uncertainty regarding trading partners' responses to future events. It is in this environment of dual uncertainty that trust becomes an important element in the effective operation of smart organizations.

Trust has long been of interest to a variety of researchers. Mayer, Davis, and Schoorman (1995) define trust as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party." Trust among partners is critical for smart organizations. Without trust, commitment to the goals of the virtual organization can waver, as members perceive the alliance as weak or disintegrating, fractured by misunderstanding or mistrust (Handy, 1995). Trust is particularly important in networked organizations that require constant and close attention to shared commitments to safety and reliability, as well as a shared willingness to learn and adapt. It has been suggested that trust permits an organization to focus on its mission, unfettered by doubts about other members' roles, responsibilities, and resources, and that with trust, synergistic efforts in inter-organizational missions are possible (Gabrowski & Roberts, 1998). Developing trust in a smart

organization is a complex task. It requires fairly constant, small group activities among partners, because it is difficult to trust people you do not know well, whom you have not observed in action over time, and who are not committed to the same goals. Trust plays an important synthesis role because with trust, smart organization can leverage the ability and willingness to learn (Coyle & Schnarr, 1995), thereby enhancing performance and attention to reliability over time. Smart organizations with high levels of trust among their members can effectively utilize interactions and communication processes at their interfaces so partners can learn together, and can develop shared mental models of reliability and a shared culture of innovation. High levels of trust also contribute to strengthening linkages among member organizations. Trust among organizational members is an important prerequisite to changing these linkages to alliances, thus mitigating risks, as organizations are reluctant to adopt alliance-like organizational structures that make them vulnerable to the uncertainties of the global market, and to impacts from other organizations, without some assurances of shared vulnerability (Handy, 1995; McAllister, 1995). Aerospace conglomerates jointly developing mission- and safety-critical systems, comprised of defense contractors, universities, government departments, and other private organizations, are good examples of the need for trust in smart organizations. In these organizations, members have different backgrounds, experiences, goals, objectives, and understandings, but belong to the conglomerate to pursue shared development of mission- and safety-critical aerospace systems. For effective smart organization management to take place, however, members needed to trust in the other members' talents, capacities, willingness to work, and interests in the alliance (Augustine, 1997; SmartBridge, 1997). Without such trust, members could duplicate other members' efforts, subvert the mission and goals of the conglomerate by providing private information about conglom-

erate members to the members' competitors, and introduce inefficiencies and costs pathological to the smart organization goals.

Trust is one of the key drivers for innovation. Many researchers support the point that trust is likely to favor technological innovation and change (Humphrey & Schmitz, 1998; Lorenz, 1999; Moore, 1999; Maskell, 2000).

Trust Building

From the above it is seen that the building and maintenance of trust is a pre-requisite for successful smart organization operation. Given the diversity among the smart organization partners it may be unrealistic to seek universal solutions on a one-size-fits-all basis. From the literature the essential conditions for trust development in a smart organization may be summarized as follows:

A Common Business Understanding

Researchers such as Wigand et al. (1997) and Fuehrer and Ashkanasy (2001) noted that a crucial element in any business cooperation is the establishment of a common business understanding. An earlier work suggests that there are three specifications necessary for the establishment of a common business understanding in the networked context. The first is a clear product specification: the design, quality, and functionality of the product or service. The second is specification of the cooperation level, which requires agreement about deadlines, liability, prices, profit allocation, and staff and resource input. The third is formal specification of agreements between the partners. In a smart organization, these specifications need to be communicated clearly among all partners to achieve a common business understanding. There is always varying uncertainty between members, however. Therefore, there is a need to guard against opportunistic behavior varies between the partners (Wicks et al., 1999).

The three specifications (production, cooperation, and agreements between partners) can be achieved by negotiating relational contracts that guide the formation, operation, and dissolution of the smart organization, thereby facilitating an increase in the level of collaboration-enabling trust. Smart organizations, like other networked organizations, create fiscal and legal issues that must be clarified but they lack a formalized legal framework. Therefore, it is incumbent on the organization's members to develop their own guidelines for the operation of the enterprise. Such agreements may include clarification of members' tasks and responsibilities, agreement on contracts, allocation of funds, potential liability, and how members will contribute their expertise. In this sense, clear guidelines, spelled out in an early stage of the partnership, serve to reduce misperceptions and to foster the establishment of trust.

Other mechanisms to establish a common business understanding in a smart organization include development of an organization handbook, design of a mutual Internet site, chat room technology, or the use of team addresses for e-mail. A specific example is Livelink, a software selected by Siemens to enable creation of a common business understanding for virtual collaboration and knowledge-sharing across geographical and organizational boundaries.

High Ethical Standards

Three factors uniquely characterize the smart organization's position in regard to business ethics. Firstly, smart organizations are rarely guided by pre-existing codified laws, where values and standards are written into legal systems enforceable in court. Since the partners are not usually legally bound to the organization, any negative outcomes or perceptions attributed to poor business ethics could result in the organization's reputation suffering (Fichman, 1997). Second, because smart organizations are intrinsically temporary, corporate ethics are difficult to develop

because members will typically be finishing one Internet collaboration and entering into another. Thirdly, smart organizations are intrinsically boundary-spanning in nature, so that they must incorporate a diversity of culturally based values and morals.

Researchers focused on the notion of advances in ICT and the related effects on social behavior agree that unethical behavior in the ICT context is predominantly caused by technological changes and by the "inside keepers of the information systems" (Pearson et al., 1997, p. 94). They also agree that social behavior needs more than "new laws and modified edicts" (Johnson, 1997, p. 60), and that ethical issues will become increasingly important to enable business transactions to be carried out safely and securely. Although technology has been largely secured by advancing software and technology for virus detection, as well as en/decryption of information to ensure the security of business processes, Johnson (1997) noted that technology could never be sufficient to control all aspects of social behavior. Consequently, online behavior is predicated on an awareness and acceptance of ethical norms and behaviors. This can best be achieved through specification and clarification of the members' tasks, responsibilities, and agreed sanctions for proscribed behavior.

Pearson et al. (1997) reported on ethical standards for the IS profession proposed by three major professional associations in this field. These associations share an agreed set of behavioral obligations to society, to colleagues, and to professional organizations. The standards aim to promote the principle that individuals within the professions act in an ethical and responsible manner in order to influence the success of their organizations (Pearson et al., 1997). Clearly, similar standards can be developed for the operation of smart organizations specifying, for instance, the obligation to partners and clients.

Other possible mechanisms to promote ethical behavior in smart organizations include formal

codes of ethics, which comprise statements of prescribed and proscribed values or behaviors, and thus provide a strategic tool within organizations to inculcate and to demonstrate ethical standards.

Mutual Forbearance between Partners

Forbearance is refraining from cheating. Cheating may take a weak form—failing to perform a beneficial act for the other party, or a strong form—committing a damaging act. The incentives for forbearance arise from the possibility of reciprocity, leading to mutual forbearance. Parties that are observed to forbear may gain a reputation for this behavior, which makes them potentially attractive partners for others. The parties to a successful agreement may develop a commitment to mutual forbearance, which cements the partnership, and, in this way, mutual trust is created, which alters the preferences of the parties toward a mutually cooperative mode. Thus, short-term, self-interested behavior becomes converted to cooperative, trusting behavior.

Competence of Partners

In a smart organization partners will be more willing to share knowledge when they trust in others' competence. It is only natural that they would want to converse with others who have the knowledge and skills regarding the topic at hand, since smart organizations almost always center around a common theme.

Effective Communication and Interaction between Partners

Through communicating with people, we calibrate them, we get a better sense of them and we understand their priorities. Members of a smart organization can therefore increase the trust they are giving and the amount they will trust others,

by actively seeking opportunities to communicate with other members.

Trust Maintenance

Besides building trust, it is essential to maintain trust among partners within smart organizations. For instance, through the Smart Bridge project the temporal quality of trust was revealed (Grabowski & Roberts, 1998). Initially, when members in a networked organization were excited about the opportunities joint software development and integration posed, much proprietary product and planning information, as well as member-confidential development and integration strategies were exchanged. Over time, however, as the smart organization matured, and the strength of the linkages between some members faded, the initial trust between some members faded. Some members, although partners on paper, were excluded from planning and integration discussions late in the project, and less proprietary information overall was exchanged as the project matured. Thus, as this networked organization matured, trust among some members waned, suggesting that management of trust in smart organizations requires at least as much effort and interest as management of the smart organization and its linkages. Meyerson, Weick, and Kramer (1996) developed the concept of swift trust for temporary teams whose existence, like partners in a smart organization, is formed around a common task with a finite life span. Such teams consist of members with diverse skills, with a limited history of working together, and with little prospect of working together again in the future. The tight deadlines under which these teams work leave little time for trust building. Because the time pressure hinders the ability of team members to develop expectations of others based on first hand information, members import expectations of trust from other settings with which they are familiar. Analogous to the hyperpersonal model

(Walther, 1997), individuals in temporary groups make initial use of category-driven information processing to form stereotypical impressions of others. After the team has begun to interact, trust is maintained by a “highly active, proactive, enthusiastic, generative style of action” (Meyerson et al., 1996).

High levels of action have also been shown to be associated with high performing teams (Iacono & Weisband, 1997). Action strengthens trust in a self-fulfilling fashion: Action will maintain members’ confidence that the team is able to manage the uncertainty, risk, and points of vulnerability, yet the conveyance of action has as a requisite the communication of individual activities. In summary, whereas traditional conceptualizations of trust are based strongly on interpersonal relationships, swift trust deemphasizes the interpersonal dimensions and is based initially on broad categorical social structures and later on action. Since members initially import trust rather than develop trust, trust might attain its zenith at the project inception (Meyerson et al., 1996).

Another effective way of holding partners together in a smart organization is through execution of business projects. In a smart organization, projects will need to be renegotiated more quickly and individual partners need the ability to be creative about ways of completing projects based on the principles of trust. The individual partner in a smart organization now has to go beyond basic task cooperation and legal arrangements typical of traditional patterns of hierarchical work organization toward a search for greater trust and autonomy. Trust allows partners to take risks with themselves by being able to make mutual disclosures to others and to develop new task execution styles. Norms of behavior can only work if people know what to expect, but expectations also require some prior commitment, which is based on belief. When rapid change occurs, existing role structures can be destroyed, but without being replaced immediately with legitimate alternative structures. However, people will resist getting rid

of norms that have meaning for them, particularly where they think they are already well accepted and approved.

Changing from one situation to another will take time in order for individuals to learn at an emotional level how to come to terms with loss and growth. People who have already invested time and energy in learning how to manage a situation may find change unwelcome when having to learn new roles. The creation of roles can be seen in the life cycle of a networked organization and is believed to go through the stages of forming, storming, norming, performing, and adjourning (Handy, 1995). Trust is vital for commitment during the norming phase. The storming phase is anomic in the sense that people are challenging each other for authority over what is true, correct, and what they want. Order is reached when people accept norms as legitimate according to some criteria and then they can perform. There should be a consensus over norms, but there is a possibility of a minority coercing the others and then legitimacy is weak. Sufficient time must be allowed for people to work through the process using open communications, otherwise they cannot be committed, particularly if there is a requirement for a major change in norms, as one would expect when both planned and unplanned changes occur frequently.

One should also consider how cooperation can be affected by smart organization partnership. Cooperation is a special form of behavior which is concerned with reciprocal actions which are to each other’s mutual benefit. Selfish behavior can in a strategic sense lead to cooperation under certain conditions where both parties are mutually dependant on each other for an uncertain period ahead. At an individual level, in one off encounters, people can afford to be selfish (using game-like strategies) because they may not meet each other again. However, where they are likely to encounter the same people again on a repetitive basis the need for cooperation increases because the risk of future retaliation may rise. If

trust does exist between people there can still be dissent but this will not involve conflict, which is at each other's expense. In the case of selfish behavior, trust in the other person is not required and behavior may become competitive, as soon as people realize that they are no longer dependent on each other. Alternatively, role relationships may exist which are exploitative because of unequal power and low levels of trust.

Summing up, failure to manage trust properly in a smart organization can be a source of failure in business today. In the following sections the need for trust-based evaluations in smart organizations will be examined.

SECURITY PROBLEMS IN AD HOC NETWORKS

Nowadays, the great flexibility of TCP/IP has led to its worldwide acceptance as the basic Internet and intranet communications protocol. At the same time, the fact that TCP/IP allows information to pass through intermediate computers makes it possible for a third party to interfere with communications in any of the following ways:

- **Eavesdropping:** Information remains intact, but its privacy is compromised. For example, someone could learn your credit card number, record a sensitive conversation, or intercept classified information.
- **Tampering:** Information in transit is changed or replaced and then sent on to the recipient. For example, someone could alter an order for goods or change a person's resume.
- **Impersonation:** Information passes to a person who poses as the intended recipient. Impersonation can take two forms: spoofing or misrepresentation.

In the case of smart organizations, many sensitive personal and business communications over

the Internet require precautions that address the threats mentioned above. Two most common approaches used to deal with the security problems are encryption and steganography (Mezgar & Kincses, 2003):

- **Encryption:** Transforming the message to a ciphertext such that an enemy who monitors the ciphertext cannot determine the message sent. The legitimate receiver possesses a secret decryption key that allows him to reverse the encryption transformation and retrieve the message. The sender may have used the same key to encrypt the message (with symmetric encryption schemes) or used a different, but related key (with public key schemes).
- **Steganography:** The art of hiding a secret message within a larger one in such a way that the opponent cannot discern the presence or contents of the hidden message. For example, a message might be hidden within a picture by changing the low-order pixel bits to be the message bits.

The increasing use of wireless ad hoc networks such as the Smart Sensor Networks pose challenges to security (Zhou et al., 1999; Zhang, 2000; Deng et al., 2002). First of all, the use of wireless links renders an ad hoc network susceptible to link attacks ranging from passive eavesdropping to active interfering. Unlike fixed hardwired networks with physical defense at firewalls and gateways, attacks on an ad hoc network can come from all directions and target any node. Damage includes leaking secret information, interfering message, and impersonating nodes, thus violating the basic security requirements. All these mean that every node must be prepared for encounter with an adversary directly or indirectly.

Secondly, autonomous nodes in an ad hoc network have inadequate physical protection, and are therefore more easily captured, compromised, and hijacked. Malicious attacks could be launched

from both outside and inside the network. Because it is difficult to track down a particular mobile node in a large scale of ad hoc network, attacks from a compromised node are more dangerous and much harder to detect. All these indicate that any node must be prepared to operate in a mode that should not immediately trust any partner.

Thirdly, any security solution with static configuration would not be sufficient because of the dynamic topology of the networks. In order to achieve high availability, distributed architecture without central entities should be applied. This is because introducing any central entity into a security solution may cause a fatal attack on the entire network once the centralized entity is compromised. Generally, decision-making in the ad hoc networks is decentralized and many ad hoc network algorithms rely on the cooperation of all nodes or partial nodes. But new types of attacks can be designed to break the cooperative algorithm. Malicious nodes could simply block or modify the data traffic traversing them by refusing the cooperation or hacking the cooperation. As can be seen from the above, no matter what security measures are deployed, there is always some vulnerability that can be exploited to break in.

It seems difficult to provide a general security solution for the ad hoc networks. A traditional cryptographic solution is not adapted for the new paradigm of the networks. As can be seen from the above analysis, what is lacked in the ad hoc networks is trust, since each node must not trust any other node immediately. If the trust relationship among the network nodes is available for every node, it will be much easier to select a proper security measure to establish the required protection. It will be wiser to avoid the untrusted nodes as routers. Moreover, it will be more sensible to reject or ignore hostile service requests. Trust-based evaluation thus becomes a before-security issue in the ad hoc networks.

SELECTION OF PARTNERS IN SMART ORGANIZATIONS

In the new economy, knowledge is increasingly seen as central to the success of organizations and an asset that needs to be managed. The ability of an enterprise to manage knowledge as an asset (and provide a good return on investment) is seen as the key to survival in a global business environment in which the efficiencies of mass production of commodity goods have been successfully exported to emerging economies. The major issue of knowledge management is to place knowledge under management remit to get value from it—to realize intellectual capital. That intellectual capital can be regarded as a major determinant of the difference between a company's book price and the total value of its physical assets. For a successful company, this difference can be considerable, representing the difference between the way the company is seen by financial experts and by the market. For example, there is a great difference between the book price and share value of recently-launched biotechnology companies, whose market value is clearly based on their knowledge assets, rather than traditional capital. However, while the world of business is experienced in managing physical and financial capital, smart organizations have difficulty finding solutions to practical questions concerning partnership management, such as:

We are involved in an exciting project with four other companies. How can we tell whether all these partners would collaborate?

Market needs change often these days and we are always bringing new partners into projects. How can we select the right partners?

The main issue is that partners of the smart organizations are quite intractable from a knowl-

edge management point of view. By their very nature such partners create a great deal of new knowledge, which as such is of high value to the smart organization. However, the knowledge of how and why they created, and what they had created is not clear since it involves the interactions among a group of different people. Since smart organization partners do not have frequent face-to-face interaction, the core company has to have total faith that the partners will do the job they are assigned, and do it right. This leaves core companies with the daunting task of selecting partners who are not only able to work on their own, but can also function within a team structure—self-motivated partners. When it works, the organization processes flow nicely. However, when one partner starts slacking, the ramifications are dire in consequence. A frequent occurrence is when a partner joins the smart organization with certain expectations, but those expectations are modified by an unexpected technology breakthrough. Suppose a regional airline was brought into a certain route-alliance smart organization to harmonized express, general air cargo and heavy express air cargo products in the Asia Pacific Region, and it is just found that there is a growing need for the smart organization to focus on harmonizing dangerous good products. Assuming that due to national aviation legislations the partner airline cannot handle this kind of product, it makes sense for the core air cargo organization to switch partners. And suppose that the original airline has invested a considerable amount of capital in developing general and heavy cargo products handling equipment for the core organization, in addition to carrying out research on European air cargo markets. In the traditional business system, each partner suboptimizes for its own goals, which in this case would provide a less than optimal service, express general and heavy cargo handling only, leaving the dangerous goods handling to the competitors. A better business system will agilely adjust to the customers' need and at the same time reward the general cargo-handling

partner for essentially putting itself out of the smart organization. In such a case, that partner has to have trust that the smart organization will deal with it fairly whether it is fully in the smart organization or out. And the smart organization has to have trust in each partner that they will strive to optimize the enterprise even when it reduces or eliminates its own role.

While trust has long been a major issue in the organizational literature, there is little agreement on a single model of trust that applies to all partner evaluation contexts. One can only see from the literature that although trust is pivotal in reducing the high levels of uncertainty endemic to the global and technologically-based environment, interfirm trust was rarely considered in the evaluation of partners in a smart organization. For effective smart organization management, it is clear that electronic handshake would need to be based on trust between partner companies as well as the correct protocol. To facilitate the evaluation of interfirm trust a partner evaluation decision support system is suggested below (Lau & Wong, 2001; Wong & Lau, 2003).

NEURAL DATA MINING SYSTEM (NDMS)

In larger organizations, many different types of users with varied needs utilize the same massive data warehouse to retrieve the right information for the right purpose. Whilst data warehouse is referred to as a very large repository of historical data pertaining to an organization, data mining is more concerned with the collection, management, and distribution of organized data in an effective way. The nature of a data warehouse includes integrated data, detailed and summarized data, historical data, and metadata. Integrated data enable the data miner to easily and quickly look across vistas of data. Detailed data is important when the data miner wishes to examine data in its most detailed form, while historical data is

essential because important information nuggets are hidden in this type of data. Online analytical processing (OLAP), an example of architectural extension of the data warehouse, has become popular in the last couple of years. OLAP refers to the technique of performing complex analysis over the information stored in a data warehouse. For instance, by using the OLAP Hub (SPSS, 2004), a commercial Web-based online analytical processing software, the managers within a smart organization can access and analyze information about organizational performance, share their findings with others immediately via the Web, and take action as opportunities arise. Consequently, more informed decisions will result and this in turn will lead to enhanced productivity and increased profitability.

Once a data warehouse is set up, the attention is usually switched to the area of data mining, which aims to extract new and meaningful information. In other words, a pool of “useful information” that has been stored in a company data warehouse becomes “intelligent information,” thereby allowing decision-makers to learn as much as they can from their valuable data assets. In this respect, neural networks can be deployed to enhance the intelligence level of the OLAP application. Neural networks search for hidden relationships, patterns, correlations, and interdependencies in large databases that traditional information gathering methods (such as report creation and user querying) may have overlooked. The responsibility of the neural network is to provide the desired change of parameters based on what the network has been trained on. Intrinsically, a sufficient amount of data sample is a key factor in order to obtain accurate feedback from the trained network. As neural network is capable of learning relationships between data sets by simply having sample data represented to their input and output layers (Herrmann, 1995), the training of the network with input and output layers mapped to relevant realistic values with the purpose to develop the correlation between

these two groups of data will not, in principle, contradict the basic principle of neural network. With a trained network available, it is possible that recommended action can be obtained with the purpose to rectify some hidden problems, should that occur at a later stage. Therefore, in the training process of the neural network, the nodes of the input layer of the neural network represent the data from the OLAP and those of the output layer represent the predictions and extrapolations. It should be noted that the output information from the OLAP could be used to refine the OLAP data cube so as to continually update the database over time.

Characteristics of NDMS

The data interchange within the NDMS encompasses three modules, namely OLAP module, data conversion (DC) module, and neural network (NN) module (Figure 1). The data repository, which aims to support efficient data interchange among the three modules, is essential for the coordination and updating of information from various sources. As for the OLAP module, it consists of descriptive data (dimensions) and quantitative value (measures), both of which generate the OLAP data cube by building up two elements, namely, fact table and dimension (Erik, George, & Dick, 1999). In the fact table, the required data and user-defined methods for analysis are specified clearly. In the descriptive data of OLAP, the different dimension levels are defined for further computational use on different views of OLAP data cube. Typical dimension includes location, company, and time; whereas typical measure includes price, sales, and profit. With a multidimensional view of data, the OLAP module provides the foundation for analytical processing through flexible access to information. In particular, this distinct feature can be used to compute a complex query and analyze data on reports, thereby achieving the viewing of data in different dimensions in an easier and more

efficient way. To illustrate the benefits of OLAP as compared to the traditional approach of data management using structured query language (SQL), an example is shown here to benchmark their underlying methodologies of associated operations.

In the SQL approach, when a user needs to retrieve information across multitable, users must clearly define the necessary tables for finding the specific information. For instance, when a user needs to know how much sales is taken for a certain year and city and uses the Internet as promotion media, the tables and their relationships must be clearly defined. In normal practice, a query command line written in SQL as shown below can be used to retrieve information from the tables:

“Select sum(a.store_sales) from sales_fact_2004 a, promotion b, region c, store d, where a.store_id = d.store_id and c.region_id = d.region_id and b.promotion_id = a.promotion_id and c.sales_country= China and b.media_type = Internet”

When using the OLAP module, the table used for the query and the data used to perform the calculation are defined separately. Then, the user builds up a complex calculation on individual members to meet the specific requirements.

Because the calculation and analysis have been precomputed in the OLAP server previously, only a simple Multi-Dimension eXpression (MDX) is necessary to construct for retrieving identical result as shown in the following:

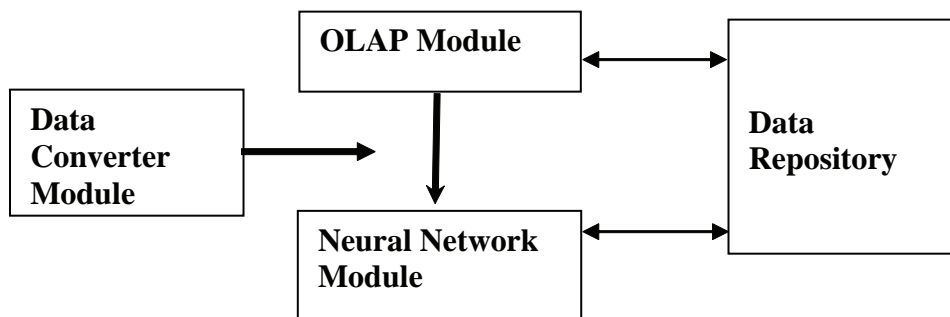

“Select [Measures].[Store Sales] on columns, [Store].[Sales_country] on rows from sales where ([Promotion].[Media_Type].[Internet], [Region].[Sales_country].[China])”

In the above expression, it can be shown that MDX is simpler and clearer than SQL statement. When the user requirement is changed, there is only a small part of the OLAP data cube needed for alteration in order to fulfill the user requirement. In this respect, some minimal change of the MDX is necessary. Comparing with the traditional approach, the SQL statement needs to be rewritten to meet the new requirement.

In general, MDX is suitable for creating decision support functionality, and a typical example has been provided as follows:

*“IF ([Measures].[Unit_Sales] > 1000, [Measures].[Store_Sales] * 0.8, [Measures].[Store_Sales])”*

Figure 1. Characteristics of NDMS

Before the implementation of OLAP, the calculated member is constructed by the measures. In this case, in an example that aims to find a suitable business partner for a particular task, the method has been depicted in Figure 2.

EVALUATION OF SO PARTNERS

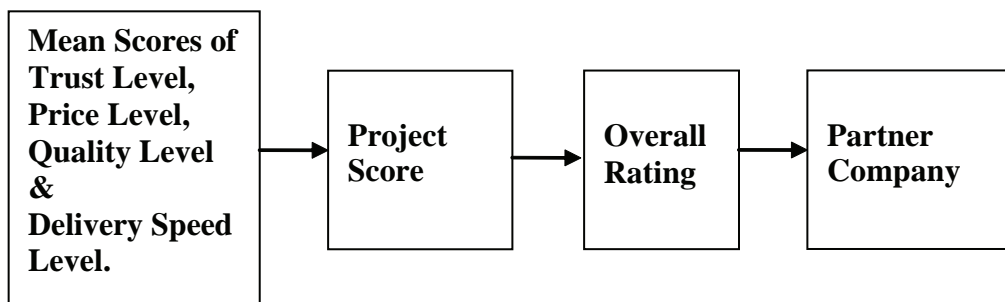

Industries in the 21st century find themselves in a world increasingly globalized and concerned with speed, quality, and cost. As a result, many enterprises now manufacture and distribute globally. The evaluation of SO partners generally involves distinct types of decisions. For instance, in the evaluation of product distributors, one focuses on a partner to handle a company’s product in the foreign or domestic market. Hence, access to markets and market intelligence are likely to be of key importance, together with reliability and control over conditions of distribution and sales. On the other hand, evaluation of supply partners involves the identification of a partner for meeting the company production requirements. In this case, supply chain variables such as material quality, price, supply lead time, and inventory control are generally considered to be of key importance. In both cases, trust between top management teams of the core and partner companies is of fundamental importance.

The selection of attributes or variables for consideration in the comparison of smart organi-

zation partners is quite important to the eventual outcome. For instance, considerations relating to financial objectives, expected quality level, safety standards, problem resolution mechanisms, and so forth. In addition, intangible benefits and risks are often present. The set of attributes should include all the criteria that are needed in order to describe the differences between partner competencies. It is desirable that the list is complete, but if there is a criterion on which all the partner competencies are equal, then that criterion can be discarded, since it will not have any differential impact on the final partner rankings.

In Figure 2, the scores of trust level, price level, quality level, and delivery speed level for each partner are used. The mean score of a project is calculated by taking the mean scores of the trust level, price level, quality level, and delivery speed level of the previous projects that have been carried out by the partner company concerned. Finally, the overall average of the partner company is determined by accumulating the prespecified weighting of the latest projects. The overall average can then be assessed by the top management of the core company. Since the OLAP technology is a user-friendly and software-independent tool, it can be embedded in most client server development tools and Web development tools. In the following case example, after the customer submits the requirement to the NDMS server, an MDX query can then be executed in order to retrieve available service providers based on the core competence specified.

Figure 2. Partner score method

With the OLAP module as a front-end component, the neural network (NN) module is employed as a back-end part of the NDMS, which concentrates on providing essential information such as alertness of abnormal scenarios based on the pattern of historical data. However, since the output data from the OLAP data cube may not be able to be used directly by the NN module due to possible data incompatibility, it is essential that a data translation mechanism (DTM) is to be incorporated to act as a “bridge” to link the two modules together to form an integrated unit.

The DTM module is meant to play this important role. In brief, the DTM module concentrates on achieving efficient data transfer between the OLAP module and the NN module, which requires specific data format for mapping the input nodes to guarantee proper operation. With the formatted data available via the DC module, the focus is now turned to the NN module, which aims to set up a suitable network topology in order to identify any correlation within the data pool. The NN module is meant to project possible outcomes—good or bad—based on the available pattern of data, thereby alerting users of detected abnormal behavior in terms of company performance and other hidden business issues. This provides important advice to support critical decision-making in the SO. In the following case example, parameters such as trust between management teams, product quality, and product cost are abstracted from recent company performance records. With the assistance of an expert team, many companies’ past behavior based on the selected parameters can be classified and ranked. In general, for the setup of a neural network, a number of inputs are required to enable such network to take into account the various multiple factors that may influence the performance assessment of a particular company. In this research, the neural network consists of four input nodes (five sets of the last five records including trust, quality, cost and speed) and five output nodes (various suggested actions to be taken), as shown in Table 1. To achieve the

objective of producing a reliable “trained” neural network, statistical data have to be mapped to the input and output nodes of the neural network. In this respect, it is recommended that at least 100 sets of data are required to train the network in order to develop a reliable module for the NDMS. With the availability of a fair amount of data sets, the next step is to train a neural network.

This means the parameters include network construction, and training data files are needed for definition. Then, users can apply analysis tools to provide insight into how the network is to be trained, as well as the appropriate topology of the network for the specific purpose. It is also likely that users will need to fine-tune the training parameters such as iteration number, learn rate, momentum, and so forth (Qnet, 2000), so that the specified values match the training characteristics for the model. After the completion of the training process, such neural networks can then be used as a knowledge repository to monitor companies’ performances, and provide decision support to users who then consider necessary actions to be taken.

After the training process, the trained neural network can then be recalled in order to process the new inputs through the network. In order to describe in more detail about the recall operation under the NN module, five latest track records of a company are required to be mapped to the input nodes for analysis. Output data from the NN module will predict the company’s performance based on the configuration of the trained network. A case example in the next section will elaborate how this works.

CASE ILLUSTRATION

To verify the applicability of the NDMS, a prototype system has been developed, based on the framework of the NDMS as proposed in this paper. Pursuing the NDMS infrastructure that has been defined in the previous section, the

OLAP module has generated a pool of useful data and accordingly, the NN module has created a reliably trained neural network. Next, five latest track records of a company have been gathered and listed as follows. In this case four factors—trust between top management, quality, cost and delivery speed—are being considered, and performance scores (PS) ranging from 1 (least point) to 7 (highest point) are used to assess the partner company, as shown in Table 1.

After such information has been input, the NN module gives an assessment report back to the user, thus supporting the user to take action if deemed necessary. In the following table, “0” output from the NN node indicates a negative suggestion to the associated statement, and “1” is the positive suggestion, whereas “0.5” indicates that there is not enough data to justify a firm suggestion.

Based on the NN output results as shown in the table, it can be seen that although Company A is trustworthy, it seems to have problem in meeting the agreed quality level, and it is suggested that additional assessment regarding the company’s performance is needed. Based on the suggestion of this assessment report, Company A was approached in order to find out the reasons behind the abrupt change in product quality. After an organized investigation of the issue, it was found that two of the key staff responsible for the quality assurance department left the company several months ago to join a newly established multinational corporation. Because of this unexpected change, the company suffered an unprecedented “brain-drain,” resulting in the sudden decline of quality level of certain mainstream products.

Because of the situation, Company A has been advised to implement some best practices related

Table 1. Five latest records of Company A

Company A	Performance Score(PS)			
	Trust between top management	Product Quality	Product Cost	Delivery Speed
Latest record	6	5.6	6.5	6.2
2 nd latest record	6.4	4.8	5.9	6.4
3 rd latest record	5.9	4.1	6.0	5.7
4 th latest record	6.6	3.8	5.6	5.8
5 th latest record	6.3	3.5	5.5	6.0

Table 2. Output from the NN module

Company A	Output from NN module
Price quoted reflects current market situation	1
Product quality has been compromised to meet the quoted price	1
Dependability of company	1
Potentially competent	0.5
Additional assessment of company performance is required	1

to quality assurance. In this case, the concept of total quality management (TQM) has been adopted and a TQM consultant team has also been requested to facilitate the implementation of such practice in the company. At this stage, it is still difficult to tell whether the company could significantly reverse the downturn performance in terms of product quality. However, because of the signal generated from the NDMS, the problem of a business partner has been revealed, and a prompt business decision could be made with supporting assessment report, thus avoiding the loss of a trusted business partner, which can in turn weaken the overall performance of the smart organization. This case example indicates that the introduction of the NN module to the OLAP module is able to significantly upgrade the decision support functionality of the smart organization. However, the results obtained, so far, are by no means perfect although they demonstrate that the suggested NDMS is viable.

LIMITATIONS AND RECOMMENDATIONS FOR FURTHER RESEARCH

This study mainly focused on the practical need to consider trust between partner companies in a smart organization. Owing to the circumstances pertaining to the schedule of the study, the perception of a limited number of managers responsible for partner selection was used to verify the importance of interfirm trust. It would be desirable to extend the analysis to all the dimensions pertaining to trust, and explore the effect of trust on the performance of partner companies. Additionally, qualitative studies on mapping the cognitive processes of senior managers responsible for evaluation of partner companies in the smart organization would also be helpful. Here conjoint analysis might be applied. In the present context, conjoint analysis is concerned with understanding how senior managers make choices

among partner companies, so that a smart organization can choose new partners that better serve its needs. Although it has only been a mainstream research technique for the last decade or so, conjoint analysis has been found to be an extremely powerful way of capturing what really drives top managers to select one partner over another, and what the top managers of a particular smart organization really value. A key benefit of conjoint analysis is the ability to produce dynamic decision models that enable companies to test out what variables they would need to consider to improve the decision-making process. Coupled with the decision support tool proposed, such a methodology would help to understand how managers actually make such decisions and use experience in partner evaluation.

CONCLUSION

In order to achieve the target mission of a smart organization, the core company must be clear about its business aims and objectives. It must assemble a set of partner companies that can deliver to those objectives. It must support them in doing so and trust them to do so. In providing security solution to ad hoc networks or in the selection of partners, a company has to analyze the trustworthiness of the potential partners, their capabilities, track record, and future potential. However, there is no single model of trust that could be applied in practical situations. Hence, there is great pressure placed on the CEOs as the decision makers for selection of satisfactory partner companies. In this chapter, an intelligent decision support system for smart organization partner evaluation is introduced. It demonstrates the benefits of using a combination of technologies to form an integrated system which capitalizes on the merits and at the same time offsets the pitfalls of the involved technologies. A special feature is that the trust between management teams of companies could be incorporated as one

of the evaluation criteria. The NDMS has been found to be feasible in predicting the problems of companies as shown in a case example described in the paper. As suggested, further investigations on (i) key dimensions relating to trust between companies within a smart organization and (ii) the impact of trust on overall performance of partner companies would be needed.

ACKNOWLEDGMENT

The author wishes to thank the Department of Mechanical Engineering, The Hong Kong Polytechnic University for supporting this study.

Chapter 6.4

E– Commerce and Small Tourism Firms

Patrice Braun

University of Ballarat, Australia

INTRODUCTION

Today's networked economy is a strategic combination of many factors, with electronic platforms and relationships underpinning competitive advantage. Enabled and driven by information and communication technologies (ICT) and connectivity, the networked economy is challenging the fundamental bases of established government frameworks, conventional business practices, and traditional marketing disciplines. To achieve business success in this techno-economic paradigm requires new ways of thinking for all.

This article examines regional development trends, such as the growing importance of connectivity, electronic-commerce (e-commerce), and industry networks for global competitive advantage. Within that context, it discusses issues facing small tourism firms in becoming part of the networked economy.

REGIONAL NETWORKS

A consistent pattern in today's economic business process is collaboration between firms, whereby

emphasis is placed on networking, knowledge sharing, and cooperation rather than competition (Asheim, 2001). The adoption and diffusion of ICT and the Internet are integral components in today's business processes, as connectivity has increased our ability to connect and communicate with others, regardless of whether they are located locally, regionally, nationally, or across the globe.

Research indicates that network building is not only a major new source of competitive advantage for any company, but also a crucial asset to business survival and an essential global and, indeed, regional development requirement (Porter, 1998). Because the processes of ICT-based information seeking, information distribution, and knowledge sharing are interactive, it is believed that a firm's information channels or interpersonal networks play an important role.

In recent times, regional development policy has undergone a paradigm shift from an exogenous or external focus to an endogenous or internal and relational network one (Storper, 1997). Networking, community building, and learning are portrayed as pivotal linkages for regional growth, whereby policy makers concerned with the perfor-

mance of regional economies are seeking to foster a networked community culture (Asheim, 2001). In geographic terms, networks can operate on international, national, regional, and local levels. Examples of this network-building trend may be found internationally on the European Commission and the APEC action agendas (APEC, 2001). The trend is also reflected in Australian regional development policy, which, in taking its cues from global trends in regional development, portrays connectivity, networking, industry clustering, regional specialization, and capacity building as pivotal for regional growth (ALGA, 2002).

As such, network formation is not a novel or emerging concept but rather a recycled notion caught up in a new policy wave. Theoretical discussions on interfirm organization can be found as far back as 1960 (Philips, 1960), although it would take several decades more until Miles and Snow (1992) identified a significant movement toward the so-called network form. Since then, myriad network structures and traits have been discussed in the literature, including firm interdependence, trust between network partners, pitfalls of network alliances, and issues surrounding change. The latter is of particular relevance in these rapidly changing times. Business networks are subject to external changes, such as a transformation in the economic and technological climate, and internal changes, such as competition and issues of power and trust (Håkansson, 1995).

Connectivity and the Internet have added new dimensions to the concept of networked firms. The advent of connectivity has boosted conventional reasons for interfirm networking, as the technology-enabled landscape provides the capacity for firms to collaborate with former competitors and potentially achieve “competitive co-evolution, enhanced by digital platform features” (Ordanini, 2001, p. 282). The concept of clustering, another form of network formation, has gained new prominence, as it can help create critical mass and facilitate the knowledge-based infrastructure needed for competitive advantage.

Porter (1998) discusses competitive advantage as being created and sustained through a highly localized process and ascribes enduring competitive advantage in a global economy to local knowledge, relationships, and motivation that cannot be duplicated by global partnering. Thus, as a result of the networked economy, it may be said that organizational change can be expected throughout regions and across a number of industries, and especially in information-based industries such as the tourism industry.

TOURISM AND TECHNOLOGY

Being among the two largest, most rapidly growing, and most dynamic industries, tourism and technology have become inextricably linked. Together, they are changing the way society operates (Werthner & Klein, 1999). The tourism industry has always relied heavily on information. In fact, until a tourist gets to his or her chosen destination, tourism *is* information rather than a physical product. While tourism services are produced and consumed in a physical world set in a regional or local context, purchase of a tourism product is generally based on information received through direct or intermediary market channels, prior knowledge, word of mouth, and perceptions of trust and service quality. As the nature of the tourism product is information-based, it is a search product that is evaluated by perusing product-related information. Being dependent on effective information flows makes the tourism product a complex one, as it is “...almost entirely dependent upon representations (such as pictures in brochures) and descriptions to help consumers make a purchase decision” (Laubenheimer, 1999, p. 279).

Tourism intermediaries typically fulfill functions such as presorting and structuring tourism product information, providing a place for the supply and demand sides to meet, and reducing uncertainty. Travel agents have traditionally been

high-profile intermediaries between travel suppliers and consumers, selling the tourism product, for which they derive a sales commission, to customers. Apart from their customer service role, a travel agent's product knowledge and expertise is the value added for the customer. Destination marketing organizations, such as regional and local tourist information centers, also perform an intermediary (booking) role, most often between consumers and tourism small to medium-size enterprises (SMEs) (Wynne, 2001).

Now information technology and the Internet enter the picture. The Internet has the ability to provide a highly suitable and major new market channel for tourist products, because it can display information and pictures. The travel and tourism sector to a large degree depends on business-to-consumer (B2C) e-commerce activity. The Internet can create a direct link between a worldwide supplier community and equally dispersed consumers. Speed is also crucial in the travel industry, and the Internet can provide an instant confirmation response to an inquiry such as flight or room availability. The influence of ICT on tourism product perusal and purchase is evident in the proliferation of travel/tourism sites on the Web (Bernstein, 1999). A search engine query on travel and tourism will return an incredible 15 million results, which includes information on anything from outback tours to deep sea adventures to bed-and-breakfast stays around the globe. To date, the sale of online airline tickets constitutes the largest part of e-commerce-related travel business. In North America alone, travel purchases before 2000 accounted for US\$4 billion in sales, with forecasts for 2003 ranging up to US\$29 billion (Pappas, 2001).

With increasing ICT literacy of prospective customers, consumer expectation of easy access to tourism product is rising. Such consumer expectations are likely to increase pressure on product providers to either offer instantaneous product information satisfaction or lose potential customers (Buhalis & Main, 1998). The emer-

gence of electronic markets and the increased ICT literacy of prospective customers, who now have the opportunity to bypass intermediaries in the travel value chain by booking directly on the Web, have kindled questions about the necessity and ability of small tourism firms to become part of the networked economy.

REGIONAL TOURISM SMEs

In many parts of the world, SMEs and micro tourism enterprises make a substantial contribution to regional economies. In this context, tourism SMEs are an important instrument for raising the profile of a region. At the same time, the requirements of the globalized economy raise the bar for tourism SMEs in all regions, with expectations toward a high capacity for ICT innovation, even on a relatively small scale (ALGA, 2002).

