The government established various institutions to boost the ICT development in Tunisia and to support research and development (R&D) at a time when no private facilities and companies were in the position to take over these tasks of national importance. Eighty percent of software development in the public sector and in public administration are covered by the Centre National de l'Informatique (CNI) (*context of strategy and rivalry*). The Centre des Etudes et Recherche en Télécommunication (CERT) is active in the field of IT services and software development also for the public sector and public administration. As an exporter it has carried out IT consulting and IT management projects in various African and Arab countries (UNDP & CEPEX, 2004).

According to the advancing information economy in Tunisia, the dominance of public ICT producers might have to be reconsidered (Lanvin, 2003). Whereas, a call for liberalization in order to open markets and growth potentials for private ICT firms has to be seen in a trade-off to other national and sectoral development priorities of the government. An important question in this regard is, which functions and responsibilities of public producers would be appropriate to be transferred to private firms according to their capabilities and strengths?

SHAPING THE MACROECONOMIC ENVIRONMENT

Legal Framework

Tunisia was the first Arab country to join the World Trade Organization (WTO) in 1995. Regarding ICT, the agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) is of particular importance. With the standardized Intellectual Property Rights (IPR) protection system, Tunisia is due to witness further integration into global

R&D (Dutta & Coury, 2003). Several national IPR-related decrees already exist. These are the trademark decree of 1936, the patents decree of 1956, and the copyright decree of 1994. From January 2005 the country is required to extend product patent protection to types of products not previously patented so extensions of the legal framework can be expected in this regard.

The government has also worked on a legal framework for e-commerce. Several laws have already been enacted. These have been adapted to the concepts on e-commerce legislation of the United Nations Commission on International Trade Law (UNCITRAL) and the European Union (EU) (World Bank, 2002). It is also important to mention the law on electronic signatures and the law on electronic commerce of 2000. Through these laws, Tunisia has achieved a more advanced and comprehensive legal framework for ICT than for example Italy, Portugal, and Hungary (World Economic Forum et al., 2003).

Supply with Capital and Finance

Efficient capital markets are essential for entrepreneurship and investments in the information economy (Raffa et al., 2002). In Tunisia, banks and the vast majority of venture capital companies show in general a preference for investment and financing projects with large enterprises in more traditional Tunisian industries such as textiles and tourism rather than in software and IT services (World Bank, 2002). This is a serious obstacle for the majority of ICT firms in Tunisia (Chaabouni & Mezghani, 2001). The availability of venture capital (*factor conditions*) is an important precondition for innovation and business development. Finance and management consultancy (*related and supporting industries*) can be necessary for the feasibility of large customer projects (UNCTAD, 2003).

Facing the disadvantage regarding the weak capitalization of firms, the government established public venture capital funds. They take part in

joint investment projects in the ICT sector together with private finance institutions. By this, the government not only might support the information economy, but this also allows banks and venture capital companies to gain experience in the field of ICT. It has to be seen how far these funds will be used by firms in the short and medium term and how they can help to change the traditional patterns of finance and venture capital provision in the long term. However, such public financial and non-financial business development support (BDS) plays a key role for getting around market inefficiencies and structural obstacles for ICT firms (UNCTAD, 1999).

BDS can have a variety of impacts on the information economy and its proximate business environment. These can be classified as direct measures undertaken to support firms either with capital (*factor conditions*) or project finance and consultancy provided to accompany specific business processes (*related and supporting industries*). Indirect impact derives from the governmental incentives for other industries to invest in ICT (*demand conditions*). For instance, the Tunisian government co-finances upgrades of IT systems in order to increase productivity and the implementation of e-commerce applications to support export businesses. As a consequence, the support policies have effectively promoted ICT investments and high technology absorption in Tunisian firms (World Economic Forum et al., 2003).

TAILORING EDUCATION POLICY

Education plays a key role in the government's e-strategy. For instance, relative expenditures for higher education increased between 1997 and 2003 from 1.27% to 1.80 percent of gross domestic product (GDP). Especially, technical studies have been vigorously promoted. The number of students in ICT-related studies increased from 3,534 in 1997 to 30,260 in 2003 (Ministère de l'Enseignement Supérieur de la Recherche Sci-

entifique et de la Technologie, 2003). Eventually, Tunisia achieved an excellent international ranking—number six—regarding the quality of math and science education (World Economic Forum et al., 2003). This way, the national human resources development in terms of quality and availability of technological expertise supports effectively an advantageous business environment for Tunisian ICT firms (*factor conditions*).

LEADING LARGE PUBLIC ICT INITIATIVES

State of ICT Cluster Development

Cluster formation is an important driver for the productivity and competitiveness of firms. Clusters foster closely linked and efficient relationships (*related and supporting industries*) up-stream and down-stream in the value chain, and among firms at the same stage of the value chain (Porter, 1998). Therefore, this is an important feature of the Tunisian e-strategy. By building technology parks, the so-called “technopôles”, the government follows the approach of the United Nations Industrial Development Organization (UNIDO) for International Business Incubation Systems (IBIS) (UNIDO, 2004).

The major project is the technology park, Elgazala, in Ariana which was established in 1999. Until 2003 the number of Tunisian and foreign ICT firms located in the park increased to 40. Similar “technopôle” projects are about to be launched over the coming years with Sakiet Ezzit in Sfax and Hammam Maarouf in Sousse.

Public research institutions are closely linked to the technology park. The Ecole Supérieure des Communications (Sup'Com) and the Institut Supérieur des Études Technologiques en Communications (ISET'Com) play a key role in driving innovation and fostering partner companies (ITU, 2002). For example, since 2001 ISET'Com is establishing enterprise incubators in order to

promote entrepreneurship in the information economy. It links research, higher education, and financial and non-financial BDS.

As outlined above, despite the governmental BDS policies and the beneficial environment that a “technopôle” offers, with the absence of sufficient finance and capital provision for the information economy on a broad basis, ICT cluster development lacks an important condition for sustained success of ICT firms (UNCTAD, 1998).

CONCLUSION

The ICT environment in Tunisia contributes to the competitiveness of ICT firms but also challenges them, especially regarding software and IT service exports. Based on the issues presented in the course of this case study, Tables 1 and 2 suggest some fundamental achievements and challenges for future e-strategy formation that might consider more competitiveness impacts on ICT firms. Again, the strategic choice of the government has to be seen in the context of national development priorities. The trade-off between social and economic development goals and possibly conflicting development goals in different sectors will result in the decisions of policy makers. Whereas, the priority has been set—software and IT service exports.

KEY TERMS

Digital Divide: The digital divide is the discrepancy between people who have access to and the resources to use new information and communication tools, such as the Internet, and people who do not have the resources and access to the technology. It can exist between rural and urban areas, between the educated and uneducated, between economic classes, and between more and less developed nations.

E-Strategy: The e-strategy defines the overall framework for the national ICT development. It has a social and an economic dimension. It consists of e-policies which concern the ICT environment, and ICT readiness and usage of three stakeholders in ICT: individuals, businesses, and governments.

GCI: The Growth Competitiveness Index (GCI) aims to measure the capacity of the national economy to achieve sustained economic growth over the medium term, controlling for the current level of development.

ICT Sector: The ICT sector is a combination of manufacturing and service industries that capture, transmit and display data and information electronically (OECD, 2003).

MICI: The Microeconomic Competitiveness Index (MICI) aims to assemble textured measures of the competitive environment of a nation.

NRI: The Networked Readiness Index (NRI) measures the degree of preparation of a nation to participate in and benefit from ICT developments.

Chapter 2.4

An Explanatory Approach to the Political Uses of ICT Initiatives for Participation: Institutions, Context, and Characteristics of the Actors

Rosa Borge

Open University of Catalonia, Spain

ABSTRACT

Political actors use ICTs in a different manner and in different degrees when it comes to achieving a closer relationship between the public and politicians. Usually, political parties develop ICT strategies only for electoral campaigning and therefore restrain ICT usages to providing information and establishing a few channels of communication. By contrast, local governments make much more use of ICT tools for participatory and deliberative purposes. These differences in usages have not been well explained in the literature because of a lack of a comprehensive explanatory model. This chapter seeks to build the basis for this model, that is, to establish which factors affect and condition different political uses of ICTs and which principles underlie that behaviour. We consider that political actors are intentional and their behaviour is mediated by the political institutions

and the socioeconomic context of the country. Also, though, the actor's own characteristics, such as the type and size of the organization or the model of e-democracy that the actor upholds, can have an influence in launching ICT initiatives for approaching the public.

INTRODUCTION

More than a decade has passed since the invention of the World Wide Web, based on the global development of the Internet, and, although it has spread very quickly throughout our personal lives, the marketplace, and civil society, it is not developing so fast in crucial areas of the political realm. Political actors, such as parties, or political institutions, such as parliaments or governments, are reluctant to use the Internet widely for connecting with or approaching citizens. Neverthe-

less, in public administration we can see a steady use of the Internet in order to provide services and information to the public and reduce the procedures that citizens must carry out. In addition, at the local level, at least in Europe,¹ public authorities are launching ICT initiatives much more than parties or parliaments for contacting their citizens and engaging them in the affairs of the municipality.

However, even public administrations and local governments are not using the Internet as extensively as the business sector, the organisations of the civil society, or individuals in their social and personal relationships. It seems that public authorities and political structures are lagging behind in the technological transformations that are affecting the private sector and relationships among individuals. So what are the reasons for this lesser use of ICTs among political actors and inside political institutions? Few studies have been carried out to answer this question. Some authors assert that there are a number of elements ranging from organisational to cultural elements that hinder the assimilation of new technologies by political actors and institutions in contrast to private companies. Political parties and representative institutions such as parliaments are more centralised, less flexible, older, and much less dependent on the “customer-citizen” than many companies in the private sector (Kippen & Jenkins, 2004; Prats, 2005), and all these trends greatly hinder a successful integration of new technologies. Society, business, and communications have changed, among other factors, because of a wider Internet usage, but the core institutions and actors of the political system are still using primarily old technological artifacts and do not appear to be very willing to transform their unidirectional relationship with the public.

Many more studies comparing the efficient integration of ICTs in business and society with the difficulties for their deployment in the representative political system are needed. Yet, it is also very important to discern why some political

actors use the new ICTs much more frequently than others. This search for an explanation is not just of academic or scientific interest, but is also of interest to politicians, public-sector officials, or development professionals who need to understand what the constraints and factors favouring deployment of ICTs are. Technicians, politicians, or activists interested in developing ICT initiatives in a transformative way for democracy must be informed of the costs and benefits of that usage and of the incentives and hurdles that they may come across.

We suspect that similar factors to the ones considered above (organisational, cultural) are affecting differences in political uses. We also know, due to the large accumulation of knowledge in the analysis of collective behaviour, political institutions, and human agency, that the political actors’ behaviour could be analysed as intentional and, at the same time, structured by political institutions and the social and cultural context.

To this effect, the main goal of the chapter will be to introduce the basic elements for the construction of a model that explains the differences in Internet usage by different political actors. These basic elements are a number of variables that must be taken into account when attempting to explain these differences in behaviour. We will not be drawing up a complete detailed model, but rather we will provide an outline of the variables that conform the structure for explanation. We leave the definition of the interactions inside the model and the very construction of the model itself for further studies. Our contributions are to bring out explanatory variables not before considered in ICT literature, to compare the variables already studied in the literature, and to think about the constraints, incentives, and opportunities that political actors face regarding ICT developments.

Internet usages vary within each country and from country to country, and they can change rapidly. In addition, the search for explanations is very difficult since contagion and diffusion of the political uses of ICT among countries and

among political actors render the analysis without clear explanatory variables. In a time of rapid change and fast diffusion of technologies, and in an increasingly globalised world, it is difficult to determine who or what shapes the course of political action, precisely, toward the new technologies. Several analysts have found common patterns and stages in the adoption of ICT by public institutions such as public administrations,² but literature on explanations is still at the beginning, and results are sometimes partial and contradictory.³

Nevertheless, we believe that social sciences should strive to understand these new phenomena and to give insights and information to public authorities, politicians, and the public in general. Also, as we mentioned before, there are enough theories, models, and methods that can be applied to shed some light on this area and thereby increase our understanding of the issues involved.

POLITICAL USES OF ICTS: THE LADDER OF POLITICAL PARTICIPATION

Before we can begin to develop the outline of the explanatory model, we have to define what political ICT usages means. In other words, what do we mean when we refer to different uses of ICT by political actors? There are a wide range of ICT initiatives with very different characteristics undertaken by parties, parliaments, public administrations, and the many other kinds of political organisations. ICTs are being used for facilitating internal communication and processes inside the political organisations or institutions, but in our study, we will be analysing specifically the external initiatives addressed to the public. These are the initiatives that can contribute to revitalising one of the pillars of democracy: the relationship between citizens and their representatives. We must bear in mind that many citizens are dissatisfied⁴ with the way the system of democratic representation works, and the Internet and other ICTs could be a

useful tool for bringing the public and politicians closer. In this sense, the Internet is being used to provide information to the public through Web sites, to establish channels of communication, such as online forums, and to expand channels of participation by means of surveys, elections, and consultations online.

In an attempt to order the various ICT experiences in public engagement, several classification scales have been developed by various analysts (Arnstein, 1969; Coleman & Götze, 2001; Goss, 1999; Navarro, in press; Organization for Economic Cooperation and Development [OECD], 2001). All of them range from the lowest step, which is the information level, to the participation in decision making, which is situated at the highest level. The progression on the scale depends on the extent of citizens' power in determining political decisions. Taking as a starting point the participation scale proposed by Arnstein, we outline a ladder of participation with five degrees distributed as follows.

A large number of empirical studies and reports describing ICT usages by different political actors have been carried out.⁵ These studies show that, generally speaking, political parties remain at the lower levels of participatory usage of ICT: information and less frequently, communication (Norris, 2001; Trechsel, Kies, Mendez, & Schmitter, 2003). In addition, government executives limit themselves to providing the public with information (and services) online through their Web sites (Chadwick & May, 2003). On the contrary, parliaments use ICTs more than parties and executives to

Figure 1. Ladder of citizen participation

develop bidirectional communication between the members of the parliament and their constituents (Coleman, Taylor, & van de Donk, 1999; Trechsel et al, 2003.). It is becoming common to establish channels of communication and consultation on the parliamentary Web sites to allow citizens to have their say about law projects and amendments, in what is called “open parliament.”⁶

More and more different areas of public administrations are moving toward the consultation level because they have an interest in knowing citizens’ opinions and satisfaction about public administration services and procedures (Accenture, 2005). And, much more frequently than the other political actors and institutions, city councils achieve the highest level, which is the one of deliberation and participation in political decisions and binding votings, beyond those already established by the ordinary system of elections (Borge, 2005; Clift, 2004; Coleman & Götze, 2001).

Of course, there are variations from this general rule. In countries like the USA, party candidates use the Internet widely and in a very innovative way. For example, Howard Dean raised money and attracted numerous supporters with the help of already well-established Web tools, bloggers, and Internet-based communities. He used Web tools like Meetup.com to form a support and fundraising group, and also received the support of the majority of the members of MoveOn.org. His campaign for the Democratic party’s presidential nomination was not centralized and led by a headquarters, but it was based instead on the Meetup.com site so that any supporter could coordinate meetings.⁷ As a result, he came close to winning the Democratic nomination for presidential candidate in spite of the lack of the financial support of big firms and mainstream organizations.

In addition, breaking the general rule of the lack of participatory and deliberative aims within governments, some national and regional executives use the Internet to involve their citizens in important political issues such as constitutional

reforms, controversial public policies, or the entry into international organizations. For instance, the British executive is the pioneer in using online solutions for participation in government decisions. Since 1997, it has developed a consultation policy on law proposals, government planning, and decisions, based on a combination of online tools such as forums, e-mails, live chats, and face-to-face meetings and panels.⁸ Recently, the Catalan government has also deployed a participatory process in order to get the public involved in the reform of the Catalan Statute of Autonomy. This initiative combined a very wide array of off-line and online actions. The online actions were three-fold. First, there was an e-mailbox called “The government listens to you,” where citizens could send an e-mail with their proposals, opinions, and criticisms regarding the statutory reform. Citizens were answered by the government in 24 hours. This became the most successful medium, with 4,530 e-mails. Second, an online forum where the citizens could discuss the reform was available, and third, there was a mailing list to which the citizens could subscribe in order to receive information about the events, conferences, and workshops about the statute.⁹

In conclusion, we can summarise the state of ICT usage by political actors with the following three statements:

1. Organisations from civil society and the business sector use ICT much more for contacting citizens and customers than political actors and institutions.
2. Parties, parliaments, and executives launch ICT-based initiatives mainly for information and communication, but rarely for consultation, deliberation, or participation in the decision-making process or in binding elections. By contrast, public administrations, and especially city councils, tend to develop ICT-based strategies to engage citizens in public affairs through online channels for consultation, deliberation, or participation.

3. Notwithstanding the latter rule, in a few countries, some parties, parliaments, and government executives also use the Internet for consultation, deliberation, and participation.

EXPLANATIONS OF THE POLITICAL USES OF ICTS: METHODOLOGICAL AND THEORETICAL APPROACHES

In looking for explanations for the different behaviour, the first and second statements cited above lead us to consider the diverse goals, values, and characteristics among political actors. If political parties, parliaments, and governments, in no matter what country, act differently from municipalities and public administrations, it is because they differ in their intrinsic characteristics (i.e., type of organisation), objectives, or values (i.e., models of democracy adopted). Nevertheless, in a few countries, parties, parliaments, and governments go a little further on the ladder of participation, and, therefore, the explanations must lie in the specific characteristics of countries, such as their political institutions or other contextual variables. Consequently, we compare a wide array of factors that may possibly affect ICT usages by the different political actors and in different countries.

Furthermore, an enormous variety of different technologies is combined for achieving the objectives that political actors seek when approaching the public. For instance, a combination of mailing lists, newsgroups, and areas on Web sites with documents available is frequently used for providing information to citizens. Bidirectional communication is usually developed making use of e-mail and chat rooms located on the Web site. Deliberation online is achieved using, in the first place, all the media cited above, and then by developing online forums, conferences, or bulletin boards. There are also other technological elements for consultation, for example, Web-based

forms of various kinds that are used for online petitions, surveys, and nonbinding referenda. Participation in the decision-making process, being the highest degree on the scale, is based on many of the technologies mentioned above that can be combined into different variants (deliberative e-polls, e-citizens' juries, e-citizens' panels, etc.¹⁰) with the objective of reaching a final decision that is binding for public authorities.

Therefore, the dependent variable (ICT usages by different political actors) and the independent variables (explanatory factors) are extremely varied. As regards the explanatory factors and in the case of collective political actors, the literature has concentrated mainly on the institutional factors (types of government, level of decentralisation, single-chamber or two-chamber systems, district magnitude, types of voting lists, etc.), the characteristics of the organisations (party size, ideology, longevity, whether the party is in power or in the opposition, etc.), and a large number of contextual variables (technological diffusion in the country, economic development, population, educational level, level of democratisation, etc.) that can affect ICT usages.

Given this variety, analysts trying to explain differences in behaviour between actors from different countries proceed by following two divergent methodologies. On the one hand, some authors select few cases and few explanatory variables in order to make the analysis more manageable and much more precisely addressed toward the confirmation of a specific hypothesis. Normally, they select cases on the independent variable; that is, cases are chosen for analysis taking into account which values on the independent variable could affect the dependent variable differently. This procedure assures no bias in case selection, but when the values of explanatory variables are very limited and no previous control variables are introduced, inferences will not be sufficiently sound for wide generalisation (King, Keohane, & Verba, 1994). Nevertheless, this kind of analysis can be very important in

the first stages of the study of a new phenomenon because it serves to discover the possible explanatory variables when there is no empirical evidence. For example, following this procedure of selecting a few explanatory variables and few cases (although many observations), authors such as Zittel (2001) and Costafreda (2005) have discovered the significant role of political institutions, such as the type of government (parliamentary vs. presidential system) or some elements of the electoral system (district magnitude and types of voting lists). Notwithstanding the significant assets of this methodology, the fact of having only a few cases and few explanatory variables, usually without controlling spurious or participatory variables, restrains inferences and limits conclusions.

On the other hand, another methodology also used consists of testing various types of explanatory factors in many countries and making numerous observations. This is the methodology followed by research teams like the one led by A. Trechsel (Trechsel et al., 2003) and important authors like Pippa Norris (2001). In these studies, the selection of cases is not intentional but a random selection drawn from a large population (Norris); or, if it is of a manageable size, researchers can select the entire population (Trechsel et al.). This procedure guarantees an unbiased sample of cases and, in this sense, conclusions can be generalised and are more valid than when few cases and few explanatory variables are examined (King et al., 1994). Nevertheless, in my opinion, the flaw of this method is on the side of the explanatory factors because they are analysed one after the other without a hierarchical pattern that could put order and meaning among the numerous possible explanations. The consequence is that, although the same cases are analysed, results between studies are contradictory, and explanatory variables found to be significant in reliable studies

like the ones carried out by Norris or by Zittel (2001) are found to be nonsignificant in Trechsel et al.'s work.¹¹

The absence of an organised pattern of explanations is due to poorly developed theoretical models, in this case, models able to account for the behaviour of collective actors toward new technologies, or in other words, models dealing with political actors' actions while at the same time offering insights into the sociopolitical uses of technology.

In political science and in sociology, there are several approaches and models that aim to explain the behaviour of collective political actors, and which have proven to be very successful. For example, there is the Political Opportunity Structure (POS), which explains that social movements and interest groups achieve their objectives and a power share when the institutions of the political system are accessible, porous, and open to their demands and participation (Kitschelt, 1990; Kriesi, Koopmans, Duyvendak, & Giugni, 1995). Institutional structures promote or deter collective actors from action by means of the incentives and benefits they would provide. The significance of institutions is also acknowledged by New Institutionalism (March & Olsen, 1989), where institutions are no longer passive constraints or a determining factor, but rather play an active role in establishing the preferences and interests of collective actors (Hoff, 2000).

Furthermore, regarding technological usages, some authors (Hoff, 2000; Aibar & Urgell, 2003; Welp, Urgell, & Aibar, 2005) point out that the SCOT (Social Construction of Technology) theory as formulated by Bijker (1995) is currently the most promising theory for studying the interplay between structures (institutions, organisations), culture, and behaviour toward technologies. The social constructivist approach put forward by Bijker states that the group uses of technology are

mediated by structures and culture and, therefore, they must be analysed within this context.

BASIC ELEMENTS AND PRINCIPLES FOR AN EXPLANATORY MODEL

In my opinion, a successful explanatory model would be a combination of the two theoretical approaches mentioned above: the one that recognises the relevance of institutions and the one that highlights that the usages of technology depend on the nature of organisations and the culture where technology is deployed. At this point, we will try to lay the basis for an explanatory model that combines three sets of elements:

1. The political institutions within which the collective actors must play. The research literature pinpoints the district magnitude, the type of voting list, the type of government, and the level of decentralisation.
2. The socioeconomic and technological context characterising the environment where the actors perform, that is, some aggregate characteristics of the country (for example, technological diffusion, socioeconomic development) or of the city or town (town size) where the actors act.
3. The nature of the collective political actors, which refers to their different characteristics in terms of aims, organisation, and values.

Continuing with the theoretical approaches cited above, there is an interplay between the three groups of factors that can be described as follows.

Collective actors make use of ICTs when institutions and context promote and facilitate their use, but always depending on the characteristics of the actors. This means that institutions and context impinge upon the structure of costs and benefits of collective action, but actors' preferences depend

on the objectives, culture, and organisation of the actors. We start from the assumption that collective actors are rational agents that use ICTs if they are useful for achieving their objectives and if there are enough institutional and contextual incentives for fulfilling their objectives better by means of ICTs. In contrast, collective actors will not make use of ICTs if they do not envisage their utility for achieving their objectives, and the surrounding institutions and context do not provide opportunities for meeting the actors' goals using ICTs.

The logic of the behaviour described above can be illustrated well by comparing two different actors that show opposing behaviour regarding the deployment of ICTs, as we have already mentioned in previous pages: political parties and city councils. In most countries, the former make very poor use of ICTs in order to reach out to the public (basically, providing information and establishing one-way channels of communication; Norris, 2001; Trechsel et al., 2003). The latter tend to use ICTs much more, in most countries, for involving citizens in participatory and deliberative processes (Chadwick & May, 2003, pp. 294-295; Clift, 2004; Coleman & Götze, 2001).

Taking into account the findings shown by the literature, we will detail the variables that could be the most influential within each of the three groups of elements for the case of parties and city councils.

Political Institutions

Regarding political institutions, and for the case of parties, the literature points to the district magnitude, the type of voting list (Costafreda, 2005), and the type of government (Zittel, 2001) as the most relevant variables. For local governments, we think that the most important variable could be the level of local decentralisation of the country and the consequential power share, budget, and attributions that city councils enjoy. In addition, legal enforcement and subsidies for

developing ICT channels for participation are proving to be crucial.

If the district magnitude is very small (uninominal or binominal) and the type of voting list is unblocked or open, parties will design ICT media to reach the voters better because candidates depend much more directly on the voters than in the case of proportional systems with large districts and blocked voting lists in which nomination depends on the power struggles inside the party. This is one of the reasons why parties in Chile, the United Kingdom, and Germany design their Web sites not only for informational purposes, but also for communication and deliberation (Costafreda, 2005; Trechsel et al., 2003). The same reasoning could be applied to the type of government. In presidential systems, parties and their presidential candidates have more incentives to launch ICT initiatives in order to contact and convince possible voters than in parliamentary systems in which the election of the head of the government is indirect through the members of the parliament. Also, the fact that a party or a party coalition winning in the elections in parliamentary democracies possesses the power to make and break governments imposes a rigid discipline on parliamentary majorities and on the party itself, and pushes representatives and candidates to concentrate on internal bargaining (Zittel, 2001, p.19). On the contrary, in presidential systems, parties and representatives have much more room to establish a closer relationship with their constituents, followers, and voters (Zittel, 2001, p.20). Zittel defends that this institutional feature is one of the most important explanations for the greater communicative ICT usage by U.S. parties as compared with their European counterparts.

With respect to local governments, the most important variable is the level of decentralisation of the country regarding the local level, as municipalities will tend to deploy ICT-based channels of communication and participation more frequently if they have the sufficient autonomy, legal com-

petences, and financial resources to do so. We consider that not only political decentralisation could achieve power and resources for the city councils, but also deconcentration or functional autonomy, where the central state gives up the management of some important functions and services to the local government. This would be one of the reasons why local governments in the United Kingdom, the Netherlands, and Finland have undertaken so many ICT initiatives for engaging their citizens in local public decisions. In addition, decentralisation is becoming a key political aim of Latin American governments, and new participatory bodies, including different ICTs usages, are being set up at the local level in countries such as Bolivia, Colombia, Brazil, and Venezuela.

Other important conditions for undertaking ICT initiatives are the legal framework and the financial incentives provided by other levels of government. For example, several planning schemes in the United Kingdom and several laws in Spain and Catalonia¹² compel local governments to design participatory plans that include the launching of ICT initiatives. Also, in these countries, higher level governments award subsidies to the city councils that develop participatory projects, including the use of ICTs. This has contributed enormously to the emergence of ICT-based strategies for participation in Catalonia.¹³

Socioeconomic and Technological Context

With reference to the socioeconomic and technological context, the variables commonly studied in the case of political parties (Norris, 2001; Trechsel et al., 2003) are the technological diffusion inside the country, the socioeconomic development, the population size, and the level of democratisation. These variables are characteristics of the country and must be controlled in order to see the real influence of the institutional variables. Trechsel et al. (2003) demonstrated in their study of 25

European countries, the European Union, and 144 party Web sites that economic development (measured by per capita GNP [gross national product]) and population size of the country have no significant correlation with an extensive use by parties of ICTs for communicative or deliberative purposes. Nor does technological diffusion have an impact on developing party Web sites with communication and deliberation channels (Trechsel et al., 2003, p.27). Nevertheless, Norris arrived at different conclusions. Her study encompasses 179 countries and 1,371 party Web sites. She found that the strongest and most significant indicator of the presence of all parties online is technological diffusion, followed by levels of socioeconomic development.¹⁴ Also, after controlling for socioeconomic and technological development, the level of democratisation¹⁵ in a country proved unrelated to the information or communication functions of parties. Therefore, it seems that the opposite conclusions from the two studies could be due to the number and type of cases analysed, and also to the different indicators used for measuring the variables. Norris examines countries from the whole world, while Trechsel's team focused on European countries. Consequently, in Norris' cases, there is much greater variation, which makes socioeconomic and technological development significant for explaining the deployment of ICTs. In addition, the differences in measurement of socioeconomic development (much more complete in Norris) and technological diffusion (much more complete in Trechsel et al.) could have led to different conclusions.

Leaving aside political parties, studies on e-government have shown that a country's GDP (gross domestic product) or per capita income affect positively governmental response via ICTs to citizens' demands for information and services (Altman, 2002; La Porte, Demchak, & de Jong, 2002; United Nations [UN], 2005, pp.117-118). This phenomenon occurs in both OECD and non-OECD countries. Nevertheless, this relationship is

not a perfect correlation because it can be mediated by each country's political institutions and culture, or each actor's aims and intentions. This is the case of Latin American countries, where D. Altman (2002) found that the more citizens are satisfied with democracy and have interpersonal trust, the lower the extent of e-government in each country. He argues that in Latin America, when there is a high satisfaction with the regime and interpersonal trust, politicians do not have enough incentives to promote e-government given the lack of economic resources and materialist perceptions in comparison to well-developed and post-materialist countries.

Regarding local governments, we can hypothesise that the socioeconomic development of the country or the city, and the technological diffusion in the country or city, or even the level of democratisation can affect the development of ICT strategies for communication, deliberation, and participation. Unfortunately, we do not have any information of this kind because the majority of studies on ICT usages by local governments are merely descriptive. Only municipality size has been analysed, although by means of simple cross-tabulations, that is, without considering relationships with other possible explanatory variables. The results show, for example, that in Catalonia, the majority of municipalities with under 20,000 citizens have not already deployed interactive spaces with their citizens on their Web sites, although in the last 2 years, these small municipalities have made a big effort to open up informative Web sites and provide access via broadband (Observatori de la Societat de la Informació [OBSI], 2004). Larger municipalities have more technical and monetary resources for implementing ICT strategies for communication with their citizens and for participation. Yet, management and politics are not so complicated in small local governments and therefore reforms toward participation or communication by means of ICTs could be more affordable and manageable once a minimum population threshold is surpassed

(for example, in Catalonia, the threshold could be situated at 20,000 inhabitants). Also, the lack of resources could be overcome through digital platforms shared by several city councils, as is being done in Catalonia or in Emilia-Romagna (Italy).¹⁶

Characteristics of the Collective Actors

In relation to the characteristics of the collective actors, we considered three variables: actors' objectives, the models or discourses on e-democracy held by the actors, and the type of organisation. These three factors are intertwined since models or discourses on e-democracy depend on actors' aims (Hoff, 2000), and at the same time, the type of organisation could condition those aims (Strom, 1990). Nevertheless, in order to simplify our outline of an explanatory model, we will focus on how objectives, models, and organisation independently affect behaviour toward ICTs.

Objectives

The literature on party behaviour within the rational-choice approach has stated three models of party behaviour based on their objectives or aims: (a) vote seeking, (b) office seeking, and (c) policy seeking (Strom, 1990). These objectives or aims could also be shared by other political actors such as local governments. Therefore, the idea is that parties and local governments will launch different ICT initiatives depending on their objectives. Of course, having one of the objectives does not preclude the others. In addition, we have to take into account that parties' or local governments' aims are featured by institutional and organisational constraints (Strom, 1990). For example, vote-seeking behaviour will be more likely to be found in majority systems (small-district magnitudes, two-party systems, low-fragmentation policies) or when parties are expected to win a large share of the vote (close to 50% in multiparty systems)

where strategic party interaction disappears and voting power leads directly to policy influence and office benefits (Strom, 1990, p. 592). Parties with these goals will develop attractive Web sites in order to "sell" the candidate and party, but will also use party Web sites and candidates' Web sites more extensively for mobilising their followers, engaging new and young voters, and contacting constituents, as is already happening in the United Kingdom and the USA.

We could hypothesise that local governments are more focused on carrying out their policy goals. Yet, they certainly want to stay in office and, therefore, they need to maintain their voters and gain more. Local governments, mostly driven by the aim of achieving votes and renewing incumbency, will not risk engaging in deliberative or participatory experiences based on ICT initiatives as the results of those experiences are uncertain in terms of gaining votes. By contrast, local governments that are mainly policy seekers will tend much more to engage citizens and networks of actors in the policy process (by means of ICTs or others) since involvement of the interested public and organised actors could guarantee an easier implementation of policies (Goss, 2001; Sabel & O'Donnell, 2000). However, just as in the case of parties, the preferences of city councils for one or the other objective depend on the incentives and constraints that local authorities will face in the institutional setting: for example, whether the central state, the regional government, or other institutions provide technical or financial support for developing participatory devices based on ICTs, or whether a legal obligation exists for city councils to deploy informative and participatory channels. As we saw before, these would be some of the incentives and constraints faced by, for example, Catalan or British municipalities.

Models of Democracy and Role of the ICTs

Very closely related to the actor's objectives are different models of democracy in which ICTs

play or could play a role. These models are pursued or assimilated by the political actors, and are showed and expressed in the discourses, strategies, and actions of the actors. Parties or city councils defend or have assimilated, more or less explicitly, different models of democracy and the role of ICTs.

There are several important studies on e-democracy models (Bellamy, 2000; Hagen, 2000; Van Dijk, 2000). These models are necessary to evaluate how ICT developments could transform the political processes and are useful for making sense of the role of ICTs inside the democratic system. They are formed by a combination of different crucial features (norms, values, institutions) that characterise the political system and the use of ICTs. Among the different studies, Bellamy's, with Hoff, Horrocks, and Tops (2000), creation and explanation of the models stands out. The main features of the models are the view on citizenship, the dominant democratic value, the political nexus, the central form of political participation, the main political intermediary, the dominant procedural norm, and the typical ICT application. The models are the consumer, the demo-elitist (or neo-corporatist), the neo-republican, and the cyberdemocratic model (Hoff et al, 2000, p.7.). Applying these models to specific cases, Tops, Horrocks, and Hoff (2000) have determined that parties are closer to the consumer model (representative democracy where the citizen is a customer who has to be well informed and deserves good public services), while local governments defend more often a neo-corporatist (pluralist democracy based on welfare policies) or a neo-republican (participatory democracy based on a strong and autonomous civil society) model of democracy. Nevertheless, the cases studied by Tops et al. are only three countries (Denmark, Great Britain, and The Netherlands) and a few parties and ICT experiences (electronic citizen card, electronic public service delivery, closed-circuit television) taking place in those countries. Therefore, more case studies are needed in order to generalise with respect to the position of the actors.

Type of Organisation

Characteristics of their own organisation affect the behaviour of collective actors. In the case of parties, Strom (1990, p. 593) identifies several organisational properties that influence party behaviour. Among these, we have selected two that may possibly affect the deployment of ICTs by parties: organisational form (capital or labour intensive) and intraparty democracy.

Party organisations are very intensive in capital when they rely on advertising technology, marketing tools, and monetary resources for the electoral campaign, for gathering information about the electorate, or for implementation of party policy. They are also the parties that receive the largest amount of money from private donations. By contrast, labour-intensive parties rely more on activists to develop these functions and they get less money from private donations. Nevertheless, in recent years, even leftist parties are shifting toward greater reliance on capital and technology as it has become a more successful strategy for mobilising supporters and getting votes (Strom, 1990, p. 575). Therefore, we can hypothesise that capital-intensive parties use ICTs widely and Web sites mainly for campaigning, while labour-intensive parties do not use so many ICT resources but frequently include participatory channels on their Web sites. For example, in Spain, analysis of party Web sites shows that capital-intensive parties like the Partido Popular or *Convergència i Unió* have developed highly attractive Web sites from a marketing point of view and have used other technical devices for the campaign, such as mobile phones, videoconferences, instant messaging, and so forth. On the contrary, labour-intensive parties like *Iniciativa per Catalunya* or *Izquierda Unida* have displayed well-constructed interactive spaces and recruitment channels on their Web sites that larger parties have not developed (Borge & Alvaro, 2004).

The same reasoning could be applied to centralised parties vs. decentralised ones. The latter

are internally more democratic and participatory, and therefore ICTs could be used for building deliberative and participatory channels. Decentralised parties transfer decisions on policy and programmes to party conferences, congresses, and committees, and the candidates for office are usually elected by means of primaries. This organisational profile could favour uses of ICTs for participatory and voting purposes. For example, in 1996, the Democratic Party in Arizona held primary elections using three channels: postal mail, the Internet, and ordinary voting. Forty-one percent of the votes were cast by Internet, and the level of participation increased sevenfold (Gibson, 2001).

Moreover, other organisational factors have been studied as possible influences on party usages of ICTs: party size and party ideology (Norris, 2001; Trechsel et al., 2003). Ideological orientation (left-right) does not have an impact on more Internet-based usages (Norris, 2001, p. 170; Trechsel et al., 2003, p.26). Only party size (major-minor) has a significant impact. Yet the difference is very small: Among the 179 countries analysed by Norris (2001, p. 156), about one third of all fringe electoral parties had developed a Web site compared with 47% of minor parties and over one half of all major parties. Trechsel et al (2003, p.26). also found that the difference in ICT introduction between major and minor parties is not important. Both authors believe that whatever political force—major or minor, left or right, incumbent or challenger—when an actor gains some initial advantage by innovating with ICT, in a short time its competitors will catch up. (Norris, 2001, p.170; Trechel et al.,2003, p.17)

The variables mentioned above are suited specifically for parties, but we think that there is one that can clearly affect ICT usages by city councils: local government size, that means, the resources and staff available. Municipality size has been analysed in previous pages and is closely related to local government size. As we stated before, larger municipalities have more technical

and monetary resources and more personnel for implementing ICT-based strategies for communication and participation. But local politics in a small town could be more manageable and the lack of resources can be overcome through digital platforms and digital know-how shared by several city councils. Therefore, mayors from small or medium-size cities that are also policy seekers could choose and afford the implementation of ICT tools for connecting with the public or for engaging citizens in policy decisions.

CONCLUSION

In the preceding pages we have tried to put some order into an area of research that is changing rapidly and that has been analysed without a systematic explanatory approach: ICT usages by political actors for connecting and engaging the public. Political actors use ICT in a very different manner depending on the type of political actor (we have examined the contrast between parties and city councils) but also on the characteristics of the country. Therefore, taking into account the findings of the literature, which are only parts of the explanatory puzzle, we have developed the basis for an explanatory model of different behaviours.

We consider that collective political actors are intentional and their behaviour is affected by the political institutions and the context in which they act. The basic elements of the model are political institutions such as the type of government, the level of decentralisation, the district magnitude, and the type of voting list; the socioeconomic and technological context; the objectives and models of e-democracy that actors hold; and the type of organisation. Consequently, part of the explanation is rooted in the contextual level and the other pertains to the level of the actors. We consider that this is the necessary combination for understanding the different political behaviours in ICT development.

The background logic is that political actors will use ICTs for achieving their objectives if there are enough institutional incentives and a favourable context for doing so. Some political institutions (district magnitude, type of voting lists, type of government) favour ICT uses for communication and deliberation in the case of parties, but other institutional features (level of decentralization, legal enforcement and subsidies) affect much more municipalities when it comes to developing ICT initiatives for participation and deliberation. Also, there are contextual variables such as the size or dimension that seem to affect municipalities much more than parties. In any case, when institutions and context are controlled and equal, that is, when we compare actors from the same country, some characteristics of collective actors such as actors' objectives (vote seekers or policy seekers) or e-democracy models adopted arise as explanatory.

Specifically, as we have shown, political parties are encouraged to make use of ICT devices if the electoral system is a majoritarian one (especially with small district magnitudes and unblocked and open voting lists) or if the type of government is presidential. Local governments are more affected by the level of decentralization, the financial incentives, and the legal framework. A high level of decentralization and legal and financial measures in favour of participation are crucial for the city councils to use ICTs in participatory strategies. On the other hand, the variables characterising the socioeconomic and technological context have been analysed by several authors and public institutions, and the results are that technological diffusion in the country and socioeconomic development affect the assimilation of ICT media by parties, governments, and public administrations throughout the world. In the case of municipalities, their small size hinders the development of interactive Web sites, though this problem can be solved by creating digital platforms jointly. Regarding the nature and aims of political actors, we arrived at the conclusion that the parties and

local governments that focus mainly on gaining or maintaining votes and that are defenders of a consumer model of e-democracy will not undertake ICT initiatives for deliberation or participation. On the contrary, city councils and parties mainly driven by policy achievement or a demo-elitist or neo-republican model will be more open to developing these techniques. Moreover, organisational properties such as organisational form (capital- or labour-intensive type of party), intraparty democracy, and party or local government dimensions can condition the deployment of ICTs for communicative and participatory purposes. Labour-intensive, decentralized, and internally democratic parties, as well as medium or large city councils will tend to develop these communication and participation techniques more than capital-intensive, centralised parties or small city councils.

In conclusion, professionals, officials, and politicians willing to deploy ICT tools for approaching the public must bear in mind the constraints and circumstances that they will face. In addition, they must be explicitly aware of their objectives and values in relation to the role of citizens in the political process. Therefore, the set of variables related throughout the chapter must be taken into account.

We leave for future research the building of a more defined and complete theoretical construct of explanations that can be applied to other political actors apart from parties and local governments. In fact, we have not fully specified the relationships between the explanatory variables and the implications of the conditions established, but we have outlined the crucial principles and elements that should structure an explanatory model of ICT usages by political actors.

ACKNOWLEDGMENT

I greatly appreciate the comments and revisions made by Ana Sofía Cardenal, Yanina Welp, and

Joseph Hopkins from the Open University of Catalonia; Josep María Reniu from the University of Barcelona; plus those made by several anonymous reviewers.

ENDNOTES

¹ Contrary to what is occurring much more frequently in Europe, an analysis of 17 Latin American municipalities carried out by M. Navarro (in press) shows that these local governments have only deployed online channels for information.

² Most public administrations have undergone three phases in the process of ICT assimilation: first, introduction of ICTs only for administrative routines and for facilitating internal communication and management; second, attempts to digitalise all the internal processes and to provide online all the information and services to the citizens; and third, the change of focus onto the demand side (the citizens' needs and interests) and toward digitalisation only if added value is achieved (Accenture, 2005; Chadwick & May, 2003; Contini & Fabri, 2001; Welp, Urgell, & Aibar, 2005).

³ Literature on explanations about different political uses of ICTs will be analysed in the following pages.