While connectivity has the potential to increase regionally-based tourism SMEs' visibility in the marketplace, small tourism enterprises have been facing difficulties embracing ICT and competing with their larger counterparts. Small tourism firms, much like other small firms, often lack the time, skills, and resources needed to implement ICT (Buhalis & Main, 1998). Micro and small tourism enterprises generally consider themselves outside the tourism industry, despite the fact that most of their customers are tourists (Evans, 2001). Their size being their main disadvantage, tourism SMEs tend to be overdependent on intermediaries for product marketing and distribution and, therefore, have limited bargaining power in the distribution channel (Werthner & Klein, 1999). Other barriers may include technology itself, where the lifestyle choice of owner-operators often entails a negative attitude toward ICT (Evans, 2001). Besides, many tourism SMEs are located in peripheral regions where the ICT infrastructure, especially broadband, can still be inadequate or prohibitively expensive due to limited demand (Anckar & Walden, 2001). In some cases, this

leads to a perceived lack of value of ICT and the Internet.

A New Zealand study of micro tourism firms identified the education and professional background of owner-operators to be significant barriers (Ateljevic, 1999), pointing to a widespread consensus that industry preparedness in terms of training falls well short of the requirements to operate within a now ICT-driven sector (Danielle, 1999). Presenting the results of a three-year study on the usage of and plans for ICT training in a fragmented and SME-dominated European tourism sector, Evans et al. (2001) note that small tourism firms may well remain lost in the electronic marketplace, unless they are assisted in the usage of ICT tools and acquire the skills needed to participate in the digital economy.

Being small businesses, tourism SMEs have rather limited marketing means and, despite the information-intensive nature of the tourism product, are not necessarily up to the task of marketing themselves online. As individual enterprises with limited marketing budgets, most small firms fail to focus on marketing planning and market intelligence. Preoccupied with the operational running of their business, smaller operators have tended to approach their markets "...less formally and more intuitively from their detailed, close contact with their guests" (Main, 1999). To make matters worse, a micro tourism Web site is easily overshadowed by the plethora of mega tourism Web sites, such as Travelocity and Expedia, currently available on the Internet. To summarize, due to their nature and scale, small tourism firms lack the advantages of larger tourism enterprises, such as resources, know-how, and access to global distribution systems and other network support systems. At the same time, there is increasing pressure on small firms to offer Web-based product information.

REGIONAL TOURISM NETWORKS

Although ICT appears to threaten the existence of small tourism firms without resources, know-

how, and access to distribution channels, regional network formation may provide a solution for small tourism firms.

The interrelationship between tourism and technology is not a recent phenomenon; it dates back to the early days of computing and the impact of post-1960s mass travel. To date, however, travel industry networks that pursue Web-enabled capabilities have been largely driven by the airline industry seeking to extend its global reach through strategically aligned partnerships, global booking and distribution systems, and cost-saving synergies in services such as baggage handling, catering, engineering, and maintenance (Pappas, 2001). Thus, the Internet provides big players with far-reaching business-to-consumer (B2C) as well as business-to-business (B2B) opportunities to enhance and develop specialized relationships with their customer base. However, as a result of the networked economy, organizational changes are now expected to affect the entire tourism industry, which is predominantly made up of small enterprises.

Almost a decade ago, in addressing tourism and technology, Poon (1993) stressed that to avoid isolation, achieve economies of scale, and maximize destination benefits, there would be no place in the future for the stand-alone tourism SMEs; and that networking would allow small tourism firms to pool their resources, reduce operating costs, increase know-how, and formulate strategic marketing plans. Research further suggests that small tourism enterprises form a natural amalgam, because the fortunes of the destination and the firms are closely intertwined. Buhalis and Cooper (1998) believe that tourism SMEs tend to cooperate rather than compete by formulating value-added networks of product and service delivery (e.g., by referring customers to each other), thus enhancing tourist satisfaction. Anckar and Walden (2001) similarly advocate that a network or information technology infrastructure is not only useful but is, indeed, essential in bringing small tourism firms and cyber customers together, as well as increasing the willingness of cyber customers to

purchase tourism products from smaller regional suppliers. In addition, mapping and understanding the processes that take place in existing tourism networks has the potential to speed up technology adoption and create effective collaborative network outcomes (Braun, 2004).

Cooperative marketing research has long confirmed that networking in the form of cooperative marketing can add value to a destination (Palmer & McCole, 2000). Traditionally, such cooperation has been used in the production of joint marketing brochures and shared stands at trade shows. The advent of the Internet and related regional development trends offer expanded opportunities for cooperative marketing. Tourism operators on both the macro (destination) and micro (individual tourism SMEs) levels are starting to see the potential benefits of using Web technologies for cooperative marketing and transaction purposes (Main, 2002). In the wake of information technology and new regional network initiatives, cooperative marketing Web sites are proliferating (Tourism Victoria, 2002).

Interesting cooperative marketing and e-commerce opportunities notwithstanding, tourism SMEs' participation in networks is far from guaranteed. Joining a network constitutes a considerable leap for small tourism firms. Barriers to entering networks have been put down to cultural factors on the one hand and lack of resources (time, staff, opportunity) on the other. Evans (1999) particularly singles out aversion to joining groups and attending training sessions and meetings, which "may be antithetic to the stress that owner-managers place on autonomy and independence—the main reason they went into business on their own in the first place" (Evans, 1999, p. 380). Small firms tend to limit their external contacts to compulsory contacts, e.g., local government and tax agencies and direct support actors and agencies, e.g., customers, accountants, and banks.

A research project undertaken with small tourism firms in North London showed that the

greatest interest in networking came from those businesses that had the strongest links to the local economy (Evans, 1999). The development of a shared destination Web site proved to be attractive to local tourism operators in terms of joint marketing and securing new business. However, the project also highlighted the firms' relatively underdeveloped knowledge of ICT and a varying degree of reluctance within the sector in terms of joining a network. Although notable research into tourism-specific cooperative use of the Internet as a marketing tool and e-commerce remains in its infancy (Beckendorff, 2000), to date the greatest interest in using ICT networks in the tourism sector has been to develop joint online marketing initiatives, indicating that many tourism SMEs have yet to embrace Web-based e-commerce processes. Initial value for tourism SMEs lies in the debunking of ICT jargon, cutting connectivity cost, gaining online visibility, gaining trust in network structures, and obtaining e-commerce skills through linkages with local partners. Continued incentives and support will help tourism SMEs get comfortable and take mental, physical, and virtual possession of a shared ICT domain (Braun, 2002).

Tourism networks, like all networks, should be seen as complex and dynamic organisms with ever-changing actors and external economic and technological influences. ICT-based network formation involves an intensive learning process for every actor involved in the network. This requires strong social ties within the network, fluid communications flows, strong leadership, and commitment to the network. In certain instances, network formation and small business collaboration will need to be fostered through the offering of incentives and training. An appropriate balance also needs to be struck between autonomy and competition in evolving small tourism firms from an individualistic business to a network culture. By drawing on a broader skill base through the forging of new partnerships between regional e-commerce experts and marketing bodies, issues

such as product and market reach can be addressed. Similarly, inclusion of small firms in global marketing and distribution systems may help advance tourism regions and, thus, small tourism firms into the global marketplace and help forge new destination management partnerships.

CONCLUSION

Today, ICT and the Internet enable tourism SMEs and tourism networks such as regional destination marketing organizations (DMO) to better cope with increased information flows, getting the marketing message out to the public, and selling their product online through e-commerce.

The Internet has the ability to provide a highly suitable and major new market channel for tourist product, because it can create a direct link between regional tourism SMEs and worldwide consumers. By using the Internet as an online network and cooperative market channel, tourism destinations, marketing organizations, and individual tourism SMEs in regions all over the world have an opportunity to contribute to regional development and keep up with a now predominantly ICT-based industry.

For many small tourism firms, joining an ICT-based network and embracing e-commerce will entail radical new ways of business thinking, which will take time. As Gretzel et al. (2000) have pointed out, success in the new information economy is more about changes in approach than about the technology itself.

KEY TERMS

APEC: Asia Pacific Economic Cooperation.

Connectivity: The ability to link to the Internet via a computer.

DMO: Destination marketing organization.

ICT: Information and communication technologies. The technology and tools used to transfer information and speed up communication processes.

Intermediary: Person or organization performing a (booking) role between consumers and business.

Market Channel: A publicly accessible means such as a newspaper, magazine, trade show, radio, billboards, television, or the Internet, used to advertise and market products.

SMEs: Small and medium-size enterprises. Refers to enterprises with a specific number of staff. A small-size enterprise generally refers to firms with less than 20 employees.

Web-Enabled: Business systems that are supported by Internet technologies.

Chapter 6.5

Towards Improved Business Planning Decision Support for Small-to-Medium Tourism Enterprise Operations

G. Michael McGrath
Victoria University, Australia

ABSTRACT

In a recent study conducted for the Australian Sustainable Tourism Cooperative Research Centre, improved business planning was identified as one of the most pressing needs of small-to-medium tourism enterprise operators. Further significant problems confronting these businesses were coping with rapid change, complexity and uncertainty. System dynamics (SD) is especially well-suited to the modelling and analysis of problem domains with these characteristics and, in this chapter, we report on the development and implementation of a “tourism enterprise planning simulator” (TEPS) based largely upon SD constructs and technologies. Scenarios in which TEPS might be used to good effect are outlined and the potential benefits of this deployment are detailed.

INTRODUCTION

A number of tourism researchers have noted that there is a demand among prospective (and current) small-to-medium tourism enterprise (SMTE) operators for improved business planning tools (see e.g., Baker, 2000; Bergin-Seers, Jago, Breen, & Carlsen, 2005; Mistilis, Presbury, & Agnes, 2004). Moreover, there would seem to be a place for online, automated tools: whether as an adjunct to traditional sources of advice or as stand-alone products. Low-cost, generic business planning software products are inadequate because they fail to take into account contextual factors important to the tourism industry. There are, however, some impressive, recently-developed destination planning support tools and these are tourism-specific—examples being the “Tourism Futures Simulator” of Walker, Greiner, McDonald, and

Lyne (1999) and the “Hotel Value Chain Profitability” model of Georgantzas (2003).

A feature of both these tourism planning and policy-making tools is that they are based upon system dynamics (SD) concepts, tools and techniques. SD has been around for over 40 years (see Forrester, 1961, for what is generally regarded as the seminal and most influential piece of work in the field), but has enjoyed something of a resurgence recently. To some extent, this is due to an increasing recognition (among researchers from many fields) that SD is especially suitable for capturing, modelling, and analysing: so-called “messy” problems; and key aspects of “change.”

Messy problems have been defined by Venix (1996, pp. 9-41) as being characterised by complexity, uncertainty, recursive dependencies, inter-related sub-problems, selective perception, self-interest, and, related to this, key stakeholders working from different views of the essential nature of the problem. A glance through any tourism/hospitality text should quickly convince the reader that these attributes all apply to the tourism domain: both at the destination level (see e.g., Ritchie & Crouch, 2003) and at the enterprise level (see Baker, 2000).

Change too is characteristic of the tourism industry. Indeed, in a recent study (McGrath, 2005), one of the most significant problems facing the Australian tourism industry was identified as rapid change: including technological change, major changes in the external business environment, and changes that are having substantial impacts at every point of the tourism supply chain (and at every level—from international to regional and local levels). The situation was summed up by one study participant as follows: “Not only are we shooting in the dark—we are shooting at a moving target” (McGrath & More, 2005, p. 4). Here, our interviewee was expressing a degree of dissatisfaction with: first, adequate data not being available to facilitate effective strategic planning; and, second, the fact that the tourism industry

is moving so quickly that, even where accurate data is accessible in a timely manner, it is often outdated and relatively useless in much too short a timeframe. However, the quote would seem to apply equally to many other problems currently confronted by the industry.

In recognition of the above, the Australian *Sustainable Tourism Cooperative Research Centre* (STCRC) recently provided funding and support for a research project aimed at producing a *tourism enterprise planning simulator* (TEPS). Distinguishing features of TEPS are:

- Extensive use is made of SD modelling technologies and tools (for capturing and simulating key aspects of change).
- The enterprise simulator sits inside a destination-level simulator. In this way, TEPS addresses a major problem associated with the multitude of generic, low-cost business planning tools available—namely, they fail to take into account tourism-specific, contextual factors.
- TEPS operates at different levels of granularity. At the very fine-grained level, actual data is used to establish relationships and to instantiate model variables. At the more coarse-grained levels, a restricted set of destination archetypes is induced and users assign values to variables through an “impressionistic” (or fuzzy) process.
- Artificial intelligence tools (such as rule-based deductive inference, case-based reasoning and fuzzy logic) are used to complement the base SD technology employed.

In this chapter, we report on the development, validation and potential use of the tourism enterprise business planning tool. The focus of our initial research is on tourism accommodation enterprises and the chapter is organized as follows: background to the research is presented in the following section and this is followed by an overview of the design and implementation of

TEPS. The following section deals with ways in which the simulator might be employed during tourism enterprise business planning and the benefits that flow from this. System validation, the current status of our project and future plans are then discussed and, finally, concluding remarks are presented.

BACKGROUND

SMTEs and Business Planning

The Australian tourism industry employs approximately 5.9% of the total workforce, accounts for 5.9% of GDP, and contributes 11.2% of total exports (Tourism Australia, 2004, p. 22). There is some argument concerning the accuracy of these figures but the recent establishment of a “Tourism Satellite Account” (Smith, 2004) by the Australian Bureau of Statistics (ABS) means that tourism’s contribution to the Australian economy is measured according to guidelines and methods established by the World Tourism Organization (WTO). This ensures that, at the very least, local tourism statistics are derived consistently with the closest thing to a generally-accepted set of standards the international tourism industry has and that international comparisons may be made with a fair degree of confidence.

In excess of 90% of Australian tourism businesses are SMTEs (Sharma, Carson, & DeLacy, 2000, p. 3) and it has long been recognized that SMTE operators have to deal with myriad problems. For example, in a recent paper dealing with the local tourism industry’s response to an Australian state government’s “come online” initiative, Morrison and King (2002, p. 111) divided SMTE firms into Techno-whizzos, Early adopters, Wait-and-sees and Wilderness operators. Members of the Wilderness group were described as generally aged 45+, with no computer or interest in them, they felt they were too old to learn more and they viewed the Internet as a waste of time. They also

had a dislike of officialdom/bureaucracy and were reluctant to participate in regional activities and networks. Somewhat depressingly, it was estimated that 60% of the SMTE sample were in the Wilderness category (with another 20% in the Wait-and-see group).

More generally, Gammack, Amaya Molinar, Chu, and Chanpayom (2004, pp. x –xi) analysed SMTEs in the Asia-Pacific region and nominated the following factors as significant inhibitors to enterprise development:

- A lack of a trained and professional workforce
- A lack of entrepreneurial skills among operators
- Low entry barriers—impacting on service quality, growth and business viability
- Lending arrangement and taxation regimes not conducive to SMTEs
- Conforming to (and supporting) sustainable regional infrastructure requirements
- Inconsistent and bureaucratic local authorities
- A lack of government recognition of the value of tourism
- A failure to recognize the potential benefits of industry clusters and collaboration
- Industry fragmentation and a proliferation of membership organizations
- A lack of technology (generally) and e-commerce (specifically) skills
- Relatively poor e-readiness and e-commerce uptake
- Scattered, poorly-integrated and difficult-to-locate business research information

A number of these factors might be classified under the broader heading of a “lack of strategic focus” and this has long been recognized as a problem among SMTE operators (see e.g., Sharma et al., 2000a; Mistilis et al., 2004; Morrison & King, 2002). This lack of attention to planning and strategy is evident in the Morrison and King

(op. cit) analysis presented above and, more recently, Mistilis et al. (2004) identified the lack of a strategic focus as the main impediment to the uptake of online technologies among Sydney hotel operators. Nevertheless, there are indications that things might be changing for the better and, during another Australian study conducted by the author (McGrath, 2005, p. 72), one State Tourism Authority (STA) representative asserted that:

Not a day goes by when we are not approached by at least a couple of prospective operators looking for help with their business planning. ... You can look at business planning as, maybe, a 14-16 step process. We talk to them [prospective operators] at Step 1, and the next time they hear from us is after they are established. Then, we are asking them for information! We need to do more for them.

Thus, at least some SMTE operators are looking to improve their business planning and, given the high rate of enterprise attrition in this sector (Baker, 2000; English, 1995), some attempts have been made to provide the necessary support. For example, the Decipher tourism data warehouse (Carson & Richards, 2004) provides business planning support through its Web site, Tourism Victoria is planning to implement an online business planning product and the STCRC has recently released a business planning “toolkit” for property owners considering “Farm and Country Tourism” ventures (Fausnaugh, Waight, Higginbottom, & Northrope, 2004). TEPS is intended to complement these products (the current intention being to eventually implement it within Decipher).

A quick search using Google (and the keywords, “business planning software”) returned just under 100 million matches. Even allowing for the fact that many of these are dead-ends, a brief perusal of a number of returned sites revealed a number of potentially useful business planning software aids. Thus, there is most definitely no shortage of generic business planning software. In

addition, adding the word “tourism” to the search string led to a few sites that (on the surface) do seem to have something to offer the prospective SMTE operator (see e.g., the “Tourism Business Development Toolbox” at <http://www.uwex.edu/ces/cced/tourism/>).

Nevertheless (while admitting that our analysis was less than comprehensive), few of these online, tourism-related, business planning Web sites appear to be well-grounded in the holistic (or systemic) view of the “sustainable tourism system.” This view is considered by some (e.g., Gammack et al., 2004, p. 1) to have its roots in the work of Brundtland (1987) and its many manifestations include the Mill and Morrison (2002) model (focusing on a “chicken-and-egg” like relationship between consumer travel decisions and destination marketing), the “triple bottom line” concept (Adams, Frost, & Webber, 2004; Elkington, 1999) (encompassing the natural, economic and cultural/social environments), and the “competitive destination” model of Ritchie and Crouch (2003). The WTO (1998) defines a sustainable tourism destination as a region where:

... tourism development meets the needs of present tourists and host regions while protecting and enhancing opportunities for the future. It is envisaged as leading to management of all resources in such a way that economic, social and aesthetic needs can be fulfilled while maintaining cultural integrity, essential ecological processes, biological diversity and life support systems.

System Dynamics

The holistic view of a tourism destination seems to be now almost universally accepted among researchers and policy makers (if not industry practitioners) and, given this, it is perhaps a little surprising that greater advantage has not been taken of methods, tools and techniques commonly employed in SD (or “systems thinking”) research and implementation to assist in the development

of better business practices amongst SMTEs. SD has its origins in the work of Forrester (1961) and, more recently, has enjoyed something of a resurgence—largely due to Peter Senge’s (1990) very influential work on “the learning organization,” and to the development and release of easy-to-use, powerful, SD-based software modelling and simulation tools (such as *iThink*, *Vensim*, and *Powersim*). Recent examples of where SD has been used to good effect in tourism include the “Tourism Futures Simulator” of Walker et al. (1999), the hotel value chain modelling work of Georgantzas (2003), the tourism multipliers model of Loutif, Moscardini, and Lawler (2000), and the information architecture modelling work of McGrath and More (2005).

The SD component of TEPS has been developed and implemented using *Powersim* (Powersim, 2003). Within *Powersim*, models are developed in what is referred to as stock-flow format and a simple model is presented in Figure 1 below.

The basic building blocks of SD models are stocks (represented as rectangles), flows (represented as arrows with circular flow regulators attached) and converters (represented as circles). In our model, examples of stocks are Region Attractiveness, Enterprise Development and Region Development. There is a level associated with each stock, which can be an actual value or a value bounded by some artificial scale. Region Attractiveness (and, indeed, all stocks in our example) are measured on a 0-200 scale and we have set the system up so that, when the value of every stock level is at 100, the system is in equilibrium. Stock levels vary with flows, which may be inflows, outflows or bidirectional. For example, RDVarn (Region Development Variation) is a bidirectional flow such that:

$$Region\ Development_t = f(Region\ Development_{t-1}, RDVarn_t).$$

Figure 1. Example of a SD model – stock-flow form

That is, in our model, the region development level at time, t , is a function of the region development level at time, $t-1$, and the region development variation at time, t . These equations are the foundation of *Powersim's* formidable simulation capabilities. The third of our basic constructs, converters, serve a utilitarian role: they hold values for constants, calculate mathematical relationships and serve as repositories for graphical functions. In general, they convert inputs into outputs (hence, the name, "converter").

Earlier (see the introductory section), we noted that many issues and problems associated with tourism fall into a class of organizational problems defined by Vennix (1996, pp. 13-41) as "messy" and that problems of this type are characterised by complexity, uncertainty, inter-related sub-problems, recursive dependencies, and multiple interpretations of the problem's essence. He then makes the claim that among the key factors that impede our ability to resolve messy problems are: (1) limitations on our cognitive powers; (2) a tendency to grossly oversimplify or circumscribe complex problems; and (3) an inability to comprehend multiple, related feedback loops. Finally, he argues that a SD approach has the potential to overcome many of these problems and, furthermore, that (collaborative) development of a model may foster consensus, perhaps leading to increased acceptance of whatever decision is eventually taken. A considerable body of research has focused on understanding, and improving, benefits that can accrue during group model building using system dynamic modelling tools (see e.g., Anderson, Richardson, & Vennix, 1997; de Geus, 1994; Morecroft, 1994; Richmond, 1997; Vennix, 1996). If used judiciously, group modelling with SD tools can assist in mastering the learning problems listed above, as well as addressing the different viewpoints and beliefs which participants from various functional areas bring with them to any learning or decision making exercise.

Although the model presented in Figure 1 is a substantially simplified version of the ver-

sion actually developed during our research, the complexity of the problem domain is clearly evident. This applies particularly to the feedback loops. For example: region attractiveness has an impact on enterprise development, enterprise development has an impact on region development, region development has an impact on the quality of the environment and the environment, in turn, has an impact on region attractiveness (thus leading us back to our starting point). Another feedback loop is: *Enterprise Development* → *Region Development* → *Enterprise Competition* → *Enterprise Development*. That is, an increase in enterprise development will (generally) result in an increase in region development which, in turn, might be expected to increase enterprise competition within the region. Finally, the increased enterprise competition may well lead to a decrease in enterprise development. This is an example of what the SD community refer to as a balancing loop: that is, enterprise competition acts as an inhibitor to unrestricted growth within the region. Another example of a growth inhibitor is environment quality.

Thus, our model contains a number of feedback loops. Vennix (op. cit), however, claims that many people are unable, at best, to understand the dynamics of a single feedback loop. Once multiple feedback loops are involved, even people who are experienced at interpreting feedback are unable to ascertain the behaviour of a system without resorting to a computer simulation (Anderson et al., 1997; Dangerfield & Roberts, 1995). During our research, we were able to adjust specific variables and observe the impact on other variables, over time, (through graphs automatically generated by *Powersim's* risk analysis software). This considerably assisted our end-users in improving their understanding of the complex, dynamic relationships present in the system. Vennix (op. cit) has argued that an advantage of involving decision makers from various areas in group modelling exercises is that they begin to understand that their actions not only affect their own

areas and interests but may have major impacts on other stakeholders as well. This, in turn, may result in improved collaboration within the model development exercise itself.

Stock-flow models, however, are not all that suitable for collaborative model development, where end-users have significant input. In their most basic form though, SD models are represented as causal loop diagrams (CLDs). A feature of CLDs is that they are both powerful and simple, relying as they do on just one fundamental construct: two variables, connected by an arrow, indicating a causal relationship. An example is presented in Figure 2, illustrating the “tragedy of the commons” archetype (Roberts, Andersen, Deal, Garet, & Shaffer, 1983), exemplified by the situation where, with cattle grazing on common land, incentives for individuals to increase herd size lead to overgrazing, eventual famine, and loss of livelihood (short-term benefits leading to long-term disaster).

The illustration presented in Figure 2 is taken from an actual case (WTO, 1998) concerning sub-Saharan African nomads who had survived sustainably in steady state for thousands of years. A well-meaning injection of aid in the 1950s

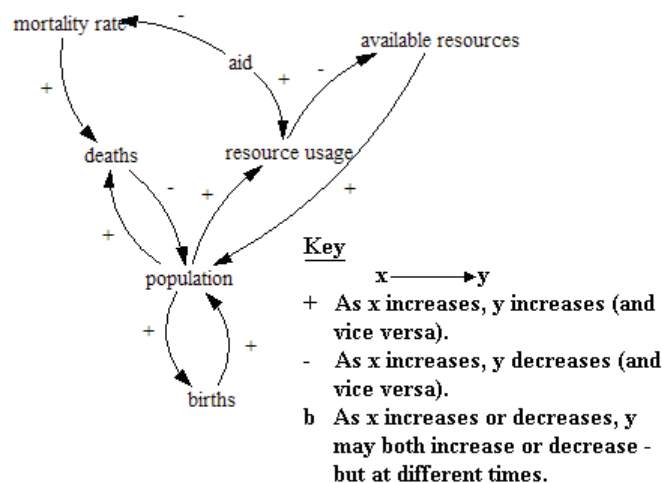

resulted in a short-term lifespan and standard-of-living increase (mainly through new medicines and greater resource usage brought about by digging deeper wells). This, however, threw the system out of balance, leading to a longer-term agricultural and cattle grazing resource decrease, desertification, stock losses, eventual famine and an increase in deaths.

We now turn our attention to our tourism enterprise planning simulator (TEPS). For the reasons outlined above, we have chosen to specify and implement the bulk of TEPS using SD concepts.

The Tourism Enterprise Planning Simulator: An Overview

The eventual plan is to implement TEPS within the STCRC’s online, business assistance Web site, *Decipher* (Carson & Richards, 2004). A high-level view of the TEPS architecture is illustrated in Figure 3. The bulk of the model is specified and implemented within an SD framework. A knowledge base, implemented primarily as rules, sits within TEPS and is called to perform specific functions (such as the calculation of certainty

Figure 2. CLD example – unintended consequences of well-meaning action

factors based on a fuzzy logic approach). Values returned from the knowledge base component are used to dynamically instantiate variables within the SD model. One such function is the calcula-

tion of a region attractiveness value. However, in this case, users may opt to bypass the knowledge base and interact directly with the SD component (i.e., TEPS may be run as a stand-alone SD ap-

Figure 3. TEPS – High-level architecture view

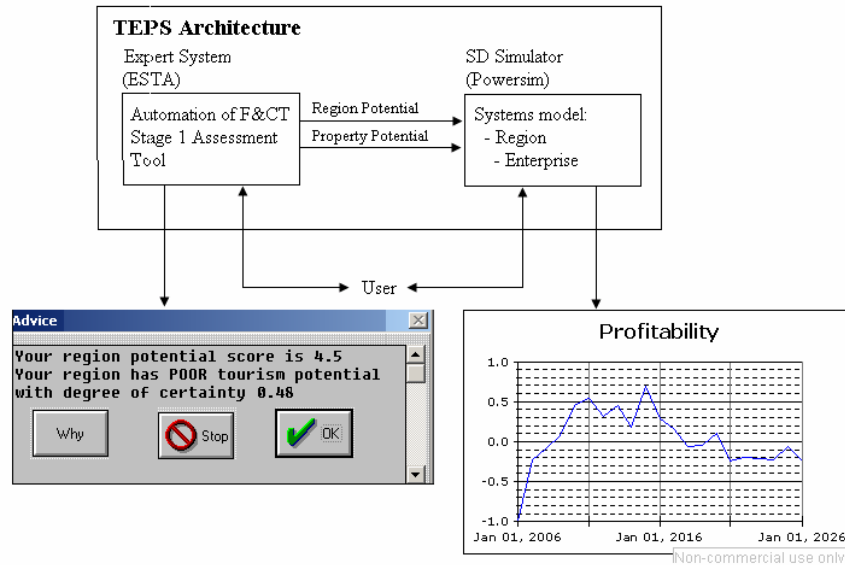

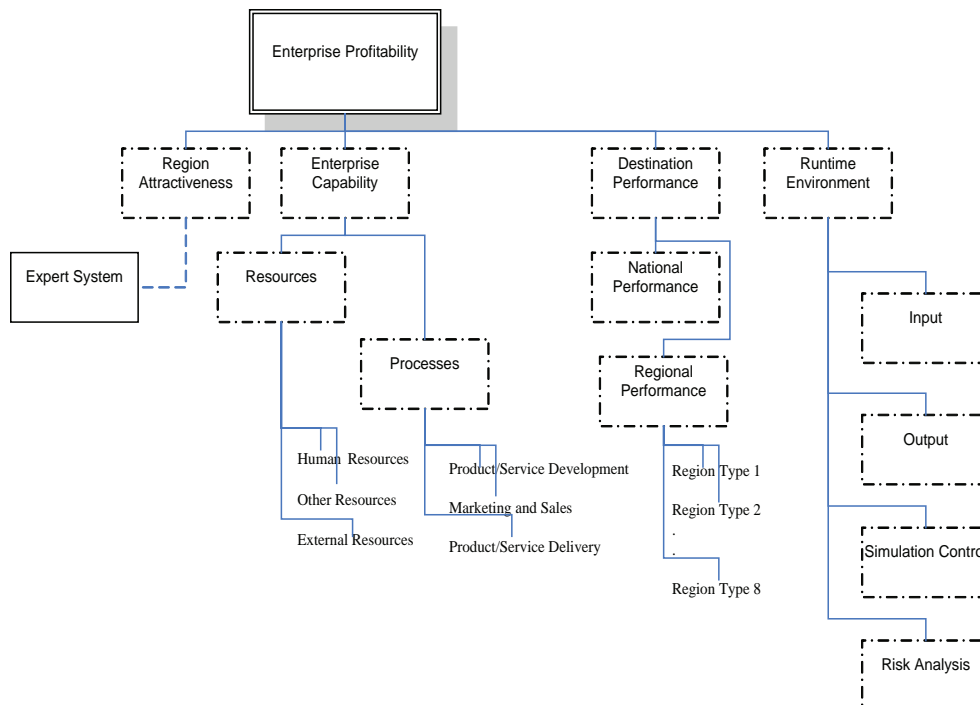

Figure 4. Functional decomposition of SD component

plication). Moreover, to date, the bulk of our effort in developing our prototype has been directed towards the SD simulator. Consequently, in the remainder of this chapter, we shall focus on this component.

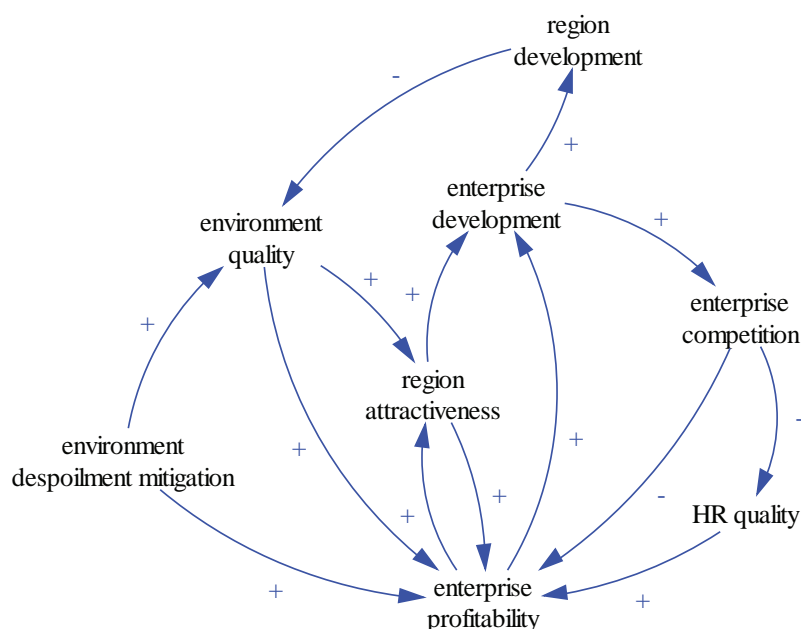

As noted above, during the previous ten years or so a number of excellent SD simulation software packages have been developed. As with almost any software tool, each of the leading tools have their “disciples” but, in our view, each of these tools have their strengths and weaknesses and tool selection often boils down to a matter of individual preference (and, oftentimes, familiarity with a previously used product). With this particular application, we opted to employ the *Powersim* development studio (*Powersim*, 2003)—mainly because it has excellent functional decomposition facilities (and, as time goes by, we believe our model will need to be broken down to more precise levels of detail).

A functional decomposition of the SD component of our prototype is presented in Figure 4.

The usual approach in developing an SD model is to: (1) specify the problem domain as a causal-loop diagram (CLD); and, then, (2) implement it in the slightly more complex stock-flow syntax employed by the software packages listed above (and illustrated in Figure 1). Here, because of space limitations, we restrict ourselves to CLD representations of our domain and a (slightly simplified) view of the Enterprise Capability component is illustrated in Figure 5.

Region attractiveness is at the core of the enterprise capability model. Attractive regions are natural targets for enterprise development and this leads to increased levels of enterprise development. More competition though, can have an adverse effect on enterprise profitability (e.g., through pressure to reduce tariffs) and this, in turn, may decrease motivation to invest further in enterprise development. Enterprise development also results in greater region development and, for the most part, this will lead to poorer environment quality. In turn, environmental despoilment (in the

Figure 5. Enterprise Capability component – top-level CLD

medium to long-term at least) will have negative consequences for both region attractiveness and enterprise profitability.

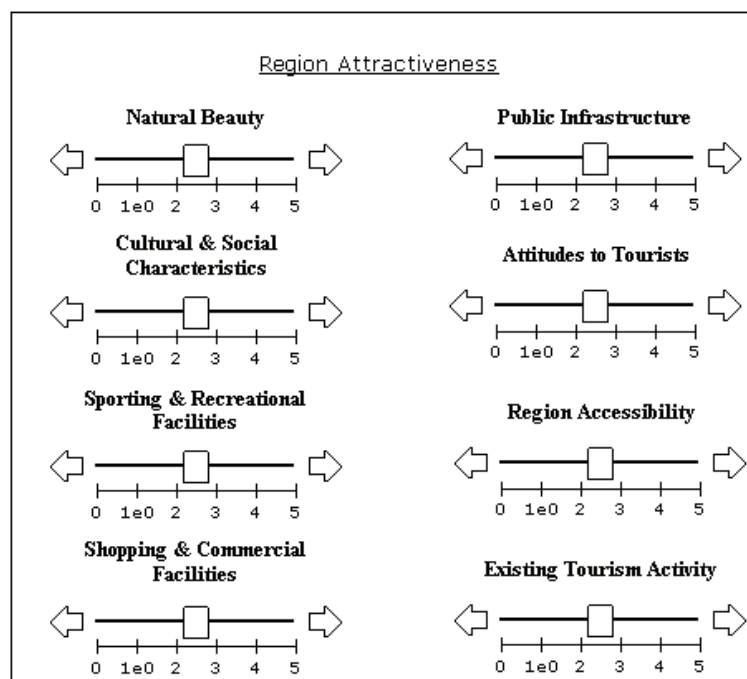

Thus, in these variables and causal links, we have a representation of (a variant of) the classic sustainable tourism model (discussed in the previous section). Essentially, if development is allowed to proceed unchecked, reinforcing loops will lead to increasingly greater levels of environment despoilment and lower enterprise profitability levels. Note, however, that environment despoilment mitigation has been included in the model as a mediating (or control) variable. That is, if a destination (collectively) is truly committed to protecting its natural resources this may keep the total system in balance and, also, work towards safeguarding enterprise profitability.

An additional variable included in our model is human resources (HR) quality. Effectively, increased enterprise competition will eventually lead to a reduction in overall HR quality

(e.g., because of poaching and better staff taking advantage of opportunities elsewhere) and, as a consequence, remaining poorer-quality staff will have a negative impact on profits (i.e., customers can tolerate only so much!).

HR Quality is implemented in our SD prototype as a 2nd-level sub-module below Enterprise Capability (see Figure 4). The structure employed here was drawn from the STCRC ‘Performance Measurement’ toolkit, designed to allow small motel operators to benchmark and improve their operations (Bergin-Seers et al., 2005). At the time this chapter was being written, “human resources” was the only domain component (of those shown in Figure 4) that had actually been implemented. However, the intention is to progressively implement functionality corresponding to the other resources and processes shown in Figure 4 (with the task scheduled to be completed by end-June 2006). Note though, that the prototype is still capable of producing useful outputs without

Figure 6. Region attractiveness – direct interaction through the SD control panel

lower-level modules being filled out with fine-grained detail (as shall be demonstrated in the following section).

Region attractiveness is calculated based on an approach presented in another STCRC toolkit; the "Farm and Country Assessment Tool (Stage 1)" (Fausnaugh et al., 2004). Using this toolkit, protective "Farm and Country" tourism operators are guided through a series of questions designed to assess the potential of their proposed tourism enterprise. One output from this process is a region attractiveness score and the functionality required to compute this value has been implemented within our expert system component. Alternatively, users may bypass the expert system and simply adjust a set of sliders within the SD component user interface (see Figure 6). Nevertheless, use of the expert system is recommended because: (1) users are alerted to many of the key factors that contribute to an attractive region; and (2) a "fuzzy logic" (Kosko, 1993) uncertainty handling routine assigns a "degree of confidence" level to the region attractiveness score calculated.

The Enterprise Capability module focuses on resources and processes specific to a particular (proposed) tourism accommodation enterprise. As noted earlier though, these are analysed within a destination context. More specifically, the National Performance component has been established so that simulation outputs accurately reflect the behaviour of key, national, accommodation sector indicators (e.g., total rooms, room nights occupied (RNO), seasonality, occupancy and revenue per RNO), on a quarterly basis over the period January 1998 to March 2005 (inclusive). Base data was taken from (ABS, 2005).

The SD simulator has been initialized to run for 29 quarters from the commencement of the current year. All variables are specified as indices. For example, RNO-national is an index of predicted RNO for total national visits (domestic and international), plotting percentage changes over time, on a quarterly basis against a base quarter. The March quarter of the current year is used as

the base quarter and is assigned a value of 100. Where later values exceed 100, it indicates growth in comparison to the base quarter while values less than 100 indicate decline compared to the base quarter. The method is the same as that employed in (TRA, 2005) and the assumption is made that accommodation trends will be similar to actual figures observed in the seven years from January 1998 to March 2005 (ABS, 2005).

The National Performance model has been "tweaked" to emulate the accommodation sector behaviour of eight different region types. Users are required to select the region type closest to the destination in which they hope to establish their enterprise and enterprise performance will then be derived with reference to the selected region type's characteristics.

Tourism region types can be classified in a great many ways (e.g., by location, activities, climate, commerce/industry mix, population attributes, life-cycle stage, etc.) and Australian government tourism authorities (federal and state) have their own classification schemes. Following consultation with a number of government and tourism industry experts, however, we decided that the following region-type classification might suit our particular needs best: (1) Major Gateway; (2) Seaside (seasonal); (3) Seaside (year-round); (4) Coastal; (5) Provincial City (non-remote); (6) Rural; (7) Snowfields; and (8) Family Holiday. Whether this classification is effective will only be determined by actual experience with use of the simulator. We also should note that the system has been customized specifically for Australian conditions and would almost certainly require some modification before it could be used elsewhere (although it is unlikely this would involve changes to the model structure itself).

Finally, a detailed description of the runtime environment is beyond the scope of this chapter. We should note, however, that our user interface is similar to the "flight simulator" control panels commonly employed in SD applications (see e.g., Maani & Cavana, 2000, p. 116).

MODEL BENEFITS AND USAGE

Scenario 1: Basic Usage

Assume that we wish to examine the feasibility of setting up a motel in Anglesea—a small coastal town, about 70 minutes drive South-West of Melbourne. It has a superb surf beach and a fairly small population (chiefly retirees, commuters seeking a better lifestyle, and “weekenders”—mostly from Melbourne). The town has a large influx of tourists during the warmer months (particularly from December through to April) but experiences a significant drop-off in overnight visitors

at other times—despite the town being right in the middle of the gateway to (the Australian state of) Victoria’s major tourist attraction, the Great Ocean Road. In recent years, real estate prices have gone “through the roof”: mainly because of a massive increase in demand from prospective “lifestylers” and holiday-home buyers, and limited capacity to increase housing supply and supporting infrastructure (without eating into surrounding coastal, national park and farming areas). The town has little in the way of industry and commerce outside of tourism-related enterprises but the wider region supports substantial farming activity.

Figure 7. TEPS – sample output (Enterprise Profitability versus Year)

Figure 8. TEPS – example of a ‘risk analysis’ assessment

Firstly, region attractiveness determinants have to be initialized. We elect to do this via the SD control panel (see Figure 6) and this yields a score of 130 (on a 0-200 scale). This relatively good score is largely the result of the assignment of maximum (or close to maximum) values for natural beauty, sports & recreational facilities, existing tourism activity and public infrastructure. These, however, are partly balanced by the assignment of comparatively-weak values to cultural &

social characteristics, shopping & commercial facilities and attitudes to tourists.

We might then set the remaining input parameters on the control panel as follows: Region Type to Seaside (seasonal); Environmental Damage Mitigation to Major; and, finally, we elect to leave the two HR-related parameters (HR Quality and HR Training Commitment) at their default values of average (HR issues are examined in some detail in the following two scenarios). Parameter

Figure 9. TEPS – impact of HR development on quality

Figure 10. TEPS – unintended consequences of HR development activity

initialization is now complete and running the simulation yields the enterprise profitability graph presented in Figure 7.

At first glance, these results appear to be quite encouraging—Figure 7 indicating that, after a couple of years of pain, a gradual improvement in profitability might occur. In reflecting on the simulation though, we might (for example) be concerned about the accuracy of the values we have assigned to some variables and, in particular, have considerable doubts about the component variables of the region attractiveness parameter.

Fortunately, *Powersim* has a powerful risk analysis package and, using this, we may investigate our model’s sensitivity to changes in independent variables (or, more precisely, variables we decide to declare “independent” for some particular purpose). Basically, all that is required is to specify a mean and standard deviation for each of our independent (sub) variables, stipulate that Enterprise Profitability is the dependent (or effect) variable and, then, initiate a series of simulation runs (in our case, we use the recommended number of 40 runs) through the risk analysis software. The result is the “high-low” graph presented in Figure 8 and, here, it can be seen that around 80% of the variance (the area between the (90% and 10% lines) is within a 30% range (approximately). We conclude, therefore, that the model is not particularly sensitive to change in region

attractiveness. We could then conduct further risk analysis experiments to determine precisely which variables (or combination of variables) do influence model behaviour most. The importance of conducting this type of “sensitivity analysis” has long been known in SD circles—early guidelines having been formulated by Coyle (1977, p. 193) almost 30 years ago.

Scenario 2: HR Development

Assume we have some concerns related to the quality of local hospitality and tourism (H&T) staff we will be able to recruit for our start-up operation and, consequently, have decided that substantial staff training will be required. As such, through our TEPS control panel, we specify that our relative HR Quality is average and set the HR training commitment parameter to significant. The relevant simulation output resulting from these settings is presented in Figure 9.

A brief perusal of the above diagram readily reveals two important features: (1) improvement in HR Quality lags some way behind investment in HR Development; and (2) after a considerable initial increase, HR Quality plateaus and then drops off somewhat. The lag between development and quality improvement would probably be expected but the second of these features is

Figure 11. TEPS – failure to address fundamental problems in favour of quick fixes (smoothed to eliminate the impact of quarterly fluctuations)

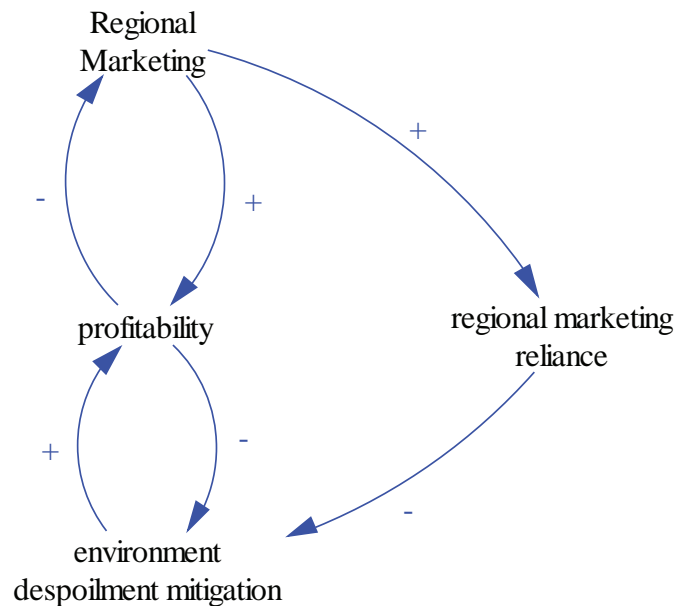

Figure 12. TEPS – over-reliance on quick fixes to fundamental problems

a little more complex and, while not an extreme case, it does represent an instance of the “fixes that fail” SD archetype (developed by the SD Group at MIT and detailed in Maani & Cavana, 2000, pp. 38-40). To understand what is happening here, we need to take a wider view of the system and, more specifically, the CLD representation presented in Figure 10.

With this “fixes that fail” example, we can see that investment in HR Development does, indeed, lead to a HR Quality improvement. However, this also results in two unintended consequences: (1) Regional Enterprise Competition intensifies (because we are now offering superior service to our competitors) and, consequently, some of our better staff may well be “poached” by our local opposition; and (2) we lose additional members of our newly-trained HR team to better-paying jobs outside our own region. Together, these contribute to substantial HR Losses and this, in turn, diminishes some of our recent, hard-won HR Quality gains. It also means that we have to invest even

more in HR Development if our HR standards are to be maintained at the desired level.

Scenario 3: Regional Marketing

In this example, we assume that regional commitment to environment despoilment mitigation is minimal and that, as a consequence, Region Attractiveness and (enterprise) profitability throughout the region will gradually decline over time. To arrest this deterioration, local authorities embark on a series of Regional Marketing campaigns. Simulation results are presented in Figure 11.

This is a classic instance of the “shifting the burden” SD archetype (Maani & Cavana, 2000, pp. 40-41), with our specific example being presented in CLD form in Figure 12. The essence of this archetype is that many (if not most) of us have a tendency to ignore long-term solutions to fundamental problems in favour of quick fixes. Thus, the Regional Marketing campaigns

produce good results in the short-term but the overall enterprise profitability trend is still clearly downwards: the reason being that short-term benefits have produced an unfortunate reliance on marketing campaigns and, as a consequence, key regional stakeholders perceive less need to address the fundamental problem of environment despoilment mitigation.

MODEL VALIDATION, IMPLEMENTATION, AND THE FUTURE

In the previous two sections, we have outlined the architecture of our TEPS system and demonstrated how it might be employed by our target users—primarily, prospective SMTE operators. The examples we have presented are specified at a fairly high level. Already though, a degree of complexity is apparent and this illustrates one of the benefits of SD modelling as claimed by its proponents: specifically, the approach can counter our tendency to over-simplify complex problems and issues into simple cause-effect relationships we can readily understand within the limits of our cognitive powers (Vennix, 1996). Of course, this is true of many conceptual modelling approaches and each of these have their own strengths and

weaknesses. SD, however, is particularly well-suited to domains where feedback loops and time are significant (Richardson & Pugh, 1981) and both of these feature prominently in tourism models (see e.g., Ritchie & Crouch, 2003, pp. 60-78).

A fundamental motive behind the development of TEPS was to attempt to encourage SMTE operators to think more strategically and to take a wider and longer, systemic view of the destination in which they intend to establish, maintain and develop their enterprise. Consequently, in interacting with TEPS, they receive feedback on the realities of inherent system features and constraints: such as the delicate development-environmental balance, limits to growth, unintended consequences and side-effects, and the folly of concentrating on quick fixes at the expense of more fundamental solutions. Much of this was illustrated in the previous section and if we are, indeed, able to reach a critical mass of our intended users, then our software tool may contribute towards tourism destinations evolving towards the type of “learning organization” described by Senge (1990).

Thus, as noted above, this educational aspect has probably been the primary inspiration for our work. Nevertheless, the fact that our simulator is capable of producing graphs of projected Enterprise Profitability, HR Quality, Regional

Figure 13. Model validation – actual versus TEPS results for AvRevPerRNO

Enterprise Competition, Region Attractiveness, Environment Quality and more is intended to act as the trigger that might prompt our targeted users to interact with the model in the first place. Thus, it seems essential that our principal outputs should be “sensible”—to the extent that we must be able to convince the average user that our projections are reasonable. Consequently, the model and its implementation as TEPS must be validated and this is being accomplished via a two-stage approach: desk checking and field-testing.

SD models are notoriously difficult to validate (Richardson & Pugh, 1981). As noted by Forrester and Senge (1980, pp. 209-210), there is no single test which might be employed to validate a SD model but, rather, confidence in the model accumulates gradually as it passes more tests and as new points of correspondence between the model and empirical reality are identified. Maani and Cavana (2000, pp. 69-70), drawing on the work of Coyle (1983, p. 362), describe this process as consisting of:

- **Verification tests**, which focus on the equivalence between the structure and parameters of the real system and the model
- **Validation tests**, which are concerned with demonstrating the correspondence between

the behaviour of the real system and the model

- **Legitimation tests**, which determine whether the model is in accord with any generally-accepted system rules

Essentially, the aim of validation is to “show that there is nothing in the model that is not in the real system and nothing significant in the real system that is not in the model” (Maani & Cavana, 2000, p. 69). An excellent example of how much of this can be accomplished through desk checking has been provided by Georgantzas (2003) where statistical measures, such as coefficient of determination and Theil’s Inequality Statistics (TIS) (Theil, 1966), were employed to compare the predictive results of a SD model focused on various key measures of the performance of Cyprus hotels against actual data (over a 40 year period). Similarly, we have subjected our own model to similar tests, concentrating on measures such as occupancy, room nights occupied (RNO) and average revenue per room night occupied (AvRevPerRNO). An example of one of our desk checking outputs is presented in Figure 13. This shows actual vs. predicted AvRevPerRNO for the region on which we based our Major Gateway generic region type.

Figure 14. TIS breakdown of the Figure 13 AvRevPerRNO trend lines

The basis of Theil's approach is that the mean square error (MSE) is divided into three components: (1) bias (U^m); (2) unequal variation (U^s); and (3) unequal co-variation (U^c). The sum of all three components equals one and, briefly, a large U^m indicates a potentially serious systemic error and, to a somewhat lesser extent, this applies to U^s as well. If U^c is large though, most of the error is unsystematic and, as noted by Sterman (2000, p. 877): "a model should not be faulted for failing to match the random component of the data." The TIS results for our example are presented in Figure 14 and, while they indicate that TEPS behaviour provides a reasonable approximation to reality (in this case anyway), there is significant room for improvement: specifically, the variance in our model is considerably greater than that of the actual data. In fact, this can be readily observed through a visual examination of the trend lines in Figure 13. The TIS results, however, are useful in that they quantify the extent of the various error types.

At the time this chapter was being prepared, much of the initial desk checking phase had been completed and, while some fine-tuning was still required, the model was judged as being sufficiently mature that the next stage of validation could commence: that is, field-testing. To this end, negotiations were underway with a New South Wales (Australia)—based tourism authority concerning field-testing TEPS within their region. Testing protocols and other arrangements were in the process of being finalized and it likely that some preliminary results will be available by end June 2006.

Medium to long-term development will focus upon the following activities:

1. Modifications and enhancements designed to address field-testing feedback and ongoing desk checking results
2. Further development of the lower levels of the model; again, this will be largely driven by field-testing feedback

3. TEPS is designed to operate at different levels of granularity. At the more "coarse-grained" levels users assign many of the system's parameters through an "impressionistic" process and this represents the current stage of development. At the very fine-grained level, actual data is used to establish key relationships and to instantiate model variables. Some of this currently takes place but one future development strand will focus on ensuring that, wherever convenient, variables will be assigned and relationships established automatically.
4. As noted earlier, the simulator will be embedded within the STCRC's Decipher (Carson and Richards, 2004) tourism business planning toolkit. This will facilitate the automatic assignment of values to parameters discussed in (3) above. In addition, it also may provide some indication of whether there is any real interest in TEPS among its intended user base—SMTE operators.
5. Further field-testing will be undertaken. At the very least, it is intended to test the simulator in an instance of each of the eight generic destination types for which the model has been customized.

Finally, as noted previously, although the current version of TEPS has been designed specifically for Australian conditions, we believe that the base model is sufficiently generic that it may well be suitable for any tourism destination and that the system has been designed such that it should be possible to conveniently customize it for different destination types (and instances of these types). Thus, while we have no specific plans at present, we aim to eventually test the model in an international setting and, thereby, go some way to establishing its external validity. Field-testing within the eight generic destination types we have identified as appropriate for the Australian context can be seen as a first step towards that objective.

CONCLUSION

We have detailed the development, implementation and use of a tourism enterprise planning simulator (TEPS) based largely upon SD constructs and tools. The motivation for our work and particular approach was: (1) the need for improved access to useful business planning tools among SMTE operators; and (2) the fact that SD copes well with domains that are rapidly-changing and, in addition, can be classified as “messy” (Vennix, 1996, pp. 9-41).

Few would argue that the tourism landscape is evolving at an express (indeed, some might say terrifying) pace and issues that need to be considered when developing tourism enterprises are certainly messy (according to the criteria listed earlier). For example, Buhalis (2000) nominates the number of different stakeholders, stakeholder relationships and goals, contradictions between these goals, and difficulties in maintaining an acceptable and sustainable balance between the interests of stakeholders, natural resources and development activity as major problems that must be confronted in destination marketing and management—and tourism enterprises cannot be established in isolation from destination-level considerations.

Validation of SD models has long been a controversial issue. In particular, the inclusion of “intangible” variables (such as friendliness) in models has received substantial criticism (Legasto and Marciariello, 1980). However, as Campbell (2000) has noted, omitting such variables from models implies that they have a value of zero (or no impact) and, generally, of the infinite number of values that intangible variables might take, the only the only instantiation that is almost certainly wrong is zero! Moreover, considerable advances in SD model validation techniques have been made in recent years and, in the previous section, we demonstrated how one statistical approach might be used to good effect. In addition, the SD approach

has been justified on its benefits and usefulness (Maani & Cavana, 2000, pp. 223-228).

For example, the model presented in Figure 5 contains four main feedback loops. As noted, Vennix (1996) claims that many people are unable to understand the dynamics of a single feedback loop. Once multiple feedback loops are involved, even people who are experienced at interpreting feedback are unable to ascertain the behaviour of a system without resorting to a computer simulation. Even though our example is substantially simplified (i.e., the total HR sub-domain is much more complex than the model illustrated in Figure 5), it clearly indicates the complexity of concept interrelationships and feedback loops within the tourism domain. Yet, it is already reasonably complex and, thus, our example illustrates another of the major benefits of the SD approach: namely that a graphical modelling approach can help to guard against over-simplification and promote shared understanding in both planning and research activity (Vennix, 1996).

Finally, ICT should work in a natural way to help grow the tourism industry. Yet, current research, including our own as discussed in this chapter, demonstrates that the reality is very different. SD offers a tangible solution to increasing our understanding of the field and leading us to more effective business planning and implementation. The use of such modelling approaches, however, must be grounded in improved ways of dealing with change as a norm—both for individual organizations and the industry as a whole. No longer can we afford the ostrich-like or reactive approach to change. Now we need change leadership that regards change as an opportunity and, as that classic management scholar Drucker (1999) suggests: focuses on policies for the future, encourages ways of looking for and anticipating change, finds appropriate ways to introduce change at micro and macro levels, and balances change and continuity appropriately. Only by so doing, by cleverly utilising technol-

ogy and change management interdependently, will the industry and its individual organisations reap the benefits they offer individually and win the challenges the global industry confronts in the 21st century.

ACKNOWLEDGMENT

This research was funded by the Sustainable Tourism Cooperative Research Centre (STCRC), an Australian Government initiative.

Chapter 6.6

Investing in Online Privacy Policy for Small Business as Part of B2C Web Site Management: Issues and Challenges

Geoff Erwin

Cape Peninsula University of Technology, South Africa

Mike Moncrieff

Cape Peninsula University of Technology, South Africa

ABSTRACT

“You have zero privacy anyway. Get over it.” These words by Scott McNeally, CEO of Sun Microsystems, represent one pole of opinion on the privacy protection spectrum in the global world of the World Wide Web and Internet. At the other end, some authors identify privacy as “... perhaps the most contentious and serious issue facing information and communication technology (ICT) managers ...” Assessing these extreme opinions, how does a small business Web site operator determine a feasible and responsible course of action for handling personally identifiable information collected in the course of business? Theoretical and practical frameworks must reinforce privacy treatment. Mishandling of the privacy issue can

disrupt both the reputation and success of an e-commerce or other Web site, threatening the return on investment for the business. This chapter explores the current developments in privacy legislation in South Africa and examines the practical issues faced by a business-to-consumer (B2C) small business Web site owner implementing an online privacy policy.

INTRODUCTION

One of the risks associated with owning and operating a Web site is the contingent liability attendant on preserving confidentiality of personal information surrendered by an e-customer in the course of a transaction.

No matter how user-friendly and attractive a Web site is, the success of the Web site can be jeopardized by the casual or systematic mishandling of personal information by the Web site owner/operator as well as the Internet service provider (ISP). To protect the investment made by the Web site owner in developing and maintaining a Web site, management should ensure that the personal information volunteered by e-customers is securely and confidentially held. In the event that personal information is sold or passed on, accidentally or deliberately, without the direct consent of the e-customer, the Web site owner could face difficulties such as liability for damages, legal penalties, loss of existing customers, and reluctance by potential customers to use the Web site. The policies and methods of privacy protection can be a significant amount of Web site development and maintenance costs. In this chapter, the authors explore various issues associated with the management of personal information on a Web site associated with the protection of an e-customer's privacy.

BACKGROUND

Privacy

Gauzente (2004) finds that there is no single generally agreed upon definition of privacy. For the purposes of this chapter, the authors have chosen a definition quoted by Gauzente from the Electronic Privacy Information Centre (EPIC) as follows: "... the right of individuals to control the collection, use, and dissemination of their personal information that is held by others."

Personally Identifiable Information

Personally identifiable information (PII) is personal information that can be linked back to an individual. Such information can form enough

evidence to link it to a specifically named individual, hence the "personal" aspect. The Electronic Communications and Transactions Act (ECT Act, 2002) includes a comprehensive definition of PII. Romney and Romney (2004), among others, offer some examples of personal information: age, height, weight, medical records, and opinions. They state that publicly available information such as job title or address is not included in the definition of personal data (PII), although, in the opinion of the authors, data such as an address could help to narrow the possible individual involved.

Gauzente (2004) describes a "privacy concern continuum" of personal information ranging from gender, at the level of least concern, through credit card details at the highest level. Each B2C Web site owner must choose a level of privacy policy and implementation that affects concerns along this spectrum, usually in a phased approach. Goodburn and Ngoye (2004) assert that aggregate information compiled from PII does not enjoy the same protection under the law as PII, provided that the aggregate data is incapable of being related to specific individuals. Organizations that collate data from a collection of individuals into summary reports, such as opinion survey facilitators, would fall under this "aggregate information" category.

The issue of the availability of PII is increasingly contentious because of the ease with which an Internet connection can be used to disseminate such information, the multiple different opportunities each consumer has to provide PII to various Web sites, and the reports of so-called Spyware being used to gather PII without the user being aware of that activity.

The Issue of Privacy in B2C E-Commerce

E-customer concerns about privacy online are considered by many authors to be a key disincentive to shopping online (Hann, Hui, Lee, & Png,

2002; Schwaig, Kane, & Storey, 2005). PII can be used by a Web site owner/operator to customize the online shopping experience for a returning e-customer (e.g., by recommending products based on past purchases). The motivation for collecting PII need not be solely for in-house use, however, as it is highly valued by marketing organizations (Goodburn et al., 2004).

Privacy issues in business-to-consumer (B2C) e-commerce constitute a double-edged sword, which can inflict damage on both sides of the relationship. When privacy is compromised, the e-customer risks exposure of PII. This can have consequences ranging from the nuisance of receiving unsolicited marketing material through more insidious threats such as identity theft or discrimination. EPIC describes identity theft as "... the number one crime in the United States." EPIC attributes the rising incidence of identity theft to improper disclosure and use of PII (epic.org, 2005).

Ashley, Powers, and Schunter (2002) identify three reasons why organizations are concerned about PII viz. legislative penalty; brand and reputation erosion; lawsuits. Security breaches at online payroll service provider PayMaxx that exposed the PII of 25,000 people, forced closure of the site (news.com, 2005). Alexa, an Amazon.com subsidiary, was obliged to destroy some PII in its databases and pay up to USD 1.9 million to its customers in settlement of a class action lawsuit (news.com, 2001).

Relevance of Online Privacy Policies

Also referred to as a privacy notice, an online privacy policy (OPP) consists of statements informing an e-customer what information is collected during the course of a transaction and how it will be processed, stored, and used (Earp, Anton, & Jarvinen, 2002). Given the statement "Privacy concerns people, whereas confidentiality concerns data" (University of Kentucky, 2005), it could be

argued that a privacy policy ought more properly to be called a "confidentiality policy."

Schwaig et al. (2005) observe that relatively few e-customers bother to read OPPs and those that do find them hard to understand. In light of this, these authors question a company's motivation to spend money on something of little use to the customer. In their view, companies may be more concerned about being seen to have a policy, creating a favourable, trustworthy image, than about the policy's content or enforcement.

The results of a survey conducted by the authors for a previous paper confirmed that many South African e-customers also experience difficulty in understanding an OPP (Moncrieff & Erwin, 2004).

Impact of Small Business Management on Privacy Policy

In the South African context, small, medium and micro enterprises (SMMEs) are defined in the National Small Business Act (Small Business Act, 1996) as owner-managed, having no more than 200 employees, total turnover not exceeding ZAR 64 million and total gross assets (excluding fixed property) of no more than ZAR 23 million.

Peslak (2005) reports that privately held companies are less likely to have privacy policies than public companies. They are also less likely to show consistency in the adoption of e-customer driven policies. Since SMMEs are by definition owner-managed, it is reasonable to expect that adoption of information technology (IT) and e-commerce will be significantly influenced by the attitudes of the business owners. It can be inferred that this influence will extend to the SMME's compliance with privacy practices.

It takes an organization more interested in preserving and enhancing customer relationships than in collected data to implement a comprehensive privacy management system (Ashley et al., 2002). In the case of SMMEs, the motivation for this must come from the business owner.

The relatively small size of an SMME usually means that the owner/manager(s) have multiple roles, such as accountant, lawyer, network operator, clerk, manager, financier, and more. This reduces the attention that can be paid to issues such as privacy, *inter alia*, compared with large organisations. A large organisation often employs a chief information officer (CIO) to marshal resources and policies to address privacy and other overarching concerns. Outsourcing of privacy compliance to a specialist service provider may be essential for SMMEs.

Legislation

One of the consequences of the advances in Internet technology has been an exponential growth in data flows unmatched by corresponding privacy protection technology (Ashley et al., 2002). These authors suggest that associated violations of privacy have prompted many countries to enact protective legislation. Rising concerns about data protection are confirmed in a South African Law Reform Commission Report (2003), “the Report,” which states that over 30 countries have implemented data protection laws, and that the number of countries doing so is increasing steadily.

The expression of personal privacy legislation varies between countries. However, there are common underlying principles set out in the Report. The Report states that “personal” information must be:

1. Obtained fairly and lawfully
2. Used only for the specified purpose for which it was originally obtained
3. Adequate, relevant, and not excessive to the purpose
4. Accurate and up to date
5. Accessible to the subject
6. Kept secure
7. Destroyed after its purpose is completed

The Report discusses two seminal agreements issued in 1981, which have had far reaching influence on national laws around the globe. These are:

1. The Council of Europe’s 1981 Convention for the Protection of Individuals with Regard to the Automatic Processing of Personal Data
2. The Organisation for Economic Cooperation and Development’s (OECD) Guidelines Governing the Protection of Privacy and Transborder Data Flows of Personal Data

The durability of these documents may in part be ascribed to the fact they were expressed in terms of principles relating to gathering, holding, and usage of personal information rather than the technology of the era. In addition, the European Union enacted the Data Protection Directive in 1995 (European Union, 1995) with the aim of enabling the formulation of consistent privacy protection laws for citizens across member states of the Union. Articles 25 and 26 of the Directive are of particular significance to international trade in that they demand that there should be no cross border flow of personal data to a country “... which does not ensure an adequate level of protection ...”. The provisions of these articles have come to be known as the “safe harbour” principles.

In the United States, the Federal Trade Commission (FTC) is the arbiter of privacy regulation. Currently the FTC favours self-regulation by industry (Schwaig et al., 2005). Self-regulation is based on five principles—notice, choice, access, security, and enforcement detailed in the Fair Information Practices report (FTC, 2000).

The Report characterizes the European Union approach to data protection as based on legal protection of a political right. In the United States, the Report considers information privacy as being “... left to the marketplace ...” and based on economic rather than political power. The Report

characterizes the Australian and Canadian models as co-regulatory, where industry develops the rules, which are policed by an oversight agency. Canadian privacy legislation entitled Personal Information and Electronic Documents Act (PIPEDA) came into force in 2004. Fines for violation of PIPEDA can be up to CAD 100,000.

Privacy legislation in South Africa may be considered to be at a formative stage. Vecchiato (2005) quotes South African Cyber Law expert Reinhardt Buys as stating that privacy is "... only dealt with on a voluntary basis ..." in the ECT Act (2002). The South African Law Commission initiated a project entitled "Privacy and Data Protection" in 2002 which, when it comes to fruition, is expected to impact on the ECT Act (2002) and the Promotion of Access to Information Act (PROATIA, 2000) (South African Government Information, 2002).

The South African Law Reform Commission Report (2003) contains the following preliminary proposals:

- Privacy and data protection should be regulated by legislation.
- General principles of data protection should be developed and incorporated in the legislation.
- A statutory regulatory agency should be established.
- A flexible approach should be followed in which industries will develop their own codes of practice (in accordance with the principles set out in the legislation) which will be overseen by the regulatory agency.

The current fluid state of privacy legislation in South Africa in no way lessens the need for organizations to be aware of their obligation to preserve privacy.

Buys in Vecchiato (2005) points to the importance that EU countries attach to privacy and the key role that privacy plays in their trade relation-

ships. The South African Law Reform Commission Report (2003) expresses similar sentiments, warning that privacy concerns can constitute an impediment to international trade.

Privacy Education

Many people believe that cryptography presents a complete solution to the online privacy and security conundrum (Orgill, Romney, Bailey, & Orgill, 2004). Cryptography plays a role in making transfers of data (largely) unreadable to an outsider or unauthorised snoop. However, this may only delay the availability of the clear text from becoming known if the Web site operator has inadequate controls in place to control such windows of opportunity as discarded backup discs and access points which are not protected.

A common approach is to recognize that unauthorised access to data (PII) will occur and make the content of the accessed data unusable. This approach is also used with security and confidentiality issues, as well as with privacy. Privacy refers to PII. Confidentiality often refers to organisational material such as business plans, salaries of directors and the like. Even when cryptography is used, there is still the aspect of the receiver/storer of PII knowingly disseminating that PII, either for monetary gain or in ignorance of the sensitivity of the data.

Orgill et al. (2004) describe human nature as the weak link in any security strategy. These authors identify shortcomings in education as one of the reasons a person may compromise the security with which they are entrusted. A practical illustration of the importance one e-commerce participant attaches to reinforcing the privacy message among its employees can be found in the following extract from the OPP of share-it!, a German software vendor:

Every quarter, as well as anytime new policies are added, our employees are notified and/or re-

minded about the importance we place on privacy, and what they can do to ensure our customers' information is protected. (share-it!, 2005)

Romney et al. (2004) point to the need for ICT professionals to be familiar with developments in privacy law because of the inevitable impact on the design and operation of databases. These authors conclude that instruction in the basis of privacy legislation is essential to an ICT education. It is commonly held that ignorance of the law is no excuse. Ignorance of the ramifications of privacy law on the part of an ICT professional carries the risk of serious consequences, economic and legal, for both the ICT professional and his or her employer (Romney et al., 2004). This can endanger the viability of the organization, threatening the whole of the ICT investment.

OPERATIONS AND SYSTEMS LEVEL PRIVACY MANAGEMENT

A Holistic Strategy

A holistic privacy management strategy should address both the information systems and operational environments of the SMME. Information systems must be capable of supporting the requirements defined by the OPP. At the operational level, management need to demonstrate commitment to policy, and employees need guidelines to ensure

they are aware of the procedures to be followed in dealing with and protecting the privacy of PII.

A Systems Level Strategy

Ashley et al. (2002) state that there is no existing technological solution to the challenge of instituting enterprise-wide privacy management. In their view, the problem cannot be seen purely as one of data security. It is more a data management problem than one of security. Core to their thinking is that PII should be linked to the OPP in force at the time it was submitted by the e-customer. They advocate a “Sticky Policy Paradigm” (i.e., the policy should “stick” to the data and govern access to it). Table 1 below shows their framework for management of collected PII.

Ashley et al. (2002) call for creation of a privacy policy by a chief privacy officer (CPO), in consultation with people who can formulate it in terms of the legal requirements, the strategy of the business and the relevant legislation, if any. Elements that the policy must address are *Data Users* (data subject users), *Data Operations* (who can do what to the data), *Data Types* (e.g., “Contact Information” as opposed to types in a database schema), *Purposes* (how the data will be used), *Conditions* (qualification of rules e.g., disclosure to statutory authorities), and *Obligations* (e.g., requirement to log certain types of access). Deployment of the privacy policy requires correlation of the *Data Types* in the privacy policy

Table 1. Proposed framework for management of PII (Source: Ashley et al., 2002)

1	Define an enterprise privacy policy.
2	Deploy the policy to the IT systems containing privacy sensitive information.
3	Record consent of end users to the advertised privacy policy when they submit privacy sensitive data.
4	Enforce the privacy policy and create an audit trail of access to privacy sensitive information.
5	Generate both enterprise wide and individualized reports showing access to privacy sensitive information and their conformance to the governing privacy policy.

to PII in the organisation's databases; *Data Users* to roles in the organisation and *Purposes* to tasks and procedures performed in the course of business.

No PII should be collected without the explicit consent of the e-customer to the terms of the extant privacy policy including every stated use of the information. Stored information should be identifiable as belonging to the data subject, and linked to the currently effective policy and the data types within the policy. Enforcement of the policy can be implemented in real-time by means of a suitable application program interface (API) and through delayed monitoring of access log files.

Reporting facilities should be provided to permit an auditor to log and review breaches of policy. The data subject user should be able to request reports detailing the information held on file and indicating which private information has been compromised in terms of the agreement under which it was submitted. The data subject user must also be afforded means to correct the data.

Operational Aspects of Privacy Management

The search for practical methodologies for dealing with privacy concerns is not new. In a paper written before the advent of e-commerce, Smith (1993) prophetically describes information privacy as possibly "... the most important issue of the information age." The same organizational issues identified by Smith in the protection of PII remain relevant today.

Smith describes privacy policy development in the organizations studied as being intermittent, responding to outside threats such as adverse publicity or changes in legislation. A negative consequence of this approach was that in the periods between policy developments, employees had either to operate with policies inconsistent with actual practice, or without policy, at all when no

new policy had yet developed for a changed environment. Smith advocates a proactive approach as the "... backbone of the privacy approach of corporations that use personal information ...". The author urges that business executives take an aggressive stance to the creation of privacy policies. Once a policy is established, the author argues that employee commitment must be ensured through education. A continuous monitoring process is essential to ensuring that practice adheres to policy.

Smith warns against reliance on implicitly inferred policies because this places employees in a position where they cannot produce officially endorsed procedures to support their actions. To avoid a situation where employees experience "value conflicts" resulting from inconsistencies between policy and practice, the author recommends that an environment is engendered in which employees can freely raise concerns about information privacy.

DISCUSSION

E-commerce has matured and moved on from the heady days prior to the dot com meltdown in the early 2000s when the industry seemed to be driven more by catchphrases than sound business principles. Whether genuinely motivated by customer concerns or simply to look good in the marketplace, all B2C Web sites will need to establish privacy policies made public in an OPP. The evolution of privacy law in South Africa will to a large degree determine the content of these organizational policies.

To avoid penalties resulting from violation of privacy laws, the onus will be on the operator of a Web site to ensure that the promises in the policy are made good in day-to-day operations. Achieving this will firstly require commitment to the OPP from the owner of the SMME. Explicitly stated in-house policies congruent with the OPP will need to be established and regularly reinforced

with all employees. To avoid the “drift” described by Smith (1993), compliance with procedures must be audited regularly.

CONCLUSION

Few SMMEs are likely to have the infrastructure to support a full-time CIO. This does not mean that the privacy of data control function can be eliminated. Romney et al. (2004) quote Catherine MacInnes writing on compliance with PIPEDA in Computing Canada as follows:

... To comply with the legislation, some organizations will have to completely overhaul their process for collecting, using, and storing personal information...

South African B2C Web site operators are in a somewhat similar situation to their Canadian counterparts prior to the enactment of PIPEDA. Although the actual form of the final legislation is not known, it can be reasonably expected to be modeled on the proposals contained in the South African Law Reform Commission Report (2003). As such, it should be expected to have teeth in the form of significant legal penalties for violators. Web site systems will be subject to privacy laws, and management needs to factor that into their investment in the development, protection, and maintenance costs.

The requirement to manage PII responsibly cannot be ignored. Organizations involved in e-commerce have an obligation to cultivate awareness of emergent privacy legislation in their employees, to harness the appropriate skills (both technical and legal), to ensure that their procedures and systems are prepared for imminent changes. All these privacy considerations are now part of the normal management task of protecting the investment in the business.

Chapter 6.7

The Use of IT in Small Business: Efficiency and Effectiveness in South Africa

Sam Lubbe

University of KwaZulu-Natal, South Africa

ABSTRACT

This chapter addresses the effective use of information technology (IT) in small businesses. Worldwide it is regarded as a problem as was illustrated in the literature review. Small business owners need to calculate and plan proper use of IT in their businesses by aligning their strategic IT planning to the business plan. A computing grid is proposed with a proper structure and guideline to help the owners.

INTRODUCTION

Information technology's (IT) use in small business had been limited to occasional glimpses of "brilliance." Most of the small business owners have rarely had training to use IT effectively and did not worry about proper use of the Internet. This article therefore investigates the present state of IT in a representative sample in Kwa-Zulu Natal, South Africa.

It firstly defines what a small business is and looks at different approaches to formalise IT in the small businesses interviewed. The instrument that is used (questionnaire) is discussed as well. The results are represented and implications as well as guidelines for small business owners are explained and linked to the theory.

LITERATURE REVIEW

Introduction and General Definitions

IT is impacting the roles and work of individuals and IT enabled change is also revolutionising business processes. It should also be noted that the real engine in association with IT, for economies in Africa, is small businesses. How a small business learns about its environment, how it selects and interprets information through its information system, and how it forms its information structure to get its information processing goals supported by appropriate resources is all fundamental aspects

of how small businesses can process information efficiently and effectively. They should keep in mind that sparks can fly between technology and small business. Chakravorti (2003) notes that the processes by which technology have an impact on smaller business is slow even though the intrinsic benefit is enormous.

DeLone (1988) notes that the majority of business organisations are classified as small and medium (SMME) enterprises. These small businesses differ from large enterprises in terms of strategy, structure, decision-making, and resource availability. He further argues that the allusion of small business research will have an impact on bigger businesses. In an earlier paper (1981), he states that few articles have studied the differences between smaller and bigger businesses (also noted by Duxbury, Decady, & Tse, 2002; Hunter, Diochon, Pugsley, & Wright, 2001; Tagliavini, Ravarini, & Buonanno, 2001). Doukidis, Smithson and Lybereas (1992) argue that IT has made an impact on large organisations but it is not as clear on smaller organisations and that little research had been done on it. Walczuch, den Braveen, and Lundgren (2000) note that small firms are not adopting the technology (e.g., Internet, etc.) with the same speed as the larger firms do. Bunker and MacGregor (2002) argue that it is also important to discover how IT is accepted and used with SMMEs.

Petkov, Fry, Petkova, and D'Onofrio (2003) note that small businesses need technology in order to succeed. Some of these technologies could be used to solve the problems of smaller businesses and accumulate knowledge for improvement of their services. Hunter (2002) argues that IT researchers have not differentiated businesses upon size. He notes that previous research has shown there is a difference in the management of small vs. large businesses in general, and specifically how IT is employed. Researchers, however, need to explore how small business may impact their use of IT. For this specific reason, the study had

been designed to study the impact of IT on smaller businesses in KwaZulu-Natal, South Africa.

Definitions of Small Business

Small business definitions range from those that encompass as few as 10 employees to up to 500 or 1000 employees (Burgess, 2003). Other definitions include turnover, assets, or variations across industry sectors. Managers, however, cannot expect that IT will be used in a similar fashion across businesses that have these ranges in size. Duxbury et al. (2002) argue that smaller business will have simple and highly centralised structures, lack trained staff resources, experience financial constraints, and take a short-range perspective imposed by a competitive environment. They further state that staff should not be more than 99 people. The possibility also exists that a small firm could behave like a big firm from an IS perspective. It is because of this range of definitions that it was decided to tie down the definition and use a standard definition for the region of KwaZulu-Natal: The owner should be involved in the control of the operation, there should not be more than 99 staff members and turnover should be less than R10 million per annum.

Architecture

DeLone (1981) states that smaller firms had been using computers for a shorter period of time than their larger brothers. He argues therefore that some smaller organisations have to make use of external services to ensure effectiveness. Smaller businesses also have smaller revenue and this can cause owners to restrict the IT they invest into. He also notes that smaller firms spend more on IT (especially hardware) in proportion to their total revenue. On the other hand, these smaller businesses take quicker decisions to invest in IT than larger businesses. He states that firms' size is directly related to the size of their IT and inversely

related to the percentage of EDP costs that are used to acquire computer equipment.

Winston (1998) notes that entrepreneurs need to have a positive attitude towards IT and the quality of its architecture. She states that positive attitudes by managers can ensure a higher quality IT architecture. Obviously, IT architecture with a low quality can impact badly on small businesses. The nature of the smaller business on the other hand would determine what type of IT architecture it would need (Rodriguez, 2003).

Purao and Campbell (1998) state that many smaller businesses get state of the art type architectures although they do not need all the computing power. Most of the issues about implementation of IS in small business also deals with the type of IT to be installed. Chakravorti (2003) argues that the players in this instance should all be connected with each other using a grid network and they should not act alone. Grid networking, however, can be an enemy of innovation and impact on the players but it should help them to work together. Barriers to prevent grid networking should be removed and connectedness would become a weapon in small businesses armoury to help diffuse the innovation and get to equilibrium faster.

Capabilities of IT

DeLone (1988) argues that the capabilities of IT should help smaller firms to react faster to market changes and their flexibility to acquire and assimilate new IT will be enhanced by this. Bharadwaj, Sambamurthy, and Zmud (1999), however, state that very little understanding as to what constitutes a firm's IT capability and how it could be measured exist. Drawing from theoretical perspectives, they conceptualize an enterprise-wide IT capability as a second order factor model. In doing this, they used structural equation modelling techniques and verified IT capability construct. They argue that recent research have paid attention to the role of IT capabilities in

enabling superior IT based innovation and business performance. These studies also identified broad capability classes such as IT infrastructure, human IT skills, and organisational resources that could apply to smaller businesses. Hunter, Diochon, Pugsley, and Wright (2001) note that dependency of IT is increased by the increased use of IT in smaller businesses. Small business owners should also ensure that IT is used as efficient as possible.

Although IT usage has been identified as a significant construct in small businesses, gaps remain in the understanding of how IT is used by different organisations and organisational members (Lee, Chandrasekaran, & Thomas, 2003). Their findings were that formalised firms facing competitive pressures have higher levels of IT usage among both management and non-management staff.

IT capabilities could also reduce the cost of business transactions and increased operational efficiency of businesses. Lee et al. note that IT capability simply refers to the use of IT by staff to improve their work processes. Their study has thrown light on business processes in smaller businesses (that is formalisation, a variable in determining IT usage) (also supported by Tagliavini et al., 2001). Organisations that want to increase IT capabilities should aim to set up work procedures, teams, and committees. Tagliavini et al. (2001) further argue that small companies seldom make use of internal IT staff. IS support is also a meaningful percentage of functional areas and should be regarded as satisfactory by the small business owner if they want to be competitive.

Zheng and Zmud (2003) note that organisational scanning and organisational information processing are two critical organisational information-processing activities. Their importance is intensified with globalisation, intense competition between small businesses and dynamic environments.

They argue that governance structures for scanning and interpretation are determined by the

Figure 1. Relationship among organisational scanning, interpretation, and decision-making (Source: Zheng et al., 2003)

need for environmental uncertainty reduction and problematic organisational equivocality resolution respectively. They note that interpretation is important, the more so for small businesses. Degrees of participation and hierarchy of authority is also important for small businesses and can provide a sound basis for future exploration of governance in complex organisational contexts such as small businesses. This will enhance capabilities of small business.

Critical Success Factors

Small business need to implement principles of CSF theory (Petkov et al., 2003). They also need to support learning in a distributed environment based on a distributed IT infrastructure and needs to be compatible with all technologies, enabling organisational learning at the same time. Bunker et al. (2002) argue that business types have an influence on the adoption of IT and some contextual differences, resultant skill, and process orientations make a difference. This could impact on CSFs and small businesses should keep this in mind.

Difference Between Large and Small Businesses

IT investment will make an impact on the competitiveness of small and medium organisations. SMEs are therefore starting to spend a higher

percentage of their turnover on IT. The sentiment is that smaller businesses should be a growth market for the IT sector in order to create this growth market. IT should be used by smaller businesses for instance to retain present customers and win new clients. Hunter et al. (2001) state that it is also useful to consider how small businesses differ from the larger sector to discover how this market could be sustained. Duxbury et al. (2002) argue that small businesses are not just little big businesses and that all small businesses are not the same—small is not always small.

The environment for management information systems might be different for small businesses and may well be missing the needs and problems of millions of small business users (DeLone, 1981). This older paper is being cited because it is an example of how this segment of business has been neglected for quite a while in the IS research field. The strategic orientation of managers of large businesses differs from managers of small businesses (Hunter, 2002). Bunker et al. (2002) note that many Western researchers based their opinion of what should happen in SMEs on what has happened in larger businesses. They argue that cross-cultural suitability should apply to small businesses as well. Their statement is based on the incorrect assumptions that research can be used to cross-pollinate other areas.

Small business managers tend to respond to opportunities with a minimum commitment of resources in a multi-staged approach. Resource

poverty must be used as an explanation of the difference between managers of large and small businesses. Resource poverty refers to the lack of both financial, technical and human resources. Managers of small businesses must therefore continually conduct their affairs with limited resources. This situation tends to increase the manager's focus on a minimum and multi-staged commitment process.

The momentum for the adoption of IT by small businesses comes from a number of sources. Small business may react to actions taken by their competition. Also, because of the prevalent use of IT, the cost to implement these systems has fallen within the reach of small business and is not exclusive to larger businesses. IT has also become more reliable and powerful and small businesses have started to recognise IT as a way to compete with larger companies. Walczuch et al. (2000) argue that a number of benefits that smaller firms are getting from using technology can be described as border crossing because these smaller businesses are always looking for potential business opportunities.

Lack of Resources

Peterson (2003) notes that the very small business suffers from lack of resources and of a sufficient customer base. Petkov et al. (2003) suggest that a lack of resources could affect the development of a CSF theory. Puro et al. (1998) argue that a deterrent for smaller business appears to be start up computerisation costs, unfamiliarity with the Internet and lack of guidance about how to start the process. The primary concern for these small business owners seems to be security hazards. All of these, according to Puro et al. could be due to a lack of resources.

Chakravorti (2003) notes that everyone was excited by the convergence of the changes happening all around and by investing resources expect this to make a profound and immediate difference. Smaller businesses had made huge

up-front commitments to reap early rewards and are then disappointed by the fact that things have not changed much.

Problems Encountered

DeLone (1981) notes that the age of the business is directly related to the experience they show while using computer services. Since many smaller businesses are not that long in business, they may lack this experience on what type of computer service they need. The bigger organisations with established computer services may experience other computing problems than those with younger services. It will therefore be difficult to evaluate the payoff of their "most important" applications. Hunter et al. (2001) state that problems occurred if criteria are not linked to the overall aims of the smaller businesses. The problem is that smaller businesses cannot keep track of technological changes taking place and cannot identify the unique challenges that lie ahead.