⁴ Since the 1970s, many indicators have shown that there is a certain degree of crisis in the representative democratic system, such as, the growing distrust toward main political institutions, politicians, and parties; the drop in membership of political parties and trade

- unions; the fall in electoral participation; the increased disaffection for political issues; and the steady rise of nonconventional participation (Dalton & Watenberg, 2000; Kaase & Newton, 1995; Putnam et al., 1994).
- ⁵ Most of them are case studies (Chadwick & May, 2003; Coleman, Taylor, & van de Donk, 1999; Costafreda, 2005; Hoff, Horrocks, & Tops, 2000; Zittel, 2001), although there are also comparative analyses of countries (Altman, 2002; La Porte, Demchak, & de Jong, 2002; Norris, 2001; Trechsel et al., 2003; Wong & Welch, 2004).
- ⁶ Examples of open parliaments are the Scottish (<http://www.scottish.parliament.uk>), the Catalan (<http://www.parlament-cat.net> and <http://www.democraciaweb.org>), and the Basque (<http://www.parlamento.euskadi.net>) Parliaments. The British Parliament (<http://www.parliament.uk>) cannot be considered an open parliament since it does not allow citizens' participation every time there is a law project or other parliamentary initiatives, but it provides the e-mail addresses, Web sites, and blogs of members of parliament so citizens can contact them and participate in the channels established by each of them.
- ⁷ Today, the official site of Howard Dean, called "Democracy for America" (<http://www.democracyforamerica.com>), is dedicated to recruiting, promoting, and funding progressive candidates at all levels of government and to keeping alive the network of people that was set up for the campaign for the 2004 nomination. In that sense, local meetings are still organised through the Meetup.com.
- ⁸ The first initiative of this kind was the Web site "Have Your Say," in which citizens were encouraged to inform themselves and discuss about the government's Freedom of Information White Paper (<http://www.foi.democracy.org.uk/html/about.html>).
- Nowadays, the UK government has opened a consultation line for specific policies and laws through its own Web site <http://www.direct.gov.uk/D11/Directories/PublicConsultations/fs/en>.
- ⁹ This participatory process is already closed, but two large reports on that experience are located on the Web site of the Catalan government: <http://www16.gencat.net/idi-gol/cat/documents.htm>. In addition, more analysis about the results of this experience can be found in Espuelas (2005) and Brugué (2005).
- ¹⁰ For a good description of different technologies and methods for online communication, deliberation and participation see Coleman & Götze (2001) and Clift (2004).
- ¹¹ For example, in Trechsel et al. (2003), the different types of government (presidential vs. parliamentary systems) does not have any effect on the online presence of legislatures in 35 European countries. However, as we stated before, Zittel (2001), following the most different-case approach, which included three countries, found that the legislatures in the presidential system use Internet technology more for communication purposes in contrast with the much more passive and unidirectional uses of the parliamentary systems.
- ¹² In 2003, a new law was passed in Spain to modernize the local government (Law 57/2003). That law requires local governments to deploy channels and mechanisms for favouring the citizens' participation in local affairs.
- ¹³ In 2005, the Catalan government enacted, for the first time, an order for providing financial aid to local plans to increase public participation and for the development of ICT-based initiatives for consultation and participation at the local level (ORDRE REP/119/2005).
- ¹⁴ Technological diffusion is measured by the

An Explanatory Approach to the Political Uses of ICT Initiatives for Participation

proportion of the population online and socioeconomic development is measured by the Human Development Index from the United Nations Development Program (Norris, 2001, p.166).

¹⁵ The level of democratisation refers to the indicator of Political Rights and Civil Liberties figured out by the Freedom House Annual Survey (Norris, 2001, p.166).

¹⁶ These digital platforms for electronic communication and participation can be consulted at <http://www.e-consensus.org/consensus> and <http://www.regionedigitale.net>. More information about the Catalan platform and the specific experiences carried out are available at Borge (2005).

Chapter 2.5

B2B E-Commerce Diffusion: The Efficacy of Institutional Discourse

Kim Virborg Andersen

Copenhagen Business School, Denmark

Helle Zinner Henriksen

Copenhagen Business School, Denmark

ABSTRACT

The chapter explores the role of institutional discourse on B2B e-commerce diffusion. Using the case of EDI in the Danish business environment, the analysis demonstrates a lack of active industry involvement and severe implications of the absence of large users in the policy forum for the national EDI-strategy. Government branches and business associations formulated by and large the visions and strategies without direct involvement of the successful EDI-players or companies that were the intended adopters. As a possible consequence, the EDI diffusion has evolved by the same companies exchanging still more messages and type of documents whereas the number of new companies adopting EDI has been fairly limited. The policy implications of the Danish EDI-case could be to have a more focused involvement of intended adopters of similar and future technologies that has high policy saliency.

INTRODUCTION

During the last decades, governments and business associations throughout the world have recognized the significance of information and communication technologies (ICTs) for businesses and public administration. The result has been institutional initiatives aiming to support diffusion of ICT among businesses and public agencies (e.g., Teo, Tan, & Wei, 1997; Klein, 1995; Damsgaard & Lyytinen, 2001). The Singapore NII initiatives (Neo, King et al., 1995; Wong, 1996), the Malaysian Information Rich Society plan (Raman & Yap, 1996), the Japanese Super Information Highway, the Al Gore Information Highway, and the European Information Society policy documents (Commission, 2001; Brousseau, 2002) are some recent examples of governmental interest in ICTs. B2B e-commerce has been an important part of the policy plans and has been given a high degree of policy saliency with various institutional initiatives to fuel development and uptake.

The objective of this chapter is to focus on institutional initiatives used to promote diffusion of EDI in the Danish business community. EDI is the ICT application presented in this chapter. We view EDI as a technology construct rather than as a business imperative (Markus & Robey, 1988; Sampler, 1996). A particular action plan that focused on diffusion of EDI in the Danish business community and the public sector (Ministry of Research and Information Technology, 1996a) is assessed by comparing actual uptake of EDI to the underlying discourse, which originally drove the action plan. It is our claim that an analysis of the content of the EDI agenda and its underlying discourse will be of value to governments, especially due to the continuous use of action plans for regulating diffusion of a given technology. In the context researched in this chapter, there are three reasons for paying particular interest to the analysis of the discourse embedded in the EDI agenda.

First, the Danish context is significant because *relations between market and government are unique* compared to other nations where market forces play a much more critical role. The Danish practice of ICT adoption and exploitation is stimulated by early coordination and commitment from both government and business associations to help fuel adoption and exploitation of ICT as a competitive instrument (Andersen, Bjørn-Andersen, & Dedrick, 2003a) in line with the Porter (2001) terminology. The case presented in this chapter also reveals the reverse side of a close interplay between government and industry. Following this approach, we are not only facing the challenge of getting the important domestic players on board; the global industry players and their (proprietary) standardization work are equally challenging.

Second, the Danish case is of interest since *the role of ICT in governmental units' own operations has been just as important as using ICT to gain competitive advantage*. The urgency of government to ensure accessibility, transparency,

efficiency, and accountability in its operations has pushed the use of ICTs. Although we find similar motives in other countries, the Danish governmental sector is unique due to its employment of one-third of the total labor force and its reallocation of 70% of the GDP. To reduce the burden of administrative costs in the public sector, the motivation to use ICT in its communication with the private sector has been very strong.

Third, an *early acknowledgment of digital divide issues* (Dybkjær & Christensen, 1994; Bjørn-Andersen, Earl, Holst, & Mumford, 1982) and policy commitments to address the issues, also in the business community, form the third interesting aspect of the Danish approach to regulation of B2B e-commerce. It has been a deliberate policy decision to target micro and small businesses based on an economic growth model where *demand pressure tends to come from the SMEs rather than the MNCs* (Andersen et al., 2003a).

In the following we summarize the major ICT research perspectives and the significance of institutional regulation of diffusion of ICT, we present a framework for analysis of the Danish EDI Action Plan, and we define the central elements presented in the chapter. The next section focuses on the policy context, which fueled the EDI Action Plan. After describing the seven key elements in the Danish EDI Action Plan, we evaluate the outcome of the plan in the respective business sectors. The chapter concludes by discussing the implications of the substantive findings from the institutional regulation attempts on EDI.

FRAMEWORK AND DEFINITIONS

The literature on institutional regulation related to ICT diffusion reveals a discrepancy in relation to the effects of coordinated efforts made by industry and trade associations and governmental units. This discrepancy is reflected in the body of literature focusing on institutional (especially

governmental units) interventions (Lai & Guynes, 1997). Changes in the remote environment (e.g., regulation) and industry structures (Gregor & Johnston, 2001) are viewed as the most powerful causes for ICT adoption (King et al., 1994). Findings from this line of research indicate that deliberate institutional interventions or decisions to refrain from interventions play a vital role in technology diffusion. This position has been challenged by Johnston and Gregor (2000) who argue that "... deliberative coordinated action by an industry as a whole, or units purporting to represent such a group position, may be severely limited in effectiveness." The objective of this chapter is to analyze the nature of the type of deliberate coordinated action. Johnston and Gregor (2000) refer to.

To analyze the action plans with respect to EDI diffusion, we make use of a two-by-two matrix (see Table 3) representing institutional involvement (low-high) and degree of EDI diffusion (low-high) in an attempt to categorize data on diffusion from different business sectors and public sector agencies. The intention is not to provide data on businesses or public sector agencies that have adopted EDI or to assess companies' use of EDI, but rather to illustrate the relative priorities with respect to EDI adoption in different business sectors and public sector agencies.

The categories in Table 3 indicate how a group of potential adopters engaged themselves in institutional efforts initiated by the partners involved in the national action plan for EDI. Institutional involvement is here defined as the decisions and non-decisions (Bachrach & Baratz, 1963) taken by governmental units, ministries, and business and trade associations to influence the content of the EDI Action Plan agenda (Laswell, 1936). In our view, the EDI Action Plan is primarily a pedagogical intervention rather than an economic incentive or normative action (Eckhoff, 1983; Henriksen, 2002). We also regard the EDI Action Plan as a discursive forum and leveler rather than as actions per se (Habermas, 1986).

THE POLICY CONTEXT

At the European Community scene, IT became a major part of the 5th IST Framework with an outset in the Bangeman report (1996) and the Key Action II program line on e-commerce within the Information Society Technology program. A very visible indication of the European policy commitment to fuel e-commerce diffusion was the creation of a new Directorate Generale (DG), namely the DG Information Society (DGXIII). A key priority for the EU with respect to EDI policies in the mid- to late 1990s was to push the UN/EDIFACT standard. Other key priorities were diffusion of ICT, primarily to SMEs, by forming networks of excellence and uptake measures. In particular, the 5th Framework for R&D activities in the EU had the rapid uptake of EDI among SMEs as a cornerstone. During the late 1990s, the challenge for the EU with respect to e-commerce policies was to instigate the IST policies to help push the e-commerce uptake. Yet, facing global competition (primarily from the U.S.) with the prospect of undercutting European competition and thereby losing jobs in the EU, diminished the eagerness to use information technology to open global market competition. Thus, the strong emphasis on European technologies and projects that had an internal EU focus appear to present a policy flavor rather than programs that increase international presence within Europe. EDI and in particular EDIFACT seemed in line with these motives.

At the Danish political scene, owing to a change of government in 1992 from a right-wing to a center-left-wing government, the small Social Liberal Party (Radikale Venstre) came into power as parliamentary support to the Social Democratic Party. The Social Liberal Party played a major role in promoting research and IT policy (see, for example, Dybkjær & Christensen, 1994). An EDI Action Plan was launched in Denmark at a time when there were strong environmental demand drivers for standards (Andersen et al., 2003a).

Apparently, it played a crucial role that the newly appointed Minister of Research and IT, Mr. Frank Jensen from the Social Democratic Party, felt an urgent need to position his ministry. Mr. Jensen was regarded as the crown prince within the Social Democratic Party. It was important for him to demonstrate results that would merit a move to more prestigious policy fields and enable a rapid political career. He launched a strong push towards deregulation of the telecommunication sector, and tried to ensure that all business sectors and micro-companies would be provided with opportunities to enter the Information Society. Other central policies advanced by the Ministry of Research and IT in the mid-1990s included standardization and dissemination of e-commerce to SMEs.

Building consistent agendas was difficult throughout the 1990s in part because IT issues were relatively new on the Danish political scene and also since none of the ministers for IT and research held their office for more than two years. The IT ministers during the mid- to late 1990s already had an active political career, or they were not viewed as key persons in the Social Democratic Party, nor using the position as minister for the IT field as a platform for improving their political position.

DANISH MODEL FOR E-COMMERCE DIFFUSION

The forerunners of the EDI Action Plan from 1996 were two policy statements published by the government and prepared for the Danish Parliament. The first statement, "From Vision to Action—Info-Society 2000" (Ministry of Research and Information Technology, 1995) was used as a lever to create awareness of the information revolution's significance. It was stated that the movement towards the Information Society was a public movement affecting everybody. Similar to initiatives in Italy (Kumar, Dissel, & Bielli,

1998) and Hong Kong (Damsgaard & Lyytinen, 1998), the strategy for the EDI Action Plan should be based on a Danish model, ensuring that market forces should not be the only factor determining this development. Although the statement primarily focused on building a strong infrastructure, it also stressed the public sector's obligations to engage in the movement. However, the role of Danish companies was by no means underestimated. It was acknowledged that the opportunities created by the Information Society would be a great challenge to Danish companies. The policy statement pointed out:

Danish companies must not only effectively introduce new technology for rationalization purposes, it certainly also means that they must be able to transform new technology into new products to respond to special customer requirements.

It was suggested that if companies adopted EDI, it "would result in considerable rationalization gains and a closer interplay between organizations." However, there were no specific directives showing how to achieve the rationalization gains and a closer interplay between organizations. It was announced that the Ministry of Research and IT, the Ministry of Business and Industry, the Danish EDI Council, and the relevant industry and trade associations were about to launch a campaign to further the use of EDI and e-mail in businesses and public administration. However, it was decided to publish another political IT statement before launching the EDI Action Plan.

The next political IT statement, published in 1996, was named "The Info-Society for All—The Danish Model" (Ministry of Information Technology and Research, 1996c). The statement announced:

...this new technology presents a number of opportunities and problems, which demand political consideration and action. A cohesive, aggressive strategy for how we wish to form developments in Denmark is necessary.

Included in the potent strategy was the EDI Action Plan. The 1996-policy statement stated:

The importance of a fast, effective, and consistent implementation of, e.g., EDI could hardly be overestimated.

First and foremost, it argued that technological landmarks such as EDI would give Denmark an international lead, improving efficiency of working procedures and the development of new products and production processes.

The EDI Action Plan aimed at providing the necessary conditions for companies and the public sector to reap the gains enabled by EDI. The authors of the EDI Action Plan acknowledged that the growing globalization of commerce made it essential for Denmark to follow the trend of doing business electronically across borders. The parties involved in the EDI Action Plan agreed that EDI as such was not a novelty. However, the diffusion of IT in the Danish society and the decrease in software and hardware prices were likely to create a fertile environment for diffusion of EDI. It was recognized that most Danish companies had a sufficient level of experience and know-how of IT to implement EDI. When the EDI Action Plan was launched in 1996, 50% of the Danish companies in the industry segment exchanged data via telephone or network technologies. Especially exchange of electronic messages to financial institutions had a high diffusion rate among Danish companies (Hørluck, 1996). The relatively new Internet had already been adopted by one out of five companies, and it was reported that 30% of all businesses planned to adopt the Internet in the near future (Ministry of Information Technology and Research, 1996b).

Thus, the time appeared to be ripe for a coordinated effort to spread electronic communications from a few sectors to all sectors in industry and trade. Based on this broad agenda, the EDI Action Plan was launched to the business community and the public sector. The foreword to the EDI Action Plan stated:

The plan is to provide dynamism and accelerate growth. This will be achieved through the public sector joining forces with a large number of commercial organizations to create joint solutions. By this approach, we will avoid a situation in which everyone waits for everyone else, or in which the approaches chosen are not coherent.

To create the necessary dynamics and consistency, seven initiatives were formulated. The initiatives aimed primarily at supporting the diffusion of EDIFACT-based transactions between private companies and the public sector. There were high expectations to the public sector's capacity in relation to development and implementation. It was clear that the public sector had to take the lead and show a best practice. By the time the EDI Action Plan was formulated, EDIFACT was considered the dominant standard framework for safe interchange of data between computers in different companies. Although some of the international companies used ANSI X.12 as well, the battle on standardization was more concerned with proprietary standards versus EDIFACT than with discussing EDIFACT versus other standards. The policy consensus was that the development of EDIFACT standards would facilitate B2B e-commerce diffusion.

The EDI-agenda had three major objectives:

- End-to-end integration of data from business-to-business, thus eliminating costly reformatting of data and speeding up business cycle times.
- Long-term focus on the use of standards such as EDIFACT within organizations to provide them with security in operations within an increasingly inter-organizational business environment.
- The use of VANS initially to achieve a more "open" data exchange, and format and transport media allowing greater flexibility of choice, costs, and value-addition for large and small organizations.

There was a general process of negotiation between the participants involved in the formulation of the EDI Action Plan, with the goal of strengthening the application of e-commerce in a B2B relationship. The target was to establish technical, organizational, and educational facilities for EDIFACT-based communication in all business sectors, including the financial sector and the public sector's exchange of data with private companies before the end of 1998. The aim was to propagate the application of EDIFACT-based communication within all relevant areas by the year 2000 (Ministry of Research and Information Technology, 1996a).

In the introduction to the EDI Action Plan, it was acknowledged that the project was ambitious and would require involvement from several business sectors and institutions. The timeframe for the adoption and implementation of EDI was short. It was expected that the use of EDIFACT-

based communication could be tested and diffused among all relevant sectors by the year 2000. As initiatives one to four in Table 1 show, it was expected that EDI could be implemented by 1998. The means to meet this end included awareness campaigns arranged by the Danish EDI Council. Another approach dealt with making the necessary arrangements to execute public procurement via EDI. However, it was the adopters that carried the main responsibility for acting according to the recommendations in the EDI Action Plan. This strategy was in accordance with the IT policy statement from 1996 entitled, "The Info Society for All—The Danish Model," which stated:

One decisive feature of 'the Danish model' is that without grandiose plans, but precisely through dialogue and effective action, we are in a position to implement the necessary infrastructure quickly and to remove the barriers to it.

Table 1. Content of the EDI Action Plan from 1996 (Source: Adapted from Ministry of Research and Information Technology (1996))

Initiative	Policy consensus
1. Establishment of EDI standards in all sectors	No later than 1998, the EDIFACT standard must be established in all industries and sectors, for all commercial documents of significance, such as orders, invoices, payment messages, transport notes and registration of real property. The goal is to ensure the availability of a vital prerequisite for companies' options to participate in the electronic marketplace within trade, manufacturing, transport, finance, etc.
2. EDI for public procurement contracts	Through forthcoming EU framework agreements, the public sector will include its suppliers' ability to participate in fully electronically-based document interchange as an integral part of its tendering conditions, no later than 1998.
3. Handling EDI in public-sector financial systems	By the end of 1998, public-sector financial systems will be able to handle all relevant commercial documents in EDIFACT format.
4. EDIFACT-based interchange of administrative information with the public sector	In order to ease the administrative burden on companies, the opportunity must be created before the end of 1998 for companies operating in areas in which serviceable standards exist to undertake EDIFACT-based electronic reporting to the public sector. And initiatives will be aimed at areas in which there is a need for new standards.
5. Development of EDI software	A number of initiatives are being aimed at software developers. These initiatives are intended to promote the development of a range of EDI software products destined for the market. The price and functionality of these products must satisfy the needs of all types of companies, regardless of an individual company's level of ambition concerning the use of EDI.
6. Legislation on digital signatures and electronic documents	New legislation on digital signatures will prepare the way for ensuring that the use of electronic communications is just as secure and clear-cut as the use of conventional communication on paper.
7. Danish EDI Council as initiator and coordinator	The Danish EDI Council will assume a central initiating and cross-sectorial role in the implementation of the action plan.

This attitude can historically be linked to the long and successful tradition of establishing cooperative dairies and abattoirs in the 19th century. The cooperative movement led to a social and economic lift for a large number of small and often impoverished farmers. The establishment of cooperative dairies and abattoirs improved the quality and quantity of the production benefiting the export of agricultural products to, e.g., Great Britain, which at that time was engaged in industrialization. From a political point of view, the cooperative movement is seen as an important factor in the development of parliamentary democracy. The parallel to the cooperative movement clearly reflected the expectations to the industry and trade associations and individual organizations.

Although the individual initiatives had to be carried out by the industry and trade associations in concert with individual organizations' action plans, the EDI Council was appointed as a coordinating unit. The ministries involved provided limited financial resources. The two ministries granted DKK 24.6 millions (about US\$3.5 million). DKK 18 million (about US\$2.7 million) were earmarked for the EDI Council's information initiatives and DKK 6.6 million (about US\$0.8 million) were made available to projects dealing with standardization issues. The EDI Council would administer the funds.

But although the EDI Council was appointed to monitor implementation of the EDI Action Plan, it had no fiscal authority in relation to the private or public sector. The active role played by the EDI Council mainly resulted in support of several projects and provision of information and publications on EDI to the business community. In their efforts to propagate information about EDI in the business community, the EDI Council presented a definition of EDI to support a shared understanding of the term:

The term EDI is defined as the exchange of structured, electronic messages. This exchange is conducted with a minimum of human interac-

tion. A requirement for defining an electronic exchange as EDI is that messages are exchanged in a standard agreed upon in advance. The format may be an individual proprietary standard or an international standard, e.g., EDIFACT.

The definition includes the elements outlined in the contemporary definitions used in academia by Hansen and Hill (1989) and Pfeiffer (1992). In this context, it is very interesting that the Danish business and administration environment was exposed to this definition. Compared to the EDI Action Plan, the EDI Council broadened the definition by including proprietary standards. The EDI Action Plan on the other hand favored the EDIFACT standard and encouraged organizations to adopt this standard.

The two IT policy statements focused on building a telecommunication infrastructure to support the Internet, and to gain the benefits and opportunities embedded in this means of transportation of information. The EDI Council's definition of EDI solely outlines the electronic exchange of messages connected to EDI, whereas the means of transportation was considered less relevant. In a similar manner, the degree of organizational integration is subject to individual interpretation, mentioning a minimum of human interaction as the ultimate goal.

THE OFFICIAL ASSESSMENT OF THE EDI ACTION PLAN

In 1998 the EDI Council evaluated the outcome of the EDI Action Plan. It was acknowledged that although a number of initiatives had been implemented within different sectors, including development of low-cost EDI software, the diffusion of EDI had failed to progress at the pace expected in the EDI Action Plan. The first initiative, establishing EDI standards, was based on information obtained from the business associations. The initiative was close to

implementation in sectors related to mortgage, shipping, and insurance. However, sectors such as industry and trade progressed at a slower pace and the EDI Council expected that the objective of standardization would be fulfilled by 1999. The EDI Council realized that especially SMEs had not implemented EDI as much as expected. In relation to standardization issues, the EDI Council realized that the XML (eXtended Markup Language) standard presented a promising alternative to EDIFACT. It was also suggested that the Internet might be an attractive means of transportation of EDI messages in terms of cost and simplicity. According to an assessment made by the EDI Council, the fifth initiative in the EDI Action Plan, development of EDI-software, had had a slow start. One major problem from the beginning was the failure to consider the different needs of the participating organizations. For instance development of EDI-software had failed to consider price and functionality in relation to individual organizations' needs and levels of ambition for EDI usage. However, remedial action had been taken by the business associations initiating a number of pilot projects.

In the overall evaluation document of the EDI Action Plan prepared by the EDI Council, it was concluded that the EDI Action Plan had been a success. One of the reasons for its success was the wide support it had elicited from the business associations. According to the managing director of the EDI Council, the criterion for success was to provide business and administration with the

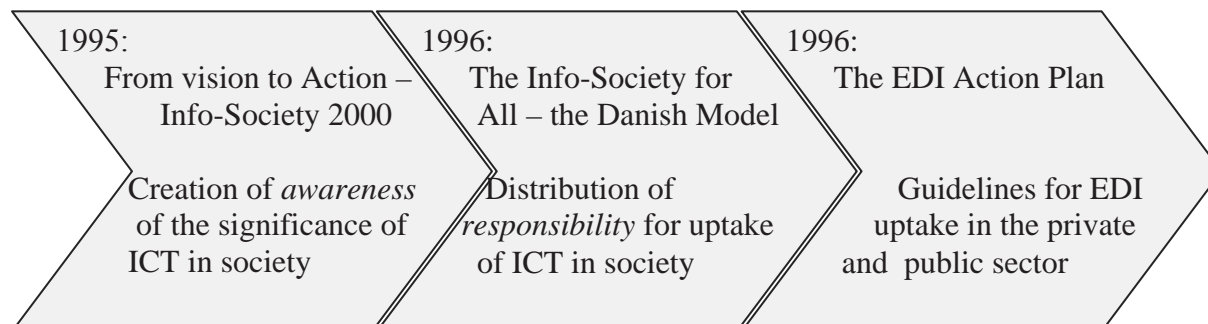

necessary opportunities and tools for EDI application. Thus, the objective was to create the opportunities to use EDI rather than to convince as many organizations as possible to adopt EDI.

EDI IN THE DANISH BUSINESS ENVIRONMENT

From the mid-1990s, when the issue of EDI adoption caught attention due to awareness campaigns launched by governmental units and professional business associations, and due to the launch of the EDI Action Plan, the national statistical bureau has made yearly surveys of the usage of EDI. Over time data from the surveys suggest that the usage of EDI has decreased. However, this downtrend is not supported by contemporary research conducted in academia.

Although there appears to be a decrease in the number of users during the period 1995 to 2001, Andersen and colleagues (2000) found continuous growth in the number of EDI messages sent via third-party vendor companies. There was a substantial growth in the number of EDI messages exchanged, ranging from an annual growth of 34% to 46%. The same study also revealed that the growth in bytes transmitted during the same period increased by the same rates, indicating that larger messages are exchanged. Finally, the study found an increase in assigned EAN numbers. This suggests a growth in EDI users if it is assumed that there is a positive correlation

Figure 1. Overview of the two policy statements and the EDI Action Plan

between the number of assigned EAN location numbers and the number of companies that are able to send and receive EDI messages. Thus, the study by Andersen indicates that the EDI traffic has increased from 1995 to 2001. However, with the exception of the health sector (Johansen, Andersen, & Krogh-Meibom, 2002), the financial sector (Bjørn-Andersen & Andersen, 2003) and the logistics/freight and agricultural sectors (Andersen, Juul, Korzen-Bohr, & Pedersen, 2003b), there has not been a general spread of EDI to the business community at large.

Studies of digital data exchange within the steel and machinery industry (Henriksen, 2002), the textile & clothing industry (Hjarup, 2001), the industry in general (Hørluck, 1996; Petersen, Petersen, & Kespersen, 2002), the retail sector (Juul & Andersen, 2001, 2002), and the public sector (Andersen & Juul, 2002) support the picture that digital exchange of orders and invoices has been the exception rather than the norm during the mid-1990s and up to the present time. But nothing seems to support the tendency presented by the Danish National Statistical Bureau that there has been a decrease in EDI usage among Danish businesses.

ANALYSIS AND DISCUSSION

In 1996 when the EDI Action Plan was launched, large companies had already adopted EDI (Andersen et al., 2000; Hørluck, 1996), but SMEs hesitated. One reason for the low level of adoption of EDI among SMEs could be that they lacked sufficient knowledge of the innovation. Another explanation could be that the SMEs did not recognize the business potential of EDI. A third and perhaps more plausible explanation might be rooted in issues related to critical mass, pressure, and power (Henriksen, 2002; Markus, 1983). However, it is a fact that the EDI traffic—viewed as number of messages and number of bytes exchanged—increased from 1996 and in the years ahead (Andersen et al., 2000), but it did not create

a large EDI landslide. A landslide could have been expected when considering that the industry and trade associations initiated several EDI projects as a result of their involvement in formulating the EDI Action Plan. The midway evaluation in 1998 of the EDI Action Plan prepared by the Danish EDI Council documented that several efforts had been made to meet the demands, but that the goals so far had not been reached.

In the EDI Action Plan there were no economic or normative interventions (Henriksen, 2002). Contrary to the TradeNet in Hong Kong, the adoption of EDI was not enforced. One natural consequence of the Danish EDI Action Plan could have been to force private businesses to report their figures to, e.g., the Inland Revenue Service via EDI messages. This would have been highly relevant since the EDI Action Plan aimed at making the public sector a locomotive for EDI adoption. Since all Danish businesses communicate with the Inland Revenue Service, it would have created a broader scope for EDI communication. The Inland Revenue Service was among the few public sector agencies that actually utilized the opportunities created by EDI usage (Andersen et al., 2000). However, no enforcement was used to involve private businesses in the exchange of EDI messages.

Another approach to the creation of a large-scale diffusion of EDI could have been a strong encouragement of the public sector to perform its procurement electronically. Part of the reason why mandatory e-procurement was not implemented was the lack of technological readiness at both demand and supply side. The municipalities, for example, had in general a low level of adoption and diffusion of EDI. But perhaps the most likely explanation for the low diffusion rate of EDI is the fact that the public sector was not managed in a top-down style. About one-third of the employees in the Danish governmental sector are employed in central government and two-thirds at the local level in the 275 municipalities and 14 counties. Local government has a large degree of autonomy, and various management reforms

Table 2. Companies using EDI 1996-2001

Year	Percent of companies using EDI	Company size covered in the survey (number of employees)	Sample size (response rate in percent)	Reference
1996	33	5+	387 (20)	Ministry of Information Technology and Research (1997)

in the 1980s and 1990s in the public sector have decentralized budgets and procurement to each public institution. Any ideas of making e-procurement mandatory in the public sector were therefore in direct conflict with the overall management agenda for the public sector. This is a paradox since the management reforms introduced in the 1990s had the overall aim to increase efficiency and effectiveness. However, the means to achieve the objective of decentralization and autonomy at the institutional level prevented a central, top-down-led strategy for e-procurement. Formulated more sharply: the overall management discourse prevented an effective introduction of an e-commerce agenda in the public sector (Andersen et al., 2003b).

Although financial resources were used as direct subsidies to support the diffusion of EDI in the Danish business community, the resources were somewhat limited and not allocated to individual businesses. The financial support was given to projects such as the TradeDocument Project (Henriksen & Andersen, 1999; Henriksen, 2002) initiated by the two major Danish trade and industry associations. Therefore, it can be argued that the economic incentive for adoption of EDI was absent in the EDI Action Plan with respect to individual businesses. The initiators of the EDI Action Plan relied more on a pedagogical approach (Eckhoff, 1983). Through information campaigns by the Danish EDI Council and the associations supporting the EDI Action Plan, the advantages of EDI were communicated to the

potential adopters. Thus, this communication process became a central issue in the adoption and diffusion of EDI in the Danish business environment. Focusing on the communication aspect, one issue is how the information about the innovation is communicated.

Another issue is how the innovation is presented. The message can be communicated via mass-communication networks or through interpersonal relations (Rogers, 1995). In the EDI Action Plan, both types of communication channels were used. The EDI Council and the professional business associations communicated their message about EDI and its advantages at the same time as the government presented its information campaigns on the advantages of the innovation via publications, newsletters, and social arrangements. This second issue—how the innovation is presented—is however even more relevant in this context. Two different types of information are involved in the communication process: signaling and know-how (Attewell, 1992). According to Attewell, signaling refers to communication about the existence and potential gains of a new innovation, whereas know-how refers to knowledge transfer in relation to the innovation. “The technical know-how is relatively immobile, and often has to be recreated by user organizations” (Attewell, 1992, p. 7). This places a heavy burden on potential adopters, since different organizations have specific needs requiring different skills and development before adoption can take place.

The first policy statement on technology from

1995 suggested that EDI adoption could lead to “considerable rationalization gains and a closer interplay between organizations.” In the EDI Action Plan, EDI was described as a tool that could give Denmark an “international lead and improve the efficiency of working procedures and development of new products and production processes.” Efficiency was an attribute connected to the innovation, whereas the traditional innovation attributes (Rogers, 1995) played a secondary role. However, the statements formulated by the business community might be even more significant. They argued that EDI adoption would result in increased efficiency, cost reduction, and competitiveness leaving the impression that the investment would pay off. This suggests that the information communicated on EDI belonged to the category of signaling rather than to the category of know-how. This is problematic in a business environment like the Danish, where the majority of businesses are SMEs, which generally have limited resources available for further investigation of innovations being offered.

An issue that played a minor role in the policy statements was the cost of EDI. One of the seven initiatives in the EDI Action Plan explicitly mentioned development of EDI software as an objective, but the cost of hardware, integration of EDI software, and implementation of EDI in organizations was not mentioned in the statements. It is generally acknowledged that to gain full advantage of EDI, organizations must integrate their internal systems with the external IOS (Riggins & Mukhopadhyay, 1999). In a survey from 1996 on EDI adoption among members of the Confederation of Danish Industries, it was found that the two highest scoring items in terms of barriers related to EDI implementation were cost of EDI and the uncertainty of realizing actual advantages from EDI (Hørluck, 1996). The third highest scoring item in the survey was related to the lack of standardization of trade data standards. Apart from serving as a tool for creating awareness of EDI, the EDI Action Plan

aimed at introducing the EDIFACT standard in the Danish business community and the public sector, but the cost of EDI was not a major issue in the EDI Action Plan.

As mentioned earlier, the aim of this chapter is to focus on the institutional initiatives deployed to promote the diffusion of EDI in the Danish business community. One outcome of this analysis is a mapping of the degree of institutional involvement in the formulation of the EDI Action Plan versus the rate of EDI adoption. Appendix A provides a list of institutional involvement at different governing levels. Based on insights gained from the research projects reported in Appendix B and the data summarized in Appendix A, Table 3 presents a qualitative mapping of the variables, institutional involvement, and EDI adoption in selected businesses and public sector agencies.

The Inland Revenue Service was involved in formulating the EDI Action Plan and was eager to gain the benefits that most likely would result from an increased EDI usage (Andersen et al., 2000). Based on information from the Inland Revenue Service, its EDI usage is assessed to be high in both dimensions in Table 3. On the other hand, representatives from the municipalities did not play an active role in formulation of the EDI Action Plan, nor did they pursue EDI adoption and implementation at any significant level with respect to EDI usage in their daily transactions both in relation to the public and private sector.

The professional business and trade associations played an active role in formulating and operationalizing the EDI Action Plan (Henriksen, 2002; Henriksen & Andersen, 1999). However, they did not succeed in influencing adoption and diffusion among their members. Our assessment is therefore that the trade and business associations’ institutional involvement was high, but the degree of adoption among their members was low.

A number of associations did not take an active part in formulation of the EDI Action Plan. These associations are clustered in the upper right corner of the two-by-two matrix in Table 3. Nonetheless,

Table 3. Institutional involvement and adoption of EDI for different industry segments

Institutional involvement	Degree of EDI adoption	
	Low	High
Low	Municipalities	The financial sector The MedCom project The agricultural sector (DLF) Transportation and logistics
High	Business and trade associations	The Inland Revenue Service

these associations represent some of the business sectors that have been most successful in utilizing EDI in Denmark (Andersen et al., 2000). This leaves the impression that critical mass and power, rather than institutional initiatives and institutional discourse, determined the rate of adoption in the Danish business community.

One of the fascinating issues concerning the Danish scene is the public sector’s role as a player in the EDI Action Plan. The Danish EDI Action Plan was not solely a governmental plan. The business associations were deeply involved in the formulation of the EDI Action Plan, and a great responsibility was laid on the business associations in order to fulfill the plan. However, the institutions in the public sector acted as major players in fulfillment of the plan. That is especially the case with respect to single units such as the Inland Revenue Service. This important insight into the role of government might however not include the traditional top-down command and the concept of “government” versus “market.” The successful EDI initiatives originate at lower levels of government and in the market where they have managed to spiral and gain success despite a lack of policy saliency. One explanation for this outcome of the EDI Action Plan could be the consensus in the formulation of the action plan between the public sector and the private sector. However, the consensus among the business associations and the governmental players did not eliminate the obstacles to the fulfillment of the EDI Action Plan. The outcome of the plan raises the question whether the resources should have been prioritized differently. On the one hand, major Danish companies such as Maersk,

Danfoss, Grundfos, and FDB have not benefited from the EDI Agenda. They have all managed well without the EDI Action Plan and have been able to influence their suppliers and shipping agents to adopt EDI—often in a proprietary format—regardless of the political agenda’s content. On the other hand, the EDI Agenda has helped to stimulate a range of EDI projects that otherwise might not have been implemented. These projects were especially targeted at the majority of Danish businesses—SMEs, which through this exposure were provided with the necessary information to consider the relevance of EDI in their businesses. If we subscribe to this last point of view, then it might only be a matter of time before a B2B e-commerce landslide takes place.

CONCLUSION

In this chapter the focus has been on institutional initiatives on diffusion of EDI in the Danish business community and the public sector. In our analysis we assessed the EDI Action Plan and found that an active use of the public sector was a dominant market demand driver in the diffusion of B2B e-commerce. Especially the attempt to streamline the internal processes in the public sector protrudes in the content of the EDI Action Plan. However, the lack of active industry involvement, apart from the business associations, stands out. Whereas the EDI Action Plan received active support from single public sector agencies and organizations, the plan had only indirect support from individual companies.

Mapping the degree of institutional involvement and the degree of EDI adoption, we found that most of the large users of EDI did not get involved in the EDI Action Plan. The majority of the institutions involved had limited market power and could be interpreted as the least-likely adopters of EDI. The market leaders and advanced EDI users were following their own e-commerce agenda, not paying particular attention to the goal of EDIFACT diffusion outlined in the EDI Action Plan.

Our interpretation of the analysis in this chapter is that the lack of direct representation will condition the future orientation and decision making in terms of current and future policy programs on diffusion of ICT: the lack of industry involvement has not made the outcome of the EDI Action Plan useless. Yet, it has led to a very limited adoption and diffusion of B2B e-commerce, especially among SMEs and public sector institutions, which were the target audience for the EDI Action Plan. The statistics indicate that it is the same industries that exchange more and more messages and types of messages (Andersen et al., 2000) and that large companies, which often are old and well established (Petersen et al., 2002) adopt ICT, regardless of campaigns initiated by institutions, as long as there is a potential for profit. Given these ex-post observations, the EDI Action Plan, with its focus on development of global standards for SMEs, is an attempt to obstruct the extensive use of proprietary standards introduced by those large companies, which hold the necessary power to set the EDI agenda.

Chapter 2.6

Enabling Strategy Formulation by ICT: A Viable Systems Approach

Dirk Vriens

University of Nijmegen, The Netherlands

Jan Achterbergh

University of Nijmegen, The Netherlands

ABSTRACT

In this chapter the role of ICT for competitive intelligence is approached from the perspective of strategy formulation. The authors hold the view that competitive intelligence can be seen as knowledge necessary for the process of strategy formulation. To determine the role of ICT, it is proposed to examine (1) the process of strategy formulation, (2) the knowledge relevant for the process of strategy formulation and (3) the knowledge processes in which the intelligence relevant for the process of strategy formulation is produced and processed. If these three elements are clear, the role of ICT for competitive intelligence can be reformulated as the support of ICT for the knowledge processes, producing and processing the necessary intelligence for strategy formulation. In the chapter, the process of strategy formulation

and the knowledge it requires will be described by using the Viable Systems Model of Stafford Beer. It results in an “ICT-architecture” for supporting the knowledge processes, producing the relevant knowledge for strategy formulation.

INTRODUCTION

An adequate intelligence function is indispensable for (re)formulating strategies in a world that is getting both “larger” as new markets are opened up and “smaller” as (information and communication) technologies develop to spot these markets and profit from them. To remain viable, organizations need to identify and define their relevant environments, to scan them for opportunities and threats, to use these scans for formulating their strategies, and to act on these strategies. The con-

tribution of business or competitive intelligence to strategy formulation (and implementation) is a key factor for organizational viability.

Because of the importance of business or competitive intelligence (BI or CI) for organizational viability, a lot has been written lately about its goals and main processes (e.g., Fuld, 1995; Kahaner, 1997; Vriens & Philips, 1999; Cook & Cook, 2000). Vriens and Philips (1999), for example, define competitive intelligence as “a process of gathering and processing information about the environment to support the process of strategy formulation.” In this definition, the function of delivering relevant “external” information is central. Others, however, see BI as a process that (also) delivers “internal” information to support formulating strategies (e.g., Dresner, 1989). In this latter category, authors point, for instance, to the information provided by means of the balanced scorecard or by data warehouses.

For (re)formulating strategies, both internal and external information (and their integration) is needed. Competitive intelligence seems to be the label, in literature as well as in practice, for a function in organizations that covers the supply and processing of information for strategy formulation.

Competitive intelligence activities can be supported by information and communication technology (ICT), and most authors agree on the importance of ICT for these activities (e.g., Fuld et al., 2002; Philips & Vriens, 1999; Kahaner, 1997; Cook & Cook, 2000). Several studies show the use of ICT in competitive intelligence activities. Vriens and Hendriks (2000), for instance, show how Web-enabled technologies may enable data-collection. Teo and Choo (2002) give an overview of how the Internet can be used for CI activities, and several authors discuss the possibilities for the electronic ‘outsourcing’ of search activities (e.g., Kahaner, 1997).

However, in spite of the awareness of the importance of ICT for CI, it remains unclear how the link between CI and ICT should be designed.

This link is the main focus of this chapter. The chapter sets out to describe the link between ICT and the process of supplying and processing information for strategy formulation. With such a description, designers of the CI process can select proper ICT support and they can judge whether the employed ICT applications support this process appropriately.

To describe the link between ICT and CI, it is necessary to define the process of strategy formulation—otherwise, it is impossible to determine the contribution of the CI process. Next, it is necessary to determine what ‘intelligence’ is needed in the process of strategy formulation. For us, as for other authors (see e.g., Kahaner, 1997), intelligence as a “product” is knowledge relevant for strategy (re)formulation. We will therefore approach this question from a “knowledge” point of view. If it is clear what knowledge the process of strategy formulation needs, the processes that produce and process this knowledge may be acknowledged. In knowledge management literature, these processes are normally labeled “generation,” “storage,” “dissemination” and “application” of knowledge (see e.g., Davenport and Prusak, 1998; Achterbergh & Vriens, 2002). Given these processes, the role of ICT in supporting them may be defined. This last step then defines ICT for CI as support tools for the processes in which knowledge relevant for strategy formulation is generated, stored, disseminated and applied.

This chapter reformulates the role of ICT for CI as the role of ICT in the knowledge processes involved in strategy formulation. It seeks to define this role of ICT in four steps. These steps are: (1) presenting a model of the process of strategy formulation, (2) deriving the knowledge relevant for the process of strategy formulation, (3) identify the knowledge processes in which the relevant knowledge for strategy formulation is processed and produced and (4) use the previous steps to arrive at an understanding of the role of ICT in the process of strategy formulation. To deal with these four issues, we organize the chapter as follows.

In the following section we unfold the process of strategy formulation. To do this, we use the Viable System Model of Beer (1979, 1981). This is followed with a section discussing the derivation of the necessary knowledge domains for the process of strategy formulation. Next, we describe the knowledge processes that produce and process the relevant knowledge for strategy formulation. The chapter then uses this model to identify ICT support for strategy formulation. The last section will conclude with recommendations for using the model to derive relevant ICT for CI.

STRATEGY FORMULATION: A VIABLE SYSTEM PERSPECTIVE

Strategy formulation aims at developing and selecting goals and plans that secure the adaptation of the organization to its environment (see for instance, Johnson & Scholes, 1999). These goals and plans may refer to specific product-market-technology combinations for which the organization hypothesizes that they ensure a stable relation with its environment. The process of strategy formulation, then, needs to generate such goals and plans, needs to reflect upon their appropriateness and needs to select certain goals and plans to guide the behavior of the organization. Moreover, it is a continuous process. Goals and plans can be seen as hypotheses about “what will work” as a means to adapt and survive. Therefore, they should be monitored constantly, and revised if necessary. In short: strategy formulation is a continuous contribution to maintaining organizational viability.

Although many authors deal with the process of strategy formulation, we choose the Viable System Model of Beer (1979, 1981) to define this process more closely. We select the VSM because Beer explicitly unfolds the functions required for the viable realization and adaptation of the organization’s identity. Since strategy formulation

particularly aims at organizational adaptation, we can directly use the functions described by the VSM specializing in adaptation to define strategy formulation. Based on the VSM, an explication of the process of strategy formulation in terms of the functions necessary for organizational viability is possible. A further reason for using this model is that it is an offset for deriving systematically the knowledge-domains necessary for strategy-formulation. Moreover, the model allows for an identification of these knowledge domains at many (recursive) organizational levels. Designers of the CI process can thus use it to identify the relevant knowledge domains at a corporate level, at the level of the business unit or at the level of a team. Beer’s model thus provides a background for defining strategy formulation and for identifying the necessary knowledge domains for strategy formulation. In this section we introduce the VSM and use it to define strategy formulation. In Section Three, we describe the relevant knowledge domains.

Stafford Beer developed the VSM to provide a model of the functions that are needed for organizational viability. An organization is viable if it is able to maintain a separate existence in its environment (Beer, 1985, p. 113). To be viable, an organization must have the potential to adapt and realize its identity and mission. This potential crucially depends on the realization of five (related) functions. According to Beer (1985, p. 115), these five functions and their relations are necessary and sufficient conditions for organizational viability. Below, we describe these five functions and their relations. We refer to a company called “Energeco”—a company specialized in supplying eco-energy—to illustrate these functions.

Function 1: Primary Activities

Function 1 of an organization as a viable system consists of the collection of its primary activities. These primary activities constitute the system’s

“raison d’être” (Espejo et al., 1996, p. 110). For example, the raison d’être of “Energieco” is to service its environment with eco-energy. “Energieco” has three primary activities: supplying solar, tidal, and wind energy. These three primary activities constitute its Function 1.

The existence of a collection of primary activities as such is insufficient to maintain the viability of an organization. Somehow, these primary activities must be forged into the larger whole of the organization. To this purpose, four additional functions are required: coordination, control, intelligence, and policy.

Function 2: Coordination

In organizations, primary activities may depend on shared resources. People, machines, shared in- or output markets, or output of other primary activities, are examples of shared resources. These dependencies make the primary activities interdependent. To give an example, specialists in high voltage energy are a shared resource between “Energieco’s” business units. Now suppose that there is no coordination between these business units. In this case, the allocation of high voltage specialists to a project in the business unit “Solar Energy” may require a revision of the allocation of these same specialists to a project in the business unit “Wind Energy.” Without a function that supports the coordination of these interdependencies, the business units “Solar Energy” and “Wind Energy” may become entangled in a process that oscillates between allocating and revising the allocation of these specialists to projects. It is the task of Function 2 to prevent these oscillations. Function 2 facilitates the coordination of interdependencies between function one activities, hence its name: *coordination*. Examples of Function 2 activities are the introduction of quality standards, the design and implementation of shared planning systems, or the introduction of a common language to discuss coordination problems.

Function 3: Control

The primary activities and coordination are necessary, but not sufficient for the viability of an organization. Each primary activity can still pursue its own goals without contributing to the realization of the identity and mission of the viable system as a whole. For this reason, Beer (1985, 1999f) argues that there must be a third function ensuring synergy and cohesion between primary activities. He calls this function “control.” Its task is to translate the identity and mission of the viable system (e.g., supplying eco-energy) into goals for the primary activities (e.g., supplying wind, solar and tidal energy) and to control the realization of these goals. In this way, control takes care of the contribution of the primary activities to the realization of the identity and mission of the viable system.

Control has three instruments to discharge for its task. First, it gives direct command to and receives direct reports from the management of the primary activities. Second, control can audit the management of the primary activities. The aim of these audits is to stay aware of problems facing the management of the primary activities and to help in finding solutions to them. Third, control ensures the synergy of the primary activities by controlling the coordination effort by Function 2.

Control not only focuses on the realization of the identity and mission of the viable system; it is also involved in the adaptation of this identity and mission. Because of control’s knowledge about the modus operandi and problems of the primary activities, its second task is to review proposals for innovation produced by the intelligence function (see below) and to assess whether these proposals are realistic given the potential for change of the primary activities. For this purpose, control is involved in a continuous discussion about the feasibility of proposed innovations.

Function 4: Intelligence

Functions 1 to 3 are necessary for the realization of the identity and mission of viable organizations, yet they are not sufficient for organizational viability. Viability also means adaptation. To make adaptation possible, a fourth function is required. Beer calls this function intelligence. It is the task of intelligence to scan the environment of the organization for relevant developments and to initiate adaptation to keep the identity and mission aligned with them (doing the right thing, instead of doing things right, Espejo et al., 1996). For instance, developments in production technology may introduce the possibility of cost-effective, large-scale production of eco-energy from biomass. Intelligence should pick up these developments, assess them, and if relevant, translate them into proposals for innovation.

Function 5: Policy

The addition of the intelligence function seems to complete the list of functions required for the realization and adaptation of a viable organization's identity and mission. According to Beer (1985, p. 258ff), this is not the case. The reason for this is the particular focus of the control and intelligence function. Control focuses on the *realization* of identity and mission of the organization, while intelligence focuses on initiating *adaptation*. If it is supposed that the interaction between control and intelligence is not coordinated, three problems may occur. First, interaction is too loose. In this case, proposals for innovations are not assessed in terms of the organization's potentials for change and existing potentials for change cannot be exploited by innovations. Both the realization and adaptation of the organization's identity and strategy may slowly stop. In the second and third problem, interaction between control and intelligence is intense, but one of the functions

dominates the other. If intelligence dominates control, the organization runs the risk of "innovatism." Innovative products or technologies are proposed and introduced that do not match the potential for change of the primary activities. If control dominates intelligence, the organization runs the risk of "conservatism." Proposals for innovation are rejected because of an obsession with current markets, products and production technologies.

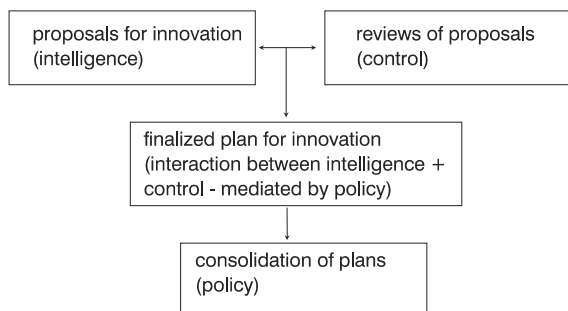

To counter these problems, Beer introduces a final function he calls policy. Policy has the tasks of coordinating the interaction between control and intelligence and consolidating its results in a (re)definition of the identity and mission of the organization in such a way that they fit developments in its environment as well as in its own potentials for change. Policy provides closure to the adaptation and realization cycle. As such, it completes the list of functions necessary and sufficient for viable organizing.

The Process of Strategy Formulation According to the VSM

The VSM not only describes the functions needed for viability. It also describes the interactive relations that should exist between them and the characteristics these relations should have. For this purpose, it divides the functions into two groups: functions that contribute to the *realization* of the organization's strategy and functions that contribute to its *adaptation*.

The first group consists of the primary activities, coordination and control. This group deals with the *realization* of the organization's identity and strategy. The second group consists of control, intelligence, and policy. This group deals with the *adaptation* of the organization's identity and strategy: its task is "inventing the organization" (Espejo et al., 1996). Together, control, intelligence, and policy attempt to keep

Figure 1: The process of strategy formulation according to the VSM

the organization aligned with relevant developments in its environment.

Keeping the organization aligned with relevant developments in its environment can be seen as the core objective of strategy formulation. In fact, the interplay between the VSM functions control, intelligence and policy describes the process of strategy formulation. Intelligence generates plans for adaptation and control reviews them. A discussion about the (adequacy of these) plans between intelligence and control (mediated by policy) should lead to a finalized plan for adaptation. Finally, such a plan should be consolidated by policy. Figure 1 depicts the process of strategy formulation according to the VSM (and its associated VSM functions).

Because strategy formulation is captured by the functions control, intelligence, policy, and their relations, we not only describe these relations, we also characterize them in terms of periodicity, detail, and potentials for standardization. These characteristics are relevant for designing supportive measures (among which are ICT applications) for the process of strategy formulation, as will become apparent in the last section. Table 1 summarizes and characterizes the relations between the functions in this group.

The VSM recommends that control and intelligence are highly interconnected and of similar complexity. The interaction between them should be continuous, intense, detailed, and balanced. Discontinuities in the interaction between intelligence and control harbor the danger of slowing down the innovation process. Feedback by control on plans for innovation or suggestions for intelligence activities by control may come too late if interaction between control and intelligence is not organized on a regular basis. Only loose and aggregate interaction between intelligence and control may lead to a culture of estrangement between ‘innovators’ and ‘makers’. To deal with the many and complex issues related to innovation requires an intensive and detailed discussion of these issues. As has been argued, unbalanced interaction between intelligence and control can lead to either “innovatism” or “conservatism,” which is detrimental to organizational viability.

Table 1. Relations between functions focused on adapting the organization’s identity and strategy

Related functions	Relation	Normative characteristics of relation			
		Periodicity	Detail	Standardization	Focus on
Intelligence—Control	Generating finalized proposals for innovation	Continuous	High	Low	Balancing and integrating proposals for innovation and potentials for change
Policy—Intelligence and Control	Balancing contributions by intelligence and control	Continuous	Low	Low	Supporting interaction between intelligence and control
	Consolidating proposals for innovation	Irregular intervals	Low	Low	(Re)defining the organization’s identity and strategy

It is the task of the policy function to manage the interaction between intelligence and control. For this purpose, policy should focus on the process of interaction. It should minimize intervention in its content.

To summarize: Beer asserts that there are five functions necessary and sufficient for organizational viability. These have been introduced shortly. Three of them are used to define the process of strategy formulation (intelligence, control and policy). Given this description of strategy formulation, the next section deals with the knowledge required in that process.

KNOWLEDGE DOMAINS FOR STRATEGY FORMULATION

Now that we know what functions are involved in the process of strategy formulation—or as the VSM puts it: the process of adapting and innovating organizations—we can take the next step. If ICT is to make its own contribution to this process, we need to specify the (domains of) knowledge the policy, intelligence, and control functions need to contribute to the process of strategy formulation. These domains of knowledge specify what knowledge should be generated, shared, stored and applied for strategy formulation, and are

thus an offset to define the contribution of ICT to strategy formulation.

The Control Function: Knowledge Domains Required for Strategy Formulation

The control function performs two main activities. It manages the synergy of Function 1 activities and reviews proposals for innovation made by the intelligence function. Since only the second activity is relevant for the purpose of this chapter, we concentrate on this activity.

To execute this activity of reviewing proposals for innovation, control needs knowledge about these proposals. Moreover, knowledge is required that allows for the translation of these proposals into new goals for existing or new business units. These new goals have to be related to the current goals of the business units that are involved. From this confrontation, the gap between the desired and the current goals of these business units can be established. To assess this gap, knowledge is required that supports its translation into the reorganization capacity required from the business units to bridge the gap. Moreover, knowledge is required about the actual capacity for reorganization of the business units involved. From the confrontation between the required and the

Table 2. Function Three and related domains of knowledge

Table 3. Function Four and related domains of knowledge

Function	Related domains of knowledge
F4: Function Four (Intelligence)	Organizational goals Goals set by, performance and modus operandi of F1 activities Developments in the relevant environment of the organization Reviews by F3 of proposals for innovation Regulatory measures to counter the imbalance between F3 and F4 (see Function 5) Finalized plans for adaptation of organizational goals (a joint F3 and F4 product)

actual capacity for reorganization, proposals for innovation by the intelligence function can be reviewed. This review is communicated with the intelligence function. This process of communication between control and intelligence results in finalized plans for adaptation of organizational goals. Table 2 lists the knowledge domains needed by control to review proposals for innovation made by intelligence.

The Intelligence Function: Knowledge Domains Required for Strategy Formulation

It is the task of the intelligence function to initiate adaptation in such a way that the activities of the organization are aligned with relevant developments in its environment. To be sensitive to these developments, Function 4 needs knowledge about goals and the performance of the organization. Against this background, developments can be assessed as opportunities and threats (such as economic and scientific developments, advances in production technology and innovative business concepts). Dependent on an assessment of these developments, intelligence may propose the implementation of new organizational goals or activities or the improvement of old ones (cf., Beer, 1979). To formulate the proposals for innovation that may be reviewed by the control function, intelligence also needs knowledge about goals and the actual modus operandi of the business units that are involved in these plans. Proposals for innovation also may have an internal drive (e.g., intelligence searches

for ways to improve primary business activities) and proposals for innovation should somehow either fit into the activities of these business units or be a meaningful complement to them given the core business of the viable system as a whole. To finalize the proposals in a way that is acceptable to the organization, intelligence requires feedback from control. This feedback adds to the knowledge base of intelligence required for the formulation of plans. Table 3 lists the knowledge required by the intelligence function to produce proposals for innovation.

The Policy Function: Knowledge Domains Required for Strategy Formulation

It is the task of the policy function to balance the discussion between control and intelligence about the adaptation of goals and to consolidate the results of this discussion.

To assess imbalances in the discussion between control and intelligence, the policy function needs knowledge about norms for a balanced relation between control and intelligence. It also needs to know about the relative contribution of control and intelligence to the discussion about the proposals for adaptation. Against this background, actual imbalances can be established. To assess these imbalances, policy needs knowledge about their causes. To perform measures that counter imbalances, the policy function needs knowledge about actual imbalances, their causes, and about experiences with the implementation and effectiveness of actions that counter imbalances.

Table 4. Function Five and its related domains of knowledge

Function	Related domains of knowledge
F5: Function Five, policy	For balancing purposes: Norms for balance between F3 and F4 Proposals by F4 and their reviews by F3 (relative contribution of F3 and F4 to the discussion on adaptation) Actual (im)balance between F3 and F4 Causes of imbalance between F3 and F4 Experiences with regulatory measures to counter the imbalance between F3 and F4 Regulatory measures to counter the imbalance between F3 and F4 For consolidation purposes: Finalized plans for adaptation of organizational goals (a joint F3 and F4 product) Organizational goals

The consolidation of the results from the discussion between control and intelligence, i.e., finalized proposals for innovation, requires knowledge about these plans. In the VSM, it is specified that policy should minimize its interference in the substance of this discussion (Beer, 1979). Still, to consolidate proposals for innovation made by control and intelligence, policy requires an overview of the organization, its goals and relevant developments in the environment. This overview should not be an in-depth knowledge about every possible detail (control and intelligence deal with detail). It should be an informed feeling for the dynamic interplay between the organization and its environment (Beer, 1979). Table 4 lists the knowledge required by the policy function to balance the discussion about innovation between intelligence and control.

It should be noted that the knowledge domains listed in Tables 3 to 5 only refer to the knowledge that is directly necessary for viability. They do not refer to knowledge that supports producing or processing viable knowledge. An example of supportive knowledge is knowledge about methods to scan the environment. This knowledge supports the production of knowledge about relevant developments in the environment—the viable knowledge in Function 4. Other examples of supportive knowledge are knowledge about how to formulate a strategy, about how to plan,

or about how to operate a particular machine. From the knowledge domains listed in the tables, supportive knowledge can be derived.

PRODUCING AND PROCESSING KNOWLEDGE FOR STRATEGY FORMULATION

This key question of this chapter is how to derive the role of ICT in strategy formulation. To this end, the previous sections unfolded a view on the process of strategy formulation and relevant knowledge domains for this process. Strategy formulation could be captured by the ongoing interaction between the functions of control, intelligence and policy. Relevant products in this process are proposals for innovation, reviews of these proposals, and finalized plans for innovation and their consolidation. To deliver these products, knowledge from several domains should be produced and processed. The question for this section is how the knowledge in these domains is produced and processed. Once it is clear what knowledge processes contribute in producing and processing the relevant knowledge for strategy formulation, the role of ICT in supporting these knowledge processes can be identified.

The question for this section is by means of which processes knowledge in the knowledge

Table 5. Functions, knowledge domains, and knowledge processes for strategy formulation

Knowledge domains	F1	F3	F4	F5
goals set by, performance and modus operandi of the primary activities in F1	G,A	A	A	
organizational goals	A	A	A	G,A
proposals for innovation made by F4		A	G,A	A
desired goals for F1 based on proposals for innovation		G,A		
gap between desired and current goals of F1		G,A		
required capacity for reorganization of F1 activities		G,A		
actual capacity for reorganization of F1 activities		G,A		
gap between required and actual capacity for reorganization of F1 activities		G,A		
reviews by F3 of proposals for innovation		G,A	A	A
finalized plans for adaptation of organizational goals (a joint F3 and F4 product)		G,A	G,A	A
regulatory measures to counter the imbalance between F3 and F4		A	A	G,A
developments in the relevant environment of the organization			G,A	
norms for balance between F3 and F4				G,A
actual imbalance between F3 and F4				G,A
causes of imbalance between F3 and F4				G,A
experiences with regulatory measures to counter the imbalance between F3 and F4				G,A

domains should be “produced and processed” so that the process of strategy formulation can take place. Several authors on knowledge management identify four relevant processes for producing and processing knowledge in general: generating, sharing, retaining and applying knowledge (cf., Achterbergh & Vriens, 2002; Nonaka & Takeuchi, 1995; Leonard & Barton, 1995; Davenport & Prusak, 1998; Bukowitz & Williams, 1999).

Generating organizational knowledge can be done by acquiring external knowledge (e.g., buying, renting or even stealing knowledge) (cf., Davenport & Prusak, 1998) or by means of knowledge creation in a process of learning (Davenport & Prusak, 1995; Nonaka & Takeuchi, 1995). The aim of the process “knowledge sharing” (or dissemination) is to make sure that (existing) knowledge gets to the right place in an organization. To keep knowledge available, some kind of “organizational memory” is needed. The process of “retaining knowledge” refers to the process of storing knowledge and making retrieval possible. The last process is the application or use of knowledge. The other three knowledge processes are subsidiary to applying knowledge.

These four knowledge processes can now be linked to the process of strategy formulation, as formulated according to the VSM. According to the VSM the functions of intelligence, control and policy contribute to strategy formulation. This contribution involves the application of knowledge in the knowledge domains to arrive at the four core products of strategy formulation: proposals for innovation, their reviews, the finalized plans for innovation, and their consolidation. For example, the intelligence function applies its knowledge about environmental developments to produce its proposals for innovation. The knowledge applied by each function is generated either by that function or by one of the other functions of the VSM. In the latter case, knowledge must be shared between functions. For instance, the intelligence function cannot adequately make proposals for innovation when the knowledge about organizational goals and performance is not shared with it. Likewise, the control function cannot review proposals if knowledge about them is not shared. Applying, generating and sharing knowledge requires the retention of knowledge. The policy function, for instance, benefits from storing knowledge about

Table 6. Functional knowledge domains tied to organizational units

Knowledge domains	Organizational units					
	production	Control	R&D	M&S	...	BoD
goals set by, performance and modus operandi of the primary activities in F1	G,A	A	A	A		
organizational goals

causes of imbalance between F3 and F4						
experiences with regulatory measures to counter the imbalance between F3 and F4						

the measures it considered to support the discussion between intelligence and control, the reasons why some of them were chosen and the success of these measures.

Table 5 provides an overview of the relation between the five functions in the VSM, the knowledge domains and the application and generation of knowledge in these domains. Based on this table, it is possible to draw conclusions about sharing and storing knowledge. In the table we only included the relevant knowledge for strategy formulation. However, some of this knowledge is generated by Function 1, and this is the reason of its inclusion in the table. For the complete table, we refer to Achterbergh and Vriens (2002).

The first column of Table 5 summarizes the knowledge domains listed in Tables 3 to 5. In this column, we eliminated all redundant entries. Columns two to five indicate whether knowledge in a specific knowledge domain is generated (G) and/or applied (A) by a specific function. Table 5 is reminiscent of the create-use matrices used in information analysis (e.g., Jackson, 1988).

The table makes apparent that some knowledge may be generated by more than one function. For

instance, the finalized plans for adaptation are a joint product of control and intelligence.

Knowledge in the domains listed in Table 5 is generated and applied for either of two reasons. The first reason is to directly contribute to the process of strategy formulation. For instance, making and reviewing proposals for innovation directly contributes to this process. The second reason for generating and applying knowledge is to regulate knowledge processes that directly contribute to the viability of the organization. For instance, knowledge about measures to counter imbalances in the discussion between control and intelligence is generated and applied to regulate the discussion that results in a direct contribution to the viability of the organization: proposals for innovation.

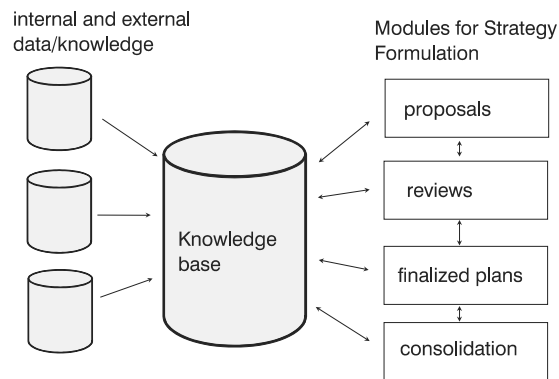

From Table 5, conclusions can be drawn about sharing and storing knowledge. Direct and regulatory knowledge should be shared between functions if it is applied by more than one function. In Table 5, this is indicated by more than one A in a row. For instance, control should share knowledge about its reviews of the proposals of intelligence with intelligence. Knowledge should

be retained in such a way that it can be retrieved by the functions that apply it. Moreover, some knowledge is only generated and applied by one function. This knowledge should be retained in a function-related database. For instance, a database could be designed to support the balancing efforts of the policy function.

Thus far, the discussion focused on the three functions relevant for strategy formulation. We did not yet link these functions to organizational units or individuals. The discussion focused on functions because this enabled us to abstract from the specific organizational embodiment of the functions. Moreover, the model is a recursive model, and can be applied at many organizational levels: at the corporate level, at the level of a business unit and even at levels below that. However, for a practical application of the model (such as deriving ICT support for the process of strategy formulation), it is necessary that designers of ICT make a choice for the level of recursion (e.g., a specific BU) and specify the organizational units and/or individuals that are engaged in realizing the functions. In this specification more than one individual and/or more than one unit may be involved in the realization of one function, and more than one function may be realized by more than one unit and/or individual.

An example of a specific mapping is given in Table 6. This table maps the knowledge domains relevant for strategy formulation onto organizational units. In the columns, for some knowledge domains, it is indicated which units are involved in the generation (G) and application (A) of that knowledge domain. More than one G may appear in the rows, because the generation may be either a joint effort of several units, or the result of several units engaged in the generation of different knowledge in the knowledge domain. For instance, the organizational units “Research & Development,” “Marketing & Sales” and the Board of Directors may all be involved in the generation of knowledge about the environment of the organization—but all with regard to dif-

Figure 2. Outline of an architecture of an information system supporting strategy formulation

ferent aspects of that environment. These three units may also embody Function 3 activities—and review (parts of) the proposals.

To summarize, Table 5 captures the relation between the knowledge needed for strategy formulation and the application and generation of this knowledge in the three VSM functions. (Table 6 further specifies this in that it ties the functional activities to organizational units.) It thus indicates which relations exist between knowledge domains, and hence makes apparent what knowledge should be shared among functions for which reasons. Finally, it indicates what functional knowledge could be clustered and retained in a “functional” knowledge base. This table can be used as a start for deriving possibilities for ICT support for strategy formulation—the topic of the next section.

THE ROLE OF ICT IN STRATEGY FORMULATION

The question for this section is how ICT can support the process of strategy formulation. To answer this question we use the theory from the previous sections to formulate an “ideal” func-

tional architecture for ICT support. Designers of ICT support for strategy formulation may use this architecture to select ICT applications. To be able to select these applications, however, one needs selection criteria. In this section we first present the “functional support architecture.” Then, we discuss selection criteria, and finally we show how designers may use these criteria to select ICT applications to realize the support architecture.

An Architecture for ICT Support of the Process of Strategy Formulation

In the previous sections it became apparent that knowledge from several knowledge domains should be generated, stored, shared and applied to take the steps in the process of strategy formulation: formulating proposals for innovation; reviewing them; making finalized plans for innovation and consolidating them. We use this description to give an outline of an architecture for an information system supporting the process of strategy formulation. This outline is presented in Figure 2.

This information system consists, ideally, of several modules and knowledge and/or databases. The “modules” (at the right in Figure 2) are applications helping to generate the products of the process of strategy formulation. With the help of these modules, the knowledge from the knowledge domains is applied to produce the proposals, reviews, and (consolidated) plans. The information system further consists of a central knowledge base in which the knowledge in the knowledge domains necessary for strategy formulation (see Sections Three and Four) is stored. This central knowledge base, in turn, may receive knowledge from other internal and external knowledge and/or databases. Below, we discuss the modules and knowledge bases in more detail:

1. **The “Proposal” Module:** The goal of this module is to help produce a list of proposals for innovation. The main product is,

therefore, a list of innovation proposals and their justification. To produce this list, one should have access to the knowledge in the relevant knowledge domains. This knowledge may be available (in the knowledge base) or it should be generated. To generate this knowledge (e.g., about technological trends or about trends in sales) the module should have access to external and internal information. For instance, it may have access to a data warehouse by means of a front-end tool or it may have access to external online databases (such as the Lexis-Nexis or Dow Jones database). Further, the module may have access to a database consisting of previously rejected or accepted proposals. The proposals for innovation produced with this module are stored in the central knowledge base.

2. **The “Review” Module:** The input for this module consists of the proposals for innovation. The output is a list of accepted and rejected proposals and the reasons for their acceptance or rejection. To make this list, the module should apply the knowledge in the central knowledge base. This knowledge may be available or may have to be generated. To generate the knowledge, access to several internal and external databases may be required. For instance, to get a clear view on the consequences of a certain innovation for the current production structure, it may be that internal information is required. Also, (external) data on the results of the current pmc’s may be an input for rejecting or accepting innovations. The review module may benefit from a database with (a classification of) reasons for acceptance or rejection.

3. **The “Finalized Plans” Module:** This module is mainly a means for the communication about the proposals for innovation (and their reviews) in order to arrive at a finalized plan. It overarches the proposal and review

module. By means of this module, results of the review module are communicated and used as input for revising the proposals (with the aid of the proposal module). The revised proposals are, in turn, used to produce new reviews (with the aid of the review module), etc. This module should (1) facilitate the communication about the proposals and (2) ensure the finalization of an innovation plan. To these ends, this module could make available to its users:

- the rules for interaction (such as discussion format and deadlines);
- criteria for imbalance in the discussion;
- a monitoring function regarding the imbalance;
- rules/incentives for countering this imbalance;
- an overview of the history of the discussion (as well as an overview of previous discussion).

Implementation could be by means of several Intranet applications (such as a kind of internal discussion site).

4. **The “Consolidation” Module:** This module has as its output the consolidation of (a specific selection of) the innovations on the finalized list of innovations. To make this selection, the argumentations used in the previous modules should be scanned and valued. Its main goal is to communicate the results of the strategy formulation process to relevant parties in the organization. It should communicate (1) the selected innovations, and (2) the reasons for their selection (and possibly their consequences for the current way of “doing business”). It may benefit from a database with (previously successful) communication formats.
5. **The “Central Knowledge Base”:** This module consists of all the knowledge in the knowledge domains relevant for strategy formulation. This knowledge should be stored and made available.

Above, an outline of an architecture for an information system supporting the process of strategy formulation is given. It shows how support should be focused on the products of strategy formulation. Moreover, the focus of the support is on the four knowledge processes involved in the production of proposals, reviews, plans and consolidations. That is, application of knowledge leads to the four products (and to new knowledge). For this production, knowledge from the knowledge domains should be generated, stored and/or shared. This knowledge is (partly) stored in the knowledge base. The knowledge may be generated by using the four modules and/or by using internal/external databases. Furthermore, knowledge from the knowledge domains may be shared by using connections between the modules.

The description of the architecture states the functionalities of the different “modules” in it and how they should be connected. The question for the next two sections is how to realize this support architecture by selecting (or building) proper ICT tools.

Criteria to Select ICT Applications

To determine whether an ICT application is suitable for supporting strategy formulation, we need selection criteria. Since the ICT applications should be tied to the production and processing of knowledge relevant for strategy formulation, ICT should be tailored to the characteristics of the knowledge it should help to deliver and of the knowledge processes it should support. These two types of characteristics make up two classes of criteria. Therefore, before we select supportive ICT applications, we first need to specify these classes of criteria.

As a basis for formulating requirements to ICT applications supportive of strategy formulation, we only take into account criteria intrinsically related to the knowledge and the knowledge processes (generation, sharing, storage, and application) needed to realize the process of strategy formulation. Extrinsic criteria—for instance,

criteria pertaining to costs—will not be taken into account. Moreover, the criteria to characterize knowledge and knowledge processes are chosen in such a way that—in combination—they actually can function as requirements to ICT applications. In combination, they point at some and exclude other types of ICT applications as effective tools to generate, share, store, or apply the knowledge to arrive at the products of strategy formulation.

The first class of criteria relate to the characteristics of the knowledge in question. That is, this knowledge can be:

1. Tacit or explicit (see for instance Nonaka & Takeuchi, 19xx, for this distinction). Tacit knowledge normally refers to knowledge that is not codifiable, while explicit knowledge is. Tacit knowledge, by definition, defies codification by ICT. However, ICT may be used to refer to sources of tacit knowledge—e.g., in the form of a knowledge map (cf., Davenport & Prusak, 1998).

If the knowledge is explicit, further relevant distinctions for the use of ICT are:

2. The knowledge is more or less standardizable. This criterion refers to the “uniqueness” of knowledge. Can the knowledge, for instance, be cast in a priori fixed standard formats (such as number of products under development of competitor X) or not? This clearly is important for the choice of ICT applications.
3. The knowledge is more or less aggregate. Does the knowledge refer to individual facts (client X bought Y at day Z) or to insights at a higher level of aggregation (all clients in a certain period bought so and so much of Y)? It is important to know at what level of aggregation ICT applications should help deliver knowledge. (To be sure, a great deal of ICT applications is, of course, capable of handling more than one level of aggregation.)

4. The knowledge is different in “size” (it may be that it refers to just a few rules or facts such as “Competitor X opens a production facility in region Y,” or it may cover a large knowledge-area).

These characteristics are important in selecting or building any type of ICT application for supporting knowledge processes. However, to support the process of strategy formulation as put forward in this chapter, these characteristics are also important in designing or selecting ICT applications that support the interaction between functions (see Table 1), because, as has been argued, the VSM prescribes different levels of detail for different relations.

The second class of criteria refers to knowledge process characteristics. The knowledge processes:

1. Can be more or less structured. The structuredness of a knowledge process refers to the traditional dimension of “structured versus unstructured tasks” (e.g., Simon, 1961). For instance, predicting trends in the environment may be seen as generating knowledge regarding the knowledge domain “developments in the relevant environment of the organization.” This generation is not very well structured. It is not clear a priori what counts as input for such a decision and it is not clear how and when to label certain environmental events as a trend. Therefore, predicting a trend is an unstructured activity.
2. Require more or less frequent communication. For instance, to produce a finalized plan of innovation, frequent communication is required between representatives of intelligence and control. In this communication process knowledge is shared, generated and applied. The VSM prescribes the level of communication between functions (see Table 1).

Table 7. knowledge characteristics: an example

SF activity	Knowledge domain	Tacit	Explicit	
			Potential for standardization	Level of aggregation
Proposals	A: ...	Yes		
	B: environment			
	B.1 Competitors	No	High	
	B.2 ecological Trends	Mainly		
	C ...	No	Moderate	

- Require communication between few or many parties, more or less proximate in space and/or time. Who is involved in the process of strategy formulation can be made apparent by means of matrices such as those given in Table 6. The required frequency of communication, the number of parties involved and the nature of their (lack of) proximity co-determine the selection of ICT applications.

A METHOD FOR SELECTING ICT APPLICATIONS FOR STRATEGY FORMULATION

Given the “architecture of ICT support” for strategy formulation (based on the functions and knowledge domains involved in strategy formulation) and given the criteria to characterize the knowledge and knowledge processes involved, we can now specify how a designer can formulate requirements to select (or build) proper ICT applications. This method consists of three steps: (1) determining the relevant knowledge characteristics, (2) determining the knowledge process characteristics and (3) selecting ICT support for the process of strategy formulation.

Before a designer can take these steps, however, some preliminary requirements should be

met. The method presupposes that the designer has an insight into the products of the process of strategy formulation and its associated knowledge domains. The designer also needs to know which organizational units are involved in the production of the relevant knowledge for strategy formulation. A designer thus requires tables like Tables 5 and 6. In these tables the knowledge domains are given and tied to the process of strategy formulation and to organizational units.

Step 1: Establishing Knowledge Characteristics

The designer should for each activity in the process of strategy formulation specify the knowledge characteristics of the required knowledge in this domain. To this end, a designer may use Tables 2 to 6. If a knowledge domain comprises knowledge that is too heterogeneous for such a characterization, the designer should decompose the knowledge domain into sub-domains and try again.

For instance, to produce proposals for innovation one needs knowledge “about developments in the environment” (see Table 3). However, this knowledge is rather diverse. It may comprise facts about competitors or models about the impact of ecological trends. Knowledge about competitors, in turn, (in terms of facts like net sales volume, product portfolio, etc.) may have different charac-

teristics than knowledge about “the impact of ecological trends.” The latter may be less codifiable and standardizable. A designer should recognize these different types of knowledge, and identify their different characteristics (i.e., codifiability, standardization, level of aggregation).

The result of this step can be presented as a table providing an overview of characteristics of the knowledge that should be generated, shared, stored, and applied to realize the products in the process of strategy formulation in question (Table 7 gives some examples of knowledge types and their characteristics for the strategy sub-process “making proposals for innovation”).

In the table, A, B, etc., refer to knowledge in certain knowledge domains relevant for the strategy sub-process “making proposals for innovation.” B may, for instance, refer to “knowledge about the environment.” B1 and B2 may refer to its re-specification into the specific knowledge-types “knowledge about competitors” and “impact of ecological trends”—which may have different knowledge characteristics. A designer should

make such tables for all activities in the process of strategy formulation.

Step 2: Establishing Knowledge Process Characteristics

In this step, the designer should specify the characteristics of generating, sharing, storing and applying the knowledge specified in the previous step. To this end, the designer needs an overview of the involvement of control, intelligence, and policy in processing the knowledge needed to realize strategy formulation (Tables 2 to 5). Moreover, the designer needs to link this knowledge with the organizational units producing or processing it (Table 6). Given these prerequisites, the designer can, for all the knowledge processes regarding the knowledge in each knowledge domain, specify the process characteristics.

The main activity of the designer, then, is to determine for all classes of knowledge in the knowledge domains (1) the structuredness of generating, applying, sharing and storing the

Table 8. knowledge process characteristics: an example

SF activity	Knowledge domain	Knowledge process	Structure	Frequency	Parties involved	Distance in space/ time
Proposals	B1: competitors	Generating	High	Regular	BU X1; Dep. Y; Empl: ... BU X2 Dep. Y, Z Empl.
		Applying	Medium			
		Storing	High			
		Sharing	High			BU X1 and BU X2 are in different countries
	B2: Ecological trends	Generating				
		Applying				
		Storing				
		Sharing				
				

particular knowledge, (2) the required frequency of generating, applying, sharing and storing the particular knowledge, (3) the parties involved in generating, applying, sharing and storing the particular knowledge, and (4) the proximity (in time, space) of those parties.

The result of this step can be expressed in the form of Table 8. This table, again, only refers to a few knowledge domains regarding the activity “making proposals for innovation.”

In the table, B1 and B2 are, as before, classes of knowledge in the knowledge domain B, “knowledge about the environment.” Class B1 refers to factual knowledge about competitors and B2 to knowledge about the impact of ecological trends. To illustrate this step, only B1 is considered. Factual knowledge about competitors may refer, for example, to the sales volume of a specific customer. The generation of these facts may be highly structured and occur at a regular basis by scanning certain external information sources. The individuals involved in the generation of these facts may be dispersed among different departments in different business units. In the table, it is indicated that certain employees from business unit X1 of department Y and from business unit X2 of departments Y and Z are involved. The application of this factual knowledge for producing proposals for innovation may be less structured, and may be carried out centrally. For knowledge sharing it may be important to know that the parties involved are located in different countries.

In this way, for all classes of knowledge in the different knowledge domains, the characteristics of the knowledge processes may be derived. In some cases, the knowledge processes will share the same process characteristics. In other cases, the designer will have to discriminate between processes to adequately describe the process characteristics. For instance, it may be the case that *generating* knowledge requires the involvement of only a few parties that are proximate to each other in space and time, while *sharing*

the generated knowledge involves many parties distant in space from each other.

Step 3: Selecting ICT Support of the Process of Strategy Formulation

The identification of proper ICT support is based on (1) the support architecture (paragraph 5.1) and (2) the requirements derived from the knowledge and knowledge characteristics (from the previous two steps). This means that the functionalities of ICT applications should match (parts of the) support architecture and the desired requirements. For instance, an application may be built that has (some of) the functionalities of the four modules from the architecture (discussed earlier). Moreover, this application should be designed to deal with the knowledge (process) characteristics.

To arrive at a list of possible ICT applications supportive of the process of strategy formulation (referring to the support architecture and to the derived knowledge and knowledge process requirements), three sub-steps can be given:

1. Express desired ICT support;
2. Analyze current ICT support;
3. Select ICT applications for strategy formulation based on the gap between desired and current ICT support.

Ad. 1 Express Desired ICT Support

To express the desired ICT support, a designer should refer to the support architecture and to the requirements from the previous two steps. Ideally, one may try to find one or more ICT applications realizing the whole support architecture. This means that such applications should have the functionalities as described earlier. The knowledge and knowledge process requirements further specify how ICT applications can be used to support strategy formulation.

With regard to the knowledge requirements, the dimension of tacit versus explicit knowledge

is important. For instance, if it is found that certain knowledge is mainly tacit, specific ICT applications should be used to deal with that kind of knowledge. A suitable application in this case might be a “knowledge-map” (Davenport & Prusak, 1998). Such a map does not try to capture the knowledge, but only refers to the knowledge carriers. For knowledge domains with knowledge that is highly standardizable, other applications may be used. Many authors on the subject of knowledge management give clues on how to match certain ICT applications to certain characteristics of knowledge (e.g., Davenport & Prusak, 1998).

The knowledge process requirements also further specify how ICT applications may support strategy formulation. For instance, these requirements make apparent what parties are involved and what the periodicity of the interaction of these parties is. This knowledge may be used to define access and to design the interaction between parties or applications.

Ad. 2 Analyze Current ICT Support

In this step, the desired functionalities from the support architecture and the knowledge and knowledge process requirements can be used to analyze the adequacy of existing support applications. A designer may draw up a list of current applications and judge to what extent they contribute to the support functionalities and to what extent they meet the requirements. From this analysis, it may, for example, be concluded that:

- the knowledge in the current knowledge base is incomplete;
- there are no applications supporting the generation of a specific kind of knowledge;
- there is no support of the interaction between intelligence and control activities;
- a data warehouse is not tailored to the specific demands of strategy formulation;

- the full range of functionalities is not covered by current applications;
- sharing knowledge that should be shared among “modules” is not supported;
- knowledge is not accessible for the right people.

This list of mismatches between desired and current ICT support should be used in the next step.

Ad 3. Select ICT Applications

Based on the gap between current and desired support of the process of strategy formulation, and based on knowledge about possible ICT tools, a first list of ICT applications may be given. This list may be used for a final selection. In this selection, additional criteria (such as costs or fit in overall ICT architecture) may be used. The final list may be used to plan the development and or purchase of ICT applications (see Turban et al., 2002, for considerations regarding planning of ICT in general).

CONCLUSION

In this chapter, we approached the link between ICT and CI from an angle differing from most treatments. We “redefined” CI as the relevant knowledge used in strategy formulation and proposed to identify the role of ICT for CI as support tools for the knowledge processes involved in the process of strategy formulation. To identify the nature of such tools and to direct the selection of applications that could act as support tools for the knowledge processes involved in strategy formulation, we (1) presented a model of the process of strategy formulation, (2) derived the knowledge relevant for the process of strategy formulation, (3) identified the knowledge processes in which the relevant knowledge for strategy formulation is processed and produced, and (4) used this “theory”

to arrive at an understanding of the role of ICT in the process of strategy formulation.

The model we used for describing the process of strategy formulation is the Viable System Model of Beer. This model is also the point of departure for deriving the relevant knowledge for strategy formulation and the knowledge processes in which this knowledge is produced and processed.

Given the overview of the knowledge needed to be produced and processed for strategy formulation, we formulated—in two steps—a method for tying ICT to the strategy formulation. In the first step we gave an outline of a general architecture of a system supporting the knowledge processes for strategy formulation. This architecture stated the general functionalities of (parts of) a support system. In the second step we discussed how, using the theory from the rest of the chapter, a selection of actual ICT applications for strategy formulation may be supported.

The approach in this chapter presents a different perspective on strategy formulation and the use of ICT for it. It also puts CI software in a different perspective; the approach enables the integration of both external and internal oriented ICT tools for producing intelligence through their support of the knowledge processes in formulating strategies.