It is also a problem with conceptualisation because measures do not take into account the vast array of IT applications with different functionalities that exist in organisations today (Lee et al., 2003). Doukidis et al. (1992) argue that the problem have increased since the early 1980s. They note that advice received in terms of IT investment conceptualisation is still not good enough and that there is little staff involvement in IS development in smaller businesses. Some of the problems that smaller businesses experience in terms of IT are insufficient training, power failures, vendor incompetence, software and hardware. There are also some problems that are encountered with suggested solutions. Some reservations include:

- Lack of computer experience
- Software and hardware selection
- Lack of productivity—people finish their work sooner but does not do more work
- Potential implementation problems

- Financial impact
- Adequate service

The biggest mistake these smaller businesses make in implementing IT is that they do not know where they cannot do everything themselves. They also do not know how to get their customers to interact with them because they do not have the knowledge or experience to do so. Other mistakes they make include trying to do too much too fast and to be afraid of making mistakes because they might lose their business.

Size of Business, IT, and Performance

Few solid results have been found linking IT, organisational structures, and performance. This is because there is a problem of defining and measuring IT, performance, and the fit between technology and structure (Raymond, Paré, & Bergeron, 1993). In smaller organizations, it was discovered that there is a link between IT and structure. Mismatches, however, could exist and could be pointed out early. Small business can compete internationally if they utilize technology in full. IT can allow them to go from high to low-entry cost and will allow them the benefit of competitive advantage. The use of IT also ensures that smaller businesses appear distinctive and allow them access to venture capital.

RESEARCH QUESTIONS

The aim of the research is:

1. To study and evaluate the approach by SA small business owners specifically in the region of KwaZulu-Natal to IT investment and benefit identification
2. To develop a preliminary theory of good practice in the field
3. To test this theory by reference to other enterprises and practitioners

4. To develop the theory into managerial guidelines

The previous literature review and the critique thereof lead directly to the fundamental objective of this study, which is to investigate the application in practice, the impact, and the effectiveness of evaluation of IT investment in small businesses in South Africa (KwaZulu-Natal). Thus, the following research questions were identified: (1) How do South African small business owners identify IT investment and IT benefits? (2) What is involved in implementing sound IT investments in small businesses? (3) Would small business owners agree that this is good practice? and (4) Is it possible to develop the theory into managerial guidelines?

CRITICAL ASSESSMENT OF LITERATURE

This section refers to attempts by researchers (e.g., DeLone, 1981; Doukidis et al., 2003; Hunter et al., 2001) to investigate the use of IT by small businesses. All these authors note that no concrete evidence of the total impact of IT has been made in small businesses. However, these studies emphasize the impact of IT on small businesses in mind while investing scarce resources in IT. Authors like Duxbury et al. (2002) also explain the importance of business size when making an IT investment.

Over the last couple of years, authors (e.g., Hunter et al., 2001) have examined the possibility of quantifying IT expenditure in small business. Bunker et al. (2002) suggest that most surveys of small businesses underestimate the total investment in IT. Some authors (Lee et al., 2003; Raymond et al., 1993) note that the link between IT and performance varies. The problem is the measurement of the business value of IT and information in small business. They all agree, however, that the value of information for small

business should be closely linked to the decision supported by the information available. DeLone (1988) claim that all the components of IT should be considered if the right pricing method for the charge back of IT is to be selected for small business.

Some authors (e.g., Doukidis et al., 1992) established a link between IT investment and an increasing profitability margin for smaller businesses. They note that an increase in the profitability margin could be found in similar organisations in the same industry. All the studies researched agree that investing in IT for small businesses could make a contribution towards the benefits, which the organisation receives.

As can be seen from the previous, not much of the work has been carried out in the field of measuring the impact of IT investment on the profitability and risk of small organisations. Because of the fact that researchers have investigated different perspectives and these credited experts have expressed different views, the authors believe that a need exists for conducting a study in SA that will make a useful contribution for managers in their attempts to obtain results from the application of information systems in small businesses.

RESEARCH METHODOLOGY

The main objective of the study is to determine whether small business owners use guidelines when purchasing (investing) IT and how they apply and use IT in their business activities and whether using IT has obtained effective results.

LIMITATIONS

This study is only an overview of the aspects that should, according to the literature review, be included in the evaluation and selection process of suitable IT for smaller businesses.

DELINEATION OF THE STUDY

The researcher had decided to exclude legal procedures and focused on IT investments from a technical viewpoint. The research scope does not include the processes (e.g., contract negotiation) followed after the decision has been made, as the researcher feels that these steps might not have relevance to the selection of the best IT.

DEVELOPMENT OF QUESTIONNAIRE

The researcher compiled a questionnaire consisting of two sections (demographics and details of the small business and “grand tour” IT questions). The first section was divided into several sub-sections and covers the demographic details of the respondent and some aspects of the small business. The grand tour consists of a focus of the IT in use.

The questionnaire was completed (on behalf of the researcher) by a reliable data collector who interviewed small business managers or somebody they identified who allowed her to speak to the identified employees. The objective of the first section was to ensure they used IT as discussed in the theory. Section B was used to collect data about the IT in use. The objective of section B was to determine what procedure they use to invest into IT, whether they were satisfied with the present IT and does it deliver on demand.

All questions were derived from the literature survey as described earlier in this paper. Open ended questions were used in the questions. The reason for this is to evaluate areas where answers from the respondents indicate in depth approaches to the use of IT.

DATA DISCUSSION

The data was collated (EXCEL, 2000) and the statistics were calculated with the use of Excel.

Figure 2 details the demographics of the respondents.

As can be seen, more than 60% of the small business owners delegated the task to complete the interview to an employee. It is of no coincidence that there are 50% more men than women in this exercise (60% men vs. 40% women). However, it might be argued that managers allow men more freedom in the running of their business and this could be the reason why more men participated in this data collection exercise. Table 1 explains the market the respondents serve.

The market served by these small businesses range from local to international (1 only). The total adds up to more than 100% because the respondents ticked more than one option. It agrees with the literature that these small businesses can (by using computers) change, to a certain extent, the customers it serves. Many of the respondents supply only local communities and this agrees with the statement by Hunter et al. (2001) that smaller businesses are unique and community based. Most of these smaller businesses employ

less than 10 employees (96%) and only one employs more than 30 employees (stated in the literature review). Three of the businesses employ between 11-20 employees. This supports the statement that most smaller businesses in KwaZulu-Natal employ less than 30 people (99%) (see definitions in the literature review). About 80% of the smaller businesses are connected to the Internet and it eventually will help them with starting a computing grid.

More than half of the small business owners are younger than 30 years old (56%) while 6% of the owners are over 40 years. This auger well for the small business sector in South Africa and can assure continuity in the sector. The one problem is that most of them lack experience. DeLone (1988) argues that experience is directly related to the application of the computer services. This could be interpreted that if they are not experienced enough that they will not apply IT as frequently in their business operations. Nearly 75% of the people working in small businesses have less than 10 years experience and another 20% have 11-20

Figure 2. The type of position the respondent holds

Table 1. Market served

Market served	Number	%
Local	60	61
Provincial	23	23
National	23	23
International	1	1

The Use of IT in Small Business

years business experience. There is a high correlation between the years of overall experience and the years of work-related experience. Most of the small business owners have a Grade 12 or college qualification (66%). Thirty-one percent has a degree and the rest have a postgraduate qualification. This shows that you do not have to have a doctorate to be successful. Most of the people that completed the questionnaire help with normal business activities and the rest is either in an administrative position or management.

Details About the Small Businesses

Nearly 90% of the small businesses interviewed have retail (they were selling general goods (83%) and some services (17%)) as their main business activity while the rest of the respondents deliver services (e.g., medical, plumbing, etc.). Most of their revenue is stable (91%) while only 8% has regarded their income as expanding. One of the small businesses stated that they are insolvent and would probably close their doors. This could impact on the use of IT and how they investment into IT. Only one business exists longer than 10 years.

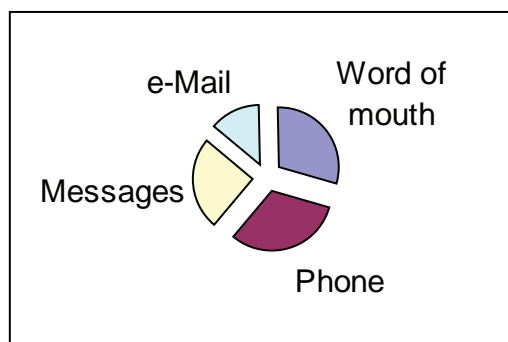

Means of Communication

Very little internal communication using digital communication takes place in the sample. Only

45% of the communication is done using e-mail. The rest of the communication takes place in the form of messages per paper (83%), using the telephone (100%), and personal messages (96%). It is clear that a new culture has to be created to ensure that total acceptance of IT takes place. External communication is by all means no different from internal communication. Ninety five percent of the respondents use oral communication as means to convey a message. Nearly all of them use the telephone to speak to people and snail mail usage is 80% while digital communication with outside people is only 30%. This needs attention and should be solved by some active research in this area in SA. This result is in agreement with the findings by Duxbury et al. (2002) who noted that smaller business do not trust digital media and has received little training in this aspect.

Advertising displays a similar trend where TV is used by only 3% to advertise their service and goods; word of mouth is used by 24%; and business cards by 3%. Newspapers are used by for advertising by 73% of the smaller businesses and the yellow pages by only 8%. Only one small business uses the Internet to market their goods. This is in agreement with Zheng et al. (2003) that small businesses do not rely too much on the Internet or electronic communication as means of advertising their business. Most of the times they use a fax or letter to order to items.

Figure 3. Internal communication

More than 60% noted that they have their own Web page, while only one small business does not know what it means. Most of the respondents know about the Internet but do not know how it will impact their business performance. About 50% of the small business owners had a clue what should be classified as IT. It is therefore clear that half of these small businesses do not have a suggestion what IS/IT entails and how it should be used. This is in accordance with Chakravorti (2003) who noted that the more things change the more (and less) they stay the same. DeLone (1981) argues that firm size and the use of computers have an impact on IT, and the previous figures support the statement he made.

The use of IT is spread over a spectrum and this agrees with the study by Bharadwaj et al. (1999) who argued that there is no defined use for IT in small businesses. The top use of IT/IS in small businesses in South Africa is the use for increased productivity and to handle their money on the Internet (e.g., payment of accounts, investment, etc.). This needs to be further investigated. This finding is also in agreement with Purao et al. who noted that there are some critical concerns and one is that there is no definitive application that stands out in smaller businesses. About 17% of the smaller businesses noted that IT/IS makes a difference but could not explain where the dif-

ference is that they noticed. Some of the uses of the computers amount to no more than number crunching and all resources that the computer offer them is not utilised at all. These include private use, some e-marketing, organising the business, maintaining databases on stock and customers, and researching and looking at new trends on the Internet. As it is evident that there is no consistent use of IT available although it seems that small business owners need to be trained on how to apply their IT.

The top uses of IT in the small business sample include the following:

- Software applications in business process (74%)
- Word-processing for typing letters (all of the small businesses use their IT for word-processing)
- Point of sales (86%)

It is clear that the smaller businesses that have computers use it for three types of exercises. There is little use in terms of WWW applications and they make employ it mainly for tasks that were done manually previously (e.g., cash register changed to point of sale application). Only 4% of the small businesses use their IT for searching on the Internet. The statement by Raymond et al. (1993) is

Figure 4. The use in small businesses (IT)

The Use of IT in Small Business

supported because they note that organisational business processes' structure is not changed even though their processes are computerised.

The investment process into IT is initiated by the owners (92%) and the managers of the small business. The investment process is based mainly on a "flashes-of-commercial-insight" (gut feeling) principle. No benefits are really considered by the investors because they do not have the experience or the knowledge how to do it, nor the time. Most of the times the small businesses are being "misled" while investing money into IT by the salesman who works on a commission base to earning a living. The IT investment done by the small business were mainly for private use (9%), business use (25%) and the main purpose why the IT was purchased was because their competitors have one and they got one but do not know how to use it. This shows there is a link between the use in the business of the IT and the actual reason for the purchase. This explains why most of them do not know what to use the IT for.

Most of the respondents stated that they have a strategic plan but this plan is not tied to their IT. They also do not tie the purchase of the IT to the strategic plan of the business. Most of them (88%) argue that their IT is delivering results but they could not explain what the results are and how this is being measured. This explains the reason why only 60% is satisfied with their investment in IS. Also, to further support this, nearly all the respondents stated that they are not too sure where it is failing them. This is supported by Raymond et al. (1993) who argued that people do not have the capacity to plan properly for the use of IT. They do not understand what the implications for performance in their business are. Nearly 60% of the small businesses agree that software developments can make the biggest impact but they stated that they do not know how to measure this impact. There is therefore a need to help the small business owner to understand and use IT properly. This agrees with the statement by Winston (1998) that attitude impacts on IT quality.

The biggest limitation to full implementation of IT into these small businesses comes down to the fact that 80% do not know how to use IT correctly. Other limitations include items such as:

- The correct use of software (7%)
- Too few clients (4%)
- Does not deliver service promised (3%)
- Not a good investment (3%)

More than 90% stated that they do not trust the information completely on the Internet (in agreement with a statement made by Lee et al., 2003). More than 80% noted that it did not help with any decision-making and is in agreement with the statement above that they do not trust information from the Internet. They all need help to apply IT correctly in the following fields:

- Marketing
- Financial
- Manufacturing
- HRM
- SCM

The research questions could thus be answered as follows:

- The data discussion demonstrated that small business owners do not have an idea of what is classified as IT investment. This is agreement with the theory discussion as well. They can therefore not identify the benefits that they should get.
- Because of the problem, they have of identifying and classifying it is difficult to nominate sound IT investments. Most of the organisations invest into IT as a token but not necessarily as part of their business procedures. This is also in agreement with the literature.

The guidelines as presented next were issued to some focus groups and they all agree that this

could be good practice but that the education of small business owners needs to be kept up to date to ensure proper application.

It was possible to develop some guidelines using the data discussion. The guidelines are presented below.

MANAGERIAL GUIDELINES AND CONCLUSION

As well as developing theory as to how IT investments are developed and evaluated in small businesses, the research also has an objective—to create a series of management guidelines, which will assist small businesses in applying formal procedures when making any IT investments.

These guidelines have been developed from the theory as well as from the results of all the different evidence gathering activities undertaken by the author during the research. The 10 principles so developed reflect elements of the theory developed into practical management guidelines for IT investment.

In order for IT investment to be formulated, implemented, and evaluated in an effective format, the small business owner should:

- **Clarify targets:** IT investments occur as the result of targets identified by small business owners. It means the organisation must look for one or more drivers that could be emphasised. IT investment is thus not just easy internal targets for IT investments. There is evidence from nearly all the case studies to support the principle and it is in line with the studies of DeLone (1988), Hunter et al. (2001), and Duxburry et al. (2002).
- Get to know the drivers for IT investment well and what is likely to change in the short to medium term. It involves monitoring the basic economics of the industry, the industry's technology, the competition, and developments in the IT industry. It would

probably require the setting up of a scanning group and incorporating these reports into the IT investment planning process. The outward process is supported by the work of Lee et al. (2003).

- Develop IT investment targets that are clear and understandable to all parties in the small business. Sub-ordinates that develop the action plans and test the IT should know what they need to do and what managers expect from them.

Outcome (benefit) objectives should be spelled out clearly because they would affect the action plans that would ensure the success of the IT investment. It applies to both tangible and intangible outcome (benefits). All these should be in a format to ensure that everything is running smoothly and that nobody will be able to state that they did not know what to do at any stage. Documentation should thus be available at all times.

Keep the small business's IT investment objectives and IT strategy in the consciousness of the staff as much as possible. Match all IT investment proposals to IT investment strategy and action plans. Make sure that all persons measuring and noting outcome (benefits) have a known and reliable performance index or measure with which to evaluate each outcome (benefit) type, both tangible and intangible. Raymond et al. (1993) support the principle in their study.

Determine the attitude of the owner. Is he or she sensitive to IT investment processes and its potential? It implies that owners are fully aware of the IT strategy and targets. Does the rest of the small business have the skills to make the IT investment process work? Furthermore, the work by Hunter (2002) and Doukidis et al. (1992) support the principle.

The small business must ensure that staff involvement receives the required attention. It may be achieved by ensuring that everybody is fully briefed. Specific thought must be given to

training schedules. Training should be part of the IT investment costs.

Develop adequate support facilities, which can handle a wide range of problems. The basis should be a partnership between all stakeholders in such a way that a two-way communication channel (a grid network exists) between groups of stakeholders who must ensure that the IT investment process is successfully completed. Petersen (2003) conducted work on the topic.

Look for IT investment targets across a wide range of issues, especially in areas that relate directly to the IT strategy and small business strategy. IT outcome (benefits) should be high on the lists of targets searched for. Regular evaluation needs to be conducted to ensure outcome (benefit) realisation. The work by Bharadwaj et al. (1999) also supports the principle.

Adequately staff the IT investment process and implementation with suitably trained and experienced personnel. Such staff must have both the skills of general workers as well as be fluent in IT. Hunter et al. (1999) support the principle.

It is clear that such a practical guideline requires considerable time and resources. Also owners need to be committed to ensure that all concerned promptly comply with these guidelines and that people do not get side-tracked by issues. In applying the guidelines suggested, many smaller businesses would have to face change of a cultural change exercise.

Chapter 6.8

Information Technology Investment Evaluation and Measurement Methodology: A Case Study and Action Research of the Dimensions and Measures of IT–Business–Value in Financial Institutions

Johan Nel

Brisbane Solution Centre, Australia

ABSTRACT

The chapter reviews the present methodology and comes to the conclusion that there is a solution for the predicament of the managers. The author is convinced that the ITIEM methodology is the solution.

the effective measurement of IT-business-value enhanced the need for this study.

The Research Objective

The objective of this study was to identify from empirical evidence, using both case study, as well as action research techniques, a pragmatic ITIEM methodology that would enable organisations to identify their IT investments with the greatest IT-business-value; that will enable the greatest business benefits, while at the same time rigorously assessing all risks, being business risks, IT risks or people (human) risks.

Thus the research question:

INTRODUCTION

The study was motivated by the researcher's concern that a fundamental area of business, ITIEM, has been found to be extremely problematic for most organisations. The lack of an integrated methodical approach to the problem as well as the isolated non-integrated research done to date on

What information technology investment evaluation and measurement methodology can organisations use to effectively evaluate and measure IT investments according to their IT-business-value?

In order to take advantage of the researcher's experience with the financial sector, the study focused on large, publicly held financial institutions. In addition, the financial sector is perhaps the most information intensive sector and has proportionally high investments in IT with proportionally high potential benefits.

The research question has not been made specific to financial institutions, as it was not anticipated that the study results nor ITIEM methodology will be specific to financial institutions. Nonetheless, the study has been conducted entirely within financial institutions, and for this reason, we have much less confidence extending the findings beyond this context.

THE INVESTIGATIVE QUESTIONS

The next level of specific investigative questions that needed to be answered in order to address the research question was:

- What are the major dimensions of IT-business-value?
- How is IT-business-value measured?
- What are the main risks to IT-business-value?
- What are the relative strengths and weaknesses of known ITIEM methodologies in a practical setting?

THE STUDY DESIGN

In order to gain better understanding of the practical issues surrounding effective ITIEM, it was decided to conduct a series of case studies of

organisational attempts to successfully implement and apply ITIEM methodologies. This was followed by action research to implement a proposed ITIEM methodology. The researcher played a pro-active role in the latter case. In both the case studies and the action research study, the unit of analysis is the ITIEM methodology.

The study design included:

1. A literature survey to identify the dimensions of IT-business-value, to identify the measures of IT-business-value, and to identify a candidate starting ITIEM methodology that is most comprehensive, addressing the most relevant measures of IT-business-value. This information was to be used to produce a draft case study protocol.
 2. A single, exploratory pilot case study of a South African bank yielding amongst other things, a revised case study protocol.
 3. A cross-case analysis of a multiple case study of five South African banks (including the pilot) yielding a draft ITIEM model.
 4. A cross-case analysis of three Australian banks, further enhancing the draft ITIEM model, and a cross-country analysis of the South African and Australian banks. The multiple case studies within South Africa and within Australia represent literal replications, while the cross-country comparison represents theoretical replication (Yin, 1994). It is predicted that there will be differences between the Australian and South African experience that are due to known differences in country contexts:
 - Inflation
 - Political stability
1. The ITIEM methodology identified in (1) was then revised to reflect the draft ITIEM model and a hybrid ITIEM methodology was proposed.
 2. The hybrid ITIEM methodology was implemented and revised with action research

resulting in the final ITIEM methodology and final ITIEM model.

- Financial value
- Contextual value

WHAT ARE THE MAJOR DIMENSIONS OF IT BUSINESS VALUE?

Cronk and Fitzgerald (1997, p. 410) suggest that the value resulting from investing in IT can be seen as IT-business-value. They provide a precise definition of IT-business-value:

The sustainable value added to the business by IT, either collectively or by individual systems, considered from an organisation perspective, relative to the resource expenditure required.

They also propose a model representing the relationships between the main dimensions of IT-business-value as depicted in Figure 1.

The literature review aided in the confirmation of the dimension of IT-business-value and following the literature review, the dimensions of IT-business-value suggested by Cronk and Fitzgerald (1997) were adapted to the following:

- Business strategy alignment
- “Soft” value

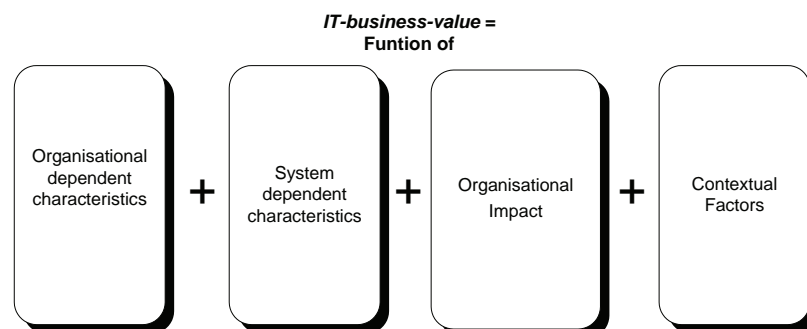

HOW IS IT-BUSINESS-VALUE MEASURED, AND WHAT ARE THE MAIN RISKS TO IT BUSINESS VALUE?

The Literature Review

The literature review aided in the identification of a comprehensive set of measures of IT-business-value, as well as the main risks to IT-business-value. By reviewing literature relevant to ITIEM, it also aided in the identification of an ITIEM method (information economics) that addresses most of the identified measures of IT-business-value.

A positive measure of IT-business-value refers to a positive value contribution to the business; where as a negative measure of IT-business-value refers to a possible negative impact to the business, a risk to the business. Table 1 summarises the measures of IT-business-value by IT-business-value dimension, as addressed by Parker, Benson, and Trainor (1988).

Figure 1. Groupings or dimensions of IT business value (Based on Cronk & Fitzgerald, 1997, p. 412)

The Case Studies

The IT-business-value dimensions and IT-business-value measures identified in the literature review were used to put forward a draft case study protocol, which was refined and finalised during the pilot case study and was then used for an exploratory, descriptive case study involving five banks in South Africa.

The South African case studies resulted in the addition of three more measures of IT-business value, namely:

- Organisational power and politics

Organisations are composed of internal constituencies that seek control over the decision process in order to enhance their position. Organisational power and politics refers to the manipulation of power in organisations using one or more power base available to the individuals. Power refers to the potential of an individual to control the behaviour of others. Hersey and

Blanchard (1980) identified five kinds of power use by people:

- **Legitimate power:** Refers to the position of the person in the organisation
- **Expert power:** Power because of knowledge, information, or expertise
- **Reward power:** Power to give or withhold rewards (praise, salary increases, promotions)
- **Coercive power:** Ability to ensure compliance by using physical, emotional, or psychological threats
- **Referent power:** Power due to loyalty to identify with a leader or evoked by the charisma of the leader

Better Sourcing of Inputs

Better sourcing of inputs refers to the organisations ability to obtain required inputs more effectively and efficiently with the use of the IT investment. In the case of banks, this refers to the ability to attract deposits.

Table 1. Measures of IT-business-value according to Parker et al. (1988)

IT-business-value Dimension	Measures of IT-business-value Dimension	Positive/Negative
Business strategy alignment	<input type="checkbox"/> Degree of integration	<input type="checkbox"/> Positive
	<input type="checkbox"/> Competitive advantage	<input type="checkbox"/> Positive
	<input type="checkbox"/> Project and organisational risk	<input type="checkbox"/> Negative
	<input type="checkbox"/> Strategic architecture	<input type="checkbox"/> Positive
	<input type="checkbox"/> Definitional uncertainty	<input type="checkbox"/> Negative
	<input type="checkbox"/> Systems infrastructure	<input type="checkbox"/> Positive
	<input type="checkbox"/> Technical uncertainty	<input type="checkbox"/> Negative
	<input type="checkbox"/> Competitive response	<input type="checkbox"/> Negative
“Soft” value	<input type="checkbox"/> None	
Financial value	<input type="checkbox"/> The quantified financial return of the IT investment	<input type="checkbox"/> Positive
Contextual value	<input type="checkbox"/> MIS	<input type="checkbox"/> Positive

Better Product Design

Product design refers to a way to add product distinctiveness through design. In the case studies, the banks referred to computer-aided design (Web pages design, etc).

These measures of IT-business-value were added due to large banks as SAB1,¹ SAB3, and SAB4 having included these measures when evaluating IT investments. These banks were also of the opinion that these measures should be compulsory when a bank evaluates IT investments.

Although information economics (IE) addresses a single measure of “project and organisational risk,” the management of the banks were of the opinion that this single aggregated IT-business-value measure does not fully address their need to assess the human factors involved when investing in IT. Mitigating strategies were developed to lower the organisational power and political risk to an acceptable level when there was consensus that organisational power and politics may hamper the successful implementation of the IT investment.

The latter two measures of IT-business-value were added by the banks mainly due to their importance in the new financial services digital economy.

The Australian case studies contributed one additional measure of IT-business-value, namely:

- **Organisational culture:** An organisation’s culture refers to the core values that are shared by a majority of the organisation’s members (Robbins, 1987). A strong culture is characterised by the organisation’s core values being intensely held, clearly ordered and widely spread. The stronger an organisation’s culture, the less management need to concern themselves with developing formal rules and regulations to guide staff behaviour.

THE ACTION RESEARCH

The action research contributed two additional measure of IT-business-value, namely:

- **Organisational communication:** Effective organisational communication was seen to be a prerequisite to realise the foreseen IT-business-value of an IT investment. All employees, managers, executives, and board of directors must understand the IT-business-value of the IT investment as well as the required behaviour to achieve the proposed IT-business-value of the investment.
- **Staff and management skill sets:** The management team of AUS3 also wanted to include the business staff and management skills in the contextual value dimension. They were of the opinion that strategic skills, training levels and skill advantage needs to be assessed because all of these are needed to realise IT-business-value.

This measure of IT-business-value was added due to two Australian banks, which included these measures when evaluating IT investments. As an example, AUS2 consisted of several financial services with different sub cultures. These services were all lumped together and future IT investments were faced with a possible weak corporate culture, at the time.

The South African case studies concluded with a draft ITIEM model. The Australian case study was used to further validate the draft ITIEM model. This model was then used as input to a hybrid ITIEM methodology.

WHAT ARE THE RELATIVE WEAKNESSES OF KNOWN ITIEM METHODOLOGIES IN A PRACTICAL SETTING?

The case studies and literature review revealed the following:

- ROI methods are less successful where IT-business-value cannot be precisely estimated in cash-flow terms and there is considerable uncertainty about the value of the estimates, or the intangible benefits are given a zero value because they cannot easily be expressed in cash flow terms (Kaplan & Norton, 1996).
- Decision analysis can be used in pre-implementation evaluation (as employed by Ozeroy, Smith, & Sicherman, 1992), to choose between geographic information systems), but it cannot perform post-implementation assessment. As a vehicle for interpretative debate, it is very reliant on the analyst and participants for inclusion of social and organisational issues.
- The most well known ITIEM methodologies are not comprehensive enough.
- IE is too complex with regards to value linking and value acceleration.
- More focus is needed on the human factors in ITIEM.

RESEARCH RESULTS

This chapter proposes a new ITIEM model that addresses the dimensions constituting IT-business-value, as well as how to measure IT-business-value. The ITIEM model of the dimensions and measures of IT-business-value was used to propose a more comprehensive, pragmatic ITIEM methodology than is available today and suggests how:

- IT investments can enable measurable IT-business-value.
- To determine which IT investments will yield the most IT-business-value for the organisation
- To ensure that IT investments and business initiatives complement each other

Table 1 lists all measures of IT-business-value identified from the literature and case studies. The measures are cross-referenced with their source ((literature and/or case study(ies)). In the sixth column, the measures are cross-referenced with IE. All measures are included in the ITIEM model.

The last five columns of the table shows which measures of IT-business-value are included in the:

- Draft ITIEM model
- Hybrid ITIEM methodology
- Action research
- The final ITIEM methodology
- Final ITIEM model

OTHER MAIN FINDINGS OF THE STUDY

The following are findings from the case studies and action research in addition to addressing the investigative and research questions.

The Case Studies

The case studies contributed the following key findings:

- Although IE addresses a single measure of “Project and organisational risk,” the management of the banks were of the opinion that this single aggregated IT-business-value measure does not fully address their need to assess the human factors involved when investing in IT. When there was consensus that organisational power and politics may hamper the successful implementation of the IT investment, mitigating strategies were developed to lower the organisational power and politics risk to an acceptable level
- During the case study, several important external factors influencing IT-business-value were identified:

- Political stability of the country
- The state of economy
- Community considerations
- Government

Although they were presented in the draft ITIEM model, the study did not attempt to address these influencing factors. These are factors beyond the control of the organisation and though of interest, beyond the scope of the study. However, this is a very important subject for further research.

The Action Research

The following are key findings from the action research:

- A strategic management process in an organisation is prerequisite to successful implementation of an ITIEM methodology in the organisation.
- Top management support for the implementation is also a prerequisite to successfully implement an ITIEM methodology in the organisation.
- The proposed ITIEM methodology by itself does not establish the IT investment priorities, but rather is an integral part of the business case presented to the IT steering to approve or reject the proposed IT investment.
- The Delphi technique used in the action research proved important for attaining consensus on the weights of the IT-business-value measures.
- An agreed ITIEM management process, taking into account the current decision-making process, is needed in the organisation to successfully implement ITIEM.
- All parties concerned with ITIEM need a clear understanding of the ITIEM methodology.
- Clear roles and responsibilities needs to be assigned to all concerned with ITIEM in

the organisation.

- The weights agreed on for the measures of IT-business-value may change when the local and/ or international economic climate changes.
- The action research confirmed that a complex set of measures will not work in practice.
- Although the researcher at first was initially of the opinion that the more thorough the evaluation criteria are, the better the initial investment evaluation would be, this now seems to be only partially true. The fact that all dimensions of IT-business-value were covered seems to be more important than the completeness of the individual IT-business-value measures. The discussion and consensus reached about the IT investment, facilitated by the ITIEM scorecard and business case details, is in the most cases more important than the actual IT-business-value “score.”
- The area of “human factors” was perceived to be highly valuable when evaluating and managing IT investments. It was confirmed that without focusing on the human aspect, the IT investment would not be appropriately used.

Assessment and Validation of IE

Although this study did not set out to test or validate the goodness of the dimensions, measures or methodology of IE, having selected IE in the literature review, it became central to the hybrid methodology we ultimately tested through action research.

From the literature survey, IE seems to be the most comprehensive method in its treatment of benefits and risks. From Table 17 it is evident that Parker et al.'s (1988) IE most comprehensively covers the identified IT-business-value measures identified in the literature, ten out of an identified fifteen measures of IT-business-value.

Although IE addresses a single measure of “Project and organisational risk,” the management of the case study banks was of the opinion that this

single aggregated IT-business-value measure does not fully address their need to assess the human factors involved when investing in IT.

In all instances, the case study banks used quantifiable IT-business-value measures, which ranged from simple pay-back-period to more sophisticated measures like NPV to take into account the time value of money.

In three instances, SAB1, SAB2, and SAB3, management confirmed that they had knowledge of Information Economics, but did not use the value acceleration or value linking concepts of Parker et al. (1988). The main concerns expressed by senior management were:

- It is complex to determine and costly to perform.
- It is sometimes impossible to “link back” the true benefit to just the IT investment

itself; many other factors also influence the accelerated outcome of “value.”

- Most of the banks had an IT investment benefit analysis process established through which the projected financial return of the IT investment could be established and evaluated in aggregate with all the other measures of IT-business-value already employed by the banks. These processes were well understood and applied by the banks.

THE ITIEM MODEL

The draft ITIEM model was further refined through the South African case study. The proposed ITIEM model was then further validated in three Australian Bank case studies and finalised during the action research. Figure 2 represents the final revised ITIEM model.

Figure 2. The final ITIEM model

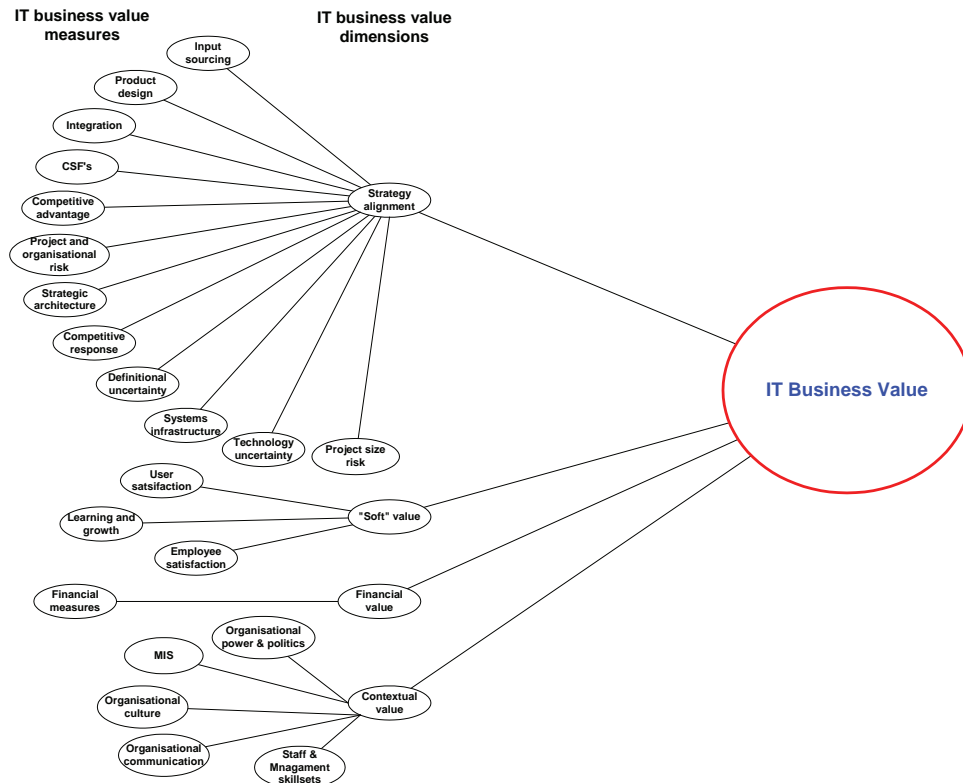

Table 2. Structure of the methodology

IT-business-value dimension	Evaluation and measures of IT-business-value dimension
Business strategy alignment	<ul style="list-style-type: none"> • Degree of integration • Fulfilment of CSFs • Competitive advantage • Strategic and organisational risk • Strategic architecture • Definitional uncertainty • Systems infrastructure • Technical uncertainty • Competitive response • Better sourcing of inputs • Better product design
“Soft” value	<ul style="list-style-type: none"> • User satisfaction • Organisational learning and growth • Employee satisfaction
Financial value	<ul style="list-style-type: none"> • Quantifiable financial measure: NPV
Contextual value	<ul style="list-style-type: none"> • Organisational power and politics • MIS • Organisational Culture • Organisational communication • Staff and management skill sets

THE ITIEM METHODOLOGY

Drawing on the literature surveyed, the knowledge gained from the case studies, the ITIEM model was applied to propose a more comprehensive, practical ITIEM methodology. The final ITIEM methodology integrated all the dimensions of IT-

business-value and the measures of IT-business value from the ITIEM model. This methodology was successfully implemented and tested in AUS3 after four rounds of reflection, change, and re-implementation. The additional identified measures of IT-business-value were integrated to complete the ITIEM methodology. The structure of the methodology is depicted in Table 2.

The MD is still satisfied today that business is taking the lead in all IT investments and that “value for money” is being attained. The head of IT can focus on his contribution, namely to deliver quality IT assets to the business. The weights needed adjustment only once, after which all parties concerned were satisfied. It took four cycles before all parties concerned were satisfied and comfortable with the methodology. Today all IT investments above \$100,000 need to be prioritised using the methodology.

Limitations of the Study

The research was confined to large financial institutions and action research carried out in only one financial institution. Thus, we cannot generalise the findings to other lines of business. At most, we can conclude that the proposed methodology appears to be successful in financial institutions in Australia.

The proposed ITIEM model was minimally tested. The possible importance of the relationships between the dimensions of IT-business-value was not addressed in this study and should be seen as a limitation.

The management decision-making structure needed to implement the ITIEM methodology successfully was not fully discussed in this thesis. Though not a focus of the study, it was addressed during the action research.

As mentioned, the author is aware of the important mediating role of “appropriate use” and other variables, but as previously stated, it could be seen as a limitation that this study only focused on (1) how to evaluate IT investment proposals on the basis of IT-business-value as defined by Cronk and Fitzgerald (1997), and (2) measurement of the IT-business-value resulting from the use of IT.

IMPLICATIONS OF THE RESEARCH

The study suggests that all financial institutions need to evaluate and measure IT investments

to ensure appropriate use and positive IT-business-value. The proposed methodology can be adapted for a particular financial institution assist financial institutions to practically align their IT investments with business strategy, and measure the success of their IT investments.

The proposed ITIEM methodology can only be used for discretionary IT investments. It does not address IT investment categories like statutory requirements, ongoing maintenance, or any other non-discretionary categories.

Study results suggest several implications for further ITIEM research:

- The dimensions of IT-business-value and the measures of IT-business value should be further empirically researched to establish their relative importance to an effective ITIEM.
- The measures of IT-business-value identified by this study, exceeding the IE measures, need to be analysed in further research as to establish their completeness and relative importance. Al-Tameem and Wheeler (2000) also suggest that further research considering human and organisational aspects will be an important departure from the conventional ITIEM approaches. This is also supported by Jones and Hughes (2000) who argue that it is now time to challenge traditional ITIEM methodologies based on hard data. Because they have failed, a soft data approach may be more appropriate.
- Although the methodology was successfully implemented in a financial institution, it needs to be extended to other lines of business.
- Jones et al. (2000) also suggest that ITIEM encompasses a complex process. This process is worthy of articulation and analysis in further research.
- Khalifam, Irani, and Baldwin (2000) argue that there is evidence to support the view that ITIEM is affected by budgetary limitations

and that the way organisations justify their IT investments affects the strategy adopted. More in-depth studies are required to address this.

Chapter 6.9

Examining the Approach Used for Information Technology Investment Decisions by Practitioners Responsible for IT Planning in Namibia

Karna Naidoo

University of KwaZulu-Natal, South Africa

ABSTRACT

Despite the technological progress made by organisations in Namibia, the impact of IT has not been studied. The existing definition of IT is not comprehensive enough to include all relevant IT expenditures. No return calculations are made, though managers are showing growing concern at the increasing IT costs. The purpose of this article is to determine what organisations in Namibia use as basis for investing in IT. In interviews with six organisations in Namibia, it was determined how they define and manage their investment in IT. Some conclusions can be drawn, the first being that organisations need to look at their definition of IT to include all aspects of IT like communication systems, maintenance,

etc. the second implication is that somebody must be appointed to take responsibility for managing the IT investment.

INTRODUCTION

Throughout history, progress in technological behaviour had profound social significance—regardless of whether it was based on mere intuition, trial-or-error, or scientific approach. Machiavelli as *cited* by Bass (1990) made the following comment about systems in general: “There is nothing more difficult to plan, more doubtful of success, nor more dangerous to manage than the creation of a new system. For the initiator has the enmity of all who would profit by the preservation of the

old system and merely lukewarm defenders in those who would gain by the new one.”

We now realise that information systems (IS) are the centre of a new business reality in the 1990s. The impact of the IT revolution is a phenomenon that is affecting every aspect of Third World societies. This revolution increasingly affects anything from the way organisations conduct business to the organisation of schools. The impact can even be stronger than the impact of gaining independence by drastically changing the course of economic development in a country. The major problem is that the use of IT is not fully understood nor studied in the Third World countries in order to yield meaningful insights.

PREVIOUS ATTEMPTS TO QUANTIFY IT EXPENDITURE

Although there has been some growth in the usage of IT over the last couple of years, no analysis of the impact of IT on sales, costs, and profits of organisations has been made in Third World countries. It is, however, important that organisations inform themselves of the impact of IT usage on operating results and profitability. Strategies can then be developed in order to gain a competitive advantage.

Weill and Olson (1989) use case studies of organisations to determine how IT is defined, how IT investments are measured, tracked, and what other factors control IT investment decisions. Some important issues emerged from their study, namely that managers must adopt a broad definition of IT and that IT expenditures can be measured and tracked against a convenient base (revenues, total expenses, or management control costs). Weill et al. believe that attention must be paid to certain factors concerning any important IT investment, namely: managers' commitment to IT, previous organisational experience with IT, user satisfaction with systems, and the turbulence of the political environment of the organisation.

A literature study based on a graphical cost/benefit approach to computer systems selection was presented by Shoval and Lugasi (1988). They note that stages, like analysing the needs of the system and defining its requirements and attributes, need attention.

Ahituv and Neumann (1990) state that any attempt to assess the value of information should be closely linked to the decision supported by the information. They noted that the selection of criteria to use in comparative analysis is the easier part in cost/benefit analysis. The complicated part is to identify all the elements which form part of cost and benefits, and determining how to measure (or estimate) all those elements.