ABSTRACT

This study examines the innovation in communication media, based on empirical survey results from five countries. First, the authors create a general framework of the media life cycle by exploring the replacement of communication media used in daily life. The shift from voice communications to mobile e-mailing is at the forefront of the media life cycle in the personal communication area. This framework also implies future media replacements in other countries. Second, by comparing two empirical surveys, done in 2002 and 2003, of communication means used among Japanese family relations, the authors

discover that certain consumer clusters lead in the innovation of communication media. This framework and discovery can be useful to deal with the vacuum between conventional media studies and the latest information technology.

DIFFUSION OF NEW COMMUNICATION MEDIA

The wide and rapid diffusion of the use of e-mail and mobile phones, called cell phones or currently smart phones in the U.S., has entirely changed the paradigm of human communications. We use e-mail and mobile phones as a part of our

everyday life. These two communication means, major products of information and communication technologies (ICTs) during the last two decades, are gradually replacing some conventional communication means, such as physical mailing or talking on fixed phones. These replacements can also change human behavior and may create new social norms and cultures. Obviously, the driving forces behind these replacements are the massive marketing activities of dot com companies and telecom operators.

However, there has been a relatively small number of social science researches on these areas because the technology changes so rapidly. Relentless and endless change of information technology is problematic for academic social science research, when it faces cutting edge technology. That kind of technology always threatens to overturn the conventional social context with rather destructive ways, and then it is difficult for scholars and academic researchers to examine the actual impact of each technology. But, we should not think that a new communication means supported by such a new technology is not a suitable subject for academic research. Looking at it from the viewpoint of social norms and cultural transition, even the newest communication means can be examined scientifically.

The most important point in the examination of the communication means and new technologies is, we believe, the innovation processes that occur while these technologies diffuse among users or consumers. Investigating the changes of interpretation in our society for each communication means and its technology is especially significant from a social scientific viewpoint. According to a common framework of innovation analysis, such as Rogers' (1995), innovation is not merely a technological matter, but the diffusion of a new understanding and behavior toward the technology. Moreover, Von Hippel (1988) examined a lot of examples in which certain user communities can act as sources of innovations. In fact, in some cases suppliers follow the innovations

created by users, instead of creating innovations by themselves. By investigating such innovation processes, we can examine the evolution of social norms and emergence of new cultures rather than merely tracing superficial trends of ICTs.

In this chapter, we would like to focus on the role of each user cluster throughout the innovation process that has taken place since new ICTs began affecting human communications. Inevitably, there are many different usage patterns by consumer cluster, such as age, class, family relation, and gender, with new electronic communication means, as well as those within conventional, face-to-face, communication means. Especially, the gender effects on the new communication usage should be considered more. As a matter of fact, many people point out that most ICTs have been developed by males, and thus, principles of these technologies have obviously been "masculine." Rogers also pointed out that especially in the ICT area in the middle 1980s, there was a significant difference of usage and innovation patterns by gender (Rogers, 1986), due to the gap of mathematical performance between male students and female students.

However, in the late 1990s, the situation began to change. Especially when useful graphical user interfaces (GUIs) were introduced into the ordinary consumer market, ICTs became much friendlier to all kinds of people. The wider the penetration of these new communication means has grown, the more supported they have become by ordinary people including women, instead of by masculine techno-fanatics. Based on these intuitive observations, we think that a certain kind of gender study in these areas will have a particular importance.

CENTRAL QUESTION AND HYPOTHESIS

In this article, we focus mainly on the case of Japanese mobile phone usage. The Japanese mobile

phone penetration rate is now approximately 70%, which means the diffusion process has already reached the “majority” stage (Rogers, 1995). In the majority stage, we can see an interesting target-switch phenomenon from male-dominant user clusters to female-dominant ones in Japanese high-tech sectors (Washida, 2005). Moreover, after this target-switch phenomenon, Japanese mobile phone services achieved greater technological innovations. This observation implies that today’s prominent innovations of Japanese mobile phone products are driven by the requirements of female users. We would like to call this type of phenomenon *consumer-generated innovation* or *the demand side innovation*, with which we can theoretically define that certain types of technological innovations emerge among users, in other words, the demand side, not the supply side.

In neoclassical economics, however, scholars have thought that all innovations are supplied by producers, and consumers can only choose good products that consist of good technologies and are sold at appropriate prices. This perspective is one of the most basic views in neoclassical economics, in which almost all of the neoclassical economic theories, such as supply and demand curves theory, the economical equilibrium theory, and a series of the marginalism theories, are built. We can say that these theories are some of the fundamental settings of today’s capitalism, especially in the 20th century. Moreover, these perspectives and economic theories have deeply influenced the major ideas in conventional media studies. Therefore, in conventional media studies, new technologies that created new media have been considered a “given” element in society. In fact, most innovations in mass media, such as broadcasting technology, writing narratives for various broadcasting programs, creating sounds and visual images, and acting in mass media, were “supplied” by a very limited number of people, compared with the millions of people making up the audience in a society. In other words, in

mass media, making innovations has been highly centralized.

However, today’s rapid development in the ICTs brings a new stage in media history. The ICT innovations are much more distributed, therefore, not only a small company, but also every ordinary user can make an innovation by adding a new meaning or value to a new technology. Although this characteristic of ICTs is intuitively apparent, few researchers empirically validate the emergence of this new stage of media history. We should say that the distributed characteristic of ICTs and their demand-side innovation effects can be important elements of the innovation in the big picture of media transition history.

The major purpose of this chapter is to examine the innovation process carried by the demand side, and explore the trajectory of near-future media transition. Which medium in which country emerges in the forefront of the media history in taking a global overview of media innovation? How social norms have been compiled in ICT usages? Who actually leads the current ICT innovation in our society? What is the difference between male users and female users? To examine potential answers for these questions, we have conducted two series of empirical surveys. The technical hypothesis for the surveys is addressed in two steps.

First, for Method 1 to identify which medium in which country is at the forefront of the media transition, we have compared frequencies of use of several electronic communication means by country. By examining the result of Method 1, we could learn which electronic communication means is dominant in each country, and which confirmed that mobile phone usage in Japan is in a unique circumstance. Based on the results of Method 1, we concluded that current increase of Japanese e-mailing use via mobile phones should be considered as the forefront of the global media transition. Second, for Method 2 to validate that a certain type of innovation emerges on the de-

mand side, we surveyed, in both 2002 and 2003, the usage patterns of communication means in Japanese families. By comparing these two-year results, we could see changes in usage patterns during the period and distinguish which user cluster has led the change. Moreover, by adding ethnological analyses toward such Japanese usage patterns, we concluded that emerging Japanese female usages led major ICT innovations during the period. Details of both methods are explained in the following sections and appendix.

METHOD 1: COMPARATIVE SURVEY ON COMMUNICATION MEDIA ENVIRONMENT

Method 1 consists of an international comparative survey program, named Media Landscape Survey 2003-2004 (MLS), which includes comparative surveys in the U.S., The Netherlands, Sweden, South Korea, Japan, and China. All six surveys used the same questionnaire translated into each language. The survey targeted people age 15-34. The major purpose of the survey was to examine the communication media environment in each country. The total sample size was 2,578 (details of the surveys are included in the appendix). In each survey we asked respondents about several aspects of communication behavior using fixed phones, mobile phones, e-mailing, instant messaging, and Web logs. Regarding mobile phones, we asked them about both the call usage and the e-mail usage. We also asked respondents whether they used online game sites and music file-sharing sites.

Based on MLS, in Method 1, we compared the usage of several communication means in five countries (the United States, The Netherlands, Sweden, South Korea, and Japan), but not in China. MLS is basically done for those who are interested in using various digital communication means in their daily lives. The five countries are relatively well developed in terms of digital communications, which are common enough to represent “ordinary”

life in each country, while China is still developing. For instance, the penetration rate of PCs in China is approximately 5%; therefore, we have to say Chinese results in MLS do not represent “ordinary” Chinese lifestyle to any certain extent. Thus we exclude Chinese data in Method 1.

The purpose of Method 1 is to take an overview of each communication means usage and to map them. By doing so, we try to investigate the meanings of each communication means in the social norms and culture. As we focus on mobile phones in this article, we identify the meaning of mobile phones in the various communication environments. Of course, every country has a unique society and culture that is reflected in each country’s usage pattern. However, by comparing five developed countries’ results, we can see some general macro tendencies.

RESULT OF METHOD 1

Tables 1-3 show percentages for each communication means usage per day and by country. In Table 1, we can see the daily usage of calls on fixed phones for personal purposes. In many countries 40-70% of ordinary people make fixed phone calls at least once a day, but not in Japan. Also, Table 1 reflects the same information on mobile phone calls, and we find that the overall tendency is very similar to that of fixed phones. Generally speaking, fixed phones and mobile phones compete with each other, and their usages seem to cannibalize one another. But it is interesting that in our survey, call usage on fixed phones and on mobile phones actually tends to be in direct proportion to one another, rather than in inverse proportion.

As shown previously, people in Japan do not make as many phone calls as do people in other countries. Of course, being a well developed country, Japan does not suffer from a weak telecommunication infrastructure. Obviously, the low usage of phones to make phone calls indicates that

Table 1. Usage of personal calls on fixed phones and mobile phones per day in each country (in %)

Country	Number of respondents	Frequency of usage More than once a day
Personal Calls on Fixed Phones		
Netherlands	177	41.0
Sweden	351	72.9
USA (East Coast)	850	62.1
Japan	400	12.6
South Korea	400	47.0
M	2178	47.1
SD	2178	21.7
Personal Calls on Mobile Phones

Sweden	351	61.1
USA (East Coast)	850	74.9
Japan	400	31.8
South Korea	400	80.7
M	2178	62.4
SD	2178	18.6

Note: All numbers of data above are verified to have significant differences against the mean with the significance level $p < .05$, in the parametric statistical test -Dunn test (multiple comparison).

in Japan voice communications are now being replaced by other communication means.

Therefore, we must determine what other communication means are replacing phone calls in Japan. The most conceivable answer is a variety of text messaging services. Table 2 and Table 3 show the daily usages of e-mailing services via PCs, instant messaging, and e-mailing services via mobile phones, respectively.

Table 2 reflects the usage of regular e-mailing services via PCs and PDAs. E-mailing services have been developed based mainly on PC-based networks. In MLS, we classified e-mailing via PDAs as a variation of regular e-mailing services because in many cases of PDA-based e-mailing usage, users are connected by the same type of network as PC-based ones, even though the physical shape of PDA usage is similar to the usage of mobile phones. Interestingly, Table 2 shows a cul-

Table 2. Usage of personal e-mailing via PCs or PDAs, and instant messaging per day in each country (in %)

Country	Number of respondents	Frequency of usage More than once a day
Emaining via PCs or PDAs		
Netherlands	177	68.8
Sweden	351	65.7
USA (East Coast)	850	74.8
Japan	400	42.8
South Korea	400	32.8
M	2178	56.9
SD	2178	17.5
Instant Messaging		
Netherlands	177	29.0
Sweden	351	39.8
USA (East Coast)	850	41.4
Japan	400	11.5
South Korea	400	50.8
M	2178	34.5
SD	2178	19.2

Note: All numbers of data above are verified to have significant differences against the mean with the significance level $p < .05$, in the parametric statistical test -Dunn test (multiple comparison).

tural or historical difference of writing behaviors among Western countries and Eastern countries. In Western countries, word processing culture has a long history, reflected in the wider usage of PC-based e-mailing. Conversely, Eastern countries have a long history of handwriting and relatively short history of word processing, and thus e-mail usage in Eastern countries is less popular, although South Korea and Japan have very high penetrations of PCs and Internet usage.

Therefore, according to our data, we cannot say PC-based e-mailing services are effectively replacing Japanese voice communications. Also, Table 2 shows the usage of instant messaging. It is a relatively new, PC-based text messaging service, by which users can see a message automatically as soon as it arrives. Because of its convenience and quickness, instant messaging is becoming popular especially among heavy Net users. Moreover,

Table 3. Usage of personal e-mailing/SMS via mobile phones per day in each country (in %)

Country	Number of respondents	Frequency of usage More than once a day
Netherlands	177	28.4
Sweden	351	36.7
USA (East Coast)	850	5.1
Japan	400	51.0
South Korea	400	18.3
M	2178	39.9
SD	2178	22.0

because instant messaging is usually used among “trusted” relations, it can relatively keep users away from spam mails and virus mails. The five countries in MLS are all well developed regarding Internet connectivity; Table 2 shows that 30-50% of Net users in these countries are using instant messaging, except those in Japan. Only in Japan, the percentage of the instant messaging usage is approximately 10%. Here again, we cannot say that Instant messaging, also a PC-based text messaging service, is replacing Japanese voice communications.

Finally, Table 3 shows the usage of mobile e-mailing services, or short messaging services (SMS). Here we find a popular use of it in European countries and especially in Japan. In the U.S. and South Korea, the usage of mobile e-mailing is not very popular, even though penetrations of mobile phones are not low in these two countries, per se. Interestingly, comparing Table 3 with Table 1, we can see the average shapes of mobile phone usage by country. In the U.S. and South Korea, voice communication is much more superior to mobile e-mail communications, while in Japan mobile e-mail communication is entirely dominant. In The Netherlands and Sweden, both voice and e-mail communications are equally popular. Based on this understanding, we can say that in Japan the frequent usage of mobile e-mail communication—in

this case more than 60% of total respondents—is replacing voice communication.

THE MEDIA LIFE CYCLE

Summing up these survey results, we can envision a framework for the life cycle of a variety of communication media. When a new communication medium appears and becomes popular, an old one becomes obsolete and begins to decline. The important point here is finding a phenomenon of usage decline, rather than merely an emergence or increase of a new medium usage, because a declining phenomenon directly means a replacement of media, and the replacement implies the existence of the media life cycle. In other words, if we observe a declining phenomenon among consumer behaviors, it proves that there emerges a replacement of medium and its technology by other new media and their new technologies. We can define the media life cycle as this alternation of media and their technologies.

In our MLS, the declining phenomenon is seen in the case of Japanese voice communication. We have also found that mobile e-mail communication is becoming the alternative of voice communication. At this point, we cannot see any other declining phenomenon in the other countries. This strongly implies that Japanese society stands at the forefront of the media life cycle due to the wide penetration of mobile e-mail communication.

It is interesting, however, that PC-based text messaging services, such as regular Internet e-mail services and instant messaging, do not seem to replace any other old communication medium, even though many analysts have pointed out that the Internet has started to replace some conventional mass media. For instance, it is true that certain kinds of newspapers, magazines, and music CDs are now in danger of decline due to the massive penetration of the Net media. How-

Figure 1. The framework of the media life cycle

	Mass Media one-way-based communication: basically one-to-many	Personal Communication Media interactive-based communication: basically one-to-one
Generation A: (before the 20th century) The initial shape of public communication system with paper	Mass print media (include newspapers and magazines)	Physical mail
Generation B: (the 1st half of the 20th century) Telecommunication with voice and sound	Radio broadcasting	Calls on telephones (include both fixed and mobile)
Generation C: (the 2nd half of the 20th century) Transferring rich contents with multiple-channels	TV broadcasting (includes cable TV)	Email via PCs (include instant messaging)
Generation D: (beginning of the 21st century) Allowing users to establish communication completely on-demand	Internet portals (include news groups and file sharing)	Email via mobile phones

ever, in the personal communication arena that we see in MLS, instead of the mass media arena, the Internet is not a threat for conventional communication media at this point. In other words, there is coexistence between the Internet and conventional communication media.

Comparing mass media and personal communication media, we can also generalize the media life cycle to be a wider map of media transitions, as in Figure 1, which includes a variety of media and technologies we use in our everyday life. The two columns, which follow, represent mass media and personal communication media, respectively, and the four rows represent four generations of media, chronologically. By nature, mass media is based on a one-way communication, from one supplier to many audiences, while personal communication is based on an interactive communication among "one-to-one" relations.

First, Generation A indicates a primitive shape of public communication in each arena, which mainly consists of paper and ink. We can classify various print media, such as newspapers and magazines in mass media and physical mail in the

personal communication media. The technology that supports Generation A media was invented several 100 years ago. These media were widely developed as public communication services long before the 20th century. However, because Generation A media are very useful and efficient in many ways, most of them survive as a part of the basic social infrastructure and coexist with new generation media even now.

Second, Generation B indicates the emergence of telecommunications with relatively simple voices and sounds in the early 20th century. We classify radio broadcasting in the Generation B mass media, and calls on telephones in the Generation B personal communication media. The basic technologies that developed the Generation B media were invented at the end of 19th century, but the public communication services for ordinary consumers using these technologies began in the early 20th century. Telecommunications enabled us to communicate, and therefore to overcome any time lag, even when there is a considerable distance between communicators. Inevitably, this was one of the most important developments of the 20th century.

Third, Generation C indicates that we can communicate a great variety of content, such as visual images, movie images, and high quality stereo sounds, through multichannel information distribution systems. TV broadcasting systems and e-mail via the Internet are classified in this category. Thanks to advanced telecommunication techniques and broader bandwidth of transmission networks, we can exchange rich content among ourselves. This revolutionary media environment gave birth to an extremely creative visual culture in the late 20th century. The visual culture is so impressive that it has overshadowed the former generation media. Actually, radio broadcasting began to decline under the influence of TV broadcasting, and physical mail began to decline due to a massive increase in e-mailing. However, as previously mentioned, e-mailing has not begun to replace voice communications at this point.

Finally, Generation D enables us to access rich content whenever and wherever we want. In this sense, Generation D is the second wave in the process of being able to overcome distance and time as Generation B did. However, we need to examine carefully what the difference is between TV broadcasting and Internet portals, or between e-mail via PCs and e-mail via mobile phones.

Let us start with Internet portals and TV broadcasting. When we compare newsgroups in Internet portals with conventional news on TV, what is the actual benefit from it? The answer may be its chronological nonlinearity and ubiquity of news content. From a news list of Internet newsgroups, we can obtain any news in any order we want to see it, while we have to obey the program schedule of broadcasting stations if we want to receive the same content from conventional TV news programs. In general, TV news programs are designed in a chronological order. Consequently, we have to behave synchronously when we depend on TV news. Conversely, if we regularly obtain information from Internet newsgroups, we are free from such synchronicity, using our limited time resources more efficiently. Moreover, Internet

newsgroups are also free from geographic limitations. By nature, conventional TV news programs focus on individual regions and countries, limiting the scope of news content. However, we can watch and read all countries' news simultaneously with Internet portals.

Next, let us examine the actual benefit from using mobile e-mail instead of regular e-mail via PCs. We find the same benefit: a chronological nonlinearity and ubiquity in communicating with others. We can receive and send mobile e-mail immediately, wherever we are. This does not mean that we are only free from geographical limitations of Net accessibility, but also from chronological limitations of communication. As many mobile e-mail users know, constant and seamless connection between friends and family consequently dispels a feeling of time lag between sending and receiving and creates a comfortable feeling of "always being linked." In general, when we send e-mail via PC, we cannot expect the receiver to immediately read it, because the receiver is not necessarily in front of a PC. But in the case of mobile e-mail, especially in Asian and European countries, we can expect the receiver to see the e-mail immediately, even though the receiver may not reply to it instantly. This difference of expectation in the receiver's behavior makes the sender feel more connected. It is curious that the loss of communication time lag leads us to a loss of chronological limitation of e-mailing behavior, even though the actual transaction of e-mail exchange in mobile e-mail is more chronological than regular e-mail via PCs. However, it is unfortunate that in the U.S., due to the low penetration rate of mobile e-mail usage at this point, ordinary U.S. people have not experienced this feeling yet.

One may think these benefits from Generation D are not absolute technological improvements but merely false benefits in the users' minds. However, from the viewpoint of social norms, we believe that the benefit in the user's mind is the most important thing. Users have spontaneously

changed the meaning of communication and its technology from *interactive* to *on-demand* in the case of Internet portals, or, from *wireless* to *ubiquitous* in the case of mobile e-mail.

Of course, the framework of the media life cycle shown in Figure 1 may seem to be overly generalized to some extent, and we can be more careful to examine each medium's specific meaning in each period. However, by having a macro viewpoint as in this framework, and especially by observing the replacement of a conventional medium by a new medium, we can understand the meaning of each technology in our society.

CONVENTIONAL MEDIA STUDIES AND ICTS STUDIES

To maintain the theoretical history of media usages, the analysis of the newest media, such as the Internet and mobile phones, is not sufficient at this point. We hope that our framework of the media life cycle can be helpful to fill this vacuum to some extent. One of the most typical of conventional media analysis frameworks is Harold Innis's (1951). He classified various media into two categories, time-binding media and space-binding media, by using the terminology *media bias*. The time-binding media includes manuscripts and oral communications, and are favorable to relatively close communications in a community, while the space-binding media includes all of print media, mass media, and probably current ICTs, and are concerned with today's wide variety of commercialism. Innis and Marshall McLuhan, Innis's colleague at The University of Toronto, thought that media and technologies were "given," and media, per se, could be messages to our society. This approach is so-called *media determinism*, and is a popular approach in media studies, journalism, and critical studies even now. This approach is quite useful to compare the magnitude of influences of various media regardless of the content of each communication. In fact, we can

see a variety of examples in which current critical media researchers use a theoretical framework that can be evaluated as a natural evolution of Innis's approach. For instance, Chesbro and Bertelsen (1996) show a media comparison framework using three categories of media classification, oral culture, literal culture, and electric culture, and explore each characteristic of these three types.

The approach of media determinism has been, of course, significant since we have observed the history of media, especially the evolution of mass media and its culture, during the decades in the middle and latter 20th century. But it is also obvious that such types of frameworks are no longer efficient enough to classify the current vast number of emerging media that includes advanced mass media and ICTs. Media determinists think that all kinds of media must be extensions of the human body, in other words, ways of self-expression. In this perspective, technology is always defined as a "given" thing, and thus it is hard to examine the degree of participation of ordinary people within the technological innovation. In the ICT area, innovation and user participation are both indispensable aspects to examine its social impact. Therefore, we have to think that media determinism is not sufficient to become a basis of our media life cycle framework.

On the other hand, Rogers (1986) has also tried to build a new framework of media classifications based on his diffusion theory. He thinks media and technologies should be "variables" in human and organizational communications, instead of a "given" thing (p. 121). This approach is more efficient to include any emerging technology, because we can add a "variable" of communications on the same framework when one new medium emerges. In this article, we basically adopted his approach and tried to widen the map to include the latest situation by adding current ICT analyses. However, Rogers did not sufficiently analyze the dynamics of technological replacements in the media innovations, because in the 1980s and the beginning of the 1990s, no ICT was powerful

enough in our society to encompass the conception of the media life cycle. As we showed with a variety of empirical survey results, today we can observe a clear signal of the replacement phenomena between old and new media. Therefore, we can build this media life cycle framework in this article.

By using our framework of the media life cycle, we can foresee the future changes of our communication behavior, both in the sphere of mass media and the sphere of personal communication. In the sphere of personal communication, mobile e-mailing is now replacing voice communications through telephones. In other words, Generation D media can replace Generation B media, while Generation D media can coexist with Generation C media. At this point, this replacement phenomenon appears only in Japan. But in the near future we may observe a similar transition in other countries in proportion to the technological innovation in mobile e-mailing. On the other hand, in the sphere of mass media, we do not observe a similar phenomenon at this point. But according to this theory, Internet portals (Generation D in the sphere of mass media) can replace radio broadcasting (Generation B in the sphere of mass media) in the near future in proportion to the technological innovation. For example, the distribution of new songs from music creators to ordinary listeners, one of the important functions of radio broadcasting, is now being replaced by MP3 music file sharing through a certain kind of Internet portal. In fact, the current MP3 controversy has been caused by a threat against new technology among present media business, not by any theoretical correctness, or any change of the ways of self-expression among music creators. In other words, the anticipation of the media replacement between Generation D and B even in the mass media sphere is already shared widely among many people.

Table 4. Communication rate, using electric communication means in daily life, with family members in Japan (in %)

Person with whom the respondent communicates	Communication rate in each year	
	2002 (n = 89)	2003 (n = 200)
Mother	82.9	81.0
Father	57.3	55.0
Sister	48.0	45.0
Brother	47.3*	31.5*
Spouse	43.7*	29.0*
Cousin	10.9	15.5
M	48.4	42.8
SD	21.2	21.1

Note: All numbers of comparison data between 2002 and 2003 above are tested by the parametric statistical test –T-test. *p < .05.

METHOD 2: A COMPARISON OF 2002 WITH 2003 IN JAPAN

Our next goal is to distinguish the exact user cluster that leads to innovation in the media life cycle. In this section, we especially focus on Japanese mobile e-mail usage as a good example of the forefront of media innovation. By investigating the forefront of the innovation in detail, we can understand what the innovation of media is.

We conducted a small, preliminary survey in 2002 that had the same questions as the MLS in 2003. Both surveys asked respondents about electronic communications with family members, all of which can represent typical communication patterns in a daily life. By comparing the two-year survey results, we can empirically distinguish one user cluster from another to determine who led the innovation from voice communications to mobile e-mailing. The preliminary survey was taken only by Japanese people aged 18-29. Then we selected a similar respondent bracket in MLS to compare results as precisely as possible.

Table 4 indicates the comparative results of the same question, in the preliminary survey in 2002 and MLS in 2003, regarding the communication rate with six family members using electronic communication means. Here it excludes any face-to-face communication. Due to a slight difference between survey methodologies from 2002-2003, the reactions in 2003 seem to indicate a reluctance to provide information. But, as a whole, we find little difference between the two survey results. The order of the surveyed family members by the communication rate in both survey results is completely the same, and the communication rates themselves have not changed greatly during 2002

and 2003. It is interesting to note the correlation between the order of family members surveyed and the descending level of their response rate. We can say that, in general, the condition of Japanese communications, using electronic means, among family members has remained unchanged.

On the assumption that the general condition of Japanese communications is unchanged, in Method 2, we wanted to see whether there was any local change in the usage rate among family members during the period. If we could observe that, we would be able to identify the forefront of media replacements along with the media life cycle framework. In other words, who led it, and how did they do this?

Table 5. Comparison of communication media usage between 2002 and 2003 in Japan (in %): Male

Person with whom the respondent communicates	Communication rate		Number of respondents	
	2002	2003	2002	2003
Calls on fixed phones				
Mother	38.7	33.2	31	78
Father	43.5	32.1	23	56
Brother	10.0	10.3	20	29
Sister	6.3	24.4	16	41
Calls on mobile phones				
Mother	45.2	42.3	31	78
Father	47.8	44.6	23	56
Brother	60.0*	24.1*	20	29
Sister	37.5	24.4	16	41
SMS or email via mobile phones				
Mother	12.9	20.5	31	78
Father	4.4	10.7	23	56
Brother	25.0	48.3	20	29
Sister	50.0	39.6	16	41
Email via PCs or PDAs				
Mother	3.2	1.3	31	78
Father	4.4	9.3	23	56
Brother	5.0	10.3	20	29
Sister	6.3	4.9	16	41

Note: All numbers of comparison data between 2002 and 2003 above are tested by the parametric statistical test -T-test. *p < .05.

Table 6. Comparison of communication media usage between 2002 and 2003 in Japan (in %): Female

Person with whom the respondent communicates	Communication rate		Number of respondents	
	2002	2003	2002	2003
Calls on fixed phones				
Mother	39.5	42.9	35	84
Father	28.6	29.6	28	54
Brother	0.0	5.9	22	34
Sister	11.1	10.2	25	49
Calls on mobile phones				
Mother	44.2	28.6	35	84
Father	53.6	31.5	28	54
Brother	27.3	26.5	22	34
Sister	14.8	8.2	25	49
SMS or email via mobile phones				
Mother	14.0	25.0	35	84
Father	7.2*	33.3*	28	54
Brother	36.4	52.9	22	34
Sister	59.3	73.5	25	49
Email via PCs or PDAs				
Mother	2.3	1.2	35	84
Father	10.7	3.7	28	54
Brother	36.4*	11.8*	22	34
Sister	14.8*	2.0*	25	49

Note: All numbers of comparison data between 2002 and 2003 above are tested by the parametric statistical test -T-test. *p < .05.

Table 7. Means and standard deviations in Tables 5 and 6 (in %)

Male						
Person with whom there-spondent communicates	Means and Standard Deviations				Number of respondents	
	2002		2003		2002	2003
	M	SD	M	SD		
Mother	25.0	17.4	25.0	12.0	31	78
Father	25.0	20.7	25.0	15.0	23	56
Brother	25.0	21.5	25.0	15.6	20	29
Sister	25.0	19.2	25.0	12.4	16	41
Female						
Person with whom there-spondent communicates	Means and Standard Deviations				Number of respondents	
	2002		2003		2002	2003
	M	SD	M	SD		
Mother	25.0	17.4	25.0	15.0	35	84
Father	25.0	18.4	25.0	12.1	28	54
Brother	25.0	14.9	25.0	18.2	22	34
Sister	25.0	19.9	25.0	29.1	25	49

RESULT OF METHOD 2

In this section, in order to make all analyses simple and clear, we examined the survey results based on communications with four major family members, mother, father, brother, and sister, and by four typical electronic communication means; calls on fixed phones, calls on mobile phones, e-mail via PCs and PDAs, and e-mail via mobile phones. Table 5 and Table 6 indicate usage rates for all combinations of family members by communication means. Table 5 shows changes between 2002 and 2003 among male respondents, and Table 6 shows the same result among female respondents.

In Table 5, we notice that calls on mobile phones to brothers significantly decreased during the period of 2002-2003, while there seemed to be no significant change in other respects. On the other hand, in Table 6, we find a couple of significant changes and some interesting tenden-

cies in female usages; calls on mobile phones to both parents tended to decrease, while e-mail via mobile phones with both parents and sisters tended to increase. E-mailing via PCs and PDAs significantly decreased. The means and the standard deviations are indicated in Table 7.

Table 8 focuses on the increase or decrease of each communication means by measuring the average usage rate of each communication means in total amount of usage with four family members. The average usage rate of a communication means x , $AUR(x)$, is defined as:

$$AUR(x) = \frac{1}{n} \sum_{h=1}^4 u(x, h) \tag{1}$$

where $u(x, h)$ is the response number of the communication means x with the family member h ($h \leq 4$), and n is the sum of each number of effective respondents for four questions: communication with mother, father, brother, and sister. The number of $AUR(x)$ indicates the average degrees of presence for the communication means x when a person communicates with all family members. By comparing the $AUR(x)$ in 2002 with that in 2003, we can directly understand the change of presence for the communication means x in ordinary life during the period.

With regard to calls on fixed phones, there is no significant change. In Method 1, we argued that in Japan, calls on fixed phones are already less popular than those in other countries. However, the result of Method 2 implies that the decline of calls on fixed phones in Japan is not the most current incident. Conversely, it is interesting that, among female respondents, calls on mobile phones significantly decreased, which implies that the forefront of the voice communications decline has started shifting from fixed phones to mobile phones.

On the other hand, we can find very important differences by gender with e-mail communications. With regard to mobile e-mail, we can find a significant increase among female respondents,

Table 8. Change of communication media usage pattern between 2002 and 2003 in Japan (in point)

Communication means	Communication rate			
	Male		Female	
	2002 (n = 90)	2003 (n = 204)	2002 (n = 110)	2003 (n = 221)
Calls on fixed phones	27.8	27.9	22.7	26.7
Calls on mobile phones	47.8	36.8	36.4*	24.4*
SMS or email via mobile phones	20.0	25.5	27.3*	42.1*
Email via PCs or PDAs	4.4	5.4	14.5**	3.6**
M	25.0	25.0	25.0	25.0
SD	15.6	11.5	7.9	13.7

Note: The numbers of respondents in this table indicate the sum of each number of respondents for four questions (communication with mother, father, brother, and sister). All numbers of comparison data between 2002 and 2003 above are tested by the parametric statistical test -T-test under the total numbers of respondents. *p < .05, **p < .01.

while e-mail via PCs among female respondents is significantly in decline. Among male respondents, we cannot find significant change of e-mailing behavior via either mobile phones or PCs.

As a whole, this result of Method 2 strongly implies that women in Japan lead the shift of the communication media cycle from voice communications to mobile e-mailing. Among male respondents, we can only observe a tendency of decrease regarding calls on mobile phones, but among female respondents we can observe both a tendency of decrease and a tendency of increase. This fact means that among male respondents the replacement of communication media has just started recently, but among female respondents the replacement is already in progress. Thus, female respondents are in a more advanced stage of the media life cycle.

From an ethnological viewpoint, this tendency has been argued widely in the Japanese mobile

phone industry. Since the late 1980s and the beginning of the 1990s, Japanese social ethics regarding female lifestyles have drastically changed and been liberated, as many women are encouraged to have full-time jobs, instead of staying home as housewives. Mobile phones are considered very useful tools to maintain family communications even though women go out frequently. Young girls are ordinarily allowed to stay with their friends until late at night if they make calls or e-mail via mobile phones to their mothers. The sense of “always being linked” caused by a wide penetration of mobile phones is becoming a new social norm in Japan. Many Japanese sociologists say that this new social norm concerning mobile phone usage may generate a new shape of family relations in Japanese society. Japanese women are no longer tied to their family and houses, and owning mobile phones encourages this new ethic. That is why, for women, mobile phones are considered as a symbol of freedom of lifestyle.

CONCLUSION AND DISCUSSION

In this chapter, we started our exploration from the rapid and wide penetration of new communication means such as mobile phones and e-mailing through the Internet. Based on an empirical survey in five countries, (MLS), we examined one of the forefront phenomena of the media life cycle in Japan, in which voice communications are gradually being replaced by mobile e-mailing communications. This discovery of media replacement from an old one to a new one in the Japanese personal communication sphere, and the framework of the media life cycle imply other future media replacements, such as those in different countries or those in different spheres.

Next, we explored deeper details of the media innovation by examining a case of Japanese mobile e-mailing usage. The most significant finding is that, during the period between 2002 and 2003, ordinary female users clearly led media innova-

tions, instead of, for instance, techno-fanatic male users. This implies that certain types of media innovation in Japan have been generated by consumers, in other words, demand side, in which consumers can generate the innovation by choosing appropriate usage of new media in their daily lives, instead of creating new products or developing technologies.

Integrating two conclusions, we can say that the media life cycle is now being processed toward the next stage by the demand side, and during this process, new social norms with the new technology are generated among consumers. In this fashion, we can observe that the media innovation with new technologies is not deterministic, and mobile e-mailing can replace the conventional voice communication by phones, which is an unexpected trajectory of the ICT future for some techno-fanatic analysts.

ACKNOWLEDGMENT

We appreciate the great contributions by Mr. Akira Odani, Mr. Masao Morinaga, Dr. Michael Bjorn, Mr. Erik Kruse, Mr. Kyu-Chol Ban, and Searchina Research Institute, to conduct the MLS 2003. We would also like to thank Dr. Nicholas Jankowski for his giving us important suggestions to our research.

APPENDIX

The Source of Method 1

Survey name: *Media Landscape Survey 2003-2004* (MLS)

Survey countries, the effective sample populations: 850 samples in the U.S. (east coast), 400 samples in Japan, 177 samples in The Netherlands, 351 samples in Sweden, 400 samples in South Korea, and 400 samples in China (Shanghai area): total 2,578 samples

Respondents: ordinary people who are interested in digital communications, aged 15-34

Sampling procedure: Internet panel survey method, provided by professional survey companies, was used in the U.S., Japanese, Swedish, South Korean, and Chinese surveys. In The Netherlands, a multi-stage recruiting method was used. In the United States, parental permissions had been taken to conduct the survey among respondents aged 15-18.

Response rate: Due to the nature of Internet surveys, it is difficult to fix the precise response rates. However, the average response rate in this Internet survey system is reported as 15-25%. In The Netherlands, the response rate was 25.3%.

Survey date: Oct. 2003 to Mar. 2004

Measurement of reliability: All numbers of data in Method 1 are verified that they have significant differences against each average with the significance level $p < .05$, in the parametric statistical test—Dunnnett test (multiple comparison).

The Source of Method 2

Survey in 2002 (preliminary survey):

Respondents: Men and women aged 18-29 living within a 40km radius of the Tokyo metropolitan area

Sample population: 89 respondents (40 males and 49 females)

Setting and sampling procedure: Self-administered questionnaire mailed and left with members of a predetermined panel.

Response rate: 100% (predetermined)

Period: January 2002

Survey in 2003 (in MLS):

Respondents: Men and women aged 20-29 living in Japan

Sample size: 200 respondents (100 males and 100 females)

Setting and sampling procedure: Internet survey

Response rate: Due to the nature of Internet survey, it is difficult to fix the precise response rate. However, the average response rate in this Internet survey system is reported as 15-25%.

Period: November 2003

Measurement of reliability: All numbers of comparison data between 2002 and 2003 in Method 2 are tested by the parametric statistical test—T-test.

Chapter 2.8

Participatory Design and Creativity in Development of Information and Communication Technologies

ABSTRACT

This chapter presents and discusses a new design framework for involving users at an early stage in a mobile ICT development project. A user-centered design process, in which participatory design principles are combined with creativity techniques, is used in order to create scenarios as a communication tool between users and system designers. The theoretical basis for the framework is described, leading to a new participatory design and creativity framework. Empirical insight into how the framework has been developed and used in practice is presented based on the experiences and results from a large ICT development project within the field of mobile communication. Finally,

the value of applying creativity as part of a participatory design process is discussed.

INTRODUCTION

Many information and communication technology (ICT) projects have experienced a gap between the system design itself and the needs and visions expressed when users have been introduced to the system developments. Within the field of human-computer interaction (HCI), several design methods and techniques have been developed to involve users in the design process and to bridge the gap between what users want and what is technically possible. Employing participatory design

methods, like PICTIVE (Muller, 1991), means that users are actively involved in the design process, aiming at gathering user requirements and reflecting them in system design. The design process very much depends on how designers collaborate with users. There are several challenges in this process: the vocabulary used between designers and users, and to what extent user requirements are expressed in usable and understandable terms for the designers. Often, it is difficult for users to express their ICT design needs, especially when referring to a future state. On the other hand, designers have a technological insight that may take the ICT system designs and services much further than anticipated by the users. Finding the right balance between the two is a challenge.

In developing familiar applications that directly interact with users (e.g., Web pages) the traditional tools for deriving user needs are methods such as contextual inquiries, participatory design meetings, focus-group meetings, surveys, and interviews (Zappen & Harrison, 2005). All these methods possess advantages and limitations that have to be taken into consideration when using them. However, when addressing mobile, wireless technologies and networks, the tradition has so far been to develop these applications without paying much attention to user needs—in other words, a technology-driven development approach.

This chapter addresses mobile and wireless ICT development and presents a framework for how user requirements can be derived from users regarding design of technology, applications, and services within this area. A basic idea is to apply the principles from participatory design and focus on scenarios in particular as the technique for establishing designer/user communication. The use of scenarios is commonly used within ICT development and design, often presented as narratives about how people use technology in different situations and attempting to explain what, when, and how events and actions take place.

When using scenarios for innovation and identifying challenging technological ideas, it is fruit-

ful to build these on creative thinking. Creativity is needed to support users in thinking ahead of and beyond their present needs, and to identify needs and situations in which current technology does not adequately support users. There is no firmly established scenario technique for ICT project design and developments (Alexander & Maiden, 2004, presents different techniques), and the aspect of creativity is traditionally not directly part of this process. Little research has been carried out in linking creativity and participatory design. Most theories of creativity are linked to either the individual or a group of people working together (Kazanjian, Dradin, & Glynn, 2000). In this chapter, creativity is used as an active component in setting up user-centred scenarios and is thus an effective factor in identifying user requirements—focusing on both the individual and the team creativity of a group of users.

The overall purpose is to present a participatory design and creativity framework developed in order to support and produce user-centered design in the development of innovative mobile, wireless ICT systems within the IST EU project “My personal Adaptive Global Net” (MAGNET, 2004). The framework has been built upon scenario construction and a set-up of successive workshops developed through practical project work.

The MAGNET project has a strong emphasis on user centricity, personalization, and personal networking. The end goal of the project has been to enable commercially viable personal networks that are affordable, user-friendly, and beneficial for all kinds of users in all aspects of their everyday lives. It addresses research issues within personal distributed environments, where users interact with a multitude of entities in their near vicinity, although potentially anywhere. These systems are defined as personal networks and constitute a category of distributed systems with very specific characteristics (Niemegeers & Groot, 2002). The concept of personal networks is related to personal communication environments, consist-

ing of a large number of devices, which can all interconnect independently of time and place. They enable a collaborative environment within a distributed network setting, which supports users in both their professional and private activities. Figure 1 illustrates a generic set-up for a personal network and communication environment that can be interconnected through different ad hoc or infrastructure-based networks.

The specific design process addressed is the process of developing personal network services and applications, progressing through system layers from the top layer consisting of devices, user interfaces, and functionality and down through the layers to hardware components. By involving users in the development process, the written system requirements specifications for networks and platforms, which induce constraints and limitations on the final services and applications, can be anticipated and already addressed when defining the first specifications. In this process, it is important to remember that “users” is a broad concept covering not only end users but also other stakeholders such as service providers, service operators, and different types of communities. In the present context, users will be understood as end users.

The chapter is divided into the following sections. First, the relevant theory within the fields of mobile systems development, participatory design, and creativity is discussed as the theoretical basis for a new participatory design and creativity framework. The new framework is then described with specific focus on different workshops structured according to creativity and participatory design principles. The practical implementation of the framework is illustrated by the MAGNET project. Focus is on how the theoretical framework has been applied to a specific case study dealing with improving the handling of health care related situations. The chapter concludes with reflections on both the theoretical framework and the practical experiences the application has provided for understanding the use of this framework.

MOBILE SYSTEM DEVELOPMENT

In the past decade, mobile system developments have been researched extensively from an engineering system development and organizational point of view. However, during the last couple of years, a new perspective has emerged—the user perspective, which as the name implies focuses

Figure 1. A personal network illustrating the user and how (s)he communicates with other environments

on user perspective and involvement. This means actively involving users, drawing social aspects into the development process, and creating a high level of user acceptance and usefulness in practice. Based on early research concerning nomadicity, mobility concepts, and later mobile system development literature, the present section briefly describes some of the important developments in this area and gives a short overview of important research carried out within the field.

Today, the combination of mobile computing and communication is rapidly changing the way we think about information processing and communication in general, and it is taken for granted that access to computing and communication is necessary from all locations, for example, office, home, and so forth, but also while in transit and when arriving at unfamiliar destinations.

The basis for some of these ideas and concepts has been discussed by computer scientist Kleinrock (1996a, 1996b), who describes and outlines the essence of nomadicity (nomadic computing and communications). This he defines as the system support needed to provide a rich set of computing and communication capabilities and services to nomads in a transparent, integrated, and convenient form as they move from place to place. From an engineer's perspective, this approach and concept are more or less based on making computers and computer communication systems mobile. According to Kleinrock, nomadic computing and communication described from a system perspective should support capabilities that enable independence of: location, motion, computing platform, communication device, and communication bandwidth, meaning that specific mobile computing environments should automatically adjust to the processing power, communication, and bandwidth available at any given time.

User Needs and Requirements

The overall viewpoint on mobile system development is mainly related to user needs and require-

ments and, more specifically, to design studies and HCI perspectives. In general, the number of wireless communication technologies and communication devices, services, and applications has increased dramatically over the last decade, albeit most of these developed and designed based on what was technologically possible with little attention being paid to specific user needs. However, during the last couple of years, increasing attention has been allocated to actually defining real user needs and designing and developing services and applications accordingly within the limits of the available technology. The big challenge within mobile system development and design is to develop mobile services and applications that actually support users in their everyday lives and also support professional working environments.

In a review of mobile HCI methods, Kjeldskov and Graham (2003) found a bias towards engineering systems using applied approaches and evaluating them, if at all, only in laboratory settings. Furthermore, they identified some gaps in the commonly used research approaches; for instance, action research, case studies, and basic research were identified as being applied rarely. The bulk of papers researched fall within the category of applied research (56 of 102 papers) and lab experiments (32 of 102 papers), whereas the remaining categories—case studies, field studies, action research, basic research, and normative writings—account for only 14 papers altogether. Based on their findings, Kjeldskov and Graham suggest a change of research focus within the area of mobile HCI in order to achieve a better understanding of the limits on design and application.

From a different perspective, Krogstie, Lyytinen, Opdahl, Pernici, Sian and Smolander (2004) explore the challenges in developing mobile information systems at the conceptual and logical levels and with a special focus on mobile knowledge workers and a user-oriented perspective. A major characteristic of mobile knowledge workers is the required ability to communicate and

interact either synchronously or asynchronously with different information systems and persons independently of time and location. According to Krogstie et al. (2004), one of the main challenges regarding future mobile information systems is related to user orientation and personalization. Specifically, the separation of content and medium is very important in relation to delivering a maximum level of user personalization, as the systems should automatically adapt to the preferences of the user.

PARTICIPATORY DESIGN

Applying user-centered design to mobile system development does not necessarily mean that users actually participate in the design process. There are many different methods and techniques within interaction design that aim at a successful transition from the identification of user needs and requirements to the development of the final product. Using participatory design means that users are actively involved in the design process phase where new design ideas are generated. Users may be involved at different levels: the focus here is on the beginning of the design process dealing with scenario construction, low-fidelity prototyping, and simple mock-ups with the overall goal of capturing and exploring user needs and requirements.

Human Values

Participatory design in accordance with the Scandinavian approach has been centred on democracy issues and was, as described in Ehn (1988), developed in close collaboration with trade unions. Activity theory used as a high-level framework for understanding of the design process, as described in Kuuti (1996), was linked together with participatory design in Bødker, Greenbaum, and Kyng (1991). The definition of functional organs and mediation from activity theory means that all human experience is shaped by the tools and

sign systems we use. This leads directly to users being actively involved in the design process. Participatory design is used in order to ensure that the finally developed applications and services will be adaptive to the users and not the other way around. In accordance with an activity theory framework (Kuuti, 1996), it is important to consider carefully how to set up a participatory design process because the results will be greatly influenced by how this is done.

Asaro (2000) presents a discussion of the different approaches to the participatory design process. Here, the conclusion seems to be that the technological rationalization perspective, including joint application design (Carmel, Whitaker, & George, 1993) and contextual design (Beyer & Holtzblatt, 1998), and the socialist and humanist perspectives—putting the sociotechnical (Mumford, 1987) and Scandinavian (Kensing & Blomberg, 1998) approaches under the same hat—have converged. The different approaches to the participatory design process have altogether converged to form a current heterogeneous field claiming the twin goals of increasing efficiency and increasing democracy. In the present context, the use of participatory design is not only aiming at more efficient and usable products but also at human values. However, focus has shifted from the original ideas of Scandinavian participatory design, in which democracy and workers' rights were at issue, to the private emotional life of the user. Today, new possibilities within ubiquitous computing and attentive environments and threats of surveillance and emotional manipulation and persuasion (Fogg, 2003) call for engineering designers who are able to perceive, understand, and communicate personal feelings and emotions. This new paradigm also calls for new experimental ways of prototyping using external cognitive aids developed as a language within the design team.

It is important to stimulate communication and learning in multi-disciplinary teams. A shared design language using external cognitive aids such as pictures and different kinds of elements

for prototyping can be used with inspiration from Muller (1991), where the PICTIVE approach guides the users with the help of predefined elements, and from Gaver, Dunne, and Pacenti (1999), where the content of cultural probes is obtained by getting the users to create their own personal stories. During a participatory design workshop, the users are asked to envision future possible products within a case. This may be rather difficult for many users, and with inspiration from future workshops (Jungk & Müllert, 1987), the approach of starting with the present can be used as a good way of initiating the development of a shared communication language within a team.

Team Work

We design the products, and the products shape our living; therefore, engineering designers must be able to contribute to the connection between human values and technology. Design tools as external cognitive aids are good to have, but the primary source of success is the team members: engineers, designers, users, and other stakeholders. A good engineering designer is curious, open-minded, and creative while having technical, design process and teamwork skills. It is challenging to facilitate team development in order to achieve a creative and innovative blend of human values and technology in the design process. One approach in developing ICT products for the future is to use development methods that facilitate creativity, human values, user participation, and heterogeneous design teams. Furthermore, it may be necessary to accept design processes that might seem somewhat unstructured while in the exploration phases. Within design teams, the agreement of a code of cooperation is also important (FoundationCoalition, 2002). This may be predefined or formulated by the team itself. It is essential that team members get to know and trust one another, and feel secure and at ease. They must also be able to recognize and handle the trade-off that can exist between designers and

participating users.

A team member must be able to understand the trade-offs inside the team, and this is commonly achieved by the use of transparency. The ability to see things from the point of view of other people is important. The concept of cognitive congruence, that is, the ability to understand and express ideas and solutions at the same level of knowledge, is also important when communicating with users, stakeholders, or other team members. These team skills are closely related to two of Howard Gardner's multiple intelligences (Gardner, 1983), the so-called interpersonal and intrapersonal intelligences. Interpersonal intelligence is the ability to understand the feelings of others, observe what is going on in a group, behave in an open and social manner, and communicate with people at an appropriate level. This intelligence is closely related to cognitive congruence. Intrapersonal intelligence is the ability to look within oneself, recognize whether emotions belong to oneself or another person, and situate these emotions where they belong. The ability to exhibit transparency is closely related to this intelligence. A person with an accurate view of him or herself possesses this skill. It is therefore necessary to spend time on the facilitation of such an environment. It does not just occur because people are put together in a team, but requires that team members learn to connect with one another in an open and positive framework.

CREATIVITY

All innovation begins with creative ideas. Successful implementations of new products or services depend on a person or a team's ability to come up with a good idea in order to develop that idea beyond its initial state (Amabile, Conti, Coon, Lazenby, & Herron, 1996). The following descriptions focus on the theoretical perspectives and techniques used, completely or partly, for the proposed framework.

Creativity is a broad concept not easily defined and often based on combinations between theoretical foundations and beliefs of the user of the concept (see Pope, 2005). Here, we apply the definition presented by Amabile et al. (1996), in which “creativity is seen as the production of novel and useful ideas in any domain”. Innovation is defined as the successful implementation of creative ideas within an organization, project, or given situation. This means that the starting point for any innovation is creativity exercised by individuals and teams.

Within the literature, Torrance (Millar, 1997) stands out with his research on creativity as a process; he views each individual as creative, and this creativity can be enhanced or blocked in many ways. Torrance believes that all persons are born creative, and it is possible to use activities, methods, and motivation to maintain and even increase a person’s creativity.

When it comes to being creative in problem solving (and design can be seen as a problem solving process), research dates back to Wallas (1926), where he described a model for the process of the individual’s creative thinking. This process has four phases:

- **Preparation:** The problem is defined and a starting attempt is made to solve the problem.
- **Incubation:** The problem is left while thinking about something else and doing something else.
- **Insight:** The person experiences (often suddenly) an insight into solving the problem.
- **Verification:** The solution is tested and can be accepted by others.

Behind this process lies the idea that creativity comes from the unconscious, leading to sudden insight, and that analytic thinking and creativity are complementary.

In an organizational context, models have been developed for the creative process that focuses

systematically on the combination of techniques in order to generate ideas and techniques for analyses and selection of alternative solutions. The models have clear similarities to the Wallas model presented earlier. One such model can be seen in Leonart and Swap (1999).

Creativity Techniques

From characterizing and researching creativity, it is a step to actually enhancing and supporting creativity. There are a large number of different methods and techniques to increase and support creativity in different situations (see, for example, Higgins 1994). One of the central principles in working with creativity is the principle of divergent and convergent thinking. Divergent thinking is characterized by the generation of as many ideas as possible regarding a specific problem or theme. After some time (and a lot of ideas produced), it can be constructive to look at the ideas produced and select a few promising ones to work on. In the divergent phase, techniques such as brainstorming and picture stimulation can be used. In the convergent phase, more structure, systematic thinking, and patterns must be recognized as well as rules and prioritizations (Vidal, 2003). In the framework that follows, the focus is on techniques supporting divergent thinking, and, as such, it is relevant to consider some details on brainstorming and picture stimulation techniques.

Brainstorming is perhaps one of the most successful and often used creativity techniques. Brainstorming was introduced by Osborn (1953) as an element of creative problem solving to stimulate the generation of ideas and facilitate their expression. The technique is excellent for strengthening fluency, imagination, and communication skills (Goff, 1998) and can be used any time there is a problem or gap and within groups or with individuals. Brainstorming generates and stimulates enthusiasm as well as spontaneity and creativity (Goff, 1998) and is often used in combination with other techniques.

The picture stimulation technique (Vidal, 2003) encourages participants to think in completely different terms. The participants look at a particular problem from different and sometimes contrasting perspectives. Pictures are used to stimulate ideas and thoughts that break away from the normal way of thinking. This technique will enhance the production of original ideas and tends to break up established paradigms (Vidal, 2003).

Creating a Creative Environment

Amabile (1989; Amabile et al., 1996) has focused much of her research on the work environment and how it affects creativity. Many factors can be identified within organizations (as well as in the individual) that may inhibit and even block creativity. Therefore, it is also important to focus on the work environment when creativity is needed. There are no specific rules for setting up a creative environment, but often it is necessary to establish physical work environments that encourage participants to relax, move around, and work in other ways than they customarily do. All aspects that stimulate the brain to become creative can be included—such as pleasant surroundings, music, good food, opportunities to walk around and sit in different positions, and being able to have a general overview of the ideas produced. These principles have been brought into the design of the workshops that are described in the creative framework.

A PARTICIPATORY DESIGN AND CREATIVITY FRAMEWORK

In the following, the participatory design and creativity theories described previously will be used and explored in relation to the MAGNET project, in which the new participatory design and creativity framework was developed and applied in order to derive valid user requirements

for personal networks. The MAGNET project focuses on three case studies which together cover different societal themes relating to areas such as “health care”, “business and working life” and “the home and private sphere”. The following is based on the case study associated with health care, more specifically, on identifying situations in which personal networks will potentially be able to improve the monitoring and management of diabetes.

The collection of data in MAGNET was mainly based on qualitative methods, especially from workshops, in order to gain some insight into the information and communication patterns within the different case studies. In general, the aim of using qualitative research methods is to gain firm empirical knowledge of a social or natural phenomenon and to construct a coherent, internally consistent argument from sequences of empirical data in the form of texts, perceptions, and social acts (Denzin & Lincoln, 2000).

Within the participatory design and creativity framework, scenarios are the preferred tool for communication between users and designers. An example of another use of scenarios is the closely related IST project *MobiLife* (www.ist-mobilife.org). There is, however, no specific way in which to develop scenarios so that they represent the user’s wishes optimally and, at the same time, address the technology issues needed for the designers. Alexander and Maiden (2004) present different scenario developments for different purposes in the systems development life cycle. Here, focus is on developing a scenario construction method which can: involve users, actively, in parts of a design process; ensure that the scenarios focus on relevant information such as user requirements in different situations, user needs, relevant user interfaces, and device interaction, as well as the social implications of the use and development of technology; link user requirements and needs with technical specifications and be based on possible and expected trends in society that may influence user needs and technological possibili-

ties and developments.

The overall principle for scenario construction is the participatory design process, which focuses on interaction between users in particular situations and technicians and engineers designing future technologies and applications. Scenarios are used as the central communication tool between the users and the technical designers—and for deriving user needs and requirements. Scenarios create a possible picture of how the users anticipate themselves in the future using one or more technologies, applications, or services. The scenarios can include both aspects of wishful thinking and also situations that the users have not necessarily evaluated positively or negatively. In order to ensure that the scenarios will provide valuable input for technologies designed for the future, scenario construction focuses on providing a general overview of trends and situations that could be part of the future while at the same time freeing users from the present-day state of technology. Since the users have to think about the future, it is essential that they are able to do so. Therefore, the design methodology includes workshops based on creativity methods that encourage users to fantasize and extend their world to possible situations in the future. There are two types of workshops that together generate the information needed—the user workshop and the expert workshop. The user workshop includes users and their wishes for the future. The expert workshop, with technical developers and engineering designers as participants, works with these ideas to make sure that user needs and visions are brought to a state in which, technology-wise, they are challenging and interesting and may be discussed in terms of possibilities and limitations for the technical design.

In the following, scenarios will be defined (based on Van der Heijden 1996) as: ... *a descriptive set of plausible and possible different futures*. These futures are based on users representing different situations using a particular technology or service. It is assumed that the scenarios

focus on longer-term ICT developments (5 years or more). In order to create scenarios that are usable for the design process, the scenarios must be relevant, likely, transparent, and coherent (Godet & Roubelat, 1999).

Scenario Construction in the MAGNET Project

The application of the participatory design and creativity framework made some practical demands on how to construct the scenarios. A scenario template was applied consisting of various steps in which descriptions and trends from the present time as well as expectations for the future were mixed together into scenarios. The approach used in the MAGNET project was based primarily on Schwartz (1991) and Van der Heijden (1996) and adapted for use as a communication tool in an ICT development project. Central to this scenario template is the direct representation of users and technicians/engineers as part of the scenario construction process through the application of participatory design principles and using creativity to focus on innovative ideas. The outcome of the scenarios is a mixture of narratives that can form the basis for creating use cases (Unified Modeling Language, UML), mock-ups of low-fidelity prototypes of devices, and pictures and graphs showing technical requirements based on the user needs and requirements.

Since the personal network architecture was to be developed over the coming years, it could be expected that trends in society would have an impact on the usage and acceptance of low fidelity devices, transmission possibilities, and the architecture itself. In order to obtain insight into expected trends, a questionnaire was therefore designed and structured according to the STEEP methodology (Johnson & Scholes, 1999). STEEP is short for Society, Technology, Economy, Environment, and Policy. For each factor, a number of questions were posed to shed light on the recipi-

ents' expectations of future developments within that particular area. The questionnaire was sent to all MAGNET participants (technical as well as non-technical). The questionnaire resulted in a number of statements and expectations that not only provided support for the project idea in the anticipated direction, but also revealed some expectations that could limit the idea or change its perspective. One such example was the concern about technology use and the potential risk of increasing the number of "throw away" devices. This could lead to thinking in terms of more recyclable products and an increased focus on battery lifetime and alternative fuels. The results of the questionnaire were used as input to the workshops in the form of questions.

Workshops and Results

In the participatory design and creativity framework, the creative user workshops are an essential part of user centricity. This is where the participatory design and creativity methods and techniques are fully intertwined. A conceptual text-based scenario landscape relating the case study must be created prior to a creative user workshop. This will be the first story users are told and acts as a prototype to be developed further during the workshop before finally becoming a complete scenario landscape. The scenario landscape should be understood as a conceptual, physical paper landscape showing different situations and pictures of how users think about the future. During a workshop, the users will be given additional external cognitive prototyping aids in the form of so-called image elements consisting of pictures, words, or short sentences. They are produced for each workshop on the basis of the case study's conceptual scenario landscape, the environmental trends (identified in the questionnaire), case study context, human activities, and important high-level user requirements. Pictures and perhaps a word will typically represent the

related contexts and human activities.

At the creative user workshop for the "health care" case study, it was decided to divide the scenario landscape into four phases, each representing different life cycles and disease treatment for a diabetic person. The four phases were: babies, teenagers, adults, and elderly people. The image elements and questions used represented predefined contexts and user situations, as well as user requirements. Predefined contexts and user situations covered: shopping, education, travel, community, collaborative work, surveillance, emergency, health care, society in general, transportation, and home. Each of these contexts was represented by a number of pictures intended to stimulate the participants in remembering and discussing their needs and requirements in these situations. They covered areas such as: usability perspectives, personalization, user experience, user interface, economy, ethical issues, security, and legal issues. These requirements were presented as questions to the participants by the facilitator at different times during the workshop. The first activity in the workshop was a shared user evaluation of aids and devices available today. The purpose was to start at a level that was familiar to users so that they could feel at ease and gain confidence in contributing to the workshop. It was also a way of establishing and acknowledging a common, shared design language that was understandable for non-engineers. The predefined conceptual landscape scenario and its life cycle phases were then introduced during a fantasy journey. The fantasy journey was a short guided meditation and was used in order to stimulate the participants' creativity while thinking about the future. Construction of the life landscape scenarios took place within teams. The participants were divided into two teams, each containing users with diabetes, health care personnel, men, and women. Each team was placed around a table where image elements were placed together with plenty of prototyping materials. They were asked to physically place pictures, notes, and other

Figure 2. A landscape scenario is under construction

prototyping material on large pieces of white paper and to describe their thinking about different situations. A landscape scenario created by one of the teams is shown in Figure 2. After the workshop, all ideas presented were analyzed and used as the basis for describing four narrative user scenarios of important situations and ideas from each life cycle phase.

After the creative user workshop from the “health care” case study, the expert workshop was held. Its purpose was to discuss different technological solutions to support the visions expressed in the user scenarios. This meant that the experts had a more specific task and that the teamwork atmosphere was stimulated more than the general creativity in the first workshop. The second workshop started with a lecture about diabetics and open discussions concerning important technical aspects to consider, focusing on core activities that were interesting for the project. The experts were then divided into two teams equally representing the project’s working groups and based on specific technological expertise and company profiles. The teams were guided by the facilitators and note takers and each given two different user scenarios, which they were given

time to read. The teams started the prototyping of a conceptual system architecture based on the specific user scenarios they had been introduced to. The teams were sequentially given questions based on subsets of previously defined, high-level system requirements. This continued until all requirements had been dealt with. The teams were encouraged to add possible sub-scenarios to the user scenarios. This was facilitated by brainstorming on activities and tasks from user scenarios accompanied by suggestions for possible new activities and tasks in the given context. Finally, the teams had to select and explore the most important/interesting activities and tasks. The results from the expert workshop were conceptual personal network architectures based on user needs and requirements expressed in user scenarios. These were then used to formulate “rich” scenarios that would sum up the findings of both workshops and be a mixture of narratives, use cases, graphic network schemes, requirements specifications, and tables containing quantitative parameters.

Within the project, creative user workshops and expert workshops have been conducted for three case studies. All workshops ended with an

open informal plenum evaluation of the workshop day, and in general the participants were satisfied with the results and felt that the day had been meaningful. Starting with the creative user workshop, the comments from the users were mainly about the process and techniques that had been applied. Some comments revealed that the process was confusing in the beginning, but by the end, a structure actually appeared in the landscape scenarios. Other comments were about the fantasy journey as being really interesting and something never tried before. The fantasy journey created a special atmosphere of awareness seldom seen before in ICT project workshops or meetings. The internal evaluation among the engineering designers was also positive; all felt that the workshops had been successful and useful. However, it was clear that it was important to find the right persons for the different workshop roles (facilitators and note takers), and that these persons were well prepared. Regarding the expert workshops, participants found the workshops interesting, and no one answered the direct question as to whether they felt that some of the activities were silly or meaningless in the affirmative.

The principles and techniques from creativity theory were applied most comprehensively in the creative user workshops. The application of the creativity techniques allowed for the participants to be surprised and to establish a common basis for discussing the future ICT ideas on the same premises. The use of the image elements introduced common and even perhaps overly divergent thinking in the scenario landscape. Many ideas were expressed using only the image elements, and no other ideas for the use of new technologies came up. However, the image elements did support the participants in thinking about new technologies and ideas they were not used to considering—or were not even aware of—within this particular context.

The brainstorming techniques were easily applied, and all participants were able to use them. The participants had never tried a fantasy

journey before. The application of this technique was perhaps the most challenging aspect for them. Whether the journey actually supported their creative thinking is difficult to assess. However, the participants were asked immediately after the fantasy journey to start their work on the scenario landscape, and this process was relatively easy for most of them. The participants subsequently expressed their positive (and surprised) attitude to the fantasy journey, and it would appear that this journey did support the creativity process.

It must be mentioned that the expert workshop participants were in a sense eager to evaluate the ideas expressed at the creative workshops only from a technically demanding point of view. However, the users did not express many innovative and technically challenging ideas, which was a disappointment to the experts. On the other hand, these experts perhaps never really understood that their task was to create technological challenges based on the users' ideas, and that they were allowed to elaborate on the users' ideas and create new ideas. In this process, the lack of focus on creativity in the expert workshop may have been an important factor for its outcome. Another issue that could be raised in this connection is the lack of open-mindedness exhibited by the participants on arriving at the workshop. The expert workshop participants were clearly reluctant, and some irritation was even expressed about the exercise before it started. After the workshop, most participants were more positive, but during the process the atmosphere was more forced and less relaxed than in the creative user workshops. It may be that the results of the workshops (and the mixing of participatory design and creativity techniques) could have been even more beneficial, if it had been possible to overcome the reluctance of expert workshop participants. It must be emphasized that in the course of the expert workshop, a teamwork atmosphere was built up during the day and that in itself can be seen as a substantial achievement. Furthermore, the experts did express a growing understanding for the user visions expressed,

which in itself supported a better link between the user-centricity and the technological perceptions and visions of the project.

During the workshops, participants were able to establish a shared communication language and feeling of ownership and responsibility for the created prototypes. All users participating in the creative user workshops contributed to the process. The participants in the expert workshop communicated well together even though they had different technological competences and were very different multi-, inter-, and trans-disciplinarily. At the creative user workshops, the core human activities in each case study were illuminated through the landscape scenarios. Based on this, user scenarios were composed and passed on to the expert workshops for further elaboration and inquiry into technical issues raised. The results from the expert workshop were conceptual personal network architectures, fulfilling the user needs and requirements in the user scenarios, and new sub-scenarios, putting additional focus on specific technological development issues. These results have then been used as a basis for deriving use cases and a final requirements specification.

The final applications and services have not been developed yet, so it has not been possible to evaluate whether the project results will be ultimately usable and make a difference. Internally in the project, however, the results based on the design framework have been used as a basis for deriving system requirements in other parts of the project. Future work will focus on how to take the participatory design and creativity approach into usability evaluations of the applications to be developed. When dealing with mobile ICT usability testing, the traditional highly controlled laboratory user testing has too many drawbacks not only in relation to real human behavior but also to changes in context. New valuable insights may therefore be obtained from exploring a complementary but very different approach.

CONCLUSIONS AND DISCUSSIONS

In this chapter, a new participatory design and creativity framework has been presented and described through a project case study within the area of mobile ICT development. The framework is based on methods and techniques from participatory design and creativity and consists of scenario construction carried out through workshops. The set-up of successive workshops has been useful in regard of generating ideas and building a “bridge” between the user focus and the technical focus represented in the project. In particular, the expert workshops have played a role in building up the team atmosphere that is necessary for major ICT projects.

The participatory design and creativity framework has to be evaluated in terms of its contribution to the real world—and the MAGNET project. The theoretical base constitutes a mixture of techniques and principles from different fields, and it is only in its practical application that it can be really tested. Three primary areas reveal something about performance and how well the framework worked in a real application. These are: workshop participants’ feedback, the experience from the mix of techniques that was used in the MAGNET project, and the extent to which the results have been useful for the project in respect of the implementation of ideas. The user and expert evaluations stated clearly that the participants felt that they had established a shared design language in the workshops. The internal project evaluation and use have shown that a transition medium between the successive workshops and the system requirements specification has been established. It is not yet possible to measure the level to which the methodology has facilitated the generation of innovative design ideas. However, both users and engineering designers found the participatory design and creativity methods and techniques useful and meaningful, which indicates that they did work together stimulating each other’s approach. Participatory design, teamwork,

and creativity have many things in common, and during the workshops, it was often very difficult to say whether participatory design or creativity was the dominating approach as a combination of both blended together in the applied techniques.

The research conducted within the MAGNET project showed that creative techniques such as brainstorming and picture stimulation were useful, easy to apply, and well received by the workshop participants. The techniques worked in two almost contradictory ways: as a source of stimulation and, at the same time, a tool for structuring thoughts and ideas. The brainstorming that was used to support fluency and volume of ideas worked both in the discussion of today's use of technology and in the construction of future landscape scenarios. However, the brainstorming session could easily have turned out to provide overly general ideas that would not necessarily be useful for the project. The image elements were used both to stimulate the participants into thinking in particular directions and to generate new ideas based on the pictures and elaborating on them.

The methods used could not have been applied without proper input from the team facilitators and note takers to structure the overall process. In the user workshops, the note takers were allowed to take a more active role and support the creation of ideas in the teams—without being dominating in any way. This clearly also stimulated the participants in thinking about future technologies and situations where technology could support them. In all workshops, it has been clear that the incubation phase was an important factor. The breaks during the workshops functioned as relaxing phases in which the participants on one hand relaxed from the “job” they were asked to do, and on the other hand “working” (perhaps unconsciously) with ideas, sometimes producing new ideas when returning from the breaks.

There is no doubt that the proper evaluation of the new design framework ought to take place repeating the framework in different projects and with different participants. This evaluation is

based on user and expert workshops held as part of the same project. However, a final evaluation of the framework cannot be performed before the project has concluded, and the results have been implemented. Then it will be possible to see the value of the ideas and the user interaction that were generated in the project design phase. Applications have been produced with a direct link to the users, since they also contributed to testing these. By looking at this whole process, we could learn something more about the value of using participatory design and the creativity techniques. However, the need for envisioning a new personal network concept together with users has clearly indicated a necessity for incorporating creativity techniques more explicitly in more traditional participatory design methods.

Using participatory design principles is challenging for all ICT projects in the sense that the engineering designers do not necessarily believe that this kind of user involvement is a good idea. However, the application of participatory design principles and creativity techniques in MAGNET has provided an understanding of new aspects that has been acknowledged by some of the engineering designers. The new participatory design and creativity framework presented here addresses many valuable aspects of technology project development. One often-overlooked aspect is the need for teamwork skills to establish a team spirit atmosphere. The experience within the MAGNET context is that the framework ideas support the development of teamwork skills, and perhaps that it in itself will increase the possibility of successful future development projects.

ACKNOWLEDGMENTS

Acknowledgments should be given to all of the user and MAGNET expert participants in the workshops, especially to the diabetic persons and staff from Aalborg University. The research was carried out within the IST MAGNET project, FP6-IST-IP-507102, www.ist-magnet.org.

Chapter 2.9

ICT and Developing Social Capital

Kate Sutcliffe

Gulf Savannah Development Inc., Australia

INTRODUCTION

Regional Overview

The Gulf Savannah region (Invest Australia and Gulf Savannah Development, 2003) of north Queensland covers 186,000 square kilometers, an area 80% the size of Victoria. The population of 8,000 live in small towns or Aboriginal communities dispersed across the region and on the large cattle stations and mine sites.

Traditionally, the region has relied on cattle, mining, and fishing for its economic base. Tourism is now fast becoming the leading industry for the area, with around 60,000 plus travelers a year visiting the region. While the basis for this assessment is partly anecdotal and gleaned from local government calculations, a recent study (Greiner et al., 2004) arrives at a figure of around 22,000 visitors per annum for two towns (Karumba and Normanton) in one Shire (Carpentaria). The Savannah Way, a themed adventure-drive linking Cairns on the eastern seaboard with Broome on the Indian Ocean traverses the Gulf Savannah region and was recently launched by the federal

Minister for Small Business and Tourism, the Hon. Joe Hockey MP. This destination is now attracting an increased visitation, estimated to be around 14% (Sutcliffe & Olsen, 2004) and provides potential niche enterprise opportunities for small business in the communities.

The beef road network developed by the federal government of Prime Minister Bob Menzies during the 1950s provides a skeletal transport framework for freight, stock, and people, but many sections are rendered impassible during the annual wet season. The road from the east coast to the largest town, Normanton on the Gulf of Carpentaria, a distance of some 700 km, was only sealed in late 2000. The western Gulf, however, is still isolated in the wet season, with the unsealed roads becoming impassible. In the past, long distances and poor roads inhibited travel across the region, and in many communities, vehicle ownership remains low, with more than 20% of dwellings having no vehicle (RIRDC, 2004). Air services link the major Gulf centres with the east coast and the major mining town of Mt. Isa. Until 2002, the cost of air travel was prohibitive and beyond the means of most residents, however,

the route is now subsidised by the Queensland Government in order to make the service more accessible for the community.

Before 2001/2002, Gulf telecommunications relied on antiquated and difficult-to-maintain land lines that were frequently damaged by fire and failed in inclement weather. Power supplies were unreliable, with brownouts a common occurrence, leading to equipment damage and failures. Use of ICT was limited, and few residents owned or could use a computer. In 2001, areas of the Gulf were reported as having the lowest proportion of people using computers at home, with less than 5% indicating usage (RIRDC, 2004). Historically, the limited transport infrastructure and the lack of reliable telecommunications and power services presented major barriers to development of the regional economy. Small business, local government, and essential services survived year to year with little change in ownership or business operations.

Inadequate communication, isolation during the wet season, and the long distances to travel over poor roads led the region to be regarded as a frontier outpost by governments of all levels and political hues for decades. To an extent, this isolation has shaped the way the communities regard governments and bureaucracies, creating a spirit of self-reliance and a measure of cynicism in response to government overtures, a factor to be considered for an e-democracy program in the region.

Demographics and Socioeconomic Features

The socioeconomic condition of the Gulf ranks it as one of the more disadvantaged regions in Australia. As reported in the *Social Atlas of Rural and Regional Australia* (RIRDC, 2004), incomes are lower than the state average, there is little secondary industry, and there is a dearth of investment capital. Home ownership is 20% below the nonmetropolitan average, and there is a

heavy reliance on public housing. Unemployment is high, with a dependence on the Community Development Employment Program and on government funding, grants, and subsidies. Recent data indicate the number of people on income support and pensions exceeds wage earners in several centres (ABS, National Regional Profile, 2004). Education standards are below par with those of urban areas, with schooling to Grade 10 available in just two centres. Due to the remoteness of the region, locally delivered training is difficult to access. Accommodation for rental is in short supply, with privately owned dwellings rented being more than 20% below the nonmetropolitan average (RIRDC, 2004), which is a hindrance to business development and expansion and results in overcrowding in some areas.

Community Social Capital

Gulf Savannah Development presented a detailed evaluation of the social capital of the Gulf region at the 2003 SEGRA (Sustainable Economic Growth for Regional Australia) conference (Sutcliffe et al., 2003). Isolated for decades and with a small population, informal networks between family and neighbours were vital for coexistence and support in times of need. As a result, the bonding social capital that developed between families and neighbours of the small communities is very strong. This has been further reinforced by the lack of fluidity in population composition, with new arrivals largely engaged to carry out specialist roles as teachers, police, and local government executives. This social environment gives strength to individuals within the community but is not necessarily conducive to acceptance of change or innovation. Newcomers not privy to the body of shared knowledge and experience feel like outsiders, a fact raised by participants at a series of capacity-building workshops delivered across the region by GSD during 2003.

The bridging social capital or the links to and between organisations and groups tends to reflect

the close bonding within the community. Each centre supports a number of small organisations comprising groups of like-minded people, often with the same key members. A common complaint is that the same people attend all the meetings and do all the work.

On the other hand, the linking social capital, the hierarchical and institutional networks from the region to external agencies, institutions, and bodies of influence in areas of higher education, professional groups, commerce, and industry require strengthening to broaden the sources of information flow to the region.

The implications for governance, regional competitive advantage, and business development were clear. To address this imbalance, GSD turned to the use of ICT as a tool to encourage communities and businesses to develop networks outside the region, to interact with governments and organisations with a view to generating knowledge of and trust in institutions beyond their immediate environs.

Existing Regional Governance and ICT

The level of trust within a community can be an indicator of the social capital of that community, whether trust is viewed as an element of social capital or as an outcome of social capital (Productivity Commission, 2003). All tiers of government have a role to play in building the social capital of a region, a key aspect of which is to build trust and confidence in governance at all levels. In the Gulf, Commonwealth and state agencies do not have permanent offices, apart from police, courts, health, and education personnel, and they are essentially outsiders looking in. For the most part, the local population sees them that way, and interaction between residents and the higher levels of government is sporadic.

Governance is essentially delivered by the five Gulf region Shire Councils. Populations are small, ranging between 350 and 1,800 people, resulting

in a low rates base and limited resources, which makes governance and community development over vast areas difficult.

Traditionally, Council activity concentrated on the three Rs—roads, rates, and rubbish. These functions are being added to as Councils play an increasing regulatory role in planning, public health, and the environment, and in developing management responsibilities in the whole area of community and social development, such as health, alcohol and drugs, community safety, and transport infrastructure (House of Representatives, 2003).

As a result, increasingly, the Councils in the region are being called upon to deal with high-level interaction with State and Commonwealth Governments, private enterprise, and the broader community. This has dramatically raised the performance bar for elected representatives and local government employees.

The Gulf local governments have reasonably sophisticated and well-managed IT communication systems for internal communications and external communications with agencies. However, e-communication between the Councils and the wider Gulf community are not advanced, with reliance on more traditional means of contact, such as newspapers and public fliers.

Currently, local government use of ICT to link with the community involves basic information provision but does not extend to development of e-democracy or any form of citizen involvement, such as surveys, data gathering, etc. It is an untapped resource for the ongoing development of social capital in the future.

WINDS OF CHANGE

Post 2000: What a Difference a Road Makes

The final sealing of the 700 kilometres of road between the Gulf region and the east coast cre-

ated a reliable, almost all-weather, physical link between the Gulf communities and the major centres of Cairns and Townsville, and that had a profound impact on visitation to the area. Data from the Main Roads Department road counters between two of the northern Gulf towns indicated an increase of 70% usage in the first few months. The Gulf immediately became more accessible; there were increasing numbers of travelers, with visitation extending over a longer period each ensuing year. The psychological barrier to traveling to the region was steadily being dismantled.

Residents were now readily able to travel out of the region, and business and tradespeople from outside the area could deliver services faster and with less wear and tear on vehicles. This had an impact on local businesses, forcing them to be more competitive. With the greater mobility of local residents, local businesses found themselves competing with their counterparts in larger provincial towns. This presents a challenge in any region, and those unwilling to face it generally vacate the field and leave opportunities for newcomers.

Telecommunications Revolution: Networking the Nation

When the Australian Government sold almost 50% of its stake in the national carrier Telstra, a proportion of the proceeds was channeled into a program to deliver more equitable telecommunications services to remote, rural areas. This program, Networking the Nation (NtN), was a catalyst for change. In 2001/2002, Gulf Savannah Development applied to NtN for funding to deliver mobile phone technology to the five key towns across the region. Additionally, for those people outside the limits of mobile phone coverage, subsidies were available for satellite phones and through a one-off offer made by Telstra and IBM, people could purchase computers and connect to broadband at a very low cost. Over 170 properties in the region took up this offer. The satellite phone subsidy will be available until 2007.

The Queensland Government also embarked in previous years on a program of community engagement, establishing regional community forums for residents along the eastern seaboard. In 2001, GSD sought to use its networks to develop a similar forum, a Gulf E-Forum, based on the Internet as a means of communication. GSD used funding available under the Queensland Community Skills Development Program to design an e-democracy project, which involved creation of an interactive Web portal (www.the-gulf.info) and basic training for Gulf residents in ICT, Internet, and e-mail use.

One of the key findings from the project was the presence of a significant number of people with no ICT access, who were not computer literate and lacked keyboard skills. This digital divide needed to be addressed. To move toward meeting this challenge, GSD is delivering a “Technology Survival Skills” program funded by the Queensland Government, which encourages those people without a computer to join small social groups to learn basic skills in ICT technology. This will enable them to access the public Internet services in each town.

IMPACTS AND OUTCOMES

Community Engagement

Improved communication is overcoming the tyranny of distance and counteracting isolation in business, governance, and social life, providing avenues for expanding networks and broadening the knowledge base for individuals and communities. This changes the dynamics of communities and challenges established views and platforms.

In terms of the regional economy, businesses have greater confidence to compete on a more level footing in a wider global market, with distance no longer being the huge barrier to access knowledge, trading, and markets. Likewise, governments can

more readily access residents and organisations, which were previously too far away to contact or interact with on a regular basis.

In the short term, we are starting to see citizen engagement at a basic level—increased use of e-mail, involvement in business forums, posting articles and calendar events, and responding to news items on the Gulf Web portal. There has been limited community input with regard to government service delivery and service requirements, e.g., in areas of health and telecommunications. Agencies have posted news items about future visits and services, and there has been a positive response to these. However, at a more advanced level of being able to influence policy, the uptake is relatively slow. For example, a survey on the Web site seeking views on the sale of the remainder of national telecommunications carrier, Telstra, a hot topic in the national media, attracted minimal response.

Businesses are using e-mail and the Web at a more sophisticated level and more frequently, with e-commerce becoming the rule rather than the exception. E-marketing and packaging of tours and taking bookings over the Web are all now commonplace, and many Gulf businesses have their own Web sites.

Changes to Social Capital Networks

In the relatively short term, we have seen practical changes in the way people communicate, a willingness to challenge the status quo and seek better services, especially in ICT. Businesses and residents are seeing the value in networking and linking to people, regions, and organisations outside their towns and shires.

Networks are developing slowly, such as the Savannah Way Visitor Information Centre (VIC) Cluster, which will provide a link for the Information Centres and tourism businesses across the Gulf region and into the Northern Territory and Western Australia. Evidence of change includes the following:

- Efficiency in business through small business banking, faster ordering, and bookings
- Enhanced competitiveness in business, as tourists and travelers have access to local operators' information on the Web
- Improved flow of information, as increased use of e-mail cuts costs of operations and overcomes slow mail delivery
- Interaction with government and agencies has been enhanced as the flow of information from the region has increased
- Improved access to global information with many businesses now trading on the Internet

FUTURE ACTIONS AND OBJECTIVES

Future activities and trends will see the region building on the changes taking place:

- Continuation of development of the concept of a community e-forum and e-governance for the region through the Gulf Web portal (www.the-gulf.info) and surveys and chat rooms.
- Identification and support for local champions to act in a mentoring role and ongoing skills enhancement to help bridge the digital divide and at the same time ensure that the traditional forms of communication are retained.
- Increased involvement of local elected representatives in community forums, more citizen engagement and online debate, and encouragement of their use of ICT to disseminate their views on local issues
- Continuing to build the social and economic capital of the region.
- Linking the e-forum to regional development processes, business development, and citizens' futures to ensure ongoing

and sustainable capacity building—e.g., encouraging Gulf residents to engage with the Queensland Government’s “Action Tracker” for the Gulf Regional Development Plan (GRDP). The Action Tracker is linked to the Gulf Web portal and enables any person to access the Regional Plan and check on the extent of work undertaken by government agencies to deliver the planning strategies.

SUMMARY

The work accomplished to date identified an existing digital divide between those with computers and those unlikely to have ready access to ICT. As we progress down the path of e-governance and e-commerce, the need to build the capacity of all residents to access the new technology is paramount if we are to ensure equality of access in a democratic society.

Improvements in ICT infrastructure teamed with the delivery of training and capacity-building programs to encourage people to maximise benefits from that infrastructure are paying dividends across the region. From our observation, Gulf residents are using ICT to a far greater extent to access knowledge and relay information and comments on a range of issues. Communities and businesses are expressing a preference to interact with all levels of government and conduct business by e-mail and Internet rather than by traditional telephone or postal services.

The social capital of communities will transform as residents become increasingly confident in the global environment and have the knowledge and skills base to deal with external agencies, governments, and institutions. This is a process of empowerment and a positive influence for the region, setting the community on the road to e-governance, e-commerce, and an increasing capacity to be innovative and have the assurance to build community enterprises.

ICT is enabling communities to be more competitive, broadening horizons, contributing to community debate beyond their immediate region and, consequently, playing a role on a far bigger stage.

KEY TERMS

Capacity Building: Building the skills, commitment, and confidence of community members to develop networks to influence what happens around them in their environment and give them the capability to contribute to shaping and planning their community's future.

Citizen Engagement: A two-way process through which a government or agency can develop an understanding of citizens' concerns and needs and respond to them, conversely enabling citizens to develop an appreciation of how they can positively contribute to and influence the future of their community and region.

Competitive Advantage: Defines a place's or region's attribute(s) with the potential to place it in a leading position in any field (generally used with regard to commercial or economic activity), such as a natural or environmental icon that may give a region a competitive advantage in terms of tourism, or a mineral deposit in terms of mining.

A region or place needs to identify and capitalise on distinctive assets and capacities to realise its competitive advantage.

Digital Divide: The gap created between those using ICT and those who do not, for a range of reasons, including a lack of access to ICT as a result of social or economic factors; lack of technical and keyboard skills to use ICT; lack of basic skills or computer literacy skills to understand the requirements and interpret the information of ICT.

E-Democracy: A qualitative term to describe the use of ICT as a medium in which to engage the community to participate in and contribute to the governance process generally, and to facilitate and enhance the capability of a citizen to have a say in the impact of governance on themselves and their communities.

E-Governance: A term to describe the delivery of the governance process using ICT rather than conventional and traditional means.

Regional E-Forum: A community and citizen engagement process linking government agencies and community, using ICT as the means of communication, and extending across and involving a region.

Chapter 2.10

A Taxonomy of Stakeholders: Human Roles in System Development

Ian F. Alexander

Scenario Plus, London, UK

ABSTRACT

Systems engineers have often paid too little attention to the nature of the so-called “users” of products under development. These are better called stakeholders, as many roles are involved, and few of those are in direct contact with the developed products. A simple and robust conceptual framework for classifying development stakeholders — a taxonomy — is proposed. The taxonomy is product centric, with concentric “circles” denoting broad categories of stakeholders. Within these, generic “slots” describe typical classes of stakeholders; these are subdivided into “roles,” which are expected to vary at least in name with the domain. Examples are given, and a popular template is reanalysed using the framework. The taxonomy has immediate value in identifying and validating stakeholder roles in requirements elicitation, helping to ensure that key viewpoints are not missed, and hence reducing the risk of instability and failure during development.