Kwong and Mohammed (1985) suggest the use of a computerised index (CI) that can quantitatively evaluate the impact of computerisation on profitability and, in the process, develop an indicator to the extent and sophistication of computerisation. The organisations used show that an increasing degree of computerisation is generally associated with an increasing profitability margin as indicated by the CI—even in the short term.

In his study involving experienced users, Davis (1989) suggests the use of determinants, the most important one being that if potential users believe that a given application is useful, they may simultaneously believe that the system is difficult to use and that the performance benefits of usage are outweighed by the efforts of using the application.

In conclusion, it can be said that IT investment uses resources of organisations. There are no consensus of the definition of IT and the measurement of its tangible and intangible benefits. This makes IT investment difficult to manage.

CASE STUDY RESULTS

Six mini case studies were conducted to help understand how organisations define and manage their IT investments in Namibia. The six

organisations compose of five large profit-making organisations, while the sixth organisation is a part of the educational system in Namibia. A lengthy, semi-structured interview was conducted with the senior representatives in information systems of each organisation. Every attempt was made to keep the identity of the organisation and sensitive information confidential.

Primary questions covered the following:

- What does the organisation regard as part of their IT?
- How do they manage and track IT investments?
- From where does the impetus for buying IT equipment start?
- What factors influence IT investment decisions?

Organisation 1—Education

Organisation 1 is in the field of tertiary education in Namibia. The interviewee is the director of the computer bureau. According to him IT is defined to include only hardware and software. During the past two years, the budget for purchasing IT equipment was drastically cut. All purchases of IT equipment were done from savings in department's budget. IT is tracked in a combined centralised and decentralised way, but no attempt is being made to include relatively small expenditures. IT equipment is not captured on the tracking of the investment if a department buys IT equipment from own savings. No ROI is calculated although departments are assessed on an output vs. input basis (output could be preparation for lectures while input could be space, equipment, number of persons in the department etc.).

The impetus to buy IT equipment originates from departments who identify a need, get top management's permission, and proceed to buy the equipment. Political considerations do play a significant part in decisions to invest in IT.

The management of the IT investment is done on a partly centralised and partly decentralised basis. There is no link between the buying of IT equipment and the strategy and the strategy of the organisation.

Organisation 2—Transport

Organisation 2 is a large organisation in the transport sector. The interviewee is the chief clerk who controls IT. The interviewee noted that the process of investing resources in IT is the responsibility of individual divisions. IT is defined as all hardware and software. The productive capacity of the IT is planned in order to allow maximum advantage of their investment. The interviewee believes that investment in IT could be maximized but stated that no real attempt is being made to do so. No return calculations are made on the investment and there are decentralised tracking of the investment. He noted that political issues do play part in decisions to invest in IT. The impetus to invest in IT comes from a central point. If the need for IT is recognised, he has to be notified. There is no link between investment in IT and the strategy for the organisation.

Organisation 3—Banking

Organisation 3 is a geographically dispersed commercial bank. The interviewee is a member of the management of the bank. The bank includes hardware and software in its general view of IT. No productive capacity planning for IT is being done in the bank. The bank keeps track on all levels of IT equipment in a combined centralised and decentralised basis. This is done as no simple measure is considered enduring enough in terms of accuracy. The bank's decision to invest in IT is done at corporate level the following inputs from base. Every department manages its own IT.

The interviewee stated that political considerations play a big part in the decision to invest

in IT. According to him, there definitely is a link between the buying of IT equipment and the strategy of the organisation.

Organisation 4—Insurance

Organisation 4 is a local firm who handles all sorts of insurance for a large clientele basis. The interviewee is the manager of the financial department. Their definition of IT includes hardware and software. No productive capacity or any tracking of their IT equipment was done. They do not conduct return calculations on their IT investment because they consider it too complicated. All IT equipment in their possession is managed from a central position.

Political considerations do play a part in their decision to invest in IT and that is why top management takes all decisions regarding IT investments. There is a link between the strategy the organisation employs and decisions to invest in IT or not.

Organisation 5—Consumer Products

Organisation 5 is a large manufacturing organisation in the consumer products industry. The interviewee is the manager of the information department. According to the interviewee, the definition includes all PC-hardware and software as well as all consumables. Productive capacity is planned in advanced as management wants to see IT equipment put to use. All IT equipment is managed in a centralised way. No return calculations are done on the investment in IT. The decision to invest in IT comes from management. He also said that political considerations play no part in decisions to invest in IT. There is a link the decision to buy IT equipment and the strategy for the organisation.

Organisation 6—Insurance

Organisation 6 is a large multi-national insurance organisation with three major businesses,

namely individual insurance, group insurance, and investment. The interviewee is the computer consultant to the organisation. The definition of IT does not include consumables but encompasses all hardware and software. Decentralisation of the organisation is the reason why managers of the organisation decided to decentralise the management of IT. No return calculation is made on IT investments. Political considerations play a part in the decision to buy IT equipment. The impetus to buy IT usually comes from managers and the lower-hierarchy based on what their opposition is doing and how they define their strategy.

ANALYSIS OF KEY FACTORS

The Definition and Tracking of IT

The majority of organisations viewed hardware and software as the only part of its investment in IT. There seems to be a trend to keep the definition of IT as narrow as possible.

IT Investment Management

Organisations track IT expenses with varying degrees of success. Tracking is done mainly on the basis of comparing it with budgeted amounts for the specific year and taking care not to exceed the budgeted amount. Another problem could be that IT investments by departments are not captured on the overall picture of the organisation. No return calculations on investments are done as people tend to think it is too difficult. The total hardware appeared as assets in the asset register though some organisations did not keep track of software expenses at all.

Political and Other Influences

Political considerations are important factors in most organisations and have significant impact on the acquisition of IT equipment. These considerations sometimes overshadow the technical and economic considerations and are becoming more important. In most cases the impetus for investment was taken by managers. This was not

necessarily connected to a decision to incorporate more IT into the organisation. In all (but two) organisations there was no link between IT and the strategy for the organisation.

IMPLICATIONS OF THE FINDINGS

The implications from the findings are: (1) Define and track IT as IT expenditures increase the need for a definition for IT becomes an important issue. This must be broadened to include all cost aspects of IT; and (2) the calculation of the return on investments in IT can be complex as no real cash flow is available.

RECOMMENDATIONS

Organisations in a Third World country like Namibia must realise that they have to manage their IT investment by:

1. **Defining and tracking IT investments:** Redefine the definition of IT so that it includes all expenditures, such as hardware, software, people, consumables, training, and maintenance. There must be accurate recording of this expenditure over time against a convenient base such as revenues or staff employed, etc.
2. **Looking at IT investment and return:** To justify IT investment poses a problem for many organisations. Return on investment (ROI) calculations sometimes does not apply to certain IT investments because it is difficult to determine a definite income stream. Managers must, however, recognise that ROI calculations are not always relevant for all IT investments. They must remember that some IT investments could be essential to the organisation's survival. Lastly, managers must keep in mind that the total IT investment needs to be calculated if they want to

see the effect of the IT investment on the organisation.

3. **Concentrating on organisational issues:** Issues that must be liked into are: Top management commitment to IT; previous experience with IT; user satisfaction with systems; and the political environment of the organisation.

CONCLUSION

It was found that IT definitions are not comprehensive enough. The problem could be that organisations do not sit down and constructively plan their investment in IT. I had the feeling that organisations in Namibia have no idea of the total amount of resources invested in IT. Another factor is that this investment is not managed satisfactorily and that nobody wanted to take responsibility for managing IT investment. My final conclusion is that workshops must be organised and people educated in the concepts of managing IT investment.

Chapter 6.10

A Case Study on the Selection and Evaluation of Software for an Internet Organisation

Pieter van Staaden
Media24 Ltd., South Africa

ABSTRACT

The author conducted research to determine whether IT managers, IT auditors, users, management, etc. (all decision-makers) use a certain evaluation and selection process to acquire software to meet business objectives and the requirement of users. An argument was used that the more thorough the software evaluation and selection process, the more likely it would be that the organisation will chose software that meets these targets. The main objective of the research was therefore to determine whether Media24 uses evaluation methods and obtains the desired results. The results confirmed that Media24 uses suggested protocol as noted in the theory for software acquisition correctly during most stages.

INTRODUCTION

There is a wide variety of methods that can be used for selection of software in various fields of business (e.g., manufacturing, service providers, insurance, wholesale, retail, etc.). This software is used for a variety of purposes in businesses. However, selecting the software that meets organisational requirements and business objectives could prove to be a challenge considering the number of vendors and software available.

Choosing the right software for your company can be bewildering. There are thousands of titles to choose from, and programs and their functionality differ frequently. (Buyerzone.com, 2002)

A hurried, uneducated choice could lead to various problems in the company. Some of these are failing to support an important business process, supporting a process inaccurately or inefficiently, unhappy customers, disgruntled employees, loss of sales, and poor financial performance.

Competition in the Western Cape requires good performance in all aspects of the electronic publication industry. Bad judgments or decisions in terms of software acquisition could cause a company some losses and complications in their daily operations. Choosing the right software is therefore important and can be achieved by using pre-determined evaluation and selection guidelines.

EVALUATION AND SELECTION OF A COMMERCIAL SOFTWARE SYSTEM

Decisions Made Prior to the Software Evaluation Process

As mentioned by Capterra's software selection methodology (2002), certain procedures should be completed before the actual evaluation is conducted. They suggest that the company should start off by interviewing some staff members, addressing corporate vision, analysing existing systems limitations and features, and looking at present policies and procedures. The company should also determine whether new software will help the business and if it will increase competitive advantage.

They argue that when the decision is made to purchase software, a project plan should be developed to evaluate and list the evaluation criteria that will be used during the process. A project team should also be selected to carry out the evaluation. This team must include representatives from all levels the organisation. If the proposed software incorporates financial aspects, the audit team should also be included.

Determine Requirements for the New Software Package

The purpose would be to create a comprehensive and prioritised list of requirements to help evaluate the software. Base Consulting Group (BCG) (2000) state that the requirements definition should consist of several processes (such as managerial requirements (budget/timing, reporting requirements), functional requirements (stated business needs, technical requirements), and IS standards (data flow diagrams, system interfaces, and hardware and network requirements with emphasis on capacity).

They also note that some companies do not develop detailed requirements and as a result may be dissatisfied with the final outcome. Romney and Steinbart (2000) support this statement and suggest that one or any combination of four strategies (listed below) should be used to determine requirements for the new software:

- Survey end-users to determine what their requirements for software is by using questionnaires, personal interviews, and focus group discussions.
- Analyse the existing system and eliminating requirements that have already been defined.
- Examine how the existing software is used, helping to determine the shortcomings of the system, and identifying any new requirements needed by users.
- Pilot demonstrations of applications/software systems could be utilised when there is a problem in identifying requirements.

Document the Requirements

The systems requirement document or software requirement specifications should be the starting point for measuring performance of the final system (Shelly, Cashman, & Rosenblatt, 1998). Users must understand the document to be able

to improve the final version. The content of this requirements document will depend on the type of company and the complexity of the new system. BCG (2000) states that the requirements document is the cornerstone to evaluate the software and should be used to identify requirements. Capterra (2002) argues that there is a methodological approach available to help with requirement analysis. This is listed in Table 1.

Selecting Vendors

Michell and Fitzgerald (1997) argue that the range of services offered by IT vendors is large and growing rapidly. They also note that while searching for the “best” vendor, it should be borne in mind that the process of selection and evaluation of a vendor is important. Base Consulting Group (2000) suggests that the project team’s first step should be to identify the vendors who offer software solutions that could be used. It could be a high-risk approach not to properly evaluate vendor companies. The sources used to compile the list of vendors should be recent and reliable. These sources include software user groups, databases, industry groups, research firms, consulting firms,

trade shows, seminars and conferences, current users, personal recommendations and contacts, competitors, IT, and business magazines, as well as Web sites.

PRELIMINARY EVALUATION OF VENDOR COMPANIES AND THEIR PRODUCT

Ward (2001) argues that selecting software from a vendor should be a simplified process. She suggests that vendors be invited to participate in a software demonstration because it reduces time spent on evaluations. Companies could work toward solving the business problems earlier resulting in faster return on investment. Base Consulting Group (2000) states that inviting too many vendors to participate increases the costs and timelines of the project. Team members may also lose focus after seeing too many product demonstrations. In order to shorten the time of the process send the request for proposal (RFP) to a shortlist of 5 vendors, and do a preliminary evaluation of the vendors.

The evaluation team should look at things like:

Table 1. Capterra’s methodology (2002)

COLUMN NAME	DESCRIPTION
Functional department, business processes, and process.	This creates the requirements hierarchy and ensures that all processes are covered (e.g., would be creditors department, cheque printing, approving cheques for printing, etc.)
Requirement type	This identifies the requirement as functional, technical, vendor related, or contractual.
Requirement description	This details the requirement itself and should be as descriptive as possible.
Priority and ranking	<i>This could be used during the evaluation.</i>
Objective addressed	This could be used to match the requirement to a business objective.
Comments	This can be used for any additional comments or justifications.

- The standard functionality and key features of the product
- Technology requirements (hardware, additional software, database, operating system, network, development tools)
- Product considerations such as viability, stability, and cost
- Products targeting different, smaller, or much larger companies or industries should be eliminated
- Eliminate products that are in development or a recent release.
- Licensing and support costs are examined and products that are over/under priced should be eliminated (licensing escalation must be considered).
- Develop a request for proposal (RFP).

According to Levinson (2001), an RFP guides buyers through a process of tying business needs to technical requirements (e.g., as the particular platform on which the software needs to run on or the systems with which the solution must interface). It clarifies why they are undertaking a particular project. Schwalbe (2000) suggests that the RFP should include: statement of the purpose, background information on the company issuing the RFP, basic requirements for the products and/or services being proposed, HW and SW environment, description of the RFP process, statement of work (SOW), and other information added (as appendices). The SOW should describe the work required for the procurement of the software and help vendors determine if they can deliver required goods and services.

EVALUATION PREPARATIONS

Gather and Organise Resources

Lars and Matthew (2002) note that a reason for not detecting errors early is because the inadequacy of

the test used by the team. The quality assurance of the evaluation project is jeopardised. To prevent this, the test team should ensure they have the resources to detect errors present. The adequacy of resources gathered should be determined at the same time potential vendors are identified. Resources could be added or updated to support the evaluation.

Determine the Evaluation Approach/Technique

Restrictions on Evaluating Software

Dean and Vigder (2002) state that, while purchasing software, there are some unique constraints on the ability to conduct effective testing. In general, it should be assumed that there is no access to the source code. If the source code is available it could not be modifiable and it means that the executable part cannot be tested internally and this rules out white box testing. Documentation should consist of user manuals and advertising materials and is not directed at evaluating the software (e.g., it does not describe the behaviour of the software in response to abnormal input).

Evaluation Techniques and Methods

Romney et al. (2000) suggest benchmarking while processing times of software are measured. Software with the lowest time is normally judged the most efficient. Oberndorf, Brownsword, Morris, and Sledge (1997) engaged scenario-based testing methods to represent typical procedures for the software to be programmed and not the software undergoing tests. Test procedures are developed based on scenarios and each is evaluated against a set of criteria. In this case, the initial scenarios are established using preliminary operational definitions. The results of this will serve as confirmation that the software performed satisfactory against set parameters.

Romney et al. (2000) suggest a point scoring technique to evaluate the vendor. Each criterion

is assigned a weight based on its relevancy. The vendor is assigned a score based on how their proposal measures up to each criterion. The vendor with the highest score is then judged the “best.” They argue that “requirements” costing is an alternative where the total cost of the proposed software is calculated. This provides an equitable basis for comparison.

Another method suggested by Voas, Charron, and McGraw (1997) is the use of fault injection techniques. This is effective when buyers do not have access to the source code. The method consists of inserting erroneous values into the control stream and checking the results. This technique is an example of evaluating (for discovery) to determine unknown or unexpected reactions of the product under evaluation.

Beizer (1995) suggests *black box testing* to allow a tester to treat each module as a unit that can be defined by its inputs and outputs (the interfaces to the module) without considering the route by which an input is transformed into a particular output. Visibility into the internal workings of the code module is not necessary and source code not required. An example of black box testing is boundary value analysis where inputs are supplied to the software to be tested (these values represent valid, invalid and parameters). The outputs are measured and accepted if they fall within expected limitations. This type of testing is used during acceptance testing and is the basis of validation testing, confirming the software performed the required functions.

Other techniques (Hausen & Welzel, 1993) include analysing product documentation, presentations, using trial versions, scheduling demonstrations, or attending training of the software. They suggest that one or more of the previously mentioned techniques could be used to supplement the evaluation of software. The project team should use discretion when selecting evaluation techniques as a company’s approach and resources may vary.

Evaluation Considerations

Hausen and Welzel (1993) mention that some of the following principles should be taken into consideration:

- Repeat testing of the same product using the same product specifications with the same testing techniques must deliver similar results (Repeatability).
- Repeat evaluation of the same product to the same product specifications by different parties must deliver similar results (Reproducibility).
- The evaluation is free from bias while achieving any particular result (Impartiality).
- The result is obtained with minimum subjective judgment (Objectivity).

Product Evaluation

Hausen and Welzel (1993) state that the evaluation process should consider software features (compared to the requirements document), product information (acquired from the RFP, product demonstration, information gathered from investigating vendors, etc.), evaluation techniques, and process information (e.g., results obtained from the testing techniques).

Capterra’s methodology (2002) states that all software should be evaluated to determine if it meets requirements (functional and technical). Any additional (functional/technical) requirements should be listed and re-calculated. Missing requirements should be listed and cost incurred to add these features should be calculated. Price and maintenance levels of the product have to be evaluated by totalling cost and maintenance levels. Firms must consider initial product costs (also long-term costs (such as training, implementation costs, maintenance, and upgrading costs). Project teams should keep in mind that software is expensive and by picking the wrong one could have costly repercussions.

Final Evaluation of Vendor Companies Providing Possible Software Solution

Pollard (1999) suggested the evaluation of the support and maintenance staff of the vendor. He notes that it is necessary to know the number of people in customer support. The response time can be measured by calling the customer support department. The availability and quality of the implementation support also ought to be evaluated. The new software could have bugs and other problems (e.g., not meeting the required deadline). The vendor must provide training because users want to use the system properly.

He suggests following up on customer references, reviewing case studies and finding out how many companies are using the software. The financial stability of a vendor is an aspect to consider. Pollard (1999) supports this by suggesting the examination of the financial history and the long-term financial stability of the vendor.

Selecting the Software System

The total score of the software should be recorded on a scoring sheet when a point scoring technique is used. All the software must be listed from the highest to the lowest. The software with the highest score would represent the best fit for the organisation. Although the software with the highest score might represent the best solution for the company, there may be reasons unrelated to the requirements that could prevent an organisation from selecting software. Inconsistencies should be identified (also extremes in scoring that may influence it—or a competency or deficiency within a single business function). Criteria such as a business partnership, potential future business, or other intangibles, must also be included.

Notify the Vendor

Once the steering committee has approved the vendor, then the vendor should be notified and a contract drawn up. The diagram (on the next page) was derived from the theory to illustrate

steps used during the evaluation and selection process.

PROBLEM STATEMENT

Brown and Wallnau (1996) state that organizations should recognize the importance of technology “refreshment”:

- To improve the quality of their products and services
- To be competitive with organizations providing similar products and services
- To remain attractive to investors

Any organization should invest in appropriate software to stay in business. Careful decision-making on investment into software is therefore essential. Whether the release of an update, or the availability of new software, should force an organization to initiate an evaluation process that provides timely, balanced information on which decisions can be made.

The problem statement was thus stated as:

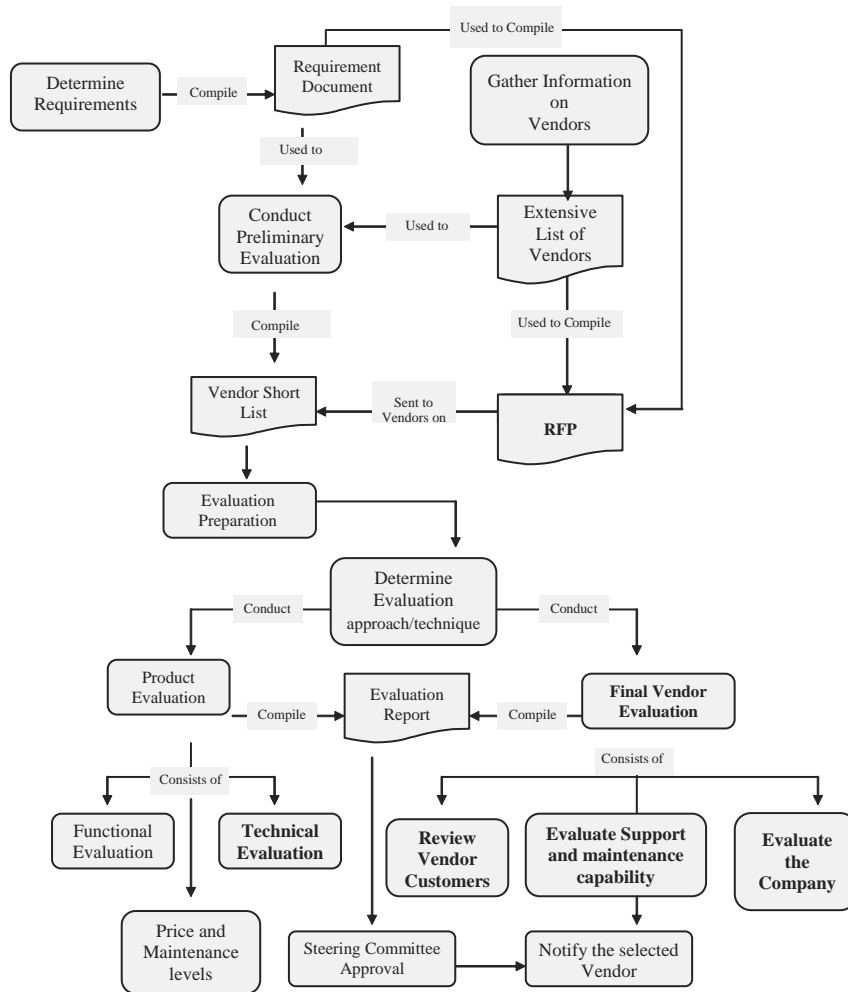

...the more thorough the evaluation of software, the greater the chances could be for the organization to select the software that will meet their business objective and the requirements of the users.

RESEARCH METHODOLOGY

Objective

The objective of the study is to determine whether Media24 uses the correct software evaluation and selection guidelines when purchasing software from a vendor as prescribed in the theory and whether these guidelines have obtained results. Based on the theory and the problem statement, the research questions were stated as follows:

Figure 1. Graphical summary of software selection

- Is the software evaluation process of Media24 thorough enough to select software that fulfils their end-user requirements?
- Does the organisation pick software that meets the business objectives easily?

Limitations of the Study

The researchers had decided to exclude legal procedures and only focussed on the project from a technical viewpoint. Also they were not allowed to use the name of any software used by Media24

as it might discredit the vendor or Media24. The research scope also does not include the processes (e.g., contract negotiation) followed after a decision has been made.

Development of Questionnaire

The researchers compiled a questionnaire consisting of two sections (Section A and B). Section A contained seven sub-sections, covering aspects of evaluation and selection processes. Section B contains the user satisfaction survey.

The questionnaire was handed to a Media24 IT manager who reviewed it. He also identified people responsible for evaluating and selecting software in Media24 to be respondents while he completed a questionnaire himself.

Section A was sent out to 15 decision-makers involved in acquiring software in Media24. The objective was to measure whether they used the evaluation techniques as prescribed in the theory. Section B was sent to 50 users of the software. The objective was to determine whether they were satisfied with present software. All questions were derived from the theory described earlier. A 5-point Likert scale was used in most of the questions (it included questions that required respondents to pick more than one answer). The reason is to evaluate areas where answers from the respondent indicates an in depth approach to the evaluation process. At the end of each section, a section was dedicated to find out in more detail what respondents think.

Analysis of Data

The results of both sections were compared using cross tabulation. The data was captured and analyzed on an excel spreadsheet. Twelve “section A” respondents returned the questionnaires and 74% of the respondents who received section B returned the questionnaire.

Section A: Evaluation Process

Nearly all the respondents agree that the steering committee correctly directs the evaluation process (11). This indicates that people realise that there is a structure in place that could oversee the evaluation of software and is in agreement with a similar comment by Capterra (2002).

All the respondents agree that there are sufficient resources available to ensure that the evaluation process runs smoothly. Nine of the respondents indicated that the project team has

Table 2. Project management structure

enough expertise to conduct an evaluation. Three indicated that they disagree with this. There might be a problem that falls outside the scope of this study and needs to be addressed by management. The organisation therefore needs to assemble a

project team that is representative of the people working in the organisation (see also Dean & Vigder, 2002). Nine of the respondents indicated that Media24 used the interview method to determine requirements. The same respondents

have also used the present system to ensure that they meet the correct requirements (see Figure 4). Six respondents have indicated that they use questionnaires to collect requirements. It seems that project teams in Media24 prefer to use three methods to determine software requirements.

All respondents have indicated that technical requirements are determined beforehand (systems interface). Ten of the respondents are happy that business objectives have been met while determining functional requirements. All agree that managerial requirements should be met when requirements are defined. Nine of the respondents noted that requirements are properly documented. Media24 needs to address this to ensure that people are in agreement otherwise it can become a problem.

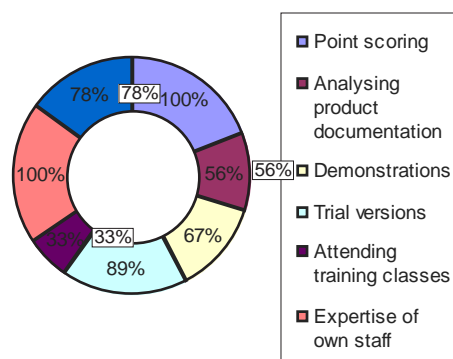

Ten of the respondents agree that many sources should be investigated to identify correct software. The same number agrees that Media24 should ensure that software that meets requirements are evaluated. This is done to limit the number of products to be considered. On the other hand, 11 of the respondents agree that the support/maintenance staff provided by the vendor is evaluated on response time while the quality of support is rated high by 10 of the respondents. It seems to the authors that 'old fashioned' values are still

important while looking at new IT investments. This is in agreement with the statement made by Capterra (2002) that end-users value help provided by the supplier.

The number of people working for the vendor is not regarded as important by the respondents; as long as their service is not affected by it (quality is rated higher). Eight stated that cost plays a role while maintenance is evaluated. Most of the respondents noted that the vendor should be evaluated on financial stability and customer references. The number of clients and long-term strategy of the vendors were not used when looking how reputable the vendor is. This is something that Media24 and similar organisations need to investigate.

Table 5 displays the data collected on the RFP. Most of the respondents agree that this is complied with by Media24. Many (10) stated that the evaluation processes are properly documented while thought is given to objectivity (11) and impartiality (9). Most (10) of them agree that repeatability is lacking while reproducibility (7) is important and needs careful attention. Impartiality is an aspect that needs to be addressed as a third of the people noted that it is lacking. The averages for the request for proposal can be improved but because there are individual items that manage-

Figure 2. Techniques used while evaluating software

ment of Media24 needs to pay attention to as stated. The common method used to evaluate the software is the point scoring technique (Figure 2). Trial versions of software have a better chance to be selected if it was analysed previously or used. The other method that Media24 uses to evaluate software is the expertise of their staff in a particular field.

Table 6 shows the evaluation process. The respondents were positive that the final score used to determine how well the software product meets the requirements is a good method. Nine respondents are in agreement that the documentation to do this evaluation is well laid out beforehand. Management needs to convince the three that does not agree to accept the documentation as presented. Objectivity is complied with

but repeatability of the evaluation is not highly thought off (and the same for reproducibility). Nine of the respondents noted that the tests were impartial. Again, it would be a task for management to convince the remaining three that this is the case before problems are experienced (also supported by Shelly et al., 1998).

Most of the people agree that the final decision to acquire software is based upon the evaluation results. Eleven of the respondents agree that they are happy with the results achieved by Media24. Agreeing meant that they use the methods as prescribed in theory but there are some methods that are not used presently (e.g., benchmarking and black box testing). These should be investigated and used to ensure that the methods presently being used is still considered the best (Beizer, 1995).

Figure 3. Number of complaints from users

User Satisfaction and Overall Effectiveness of Evaluation Process Used

Nearly all the respondents (11) at Media24 are satisfied with the software that was purchased by Media24. Eight of the respondents have agreed that it falls within the parameters set by the organisation. The respondents that do not agree (4) may be users that were not part of the project team. They should be convinced that the software is of benefit to Media24. Eleven of the respondents agreed that the software meet their requirements. This is supported in their article by Michel and Fitzgerald (1997) who stated that

normally most of the users who were part of the process are happy with the software.

This could mean that the individual user requirements agree with Media24’s requirements. However, seven of the respondents agree that there is room for improvement This should be investigated in another study as this falls outside the scope of this study. This does not agree with previous statements made by the respondents. Maybe the present evaluation procedure should be extended to inquire about reasons why the respondents argue that there is room for improvement. This should be included as part of the evaluation.

The respondents (9) complain about the software occasionally to ensure that management pay

Figure 4. Key area's average

attention. Seven of the users argue that there is room for improvement. This would require another survey to find out why users complain about the software and if there is room for improvement.

Section B: Assessment

The main objective of section B was to assess whether the users were satisfied with the software acquired by Media24. There are some complaints lodged by the respondents (e.g., the systems response time and redundant processes and procedures included in the current system and that the software does not integrate with other software). The figure on the next page illustrates the percentage respondents who agreed that they use the correct evaluation techniques. The results are summarized according to key areas.

An area of concern should be the evaluation of the product for management (only 63% average with some areas that were identified that needs attention). Eighty-six percent of users agreed that they were satisfied with the software obtained. Sixty-five percent of users verified that the software systems meet the business objective and 84% noted that the software they are using meets their requirements (also supported by Voas et al., 1997).

DISCUSSION AND CONCLUSION

From the findings, the researchers conclude that Media24 has identified and used the better suited evaluation techniques as described in the theory. End-users were generally satisfied with the software and agreed that the software meet their requirements and business objectives. The above-mentioned statement answers the first research question. It is evident that software that help Media24 achieve its goal has a better chance of being selected (answer to the second research question).

The researchers note that there were some complaints mentioned by end-users. They feel that this “unhappiness” could be because not all employees were actively involved in determining the requirements or because the requirements were not communicated to all users. A manager during an interview noted that the software he was using does not integrate with one of the sub-systems. This eventually leads to more work, as manual reconciliation has to be done between the sub-system and the software. This could be because the requirements or the software weren’t described properly in the request for proposal. Most of the statements indicated that e-commerce organisations should be careful how they select software (Capterra, 2002; Hausen & Welzel, 1993; Lars &

Methven, 2002). This was also supported by the research findings of this study.

FUTURE RESEARCH

Further research might be needed to refine or redesign the evaluation approach used by Media24. The reason is that the current software will be outdated soon and with the rise of new technology, the evaluation and selection process might have to be adjusted. There were also some issues that were not picked up before the installation of the product (e.g., integration with sub systems). This indicates why the evaluation and selection process might have to be revised. Other studies could help place emphasis on the use of specific evaluation models. In order to speed up the process and to gather more data more respondents will have to be included in the sample before the next survey is conducted.

Chapter 6.11

Managing Socio–Technical Integration in Iterative Information System Development Projects

Bendik Bygstad

Norwegian School of Information Technology, Norway

ABSTRACT

The challenges of information systems (IS) development have changed significantly in the past 15 years. From a situation where the main problem was to build stable systems based on a requirements specification, the IS project manager now faces challenges of integration; for example: how to integrate a new information system into large existing information infrastructures and unstable business processes? Building on a socio-technical perspective, four types of integration were identified and analyzed: external and internal stakeholder integration, and internal and external technical integration. A longitudinal case study of an e-business development project in the airline industry identified and highlighted some managerial challenges of integration. Findings include: Internal technical and (to some extent) stakeholder integration is well supported by

traditional project management techniques and software engineering frameworks, such as the Rational Unified Process (RUP). However, the challenges of external stakeholder and technical integration is underrated in IS development research, and not well supported in RUP.

INTRODUCTION

Fifteen years ago, most IS projects were greenfield projects; on the basis of a requirements specification, a brand-new system was designed and programmed. When (eventually) finished, it was installed and run, and the users were trained in new interfaces and routines. The main challenges for the project manager were to get the requirements specification right and complete, and to develop the system to be technically stable.

Of course, this is still a demanding craft, requiring specialized skills, sound methodologies

and competent project management. However, the project manager today faces two more challenges:

- Most information systems are developed to support a business process, whether the scope is a dramatic process transformation or process improvement (Davenport, 1993; Laudon & Laudon, 2004). It is essential that the new system integrates with the business process, because a project that fails to do so will be a failure, even if the software product is well designed and programmed.
- A new system must also relate to an existing information infrastructure. The information infrastructure is seen as a heterogeneous network, comprising an installed base of technology, organization, culture and work practices (Hanseth & Lyytinen, 2004; Hanseth & Monteiro, 1996). Both opportunities and constraints are heavily influenced by the attributes of this base. In a successful organization, this heterogeneous network is an immensely valuable resource; it constitutes the backbone of the organization. But in a world of change, it also may be a barrier to business adaptation or innovation, because the information infrastructure is hard and expensive to change.

The successful IS project manager must address both these challenges. In a way, this redefines the role of the project manager, making him or her an integrator of both social and technical forces. The question is: How is the manager going to make people and technology work together in a complex and unstable setting?

Ideally, the process models of Business Process Reengineering (BPR) and IS development should answer this question. Unfortunately, the BPR community never really developed a full methodology for this integration (Giaglis, 1999). During the late 1990s, the software engineering community embraced *iterative and incremental*

process frameworks (Larman & Basili, 2003), such as RUP (Jacobson, Booch & Rumbaugh, 1999), Object-oriented Process, Environment and Notation (OPEN) (Henderson-Sellers & Unhelkar, 2000), Extreme Programming (Beck, 2000) and Dynamic Systems Development Method (DSDM) (Stapleton, 2003). The growing practice communities contend that these frameworks have the potential to integrate the business process and the new information system through step-wise stakeholder and technical integration (Blomberg, 2001; Kruchten, 2000; Stapleton, 2003). The basic mechanism is the short iteration that produces a small release that can be tested, integrated into the information infrastructure and assessed by the business organization.

This deserves attention not only in the realm of software engineering, but also in the broader context of information technology (IT)-based organizational change. While skeptics have pointed to lack of practical integration support for e-business architectures (Smolander, 2003), and poor project management support (Henderson-Sellers & Unhelkar, 2000), the large RUP community points to a number of success projects (Rational, 2006b). This paper explores, analytically and empirically, two important questions in this context:

- How can the IS project manager integrate the new information system with the business process and the information infrastructure?
- What integration support is there in software engineering frameworks, like RUP?

The rest of this paper is structured as follows. In the next section, the concept of integration is defined and discussed. Then, the integration support in RUP is briefly assessed. The research approach, longitudinal process research (LPR), is presented. Next, the integration challenge is investigated empirically through a longitudinal case study of an IS project in the airline industry.

The findings in the case study are discussed, and implications for practice and research are assessed. The last section concludes and points to further research.

DEFINING INTEGRATION

According to Webster, integration is “a combination and coordination of separate and diverse elements into a more complete or harmonious whole” (Webster’s, 1986, p. 1174).

Building on the socio-technical IS development tradition (Avison & Fitzgerald, 2003; Coakes & Elliman, 1999; Kling & Scacchi, 1982; Mumford, 1985) and actor-network theory-inspired IS research (Ciborra, 2000; Garrety, Robertson & Badham, 2004; Hanseth, 2002; Hanseth & Monteiro, 1996; Walsham, 1997), the two key element types to integrate are seen to be *stakeholders* and *technology*. Stakeholders are anyone (both humans and organizations) affected by the process, while technology may be networks, systems and components.

Stakeholder integration is defined here as a management activity that aims at facilitating cooperation between people and organizations, and helping them work together to create value. The mechanisms for achieving this may be structural (assigning formal roles and responsibilities) or process oriented, focusing on informal interaction (Heugens, van den Bosch & van Riel, 2002). In both cases, trust is important to keep the relationships alive.

Technical integration is, correspondingly, defined as a management activity to assemble components and systems in a way that make the resulting system work as intended. These components are often a mix of internally produced software, existing internal legacy systems, commercial software (COTS) and large networks, like Virtual Private Networks (VPNs) or the Internet. To make them work together is usually dependent on a combination of different actions: Designing correct interfaces, establishing stable operations and giving sufficient support from technical personnel. In the end, however, the most important element is probably correct use, thus connecting technical integration closely to stakeholder integration.

A basic idea in the socio-technical tradition is that the object of interest is not an *artifact*, a piece of technology, but rather the structuring and reproduction of a socio-technical network, consisting of both technical and social elements (Kling & Scacchi, 1982). Thus, the goal of an IS development project is not primarily seen as the construction of a software system, but to establish a working socio-technical network.

Both stakeholder and technical integration may be seen as management activities aimed at establishing *linkages* to different elements that have to work together. In large projects, the number of linkages will grow into complex networks, and this complexity leads to increased risk (Hanseth, 2002). The risk is enlarged by the fact that both the business process and the information infrastructure are unstable; they may change during

Table 1. Integration types

Context	Stakeholder perspective	Technical perspective
Integration within development process	(1) Internal stakeholder integration	(2) Internal technical integration
Integration with business process and infrastructure	(3) External stakeholder integration	(4) External technical integration

the project time, due to external pressures or internal shifts of power.

Internal and external integration. Many integration activities are internal to the project, such as managing project teams, programming and testing components. But many integration activities are external to the project; aligning the project with business needs, modeling with future users, using external components and other systems. Thus, the integration process is multidimensional. It includes both stakeholders and technology, and the activities are both internal and external to the project. Thus, four types of integration are suggested in Table 1.

It is documented that integration is usually easier if done step-wise, because it reduces the technical risk and allows both the development project and the business process people to learn (Boehm, 1988; Davenport, 1993). Early user participation has long been established as an important success factor (Garrity & Sanders, 1998). On a more political level, it also enables enrollment of important allies into the project (Hanseth & Monteiro, 1996). Early technical integration secures the integrity of the system; testing is performed in each iteration, and performance issues may also be addressed early (Jacobson et al., 1999). This is recognized in the iterative software engineering frameworks: For each iteration, new stakeholders are drawn into

the project. And for each iteration, a small piece of solution is implemented, either in a test or pilot environment or in real production.

It may sound easy, but it is not. As Giaglis (1999) noted, the problem is not getting acceptance for the need of an iterative and integrative approach, but to actually manage it. The RUP framework was selected for this study as an example of a well-known framework. Therefore, the first step in this research was to assess to which degree RUP supports the IS project manager in his or her integration challenge.

ASSESSING INTEGRATION SUPPORT IN RUP

RUP is a large framework for software engineering developed by Rational Corp. in the late 1990s, building on Jacobson’s work at Ericsson (Jacobson et al., 1999). As illustrated in Figure 1, RUP is structured in four phases: inception, elaboration, construction and transition. Within each phase are one or several iterations consisting of disciplines, starting with business modeling and ending with the physical deployment of software components. RUP is both a process framework and a commercial Web-based product. The Web product is RUP online (Rational, 2006a), with 3,700 Web pages describing the principles of RUP

Table 2. Distribution of RUP activities supporting the integration types through RUP phases

Phase type Integration	Inception	Elaboration	Construction	Transition	Sum
(1) Internal stakeholder integration	5	4	4	4	17
(2) Internal technical integration	11	23	23	14	67
(3) External stakeholder integration	14	5	3	7	29
(4) External technical integration	3	3	1	4	11

and providing a rich toolbox of guidelines, risk lists and document templates.

To assess the degree of integration support in RUP, a rather simple but systematic analysis was performed. The basic material was the templates of detailed activity lists provided in RUP online to help the IS project manager to plan the phases of the project. These lists are certainly not sufficient to plan a RUP project, but they give a reasonable picture of the profile of activities in each phase.

The assessment was done as follows: Each activity was classified within the four integration categories presented in Table 1. The resulting distribution of activities is shown in Table 2.

As the table shows, integration support is unevenly distributed. It is quite strong regarding internal technical integration throughout the phases, while it gives surprisingly little external

technical integration support. Internal stakeholder integration is weak throughout the project, confirming, perhaps, the critique against RUP for poor project management support (Henderson-Sellers & Unhelkar, 2000).

Support for external stakeholder integration is strong in the inception phase, but gets weaker in the later phases. A more detailed analysis of these activities shows that RUP gives strong high-level support to external stakeholder integration, but little practical support at the operational level. The same pattern is found regarding external technical integration. This may indicate another limitation in RUP: It endorses step-wise external integration, but little practical support.

**THE CASE STUDY:
DEVELOPING AN E-BUSINESS
SYSTEM FOR AN
INTERNATIONAL AIRLINE**

To investigate the challenges in more depth, a longitudinal case study was designed, studying an IS development project in the airline carrier industry. The research approach was LPR, which aims to study organizational change over time through intensive research in the actual context (Ngwenyama, 1998; Pettigrew, 1985, 1990). LPR focuses on building theories strongly embed-

Figure 1. Structure of RUP (Rational, 2006a)

Table 3. Data collection

Phase/dates	Activities	Stakeholders	Documents
Phase 1 Sept. 2001	Initial meeting with management to agree on objectives and procedures in the study.	Line manager Project managers	Project objectives and plans
Phase 2 Nov./Dec. 2001	Workshop with project and business stakeholders to get the broad picture, followed by separate interviews	Project manager Project group Business users	Status reports Technical and architecture documents
Phase 3 Sept./Oct. 2002	Separate interviews with stakeholders to construct full timeline in project	Project manager Project group Business users	Status reports Project evaluation report
Phase 4 Dec. 2002/ Feb. 2003	Last round of interviews. Validation meeting to confirm and discuss findings.	Line manager Project manager Business users	Case description

ded in the context of study. Reflecting Giddens' structuration theory (Giddens, 1987), context is seen by Pettigrew not only as an environment, but as "a nested arrangement of structures and processes where the subjective interpretations of actors perceiving, comprehending, learning and remembering help shape the process. The processes are both constrained by context and shape contexts" (Pettigrew, 1990, p. 270).

Important criteria for data collection are, according to Ngwenyama (1998):

- Ongoing engagement with the research site, to observe changes over time
- Participant observation, to contextualize and make sense of observations
- Multiple data sources, to record different interpretations of events and ensure validity of findings

The case, a RUP development project at Scandinavian Airline System (SAS), was researched for 16 months, using several techniques for data collection: Project managers, developers and users were interviewed at four intervals. Project meetings were observed, and a vast amount of project documentation was analyzed.

Data collection was done in four phases, as summarized in Table 3.

Ngwenyama (1998) suggests three modes for data analysis: (1) Comprehensive analysis, which helps to identify underlying structures and patterns of the organizational process; (2) temporal analysis, which helps contextualize findings by placing events and situations in a narrative structure; and (3) member verification, which ensures that the case description and interpretation researcher are considered correct and meaningful to the organizational actors.

The SAS case was analyzed in the following steps: Data was coded following the guidelines of Miles and Huberman (1994). After the videotaped interviews were summarized and registered into an Atlas database, texts were coded with in-vivo

codes, using only domain (project) terms. The large volume of project documentation was coded the same way.

First, a timeline with significant events was produced. Then, each iteration of the project was analyzed in detail, while in parallel looking for repeating patterns. Looking for integration related terms, a new layer of codes were applied: "Technical integration" was mapped to *component integration, testing, interface* and also to *legacy (and other) systems*. "Stakeholder integration" was mapped to *stakeholders, actors, users, customers, organizations* and *vendors*. The integration context was also coded; whether it was *internal* (to project) or *external* (to business process and information infrastructure) integration.

Validating the Case Description

Suggested mechanisms and patterns were validated using criteria suggested by Klein and Myers (1999).

The principle of dialogical reasoning addresses the validity problem of the relationship between the assumptions behind the research design and the actual findings. In the case study, this aspect was important in the coding process described in the previous section. Moving from codes to patterns, systematic attempts were made to construct the opposite pattern and ask whether it could make sense on the same data.

The principle of multiple interpretations calls for sensitivity in interpreting conflicting accounts of the same case. In the case description, special care was taken to analyze instances where data was contradictory; for example, when developers and user representatives had different accounts of what had happened.

The principle of member verification (Ngwenyama, 1998) was implemented as follows: After the initial workshop with important stakeholders, a timeline for the project was constructed. This was sent to participants for verification. After about a year of studying the project, a preliminary

case description was written and commented on by stakeholders. Last was a validation meeting, where project managers, developers and business users were invited to assess and comment on the final case description.

The SAS Content Management Interface (CMI) Project

The case is described from a socio-technical integration perspective, focusing on the stakeholder and technical integration challenges.

SAS is an international airline carrier based in Scandinavia. It is owned by the Swedish, Danish and Norwegian governments (50%) and private investors. In 2003, the SAS group had 34,000 employees, and turnover was 57 billion Swedish krona (SEK).

As a part of the marketing division, SAS established in 1999 the Electronic Direct Channel (EDC), directed at selling airline tickets and hotel reservations on the Internet. The EDC owns the SAS home page, including campaigns and online booking services. Simplified, the e-business process consists of these steps: Marketing air tickets in different national markets on the scandinavian.net Web site, and receiving electronic orders. Feedback mechanisms are Web hits on the home page and actual bookings.

The first generation of the SAS Web site was primarily available in Scandinavia, with content managed by editors using HyperText Markup Language (HTML) and FrontPage as publishing tools. In 2000, acknowledging the commercial potential of Web-based booking, SAS decided to establish a Web-based marketing channel in all important SAS markets, including Europe, Asia and the Americas. To support this new business process, a new content management and publishing solution was needed, and implementation was based on the Vignette platform. A project was initiated, with the following objectives:

- To establish a Web-based marketing channel in all important SAS markets, including Europe, Asia and the Americas.
- To enable the editors to publish materials and campaigns with an easy tool, a CMI.
- To integrate this new system with SAS' (legacy) booking system and the European Amadeus booking system.

In spring 2001, the IS development project was set up by SAS' daughter IT company, Scandinavian Information Group (SIG), with a project group of five: one project manager, one Web designer and three programmers. In parallel, an SAS project group, consisting mainly of marketing editors, was established to provide a strong business and user link with the development group.

Following a corporate decision from 1999, the project was planned within the RUP framework. Each iteration was set up to follow the disciplines in RUP, starting with a revision of requirements; proceeding with design, coding and testing; and ending with an increment, a temporary release, to be validated by users. Also, in accordance with RUP, a stakeholder and risk analysis was done.

The First Two Iterations: Unsuccessful Stakeholder Integration

The initial requirements specification, written by IT personnel at SIG, contained 14 use cases for the CMI application. In two workshops, the two project groups extended the number of use cases into 20 detailed ones. Then they started working on a graphical prototype to visualize the use cases.

The workshops were not very successful, and they were interpreted differently by the actors: The SAS project manager, who was now elaborating the requirements specification, was moderately satisfied:

The workshop in the first iteration was OK because it gave the users an impression of the system. The workshop in the second was useful, but we were not able to show the users how the system would work.

Some of the editors felt alien to the whole concept:

We spoke different languages, and they had no idea how we worked. We were polite, and there was no conflict, but that was how we felt. We thought we might get it straight later on in the process. The use cases were very – theoretical, and it was hard to participate. Also, I was so busy running the existing site that I had no time to spend on this, really. I felt guilty because of that, because I should have given much more input.

Another editor said:

Use cases focused on the new system, not on how things were solved today. Development was system oriented, not on the work process.

The developers later said:

Of course, the graphical prototype should have been a full architectural prototype – but this was not possible, because the presentation engine component was not ready. In addition, the editors did not really prioritize the workshops.

Not surprisingly, the results were unsatisfying. Nobody felt that the graphical prototype was useful. The presentation engine component, which was crucial for creating a page, was developed in another project in Copenhagen, and it was seriously delayed. Thus, by the end of the elaboration phase, the two main goals were not reached: The users and developers did not have a unified view of the system, and the architecture of the system was not stable. The situation was analyzed and the risks were assessed by the customer and the

project managers. Because of time pressures, they decided to proceed, and took care to prepare as much as possible to integrate the missing component later.

Iterations Three and Four: Successful Internal Technical Integration

No code had been produced in the first two iterations. In the third iteration, the project group got a better grip on the technology, and started to work more closely with the SAS project manager, who was now sitting in the same room. This iteration produced the basic CMI functionality, enabling the CMI users to upload content to the content database.

In the fourth iteration, the first release of the presentation component arrived, and the crucial functionality for creating pages was developed. In a few intense and informal work sessions, a design was developed as the application was prototyped. Commented one of the developers:

When the SAS project manager really joined the team, the whole atmosphere changed. We were able to experiment with screens and solutions at a practical level. Also, it was important that he really understood the technical difficulties involved. We were sitting long hours together, solving real problems. It was very productive and also great fun!

Test cases were also produced, and at this time the project group felt things were on the right track. While the user group was not involved, the SAS project manager communicated frequently with the editors, assuring them that the project was on track.

After the start of the fourth iteration, the September 11, 2001 terrorist attacks in the United States (U.S.) shook the whole airline industry, and as a result of this, combined with a tight project deadline, the project was scaled down. Only 10

of the initial 20 use cases would be developed. By the end of November, the user group started testing the system. Towards the end of the iteration, the SIG project manager went on maternity leave, and the SAS project manager was made in charge of the whole project.

Iteration 5: Improvised Integration

So far, the project had proceeded more or less as planned. But now a different phase started, which was not characterized by planned iterations but rather by problem solving and improvisations. The project manager commented:

At a certain point in a project the focus changes: Budget and plans are no longer the main consideration, and everything is focused on getting the product finished.

There were two reasons for this. First, the project experienced external technical integration problems. In the fourth iteration, the project waited for the completion of two important software components that were programmed by another SIG project in Copenhagen. Both were seriously delayed and not stable until spring 2002. There were also other technical problems. SIG had four different technical environments: Development, integration testing, production testing and production. In this case, the test environments did not fully support the CMI, and intermediary solutions had to be made. Complicating matters even more, a memory leak occurred, which took a long time to identify and fix. These problems made testing more difficult. Second, after beta testing had started, there were a rising number of change requests from the user group, and changes were introduced frequently during spring 2002. One of the editors said:

From the end of February, we started testing at our workplace. At that time I had no mental picture of the whole systems, only fragments. In March, when we started to load real data, I was able to

understand the workings of the system. Until then, it was like looking at the system through a pair of binoculars.

As the editors got more experience, the number of change requests increased. Said the Oslo editors:

The period around the start of the system we sat together with the developers and really understood the whole system. This was great, and the first time we really could give real input.

In March, there was a 2-day course in Stockholm for all the editors, at that time numbering around 30. Most of them were introduced to the system, and in spite of technical stability problems and long response time due to slow interfaces (APIs) in the Vignette platform, the course was perceived by the EDC and CMI project as rather successful for most of the editors. A few of them were less motivated, and lacked the basic IT user skills. After the course, the editors went home and started to load materials into a test database, which was later set into production. In this period, the CMI project worked hard with error corrections and use case change orders. The project manager said:

Many new features were wanted from editors, both Scandinavian and the others, especially navigation features tightly connected to their work processes, page search and design. We were surprised by the volume of change orders.

Results

Everything was set into production May 30, 2002, and has been in stable production since. The three goals of the project were achieved: a Web-based marketing channel in all SAS markets was established; the marketing editors in this organization had access to an easy-to-use tool to tailor the marketing and selling of SAS services

Table 4. The managerial challenges of integration

Integration type	Managerial challenge	Support in RUP
Internal technical integration	Step-wise internal integration of components needs careful planning and competent execution.	<i>This is well supported in RUP and in traditional project management techniques.</i>
Internal stakeholder integration	Step-wise integration of project team members calls for sensitivity, especially in relation to user representatives.	<i>This is partly supported in RUP.</i>
External technical integration	Integrating to the technical infrastructure is outside the direct control of the project manager. It calls for careful planning and risk management, but also for improvisations.	<i>RUP gives some high-level support, but not at the operational level.</i>
External stakeholder integration	Integrating to the business process is also outside the direct control of the project manager. It calls for planning and risk management, but also for political skills and improvisations.	<i>RUP gives some high-level support, but not at the operational level.</i>

to their local markets; and the Web pages were integrated with the booking systems, enabling customers to buy tickets online. However, during the first 6 months of production, there were still a large number of change requests from the marketing editors.

The case study highlights a number of managerial challenges associated with integration. These will be discussed in the next section.

DISCUSSION

This section first discusses the findings of the case study, in terms of managerial challenges of integration. Then some implications for practice and research are proposed. Finally, some limitations of the findings are assessed.

Managerial Challenges of Integration

The findings of the case study are discussed within the framework of the four integration types (presented in Table 1). They will also be related to the analysis of integration support in RUP presented in an earlier section.

In the described case, integration is seen as a *process*. It was partly or fully achieved through different managerial interventions, supported by the iterative and incremental structure of RUP. The managerial challenges associated with the four integration types are discussed below and summarized in Table 4.

Internal Technical Integration

This aspect was, after some initial problems, solved very nicely in iterations three and four. The CMI system was built incrementally and controlled, utilizing the rich mechanisms in RUP for step-wise integration and testing.

Findings: For the technically competent project manager, a software engineering framework such as RUP provides sufficient support for step-wise and controlled technical integration.

Internal Stakeholder Integration

At the start of the CMI project, the most central users in the business process, the Scandinavian editors, were drawn into the project and given a central role in the workshops. The workshops in

iterations 1 and 2 were not successful, mainly because the project managers failed to convince the editors of the need for a new system. The project group responded to this with a certain degree of isolation, establishing a close team with the SAS project manager, who “changed sides”; that is, who identified more with the project than with the business process.

The progress of software development benefited very much from this cooperation. However, when the number of change requests increased in the later parts of the project, it was an indication that the iterative approach was not working optimally regarding user requirements.

Findings: Iterative IS development projects are not based on a frozen requirements specification, but rely on a step-wise interaction with business representatives through the iterations. Thus, it is critical to align project goals with business and user goals even after the initial top-down analysis. RUP does not give sufficient support for this task, as shown earlier.

External Technical Integration

The CMI project suffered from being dependent on components that were delayed. Thus, while skillfully planned, the step-wise technical integration was not working properly. Instead, the external integration problems appeared at a time when the editors tried to integrate the system into their organization, and it threatened the whole implementation.

The main technical problems arose from the fact that the development environment, and also the test environment, was configured differently from the production environment. In the test phase, this led to a series of small but important problems of instability. In the production phase, it led to the cache problem. As the project was designed, this kind of risk was hard to avoid, because a test environment mirroring a changing production environment would have been exceedingly expensive. In the end, the problem

was gradually solved by a competent data center, using problem-solving techniques, and not a structured development process.

Findings: Integrating with a large, existing information infrastructure calls for careful planning, but also for improvisations. Often, the infrastructure is subject to change during the project, and it is therefore impossible to integrate in a step-wise manner. Obviously, the project manager has to comply and adjust to these changes, whether or not they were planned. This aspect is underrated in RUP.

External Stakeholder Integration

The main target group for the CMI specification was the international editors, who needed a standardized and simple interface. Unfortunately, during the first four iterations they were not yet appointed, and could not participate. Thus, the continuous change of the business process made step-wise stakeholder integration unfeasible.

On the other hand, the international stakeholders were successfully enrolled in the project from March 2002, and during the busy, and partly improvised, period towards the production date, most of their requirements were satisfied. It should be noted, however, that during the first 6 months of production, there were still a large number of change requests, indicating that important business needs were not covered in the specification. It should also be noted that the late integration of stakeholders was done by improvisation.

Findings: Integrating with the business process calls for political skills and improvisations. Political skills are needed to build the alliances that make the solution work. Improvisations are necessary to integrate with an unstable process.

Of course, it is unreasonable to blame RUP for the late integration problems in the CMI project. But the “extended iteration” in the project, where the structured method gave little support and the project manager resorted to improvisation and problem solving, also indicates that this challenge is underrated.

Summing up: IS development in a complex and unstable technical and business environment, as illustrated in the SAS case, highlights the need for step-wise socio-technical integration.

Iterative IS development has an interesting potential to support this challenge, because the iterative structure allows for step-wise learning and incremental improvement. It also, to a certain degree, acknowledges the emergent nature of socio-technical interaction. However, in its present condition, RUP is too heavily influenced by its purely technical inheritance to give sufficient support to the full range of interaction challenges.

Implications for Practice

The CMI case highlights an important insight for practitioners: The integration challenge of iterative software development projects is larger and more complex than is described in the research and text book literature. Even the very competent CMI team experienced serious problems with external integration. For practitioners, this is an important factor in risk management: To succeed, the project manager must manage something that is basically outside his or her control.

The root of this risk is the fact that both the business process and information infrastructure are unstable in most enterprises. As illustrated in the CMI case, the focus in a development project may change considerably over time, making it hard to plan in detail. And changes in the business process and information infrastructure should be treated as a normal feature, not as an unexpected incident. For the project manager of iterative projects, this aspect also presents opportunities, but in a world of tight schedules and budgets, the external technical and stakeholder integration is a significant risk.

For the IS project manager, this implies that risk management focusing particularly on external integration—is as important as internal planning and control.

Implications for Research

At a general level, these risks are acknowledged in the IS development research (Avison & Fitzgerald, 2003) and in iterative software engineering frameworks (Jacobson et al., 1999; Stapleton, 2003).

However, as illustrated in the the SAS case, these risks are not appendices in handling a primarily technical task; on the contrary, they constitute a significant threat to the success of such projects. As the RUP analysis in the earlier section shows, the support in RUP is not sufficient to handle this challenge, in spite of some minor contributions (e.g., Kruchten, 2003).

Thus, on a practical level, RUP needs stronger support for external stakeholder and technical integration; in particular, in the construction and transition phases. In practice, this means emphasizing the external component/legacy system issues in the architecture description, and supplementing risk lists, iteration plans and task descriptions with activities that address business process stakeholder issues more explicitly. At the same time, it should be acknowledged in the RUP guidelines that the external integration cannot be planned in detail.

Planning and Improvising

External technical and stakeholder integration were seen to depend on both planning and improvisations to succeed. Finding that improvisations are important in change processes is congruent with the emergent view on organizations and with other related IS research (Ciborra, 1997, 2000; Ngwenyama, 1998; Orlikowski, 1996). However, it should not lead us to conclude that better planning is unnecessary or impossible. As the CMI case shows, improvisation puts a lot of pressure on a project manager, and introduces more risk into the project. The strength of an iterative software engineering framework is to reduce that risk, through step-wise integration. Thus, it is important to extend the capabilities

of RUP and other frameworks, to include better external integration.

Limitations

Limitations to the findings presented in this paper derive from the research approach. LPR is aimed at developing contextualized theory (Pettigrew, 1985). This suggests that the area of validity is the context of a large organization with an iterative IS development process in a setting of unstable business processes and a complex technical infrastructure.

CONCLUSION

The objective of this study was to understand the integration challenge in modern iterative IS development projects. Two questions were asked:

1. How can the IS project manager integrate the new information system with the business process and the information infrastructure?
2. What integration support is there in the software engineering frameworks, like RUP?

Integration was defined in a socio-technical perspective, and four types were suggested: external and internal stakeholder integration, and internal and external technical integration. A longitudinal case study of an IS development project in the airline industry identified and highlighted some managerial challenges of integration. Findings include:

- Internal technical and (to some extent) internal stakeholder integration is well supported by traditional project management techniques and software engineering frameworks such as RUP. The iterative approach enables a step-wise and controlled internal socio-technical integration.

- However, the challenges of *external* stakeholder and technical integration is underrated in IS development research. Integrating a new system with an unstable business process and a large, existing information infrastructure calls for careful planning, but also for improvisations, since it is outside the direct control of the IS project manager. This is not well supported in RUP.

These challenges are suggested to constitute a significant risk for the success of modern iterative IS development projects. For IS project managers, the implications are that risk management of external integration is an important part of iterative project management. For software engineering research—in particular for RUP—the findings indicate a strong need to provide stronger support for external stakeholder and technical integration; in particular, in the construction and transition phases.

Further research could study other iterative projects and look closer into which integration patterns emerge. One might also investigate new models for how IS project managers may contribute more actively to align the development projects and the business innovation, as recently done by Boehm by the introduction of *value-based software engineering* (Boehm, 2003). This is an area well suited for cooperation between researchers and practitioners.

ACKNOWLEDGMENTS

I am indebted to the different stakeholders of the SAS project, in particular Christian Mejlvang, Jorun Akerberg and Gunilla Johansson, for access to the project and for commenting on various versions of the case description. Further, the comments from the anonymous reviewers of the *International Journal of Technology and Human Interaction* were very helpful. Thanks also to the following scholars and practitioners for comments:

Peter Axel Nielsen, Bjørn Erik Munkvold, Henning Denstad and Cecilia Haskins.

NOTE

An earlier and shorter version of this paper was presented at the 37th Annual Hawaii International Conference on System Sciences, January 5-8, 2004, Big Island, Hawaii.

Chapter 6.12

Several Simple Shared Stable Decision Premises for Technochange

Richard Diamond

University of East Anglia, UK

ABSTRACT

This study explores decision premises that were used to manage and stabilise a complex technochange programme in a financial institution. Decision premises were extracted from business maxims, principles and rules using linguistic techniques. In the paper, the premises are juxtaposed with their consequences. The evidence of documents, observable practices and software configurations supports the analysis. It is found that decision premises form a hierarchical, self-causal as well as self-contradictory system of reasoning that was applied over any individual situation, particularly a conflict. By virtue of being several but not many, decision premises reinforce the 80-20 rule of many consequences stemming a few causes. In the case firm, decision premises were used in order to make technochange efficient as well as institute cost-saving and business

ownership of software development. But there were drawbacks of intensified politics, software development delays, short-sighted capability decisions and work fragmentation for the front-line employees.

INTRODUCTION: DECISION PREMISES AND IT MANAGEMENT

In organisations, many decisions and processes are based upon premises that go without question. Everyone is familiar with decisions, which appear irrelevant or inefficient at the moment, but turn out to be wise. The wisdom, in part, is about the benefit of continuity. Good decisions are typically made within a system of premises, be it an explicit corporate strategy or not-so-obvious top managers' beliefs about how to run a business. A list of

beliefs can be short and simple, but they usually comprise a densely connected system with certain hierarchical relations between beliefs.

Having the benefit of hindsight, after the exploration of top managers' decision premises, I propose that their disregard of circumstances and workplace issues is an outcome of dynamics rather than intention. Critical management researchers observed that organisational growth does not provide opportunities to improve the contemporary workplace that is characterised as tense and fragmented (Marchington, Grimshaw, Rubery & Willmott, 2005). Organisation behaviour researchers observed the self-contradictory expression and double-bind of middle management's position, as managers needed to demonstrate sympathy and make necessary changes at the same time (Huy, 2002).

What makes it harder to make good decisions is a degree of lock-in that occurs in complex projects of technology implementation, because 'small' decisions mount up and make future changes expensive. Also, organisation-wide implementation of information systems or any other high technology is inseparable from change in business processes, culture, and strategy. In order to conceptualise this, Lynne Marcus (2004) introduced the idea of *technochange*. Central to technochange are the ideas of interdependence and diversity of initiatives and outcomes. In highly interdependent circumstances of technochange, it is difficult to either forecast the results of individual decisions or follow a logical and elaborate strategy. It is also difficult to forecast how much of resources will be spent, committed, or gained. Scientific and operational research methods provide only limited assistance in such forecasting. Therefore, a study of 'primitive' but practical ways of complexity managements of operations would be a contribution. This article makes an initial step towards the objective. It utilises understandings of applied linguistics and coaching practice in order to identify a system of decision premises

as 'a map of the world,' within which managers make decisions in technochange projects.

DEFINITION AND DYNAMICS

The term 'decision premises' was introduced by March and Simon (1958). Other names were 'business maxims,' interpretative schemes, and cognitive maps. I consider three dimensions to a definition of decision premises that shed light on how decision premises operate. The dimensions are presuppositions, frames, and beliefs.

Presupposition is an implication of a statement that remains logically true, whether or not the statement itself is true (Bandler & Grinder, 1975). For example, a business process might or might not have an owner, but it is presupposed that there is ownership. For another example, a decision might be made to fix a flaw in software because it will save future costs, or the same flaw can be left based on the same premise of the necessity of making the most economical decisions about costly IT.

An epistemologist would say that every activity or communication is made within a frame that defines its meaning (Bateson, 1972). Alternatively, meaning of a communication can derive from its context and surrounding communications. Frames are a construct of a higher logical order. For example, the frame of a strategy-away day is different from the frame of a board meeting. The term 'technochange' is a frame itself as it regulates broader consequences than the term 'software update' would.

Term 'decision premises' presupposes, literally, that decision premises do not exist in isolation. Typically, there are several, but not many, decision premises and they form a system with its own self-developing (sometimes self-referential) logic. Therefore, personal development literature talks about 'belief systems' and 'value systems.' In this study, beliefs are treated as something that

is either described by managers or observed in behaviour, documents, or decisions. Therefore, a clear boundary is set in order to prevent psychodynamic and psychoanalytical interpretations. With these brief definitions at hand, we only highlight the linkages between decision premises and the dynamics of human values.

Operation Out of Stable Decision Premises

Decision premises about ‘how to manage’ are generalised from rich experience and ongoing evidence. But when such a generalisation is formed, it is applied *over* any individual situation. Thus, decision premises are oriented towards process and structure, rather than content.

Decision making occurs within ‘a model of the world’ that is only a model. In order to raise awareness about this, Gregory Bateson (1972) points out that ‘the map is not the territory.’ Hence, the value of a belief system is not in being true but in providing guidance. It is *useful* to operate out of certain beliefs in order to get things done, even and especially if actual circumstances are not favourable. Under complexity and uncertainty, humans naturally and gainfully adhere to their familiar beliefs (Weick & Sutcliffe, 2001). This strategy also helps to economise on information processing and avoid information overload.

In the world of business, talented, highly paid and irreplaceable consultants and CEOs are those who internalised a good system of decision premises that, in turn, facilitates core competencies (Miles, 1982; Prahalad & Hamel, 1990). Such value systems are hard to imitate and replicate. The mental habits of holding a vision and treating decision premises as always-true presuppositions make their impact on reality strong, enduring, and observable. Thus, for talented managers ‘territory is the map;’ they utilise technology, people, and organisational resources in their attempts and achievements of change of reality.

RESEARCH METHODOLOGY

Search for Decision Premises

The article is based on a longitudinal empirical case study of a retail bank, referred to as *Alpha*. A breadth of data was collected about Alpha’s IT and business operations. Generic data was collected about the company’s strategy formation (e.g., balanced scorecard, structure of top management, and steering committees). Some decision premises are simply repeated with high frequency in such data. To check the actual consequences of decision premises, interviews with top managers were juxtaposed with documents and observations made at banking branches. Detailed data about computer systems was collected including printouts of screens, software specifications and instructions, and drawings of the corporate IT infrastructure. However, technical information told relatively little about decision premises of technology management, which characterises value-based dynamics of decision premises, rather than circumstance-based.

It was interesting to explore implementation and distortion of decision premises in practice, in other words, to compare ‘what they say’ to ‘what it means’ in terms of observable consequences. Gathering data about ‘what they say’ included interviews with top managers and application of linguistic and behavioural techniques. Gathering data about ‘what it means’ included documentary analysis and interviews with people at the lower organisational levels, specifically, professional contractors and workers at the front-line of customer services and software development.

Along with typical research methods of qualitative enquiry described above, three specific techniques were used in order to identify and confirm decision premises. (1) Linguistic search for presuppositions was based on reverse scenario questions (e.g., what if the situation is precisely the reverse) (Bandler & Grinder, 1975). (2) Literalism of the definition of ‘several simple shared stable

Several Simple Shared Stable Decision Premises for Technochange

decision premises' directed the search towards simple language forms and phrases that were shared by the most people. (3) Behavioural signals of value activation and personal significance were observed (Andreas, 2002).

The interviews, especially ones with executive and top IT managers, provided the most input to the study of decision premises. 27 semistructured interviews were conducted; an average interview continued for one-and-a-half hour. Interview schedule is presented in Table 1. The people from all business functions were interviewed. Particularly interesting exchanges happened with the Alpha's Associate Director of Risk & Compliance and Associate Director of IT Support & Infrastructure. Overall, the selection of interview-

ees was defined by the *network traversal* of task and other interdependencies that were explored well beyond the formal authority hierarchy. The network traversal method involves exhaustive and sometime repetitive exploration of all task relations named by an interviewee. In order to keep track of interdependencies, Protégé software was used. The dataset allowed dynamic interaction; that is, the researcher interacted with the dataset on his laptop and asked questions about presence and details of interdependence in question. The visual representation plug-ins of the software allowed quick identification of the individuals who were in key positions in relation to a particular issue or business process, thus making network traversal intelligent.

Table 1. Alpha case: Interviews

Role	Amount
Operations and IT Director, Technochange Project Co-Director	3
Business Change Director, Technochange Project Co-Director	4 (1 in Jan, 1 in March, 2 in May)
Project Manager (long-term professional contractor)	1
Project Analyst (Project Office)	1
Associate Director for IT Infrastructure	1
Design Authority Team Leader (systems specification)	1
Assistant to Operations and IT Director	1
Business Operations Support Function Leader and liaison between branch (sales) and centralised customer services (operations)	3 (1 in April and 2 in May along with time spent in branch visits)
Training and Communications Team Leader (consultant)	3 (1 in April, 1 in May and 1 in June)
ACE Team Leader	1
Associate Director for IS Development	1
IT professional (SOS Division)	1
Delivery and Acceptance Team Leader	1
Associate Director for Compliance and Operational Risk	1
Financial Officer (liaising AlphaCoreIS project)	1
Various branch staff	3 plus one-off questions, observation and hearing to situations at work (day) 2 (Branch Manager, Branch Associate)
Total:	27

Several Simple Shared Stable Decision Premises for Technochange

Social encounters also provided a valuable opportunity for data interrogation (e.g., with unprepared replies). Under a condition of limited access to financial and operational plans, social encounters were particularly helpful in gaining information that was not recorded formally, but one would expect it to be so. Such information concerns long-lasting IT issues, prioritisation of IT tasks, and real options of the technochange.

Case Study Vignette

Alpha is a top U.K. building society. After three acquisitions in early 2000s, Alpha now operates

a network of more than three hundred branches. With its developed brand, Alpha pursues ‘a branch-led blended distribution strategy’ and focuses on mortgages and savings. In the summer of 2000, Alpha completed its IT strategy review and a five-year corporate strategic plan. The main result was a decision to purchase the new banking systems as an integrated package. The International Comprehensive Banking Systems (ICBS) software was purchased for £17 million. The strategic change concerned IT infrastructure, customer services, back office, risk management, and regulatory compliance. The project was publicised and given a clear priority against other projects.

Table 2. Several stable shared simple decision premises for technochange

‘What they say’: surface language structure	‘What it means’: political uses and observable implications
Technochange Management (business processes and software development)	
(1) ‘Business change first’	Considerable business change is necessary in order to succeed in technochange, but IT professionals exploit the idea in order to pursue technological solutions that are easier to maintain
(2) ‘It is easier to change business processes rather than software.’ ‘Adjust business processes to IT solutions’	Organising and structuring <i>around</i> information systems. Decisions about IS made difficult and institutionalised (e.g., checked against ‘how is it done elsewhere?’)
(3) ‘It is OK for business process to have caveats.’ This was used in sign-off procedures	Commitment is necessary in order to make operations managers to sign up to work with new software and processes
(4) ‘Each business process should have an owner’ (5) ‘Business ownership of software development’	A personalised owner is assigned to each business process and can resign only if another owner is found Business functions are responsible for their software development But the IT function retains control over releasing software in ‘the production mode’
(6) ‘Brokerage of acceptable business solutions, and quality of the relationships with vendors’ are responsibilities of top managers	Practices of championship and sponsorship were expected from top management for mustering political support and securing necessary commitment. Assignment of certain tasks to top-managers directly creates ‘ambidexterity’ and benefits IT professionals
Technochange Economics	
(7) ‘Change in practices is cheaper than change in IT solutions.’	Implications for work organisation were increased workload, disturbance, and stress for the front-line workers
(8) ‘IT department is committed to providing an efficient and cost effective service.’	As economic beliefs begin to govern IS strategy and delivery, the politics of IT support thrives on economics
(9) Institutional criteria for software selection, for example, ‘Where else is the software installed?’	Purposefully simple and institutionalised criteria for selection of software and complex IT solutions
Complexity Management (rules for interdependence and trade-offs)	

continued on following page

Several Simple Shared Stable Decision Premises for Technochange

Table 2. continued

(10) 'Process orientation' (11) 'No key-man dependence'	Interdependence within the overall organisation increases
(12) 'Processing of operations that require expert knowledge should be centralised.' The sorting of knowledge-intensive and labour-intensive operations	Risk-averse decision of avoiding investment into the high-turnover branch workforce. Removal of capability (e.g., knowledge and know-how of software use) from end-users in banking branches. New professional groups and ambidextrous organisational forms (e.g., Business Operations Support and software rules team)
(13) 'Queue management'	Acceptable queue levels were defined as policy and constitute main efficiency criteria around which work was organised in retail branches and the call centre both
(14) 'Cultural change from service to sales'	Cultural management of complexity perceptions, which resulted in appraisal schemes, tension and 25% turnover

ANALYSIS AND EXAMPLES OF DECISION PREMISES IN IT MANAGEMENT

The result of the analysis of the decision premises are presented in Table 2. They formed clusters or shared themes of technochange management, economising on IT-operations, and complexity management. The first two set priorities and the third set process rules. Technochange management resembled commonplace ideas about business process re-engineering. Complexity management was not articulated but regulated quite specific parameters (e.g., team size, difference between) using intuitive rules, such as 'no key-man dependence.'

Decision premises had a systemic organisation. There were at least three kinds of connection, specifically, *repetition-embeddedness*, *cause-effect*, and *contradiction*. Let us provide some illustrations. The premises (2) and (7) are repetitive about the core idea of adjustment of business processes and work practices to IT solutions. The premises (2) and (7) altogether causally support the premise (9); that is, application of simplistic institutional criteria. The premise (5) about the separation of work on software development and

IT infrastructure is a specific version of a general complexity management rule (12) about separation of knowledge-intense and labour-intense operations. In other words, the premise (5) is embedded in (12). The contradiction is also a necessary element of a system of values. For example, the premise (1) 'business change first' contracts the premises (2), (7), and (8) that advise of the most economic IT solutions and adjustment of business to those solutions.

Now, we will provide several quotes from documents and interviews that illustrate the actual implications of decision premises.

Cost-Saving

Cost-saving was constantly emphasised in IT policy documents and interviews of IT top managers. As a consequence of sharp categorisation, more than two thirds of IT task requests were rejected or put on hold with resolutions 'good, will wait' or 'we will return when resources are in place' (Associate Director IT Support).

'The IT department is committed to providing an efficient and cost effective service to its customers' (IT Service Level Objectives Agreement).

[Category of IT Task Request] B – Highly desirable (i.e., the work has a demonstrable short term payback). (Project Methodology: IT Task Request)

Business Ownership of Software Development

Decision premises prescribed that a manager of a suitable business function should take responsibility for adjustment of software functionality as necessary. This led to the separation of IT support and software development work as described in Table 3. ‘Business ownership’ shifted responsibility from IT professionals to business managers, but the need of an active involvement of IT specialists did not disappear. In the onion-like IT infrastructure, a ‘small’ change in software might require further changes on the various levels of database design, client-server middleware, operation systems, and network configuration that, in turn, might require changes in hardware and telecommunications. These technical changes were not facilitated by the fact that IT professionals prioritised technology and business-as-usual over software development and technochange.

Priorities are clear: telecommunications, banking branches, new software project.(Associate Director IT Support)

As a result, the second-order effect of cost-saving decision premises was not as cost-saving.

The practice of business ownership satisfied the decision premises of IT economising but caused considerable delays of the in-house software development—that is, delays of delivery of much needed business functionality.

Things take a lot longer...2-5 months delays in in-house software development became normal. (Team Leader of Systems Development).

How much does it take for IT people to deliver computer environments? Is it a tricky question? In practice to prepare some small database on customers, it took a week to communicate and prepare. Such work is supposed to be one-off. Communication back and forth on computer configuration [with SOS Division] is generally an issue for struggle. (Team Leader for developing marketing campaigns functionality).

Table 3. Practice of ‘business ownership for software development’

Tasks charged to business functions	Tasks cannot be done without IT teams
Specification of business needs into software requirements, a job of business analyst.	Most operations with software development required assistance by the specialised teams of Systems Operation Support (SOS) Division.
In-house programming and adjustment of third-party software. Provision of management information and customised documentation (e.g., letters to customers).	The typical of such operations area bout helping with software development tools, dataset preparation in a corporate DB/2 database and computer environment preparation.
Configuration of International Comprehensive Banking Systems (e.g., branch information and product information).	SOS Division retained the right of release of software into ‘production mode’ in which the software is expected to run at the agreed level of stability.
Support of software-in-use, such as preparation of instructions and ongoing in-house training.	

Logic of Systems

Even if business functioning was aligned by decision premises, every software had its own 'built-in' logic. Workarounds and the sheer complexity of such logic can override decision premises. The logic manifested itself in about 30,000 specialised and interlinked parameters of the International Comprehensive Banking Systems software that was used by Alpha.

There are experts in certain business areas, but even they tend to forget the meaning of parameters they use... effects could be unpredictable, difficult and timely to resolve and ramify. ... There are 29 products and large number of parameterised rules for each one. There is a clear issue to maintain rules, we do not understand all the rules' meaning and consequences. To discover the right setting of one parameter for product maturity took 7 days. (Business Change Director)

DISCUSSION. IMPACT OF DECISION PREMISES

Irregularities of IT Management

People do hide issues. (IT and Operations Director)

This was perhaps the major reason for having decision premises in the first place. The Directors of Alpha acknowledged 'managerial problems' of the large federalised IT-operations function. IT professionals arranged their work organisation with hidden, amorphous, and ambidextrous structures, all underlined by high interdependence. Prioritisation of tasks by IT professionals was far from clear. IT professionals were also exploiting 'the strategic use of information' (Pfeffer, 1992), such as interpretation from an advantageous viewpoint, selective presentation, and creating an appearance of rationality and success with regular presentations to end-users that were held

in executive suits. In their dealing with end-users, IT managers relied upon *frequent communication* and *enforcement of policy* in order to stabilise technology usages and secure operations within certain boundaries of reliability. The decision premises of economising guided the preference of enforcement of policy rather than configuration of complicated software—the first one is deemed as quicker and cheaper. Alpha's policies were framed in the language that *limited IT service delivery levels, provided rules to refuse or postpone task requests, formalised and limited definitions of faults, as well as outlined responsibilities of end-users.*

The decision premises overall and particularly (9) and (5) served the interest of IT professionals who limited their own responsibility but retained control. They also made IT support less accessible. Getting new functionality or new form of reporting delivered or getting an issue to the top management's agenda became burdensome and political activities.

The dynamics of decision premises also questions the productivity of *hybrid managers*, an approach that suggests a transfer of business managers to IT projects (Earl, 1989). The transferred managers in Alpha ended up being constrained by budgets, scarcity of qualified IT human resources, and project schedules even more than IT managers, because they were lacking background, professional affiliation, and support from the core IT staff who retained control over infrastructure and databases.

Change of Work

The following decision premises particularly affected the work organisation and day-to-day running of banking branches in Alpha.

- (2) *It is easier to change business processes rather than software. (7) Change in (workplace) practices is cheaper than change in IT solutions.*
- (12) *Removal of complex, knowledge-intensive operations from branches. (This was deemed*

good for branch personnel because it lessens their workload and helps to maintain low queues.)

- (13) *Delivering of only acceptable levels of service (e.g., as measured by queue size) whilst maintaining operational efficiency.*
- (14) *Service-to-sales cultural change.* (Every employee was expected to look for sale opportunity and refer customers to a specialised advisor.)

The consequences of these simple decision premises were far-reaching. The new software and ‘service to sales’ cultural change threatened the autonomy of the Alpha’s operational workforce. Such autonomy was built upon knowing and having a relationship with their local customers. Also, pressure was put on branch staffs in order to input customer relationship information into the system in a real-time mode. Branch staffs used to organise their work with a paper diary.

The [paper] diary is an advance warning of what is going to have to be done on the system, although you’re right that some pieces of work like following up on a lead or calling a customer—the procedure is that they should record that on the contact log on the system, but in a busy branch like that, I doubt they do both steps, I suspect that they rely on a paper version. (Branch Associate).

The removal of complex operations from branches did not relieve staffs’ responsibilities to customers but did leave them without knowledge of rather proprietary systems. It became harder for them to maintain a relationship with customers and explain all sorts of delays, loss of original paperwork, and other issues of centralised processing.

Sometimes [the centralised] branch support is really good, you can get things done. Financial Accounts—you have to e-mail, Taxation—you

have to e-mail... that’s fine and that’s usually done within 2-3 days. They don’t respond back and say ‘it has been done.’ We do have problems, when things get lost, especially if we’re sending up to head office, power of attorney, if it’s going on account, we take all documents and it goes to head office. I am sure you can work out how to do it [within the software locally], but I won’t do it. (Branch Associate)

We did a pilot in a different branch, when all of the calls for that branch went to the head office. But we found that 70-80% of those calls were still for the branch, so they ended up being put through, so they would then were double-handled. There were things that could only be answered at that branch. (Business Change Manager)

As we can observe, top management applied the decision premises *over* the existent context of work organisation in branches purposefully and consistently. Reduction of the staff’s knowledge about software led to a reduced need of IT support. Overall, the decision premises, the quick roll-out of new systems (6 months), and the pressure to sell, all led to a high staff turnover of 25% annually. Nonetheless, the dynamics of decision premises helped to achieve the standardised levels of customer service with relatively low-qualified staffs.

CONCLUSION

The usage of the decision premises was a prerogative of Alpha’s top management who were applying them in routine situations as well as critical decision making. The dynamics of decision premises can be summarised as follows:

- applied with limited attention to the context of circumstances and people; sometime, applied ‘ahead of the game.’

Several Simple Shared Stable Decision Premises for Technochange

- activated in order to manage ‘no win’ situations and trade-offs (e.g., sales vs. service); and
- upheld in conflict situations.

The system of decision premises was multilevel (e.g., specific premises were embedded into general ones), self-causal, as well as self-contradictory. It embraced both continuity and discontinuity. The system also produced *durable and multiple outcomes*. By virtue of being several but not many, the decision premises reinforced the dynamics of many outcomes stemming from a few causes, known as ‘the 80-20 rule.’

One interesting and specific outcome of the decision premises operating as a system was *irreversibility*. Software can be reconfigured, and locked-in computer platforms might be changed. However, decision premises define the usage and social order around any technology. Thought operations with technology have an immediate effect – they are easily reversible. On the other hand, policy choices might go unnoticed but, being enforced, they have enduring effects and ‘maximize the power of the guy at the top to influence action’ (Quinn 1998, p. 4).

The *system* of decision premises was also a tool of operational efficiency. It is well known that coordination is effectively (and most cheaply) facilitated by shared norms. The decision premises helped to limit the number of ways of usage of software, thereby, ensuing stable operations. In Alpha, the dynamics of decision premises led to the situation of *triple economising* on technology, coordination, and adoption.

The IT efficiency outcomes of the system of decision premises had two problems. First, the stable IT-operations should be juxtaposed with severe delays and overload of in-house software development. Second, decision premises stimulated fragmentation of work for the front-line workers in banking branches and processing centres (Frenkel, 1999). It was observed and confirmed with interviews that banking branch

workforce ended up with more demanding and fragmented work, yet the same pay and fewer incentives for learning.