INTRODUCTION

Motivation

The structure of stakeholder roles and their relationships such as surrogacy have been very little investigated in the requirements world (though much more extensively in the political, ethical, and information systems worlds — one reason for believing that an attempt at an interdisciplinary look at stakeholders may be worthwhile). Requirements work almost inevitably involves dealing with stakeholders of widely varying kinds, and hence demands a commensurately wide range of elicitation techniques. The first step in identifying which techniques should be applied is therefore to identify the stakeholder composition for a new project, and this in turn demands a suitable taxonomy of stakeholders.

Too many projects focus their attention too closely on the product — perhaps especially when that is software — to the exclusion of non-

operational roles, and often even of secondary operational roles such as maintenance. I suspect this is due to “inside-out thinking” where the system is seen as important, and the user as secondary. Such thinking is a hangover from the past. When I was at university, an IBM 360 mainframe occupied the only air-conditioned tower on the campus. Students were permitted to approach only the card reader with a deck of punched cards; only trained operators were allowed upstairs to see the computer itself. This was truly a priestly hierarchy (in Greek, *hieros* is holy, *arches* is ruler) of operator roles. As Christopher Locke writes, “Even the word ‘users’ is an artefact of the [command-and-control] mentality” (Levine, Locke, Searls, & Weinberger, 2000). It is time to move on from treating “the user as a computer peripheral” (in Julian Hilton’s words). The system is made for man, not man for the system.

Many industrial development problems seem in practice to be caused not so much by a failure to write requirements, as by a failure to perceive that specific stakeholders’ viewpoints are relevant. That failure causes whole groups of requirements, typically those related to scenarios involving the missing stakeholders, to be missed.

A similarly unhappy result is obtained when one stakeholder, for example, a software developer, assumes one scope for a product, while another stakeholder, for example, a purchaser, assumes another. For instance, when a developer assumes that it will be sufficient to design, code, and test a piece of software, but the purchaser hopes to have everything set up and that the operators are trained, then the points of view of the installer, the trainer, and to some extent that of the operators have not been adequately considered and made explicit. Legal disputes and financial losses are then likely.

It seems likely that stakeholder composition is a good predictor of project risk; hence, it should be cost effective to characterize projects at their initiation according to their likely stakeholder impact (and to other variables, such as safety

relatedness, technological innovation, similarity to previous projects, and so on).

In addition, maintaining a model of stakeholders throughout a development allows changes in stakeholder composition to be modeled explicitly, leading to appropriate changes in requirements.

Stakeholder surrogacy has powerful and paradoxical connotations in requirements engineering. It is almost a dogma that projects should seek out ever-closer dialogue with stakeholders — consider the current fashion for integrated project teams, facilitated workshops, rapid prototyping, agile development with user stories, and so forth. Yet all the time, the obvious truth is glossed over: that it is remarkably rare to be able to talk to many stakeholders in the flesh. Every requirements engineer knows that the basic answer to the client organization’s boss who says, “I know everything that happens in my department; ask me,” is, “Well, that’s fine, but can I see if the people on the shop floor know of any small issues?” To put it more formally, standardized procedures, no matter how critical¹ and how carefully defined in writing, are always modified when operationalized “on the shop floor.” Therefore, it is essential to talk to stakeholders directly — without intermediaries — to find out what actually happens. Yet, requirements engineers are themselves intermediaries! Stakeholder surrogacy is accordingly discussed at some length below.

Worse, many kinds of stakeholders are inaccessible: They may be distant geographically, separated by contractual and procedural barriers, hidden within organizations (with cultural barriers), simply unaffordably expensive to contact given scarce project time and resources, or not yet in existence (for future products).

The naive “go and talk to the users” — whoever may be meant by that phrase — is therefore far from helpful as advice. This paper considers what we mean by stakeholder roles in development projects, and it offers both a theoretical framework for classifying them and some practical suggestions for making use of that knowledge.

A Taxonomy of Stakeholders

It may be that the approach can be applied outside system development, for example, to model political and business stakeholder structures, but that is beyond our scope.

Structure

The remainder of this paper is structured into sections as follows.

- Research Review
- The Proposed Taxonomy
- Applying the Taxonomy in Practice
- Discussion: Features and Limitations of the Taxonomy
- Conclusion

RESEARCH REVIEW

The focus of this paper is on the place of stakeholder analysis in system development, and perhaps especially in requirements elicitation. However, the subject of stakeholders is far wider than that. This section therefore attempts to set the current work in its system-engineering context, and briefly also in the wider onion circles of information systems research and business studies. These literatures are voluminous, so references are confined to key papers on each topic.

This research review section is organized by topic as follows.

- Stakeholder Analysis
- Onion Models
- Taxonomies and Hierarchies
- Goals and Viewpoints
- Human Aspects of System Development
- Surrogacy

The logic of this should become apparent, but in essence, the information systems and other literatures on stakeholders are briefly introduced; the background to the paper's use of onion models and a taxonomy of stakeholders is sketched; existing

work related to stakeholder classification in the requirements engineering and usability fields is examined; and finally, since stakeholder surrogacy seems to be significant in system development, research on surrogacy is explored.

Stakeholder Analysis

Mason and Mitroff (1981) helped to introduce stakeholder analysis to business practice. Their definition is, "Stakeholders are all those claimants inside and outside the firm who have a vested interest in the problem and its solution," (p. 43) and, "[They] are the concrete entities that affect and in turn are affected by a policy" (p. 95). They suggested ways of identifying stakeholders, including considering standard demographic groups (age, sex, etc.) for relevance, asking people who they consider to be the key stakeholders, and studying accounts of ethnographic fieldwork to discover who seems to have a valid interest.

An authoritative account of business stakeholders can be found in Donaldson and Preston (1995). The paper describes a corporation "as a constellation of co-operative and competitive interests possessing intrinsic value" (p. 66). It states that the stakeholder theory is descriptive of the corporation, instrumental in helping people to examine stakeholder management practices, normative in establishing that stakeholders deserve attention, and managerial in recommending attitudes, structures, and practices. However, it considers the corporation as the system of interest, and does not look at software or product development.

Pouloudi (1999) examines the concept of stakeholder and its use in information systems development. The paper is an excellent introduction to the extensive information systems literature on stakeholders, and it analyses some of the weaknesses of the concept (including it being "almost a cliché," quoting from D. Willets). For our purposes here, one key point is that it does not make sense to treat human and nonhuman actors symmetri-

cally: They are simply different. Pouloudi notes the discomfort of Vidgen and McMaster “about assigning anthropomorphic properties to nonhuman resources,” and states that

I do not subscribe to the symmetrical treatment of humans and non-humans or the treatment of non-humans as stakeholders, although it is interesting and indeed necessary to consider the way in which non-humans — including...information systems — “inscribe, represent, and speak for” the interests of stakeholders. (p. 13)

In the taxonomy presented here, all stakeholders are human; interfacing systems are represented by humans responsible for them, that is, in accordance with Pouloudi’s approach. Pouloudi has also studied stakeholder identification, for example, in a medical context (Pouloudi & Whitley, 1997). This is a very different context from that of system development, but the paper is of interest for its clear thinking and practical approach.

Sharp, Finkelstein, and Galal (1999) suggested a simple recursive procedure, starting from an initial contact person, and asking each interviewed person who might be worth speaking to. The procedure terminates when no new names arise or when the new names are found not to be relevant. The paper described a simple method for identifying stakeholders starting from the initial point of contact (which might typically be the project sponsor). This is one of the few papers to address the issue directly, and its suggestion is sensible. However it is not a substitute for a template (based on a taxonomy); the method could be time consuming and it is likely to reveal only the stakeholders that everybody knows already. To be fair, the method of asking each interviewee who else might be relevant is almost an obvious good practice during requirements elicitation. The paper also pointed out that stakeholder classes (slots) should be characterized by their relationships to the system, to other stakeholders, and by the priority to be given to each stakeholder’s

view. These dimensions are used here, though they are rough guides at best (along with the time that each slot might be relevant).

Robertson and Robertson (1999) distinguish clients, customers, and other stakeholders including subject-matter experts, marketing people, product managers, and so on, and attempts to prioritize them: “the principal stakeholders are the users, clients, and customers” (p. 35). However, the general effect is a flat, unstructured list of many interested parties. The Volere template (by the same authors) similarly proposes a flat list of roles as one axis of a matrix to organize which kind of stakeholder to consult for which “class of knowledge” (Volere, 2004). The taxonomy proposed in this paper offers a richer and more-explanatory structure, and suggests the significance of key roles and their interactions.

The work by Alexander and Stevens (2002) contains a chapter on identifying stakeholders (pp. 19-26). It also distinguishes “users” from clients, suppliers, managers “who are concerned for the system to succeed” (and by implication, other people with that concern), and regulators, and it briefly discusses the role of people in the development organization (p. 7). The variety of roles is illustrated with a cartoon of stakeholders in a space telescope project (p. 20), which shows an astronaut carrying out maintenance, a ground station engineer operating the spacecraft, an astronomer discussing the data produced by the telescope, and a politician gaining political benefit from the system (Figure 1). The discussion of these roles makes clear that these represent different viewpoints, not necessarily conflicting. This was a sensible and pragmatic position, but the proposed taxonomy looks far more deeply at the structure and possible conflicts between stakeholders.

There is much pragmatic wisdom in dealing with stakeholders in Peter Checkland’s many writings, for example, Checkland and Scholes (1990). He does not write on the whole focus on the development of products or services, and

A Taxonomy of Stakeholders

Figure 1. Space telescope stakeholders (Alexander & Stevens, 2002)

indeed he seems to believe that that is the easy part of the problem! For example, he says

It now seems that, in the future, the computer project managed through a “project life cycle” will increasingly become the occasional special case in which some uncontentious and relatively mechanical administrative procedures are computerized. Where perceptions and meanings, and hence tasks, are more problematical, the “project” approach needs to be complemented by a process for the continuous rethinking of organizational tasks and processes... (Checkland & Scholes, 1990, p. 312)

While we may readily agree with Checkland’s emphasis on process rather than project, and take his advice on (human) “perceptions and meanings” and “rethinking” as a hint to keep up to date with our stakeholder analysis, we do not think that software only implements uncontentious mechanical procedures. Indeed, major products such as enterprise resource planning tools can have a powerful and sometimes deleterious impact on organizations (note that we consider the customization of such COTS tools for an organization to be a kind of development project).

Another worker — both researcher and practitioner — who helped to pioneer sociotechnical design is Enid Mumford. In her long career and her many writings (e.g., Mumford, 1996), she emphasized a humanistic and ethical approach to the people whose work was affected by process redesign and automation. She talks more often about specific people, individuals, clerks, groups, staff, and so on, rather than using generalities like stakeholders. However, much of her work was precisely about paying more attention to the different groups of people involved in or affected by a project. For example,

At these meetings a large number of organizational problems emerged and she [Mumford] suggested to the clerks that they should think about how these might be solved.

She then forgot about this request and fed-back the results of the survey to the members of the technical design group. They subsequently designed what they thought was an excellent socio-technical system, called a meeting of all the clerks, described their proposed system and sat back and waited for the applause. To their astonishment there was silence. Then one of the senior clerks stood up... He then produced an excellent blue-print for a work structure that solved most of the office’s efficiency and job satisfaction problems.

...The author learnt a very important lesson from this experience... This is never to underestimate a group’s abilities. (Mumford, 1996, p. 87)

Onion Models

Peer: (Pulls off several layers at once.)

*What an enormous number of swathings!
Isn’t the kernel soon coming to light?*

(Pulls the whole onion to pieces.)

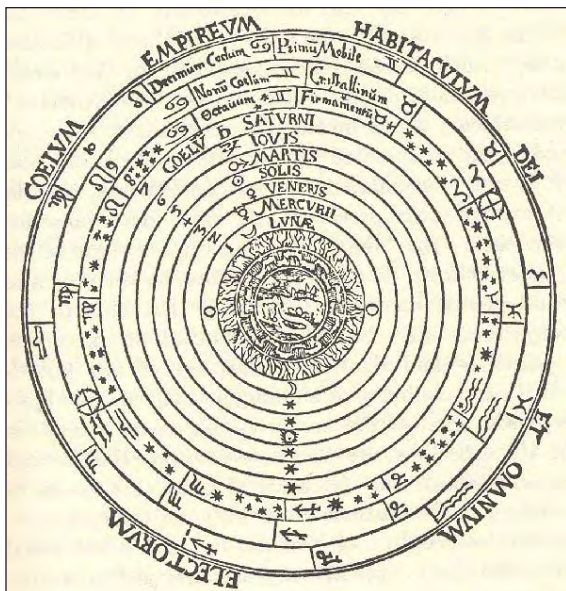

*I'm blest if it is! To the innermost centre, it's nothing but swathings-each smaller and smaller.
- Nature is witty!*

(Throws the fragments away.)

Peer Gynt, Act 5, Scene 5, by Henrik Ibsen (1867/1992)

Onion models have been used for centuries to indicate hierarchical spheres of influence. Alexandre Koyré's wonderful *From the Closed World to the Infinite Universe* (Koyré, 1957/1968) uses the beautiful 11-layered onion diagram of Peter Apian's 1539 *Cosmographia*, a pre-Copernican model of the universe, on its cover (Figure 2). Apian has the imperfect and changeable Earth at the centre and *Coelum Empireum Habitaculum Dei et Omnium Electorum* (i.e., the Empyrean heavens, the dwelling place of God and all the elect) as the outermost, perfectly unchangeable layer.

Figure 2. Apian's onion diagram of the universe (Koyré, 1957/1968)

This implied a fixed frame of reference for each class of beings in the Great Chain (Lovejoy, 1936/1990), very far from the dynamic situation-dependent stakeholder webs of Coakes and Elliman (1999) who describe the role of stakeholders in managing change. Their term, stakeholder webs, has entered popular currency, perhaps by association with fashionable terms like World Wide Web and semantic web, and may have done much to get people thinking about stakeholders in software development.

Their webs are drawn as cobwebs with radial lines and concentric ellipses. This makes them look something like onion models, but,

The importance of the web is not in the exact labelling of sectors and boundaries but in seeing the web as a continuum. The sectors and labels shown in [a figure] are not a prescriptive or a priori model for all webs but...the groupings that emerged from the case study. (p. 9)

Thus, the Coakes and Elliman stakeholder web is expected to be different for each examined system: There is no recognizable taxonomic pattern common to different developments. Somewhat in contradiction to this, Figure 1 of their paper illustrates the choice of the system boundary, based on Midgley (1992), which shows concentric circles labeled "Technical System Boundary," "Organizational Boundary" outside that, and finally "Human or Total System Boundary" on the outside (Figure 6). Within the technical system boundary are three items linked by bidirectional arrows: computer information system, whose boundary is labeled "Automation Boundary," direct system users, and system designers. Within the organizational boundary is a text label "Executive and wider Management, Other Divisions and business activities." Within the human or total system boundary is a text label "Shareholders, Clients, Government, and other Stakeholders, beyond the organizational boundary" (p. 6).

A Taxonomy of Stakeholders

Figure 3. A stakeholder web (Coakes & Elliman, 1999)

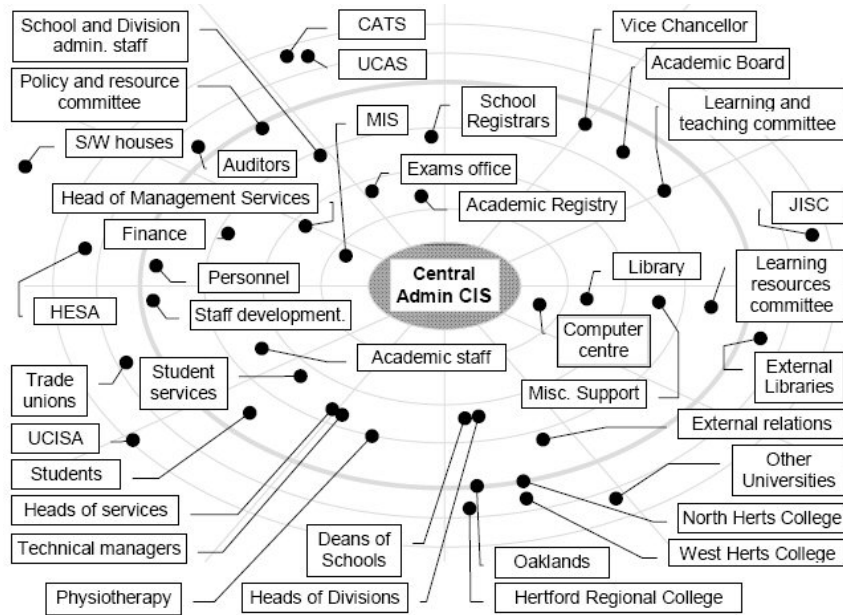

Figure 4. Midgley's onion (Coakes & Elliman, 1999)

This is clearly a rudimentary onion model. We can make the following assignments.

- computer information system is (an example of) our kit or product
- direct system users are our normal operators (but see criticism of the term “users” below)
- System designers are our developers, who seem oddly placed within the technical system, given that they may have no part in the system’s daily operations. It looks as if the operational boundary is here confounded with the boundary of all matters engineering and technical. The figure is criticized by both Midgley and Coakes and Elliman, who argue that the “critical setting of the system boundary” needs to be “determined by examining the viewpoints of stakeholder groups...rather than technical issues” (p. 6). However, the automation boundary remains important as a contractual and developmental reality; while the figure is clearly defective as regards to the technical system boundary, it can be corrected by removing the system designers from it, and inserting any other types of operators that may be needed, as is argued below.
- Similarly, executives and management may loosely correspond to our functional, financial, or political beneficiaries, but there is no reason why the organizational boundary should fit neatly within the total system boundary if this is taken to mean our wider environment with respect to a specific kit or product: Some parts of the organization’s management may be involved, others not. Simply because some deadwood paper-pushers are within the organization does not make them valid stakeholders: That way madness lies.
- Again, shareholders, clients, and government can reasonably be equated with our financial beneficiaries, purchaser (perhaps client is a

slippery term), and political beneficiary (or perhaps regulator, depending on the situation).

Coakes and Elliman (1999) are probably right, therefore, to reject the Midgley (1992) onion model, but a more-carefully considered model may overcome their objections. Designers and developers do not belong inside the technical system boundary — in any case, since it contains people, it must be sociotechnical. The organizational boundary is the wrong one to choose (unless, of course, it is the organization rather than a product or development which is your focus), and the human or total system boundary does seem rather vague. On the other hand, there is usually a containing system (in our terms, see “Structure of the Onion Model”) that makes use of the results or outputs of the (sociotechnical) system that we are developing — otherwise, why would anyone pay to develop it? — and there are indeed stakeholders such as shareholders and the government who may have an interest in aspects of the system, while not themselves playing any part in its development or operation. The problem with a stakeholder web formed afresh for each new system is that it offers little guidance, whereas the engineers working on yet another telemetry system (say) are immediately aware that what they are doing is very similar to what they did on previous projects. Coakes and Elliman throw out the baby with the bathwater.

A modern onion model related to stakeholders can be found in Donaldson and Preston (1995, p. 74). However, their model’s circles, starting from the centre, are the normative, instrumental, and descriptive aspects of stakeholder theory (Figure 8). These

are nested within each other...The external shell of the theory is its descriptive aspect; the theory presents and explains relationships that are observed in the external world. The theory’s descriptive accuracy is supported, at the second

Figure 5. A wholly different onion model (Donaldson & Preston, 1995)

level, by its instrumental and predictive value; if certain practices are carried out, then certain results will be obtained. The central core of the theory is, however, normative. (p. 74)

The Donaldson and Preston onion model is thus used to help visualize the structure of the theory, not the relationships of the stakeholders and a product under development.

Hirschheim and Klein, 2003) reflect on the state of information systems research in a long and discursive paper. In a nutshell, they wonder whether information systems can effectively mediate social dialogue, and if so how the field would have to be structured. Understanding organizational stakeholders better would form an important part of that program. The authors refer to “immediate,” “external,” and “societal” stakeholders, implying something like an onion structure, though not exactly the one described here. Immediate roles, for instance, include “a managerial elite and their masters, the shareholders” (p. 271), though it is not clear if in fact the shareholders are immediate or one-jump removed by being the masters of the managerial elite. If

the latter, then there might be a reasonable match with the onion model given here: managers are functional beneficiaries and shareholders are financial beneficiaries. However, the focus of the paper is not on products, but on information systems professionals, themselves.

Taxonomies and Hierarchies

The general subjects of taxonomy and hierarchy are far too broad to be addressed here in any detail. Susan Leigh Star has written engagingly about classification (e.g., Bowker & Leigh Star, 1999). She states that classification systems should exhibit consistent principles, mutually exclusive categories, and completeness. It is hard to make any such classification of stakeholders; while the roles listed here seem to be usable consistently, and are mutually exclusive, one person can play several roles and it is impossible to be sure that new roles will not arise, so completeness is unattainable. Any taxonomy of stakeholders must be tentative at best.

Under the heading of “Hierarchical Structure,” Jackson (1995, pp. 92-95) wittily makes the point that one taxonomy can only do one job; very often several different hierarchies are needed. Indeed, one of the key principles of Jackson’s JSD and JSP methods is to make sure that your representations adequately span the problem. You may need one data structure that understands files (file start - data - file end) and another that understands transactions recorded within those files (start event - more events - end event). Either on its own is insufficient: A transaction might, for instance, span two files. Analyzing stakeholders by their relatedness to a product is only part of the story.

Goals and Viewpoints

Two areas of requirements engineering related to stakeholder analysis are goal modeling and viewpoint analysis.

A goal is an intention that a stakeholder has for a development project (or more widely, for a business, or indeed, for a lifetime), for example, that it will make preparing accounts easier. Goals may interact positively or negatively; achieving one goal may make it easier or harder to achieve another. Such interactions can easily be modeled graphically, making conflicts easy to visualize. Hence, modeling goals and their interactions is one way to explore the relationships between stakeholders with different needs. What goal modeling is not designed to do is to identify or classify the stakeholders themselves, though it can explore their social and operational interactions (and even their beliefs). Goal modeling is therefore, like most other approaches, likely to discover operational (“Our System”) roles rather than those in the wider circles of the onion model. There is extensive literature on goals; a good starting point is Yu and Mylopoulos (1998).

Negative interactions can also be intentional and dynamic, in which case they may more directly be modeled as negative scenarios or misuse cases (Alexander, 2002). This approach has the merit of considering threats, risks, and hazards, whether caused intentionally or not, and how to mitigate them. It will therefore put the spotlight on negative stakeholders as well as normal operators. However, this approach, too, tends to direct attention mainly to operational issues.

A viewpoint is either the perspective that a given stakeholder has on a development project or its product, for example, that they will continue to have an interesting job and a decent salary, or the projection (e.g., of requirements) onto the system from the position of a given stakeholder role, for example, an employee’s. Analyzing viewpoints helps to discover whole groups of requirements, can indicate possible conflicts, and, hence, can help to create better and more stable specifications.

A readable introduction to viewpoints is in Kotonya and Sommerville (1998). It describes a method of viewpoint-oriented requirements development (VORD), explicitly a stakeholder-

centered approach. As well as describing a method for discovering viewpoints and resolving stakeholder conflicts, it presents a simple taxonomy of “abstract viewpoint classes” (p. 219), classifying viewpoints into direct and indirect. These do not correspond exactly to our operational and non-operational. Instead, direct includes the system (our interfacing systems, see “Structure of the Onion Model” below) and the operator (our normal operator). Indirect is divided into engineering (maintenance and standards; we consider maintenance to be operational, while standards mean the regulator), regulatory, organization (procurer, policy, and training) and environment. A further paper by the same team (Sommerville, Sawyer, & Viller, 1998) describes the PreView approach in which viewpoints are treated as projections onto a system. One stakeholder viewpoint then naturally corresponds to a substantial set of requirements.

Multiview (Avison & Wood-Harper, 1990) is a well-respected approach to system design based on the idea of multiple stakeholders’ views on the system, and on choosing appropriate tools and techniques according to the problem situation thus defined; as such, it owes something to soft systems methodology (Checkland & Scholes, 1990). Both “soft” and “hard” aspects are considered: human exploration and sociotechnical analysis on the soft side, information analysis and specification on the hard side. This is obviously sensible and practical. However, it does not attempt to classify stakeholder roles. Multiview 2 went further in several ways, including a “systemic stakeholder analysis” within its organizational analysis, and using ethnography in the sociotechnical analysis (Bennetts & Wood-Harper, 2000). However, it did not attempt a taxonomy of stakeholders.

Human Aspects of System Development

There is extensive literature on human aspects of system development. It seems, however, to focus

A Taxonomy of Stakeholders

quite naturally on the user (by which is generally meant our normal operator) at the expense of all other roles. This is no place for a full literature survey, but a good starting point is Sutcliffe (2002), which approaches requirements engineering from a background in human-computer interaction and has an extensive bibliography.

Sutcliffe distinguishes customers, users, managers, software engineers, system testers, and system maintainers — ‘Maintenance personnel are rarely consulted in requirements analysis yet they depend on accurate requirements documentation more than most’ (p. 17) — and it could be added, they have more to contribute than most, too. These roles are notably concentrated on in “Our System,” but to be fair, they are said to be those that can write requirements. Stakeholders are further classified (pp. 56-57) as follows.

- **primary** stakeholders “who will actually operate the system” (our normal operators, and possibly also our maintenance operators, equivalent to UML actors)
- **secondary** “users who will not actually operate the system but will consume its output and depend on its operation for successful completion of their work.” The astronomer of Alexander and Stevens (2002; see above) would be an example (our functional beneficiary). Note the typical awkwardness and circumlocution necessitated by overloading the term users to mean both operator and beneficiary.
- **tertiary** “senior managers who rarely consume the system output directly but make use of information for planning and strategic control of the business.” This seems to denote either our functional beneficiary or our political Beneficiary.

Sutcliffe’s classification is interesting but limited to thinking about people who receive information outputs. However, the book also describes more-general stakeholder analysis

methods, somewhat surprisingly quoting the ruggedly practical and pioneering Gause and Weinberg (1989) rather than the more academic Kotonya and Sommerville (1998), which one might have expected.

Surrogacy

Surrogacy has apparently scarcely been researched as a requirements engineering issue. It is mentioned briefly in some of our own earlier work on stakeholders (Alexander, 2003) and in a practical way on the Scenario Plus stakeholders template (Scenario Plus, 2004).

Damian and Zowghi (2002) state that a business management department acted as a surrogate stakeholder: “Hence BM became a surrogate customer for the developers in Australia and the need for effective collaboration with DM group emerged as critical in order to meet commitments made to the customers.”

The point is not developed further, but it is clear that in the context of using technology to support requirements engineering (RE) across sites on different continents (America, Australia, Europe), the issue of who you can actually speak to, and whether they fairly represent who they claim to, is highly significant.

A set of guidelines (Kitapci & Bhuta, 2003) for using the EasyWinWin (requirements negotiation) tool and approach (Boehm, Grünbacher, & Briggs, 2003) tantalizingly mentions appointing “one of the team members as a surrogate customer if the customer would not be using the EasyWinWin tool.” However, the significance of surrogacy is not considered.

Surrogacy is also occasionally mentioned in nonrequirements work on stakeholders (i.e., to do with steady-state business, not with system development). For instance, Wood (1999) writes, “The Chief Executive Officer acts as the surrogate employer of teachers, but it is unclear who is responsible for the teacher relationship.”

Similarly, Younkins (2001) expresses the sentiment,

The corporation should be managed for the benefit of its stakeholders and the groups must participate in decisions that affect their welfare. Such participation is indirect with managers having surrogate duty to represent the stakeholders' interests. Managers are said to have a fiduciary relationship to stakeholders and must act in the interests of the stakeholders as their agents.

The focus of such work is, however (in both these examples), on the political and social significance of stakeholder responsibilities, not on surrogacy as such.

Donaldson and Preston (1995) begin, interestingly, with a quotation from E. Merrick Dodd, Jr., writing in the *Harvard Law Review* of 1932. Dodd does not use the term stakeholder, but he is plainly thinking of the same concept: "If the unity of the corporate body is real, then there is reality and not simply legal fiction in the proposition that the managers of the unit are fiduciaries for it and not merely for its individual members, that they are...trustees for an institution [with multiple constituents] rather than attorneys for the stockholders." Both the concept of stakeholder and the importance of surrogacy are evident from this early discussion.

Potts (1995) does not explicitly mention surrogacy, but does consider the relationship of customer and developer and some of the misunderstandings that can arise across the gap between them, for example, the contractual interface and hence the supplier-purchaser roles that are created (with inevitable surrogacy). His talk's provocative title also led requirements people to reflect on the nature of the stakeholder-developer interface.

THE PROPOSED TAXONOMY

A project's stakeholder sociology can be modeled graphically on an onion diagram (Figure 6). This

Figure 6. Onion diagram of product stakeholders

deceptively simple-looking model documents a wealth of information about a project. It presents a view of the project that is centered on its product, and serves as an overview of our stakeholder taxonomy.

The onion diagram displays a customizable set of named slots (silhouette icons), containing stakeholder roles, in three or more circles centered on the kit or product. For example, pilot is a role (not shown) in the normal-operator slot in the "Our System" circle, where product is an aircraft.

Structure of the Onion Model

This section introduces and defines the terms used in the onion model and the associated taxonomy of stakeholders. The onion model consists by default of a set of three concentric circles. Each circle logically contains the circles drawn inside it. (The term "annulus" may be used where it is desired to refer to the contents of a circle without those of the circles it contains.) Other circles may be added, most likely by subdividing the default circles.

A Taxonomy of Stakeholders

Figure 7. Viewpoints as attributes of traceable slot and role objects

ID	Stakeholder Slots and Roles	Brief Summary of Viewpoint	Polar Angle
SH-37	2.1 The Wider Environment		
SH-55	2.1.1 Consultant	gives advice	150
SH-56	2.1.1.1 Tools and Techniques	advises on efficient use of technology	
SH-65	2.1.1.2 Environmental Impact	advises on likely impact of product on the environment	
SH-39	2.1.2 Financial Beneficiary	stands to profit from system	240

Hence, a circle denotes a subset of entities in the world relevant to a development project. Those entities are slots and circles.

The innermost ring (not strictly a circle) denotes the kit, a conveniently short term for the equipment or product under development, whatever its nature, for instance, software or electronics hardware. This could be a one-off piece of custom financial software, or a mass-market product such as a handheld information device. It could equally well be the tangible equipment for a large system such as a railway line: the system with its many human operators would of course be more than just that equipment. The innermost ring thus differs from true circles in not containing stakeholders.

A slot is a class of roles that is drawn by default (empty if necessary) in an onion diagram. In effect, it is a prediction or suggestion that roles of a certain kind may be important in a project. For example, the normal operator is a default slot in the “Our System” circle. The existence of the slot is a prediction that in any system, there will probably be one or more normal-operator roles. The slot might remain empty in a supposedly “wholly automatic” system, though such a system might still have other human roles such as an installer, configurer, and maintainer within the “Our System” circle.

A slot is said to be empty in an onion model when it contains no roles. For example, take a product like a distress-signal flare. This product

is fired by a sailor to attract rescuers; whether it succeeds or fails, it is then disposed of. No maintenance work of any kind is carried out on it, so it has no maintenance operator, and that slot is empty.

A role is a class of stakeholders with a distinct relationship to the product under development. For example, in a passenger aircraft, both pilot and flight engineer are roles within the normal-operator slot.

A role is said to be a surrogate if it is conducted on behalf of another role that cannot speak directly for itself. For example, a product manager acts as the purchaser of a new type of product until such time as the product can be sold on the mass market; then the consumers buy instances of the product (or not) for themselves. As another example, the regulator acts as a government-sponsored voice on behalf of the public to ensure safety and so forth. Surrogacy is discussed in more detail below.

A role is said to be negative if it is associated with viewpoints opposed to the successful completion of the product’s development or its coming into service, or its successful operation. Viewpoints, statements of the points of view of stakeholders in a role with respect to the product, do not appear in the onion model as such, but can be documented briefly as text attributes of role objects in an associated database (Figure 12) or in full as sets of requirements (not shown) linked to role objects. It may be useful to document generalized viewpoints as attributes of slot

objects, summarizing a group of more-specific role viewpoints. Tool support is discussed below (“Tool and Template Support”).

In this example, consultant is a slot in the “Wider Environment” circle, containing two currently defined roles. Other attributes include viewpoint text (here with very brief examples); “Polar Angle” specifies where icons should appear on the diagram, and so on. Traceability links (indicated by triangles) can be inserted between stakeholder roles and detailed viewpoint requirements, and so forth.

A stakeholder is an individual person or other legal entity able to act like a person (e.g., a limited company, an industry regulator, a registered charity) playing one or more roles. Note, however, that in accordance with common usage, we loosely describe both slots and roles as stakeholders when the class-instance distinction is not of immediate concern.

It would also be possible to limit the definition to “individual person”; this would have the advantage of avoiding possible confusion between Company XYZ as a stakeholder and the Company XYZ containing system as a circle. Furthermore, while a suitably placed individual (e.g., the chairman, the press relations officer) can legitimately represent the voice of a company as a corporate legal entity, that individual cannot legitimately claim to speak for each of the many roles within the company as far as their viewpoints and requirements are concerned. There are thus some dangers associated with treating legal entities as stakeholders, but there are obvious advantages. For instance, if a conservation body chooses to oppose a development, its negative stakeholding can reasonably be treated as a single voice, in accordance with its legal status.

Circles

The four default circles used in the onion model are the following.

1. “The Product” or “The Kit”: the item under development, for example, a software program, a consumer electronics device, an aircraft, or a communications network.
2. “Our System”: the product plus its human operators and the standard operating procedures or rules governing its operation.
3. “The Containing System”: our system plus any human beneficiaries of our system (whether they are involved in operations or not).
4. “The Wider Environment”: the containing system plus any other stakeholders.

Other circles may be introduced as necessary. For example, an additional circle might be created outside “The Containing System” to divide stakeholders relatively closely involved with the project from those more distantly involved in the wider environment. That might be helpful when a product forms a component of a subsystem within a larger system. For example, when our product is a control box for a train (the containing system), we might wish to consider a “Wider System” circle, namely, a railway line with stakeholder roles such as line controller, and even a “System Environment” circle, namely, a complete railway network with roles such as network timetable scheduler, as distinct from the wider environment which might include stakeholder roles such as the general public and the government.

The “Kit” or “Product” circle is considered to be the part of our system that can be sold, so it does not contain humans. All the other circles contain stakeholders. This does raise an interesting problem of consistency: Since it is a purely relative matter which system in the real world we consider to be our system, it is perfectly possible for somebody else to treat our system as a component part of their product. What is happening here, however, is that they are focussing attention only on the machine (nonhuman) aspects of our system for the purposes of product development. Of course, the stakeholders do not disappear, but

A Taxonomy of Stakeholders

they will either be treated as insignificant from the (larger) viewpoint, or they will be promoted to the rank of stakeholder in the larger product.

For example, if the larger product is a train, its normal operator is a driver. Our component product, the train's control box, is also operated by the driver, who only appears once in the model outside the product, the train, as one would expect. The fact that the driver also operates a subproduct of the train (the control box) does not make the driver a part of the product. Thus, at the level of detail of the larger viewpoint, there is no need to consider separate subproduct stakeholders. In general, therefore, as long as one considers just one system at a time, there is no problem of consistency. A shift of viewpoint to consider a larger or smaller product rightly causes a change in the perspective of the onion model.

One might ask whether distance from the kit means less influence on the requirements for it: This would be a simple application of the spatial metaphor of the onion diagram. (See "Visual Metaphors" for a fuller discussion of visual metaphor.) However, there seems to be no reason to believe this. On the contrary, the approach here emphasizes that stakeholders who never see the kit may be crucially important to a development project. As Coakes and Ellison (1999) say of their stakeholder web diagrams,

The...diagram is not intended to depict stakeholders from some judgmental position such as degrees of power, influence, or interest. In particular, care must be taken not to interpret distance from the central [product] as an indication of importance. Some of the most influential stakeholders may be remote from the organization. (p. 11)

A well-known example is the occasion where English Heritage stopped a rail resignaling project the day before it was to launch as an attractive redbrick Victorian railway viaduct would have been demolished. No knowledge of signaling or interest in it was necessary. It may be that dif-

ferent stakeholder slots come with presumptions about their likely (default) importance, but that is a weaker claim.

The Slots of the Onion Model

The onion diagram by default displays the following slot icons in the named circles. Other slots may be added as necessary. In each case are defined, based broadly on the framework of Sharp et al. (1999),

- the nature of the roles in the slot with respect to the kit,
- the most likely interactions with stakeholders in other slots,
- the stage(s) in development that the slot is most likely to be relevant, and
- the likely priority (relative importance) of stakeholders in the slot.

Note that the following are what are considered to be the bare minimum of slots, not an exhaustive taxonomy.

Our System

- **Normal Operator:** role that involves giving routine commands and monitoring outputs from the product, whether these are via a human-computer interface or not.

Normal operators interact directly with the product with other operators (e.g., maintenance, operational support) and with functional beneficiaries (e.g., providing them with processed information and receiving instructions from them).

Operator requirements are relevant throughout development, but especially during user-interface design.

Operability requirements are always important, perhaps especially so for mass-market products (where operability is a selling point) and for control systems (where safety is involved).

- **Maintenance Operator:** role that involves maintaining the product, such as servicing hardware, and diagnosing and fixing faults. (The so-called maintenance of software involves changing the design of the product, and is the responsibility of our developer slot; it is not maintenance in our sense.)

Maintenance operators interact with the product and with normal operators.

It is worth noting that now that outsourcing is in fashion, maintenance people may be contractors. If so, there is a contractual boundary that crosses the “Our System” circle (and others outside it). This can easily act as a “geological fault line,” impeding communications and possibly rupturing if anything goes wrong. For example, some organizations outsource their computer and network administration (maintenance operations) while retaining normal operation of the equipment in house. This typically creates bureaucratic delay and difficulty, which in turn creates tension between the two roles. It may be helpful to draw contractual or other boundaries on the onion diagram, and to annotate these with their significance for the project.

Maintenance is often not considered until late in projects; however, maintainability needs to be designed in, whether as built-in test and diagnostics, internationalized error messages, accessibility of equipment, or spares holdings. Requirements for these need to be in place early in a development.

Maintenance requirements are often more important than they seem. The whole-life cost of many products — from cars to jet engines — depends much more on the cost of maintenance than may be realized. Similarly, maintainability requirements such as the time to repair or replace components can significantly affect quality of service.

- **Operational Support:** role that involves advising normal operators of a product about

how to operate it. These roles are very close to operations, but support rather than conduct productive use of the product itself. We have chosen to include them in our system for two reasons:

1. they behave as operational staff in their daily work and
2. like maintenance operators, they help to keep the system fully operational (enabling the normal operators to continue working effectively).

Operational support people such as help desk staff and trainers interact mainly with normal operators. They are maintenance for the humans involved, rather than just for the product. The comments on outsourcing under “Maintenance Operator” can also apply here.

The priority of support probably deserves to be higher than it is on many projects. As with maintenance, good support raises operational effectiveness and availability. Clearly it is secondary to other slots such as normal operator and functional beneficiary.

Support needs to be considered when preparing manuals and training materials, that is, relatively late in the project; however, supportability may also need to be evaluated earlier, for example, when designing software to yield intelligible error messages and so forth.

Containing System

- **Functional Beneficiary:** role that benefits from the results or outputs created by the product. For example, an astronomer benefits from the astronomic data captured by a space telescope, though he or she cannot operate the instrument directly. Since products are or should be designed to produce results, this is an important slot.

They interact with operators, giving them instructions and receiving information and any other

A Taxonomy of Stakeholders

benefits that our system is designed to provide.

Functional requirements form the centerpiece of most specifications. They need to be available early and are used throughout development, for example, in design and for specifying functional tests. They are of the highest importance.

- **Interfacing System:** role responsible for neighboring systems that have electronic or other interfaces to and from the product. Such systems behave much like human operators in terms of demanding specific capabilities from the product, but naturally, the interfaces are precisely defined as protocols and so forth.

They interact with operators and/or the product; any other interactions they may have are most likely but not necessarily outside our scope.

Interface requirements form a crucial part of the definition of many developments. They are required from the start. Shifting interfaces and scope are serious risks to projects.

- **Purchaser:** role responsible for having the product developed. There are certainly several of these, ranging from product manager (with knowledge of what can be sold) to procurement (responsible for obtaining a contract with a supplier). In the case of a mass-market product, the purchaser is a product manager, a surrogate role, acting on behalf of millions of consumers who will, if all goes well, ultimately buy the product. Purchasers interact with developers and consultants, and (to obtain requirements) with beneficiaries and marketing, also.

The purchaser's input is required from the start, and is critical in getting development started and ensuring that funding for it is not withdrawn. It always has high priority (possibly more than it deserves, but that is out of the control of those working on a project).

- **Product Champion** (aka “**Sponsor**”): role responsible for initiating development of the product, for obtaining funding for it, and for protecting the development from political pressures and funding cuts. The role requires positional power within the purchasing organization (e.g., the company creating a mass-market product). The product champion is perhaps the best person for the requirements engineer to meet with first; an effective champion can indicate the scope and purpose of the development, the opportunities and threats, and can suggest who the key stakeholders are. All of this helps to cut the risk to the project.

A product champion's effectiveness is clearly related to the ability to interact with other stakeholders, especially beneficiaries and negative stakeholders (including those within the organization).

The product champion is critical from before the start of a development, and remains important throughout. The role does not necessarily or even desirably contribute to product requirements: It functions mainly at a political rather than a technical level.

Wider Environment

- **Negative Stakeholder:** any role that could be harmed by the product physically, financially, or in any other way that might be found justifiable by the authorities (e.g., a court of law, a regulator), or conversely that could attempt to harm the product. For example, negative stakeholders could be householders living close to the route of a planned railway, a nature-conservation body with interest in land threatened by such a route, activists opposed to pollution that might be caused by a product under development, employees finding their decision-making abilities reduced by “intelligent” software, employees

that perceive their tasks being oversimplified or made too complex, or groups feeling that collaboration or communication would be made more difficult.

- **Hostile Agent** (a special kind of negative stakeholder and possibly a distinct slot): any role that actively seeks to hinder or harm the development and operation of the system. Actively means using some degree of intelligence and creativity to oppose the system. Examples include military enemies, political and commercial spies, hackers, spammers, virus writers, thieves, and fraudsters. Clearly the degree of harm intended by such agents varies from complete destruction through malicious pleasure to unauthorized acquisition of assets (with essentially unintended harm as a side effect).

Negative stakeholders may interact with regulators, beneficiaries, and with any roles in the wider environment able to wield influence, for example, the press, politicians, or other pressure groups.

Hostile roles can be treated as a kind of negative stakeholder, or may perhaps be promoted to a slot in their own right. Hackers and virus writers are obvious hostile roles. Competitors, too, could be considered: Their relationship could be anything from passive victim to active threat. In the case of military systems, the enemy's expected behavior and capabilities are naturally a primary consideration.

Negative roles are important from before the start of a development, and then whenever issues like security, marketability, and environmental impact are considered. These affect requirements and design. Security may demand special effort in system testing.

- **Political Beneficiary:** any role in public office or private business that can benefit in terms of power, influence, and prestige through the success of the product. For ex-

ample, a space agency's management could benefit politically from a successful space mission.

Interaction with other roles is usually infrequent and typically indirect, for example, via senior management (purchaser, functional beneficiary, etc.).

Political forces within an organization can also be negative (see the discussion of product champion above). It might be worth representing the political opponent, though such explicitness can be dangerous, as Checkland mentions (Checkland & Scholes, 1990): "There is an unavoidable political dimension...to any human affairs which entail taking deliberate action...[D]elicate judgements are usually required...if the results (of political analysis) are all bluntly made public, then those results can themselves easily become a potent commodity of power in the 'real' politics of the situation. There is potentially an infinite regress here in which the politics of the situation forever escapes open analysis" (pp. 50-51).

Political roles are important (see "Sponsor," above) throughout a development and indeed, from before it begins.

- **Financial Beneficiary:** any role that can benefit financially from the success of a product, for example, shareholders and directors in a company making a mass-market product

They often interact weakly with other roles, except perhaps with the product champion and other senior beneficiaries.

Development staff perhaps need to consider financial beneficiaries directly only rarely; project and program management may be more concerned. Perhaps the most usual situation is that financial beneficiaries are represented by surrogate roles such as line management. Conversely, financial beneficiaries are likely to take a direct interest only

A Taxonomy of Stakeholders

in the largest of developments. They are important at the main gates in a development.

- **Regulator:** any role responsible for regulating the quality, safety, cost, or other aspects of the product for example, aviation authorities, health and safety executives, rail regulators, radio regulators, and financial service authorities

The regulator is most likely to interact with senior developers. Regulators act as surrogates for the public, interacting with developer and beneficiary roles as necessary; for example, the aviation authorities certify components on receipt of a satisfactory safety case supported by evidence from the development organization's safety officer.

In the case of a software product, we could view standards organizations like ISO as nonstatutory (voluntary, not enforcing) regulators.

Regulators impose requirements that act as qualities and constraints (rarely as functions). These are important in defining the requirements for a product, and again for acceptance and certification. In the case of safety-related products, they are of crucial importance.

- **Developer:** any of the many roles (requirements engineer, analyst, designer, programmer, tester, safety engineer, security engineer, electronics engineer, metallurgist, human factors engineer, project manager, etc.) involved directly in product development. Note that none of these roles are operational unless tied into operations via a maintenance contract, in which case the affected people have hybrid developer-maintenance roles.

Developers interact mainly with each other (often adopting surrogate customer roles in the process; see discussion below), but also contractually with purchasers. Ideally, developers in the form of requirements engineers and analysts

would interact with *all* other roles, but this is rare and often impossible for reasons of time and restrictions on access, for example.

Developer roles are mainly involved once development has started; it may be helpful to involve a developability opinion (a consultancy role) before that, and to keep developers involved (via maintenance) during operations. Clearly the priority of a developer's requirements is secondary to those of the beneficiaries, though manufacturability is an important consideration for mechanical products such as jet engines.

Suzanne Robertson suggests (personal communication, March 18, 2004) that it may be helpful to create an extra circle for development project responsibility. It may be best for this not to be a concentric circle—in a way, development is another world from operational usage. Developers are in the outermost circle from the point of view of the product, but intimately involved from the point of view of development. Hence, it may be an oversimplification to try to force the two taxonomies into one. However, as she says, drawing a development circle “highlights the necessity to have adequate representation of the ongoing maintenance operator and operational support roles and [to separate] real maintenance from new development.”

- **Consultant:** any of the many roles (marketing expert, software expert, business analyst, management specialist, etc.) involved in supporting some aspect of product development, characteristically from outside the development organization. Internal consultancy is possible but problematic, as it is hard to speak out in the face of political pressure within the organization (except with the help of a sponsor; see above).

Consultants may interact mainly with the product champion, purchasers, or developers, depending on when they were hired, by whom, and for what purpose.

For priority and timing, see the comments on the developer.

- **Supplier:** a role involved in the manufacture and provision of components, whether custom or commoditized, for the product. In the case of custom components, this is close to a developer role, initially. During system operations, both custom- and commoditized-component suppliers have a role closer to maintenance, supplying whatever is needed to keep the system operational.

Suppliers are important in product manufacture, maintenance, and sometimes in development. In extreme examples such as the manufacture of a jet engine's intercase (a complex, three-dimensional casting), the supplier is critical to development, as the lead time for the manufacture of the component is comparable to the lead time for the entire engine development. Hence, suppliers may need to be involved very early in a project, possibly even before it begins.

APPLYING THE TAXONOMY IN PRACTICE

Requirements Elicitation

The simplest and most essential use of a taxonomy of stakeholders is as a guide to the likely kinds

of people to interview, observe, and invite to workshops to help gather the requirements for a project. As stakeholders are successively identified and brought into the project, an onion model and associated database can be used to document their roles, contact details, viewpoints, and ultimately, their requirements. The onion model then gives a direct visual report on the progress of stakeholder discovery and provides pointers to slots that require further investigation.

Characterizing the Project

The nature of the stakeholder taxonomy for an individual project determines the kind of stakeholder involvement that will be necessary during the life of the project. One application of the taxonomy is therefore to characterize the project in terms of the requirements elicitation approach and the degree of stakeholder participation that should be selected. This is one of several characterization dimensions, each of which can help to reduce risk. Other dimensions include whether and how far safety is involved, how complex the interfaces are, and how new the needed technology is.

Elicitation techniques vary widely, from interviewing and holding workshops through ethnographic fieldwork to having market surveys, prototyping, and product trials. Most requirements textbooks describe a range of such techniques (e.g., Alexander & Stevens, 2002; Kotonya & Sommerville, 1998; Robertson & Robertson, 1999).

Figure 8. Eliciting from operational roles (outer circles suppressed)

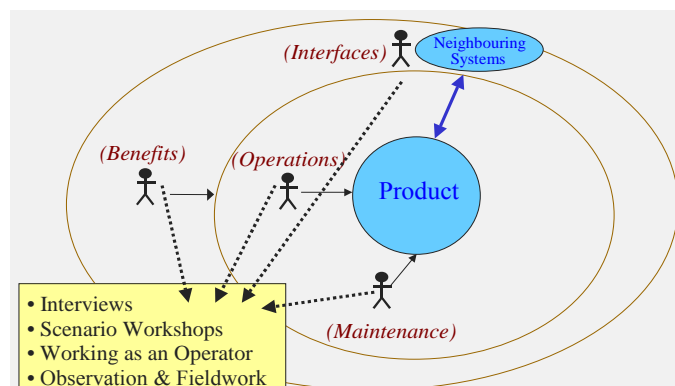

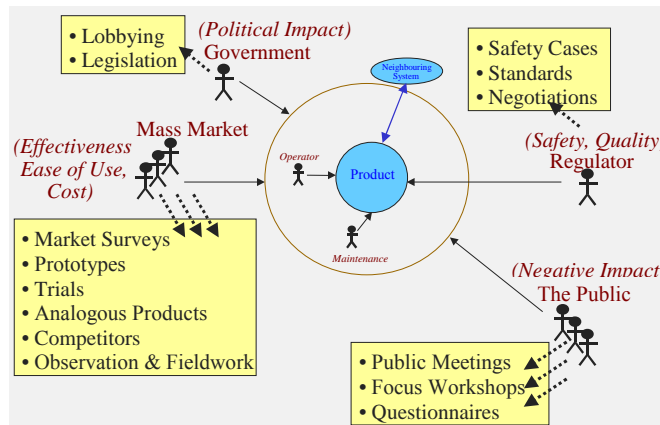

Figure 9. Eliciting from nonoperational roles

Textbooks with a user-centered orientation offer a still-wider range (e.g., McGraw & Harbison, 1997; Sutcliffe, 2002). The choice of techniques is in practice, however, strongly driven by the stakeholder roles involved. Figure 14 illustrates some common elicitation approaches for operational stakeholders.

Characterization can be carried out by assessing which kinds of stakeholders are likely to be most significant in a project, and then assigning the most appropriate development life cycle to respond adequately to those stakeholders. For example, if the operational needs are simple but meeting regulatory demands is long and complex (e.g., for a jet engine), then the life cycle must focus on achieving certification with careful attention to verification and the gathering of evidence for the regulator.

Conversely, if regulation is minimal but operational needs are rigorous (e.g., for a portable consumer product), the life cycle must focus on satisfying users (i.e., hybrid normal operators-functional beneficiaries) in that the product is suitable through involvement with the development, which will presumably be iterative to permit it to respond to user reactions.

Checking for Stakeholder Problems

Checking for Empty Slots

A tool that records details of slots, roles, and stakeholders can readily detect empty slots. These might indicate forgotten stakeholders or, for example, a missing sponsor, threatening project success.

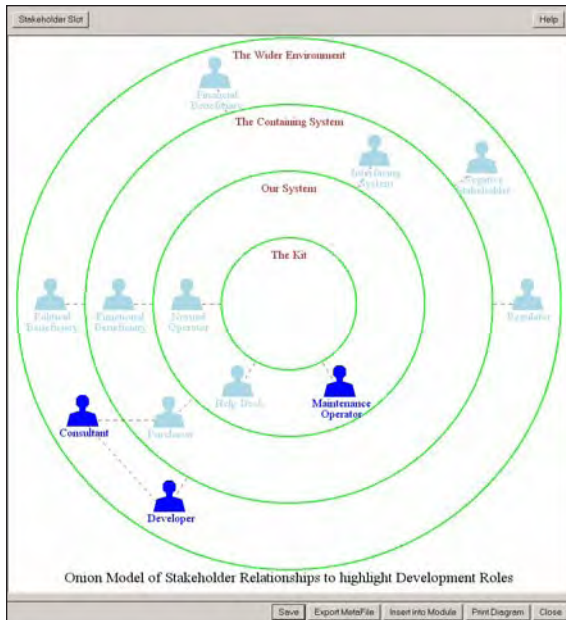

Checking for Multiple-Filled Slots

Similarly, a tool could readily detect slots populated by more than one role. This is sometimes acceptable, but could indicate sources of conflict. For example, conflict is likely if two departments (e.g., international marketing and product development within a multinational carmaker) both believe they are funding and therefore have control of a development project.

Checking Traces to Use Case Actors

A tool that in addition records traces between items such as requirements could detect any system roles not traced to use case actors, and thus documents them in operational scenarios, and

Figure 10. Onion-model tool displaying current status of stakeholder slots

vice versa. Lack of traceability could indicate a disconnection between stakeholder analysis and implementation work.

Analyzing/Visualizing Contractual Fault Lines

An onion diagram shows a product and layers of its environment as concentric circles. Contractual boundaries (see the discussion on maintenance, above) may not coincide with these circles. A diagram with overlaid boundaries may help stakeholders to visualize the risks inherent in outsourcing or otherwise sharing responsibilities.

Tool and Template Support

The taxonomy presented here has, as described above, several possible practical applications. These do not necessarily require tool support: Onion diagrams and hierarchies can be created quite easily in ordinary office software, on paper,

or on flipcharts, provided that traceability is not required.

When models must be maintained for extended periods during which a steady trickle of change must be accommodated, tool support with configuration control and traceability to requirements becomes essential.

Requirements Database Tool

A tool (Figure 10) supporting some of the applications mentioned above has been implemented in a requirements-traceability tool environment (Telelogic DOORS) and is available for free download (Scenario Plus, 2004). This both demonstrates the feasibility of building such a tool, and allows workers to experiment with uses of the approach in a controlled environment (e.g., with a complete audit trail). Figure 8 incidentally illustrates part of the tool's (very straightforward) data model.

The tool permits the creation and editing of an onion-model diagram. As illustrated, the tool also acts as a display of the status of the model, making it apparent which slots are filled and which are empty. The tool manages a conventional document-like data structure (a formal module, see Figure 12) in which each slot, role, and stakeholder is represented as a separate object within a hierarchy. Details of each stakeholder are held as a database record within the object; these include name and contact details as well as a text summarizing the stakeholder's viewpoint. Objects can be given (bidirectionally navigable) traceability links to any other objects (e.g., requirements) in the database. Hence, the tool enables the requirements engineer to provide traces from any number of requirements, use cases, actors, and so forth directly to stakeholders.

Tools can readily calculate metrics on the status of the onion model. For example, the number of system slots that are not linked to use case actors gives a measure of the completeness of coverage of known human operators in the use case model.

Figure 11. Fragment of the stakeholder template

3.1 Beneficiary		
3.1.1 Functional Beneficiary		
Stakeholder:	Viewpoint:	
John Smith	wants to see accurate weekly & monthly sales figures and forecasts	
3.1.2 Financial Beneficiary		
Stakeholder:	Viewpoint:	

Clearly the same information architecture could also serve as the basis for other forms of stakeholder analysis including conflict detection and resolution. These do not necessarily demand tool support, but they do require systematic handling, for which a tool can be beneficial. Small projects may instead choose to apply a simple template of likely stakeholder roles, discussed in the next section.

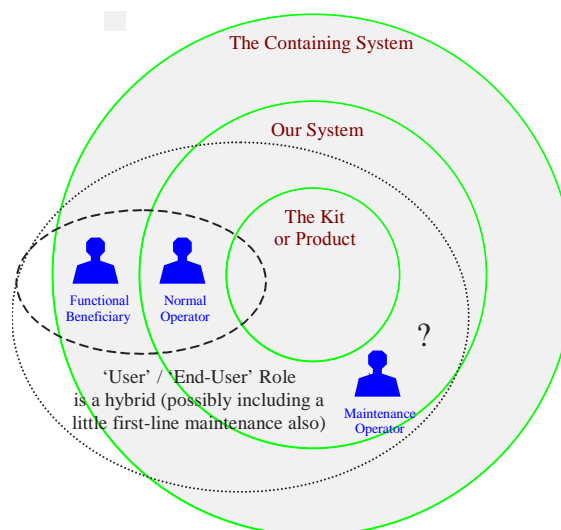

The Scenario Plus tools could in principle be implemented in any automated software or system development environment that supports traceability between items and provides a suitable application-programming interface. The hybrid hierarchical-tabular data structure of DOORS' formal modules was very convenient for implementation, but stakeholder information could certainly be represented without it.

Stakeholder Template

A document template (Figure 11) based on the onion model and in a choice of formats suitable for popular word-processing and spreadsheet tools is available for free download (Scenario Plus, 2004). While there are clear advantages for large projects to work within a traceability tool environment, smaller projects can benefit from stakeholder analysis and other forms of modeling using simpler tools.

Customizable templates such as Scenario Plus and Volere (2004) allow stakeholder analysis to take place in essentially any development environment, including, indeed, those without any special modeling tools whatsoever. The analysis could take place in Word or Excel, with an onion diagram in PowerPoint or CorelDraw. Clearly there are advantages for larger projects to work with traceability and configuration management tools so as to keep track of changes more reliably.

Figure 12. User as a hybrid role across two or more slots

DISCUSSION: FEATURES AND LIMITATIONS OF THE TAXONOMY

User: A Hybrid Role

One slot that is not provided is the user. We consider this term to be both dangerously overloaded and confusing. It has many loose meanings in colloquial engineering parlance, including

1. all stakeholders,
2. all stakeholders other than us, the developers (this meaning verges on the derogatory, and should be avoided),
3. any stakeholder who gets any benefit from the product, and
4. any stakeholder who operates the product.

However, perhaps the most widespread meaning is an interesting hybrid of two of our slots: normal operator and functional beneficiary (Figure 12). For example, consumer electronics companies speak of users. They seem to mean the people who both push the buttons on their products, and who enjoy the resulting entertainment (music, video, games, etc.). This user-consumer role seems necessarily to combine the roles of operator and functional beneficiary, and, of course, the role of consumer and mass-market-product purchaser—not to be confused with the important surrogate role of purchaser adopted by product managers and procurement departments—is not far away, either. Indeed, if changing the batteries is considered to be a maintenance operation, then the role is multiple hybrid.

Popular variant terms such as end user do not clarify the situation. End user seems sometimes to mean the actual operator of the product, as opposed to the purchasing organization that is paying for its development, in which case its slot is normal operator. At other times, the implied slot is functional beneficiary, as when astronomers are called the end users of a scientific satellite because

Figure 13. UML only explicitly addresses stakeholders inside our system with its use case actors

they make use of the data it collects. In any case, we may ask, “The end of what?” with respect to the chain of beneficiaries on the left of the onion model, and indeed to the shifting perspectives of the onion models drawn with respect to different products within a system-subsystem hierarchy.

Therefore, the terms user and end user have little value, may be harmful in diverting attention away from nonoperational stakeholders, and should not be chosen as fundamental taxonomic units.

Overlapping Taxonomies

Clearly, this model is productcentric, though by intention people focused. It is possible to create processcentric models (around the developer and development activities, the business processes and system usage), and as argued in “Research Review,” most of the requirements literature seems to be tightly productcentric to the exclusion of most kinds of stakeholders.

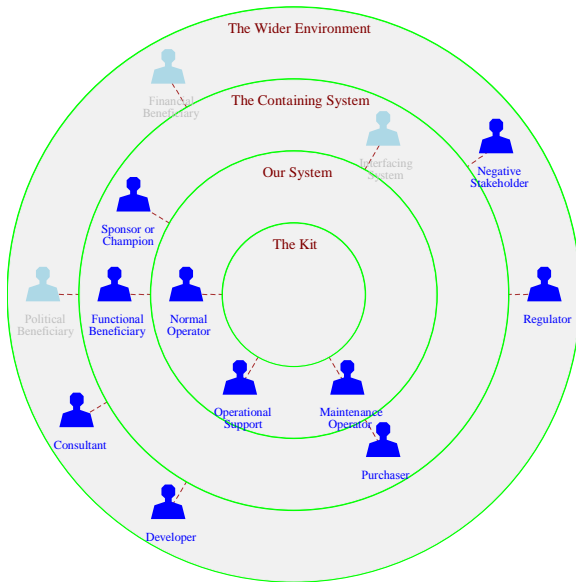

It is unwise to try to make a single taxonomy or hierarchy do too much (Jackson, 1995); the aim here is to provide a practical way of discovering and remembering the viewpoints necessary to a development’s success. Other models may be needed to cover business processes that stakeholders are involved in. Other hierarchies may be needed to suit other purposes such as defining company responsibilities. More is said on the dangers of reading too much into the model in “Visual Metaphors,” below.

A Taxonomy of Stakeholders

Table 1. Classification of Volere stakeholder roles into the onion model

Onion Model tailored for Volere	All 37 Stakeholder roles defined in Volere.co.uk template	Volere Row No.
The Wider Environment		
Financial Beneficiary	— none —	
Negative Stakeholder	Opponents of project/product	38
	Public Opinion	41
Developer	Packaging Designer	28
	Manufacturer	29
	Project Management	32
	Business Analysts	33
	Requirements Engineers	34

Our System		
Maintenance Operator	Product Installer	30
	Maintenance Specialist	27
Normal Operator	Clerical User	14
	Technical User	15
	Potential User	16
Operational Support	Training Staff	31

Figure 14. Onion model of Volere stakeholder roles

Several slots (greyed out) remain unfilled. Several other slots (especially consultant, developer) are heavily populated (see Table 1).

Usage-Centric Taxonomy

We have chosen to emphasize the range of roles across onion model circles as a counterbalance to the prevailing emphasis on (software) product usage to the exclusion of almost all other roles. For example, the unified modeling language’s (UML) “actors” are chiefly normal operators; the narrowness of the UML framework (Fowler & Scott, 1999) often causes even maintenance operators to be forgotten, while the surrounding context of other stakeholders able to contribute requirements is essentially undescribed (Figure 13). On the other hand, starting from an onion model, any operational role (in the “Our System” circle) is a candidate UML actor.

Readers from other backgrounds accustomed to paying attention to a myriad of stakeholder groups may find the need to counteract excessive actor-fixation parochialism; perhaps the most that can be done here is to assure them that it does seem

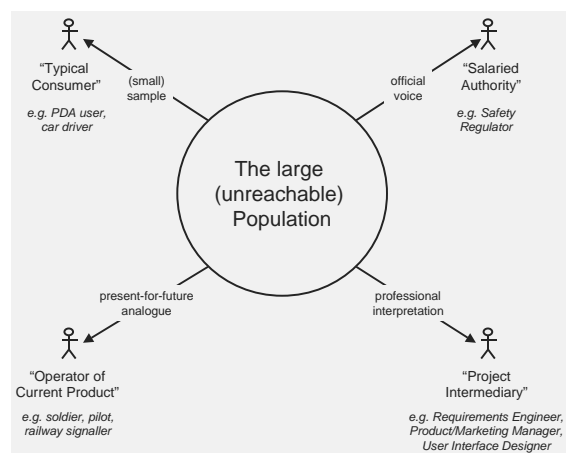

to be a problem. The current unhappy emphasis on security requirements, in response to threats as diverse as hacking and terrorism, may however be helping to make even the most software-fixated developers aware that stakeholders do matter.

Developer- or Requirement-Centric Taxonomy

The Volere template (Volere, 2004) contains an interesting and useful list of stakeholders, certainly far more comprehensive than most others in the literature. These are not easy to map into our taxonomy from the stakeholder role names alone: For instance, should maintenance specialist be treated as a maintenance operator role or as a consultant role? It could clearly be either. However, the list seems rather developer oriented; most of the roles appear to fall into the developer and consultant slots (Table 1).

The numerous consultant roles in the Volere list—their names ending in “Specialist” or “Expert”—make sense if seen from the point of view of a classification of nonfunctional requirements: Perhaps the thinking ran, “Here are some usability and some security requirements; we better consult some appropriate specialists about these” (i.e., the knowledge, role, person triangle was the driver for discovering requirement-related knowledge;

Figure 15. Four kinds of stakeholder surrogacy

A Taxonomy of Stakeholders

Table 2. Stakeholder surrogacy relationships

Type of Surrogate Stakeholder	Example	Relationship with Stakeholder Population	Advantages	Risks
'Typical Consumer'	Car drivers paid to give opinion of new models of car	statistical sample	is a real operator/ beneficiary of the product	may not be typical; danger of mis-sampling
'Operator of Current Product'	Soldier helping to define military equipment needs 25 years into the future	present-for-future analogue in the domain	is a real operator of analogous products	analogy may not hold in future environment; obsolescence
'Project Intermediary'	Requirements Engineer writing other people's requirements; Product Manager purchasing development of product on behalf of both consumers and financial beneficiaries (e.g. shareholders)	professional interpretation	familiar with engineering development	misinterpretation through lack of domain knowledge; over-technical focus (bias towards technology); invented requirements (Potts 1995)
'Salaried Authority'	Aviation Authority (Safety Regulator) checking safety on behalf of public	official voice	statutory position; enforcement of requirements enshrined in law	remote from population and product operations; bureaucracy

S. Robertson, personal communication, March 18, 2004)). Thus, it appears that the Volere template is perhaps more-specifically requirementcentric than developercentric. On the other hand, the negative and champion slots are rightly stated to be project- and productcentric.

The resulting onion diagram (Figure 14) shows that (for all the length of the Volere stakeholders list) several slots remain unfilled, perhaps surprisingly including the one for stakeholders responsible for interfacing systems.

Several other slots are only weakly represented; for example, the auditor is the sole (and rather doubtful) role in "Regulator."

Volere's customer and client are slippery terms; in this analysis they are assumed to correspond roughly to our purchaser and functional beneficiary, respectively. Client can, however, also include financial beneficiary.

Surrogacy

One aspect of stakeholder sociology that is brought out clearly on an onion diagram is surrogacy: the

representation of one stakeholder's viewpoint by some other person. Surrogacy has (when it has been considered at all) always been seen as a dangerous obstacle to successful requirements work. It is therefore remarkable that stakeholder surrogacy (Figure 15) is both central to RE and scarcely discussed in the RE literature (see "Research Review").

Figure 15 describes some of the surrogacy issues around requirements engineering as a whole, and stakeholder sociology in particular. It is immediately apparent that the different stakeholder-surrogate relationships each have their own advantages and risks. These are briefly analyzed in Table 2.

Other forms of surrogacy are also involved, given that both in development projects and in ordinary work (using the developed products), people are usually working on behalf of other people.

Combinations and intermediate types can also be identified. For example, environmental pressure groups and "not in my backyard" campaigners may create leaders who, though unofficial

and unpaid, may act almost as regulators, being invited to meetings and having their (negative) opinion sought.

The history of computing can be seen as a steady retreat from the assumption that we know how to program what we want done in machine language: Successively more human-oriented languages and tools (such as assembly language, Fortran, visual programming, databases) have been invented to fill the gap.

The history of requirements can be seen as a steady retreat from the assumption that we know how to say what we want done in atomic “shall” requirements: Successively more stakeholder-oriented documents and diagrams (such as user requirements, concepts of operations, use cases, goal models) have been invented to fill the gap.

The roles people play — what they do and what they want to do — thus seem to be becoming increasingly important to our discipline of RE. Our “machine codes”, individually prioritized and traceable requirements, will not simply disappear. But like hexadecimal, the writing of requirement text is moving steadily into the background as more abstract representations of what people want are invented and adopted in practice.

A user requirement has the general form

<named stakeholder role> wants <result>.

If the gold standard for RE is to create requirements like this, claiming that specific stakeholders (we will pass over the class-instance issue for a moment) want that result more or less personally for their own work (by which we include leisure uses of consumer products, etc.), then surrogacy is a rampant anomaly. All that surrogate stakeholders can give us are statements of the general form

<named surrogate role> believes that <named role> wants <result>.

Law statements of this kind are called “hearsay evidence”, which is rarely admissible in court.

But our surrogates often cannot even claim to have heard anyone else expressing their requirement, however distantly. In the clear-cut case of the procurement of military equipment on behalf of as yet unborn soldiers, there can be no claim even to hearsay evidence: The requirements are wholly invented.

Surrogacy thus interferes with the core trend and practical process of RE: the move towards gathering requirements directly from real stakeholders. Yet, as Figure 24 indicates, surrogacy cannot readily be avoided (even when the unreachable population is not especially large). Perhaps this is one of the fundamental limitations on the engineering of requirements, systems, and software.

Suzanne Robertson comments that it can help to invent a surrogate, for example, Erik the systems analyst. Erik could then be consulted on his needs:

Whenever we were stuck (should this be in or out, more or less detailed) we went and talked to Erik. Yes really, on our notice board we had a photo of him clipped from an SAS airline magazine. He looks like a good journeyman systems analyst; he works for a company that makes fruit juices. Medium height, pleasant expression, Scandinavian glasses. (S. Robertson, personal communication, March 18, 2004)

Without the surrogate, they would never have been able to finish the job.

Visual Metaphors

An onion diagram inherently embodies a set of visual metaphors, and these are exploited more or less consciously to give a feeling for stakeholder relationships in a development project. Metaphors inevitably break down at some point, so some caution is required. Attention is drawn to the limitations of the onion model below.

A Taxonomy of Stakeholders

The most immediate of these visual metaphors is the feeling of successive (indeed recursive) containment of one onion within another. As Peter Checkland and others have emphasized, there are always many systems to consider (Checkland & Scholes, 1990). This leads to practical issues of project scope. The scope of a system of people and equipment is always larger than the scope of the equipment or product alone, so it is essential to be clear about the existence of the two boundaries (e.g., Robertson & Robertson, 1999).

A circular diagram inevitably announces that something is in the centre of attention, and in a development, that is rightly the product; at the same time, it shows that people are all around it and have importance. It also suggests the metaphor of closeness for relatedness, and, for example, developers are shown close to purchasers for this reason. Distance could suggest that stakeholders in the outer circles are less important, but this is not intended. Indeed, negative stakeholders, regulators, and political beneficiaries are all able to “stop the show” and must be considered essential.

We also habitually make use of other spatial metaphors; supporting roles seem naturally to find a place below the product, while interfacing systems and regulators can go off to the side somewhere.

A cautionary note should be sounded here: A naive reading of the onion model with the equation of outer equals higher in the system or company hierarchy, with regulator in the outermost circle, would imply the equation of regulator equals responsibility for the highest level of system. This is simply wrong. As Michael Jackson cautions (Jackson, 1995; also see “Research Review”), there may be many overlapping hierarchies. Three that are often important in thinking about system development are as follows.

1. the scopes of the product and the systems that contain it. This is the primary and intended meaning of the onion diagram. The

operational stakeholders are those inside the system, as explained below.

2. the organization (e.g., company) hierarchy, with the workers inside at the bottom and the managers and directors outside toward the top. This is not what is intended here. Managers may or may not be stakeholders in a development; nonoperational company workers and executives are not automatically assumed to be relevant.
3. the structure of the organization and stakeholder relationships involved in accepting or rejecting a development, for example, the relationship of the regulator with the developer. This structure is secondarily suggested by the onion diagram, but this does not mean that questions like, “Which level of system is the regulator in?” make any sense. The regulator is in a system — that of the political and legal framework of a country or the world — but that is certainly not the same as any onion circle of any ordinary development project.

The onion has its uses in helping people to think about multiple scopes and the need to involve people outside the development team, but it cannot do everything.

Another metaphor that seems quite natural (though perhaps mixing oddly with onions) is that of the chain of command, where a person makes use of a system under their command as an instrument to achieve a political goal. They do this by instructing an immediate subordinate—some at the adjacent or immediately contained level—to carry out some operation. That person in turn may achieve their goal (a successful operation) by instructing an operator to use a piece of equipment to deliver a specific result. The chain metaphor could also be represented as a scale from higher to lower if you like the idea of a great chain of being from God to man to animals (Lovejoy, 1936/1990); I have chosen to make it the rather

more-egalitarian left to right (with the slight suggestion that actions, like writing, may proceed in that direction).

CONCLUSION

The trend in system specification away from the machine toward human users leads to a natural end point in modeling and analyzing the nature, goals, and viewpoints of human stakeholders. While there has been some academic interest in goal and viewpoint modeling, the stakeholders themselves seem largely to have been overlooked within systems and software engineering (though quite the reverse in soft systems and information systems research).

The onion model diagram has an attractive and intuitive simplicity about it, organizing a substantial amount of complexity in analysis of stakeholder sociology and relationships. This is part of a wider interest in and intention to improve the attention that practising engineers pay to stakeholders, including surveys and a reconsideration of development life cycles and project information models (Alexander & Robertson, 2004). The default onion model with three circles and the basic slots is often in itself helpful in projects, but it is readily tailored for more complex situations with additional circles and slots. Ralph Young has adopted the approach in his new book (2004), and Suzanne and James Robertson are similarly doing so in their latest book (2004). Needless to say, it is also pressed into service in my forthcoming book (Alexander & Maiden, 2004).

Tool support is available, but the approach can be applied with nothing more than a hand-drawn diagram and a textual hierarchy of headings for circles, slots, roles, and if desired, named stakeholders.

The analysis of stakeholders does not presuppose any particular development approach, and

while it is clearly suitable for an object-oriented worldview with use cases and their actors, it can equally be added to conventional or agile development.

This paper has presented a simple but, it is hoped, generally applicable and readily customized taxonomy of stakeholders, and has suggested some uses for it. If it contributes to encouraging even a few projects to think a little more deeply about who their stakeholders are and what they want, it will have succeeded.

ACKNOWLEDGMENT

I am grateful to Isabel Ramos for her suggestions and encouragement for this paper, to Andrew Farncombe for his clarity on terminology and multiple hierarchies, to Sabina Malfatti for drawing my attention to the onion layers in Peer Gynt, and to Suzanne Robertson for her continuing enthusiasm and support. I would also like to thank the anonymous reviewers for their perceptive comments and suggestions, especially on the voluminous information systems literature, and the editor, Bernd Stahl, for his measured criticism and direction.

Chapter 2.11

A Practitioner–Centred Assessment of a User–Experience Framework

John McCarthy

University College Cork, Ireland

Peter Wright

University of York, UK

Lisa Meekison

Anthropologist and Freelance Consultant, Canada

ABSTRACT

In this article we outline a relational approach to experience which we have used to develop a practitioner-oriented framework for analysing user experience. The framework depicts experience as compositional, emotional, spatio-temporal, and sensual, and as intimately bound up with a number of processes that allow us to make sense of experience. It was developed and assessed as part of a participative action research project involving interested practitioners. We report how these practitioners used the framework, what aspects of experience they felt that it missed, and how useful they found it as a tool for evaluating Internet shopping experiences. A thematic content analysis of participants' reflections on their use of the frame-

work to evaluate Internet shopping experiences revealed some strengths and some weaknesses. For example, certain features of the framework led participants to reflect on aspects of experience that they might not otherwise have considered, such as, the central role of anticipation in experience. The framework also captured aspects of experience that relate to both the sequential structure of the activity and its subjective aspects. However, it seemed to miss out on the intensity of some experiences, and participants sometimes found it difficult to distinguish between some of the sense-making processes, for example, interpreting and reflecting. These results have helped to refine our approach to deploying the framework and have inspired an ongoing programme of research on experience-centred design.

INTRODUCTION

As computers migrate from work to leisure and family life, new perspectives and conceptual tools are required to understand human activity and the participation of technologies in activity. Developments such as the World Wide Web, virtual reality, and cyberspace; the penetration of computers into homes, cars, and games; and the integration of information and communications technologies resulting in wireless, mobile, and ubiquitous computing suggest a revision of how we construe both people and technology. A person's attachment to the mobile phone is not just functional, it is also aesthetic (Katz & Aakhus, 2002; Taylor & Harper, 2002), and their use of the Internet is as much an expression of their sociality as it is a mark of their productivity (Markham, 1998; Turkle, 1995). Interacting with computers is now as much about play, fun, entertainment, community, and personal identity as it is about goals, tasks, and work. It is as much about children playing with cyberpets, teenagers gender swapping, and elderly people socialising on the Net, as it is about the middle-aged executive managing knowledge assets (Jordan, 2000; Blythe, Monk, Overbeeke, & Wright, 2003; Norman, 2004). As Kuutti (2001) characterised it, the user, who started out in the 1970s as a cog in a rational machine and became a social actor in the 1990s, is now a consumer.

The transition that Kuutti described points to the fact that people need to be able to *live* with emerging technologies, not just *use* them. Therefore the focus for designers has to move beyond usability to *experience*. The general impact of an emphasis on experience with technology can be seen in the popularity of works such as Turkle's (1995) analysis of "life on the Internet," in which she explored the social meaning of computers, the cultures of computing, and the impact of the Internet on our sense of self. The specific impact can be seen in attempts to understand and act

on the concept of *user experience* in consumer arenas such as electronic commerce (for example, see Pu & Faltings, 2000; Lee, Kim, & Moon, 2000). However, while the notion of designing for 'user experience' is gaining currency (Garrett, 2002; Laurel, 1991; Shedroff, 2001), conceptual development of user experience is only beginning (Dourish, 2001; McCarthy & Wright, 2004).

Our contribution to the conceptual development of user experience in this article is to report an action research assessment of the use of a framework for analysing user experience (Wright & McCarthy, 2003). The aim of the assessment is to explore whether the practitioners who collaborated with us in this research can make use of the framework and, if so, to identify what they gain from its use. It is hoped that their experience with the framework will inform and refine our understanding of user experience and of the framework. Before we report the assessment, we will first outline our general approach to experience and then briefly describe the framework.

CONCEPTUALISING EXPERIENCE

Although it is clear that the turn to experience in technology design reflects an attempt to engage with the experience of people using technology, the concept 'experience' is elusive and difficult to specify. In dictionaries (see the *Oxford English Dictionary*, for example) and in social scientific discourse, experience has often been defined and used in ways that reduce it to subjective feelings, behaviour, or knowledge (Dewey, 1925, 1934; Bruner & Turner, 1986). In contrast, Dewey's (1925, 1934) pragmatist philosophy was geared towards a clarification that would end the tendency to reduce experience. He argued that experience is the irreducible totality of people acting, sensing, thinking, feeling, and meaning-making in a setting, including their perception and sensation of their own actions. Experience, he wrote:

...includes what men do and suffer, what they strive for, love, believe and endure, and also how men act and are acted upon, the ways in which they do and suffer, desire and enjoy, see, believe, imagine—in short, processes of experiencing...It is 'double barrelled' in that it recognises in its primary integrity no division between act and material, subject and object, but contains them both in an unanalyzed totality. (Dewey, 1925, pp. 10-11)

According to Dewey, then, experience is the continuous transaction between people and their environments, which includes sensations, thoughts, feelings, and values. Seeing experience as the dynamic interrelationship between people and environment, or as the continually changing texture of their relationship, effectively makes person and environment a whole, or as Dewey put it, “an unanalyzed totality.” This holism is pivotal to pragmatic conceptualisation of experience, arguing that there is no point in trying to understand person and environment as separate from one another. In Dewey’s two major works on experience, *Experience and Nature* (1925) and *Art as Experience* (1934), the starting point is the creature living in an environment, neither of which could exist in quite the same way without the other. His approach, which has also been described as natural humanism, sees continuity between human experience and all other animal experience. This is clearest in the weight he gives to sensory and affective sense making. For him, the sense we make of our experience has its roots in the feelings of fear, recognition, threat, or joy that accompany a sound, smell, or sighting. In this context, Dewey (1925) argues that, “Feelings are no longer just felt. They have and they make sense” (p. 258). In and of themselves, feelings are the immediate meaning of an event or situation: the feeling of warmth and friendliness in a friend’s house or in a chat room; the feeling of excitement at meeting a person or trying out a

new system for the first time. The weight given by Dewey to predominantly pre-linguistic sensory and affective sense making has been borne out in more recent times in the neurosciences and evolutionary psychology (e.g., Demasio, 1999; Donald, 1991, 2001).

Taking account of the emergence of language, community, and values, Dewey (1925, 1934) viewed emotion, an elaboration of sensory and affective sense making, as the pivotal moment in human experience, the quality of the dynamic interrelationship described above. According to Dewey, the paradigmatic experience is an aesthetic experience in which any sense of alienation from other people and the environment is overcome, and in which the natural human need for a sense of meaning and value is satisfied. For him, the unity of aesthetic experience is a felt or emotional unity. Therefore a central feature of Dewey’s approach to experience is the idea of unifying emotion holding experience together and giving it an aesthetic quality. He argues that emotion “selects what is congruous and dyes what is selected with its color, thereby giving qualitative unity to materials externally disparate and dissimilar” (Dewey, 1934, p. 42). So even though a day’s hill walking comprises many disparate elements and will inevitably have good and not-so-good parts, according to Dewey, its emotional quality gives it an experiential unity that shapes our perception of the event as it unfolds, and our memory and recounting of it afterwards.

Dewey (1934) identifies a number of conditions necessary for a fulfilling experience. They are:

- A sense of anticipation about the experience and of continuity between that anticipation, the experience as it unfolds, and reflections on it afterwards
- A sense that each part of the experience accumulates into something meaningful for the person (e.g., planning the walk, driving to the start, the less interesting part through

- scrubland, the challenge of the climb, the great views from the hill, etc.)
- Some level of tension (e.g., about the difficulty of the climb or whether the views from the top will match expectations)
- A sense of fulfilment

These conditions can be seen as an analytic tool to be used when we encounter problems with the unfolding of an experience — what went wrong, why we lost interest, why others got restless, and so forth. In parentheses above, we have referred to aspects of a countryside walk to clarify the conditions for a fulfilling experience. Using these conditions as an analytic tool would facilitate enquiry into the experience of irritation or frustration that might accompany encountering a dead-end midway through the walk. Dewey's conditions suggest that such frustration is due to being unable to complete the walk and fulfil anticipated experiences of the climb or the view from the top, and now anticipating the anti-climax of telling fellow walkers about this frustrated attempt. Often there is little that can be done about such frustrations on a country walk, and natural or man-made obstacles become part of the discourse of communities of walkers. This should not be the case with interactions with technology that has been designed for use by people. Attention to user experience in design should minimise such occurrences, and Dewey's conditions may help in this regard.

Although the sensory and affective are the starting points of Dewey's conceptualisation of experience, his theory also embraces the sense we make of immediate qualitative experiences in the longer stretch of our life experience, and addresses the relationship between the immediate and long-term aspects of experience. And although the immediate sense of surprise, warmth, sleaze, or comfort that we have when we enter a new situation or when we engage with a new technology is transitory, it can also be vivid or intense.

Indeed Hickman (1998), commenting on Dewey's theory of experience, suggests that it is precisely the impact of something vivid but transitory in a situation that makes us pursue that situation again in the future. For example, for hill walkers the vivid but transitory experience of the view from the top may make them want that experience again. It becomes a project, and hill walking becomes an interest pursued in reading and discussion as well as in the actual activity itself. In the process, elements of our experiences and situations become known, not just had. As they become known they enter into the realms of community and cultural sense making, where we bring the resources of community and culture to bear on our appropriation of experience. Through imagination — for instance, imagining how friends might feel about a walk I have just done or indeed about my shopping on the Internet — experience becomes expressive and meaningful in a way that can be shared with others. The meanings appropriated through such imaginative acts can find their way into present interaction, colouring the immediate quality of another experience.

Bakhtin (1986, 1993) provides an account of the relationship between experience and meaning-making that is complementary to Dewey's. Bakhtin's work is useful when considering how the immediate quality of experience is made personal. In terms of ongoing experiences of technology, Bakhtin's work shifts our focus from the immediate quality of an experience to the sense we make of an experience in terms of our experience of our selves, our culture, and our lives.

Bakhtin's central contribution in this area is the idea of dialogicality. Dialogically, any account of experience, including a person's own account to themselves of an experience of buying through the Internet, is social, plural, and perspectival. In Bakhtin's terms, it is *interanimated* with the discourses of others. For example, my sense of myself as someone who supports small local bookshops is interanimated by discourses on global

capitalism, the importance of choice provided by small specialist booksellers, and the centrality of a personal relationship in choosing which books to buy. These discourses however might be accommodating of an Internet bookseller who appears to try to develop a buyer-seller relationship with me based on an understanding of my reading preferences, provides specialist choices, and seems to support small specialist booksellers. If my book-buying activity moves from the small local bookshop to an Internet store that presents itself as engaging meaningfully with some of these discourses and that has other qualities of interest to me also, for example speedy completion of an order, my sense of my self is subtly changed through dialogue with that bookseller.