In our case study, the decisions that defined the course of technochange were not made by IT professionals. Still, the dynamics led to the focusing on efficiency of technology and compromising on business processes, products, and quality of working life.

This is only an introductory study of decision premises. Further connections are possible to the body of knowledge about human values. For the purpose of being practical, relevant, and inductive, the article was limited from interpretations and elaborates frameworks of psychological theories and decision-making theories of economic sort.

ACKNOWLEDGMENT

I would like to thank my good colleagues Anita Greenhill and Bernd Stahl with who we convened a stream of work on post-modern elements in technology management and related organisational change, and an earlier special issue of this journal.

Chapter 6.13

Integrating Real Option and Dynamic Capability Theories of Firm Boundaries: The Logic of Early Acquisition in the ICT Industry

Alfred G. Warner
Penn State Erie, USA

James F. Fairbank
Penn State Erie, USA

ABSTRACT

Firms often acquire other firms to source technology but it is unclear why they might assume such risk by buying before a product standard is established in their industry. We draw upon real options and dynamic capability theories of firm organization to develop an integrated framework that explains why firms might acquire early and which firms are more likely to do so. We develop propositions regarding certain firm attributes as predictors of acquisition timing relative to passage of a technology standard. We argue that from a real options perspective, the primary reason firms acquire early is related to the firm's knowledge of the technology. However, attributes such as politi-

cal influence in the standardization process, prior experience making acquisitions, and how the firm resolves uncertainty about the technical expertise of potential acquisition targets are capabilities that also enter the acquisition timing decision. We provide a model based on those propositions and address how it can be empirically tested.

INTRODUCTION

Competition in industries where product standards define winning technologies has been compared to a particularly chancy casino game: Not only are outcomes and risks unknown, but the rules for competition emerge only in the process of

playing (Arthur, 1996), defining (or re-defining) which firm skills, abilities, and know-how are valuable. Entering early (i.e., before the successful or standardized technologies are defined) with particular skills or resources is risky because they could be the wrong resources and ultimately have no value. This problem is exacerbated when firms enter via acquisition of another firm, as acquirers notoriously fail to realize value after the purchase. Yet, in the information and communication technologies (ICT) industry, firms have increasingly chosen to enter this way and do so well before standards are established.

As an example, Table 1 shows acquisitions in the ICT industry in three key technologies over the period 1995-2000. Public records show that although almost all acquisitions of firms providing Fast Ethernet technologies occurred after the Institute of Electrical and Electronics Engineers (IEEE) generated the 802.3u standard, about half of the acquisitions in Gigabit Ethernet occurred before 802.3ab was accepted. At about the same time, firms like Cisco and Cabletron were acquiring asymmetric digital subscriber line (ADSL) startups well before the ITU G.Lite 992.2 standard was accepted in 1999. Acquisition has become an

ADSL acquisitions (ITU G.992.2, effective June 1999)

increasingly common mode of entry and a key element in how firms manage technology (Chaudhuri & Tabrizi, 1999; Karim & Mitchell, 2000) but it is not obvious why firms would choose to spend millions or billions of dollars to enter new technologies in standards-based industries before the standard is defined and uncertainty about outcomes is high. In this article, we integrate recent work in real options and dynamic capabilities theories as an explanation and framework for further empirical research.

Real options logic (ROL) is a theory of governance or firm boundaries with emphasis on how

firms manage uncertainty. It has historically been viewed as the purchase of the right to make staged investments where the value lies in the ability to defer further expenditures (Adner & Levinthal, 2004; Kogut & Kulatilaka, 1994). Currently, however, researchers have developed the idea that value can also derive from growth opportunities if firms can invest to secure technological positions or access to new capabilities (Folta & O'Brien, 2004; McGrath, 1997), particularly if managers can act strategically to influence the standardization outcome (McGrath, 1997). For example, when Cisco Systems acquired AuroraNetics for their resilient packet ring technology in 2001, other members of the IEEE 802.17 working group reportedly feared that Cisco could then dominate the standard-setting process (Matsumoto, 2001). Both internal development projects and acquisitions can be considered the purchase of a real option (Folta & O'Brien, 2004); accordingly, in this article we argue that early acquisition represents the purchase of a growth option.

However, if growth option ROL can explain *why* firms might acquire before a standard is adopted, it is ambiguous with respect to *which* firms might do so and is therefore incomplete as a theoretical explanation. Firms purchasing this sort of real option should be concerned with two issues: Will the technology acquired become part of the standard and, if so, will the acquirer be able to exploit that opportunity? A more complete understanding of the early acquisition decision requires the integration of another theory of firm boundaries where specific capabilities of the acquiring firm play a key role.

Dynamic capability (DC) theory is an extension of the resource-based view (RBV) of the firm. In the resource-based view, competitive advantage derives from the control of valuable, rare, and difficult to imitate resources (Barney, 1991; Peteraf, 1993; Wernerfelt, 1984). These include assets such as specialized equipment, human skills, technical knowledge, and organizational abilities (Eisenhardt & Martin, 2000). Dynamic

capabilities are regarded as higher-level resources in that they address how firms manage in turbulent environments through reconfiguration or transformation to achieve greater effectiveness (Teece, Pisano, & Shuen, 1997; Zollo & Winter, 2002). This is an alternative view of why firms make the governance choices they do, but it fails to specifically address what resources are best for future competitiveness. Success depends on the firm having superior knowledge about the future value of a resource or making a fortuitous buy (Barney, 1991; Eisenhardt & Martin, 2000). Some have argued that this lack of clarity on resource identification until after the fact makes the RBV/DC tautological (Priem & Butler, 2001). For these reasons, we believe that early acquisition can be better explained if growth oriented ROL and the RBV/DC are regarded as complementary rather than competing explanations. Firms might manage the rules of competition by entering early enough to influence the shape and structure of the standard (i.e., purchasing an option on growth opportunities to secure what could be extremely valuable resources), but this only makes sense when the decision to buy is supported by a set of key organizational capabilities. ROL and DC theories address different phases or aspects of the same resource acquisition process, and a synthesis of the theories might be useful in explaining acquisition timing.

Using the ICT industry as a frame, we develop a theory of how specific firm-level attributes can explain early acquisition. First, we argue that a significant gap in firm resources is the primary motivation for early acquisition as a real option, but that it is not a sufficient cause. We further describe how capabilities such as alliance experience and political power moderate and reinforce the real option by helping to manage the uncertainty problem. We also posit that other capabilities, such as acquisition experience, are important in managing integration of acquired firms. If the acquiring firm succeeds with the option play,

effective and efficient integration improves the likelihood of a win in the market.

Theories of governance or firm boundaries involve what activities the firm will conduct internally and what activities will be conducted outside through market or alliance. As Leiblein (2003) observes, such theories are often treated as independent explanations, whereas integration of relevant theories would enable the development of a more robust theory of governance. Our article represents a step toward that objective, as we argue that neither real options nor the resource based/dynamic capabilities view is sufficient to explain acquisition patterns in the ICT industry, but that as complements, they can. Though this article is not intended to be an empirical analysis, it does develop a basis for testing the extent to which these governance theories can be integrated.

BACKGROUND AND THEORY

Acquisition as a Real Option Investment

Real options are likened to financial options because the purchase of the option conveys the right, but not the obligation, to make further investment (Adner & Levinthal, 2004; Kogut & Kulatilaka, 1994). To illustrate, a financial option might be the purchase of a call on a stock at some time in the future. If the price of the stock rises high enough, the investor can strike the option by purchasing the shares at the option price and then re-selling them at the higher, actual price. If the price does not rise high enough, the investor can abandon the option. The key attributes of this model are the uncertainty about the future price, the contrast between limited downside risk and unlimited upside potential, and the property rights conveyed by ownership. Similarly, ROL argues that managers can undertake projects that more traditional valuation techniques, such as net pres-

ent value analysis, might undervalue if they have discretion in the timing of investments, can wait for the resolution of uncertainty (Leiblein, 2003), and then choose to take further action, defer, or even abandon the opportunity (Bowman & Hurry, 1993). Real options have generally been used to assess internal development decisions (such as R&D for new technologies), but have also been applied to investments between firms, such as joint ventures. An emerging line of real option theory recognizes that growth options emerge if particular capabilities (Folta & O'Brien, 2004) or technological positions (McGrath, 1997) can be generated by investment under high uncertainty. Growth options are particularly valuable in high technology environments because they create the opportunity for firms to participate in subsequent generations of products (Leiblein, 2003).

Real options logic has recently been applied to technology development in a standards environment in several important ways. Modularity or task splitting in overall system design (such as computers or local area networks) can lead to the components of the system comprising a "portfolio of options" (Baldwin & Clark, 2000), the value of which is greater than that of a unitary design. More specifically, Gaynor and Bradner (2001) have shown that the competition between modularized technical solutions in an open standardization process creates real options for participants. They also clearly demonstrate how uncertainty about which technologies will be used, and how, permeates the standardization process. For example, they observe that asynchronous transfer mode (ATM) technology was standardized as a potential competitor to other LANs, but became most successful in high-speed IP routers and DSL technologies, which exemplifies the unpredictability of standardization.

This uncertainty is key to the value of a real option. First, because managers cannot accurately foretell the future, the option permits them to secure a position with property rights when uncertainty is high and wait until the uncertainty is

resolved to take further action. An incremental approach limits downside risk (the price of the option) while endowing the owner with potential upside gains (Amram & Kulatilaka, 1999; Gaynor & Bradner, 2001). In technological opportunities, the uncertainty can be decomposed into several components. Initially, it is often unclear whether a particular technological approach will work. This has been termed "technical" uncertainty and can be resolved endogenously by investing in development (Dixit & Pindyck, 1994; McGrath, 1997), which is a function of the property right implicit in the option. Later, as technologies compete, the "market" uncertainty about which technology prevails is resolved in terms of a particular solution. In formal standardization, as Gaynor and Bradner's (2001) ATM example shows, resolution may come first as a win in the standards process and subsequently as a win (or loss) in the actual market competition between standardized technologies.

Second, the uncertainty around which technology wins is usually considered exogenous and outside the control of the firm (Amram & Kulatilaka, 1999), but scholars have recently developed the idea of a third form of uncertainty external to the firm but, unlike market uncertainty, subject to strategic intervention (McGrath, 1997; McGrath, Ferrier, & Mendelow, 2004; Miller & Folta, 2002). In these circumstances, managers can invest and act strategically to shape how the uncertainty is resolved.

Firms can secure growth options in several ways. The most often used example is entry into a new technology through internal development, which may clearly be construed as the exercise of the right generated by an investment in R&D as described above. How real options logic applies to inter-firm arrangements is less clear, but a property-rights perspective can be seen as parallel to internal development. Internal projects are the property of the firm that undertakes them, so it is clear they have a right to invest further or abandon the project. In the sense of securing an

equivalent position, acquisition of another firm conveys equally strong property rights to the buyer and, if undertaken when the relevant uncertainty is still high, is strategically equivalent to the same stage opportunity created by internal investment. For this reason, Folta and O'Brien (2004) consider entry through internal development and entry through acquisition as theoretically parallel in their analysis of "dueling options." Thus, either internal development or acquisition into a standards-based technology before the uncertainty over which technology will prevail is resolved can reflect a positioning response to innovation or a growth option (Folta & O'Brien, 2004).¹

The decision to secure a growth option through acquisition should be a function of the firm's relevant knowledge about the emerging technologies. Technological change ranges from incremental to radical (Anderson & Tushman, 1990), but this is relative; heterogeneity in firm investments, history, and resources suggest that within a particular industry, firms will regard the significance of technological innovations differently. Firms with relevant knowledge resources might view imitation of a new technology as relatively straightforward because it is near their existing capabilities and their prior investments have generated absorptive capacity (Cohen & Levinthal, 1990) or the ability to integrate and apply new knowledge. Firms that have made long-term and irreversible commitments to competence in other domains will find they lack the proper resources for imitating new technologies because they lack relevant absorptive capacity. These organizations might try to develop the skills internally but find that the time required to learn cannot be condensed easily or inexpensively. While this can be partially overcome through accelerated investment (Kim, 1997), there are time compression diseconomies involved that restrict the return to investment in learning (Dierickx & Cool, 1989). Even hiring talent away from competitors can be difficult because the resources might

not be easily tradable or accessible in the market (Barney, 1991; Teece, et al., 1997).

The effect of timing further complicates the choice of how to develop a response to new technologies. Late entry can adversely affect profitability (Ali, Krapfel, & LaBahn, 1995), market share (Lawless & Anderson, 1996), and even survival (Christensen, Suarez, & Utterback, 1998; Mitchell, 1989). In standards-based industries, entry timing can have another role. Since formal standards are often established in anticipation of market competition, solutions that eliminate particular approaches can put firms at a competitive disadvantage relative to those whose technologies are supported by the standard. This suggests that the critical time for entry and intervention is before the standard has been established, and firms lacking relevant knowledge resources must find a way to acquire them so they can compete or else be compelled to enter late and face the challenges of playing "catch-up." Therefore, firms increasingly turn toward acquisition to acquire the requisite high-technology skills (Chaudhuri & Tabrizi, 1999).

We therefore argue that initial differences in knowledge endowments for firms facing innovation will dictate the sort of real option purchased. We would expect firms that have relevant resources to attempt internal development first and if they acquire, they would be more likely to do so after the standard is complete. If firms that lack the relevant resources cannot learn about the technology quickly enough to attempt internal development, we argue that the real option perspective should lead them to acquire before the standard has passed. For example, Cisco CEO John Chambers once characterized the firm's most likely competition as IBM and Nortel (O'Reilly, 1998). If, as we discuss below, technical knowledge can be proxied by patent portfolios, IBM's wealth of patents in relevant fields and Cisco's lack in the same should imply that Cisco would be more likely to acquire early and IBM acquire

late, if at all. This closely reflects the acquisition patterns that actually occurred. Clifford Meltzer, another Cisco executive, explained the strategy: “We don’t believe we are smart enough to know all the important technologies over the next few years. You pick some, and then watch the industry” (Rogoski, 1997). We thus propose:

Proposition 1a: *Early acquirers (i.e., firms acquiring before the standard is accepted) will be more likely to lack relevant technical knowledge than will late acquirers.*

We also argue that the extent of overall invention in the industry moderates the value of resident knowledge stocks. If there is relatively little inventive work occurring, then the chances of a firm’s stock of knowledge being made obsolete are less likely. If, however, the rate of invention is high, firms might be compelled to look outside for knowledge resources, particularly if there are multiple approaches to solving a technological problem (Steensma & Fairbank, 1999). That is, the intensity of the “trigger” for the investment decision can vary (Zahra & George, 2002). In optical networking, for example, Nortel had established a very strong position in SONET/SDH technologies research and development (Arellano, 1999). However, the emergence of dense wave division multiplexing (DWDM) technologies, evidenced by a surge in US patents, apparently outstripped Nortel’s capacity to leverage earlier optical expertise. DWDM systems are complex and includes component such as laser modules, modulators, pump lasers, receivers, multiplexers, among many elements (McEuen, 2000). Although the firm was able to internally develop some components such as tunable lasers, Nortel eventually turned to acquisition to meet the demands of market pace (LaBarba, 1999), buying firms such as Cambrian Systems for metro DWDM capabilities, Qtera for long-range optical signaling, Xros for optical routing, and Core Networks for their tunable lasers. Accordingly, we propose:

Proposition 1b: *When the rate of invention in a technology family is high, firms will be more likely to perceive themselves as lacking relevant technical knowledge and will be more likely to acquire early (i.e., before the standard is accepted).*

How Dynamic Capabilities Moderate the Acquisition Decision

If the uncertainty around the standard is exogenously resolved, this gap in knowledge assets should be sufficient motivation for firms to make the real option acquisition and we should expect no other regularities among earlier acquirers. However, if managers can act strategically to affect outcomes (McGrath, 1997), then characteristics internal to the firm should emerge as commonalities among early acquirers. We argue that firms undertaking early acquisition will seek both the right technology and the right target, that is, a technology that shows promise and a target that can be successfully integrated and exploited by the acquiring organization. Meeting either objective will depend on specific firm attributes that directly support the option investment and/or the process of acquisition, and therefore moderate the acquisition decision. Such attributes are best characterized in a dynamic capabilities framework, since they become routine, learned processes, refined through experience. According to Eisenhardt and Martin (2000), these capabilities are “the antecedent organizational and strategic routines by which managers alter their resource base—acquire and shed resources, integrate them together, and recombine them—to generate new value-creating strategies” (p. 1107), and advantage goes to firms that use these capabilities sooner or more effectively than the competition.

Recent work illustrates three such routines or capabilities which can directly support the option aspect of the acquisition: political, alliance, and integration skills (Eisenhardt & Martin, 2000; Zollo & Singh, 2004). We expect that acquirers will exhibit differences in political or process

power and that more powerful firms will find it beneficial to enter when their power can be deployed. As Wernerfelt and Karnani (1987) note, the ability to influence outcomes is itself a sufficient motivation to enter when uncertainty is still high. We also argue that acquirers with alliance experience should be able to asymmetrically resolve some of the technical uncertainty around the option, which also influences timing. Capabilities can also affect how well the acquisition process is managed. Alliance experience serves a second role here in that firms can more effectively determine if partners would be good acquisition targets and integrate well. Finally, firms that are experienced in integrating acquisitions should better understand the time, organizational, and cultural requirements of such purchases. We examine each capability below.

Political Capabilities

The standardization process in the ICT includes the work of several types of bodies ranging from the formal international structure (such as the International Telecommunication Union (ITU) and the International Electrotechnical Commission (IEC)) to the formal regional organizations, such as the European Telecommunications Standards Institute (ETSI). Further, many of the standards in the ICT industry are developed by “gray standards bodies,” a classification that includes self-organizing regional entities such as the Institute of Electrical and Electronics Engineers (IEEE) and the European Computer Manufacturers Association (ECMA), as well as industry groups such as the ATM Forum. These groups are open in process and multi-vendor oriented (Egyedi, 2000) and vendor firms can sponsor technologies and participate in the process that accepts or rejects those technologies.

The influence of firms is such that they are increasingly regarded as a dominant force in standard-setting worldwide (Heywood, Jander, Roberts, & Saunders, 1997), but we argue that

firms will differ in their power in this context and those with greater perceived influence will be able to move markets or the processes that lead to markets. We anticipate that the specific standardization process will moderate this ability.

Standardization has been described as a social exercise in the construction of technology in that actors collectively establish processes and routines for the definition and solution of problems (Tushman & Rosenkopf, 1992). To the extent that the social construction also reflects the competitive orientation of the vendor firms involved, differences among the firms should enter the analysis. For instance, standardization processes are increasingly complemented by the work of block alliances that expedite technical testing and coordination. Examples include the Fast Ethernet, Gigabit Ethernet, and 10Gigabit Ethernet Alliances that coexisted with and complemented the work of the relevant IEEE 802.3 committees as well as the Universal ADSL Working Group and its recommendation to the ITU. These block alliances are explicitly vendor based and, in gray standardization work, usually comprise firms that are concurrently involved in the standards process (Warner, 2003). Even if firms are not directly involved in the formal standardization process, the effect of power can persist if the work of the block alliance is included in the standard. The power of firms to influence how that work is developed at the alliance level is then reflected in the ultimate formal document.

Thus, firms that have more market or financial power (Munir, 2003; Wernerfelt & Karnani, 1987) or are central firms in long-term networks (Soh & Roberts, 2003) might be able to influence outcomes based simply on their choice of technologies. Soh & Roberts (2003) have mapped the networks in the US data communications industry and show that network central firms were early entrants and leaders of coalitions. Central firms may also form cliques that can dominate the technological decision process (Rosenkopf & Tushman, 1998). For example, in the work between the ADSL Forum

and the Universal ADSL Working Group, Forum vice-chairman Bill Rodey argued that contention over technologies within the groups was minimized because the major firms had banded together (Oakes, 1998).

In addition, success in leading market entry strengthens or maintains the dominance of central firms for the next technological opportunity (Soh & Roberts, 2003) or for advances within the technology (Chiesa, Manzini, & Toletti, 2002). Finally, firms may seek to employ individuals they feel are influential in the standardization process or influence who staffs key administrative positions in standards committees (van Wegberg, 2004) or simply swamp the process with voting representatives (Heywood, et al., 1997). Therefore, firms with more power or clout should be more likely to enter early (particularly in gray standardizations processes) because they would be better positioned to shape outcomes.² While this capability supports the real option for either internal development or acquisition, with respect to acquisition in particular, we propose:

Proposition 2: *Early acquirers will be more likely to have greater influence in the relevant standardization community than will late acquirers.*

Alliance Capabilities

Alliances present opportunities to not only learn what partners know, they also allow firms to learn *about* partners more deeply and thus moderate the option investment decision in two ways. First, alliances allow partners to judge the content and applicability of the knowledge and skills the other brings to the collaboration (Grant & Baden-Fuller, 2004), which can reduce uncertainty about technical merit. Second, the process of establishing and maintaining an alliance provides information about each partner's culture, capabilities, and systems beyond the expressed motive for the venture (Zollo, Reuer, & Singh, 2002) which affects the ease and likelihood of successful integration.

Those with alliance expertise should have better information about (and be better able to judge) partners/targets than firms that do not have such experience. This expertise can vary along dimensions of investment level and scope.

How alliances are structured in terms of ownership can affect the level of information generated. Firms that have equity investments in candidate targets privately reduce information asymmetry relative to other potential acquirers and are in a better position to assess the relevance of the target's technology. Equity alliances are frequently used in R&D ventures because of the problems associated with knowledge expropriation (Gulati, 1995; Oxley, 1999). In order to gain financial backing, managers of private, capital-seeking firms must reduce information asymmetry by disclosing important information about their firm to potential backers including financial records, plans, and assets (Janney & Folta, 2003). This privileged access gives firms the ability to assess candidate technologies and reduce technical uncertainty. Provided the technologies meet the acquirer's relevance test, these firms should be more desirable acquisition targets than firms about which the investor does not have equivalent information.

Furthermore, firms vary in the extent to which they have developed alliance portfolios or strategies. In the late 1990s, some firms in the ICT industry began to operate not only as technology producers but also as managers or coordinators of venture capital funds, taking equity stakes in a wide array of firms with emerging technologies. Intel is a good example in that they have three equity funds (the Digital Home Fund, Communications Fund, and the China Technology Fund) and investments for each fund are publicly available (Intel, 2005). Other ICT firms that have implemented similar approaches in the past include Nokia (Nokia Venture Partners, now known as BlueRun Ventures), Lucent's New Venture Group, Nortel's Business Venture Group, and Cisco's Business Development Group. At the

same time, non-equity based consortia or block alliances became popular ways to generate rapid standard development and interoperability testing and to coordinate the contributions of firms to standardization (Warner, 2003). Firms in these blocks should therefore have information not available to those outside. Overall, these alliance structures should allow participating firms to develop a richer acquisition environment and are capabilities that directly support both the real option and the subsequent integration process. We propose:

Proposition 3a: *Early acquirers will be more likely to have had an equity alliance with the target than will late acquirers.*

Proposition 3b: *Early acquirers will have larger alliance portfolios than will late acquirers.*

Integration Capabilities

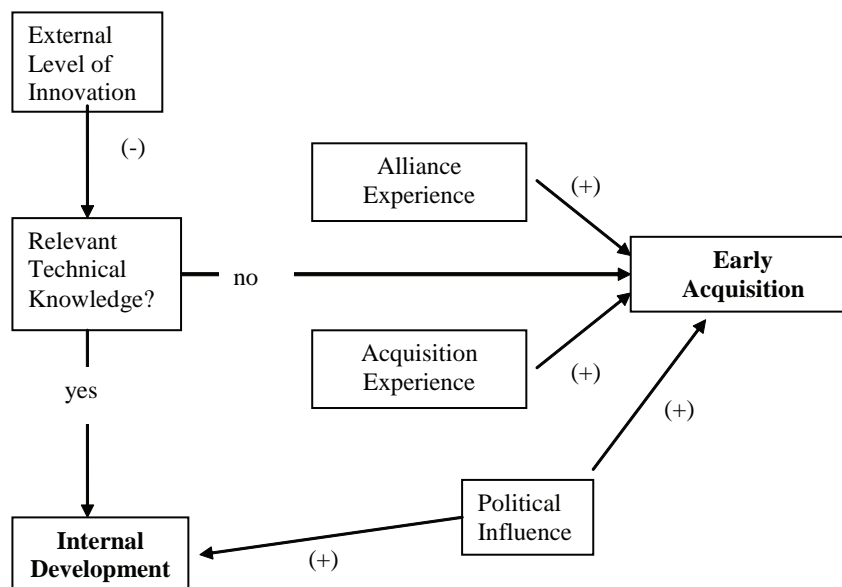

Extracting value from acquisitions, particularly in the sense of integrating new knowledge, is difficult and firms often fail to achieve desired objectives (Chaudhuri & Tabrizi, 1999). First, learning takes time even under good conditions. Transferring skills within the organization can be difficult and time consuming (Teece, et al., 1997; Zander & Kogut, 1995) and the problem is exacerbated when acquirers and targets have different prior knowledge sets. The two organizations must establish a common ground for discussion and exchange before the new knowledge can be exploited.

Second, even when the new knowledge is “understood” by technicians and managers on an individual level, it must be transformed into routines and processes that the firm can use, which involves changes at many levels in the organization. This process can be blocked if the implementation too strongly challenges existing technical and managerial systems (Leonard-Barton, 1992). Recent research focusing on innova-

tion output after acquisition has concluded that firms commonly underestimate the difficulty of integrating new information into the organization (Ahuja & Katila, 2001). Finally, integration is more difficult when there are significant size, structural, cultural, or other differences between the acquirer and target firm (Inkpen, Sundarum, & Rockwood, 2000).

Given these difficulties, prior acquisition experience has been shown to positively affect subsequent performance (Haleblian & Finkelstein, 1999; Hayward, 2002). This is due to several learning related causes. First, experience can lead firms to develop more efficient screening of acquisition candidates (Vermeulen & Barkema, 2001). Second, experience creates a more informed understanding of the time and skills required to integrate an acquisition and extract the value from the knowledge resources. Zollo and Singh (2004) argue that the process of codifying experience for application to subsequent purchases is key to managing the acquisition and assisting in the integration of targets. These assessment and integration routines are learned and practiced and constitute a dynamic capability (Eisenhardt & Martin, 2000). Experienced acquirers should be more conscious of the time investment to make a purchase successful. As a general illustration of these ideas, we note that Cisco is well known as a remarkably successful acquirer. Some of the reasons advanced for this include the due diligence process by which the firm qualifies targets with a strong focus on the social and cultural characteristics of the proposed target, identifying the prospects for a good fit with Cisco (Mayer & Kenney, 2004). For this reason, the firm prefers to target relatively young, small firms it can more easily integrate, particularly with respect to retention of key personnel. This conservative approach, according to CEO John Chambers, means that Cisco “has killed nearly as many acquisitions as we’ve made” (O’Reilly, 1998, p6). Another reason for Cisco’s success is in the integration process itself. Once the deal is

Figure 1. Factors affecting entry timing

closed, Cisco’s ten-step systematized integration process took over. Those steps include merging information systems such as conversion to Cisco’s MRP, vendor evaluation and rationalization, and implementation of statistical process controls (Wheelwright, Holloway, Kasper, & Tempest, 1999), and were played out in 90- and 180-day programs (Mayer & Kenney, 2004). Because of the importance of experience in forming acquisition integration practices, we propose:

Proposition 4: *Early acquirers will be more likely to have prior acquisition experience than will late acquirers.*

To summarize our propositions, we argue that in the ICT industry, the timing of acquisitions reflects both the need and ability of some firms to invest in real options. Early acquisitions will more likely be undertaken by firms that lack appropriate knowledge resources which still seek to enter the market in a timely fashion and manage

the outcome of the standards process *vis-à-vis* that technology purchase. This will be moderated by the rate of invention in the industry: When the level of invention is high, we anticipate that firm knowledge stocks will tend to be less relevant and increase the likelihood of early entry through acquisition. Certain capabilities will support the likelihood of option purchase. Early acquirers will more likely possess political influence or clout because firms lacking this power would regard the resolution of the uncertainty as exogenous and out of their control, and are thus disincented to enter before the standard is passed. We also argue that acquisition timing reflects asymmetries in knowledge about potential candidates. Alliances eliminate some uncertainty for acquirers in this strategy and partners from prior alliances, especially partners in which the acquirer has had an equity stake, will more likely be acquired early. Finally, acquisition timing will be a function of preference and experience in the process. Firms might historically prefer acquisition as a sourcing

mode and thus have developed skills and knowledge stocks regarding acquisition integration. Under these conditions, acquisition is likely to be early. Figure 1 provides a simple illustrative model of the relationship between our propositions and early acquisition.

DISCUSSION

As it stands, our model describes how we expect firms to behave with respect to acquisition and entry timing in the ICT industry. However, there are normative implications to an integrated approach. Earlier work in real options theory was prescriptive in the suggestion that the firm be viewed as a bundle of options (Bowman & Hurry, 1993). That is, when conditions are uncertain, firms should invest in a series of options to preserve flexibility and position. A key assumption is that the uncertainty will be resolved exogenously, which means that all firms are on an equal footing. In other words, the only issue for firms is if they have the wherewithal to purchase the option. Even so, a recent critique of the theory observes that real options promoted as a general means of creating firm-wide flexibility are “oversold” (Barnett, 2003) and that they are better as a project-specific tool. Barnett (2003) also notes that developing effective options is resource intensive, much like creating key organizational capabilities. We believe this is an important argument on several grounds.

First, as we have discussed here, acquisition can be construed as a real option but one that requires investment beyond merely purchasing the target. In order to make the acquisition successful, firms will need to leverage a number of other capabilities in the wake of the purchase. Thus, these growth options are not simply a “buy and wait” proposition, but require active management. Second, particularly in this context, we would argue that these real options are not merely “like” developing capabilities, but are expressly developing them.

This occurs on several levels. If the acquisition is successful, the firm has acquired new technical skills that are not only useful in current applications but as a springboard for future development within the same technology. Moreover, the acquiring firm has reinforced the political and integration capabilities that supported the acquisition, improving their position for subsequent option investments. Thus, from a normative position *contra* earlier options reasoning, we argue that not all firms are capable of taking these options and that undertaking acquisitions as an option can be a highly risky process for firms lacking the supporting capabilities.

Our integrated model is testable. If early acquirers fail to show some, if not all, of the regularities we predict, then the theoretical integration is superfluous. We consider several issues in empirically testing these propositions since operationalizing the variables we propose will require some judgment. The dependent variable—acquisition timing—is a good example. Because agreement on standards evolves, and at some point prior to actual adoption the debate has ended and there is no longer opportunity to influence the outcome, acquisition is “early” only if conveys at least the opportunity to affect the shape of the standard. One way to define this is to track the actual course of discussion within the standard process and to assert that acquisitions made when disagreement was still high should be considered early. However, not all such processes can be easily monitored because they might involve off-line actions (such as vendor groups), they are difficult for researchers to access, or because they are concluded and acquiring the relevant primary information is not possible. We suggest that a first cut approach might simply establish a cutoff time prior to standard passage that distinguishes acquisitions made under greater or lesser uncertainty. For example, the set of acquisitions made at least six or twelve months prior to the first passage of a standard should have been made under conditions of much greater uncertainty than the set of later

acquisitions. This time frame reflects how the pace of standardization has increased over the past decade and what once took years might now only require months (Rada & Berg, 1995).

Another issue will be operationalizing technical knowledge. We suggest the use of patent portfolios as a general metric. Patents have served as proxies for the stock of codifiable knowledge—that which firms draw upon to learn (DeCarolis & Deeds, 1999; Dierickx & Cool, 1989) and in the ICT industry, patents have been used to model technological competence (Madden, Rao, & Galvin, 2002; Rao, Vemuri, & Galvin, 2004). Further, patents will be useful in such a study because they are classified by technology, which provides information on both the rate and direction of inventive change (Archibugi & Pianta, 1996). Though recent work has argued that firms with significant knowledge assets, such as patents, may resist joining standardization movements to avoid knowledge spillovers (Blind, 2006), we note that this analysis addressed ten industries (and did not include the ICT industry) where firms with sufficient market power could take effective unilateral action outside the standards process. However, the modularity of system design in the ICT industry (Baldwin & Clark, 2000) constrains the ability of firms to opt out of standardization and introduce proprietary products. While this suggests that standards may vary across industries in their perceived downstream importance, and opens up research possibilities into the interaction between importance and standardization participation, it does not obviate the use of patents in this industry as one measure of technical knowledge.

Measuring prior acquisition experience should be straightforward because if the acquirer or target is a publicly held firm (and virtually all acquirers in the ICT industry are publicly held), acquisition is a matter of public record. The issue for research is the extent to which the marginal returns to learning through acquisition persist. That is, are more acquisitions always better or do the marginal benefits of learning how to integrate purchases

disappear after some (presumably small) number of acquisitions?

Alliance portfolios will be more difficult to measure than acquisition experience as firms do not face the same reporting requirements. There are several potential approaches to this problem using available information. First, non-equity alliances, particularly memberships in industry groups and consortia, are generally announced either by firms party to the alliance or, in the case of industry groups, by the group itself and are a matter of record. Information about equity alliances is sometimes retained because it can convey strategically important information to competitors, but investments are increasingly announced by investors or the recipients. For example, if firms have corporate venturing portfolios, the information about firms in the portfolio is publicly available. Finally, if a publicly held firm has a stake in an acquisition target, this is always disclosed in the announcement of purchase.

The ability to influence processes is a complex variable that poses a number of measurement challenges. Based on the work cited above, we expect that operationalizing influence will include firm characteristics such as size, and the extent to which the firm is or has been a leader or founder of successful industry consortia. Alternatively, researchers may turn to network analysis tools to assess how central firms are in the industry, particularly over time. The work of Soh and Roberts (2003) may provide a direct measure of centrality as would a cumulative measure of membership in consortia, particularly founding membership.

CONCLUSION

This article has developed a descriptive model showing how early entry through acquisition can be explained by integrating the principles of real options and dynamic capabilities theories of firm boundaries. Real options theory explains why

firms may generally invest in a new technology through acquisition but does not specifically inform us as to which firms might be so inclined. The dynamic capability perspective shows us which firms could best incorporate new resources but not how to select those assets, suggesting that acquiring resources that convey competitive advantage is sometimes just a matter of fortune. That is, dynamic capability theory provides a more useful explanation after the resources have been acquired. In combination, however, real options and dynamic capabilities show how firms can identify opportunities and, if they possess the requisite capabilities such as political, integration, and alliance skills, purposefully move to acquire resources and take the actions that make those resources valuable. This integration should help explain why and which firms acquire early in the ICT industry.

ENDNOTES

- ¹ Internal development and acquisition are clearly not the only ways of entering new markets. Firms can use alliances or product licensing as alternative entry modes. However, these governance modes typically do not convey property rights, such as the ability to modify or customize supplied products. This inability was one reason cited in Cabletron's acquisition of FlowPoint in 1998 (Sweat, 1998). The real option right to decide to abandon or invest further is a specific outcome of how the option purchase conveys property rights.
- ² We are indebted to an anonymous reviewer who points out that the effect of such power may not be linear. In some processes, the

efforts of very large firms are stymied by a coalition of other firms or entities, suggesting a liability to perceived power. Therefore,

we agree that the effect may be curvilinear and that there may be decreasing returns to these measures of political strength.

Chapter 6.14

IT Training as a Strategy for Business Productivity in Developing Countries

Shirish C. Srivastava

National University of Singapore, Singapore

Thompson S.H. Teo

National University of Singapore, Singapore

ABSTRACT

Most existing studies on technology training address the operational issues of training process (e.g., training needs assessment, learning, delivery methods, etc.). The strategic concerns of IT training for enhancing business productivity largely are not addressed by the current literature. In this article, we explore the strategic concerns of IT training in hierarchical organizations, which are typically prevalent in developing countries. We synthesize various ideas in the literature on change management, training needs analysis, and IT adoption in order to evolve a strategic IT training framework for hierarchical organizations. The proposed framework recognizes the differences in IT training requirements for different levels of employees and suggests a differentiated train-

ing content for different segments of employees. The training framework provides an actionable and comprehensive tool that can be used for systematically planning IT training for enhancing productivity of organizations.

INTRODUCTION

Most existing studies on technology training address the operational issues of training process in the context of the western world; for example, training needs assessment (Nelson, Whitener, & Philcox, 1995), learning styles (Bostrom, Olfman, & Sein, 1990), and delivery methods (Compeau & Higgins, 1995; Sein & Bostrom, 1989). The strategic issues related to IT training in developing countries (e.g., what kind of training is required

for employees; should the training given to all employees be similar in content and delivery) remain relatively unexplored in past research. In this article, we explore these strategic concerns of IT training for hierarchical organizations, which are more prevalent in developing countries. We reiterate the strategic objectives of IT training that usually are lost sight of in the mundane and routine training activities in organizations.

Need for Systematic Training

IT training in many organizations is a matter of chance rather than a planned initiative. Training, in contrast, refers to a planned effort by a company to facilitate the learning of specific knowledge, skills, or behaviors that employees need in order to be successful in their current job (Goldstein, 1992). The pressure for better training is expanding due to the increasingly popular view that people, rather than technology, represent the primary source of enduring competitive advantage (Ford, 1997). Although the need for training is being realized by many organizations, in many cases in developing countries, the training for new technology is not in tandem with organizational requirements. Some employees do receive IT training, but it is mostly a result of the personal initiative of that particular employee in the field of his or her interest. This field may or may not be of direct consequence to his or her job. In some cases, it is the mere persuasion of the training provider that initiates the training nominations from these firms. Consequently, the content and context of IT training often is decided by the training provider and not by the firm. This results in incongruence between training outcomes and organizational requirements. Effective training has to be in consonance with existing organizational structures and practices. There is a need to consider the interface between the organizational system and training (Goldstein, 1992; London, 1989) in order for the outcome to be fruitful and effective.

In many cases, IT training is thought of as a necessary evil and not as a strategic tool for enhancing productivity. For example, Indian Railways, one of the biggest employers in the world with more than 1.6 million employees, does not have a systematic IT training program for its employees, though it is one of the biggest users of IT resources. Employees are imparted IT training on the basis of their emergent skill needs rather than as a part of a well-thought strategic plan. Some firms are proactive in realizing the importance of IT training but till are not able to plan their training modules systematically for want of critical knowledge about the who and what of IT training (i.e., which employees should be trained in what aspects for better leveraging of IT resources). An example in which the firm's success can be attributed to its well-thought-out and planned IT training is the Housing Development Board (HDB) in Singapore. HDB realized the importance of systematic IT training for its employees and was able to leverage training for its success. One of the major contributing factors was top management's proactive attitude toward IT adoption and training (Teo, 1999; Teo & Ranganathan, 2003).

There is no doubt about the fact that everyone in an enterprise does not require the same kind of training in IT for effective adoption and performance (Srivastava & Teo, 2004). In the context of developing countries, where most of the organizations are hierarchical in nature, these organizations have a well-defined chain of command, and the position of employees in the organizational hierarchy determines their responsibilities. The proposed framework seeks to identify the training requirements for different segments of employees so that customized IT training programs can be designed to facilitate speedy and fruitful IT adoption by these enterprises. Effective training requires a systematic approach to training needs assessment, which determines not only who to train but also what to train (McGhee & Thayer 1961). McGhee & Thayer (1961) also cite a lack of

theoretical models for providing systematic training. Surprisingly, this gap in IT training literature still has not been addressed in a systematic and convincing way. This study seeks to present a comprehensive, conceptual, actionable strategic IT training framework for business enterprises, which will help in efficient and effective IT proliferation and usage.

Strategic IT Training Framework

Noe and Ford (1992) have stated the need for training practice to be used as a part of the strategic planning process of the firm. In contrast to this, most firms view IT training as an operational or functional necessity rather than as a strategic tool to gain competitive advantage. In line with the changing market conditions, the training systems in organizations also have to evolve continuously. Using training as a strategic tool is equally valid, not only for IT but for all other functions as well. IT training presents yet a more challenging endeavor, because it calls for a complete transformation of most of their existing systems. For example, the proliferation of ERP and CRM techniques often are based on the concept of business process re-engineering, which requires a major revamping of the existing systems. The rate of evolution for all new technology tools and methods, including IT, definitely has to be at a much faster pace. Tannenbaum and Yukl (1992) have stressed the need for training to be viewed as a system embedded in the organizational context. Training should be conceptualized as integral to the strategic goals of the organization (Schuler & Walker, 1990) and a component of the human resource planning process (Jackson & Schuler, 1990). The orientation of training typically has been micro in its orientation with a focus on individual learning development and change. This is true despite the fact that at the conceptual level, training needs assessment (McGhee & Thayer, 1961), evaluation (Kirkpatrick, 1967), and instructional design models (Goldstein, 1992) state that training

should be aligned with the organizational goals. A key question to be addressed is “what is to be learned?” (Campbell, 1988), and equally important is to know “by whom.”

McGhee and Thayer (1961) and Goldstein (1992) argue that a thorough need analysis will include (a) organizational analysis, (b) task analysis, and (c) person analysis. At the organizational level, we are concentrating on typical organizations, which are hierarchical in structure. At the task analysis level, we are considering the job requirements of various levels of management, and at the person analysis level, we are generalizing the personnel at different levels. Ostroff and Ford (1989) applied a multilevel perspective to needs analysis and noted that the previous three facets may reside at different or even multiple levels of analysis. The training program of the organization needs to be linked to the organizational business strategy (Brown & Read, 1984), the changes in the strategic plan should be reflected in the revised training objectives (Hussey, 1985), and the needs assessment must incorporate a future orientation (Scheinder & Konz, 1989).

Levels in an Organization

All personnel in an organization can be classified in three distinct levels based on the kind of work that level performs. Anthony (1965) made the distinction between the three levels of management based on their decision-making functions (strategic, tactical, and operational). The three levels into which all the employees of an organization can be classified are top, middle, and frontline. The top level includes the CEO and various unit heads. They are the people who are responsible for spelling out the road map of the company. Their decisions have long-term implications not only for the company but also all for its employees. The role of this level in smaller organizations like SMEs is even more important, because not only are they aware of the key strategic problems of the company, but the

smaller size of the company brings them closer to the actual workplace; hence, they also are able to monitor the effects of their decisions. The middle level includes the functional managers. They are largely responsible for the smooth functioning of the areas under them within the broad framework of policies and guidelines spelled out by top management. They are required to plan and source the various resources for production and marketing. This group of personnel requires having a thorough knowledge of working procedures of the industry. The frontline personnel include all the employees excluded from the upper two categories. They include supervisors, inspectors, and workers. They are the employees who actually are involved in the day-to-day business operations and are required to have well-developed skills in handling the various devices and systems that they operate.

Since different levels of employees have different kinds of functions to perform, it implies that these three levels have different informational needs in relation to their function. Hence, their training needs also are quite different from each other (Daft, Lengel, & Trevino, 1987; Srivastava & Teo, 2004). Further, the different levels require

different kinds of knowledge, skills, and attitudes (KSAs). The different types of knowledge acquisition require different types of training methodologies. Anderson (1982) made a distinction between declarative knowledge, which is fact knowledge (knowing what), and procedural knowledge, which is knowledge of procedures (knowing how). The frontline level may require more of the procedural knowledge, whereas as we go higher, the personnel may require more declarative knowledge related to IT.

Figure 1 presents a strategic IT training framework for organizations, which takes into consideration the hierarchical nature of most organizations in developing countries. The framework recognizes that the IT training needs for the different levels of employees in organizations are quite divergent in terms of content. The three broad contents of IT training are attitude toward IT, knowledge of IT, and on-the-job IT operational skills. The change in the breadth of the triangle and quadrilateral in Figure 1 indicates the change in requirement of the training content for different levels of hierarchy.

The proposed framework seeks to offer answers to questions regarding training component

Figure 1. Strategic IT training framework

for different levels of the organization and serves as a practical tool for hierarchical organizations in planning their IT training initiatives. The profound problem with IT training has been that, in most of the cases, the training is not directed to the informational needs of that level, and often there is a mismatch. This mismatch of the IT training content with the informational needs of the employee results in a twofold wastage. First, the money spent on training that employee is wasted, since it will not help the employee in his or her job. Second, the time spent on training is also a wasted resource. The proposed framework (Figure 1) explores IT training for different levels of organizational personnel with regard to training content. Training content expounds the broad parameters (in terms of knowledge, skills, and attitudes) on which the planners should organize the training for the different levels of employees. A summary of the training content is illustrated

with illustrative examples in Table 1 in the context of ERP implementation.

This differential hierarchical IT training of employees has been implemented successfully by the Housing and Development Board (HDB) in Singapore, which encompasses formal and structured IT training programs for different levels of staff from junior officers to the CEO (Teo, 1999). The IT training programs are designed according to the job and informational requirements of the level of personnel.

Top Level

Top-level managers are usually the perpetrators of underlying currents and culture in an organization. In most traditional organizations, the top managers often are viewed as trendsetters whom all employees in the organization try to emulate. Hence, it is very important for top management to

Table 1. Summary of training content

Training Content	Fundamental Question	Explanation With Example
Attitudes	<p><i>Why?</i> The answers to such questions determine the strategic direction of the firm and are usually provided by top management</p>	<p>It seeks to explain the importance of IT and why it should be adopted by the organization, the kind of benefits (long-term as well as short-term) that can be derived from the use of IT. The emphasis is more on molding the views toward leveraging IT in order to improve business productivity and competitiveness. In the case of ERP, such training will inform the participants about the significant benefits that IT is capable of giving to the firms. It seeks to develop the enthusiasm and remove inhibitions by informing about the real business value of IT. The trainees are taught about the various technologies available as well as their potential impact so that they can better decide on the choice of technology for the company.</p>
Knowledge	<p><i>What?</i> These decisions determine the tactical course of action of the firm and are mostly in the domain of middle management of the firm</p>	<p>This seeks to inform about the details for a particular technology. It aims at empowering trainees with the requisite background in order to distinguish and decide which among the options available for a particular technology may be beneficial and suited for their business. Going further with the ERP example, the knowledge component of the training provides the ability to decide among various choices of ERP systems that are available to suit their needs.</p>
Skills	<p><i>How?</i> The frontline workers require this expertise to operate the various systems in an enterprise</p>	<p>This aspect of training provides the necessary ground tools to the workers to actually work on the chosen systems. It provides workers with the necessary expertise to operate the specific software and hardware chosen by the company. An example of skills may include the techniques for operating the different modules in SAP ERP system. This skills training logically comes after the two vital preceding decisions have been taken (1) to use ERP system in the company and (2) among available ERP systems to use SAP</p>

have positive and favorable attitudes toward IT and new technology adoption. This has implications on the training content for these top-level managers. This group of people requires more attitudinal training toward IT (Table 2). They should be able to realize the importance of IT and the impact that it can have in transforming their enterprise. They require relatively little IT-specific knowledge or skills. These leaders should be trained in a way so that they understand the potential benefits of IT adoption as well as the potential costs of not adopting IT. Such understanding by top management would enable them to be better able to enthuse and motivate their employees for IT adoption. The tapering pyramid in the proposed framework expounds training mostly in understanding “whys” (i.e., attitudes). The requirement of training about

“what” (i.e., knowledge) and “how” (i.e., skills) is comparatively less.

Their preparation should be aimed more toward the developmental dimension than toward the training dimension. They require having a broad understanding of the various ways in which IT can help their business. They should be aware of the various kinds of IT available in the market and the latest trends in the industry worldwide. They should have enough knowledge in order to decide about the kind of systems relevant for the business.

The objectives of employee development are not tied necessarily to a specific job or task. London (1989) defined development as courses, workshops, seminars, and assignments that influence personal and professional growth. Development is

Table 2. Training requirements for different levels of employees

Level/ Requirement	Attitudes	Knowledge	Skills
Top	<ul style="list-style-type: none"> · Positive belief toward IT relevance · Enthusiasm for IT proliferation · Creative, innovative, and risk-taking attitude · Ability to enthuse and motivate others for IT adoption 	<ul style="list-style-type: none"> · The latest developments and trends in IT · In-depth business knowledge and emerging IT standards for their industry 	<ul style="list-style-type: none"> · General office and communication software (e.g., e-mail, word processing, spreadsheet, etc.)
Middle	<ul style="list-style-type: none"> · Positive, proactive, and enthusiastic toward IT adoption · Attitude to learn and teach new things for better efficiency and productivity 	<ul style="list-style-type: none"> · In-depth knowledge about the capabilities of the available hardware and software systems · Knowledge about the implementation impediments for various IT systems · Latest developments and trends about IT usage in similar industries 	<ul style="list-style-type: none"> · General office and communication software (e.g., e-mail, word processing, spreadsheet, etc.) · Understanding of the operational requirements for the software and hardware systems being used by their department · Specific skills for the critical IT systems in their department
Frontline	<ul style="list-style-type: none"> · Positive and enthusiastic toward new learning and IT adoption 	<ul style="list-style-type: none"> · Generic knowledge about the capabilities of IT for their industry and specific knowledge about the IT systems on which they have to work 	<ul style="list-style-type: none"> · General office and communication software (e.g., e-mail, word processing, spreadsheet, etc.) · Understanding of the software and hardware systems being used by their department · Specific specialist operational skills for the software and hardware systems being used by them · General skills and ability to handle related IT systems in their organization

focused less on specific skills; instead, it focuses on the comprehensive knowledge and attitudes required for improving the long-term personal effectiveness of the employee, which results in an overall benefit to the firm. Top management in a firm is responsible for deciding the course of action for the enterprise; hence, their overall development in IT will result in empowering them with the right attitudes for executing this function effectively and efficiently.

Middle Level

The middle level is concerned mostly with the tactical decisions in an enterprise. Middle-level managers are required to make decisions on how to best utilize the existing systems in an enterprise per the directions of top management. Suppose top management has been imparted an attitudinal training in IT, and they decide that ERP system is suitable for their enterprise. They give necessary directions to middle-level management to implement ERP in their organization. Now, middle-level management should have the critical knowledge to appreciate the functionality of the ERP system. They should be able to spell out the relative benefits of using the ERP system and, consequently, help top-level management choose the required system, consultants, and so forth. Thus, their training sequence is next in importance to the top level, and their training content is focused more on the knowledge aspect of training. They require a thorough knowledge and understanding of the various systems of the firm and the IT capabilities and, more importantly, how they can be integrated.

The training program planning procedures need to identify and consider the technical as well as the managerial skills needed for advanced technologies well in advance of its implementation (Kozlowski, 1987; Majchrzak, 1988). This requires knowledge of planning techniques that are not well-represented by the conventional needs

assessment models (Kraut, Pedigo, McKenna, & Dunnette, 1989). The hexagon shown in the framework emphasizes the need to have a greater emphasis on knowledge-related aspects of IT in training rather than attitudes or skills. Once they are able to spell out what is to be adopted by the enterprise, then the frontline workers can be imparted the specialized training of skills set. Thus, the training programs for middle-level managers should be more knowledge-related so that they are able to comprehend the IT options available in the industry and are able to make informed decisions (Srivastava, 2001). Many German mid-size firms are adopting Linux as their cost-effective platform (Blau, 2003). Such a decision can come only from a well-informed middle management that has a thorough knowledge of the various options and has the capability to make a comparison.

Frontline Level

The frontline workers are the actual executors of the various tasks in an organization. Top-level management brings the idea (concept) into the enterprise, middle-level management gives form (methodology for operationalizing the concept) to that idea, and frontline workers actually execute (operationalize) this idea. Frontline workers should have rigorous training in the actual systems and IT modules related to their jobs. If we consider the ERP implementation example again, then frontline workers require requisite skills for operating the selected modules of the IT systems chosen. Their training may be very specialized, depending on the skills set required for operating the particular systems. As shown in the proposed framework, they require maximum training in specialized skills and comparatively less in knowledge and attitude-related training. There is no doubt about the fact that they do require a positive attitude toward IT, and this attitude can be instilled in them through socialization and proliferation from top management. Their training need not be directed toward IT-related attitudes and knowledge but

should be focused on the specific skills required by them for execution of the particular job. Their skill-acquiring activity can begin only after top management is prepared to embark upon the IT odyssey and middle management has chosen the ship for this journey; hence, logically, the sequence of their IT training in an enterprise is after top and middle management.

General and Special Training

IT training requirements of personnel in any organization also can be classified as general and special. General training (composed of attitudes, knowledge, and skills) is the common training component that has to be imparted to all employees for efficient functioning in the organization; whereas, special training is given according to the specific job requirements of the employee. Specialist training can be person-, group-, or level-specific. The strategic training framework in Figure 1 captures this in terms of general and special training for all levels of employees. From the framework, it is clear that all categories of employees require some basic grounding in IT-related attitudes, knowledge, and skills for efficient functioning. The only difference in the content in the specialist and general training is that top management may require negligible specialist training in IT skills, whereas frontline management may require much less specialist training in attitudes. At this point, we also would like to emphasize that it is not possible to achieve IT success in an organization without imparting some general IT training in all three aspects (attitudes, knowledge, and skills) for all categories of employees. For example, in an organization, top management may require general IT skills such as checking e-mails and working on a word processor and a spreadsheet, but may require specialist training in attitudes (e.g., being more creative and proactive toward new technologies, risk-taking ability, perseverance, persistence, etc.). On the other end of the spectrum, the frontline

staff may require specialist knowledge about the various IT-related systems that it is using for different operational requirements (e.g., specialized software packages) and functional knowledge of ERP modules. Their requirement of operational knowledge does not discount their basic attitudinal requirements of their enthusiasm for learning and using new technologies. The point about general and special training for different levels of organizational personnel also is highlighted in Table 2, which charts the requirements for different levels of employees.

Huang (2002) also has highlighted the importance of training employees in certain fundamentals of information technology, which will remain nearly constant even in a dynamic technological environment. The general training in the proposed framework (Figure 1) is similar to general technology education, and the special training has been captured in the business application training and just-in-time training (Huang, 2002)

Again considering the case of IT training in HDB, Singapore, the training categories are divided into four levels (basic, advanced, extended, and continuing), depending on the job requirement and computer literacy of the individual staff member (Teo, 1999). This is done with a view to provide a better fit between the actual training imparted and the job requirements (Brown & Read 1984; Kirkpatrick 1967). The attitudinal training in HDB also is brought about through seminars, conferences, and discussions as well as through the promotion of professionalism among IT users through formal certification (accredited by the Singapore Computer Society) of its staff (Teo, 1999; Teo & Ranganathan, 2003).

CONTRIBUTIONS AND CONCLUSION

The motivation for this article is to provide a theoretical basis for providing an IT training framework applicable to hierarchical business

organizations, which is more common in developing countries. Through this study, we provide a comprehensive, actionable, conceptual strategic IT training framework, which is the first contribution of this study. As systematic training is an important input for IT adoption in enterprises, we hypothesize that the presented IT training framework will help to transform technological shyness to technological savviness, leading to enhanced business productivity and competitiveness. We have highlighted the applicability of the proposed framework by drawing some examples from HDB, Singapore, an organization recognized for its efficient and effective IT training programs (Teo, 1999; Teo & Ranganathan, 2003).

Second, we reiterate that training should be viewed not only as a means for serving operational needs but also as a strategic tool (Noe & Ford 1992; Schuler & Walker 1990). The proposed training framework segments organizations in the traditional hierarchical structure and identifies the broad content of IT training in the context of these levels of employees to facilitate IT adoption in a systematic way. Top management personnel of an enterprise who are supposed to provide a strategic direction to the enterprise are the ones who should have a positive attitude toward IT adoption and should understand the tangible and intangible benefits that IT offers them in the short as well as the long term. They not only should be the first ones in an enterprise to be trained in IT, but their training also should focus on empowering them with the attributes that result in fruitful IT adoption by these enterprises. Once top management sets the ball rolling with their right attitudes, then middle management should be in a position to execute the IT plans in an enterprise. Hence, they must have the right knowledge in order to make the right decisions about the choice of platforms, software, and so forth. Their training, therefore, should infuse in them the knowledge to understand and to make decisions best suited for the firm. The role of the frontline workers is at the delivery stage of the

IT plan, conceptualized by top management and operationalized by middle management. These frontline workers should be skilled in operating the chosen software and hardware systems so that right results are delivered to the firm by IT adoption. Hence, their training requirement is more on the skills aspect and actual performance at the delivery stage.

Third, enterprises are faced with the problem of dwindling resources and increasing competition. The proposed framework provides guidelines to practitioners and managers to efficiently deploy their resources on fruitful IT training. It gives a direction to managers for planning IT training of its personnel so that there are no wastages and so that the various levels of personnel get the IT knowledge that is functionally and strategically relevant for them.

Fourth, the proposed framework reiterates that not all employees in hierarchical organizations require similar kinds of IT training, which is especially applicable in the context of developing countries. The informational needs of top, middle, and frontline personnel are very different. Hence, IT training programs for these levels must be designed according to their roles and requirements in order to avoid wastage of scarce resources. Systematic IT training per the proposed framework will make these enterprises competitive in the global economy. Overall, the framework provides researchers and practitioners with a useful tool in order to better understand the different training requirements for different levels of the organization. Such understanding would pave the way for more effective usage of scarce resources to ensure that personnel at various levels are adequately trained to leverage IT effectively in order to improve business productivity and enhance competitiveness.

There are three main limitations of this framework. First, in the present-day world, organizational structure is undergoing a major transformation. We are gradually moving toward flatter organizations in which the classification

per the traditional structure may not hold good for many organizations. However, organizations (especially those in developing countries) tend to be slow in adopting newer organizational structure and tend to continue to have a hierarchical structure. Second, some organizations are relatively small, and top management at times also may be performing the operational and tactical role in addition to the strategic role. Hence, the framework has to be modified suitably for such enterprises. Third, we have assumed that IT adoption should be driven from the top. Sometimes, middle-level and frontline personnel are the ones who bring to management's attention what the competitors are doing with regard to the deployment of IT. Nevertheless, top management support for IT is an essential element for successful IT deployment. Such support will be difficult if top management does not have favorable attitudes toward IT adoption.

Future research can identify the detailed elements of KSAs required for the various levels of personnel for particular IT system implementation (e.g., ERP and CRM). Extensions of this article also can be done by studying some of the successful organizations and by analyzing their IT training strategy for its employees compared to the proposed strategic IT training framework.

Chapter 6.15

Action Research Methods

Patrice Braun

University of Ballarat, Australia

INTRODUCTION

To date, most research into the implications of the Internet for SMEs has focused on individual business barriers to ICT and e-commerce adoption. Such research has shown that SMEs tend to be time- and resource-poor, with their size being their main disadvantage vis-à-vis ICT adoption (OECD, 2000; Van Beveren & Thompson, 2002). Perhaps the question is not whether small firms have adopted ICT, but rather where are small firms in terms of their ICT adoption. ICT encompasses a series of separate yet interrelated components; for example, electronic mail (e-mail), the Internet, the Web, and e-commerce, which can be adopted in a variety of social and business settings. Hence, it is suggested that ICT cannot be considered as a single technological innovation but rather as a series of (process) innovations, potentially resulting in variable ICT adoption patterns (Walczych, Van Braven, & Lundgren, 2000).

Keeping up with rapidly changing ICT trends and moving ahead with the adoption of the various ICT components is a challenge for all firms but may be particularly confronting for resource- and time-poor SMEs (Earl, 2000). To counter this

phenomenon, a SME aggregation or cluster argument may be made for the use of ICT to develop joint e-marketing and e-commerce economies of scale (Braun, 2002). In the context of emerging technologies and related knowledge-economy business models, linking stakeholders in dynamic clusters is believed to enhance competition and regional innovation (OECD, 2000). Indeed, the literature is saturated with views on geographic proximity, or clustering of industries and companies, to create innovation and competitive advantage (Asheim, 2001; Porter, 1990).

The geographic scope of a cluster can vary from a single city, state, or region to a network of companies across state borders or even country borders. They can be formal or informal, in the public or private sector, horizontal or vertical, or physical as well as virtual (in an online environment). In a horizontal network, companies within the same industry sector might share an industrial or technological base, operate within a common market, and use a common purchasing or distribution channel. Vertical networks include horizontal cluster participants, as well as suppliers, users, and related services. Porter discusses competitive advantage as being “created and sustained through

a highly localized process” (Porter, 1990, p. 19) and ascribes enduring competitive advantage in a global economy to local knowledge, relationships, and motivation that cannot be duplicated by global partnering (Porter, 1998).

Connectivity has boosted conventional reasons for interfirm networking and virtual clustering—for example, by creating critical mass online—as it facilitates the knowledge-based infrastructure network imperative for today’s competitive advantage. While a number of recent studies have shown benefits in physical SME clustering (Enright & Roberts, 2001; Lowe & Berrisford, 2002), notable research on ICT adoption in a virtual clustering context and studies on network use of the Internet as a cooperative e-commerce tool remain in their infancy.

Building on the concept that global positioning and competitive advantage for SMEs may be achieved through connectivity and clustering, this article first explores the conditions for small business network formation underpinned by technology, then presents the results of an action research study with a regional Australian SME tourism network seeking to establish a virtual e-marketing and e-commerce portal environment.

SMALL BUSINESS NETWORKS

Implementing new business models to achieve competitive advantage in the techno-economic innovation paradigm bring to the fore ICT adoption, strategic planning, and network issues.

Research into the adoption of networked technologies by SMEs indicates that the adoption of network structures and networked technologies by SMEs is generally related to the size and nature of SMEs and largely depends on their perception of affordability and business growth opportunities for their business (OECD, 2000). SMEs generally approach clustering and networked infrastructures such as the Internet with caution and hesitate to invest their time and

money in a rapidly changing economy. SMEs do not necessarily view the Internet as a vehicle to transform their individual business capability from a parochial to a networked or global level, which may be achieved through the setup of electronic commerce (e-commerce) portals or other Web-enabled cluster structures (Murray & Trefts, 2000). The latter study cites lack of technology skills, lack of a strategic sense of how to move forward, and fear of competitor use of the Internet as significant barriers for uptake of networked technologies by SMEs. Therefore, creating network infrastructures and collaboration between small firms is contingent not only on adoption of ICT technology, but also on economic and social contexts.

European studies on SME positioning in the networked economy point to SME’s networking as being contingent on favorable economic conditions, for example, by providing government-sponsored external networks (Cooke & Wills, 1999).

An Asian study similarly provides empirical evidence that successful SME collaboration needs to be underpinned by resources that provide SMEs with the tools to become global players (Konstadakopoulos, 2000). The European studies on SME positioning in the networked economy also associate social relationships with enhanced business, knowledge, and innovation performance (Cooke & Wills, 1999). While connectivity through public or private initiatives may facilitate the electronic linking of SMEs to one another for potential business-to-business (B2B) resource and transaction sharing, and help to reduce isolation of individual SMEs, there is another critical factor to consider in terms of network building between SMEs, namely trust.

Trust is an attribute not only of organizations but also of communities, industry networks, or even entire geographic regions, which can help expedite economic development and facilitate large-scale economic activities (Fukuyama, 1995). Trust between network partners is said to

reduce fear of opportunistic behavior and improve collective learning and knowledge sharing. The trust may be historical and already exist between different firms, as illustrated above, or it can be built during the relational exchange (Gulati, 1995). Some scholars argue that relationships do not necessarily have to be based on trust, as long as systemic mechanisms are in place that allow stakeholders to have confidence that network partners will exhibit cooperative rather than opportunistic behavior and not take competitive advantage of knowledge-based exchanges (Das & Teng, 1997). In the aforementioned Asian example, SME collaboration was in fact taking place based on prior existence of trust and in an atmosphere of continued trust building between stakeholders (Konstadakopoulos, 2000).

In summary, SME (virtual) clustering seems contingent on favorable network conditions such as connectivity (infrastructure), network relationships, and trust. ICT and related capabilities, such as virtual business network environments, can potentially have a significant impact on how interorganizational relationships are developed. Conversely, the structure and culture of an existing network of firms can have considerable influence on the way in which the telecommunications network is developed, implemented, and used.

CASE STUDY

An action research study with a regional Australian SME tourism network seeking to adopt ICT and e-commerce provides some practical insights into network-based ICT and e-commerce adoption. Action research (AR) is a methodology and intervention process that is collaborative in nature, as it aims to work with stakeholders rather than on them (Reason & Bradbury, 2001). All action-oriented interventions value some form of participation, although there are varying degrees of collaboration depending on the method of invention. The participatory and action-oriented

nature of action research is particularly suited to technological innovation, such as the adoption of ICT and portal technology, as it is flexible enough to meet the emerging issues of technology-related change.

In the pursuit of introducing ICT-related change in the tourism network, AR was found to be particularly suited to ICT-related organizational change, as it enables inquiry into and integration of the technical, economic, organizational, human, and cultural aspects of the intervention. AR-type consultations typically include a cyclical and action-oriented design that includes a diagnostic phase, a planning phase, a taking-action phase, and an evaluation phase. Apart from its cyclical approach and practicality, AR is generally appropriate when a project relates to “an unfolding series of actions over time in a given group, community or organisation” (Coughlan & Coughlan, 2002, p. 227).

The AR intervention ensued from a portal development consultancy with a geographically dispersed regional tourism network in the state of Victoria, Australia. Tourism network formation in the form of cooperative destination marketing has been in place in Victoria since 1993 as part of the state’s strategic direction to develop integrated marketing campaigns for its product regions and to attain competitive advantage through collaboration (Tourism Victoria, 1993). Each product region has a so-called campaign committee, a voluntary organization made up of representatives from local industry and local government. Campaign committees are responsible for the marketing of the product region and the maintaining of communications with industry stakeholders in their region.

The AR project was undertaken with one such campaign committee, the Grampians Campaign Committee (“the Committee”), seeking to extend its traditional marketing media range and upgrade its basic ICT network to include an online marketing and transaction presence. The Grampians are considered one of Australia’s renowned tourism

attractions, drawing in excess of 1.2 million visitors annually. The region encompasses some 900 tourism SMEs, seven major townships, numerous villages, and seven local government shires.

The brief was to design a portal model that would support business-to-consumer (B2C) marketing and e-commerce transaction efficiencies and serve as an interfirm B2B interaction and knowledge-creation platform for tourism SMEs in the product region. The AR intent was to ensure that an appropriate portal model would be implemented that reflected stakeholder interests and portal needs. Although AR is an emergent process, and designing such a process is often considered incongruous with the nature of the intervention (Van Beinum, 1999), an overarching portal development approach was nonetheless adopted to provide starting conditions for the process, whereby the intention was to involve as many portal stakeholders as possible in the portal design process. The AR actions proposed to regional stakeholders were to:

- Take part of a data-gathering phase and collect stakeholder e-commerce inquiries and portal needs prior to the design phase of the portal
- Participate in a one-day forum to collectively formulate an initial e-commerce model for the product region
- Take part in follow-up communication to finalize the portal model

Interaction occurred between mid-2001 and early 2002 with a group of 20 stakeholders, who were either part of the Committee, representing tourism industry SMEs, or had a direct industry interest in the portal. After the completion of the AR intervention, all electronically available data—such as e-mail messages, audiotaped conversations, field and journal notes, ICT and tourism policy documents, speeches, and other pertinent documentation—collected during the course of

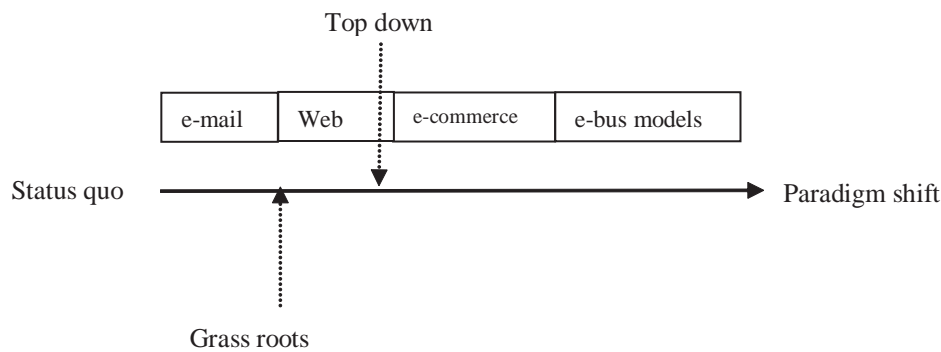

the intervention were aggregated into a qualitative software program for data analysis.

STUDY RESULTS

In conducting and tracking the AR process of developing a product region portal, study results indicate that embracing portal technology is a complex and phase-based process. While e-mail had become the standard communication method for internal Committee business, it had not yet ubiquitously been adopted as the external mode of communication with SME stakeholders across the product region. The AR study indicated that both the hard technology (the telecommunications infrastructure that underpins the uptake of ICT) and the soft technology (the formal and informal skills and knowledge required for the uptake of ICT) remained inadequate. Contextual factors, many in existence prior to ICT adoption, such as stakeholders possessing (access to) ICT knowledge, infrastructure, skills, and time, played a significant role in portal adoption patterns across the product region.

Overall, stakeholders lacked both time and strategic vision, which resulted in a low level of participation in the AR process and lack of “ownership” of the portal. In examining connectivity through conversation and e-mail traffic analysis, it became apparent that institutional stakeholders (e.g., those with work-related access to network infrastructure) were markedly more “connected” than industry (SME) stakeholders. While many product region stakeholders were aware of the Web, the study indicates that most SMEs had not yet progressed to the e-commerce phase, confirming that adopting e-business technologies is indeed an evolutionary process that requires the negotiation of a journey that involves continuous learning and change. Adoption of the entire cluster of ICT technologies could, hence, be viewed as a linear process along an adoption continuum

Figure 1. ICT adoption continuum

(Figure 1). After adopting e-mail, the Web is the second step for adoption consideration; e-commerce is the third step. This is then potentially followed by adoption of a complete e-business model, at which point we might speak of complete ICT adoption or an ICT paradigm shift.

In further considering the SME approach to portal adoption within the network, the study suggests a strong relationship between portal development and network makeup, both in terms of place, e.g., stakeholder position in the network, and space, e.g., the geographic makeup of the network. The Grampians history and the vast boundaries of the Grampians product proved to be pivotal factors negatively influencing ICT network cohesion and SME interest in, and engagement with, the portal. The latter, in turn, influenced the scope of portal adoption within the product region and the SME approach to virtual clustering to achieve economies of scale.

On the whole, clustering was regarded as an interesting but far-fetched idea. Despite the Committee's interest in aggregating domain stakeholders, communication strategies or incentives to create industry awareness of clustering were not

part of the product region's vision or strategic plan. Grampians SMEs were generally still too new to the virtual world to understand the relevance of clustering for their own small business, let alone as a crucial economic strategy for their product region. Because e-commerce was still beyond most Grampians SMEs' level of ICT adoption, the aggregation of SMEs in a virtual cluster or any other potential value added that might have been established along the regional value chain remained unrecognized and, hence, untapped. The specially designed industry clustering tier in the portal was not conducive to augmenting ICT adoption or to fostering an SME cluster culture.

The Grampians' reluctance to cluster may be attributable to various causes. First, the Grampians product region may have been too vast, with SME firms being too geographically dispersed to maintain relationships with and build trust between firms. Second, ICT alone could not permeate subregional barriers or initiate an inclusive virtual cluster culture. As other SME network research has indicated, network conditions need to be conducive to clustering.

CONCLUSION

ICT and related capabilities such as virtual business network environments can have a significant impact on competitive advantage in the networked economy. However, as this article has demonstrated, embracing the cluster of ICT technologies, including portal technology, is a complex and phase-based process. Many SMEs are not yet aware of the potential and value of collaborative e-commerce structures. Merely adding ICT and e-commerce capability to a network structure does not necessarily change or increase SME interest in virtual clustering. For SMEs to take mental, physical, and virtual possession of a shared ICT domain, they will need to get comfortable with ICT and better understand the value of virtual clustering in terms of competitive advantage and economies of scale.

Becoming a network stakeholder may entail an enormous conceptual leap into the future for many SMEs. Network novices will need substantial encouragement and support to make them willing to take the network plunge (Braun, 2002). Creating awareness of networked opportunities, developing skills in using networked technologies, and increasing SME understanding of the potential of (virtual) cluster environments may be helpful. When favorable network conditions are present, participation in an SME virtual cluster is likely to produce economically beneficial outcomes.

KEY TERMS

AR: Action research. Action research is an action-oriented methodology or intervention process that is collaborative in nature. It aims to work with stakeholders.

B2B: Business-to-business trading; involves the sale of goods or services by a business to another business.

B2C: Business-to-consumer trading; involves the sale of goods or services by a business directly to individual customers.

Cluster: A group of linked enterprises that share a common purpose of gaining competitive advantage and economies of scale.

Competitive Advantage: A condition that enables companies to operate in a more efficient or higher-quality manner than the companies it competes with, and that results in financial benefits.

Connectivity: The ability to link to the Internet via a computer.

E-Commerce: Connection, electronic data exchange and transaction capability via the Internet.

Economies of Scale: This refers to the notion of increased efficiency for the production and/or marketing of goods/products by pooling or sharing resources.

ICT: Information and communication technologies; includes phone, fax, e-mail, the World Wide Web, and the Internet.

Portal: A Web site or service that provides access to a wide range of services.

SMEs: Small and medium size enterprises; refers to enterprises with a specific number of staff. A small size enterprise generally refers to firms with less than 20 employees.

Value Chain: A value chain is a string of diverse companies working together to create or satisfy market demand for a particular product or a bundle of products.

Chapter 6.16

The Impact of IT Investment in South African E-Commerce SME Organizations

Sam Lubbe

University of KwaZulu-Natal, South Africa

ABSTRACT

This chapter considers the possibility of a link between organisational performance and information technology (IT) investment intensity in SME organisations practising e-commerce for the period 2001/2002. The answers to the research questions note that in top performing organisations; (1) IT costs as proportions of operating costs were higher; (2) IT costs as a proportion of turnover was lower, than in weak performing organisations; and (3) that a positive correlation exists between the computerisation index (CI) and the operating costs ratio. The investigation also reveals that chief executive officers (CEO)'s expect additional output while planning e-commerce operations and keeping IT budgets constant. Evidence is presented that company performance is linked to the level of IT investment intensity in the sample of organisations investigated, even though more output was expected from the IT department.

INTRODUCTION

Achieving business value from information technology (IT) and e-commerce investment at the same time is probably one of the more common organisational concerns of (CEOs) today (Lubbe & Pather, 2002). IT and e-commerce are the growing areas of investment in most organisations; in fact many organisations will not be able to function without IT or digital commerce. The role of IT has also been redefined by some organisations to include attempts to embark on e-commerce operations. The role of IT in organisations is not merely a tool for processing communication, but a strategic weapon that can thus affect an organisation's competitive position (Lubbe et al., 2002; Weill & Olson, 1989).

Some of the variables that will be discussed include IT, e-commerce, investment, and achieving value from IT investment. The contribution of this article is significant, as it will contribute to the understanding of managers that the impact

of e-commerce may change the way organisations handle their total IT investment. The article will, however, review only South African organisations and aims to improve on the topic's understanding off IT and digital investment by managers and academics.

REVIEW OF PAST RESEARCH

Mason, McKenney, and Copeland (1997) argue that information systems (IS)¹ as a discipline has not yet developed a tradition of historical research. This historical analysis by them broadens the understanding of the processes and designs during which IT is introduced into organisations and the forces the shape IT investment uses. They argue that a dominant design for this shape could be manifested in several ways; a new organisational infrastructure, new functionality, new products, new services, new production functions or new cost structures. The problem with historical analysis is to discover why some organisations lead their respective industries in the use, design and application of IT, and why other organisations, having spent millions of dollars achieved modest success rates.

Hu and Plant (2001) argue that the promise of increased advantage was the driving force behind large-scale investment in IT since the 1970s.

Current debate continues amongst managers and academics with reference to the measurable benefits of IT investment. Return on investment (ROI) and other performance measures in academic literature, indicates conflicting empirical findings. They also submit that it would be convincing to infer causality if IT investment in the preceding years is significantly correlated to the performance of the organisation in the subsequent year. Hu et al. (2001) used the Granger causality model with three samples of organisations and discovered that there was no increase in the level of financial performance. Rather, it is the other way round—increased financial performance lead to increased IT investment.

Li and Johnstone (2002) argue that a manager can use the framework within which the appropriateness of using real options theory in strategic IT investment by systematically justifies the use of it. They classify IT costs and provide some insight about the relationship between technology standardisation and IT investment decisions. Research by Lubbe et al. (2002) also reflects that managers of organisations are concerned whether their organisation is achieving IT and e-commerce value from their organisation's IT investment (Figure 1).

Bui, Sankaran, and Sebastian (2003) argue that technology and societal changes are moving the global market rapidly towards a new economic

Figure 1. Top managers and IS managers are most concerned about achieving value from IT and e-commerce

order rooted in e-commerce. They investigate some factors including macro economy, ability to invest, access to skilled workforce, cost of living, and pricing. The authors also state that many organisations face a chronic shortage of resources (including funding). Management should be aware that e-business is part of the complex and general economic structure and the success of organisations depend on that structure as well as the optimum allocation of resources.

Dykman (2003) notes that information systems (IS) represent a significant investment for many organisations. Managers need to know that the decision made to spend money on IS should be analysed like any other major purchase. She argues that general management often gives in to the expert power of the technologists, both internal and external to the organisation to invest in IS. The ROI on an IS acquisition may not be quite as simple or straightforward as other capital expenditure. She, however, states that it is still possible to do the financial analysis for the investment.

Dykman (2003) argues that it would be of great benefit if there were a general recipe that could assist to ensure success. Ideally all the strategies (e-commerce, IT, and organisation), including the framing of all investments, could be aligned around business requirements, rather than on technology requirements. She states that it needs a workhouse of a system to facilitate the operations of the organisation as it works to realise its strategic vision. She further argues that managers should be measured against the accuracy of their tangible financial projections for IS investment. Every investment should be justified with concrete revenue (benefit) and expense commitments. Dykman (2003) notes that managers should aim to do a better job assessing the benefits associated in a proposed IS investment in tangible and financial terms. Executives demand this when evaluating the approval, or denial, of any other capital expenditure. IS investment decisions are business decisions and therefore not technology decisions.

Moodley (2003) argues that e-commerce technologies are becoming increasingly important to South African apparel producers as they are integrated into global value chains. Moodley (2003) suggests that the empirical evidence emanating appears that e-commerce is still in its infancy but there is potential for growth. The problem is to ensure that there is sufficient financial support to sustain success. Moodley (2003) argues that South African organisations should increase their investment in e-commerce.

Quayle (2003) notes that the awareness and level of implementation of e-business in European small and medium enterprises (SME) differ in some aspects from larger organisations. He argues that the issues of highest importance are leadership, time to market, marketing and financial management, and a narrow vision of business survival. He further states that small firm's perceptions of quality, price, production reliability, service reliability, and capability to provide support are normal buyer's demands. Nowhere is the aspect of value from IT investments reflected. The idea is that the cost to execute transactions be reduced. He states that developing e-business expertise is essential to sustain the competitive advantage. SMEs must be aware that some aspects such as financial management could impact on their future plans.

It is also argued by Santhanam and Hartono (2003) that the resource-based view can be used to investigate the impact of IT investment on organisational performance. A strong IT capability can support improved organisational performance. Furthermore, their results indicate that organisations with superior IT capability, exhibit current and sustained organisational performance. They note however, that previous performance must be taken into account while doing these calculations.

Kearns (2004) states that while IT investment has the potential of providing competitive advantage, actual returns on such investment vary widely and a majority of CEO's rank past

IT investment disappointing. There are many methods for investment evaluation, but traditional methods do not adequately account for the intangible benefits that characterises strategic investments. They also lack other features of portfolio selection. He describes a model based on the analytic hierarchy process that could possibly overcome the deficiencies associated with traditional approaches to economic evaluation of IT investment. This approach reflects both on tangible and intangible methods and links IT investment to business strategies.

THE RESEARCH QUESTIONS AND RESEARCH METHODOLOGY

Research Questions

The Relationship Between Profitability and IT Investment

Lubbe et al. (2002) noted that a relationship exists between profitability and IT expenditures in South African e-commerce organisations. Quayle (2003) notes that no relationship exists between organisational performance and the relative portion of resources allocated to IT. He argues that the measure of performance will not capture all factors that contribute to the organisation. Using case studies, Weill et al. (1989) reveal the importance of converting IT investment into productive inputs with different levels of effectiveness, depending on the organisation. There is also empirical evidence that the use of IT results in lower cost (Santhanam et al., 2003). The first research question can thus be formulated as:

Is there a negative correlation between IT investment with profitability in e-commerce intense organisations?

The Relationship Between Profitability and Computerisation Index 2

Weill et al. (1989) argue that two key factors are emerging determining the return on investments (ROI) on IT is difficult; and investment in IT alone is not sufficient. Dykman (2003) suggests that IT investment reduces the cost of revenue generation. Santhanam et al. (2003) suggest that evidence indicates that organisational performance is linked to the level of IT investment intensity. This research question specifically compares the overall performance of the organisation with the CI index (another measure of computerisation) and not the IT expense (ITEX) ratio as used previously.

The second research question can thus be stated as (based on the study of Santhanam et al. 2003):

Is there a positive correlation between IT investment intensity and organisational performance?

The Relationship Between Profitability and IT/E-Commerce Strategic Management Integration with Organisational Strategic Management

The third research question is formulated as:

Is there a positive correlation between IT investment and strategic management of IT and e-commerce operations?

RESEARCH METHODOLOGY

The author had decided to use qualitative research because it is designed to help him understand the people and the social and cultural contexts within which the organisation operates. To establish the best design it was decided to collect the data needed

to answer the research questions discussed above using a structured questionnaire. The population consisted of all IT intensive organisations that have just started an e-commerce operation during the period 2001/2002. From this list, a number of companies were selected who indicated their willingness to cooperate with the investigation. They were mailed a copy of the questionnaire with a request to include financial statements for the period covered (2001/2002).

The completed questionnaires were analysed to extract the data. The CI was calculated from data collected using the questionnaires. Financial ratios were calculated using data from the statements and the questionnaires. Data showing the relationships between the CI and measure of financial performance were plotted on graphs using Microsoft Excel.

Limitations of the Study

It is acknowledged that there are other factors that could affect the research but the author has decided to limit the study to the papers that were available to him. It was assumed that the organisational financial and other figures, as rendered, were accurate and complete where they could be verified with audit/working papers. Additionally it was assumed that the respondents completing the questionnaire did so accurately. However, a possible source of error lies in the respondents' interpretation of the terminology used in the questionnaire, although it was pre-tested.

Furthermore, some data given by the respondents could not be verified fully, owing to its sensitivity. Also, it was not possible to check the method of accounting and it is acknowledged that this could have influenced some financial ratios. However, given these limitations, it was still possible to use the models to answer the research questions since these sources of error did not differ from those evident in other studies (e.g., Lubbe et al., 2002; Weill et al., 1989). It was also possible to interpret the results based on the

data obtained as no statistical technique could show them to be unreliable.

The Results

Information Systems in South Africa in Context

South Africa is a medium sized country, 471,000 square miles at the southern tip of the African continent with a population of some 45 million people. Relative to the rest of Africa, South Africa is substantially industrialised. South Africa is a wealthy country from an industrial and agricultural point of view and computers have been actively in use in South African business, education, and industry since the early 1960s when both IBM and ICL opened offices in Johannesburg. Today South Africa employs computers in every aspect of industry, business and government as well as having a relatively high percentage of home computers among the middle class. All the major vendors are present and there is considerable interest in hi-tech.

The business and industrial sectors in South Africa are as sophisticated as anywhere in the world in the use of information systems. South Africa leads the world in deep level mining and supports this activity extensively with computer systems. The country also has a substantial financial services sector that has won international recognition for its excellence in information technology. For example, the First National Bank (FNB) of South Africa was named one of the world's top 100 computer users by ComputerWorld Magazine in May 1995 and in July 1996, the same bank also won the prestigious Smithsonian Institute prize for the innovative application of biometrics in their information technology.

Discussion of the Results

In order to test the validity of aspects of the questionnaire respondents may have had difficulty

understanding when answering, a pilot study was conducted using some of the companies in the sample. This was done to ensure that it was possible to collect all data required for the ratios. Ambiguities were removed in order to reflect a concise research instrument.