This relational subjectivity can also be seen in the reflections of filmmakers and writers. Writers and filmmakers practise their craft under the influence of a practical understanding of experience and how they might influence or help create experience. Boorstin (1990), a Hollywood script writer, argues that the filmmaker must be able to experience the film in the way the public will, but in addition must know what it takes to ensure that the public will construct just that experience. He demonstrates how filmmakers deploy technical knowledge of how an audience responds to different kinds of framing, lighting, rhythm, and character — different combinations of which can make a second very long or short and a relationship warm or claustrophobic — to help the viewer create a particular cinematic experience. He argues that one of the sensibilities of great filmmaking is, having deployed technical knowledge and experience, to see like the audience, always anew and open to surprise.

Our aim in drawing together the writings of philosophers such as Dewey and Bakhtin and reflective practitioners such as Boorstin is to try to understand experience to help designers and evaluators create fulfilling interactive experience. This review has enabled us to conceptualise ex-

perience as an irreducible, dynamic interrelationship between person and environment, in which meaning has sensory, affective, and emotional dimensions, as well as the cognitive and socio-cultural aspects that we are used to dealing with in psychology and the social sciences. We have also seen that it may be useful to distinguish between the immediate experience that a person has and the meaning of that experience as it becomes known and thereby appropriated personally and communally. The dialogical dimension added by Bakhtin's work draws our attention to the ways in which immediate experience is associated with personal, social, and cultural sense-making processes, specifically relational aspects of interpretation and reflection, and communal processes such as telling others of our experiences. Implicit in much of the foregoing is a sense of experience unfolding across time and space. This can be seen in both the transitoriness of the immediate experience and in the spatio-temporal relations between the immediate and the lifelong.

The pragmatist literatures on experience that we have trawled offer a very rich account of experience, with some of the characteristics that we have just summarised emphasised more in the work of one writer or another. In order to appropriate these literatures for use in the design and evaluation of rich person-technology experiences, it may be useful to make explicit those aspects of experience that we judge most relevant to the task. To do this we have constructed a framework, based on the above work, which pulls together a set of concepts that may be useful as tools to evaluate user experience with emerging technologies. Taking a pragmatic orientation to theories and concepts as tools to be used, the value of this framework can only be assessed in terms of its value in enriching interactive experience. Therefore in the next section we describe the framework, and then take a first step in using it and—together with a team of e-commerce practitioners — assessing its use.

USER-EXPERIENCE FRAMEWORK

The framework that we present in this section represents an attempt to model experience in a way that designers and analysts of interactive systems would find useful. It is derived from the literatures reviewed in the previous section; the provenance of each element in those literatures has already largely been established. For example, Dewey's concern for a holistic approach and the equal weight he gave to affective and intellectual sense making is manifest in our characterisation of four intertwined threads of experience. Some of Boorstin's perspectivalism is reflected there too. In terms of sense making, Dewey's concepts of anticipation, reflection, and the pre-linguistic sense of meaning are echoed in our account of the sense-making processes. Bakhtin's concern for unity as an active accomplishment is reflected in our characterisation of appropriating, reflecting, and recounting. But more subtly, what we have tried to do in our presentation of these threads and processes is to understand Dewey through Bakhtin's dialogical lens. Thus, self-other relations as continually constructed permeate the framework.

Earlier, when we described Dewey's (1934) conditions for a fulfilling experience, we briefly demonstrated how the conditions could be used as an analytic tool to explain why a particular hill-walking experience might be frustrating. The framework we present here is intended to perform similar work for people's experiences with interactive systems by helping to explain why, for example, particular interactive experiences are satisfying and others frustrating. So although there may be more elegant ways of describing experience, such as the narrative, analogical approaches used in ethnography (see for example Anderson, 1994; Geertz, 1993; Orr, 1990), our hope is that the explicit separation and classification of aspects of experience in the user-experience framework will prove useful in the design and evaluation of

Figure 1. Threads of experience and the sense-making processes

interactive systems without losing too much of the relational, holistic approach to experience from which the framework is derived.

The framework is composed of two simple lists. The first, the four threads of experience, describes the major aspects or components of experience that we draw from the literatures reviewed earlier. The second identifies six sense-making processes associated with meaning in the same pragmatist accounts of experience.

Four Threads of Experience

Following Dewey and Bakhtin, we propose that the braid of experience is made up of four intertwined threads: the compositional, the emotional, the spatio-temporal, and the sensual.

The *compositional thread* is concerned with relationships between the parts and the whole of an experience. Looking at a painting, composition refers to the relations between elements of the painting and their implied agency, and between viewer, painting, and setting. In an unfolding interaction involving self and other, in a novel, play, or technologically mediated communication,

it refers to the narrative structure, action possibility, plausibility, consequences, and explanations of actions. In Internet shopping, the choices that are laid out for us can lead us in a coherent way through ‘the shop’ or can lead us down blind alleys. Attention to the compositional thread evokes questions like: “What is this about?” “What has happened?” “Where am I?” “What will happen next?” “That doesn’t make sense?” “I wonder what would happen if...?”

The *sensual thread* of experience is concerned with our sensory engagement with a situation, which orients us to the concrete, palpable, and visceral character of experience, the things that are grasped pre-reflectively in what Dewey (1934) refers to as the immediate sense of a situation. For example, the look and feel of a mobile phone, the garish colours and grating sounds on a Web site, and the sense of warmth and welcome in a room. Whether or not sensual attraction to an object (e.g., a mobile phone or a Web site) is welcome depends on our needs, desires, and what we value at that particular time. Such attraction could be unwanted and lead to frustration or disgust, or it could complement the emotional content of the experience.

This *emotional thread* refers to judgments that ascribe to other people and things importance with respect to our needs and desires. Our frustration, anger, joy, and satisfaction acknowledge our need for others or the other in our struggle to achieve emotional unity. We can reflect on our own emotional aspect of an experience, and we can through empathy relate to the emotional aspects of others’ experiences. Relating to a character in a movie is an obvious example, but we might also empathise with the artist or designer who creates an artefact even though that person is not materially present in the situation.

We need to distinguish between the sensual and emotional threads, since we can engender emotions associated with achievement through the exercise of control over sensations such as at-

traction, fear, or anxiety. Although I might get an immediate thrill from buying the most beautiful mobile phone in the shop, it may cut against my commitment to not being conned by surface features and advertising. My decision not to buy the most beautiful phone and instead to buy a plainer one that is half the price but just as good may leave me with a strong feeling of self-satisfaction. Here the sensory and emotional threads interact to shape the experience, the actions chosen, and the sense we make of them.

An intense emotional engagement can make our sense of time change. A frustrating experience can leave us perceiving space as confined and closeting. Space and time pervade our language of experience. We talk about needing space to settle an emotional conflict and of giving people time. Time may speed up or slow down, pace may increase or decrease, spaces may open up or close down. Space and time may be connected or disconnected. In our construction of the *spatio-temporal thread* of an experience, we might distinguish between public and private space, and we may recognise comfort zones and boundaries between self and other, or present and future. Such constructions affect experiential outcomes such as willingness to linger or to re-visit places, or our willingness to engage in exchange of information, services, or goods.

Making Sense in and of Experience

According to Dewey (1925, 1934) and Bakhtin’s (1986, 1993) ideas on experience described above, people actively construct or make sense of experience. Bakhtin’s emphasis of the dialogical in sense making suggests that making sense of experience is reflexive in that we always view experience from a personal perspective, whether it is the first person or the third person, or whether it is by recounting an experience to oneself or for others. This is central to what it means for something to be an experience. For both Dewey

and Bakhtin, there can be no experience without self and other, or subject and object, interacting reflexively. As indicated earlier, we have extracted the following six sense-making processes from Dewey and Bakhtin's work as an explication of processes that may be useful for understanding people's experiences with technology. There is no implication of linear or causal relations between these processes. It is conceivable, for example, that in anticipation of some future planned action, we reflect on the consequences of that action engendering a certain sensual response. Or it could be that how we recount our experience to others may change how we reflect on it.

Anticipation or expectation is a continuous process in experience. When visiting the Web site of a well-known company for the first time, we bring expectations, possibilities, and ways of making sense that we associate with prior experience with the brand. Although anticipation suggests something that is prior to the experience, it is important to remember that it is not only prior. The sensual and emotional aspects of anticipation, and our expectation of the compositional structure and spatio-temporal fabric of what follows, shapes our later experience. It is the relation between our continually revised anticipation and actuality that creates the space of experience.

Connecting refers to the immediate, pre-conceptual, and pre-linguistic sense of a situation encountered. In the spatio-temporal aspect, this may be an apprehension of speed or confusing movement or openness and stillness, for example. Sensually, connecting may engender an immediate sense of tension or perhaps a thrill of novelty. Emotionally and compositionally, connecting may engender nothing more than a sense of relief or anticipation at something happening.

Interpreting an unfolding experience involves discerning the narrative structure, the agents and action possibilities, what has happened, and what is likely to happen. The process of interpreting may evoke a sense of the thrill of excitement or

the anxiety of not knowing. At an emotional level, we may feel frustration or disappointment at thwarted expectations, or we may regret being in this situation. On the basis of our interpretation falling short of our anticipation, we may reflect on our anticipation and alter it to be more in line with our interpretation. From a spatio-temporal aspect, the questions are: Can we make sense of the experience in space and time? Do we know where we are, where we've been, and where we have to go?

At the same time as interpreting, we may also make judgements about the experience as it unfolds — *reflecting*. We may try simply to make sense of the things that are happening and how we feel about them, or wonder whether there is progress or movement towards completion. From an emotional aspect, we may relate events to motivation and whether we achieved any sense of fulfilment. How does the experience tally with our anticipation and how do we feel about being in this situation and this time? From a sensual perspective we wonder why we are anxious or bored. This is like an inner dialogue that helps us to meaningfully recount our experience to others, the anticipation of which may help us to reflect. "I wonder what Tom would think of this?"

By *appropriating*, we mean making an experience our own by relating it to our sense of self, our personal history, and our anticipated future. If it turns out to be an experience we identify with or want to experience again, the centre of our personal universe may have shifted slightly. Moreover, by imagining the experience in the context of a past and a future, we may give it a meaning that is more personal to us. Does our sensual "white knuckle ride" of the theme park or the unique sense of immersion in undifferentiated colour when, as a first-time scuba diver, we descend into "the blue" change who we are, make us rethink how we want to be and want to be seen? Do the compositional aspects of the experience relate positively to our sense of self or not? Do

we feel it is morally right or socially acceptable to go shopping at a virtual supermarket? Is the experience of using a video phone one in which new possibilities for action in our everyday life become apparent, or is it yet another concession to an undesirable technological future?

Recounting is fundamentally dialogical, as it involves telling others or ourselves about the experience. Like reflecting and appropriating, it takes us beyond the immediate experience to consider it in the context of other experiences. Recounting gives us the opportunity to savour the experience again, to find new possibilities and new meanings in it, and this often leads us to want to repeat the experience. And as a dialogical process of meaning making, recounting facilitates our accommodation to the valuative responses of others. As we tell the experience, it can change depending on the moment-to-moment response of the other.

Earlier on, we reviewed literature on experience in an attempt to begin to provide a sound basis for conceptualisations of user experience in people-technology relations. In this section, we have shaped some of the ideas from above into a framework that we hope will be of use to designers and evaluators of interactive systems who are concerned with the quality of experience people have with their systems. Next we will report an action research assessment of the use of the user-experience framework in a commercial setting which was designed with some e-commerce practitioners to assess the use of the framework by themselves and their colleagues.

INTERNET SHOPPING AT VIRGIN

An Action Research Study of the Framework in Use

This study was carried out with the support of Siegelgale, a leading international branding and

e-commerce consultancy, and Virgin. Virgin was chosen because participants in the study were familiar with the company, already having had Virgin shopping experiences, and because, at the time, Virgin had an ideal mix of shops and services for our purposes. For example, they had a strong online presence, including several purely Internet-based offerings, bricks-and-mortar stores, a WAP service related to Virgin Radio, and multiple products and services.

The aim of the study was to explore with practitioners, who were involved in evaluating online and offline shopping experiences, their use of the user-experience framework. The practitioners became involved in this research because they felt that an understanding of user experience would help them in their work. In the spirit of participatory action research (Rapoport, 1970; Wadsworth, 1998), some of the participants were involved in devising the assessment process, and all of them were free to choose a Virgin shopping activity that was of some interest to them when assessing the framework. Moreover, the research was intended to help authors and participants refine their understanding of user experience and of the usefulness of the framework in their work. Specific research questions were:

1. What kinds of insights into Internet shopping experiences would the framework elicit?
2. What aspects of Internet shopping experience would it miss?
3. How useful would it be as a tool for helping make sense of experience?

Method

The method employed was qualitative action research in which participants were required to have and record 'Virgin experiences'. Because it was conceived as an exercise in participatory action research and design (Schuler & Namioka, 1993), in which those who are likely to use a tool

participate in its development, participants had the freedom to explore and critique the framework in a setting close to real-world use. Therefore within the constraints of practicality and availability, they were allowed to select their own Virgin shopping experiences.

In this study, the user-experience framework was used to guide participants' sense making with a view to understanding the kinds of insights it elicits, the aspects of experience it misses, and the extent to which participants felt it helped them to make sense of their shopping experiences. The user-experience framework suggests two possible starting points for enquiry: the threads of experience and the sense-making processes. We chose the sense-making processes because we thought they provided the more accessible starting point. Each process was unpacked for the participants in the form of a list of questions that suggested what aspects of sense making that process was intended to explicate. The full list of questions is available in Appendix 1.

The study was designed to collect data at three points:

1. Baseline data was collected in the initial interview in which participants' impressions of Virgin, their expectations of what shopping with Virgin would be like, and the sources of those expectations were elicited.
2. Participants made contemporaneous notes on their shopping experiences. It was suggested to them that they use the sense-making processes part of the framework to structure these notes. The resulting notes are the primary source of data on the experience of Internet shopping and on the framework as a resource for making sense of the experience.
3. After participants handed in their notes, we held individual debriefing sessions with them in which we asked them questions about their experience to elicit an oral recount-

ing of the experience. In the debriefing, participants were also asked to comment on the usefulness of the framework as they had employed it as a tool for eliciting accounts of interactive experiences.

Participants

Seven employees of Siegelgale, two men and five women aged between mid-twenties and mid-thirties, volunteered to take part in this study. They were all graduates and regular users of a variety of information and communication technologies, particularly Internet and phone-based services. In keeping with the participatory action research approach of this study, they were all also involved in the design and/or evaluation of e-commerce, and were therefore in a position to judge whether the framework would help them in their work.

Procedure

During the first meeting with all the participants at their workplace, they were each briefed individually on the aims and objectives of the research and on the idea of making sense in and of experience. They were also specifically introduced to the sense-making processes identified in the framework. These processes were explained to them with the aid of a set of questions for each process that expressed what was meant by the particular process. These questions were intended to illuminate each of the processes and to clarify the differences between them. The questions are listed in full in Appendix 1.

Once the participants felt comfortable with the concepts in the framework, we asked them to choose some Virgin services that they would like to experience. Most elected to have three experiences, although some chose two. The full list is in Table 1. We completed this first interview by asking participants what they felt about Virgin, what they anticipated their experiences would be like, and how those expectations had formed.

Table 1. Shopping experiences that participants chose to attempt

Participant	Virgin Shopping Experiences to be Attempted
1	Make enquiries at virginmoney.com
	Buy books and records at virginmega.com
	Buy books and records at a traditional bricks and mortar Virgin Megastore
2	Find the price of a flight at virgin-atlantic.com
	Make an enquiry at virginmoney.com – how much do I need to save to retire at 60?
	Buy a CD at a traditional bricks and mortar Virgin Megastore
3	Upgrade phone at virginmega.com
	Find out details about phone handsets at a traditional bricks and mortar Virgin Megastore
	Find Virgin shop locations from Virgin WAP
4	Listen to music and buy a CD from Virgin WAP
	Check music schedules, gigs etc. on Virgin WAP
	Buy a CD at a traditional bricks and mortar Virgin Megastore
5	Get information on buying mutual funds at virginmoney.com
	Check availability of CDs by a particular group and buy one that I don't have at virginmega.com
6	Check availability and price of two CDs and possibly buy them at virginmega.com
	Make enquiries about mortgage quotation and debt consolidation at virginmoney.com
	Buy a CD at a traditional bricks and mortar Virgin Megastore
7	Buy books and records at virginmega.com
	Buy books and records at a traditional bricks and mortar Virgin Megastore

The participants engaged in their respective shopping experiences over a maximum period of four days. They were permitted to approach the experiences in whatever order suited them and to complete them in the time that suited them within the four days, from one sitting to a number of sittings over the full time allowed. They were required to make contemporaneous notes on their experiences and were encouraged to use the framework of the six sense-making processes to structure these notes. Having completed their shopping experiences, they then handed in their notes, and we conducted one-on-one debriefing sessions that gave them the chance to give an oral recounting of their experiences. We also asked them to describe what it was like to use the framework and the methodology to order the events and feelings of their experiences.

Thus, at the conclusion of this research, we had three sets of data to analyse: the initial interviews,

the participants' records of their experiences, and the content of the debriefing. The analysis consisted of a thematic content analysis of the records of the initial interview, final debriefing, and of the participants' contemporaneous notes.

Analysis of Data

Initial Interviews: Expectations and Prior Perceptions

In the initial interviews, participants expressed a variety of opinions about what they expected their Virgin experiences to be like. Participants identified their anticipations as stemming from a number of sources, listed in Table 2.

The majority of the participants were well disposed to Virgin prior to their participation in the research, as can be seen from Table 3, in which the Virgin attributes they identified are listed.

Table 2. Sources of expectations about Virgin experiences identified by participants

Prior experiences with the same Virgin service in the same channel.
Prior experience with the same service in a different channel.
Prior experience with a different service in the same channel.
Prior experience with a different service in a different channel.
Other peoples' narratives about Virgin experiences.
The name of the service, especially if it appeared descriptive (for example, Virgin Money).
Advertising.
Experiences with different products and services (for example, the online bank Egg) overlaid with assumptions about Virgin.

Table 3. Attributes of Virgin identified by participants in the initial interview

Positive Attributes Identified	User friendly with a "feel good" factor; Entertaining; Funky; Modern; Colourful; Young; Honest; Fun; Informal; Good customer service; Fresh; Provocative; Anti-establishment; Innovative
Negative Attributes Identified	Gimicky; Cheap; Appearance-driven

Contemporaneous Notes: Shopping Experiences

Positive expectations notwithstanding, it was clear from analysis of the contemporaneous notes that some participants had had difficulty achieving some of their objectives for their various experiences. Their troubles stemmed from the following causes:

- *Inaccurate expectations of the service.* While this occurred in several instances, there was a particular problem with virginmegastore.com. One participant noted that the site was "not as rewarding [an] experience as I'd hoped for, it was more of an information site as opposed to a interactive site." A number of participants assumed that it would be both an informational and a transactional site, but found instead it was a promotional 'magazine-like' site. This caused much irritation.
- *The services, be they online or bricks and mortar, had usability problems.* At virginmoney.com, for example, while one participant sailed through the registration

process, two others had numerous difficulties. resulting in error messages and general confusion. Further, at Virgin Megastore, one said that it took a long time to find a store plan that would inform him where he could find the books section. Thus, by the time he found the section, he already felt that he had wasted time and was unwilling to spend more time browsing.

- *There was poor localisation, resulting in confusion about the real-world location of online services.* All of the participants read the Virgin brand as British, and thus expected access to all of the services linked to the virgin.com site. Those who went from there to virginmegastore.com were perplexed by the fact that they landed on a U.S.-based site with, for example, a U.S. and Canadian store locator, but no information at all about British stores. One participant commented that the site was "not that useful to me as it is very U.S. oriented." Worse, it often took participants a few minutes to figure this out, time they later considered "wasted."

- *There was no clear reason given on the site for participants having to register—which was a requirement for obtaining information and services.* This was only relevant for virginmoney.com, which demanded registration to access anything more than the most basic information on the site. Participants didn't understand why they had to register just to use goals calculators and so forth, and often chose to leave the site and perform the same tasks elsewhere, where they would not have to register. One commented as follows in her notes:

“Oh! They want me to register now. I'm confused...can't I just look at financial planning stuff? I don't want to register yet. I'm going to leave.”

In the context of the foregoing comments, it is worth noting that many aspects of Virgin sites and services have been changed since this study to improve usability.

Participants assigned responsibility for failing to achieve their objectives to a number of different sources, which are listed in Table 4.

Those participants who started out well disposed to Virgin were the most likely to trace the responsibility for their difficulties to a source other than Virgin. Nevertheless, if these particular participants subsequently had problems achieving their objectives in the course of another Virgin experience, they were apt to feel particularly let

Table 4. Sources of responsibility for failing to achieve objectives identified by participants

<p>'Bugs' and/or limitations inherent to the channel (this was especially the case for WAP). The service in and of itself.</p> <p>A particular articulation of the service, e.g. the Virgin Megastore on Oxford Street versus the one at Piccadilly.</p> <p>The participants themselves.</p> <p>Virgin.</p>

down, as if a trusted friend had betrayed them. Participants blamed themselves in the instances where they realised they had inaccurate expectations of the service to start with, and tended to readjust their objectives to what they perceived the service offered. For example, most participants expected virginmegastore.com to be transactional, but promptly set themselves other goals when they felt that it was not. However, if participants found their new objectives thwarted as well, they tended to shift blame to the service, stating that their expectations were being poorly managed and thus their time wasted. For example, one participant wrote, “The Web site visit was so bad that I might relish recounting the experience to friends...”

Although the participants' accounts highlighted where Virgin is delivering poor or fragmented customer experiences, they also indicated where Virgin is 'getting it right', that is, providing consistent experience, creating and meeting expectations, and even creating the new or wonderful. Particular successes included:

- *Participants generally knew they were in a Virgin environment.* The consistency of the Virgin look and feel, the tone of voice, 'hip or trendy' design, and the positioning of the logo all contributed to making participants feel that they were in the right place.
- *Some services, such as Virgin Atlantic, are delivering a consistent service across touch-points, leading to a seamless experience.* For example, one participant reported, “The va.com site seems to try to make the potentially dull site more fun, with simple perks and design features, much like the airline itself.”
- *Even where some Virgin offerings fail to provide a consistently good experience across touch-points, one may stand out for its excellence and save the experience as a whole.* One participant was attempting to get information on switching to Virgin,

and on upgrading to a Nokia tri-band phone. Having found neither the Virgin shops nor virginmobile.com helpful, she started to despair that Virgin was “all hype and no substance.” However, she then tried the Virgin Mobile call centre, where she had a remarkably different experience. She didn’t have to wait for service, and the salesperson was well informed, friendly, and easy to speak to. Thus her final impression of Virgin was “cool and upbeat.”

- *On occasion, Virgin was able to elicit strong and positive emotional responses from the participants.* For example, one participant commented that the site “made me feel good, happy feeling...Felt comfortable straight away because felt like I was in a familiar environment — reflects what I know about Virgin.”

Participants’ responses to Virgin point to several conditions that help create these strong feelings:

- a. If customers perceive themselves to be in control of the experience, they feel “relaxed and empowered,” and are more likely to trust the service provider. Crucially, they may also be more likely to invest time.
- b. Beautiful, “fresh” design — be it online or in-store — is affective and thus effective. It also makes a strong first impression and has the power to generate excitement.
- c. Innovation, novelty, and humour, which appear to participants as key aspects of the Virgin brand, can create difference and enchantment. For example, one user was charmed to find “Pardon?” written on the package of the ear plugs supplied by Virgin Atlantic, when she had previously flown with them and three out of three participants mentioned VirginMoney.com’s exhortation to read the small print on the site — “be-

cause it came from our lawyers...[and was] expensive.”

- d. Participants responded warmly to those touch-points that appealed to their curiosity and offered them the chance to play, be it with in-store listening consoles in the Virgin Megastores or interactive calculators on VirginMoney.com.

Final Debriefing and Interview: Evaluating the Framework

Analysis of data from the debriefing and final interview suggests that the framework was useful for evaluating shopping experiences. There was a general consensus that the framework was useful in both online and offline settings, and that it provided a process for evaluating experience, especially the consistency of experience across multiple channels. The main comments of participants on the value of the framework include the following:

- *It was helpful to address the issue of anticipation at the outset, as what one expects and hopes will happen sets the stage for what does happen.* Indeed, several participants said that this was a subject worthy of investigation in its own right, especially as it pertains to attempts to create a totality of experience across multiple touch-points.
- *A particular strength of the framework is that it provided the means to capture both factual (e.g., “this happened, then this happened”) and subjective aspects of experience.* In their contemporaneous notes, all participants had included records of events that had happened while shopping and some comments on their feelings about how those events unfolded. In the debriefing, a number of participants commented that the framework had been a useful reminder to attend to both aspects in their notes. One commented that the frame-

- work was good at “capturing both factual as well as subjective aspects of experience.”
- *The framework dealt with experience in depth.* Some participants said that they felt the framework was embracing enough to cover the full gamut of their thoughts, feelings, and actions during the experience. For example, one participant said that the framework was “good for capturing expectations and emotions, capturing of fact and being conscious of separation.” Though, as we shall see later, some also felt that the framework did not always capture the highs and lows of experience.
 - *The framework not only provides the means to analyse experience, it could implicitly guide strategists and designers as they create purpose-built user experiences.* By delineating the threads and the sense-making processes of an experience, the framework provides a tool for designers to look at experiences from a user’s perspective. This means thinking about not just what users see, but additional factors including other sensory stimuli, location, sense of time, visceral reactions, emotional connections, and the way users may relate a given experience to other experiences.
 - *The framework does not always capture the highs and lows of experience.* A weakness of the framework noted by one of the shoppers was its failure to address the kinds of high points and low points that can become the focus of attention in recounting. This comment seemed to reflect a sense that the framework lacked explicit attention to the intensity of emotions and feelings.
- While our questions concerning ‘Anticipating’ adequately covered issues such as the perception of the company and the expectations of the channel, some participants felt we overlooked the *feelings* attached to tasks, such as the excitement of arranging air travel, or the trepidation surrounding WAP. Participants found these feelings so significant that, despite the fact that the framework itself inherently accommodates such emotional factors, they suggested that they should be emphasised in the method.
 - Some participants were unsure about the separation of some elements such as ‘Interpreting’ and ‘Reflecting’. This suggests that, while appropriate in the framework itself, it is too strange for users to try to interrupt the flow of experience to gauge such nuances in their own reactions.
 - Some participants felt that being primed by knowledge of the sense-making processes in advance helped them to think about what should be noted but other did not. There was also some disagreement about whether to use the framework to sensitise users to aspects of experience or as an analytic resource for evaluation.

CONCLUSION

In designing this study, we wanted to get a sense of what insights practitioners would get into shopping experiences. We also wanted to know what aspects of experience the framework might miss and how useful participants would find it as the tool for evaluating experience. The thematic content analysis of participants’ contemporary notes on their shopping experiences indicated a number of ways in which their shopping experiences were more or less satisfactory. These were summarized above. Discussing these observations with participants suggested a number of issues. They include:

One of the main aims of the case study was to determine if people could work with the framework in order to articulate user experiences. Our participants’ experiences with the framework suggest that certain issues need to be resolved for future use. These include:

- Expectations are an important factor in shaping a person's experience. It is the relationship between a person's expectations and their actual experience that affects the emotional quality of the interaction, leading for example to disappointment, surprise, satisfaction, and so on.
- The issue of localisation highlights the fact that people enjoy feeling that they know where they are, and that where they are is where they expect to be. For example, links to shops that, without warning, take people from a British site to an American can be disorientating.
- People may be reluctant to provide personal information without a clear rationale or an obvious benefit to them. They may for example assume the reason is unwanted follow-ups and marketing.
- Poor usability can still be a problem, even on professionally designed sites, leading to erosion of trust in the service provider.
- People consider Internet services as part of a broader relationship with a company or organisation and seem to value consistency across touch-points.
- An emotional commitment to an Internet shopping service depends upon, among other things, customers: perceiving themselves to be in control of the experience; finding their curiosity and playfulness aroused by the site; and feeling that the site is novel and appealing.

Although not all of these findings are novel, what they suggest is that the framework was successful in allowing the participants to identify and articulate important design factors. We also asked the participants to reflect on the experience of using the framework as a tool for analysis. When reflecting on their use of the framework, participants picked out certain features that led them to think about aspects of experience that

they might not otherwise have considered. For example, they had not considered the role that anticipation and expectation plays in how we make intellectual and emotional sense of an experience, and how this might be included in an empirical evaluation of experience. In many accounts of user experience, it is assumed that the experience begins when we log onto a site and ends when we press the 'confirm' button. The framework helped participants to expand their consideration of experience in both directions—to what goes on before the interaction and to what goes on after it, for example the way in which through reflection and recounting we may or may not decide to go back to a site for a second or subsequent visit.

The participants valued the way in which the framework helped them relate the affective aspects of interaction to behavioural aspects of the experience such as what they had to do and in what order. The affective aspects allowed them to think about issues such as sense of time, visceral reactions, and emotional connections between different experiences in ways that were more insightful than other approaches. They also felt that the framework provided a 'commonsense' account of experience that could be used by other types of practitioners such as designers and business analysts for whom a user perspective is of value.

The participants also had some critical comments on the framework that fell into two categories: ones that pointed up some limitation of the framework as it stood and ones that would have liked the framework to be able to do extra work that it was not originally designed for. For example, some participants had difficulty separating the sense-making processes 'Interpreting' and 'Reflecting'. Although we still believe that there is a distinction between these two processes that is worth preserving in the framework—between the activity orientation of Interpretation and the evaluative orientation of Reflection—it is clear that we shall need to make the difference

between them much clearer to future users of the framework. Another comment — that the framework did not capture the highs and lows or intensity of experience — seems to ask the framework to do analytical work that it was not originally intended to do. In response we would suggest that the emotional thread identified in the framework accommodates aspects of the intensity of experience without, however, attending to its measurement, which was not our intention for the framework, but which might be a subject of future research.

Any such critical comment notwithstanding, the most positive outcome from our perspective is that, despite participants finding some aspects of the framework difficult to work with, they were consistently able to generate the kind of data that would allow designers and analysts to understand user experience and to use that understanding in designing better interactive experiences.

While the strength of this study was the participatory action orientation that led us to test the framework with practitioners in a practical setting, it had some limitations that would need to be addressed in further evaluation of the framework. The main weaknesses relate to the method used to deploy the framework in this study, that is, asking participants to relate their experiences to the six sense-making processes. It required an a priori introduction to a technical element of the framework that might have better been employed to explain experience already had. It may have also implied that more weight should be given to the sense-making processes than to the threads, resulting in a sense that the intensity of experience was underplayed. Another aspect of the method was that it required participants to make contemporary notes on their experiences. It is arguable that this could have contributed to shaping the experiences as more reflective than they might otherwise have been.

Because the framework is open rather than prescriptive, it provides fertile ground on which to develop alternative methods of deployment. These would likely be project dependent, although we do already have some ideas about how to create more elegant and participant-friendly methods. One possibility for this would be to ask participants to focus on describing the ‘threads’ rather than the sense-making processes of experience. Contrary to our original expectations, the threads may be more immediately accessible to participants than the sense-making processes. Another would be to partner with participants during the course of their experiences, asking them the kinds of questions that were used in this study to explain the sense-making processes, but freeing them from the burden of contemporaneous note taking. This might create a more natural situation, something akin to a socially shared experience. A third possibility would be to ask participants to generate a ‘stream of consciousness’ narrative of their experience in real time or retrospectively, or even to send text or voice messages to the researcher, and for researchers and participants together to use the framework to explain and evaluate the experiences recounted.

Our experiences of working with Siegelgale and of developing and assessing the framework in a practitioner-centred way has led us to further action research projects concerned with experience-centred design. These will address some of the shortcomings of the current study. In these projects we have a long-term involvement with a number of companies involved in experience-centred design. The literature on experience-centred design that has appeared while we have been engaged in the study reported here (e.g., Garrett, 2002) strongly confirms our view that a richer conceptualisation of experience and related methods are required in order to improve design practice. In our current projects we are working closely not only with users but also with

designers, developers, and consultants to analyse experience-centred design practice and how this practice impacts on user experience. This involves participation in design meetings and working on a one-to-one basis with designers and developers to understand experience design practice and to identify how the user-experience framework can be used to improve that practice. Our work with users in this project involves us bringing accounts of user experiences back to the designers to help them reflect on the relationship between their design decisions and user experiences. In these projects the framework is used as a critical lens on user experience and experience design. In the process the framework is again being assessed and refined.

ACKNOWLEDGMENT

We would like to thank two anonymous reviewers and the associate editor Professor Marchewka for their help in making this a much clearer and more useful article than it might otherwise have been. We would also like to thank Siegelgale and Virgin for their participation and support, and the EPSRC for funding a visiting fellowship (GR/S18799/01) that supports the collaboration between Peter Wright and John McCarthy.

APPENDIX A

Questions Supplied to Participants to Help Clarify the Sense-Making Processes

The following questions were devised with two of the participants as a way of clarifying what each of the sense-making processes mean in terms of the user experience framework. For example, the questions listed under 'Anticipating' are intended to clarify a variety of aspects of anticipating an experience, specifically in this case an experience of Internet shopping. During the first meeting with the participants in which they were briefed individually on the aims of the research, they were specifically introduced to the sense-making processes in the framework. At this point the questions listed below were used to help explain the sense-making processes. During the rest of the study, participants had a list of these questions to refer to. However they were not expected to answer these questions per se; rather they were to use them to guide the notes they made on their shopping experiences.

Anticipating

- What do you expect will happen?
- What do you think you will be able to do?
- Describe what you imagine will happen as you begin your task.
- Does your sense of who Richard Branson is and/or what he stands for affect your sense of what to expect at all? If so, please explain.
- What expectations do you have based on previous Virgin experiences with the same service/channel or different service/channel?
- What expectations do you have based on completing the same tasks in the past with different companies or brands (or sites/stores/airlines)?
- What expectations do you have based on something someone else has described about this service, this channel, or Virgin as a brand?
- What is going on in the environment around you that might affect your anticipation, e.g., fighting down Oxford St. and hoping for peace in the Megastore, furtively trying to shop for a mortgage while at work, etc.

Connecting

- What is your first impression?
- When/how do you feel that the experience actually starts?
- What do you first apprehend of the experience?
- Colours, tempo, movement, salespeople, etc.
- How do spatio-temporal factors affect this, and why?
- What does this first impression make you feel?

Tension, Thrill of Novelty, etc.

- Is there anything in particular that immediately engages you or puts you off (e.g., colour, sound, images used, etc.)?
- What sensual/sensory and emotional factors of this experience or episode allow a connection with the brand or create a feeling of disconnectedness with your expectations of the brand?

Interpreting

- How are you making sense of what you are finding?
- Do you feel that the experience is living up to what you anticipated? Please explain.
- Do you feel that there is a logical and coherent order to what is happening?
- Have you “settled into” a response or feeling about what the experience is offering?
- Do you know where you are, where you’ve been, and where you have to go, e.g., do you know what you have to do next? What cues provide this guidance?
- Are there bottlenecks somewhere? Why?
- How aware of time are you? Is it taking a long time to do what you want, or is time racing by?
- Is there a clear end point?
- Could you accomplish your task within a reasonable amount of time?
- How does the composite of these elements affect your interpretation of the brand?

Reflecting

- What are you feeling about the experience?
- Are your feelings about the experience consistent throughout, or do they change?
- Do you feel motivated to continue or frustrated at what’s going on? Do you wish you could shorten or prolong the experience? Why?
- Who do you feel is in control—you or Virgin or someone/something else?
- Do you trust the information or service you’re getting? Why/why not? Is anything happening to enhance or undermine that trust? Please explain.
- Do you feel a sense of ongoing engagement?
- If this experience is indeed different to what you expected, how do you feel about that? Do you feel inclined to give a little leeway to the service/brand/channel? Why or why not?
- Do you feel that the experience is being directed at you? Why/why not?
- Do you feel a sense of fulfilment or achievement at the conclusion of the experience? Why/why not?
- How is the experience consistent or inconsistent with the values you associate/d with the brand?
- Do you feel the brand is fulfilling its promise?

Appropriating

- How are you making sense of this experience within a larger framework of experience, e.g., with Virgin or with the channel?
- Did it fit in with how you like to do things?
- How did it change or deepen your impression of the brand/service/channel?
- Was there any aspect of it that made you feel uneasy? Please explain.
- What aspects did you find particularly rewarding?
- Was there anything that surprised you? If so, what was it and why?
- Did the experience remind you of anything and, if so, what?

Recounting

- How would you describe the overall experience?
- What were the most memorable things about it?
- Do you feel much inclined to describe it to anyone? Does it make a good story?
- Are there any bits you particularly enjoy remembering?
- How do others react to your story?

Chapter 2.12

Different Levels of Information Systems Designers' Forms of Thought and Potential for Human-Centered Design

Hannakaisa Isomäki
University of Lapland, Finland

ABSTRACT

This article describes a study clarifying information systems (IS) designers' conceptions of human users of IS by drawing on in-depth interviews with 20 designers. The designers' lived experiences in their work build up a continuum of levels of thought from more limited conceptions to more comprehensive ones reflecting variations of the designers' situated knowledge related to human-centred design. The resulting forms of thought indicate three different but associated levels in conceptualising users. The separatist form of thought provides designers predominantly with technical perspectives and a capability for objectifying things. The functional form of thought focuses on external task information and task productivity, nevertheless, with the help of positive emotions. The holistic form of thought

provides designers with competence of human-centred information systems development (ISD). Furthermore, the author hopes that understanding the IS designers' tendencies to conceptualise human users facilitates the mutual communication between users and designers.

INTRODUCTION

As information systems (IS) increasingly pervade all aspects of everyday life, of utmost importance is how applications of IS are adjusted to human action. In particular, in current information systems development (ISD) it is essential to take into account human characteristics and behaviour; that is, to humanise IS (Sterling, 1974). In the same vein, Checkland (1981) argues that ISD should be seen as a form of enquiry within

which IS designers' understandings regulate an operationalisation of their intellectual framework into a set of guidelines for investigation that require particular methods and techniques for building the system. Regarding the humanisation of IS, a notion concerning the nature of the human being is a crucial element of the intellectual framework. As a consequence, within this kind of enquiry, the way humans are taken into account in ISD is dependent on the operationalisation of the IS designers' conceptualisations of users. With respect to human-centeredness, attention should be paid to the fundamental qualities of people without any explicit or implicit domination of the other elements of IS, such as data, formal models and technical appliances, or managerial belief systems that treat humans instrumentally. This is necessary in order to conceptualise humans in their own right, and thus avoid the reduction of humans to something that exists only in relation to particular instrumental needs and purposes (cf. Buber, 1993).

Of essential importance is the nature of IS designers' insights into human characteristics and behaviour that are essential with respect to the IS-user relationship. The most crucial insight regarding human-centred design is to be able to conceptualise users as active subjects comprised of physical, cognitive, emotional, social and cultural qualities, an insight which is the prerequisite for design that promotes subsequent user acceptance and satisfaction. Yet conspicuously absent from contemporary IS literature are empirical studies investigating IS designers' conceptions of the human users, which have been studied more intensively two decades ago when the systems designers' inadequate view of the user has been stated to be one reason for the behavioural problems often experienced while implementing IS (Bostrom & Heinen, 1977; Dagwell & Weber, 1983). Also, the lack of knowledge of human needs and motivation on the part of the systems designers has been claimed to cause IS imple-

mentation failures (Hawgood, Land & Mumford, 1978). Further, Hedberg and Mumford (1975) have defined the nature of the view of human being held by systems designers as an essential factor in the IS design process. The systems designers' view of the user is also included in some studies as one of the targets of value choices during the ISD process (Kumar & Bjørn-Andersen, 1990; Kumar & Welke, 1984) and is therefore defined as a value rather than an insight in these studies. Dagwell and Weber (1983), in their replication study, rely on Hedberg-Mumford's definition of the concept but also refer to Kling (1980). "we know very little about the perceptions that computer specialists have of the users they serve and the ways in which they translate these perceptions into concrete designs (p. 47)." Bostrom & Heinen (1977), in turn, define systems designers' assumptions of people as one of the system designers' implicit theories or frames of reference. These previous works do not take an explicit stance toward the definition of the concept "conception," and do not align the nature of conceptions in detail. For instance, from where do conceptions derive their origins, and what is the nature of those conceptions? In a more recent study, Orlikowski and Gash (1994) discuss their definition of the IS designers' views. They elaborate the concept "*frame of reference*" by comparing it to the concept "*schema*" (Neisser, 1976, pp. 9-11), "*shared cognitive structures*" or "*cognitive maps*" (Eden, 1992, pp. 261-262), "*frames*" (Goffman, 1974, pp. 10-11), "*interpretative frames*" (Bartunek & Moch, 1987, p. 484), "*thought worlds*" (Dougherty, 1992, p. 179), "*interpretative schemes*" (Giddens, 1984, pp. 29-30), "*scripts*" (Gioia, 1986, p. 50), "*paradigms*" (Kuhn, 1970, p. 43), and "*mental models*" (Argyris & Schön, 1978). They end up by defining their own meaning for the concept frames as a general concept of shared cognitive structures, not especially regarding humans.

This article describes a study which aims to clarify IS designers' conceptions of users of IS

by drawing on in-depth interviews with 20 IS designers. The analytical choices carried out in this study regard IS designers' conceptions of users as experiences inherent in their lifeworlds, particularly during the different phases of ISD. The lived experiences build up conceptions that form a structure of meaning, which incorporates a continuum of levels from more limited understandings to more comprehensive notions; that is, different levels of thought reflecting variations of the designers' situated, practical knowledge. In this way the development of IS is understood as knowledge work. It is an intellectual and personal process which takes its form according to the conceptions of the performers of the process. IS designers are then applying the ISD methodologies according to their own observations and thinking (Avison & Fitzgerald, 1994; Hirschheim et al, 1995; Mathiassen, 1998). Then the most important tool for ISD, and a key resource in contemporary IT companies, is the IS designers' thought and insight (Nonaka & Takeuchi, 1995; Quinn, 1992). Particularly with respect to the humanisation of IS, designers' conceptualisations of the human users are seen as knowledge that reflects the designers' competence in humanising IS. In this way, IS designers' conceptions may be seen as intellectual capital that mirrors the know-how, practices, and accumulated expertise of practitioners within a particular profession (Kogut & Zander, 1992).

In what follows, first, the assumptions informing this study are presented by introducing the interpretative approach referred to as phenomenography. Second, the resulted forms of thought are presented and discussed. The IS designers' conceptualisations presenting their mental schemes of the human user result in three forms of thought, revealing both context-centred and human-centred understandings of what humans are. These three levels of understanding indicate that IS designers tend to conceptualise uses in terms of technology, business and work, and that seldom are users taken into account according to their human qualities. Finally, the different levels of conceptualisation are discussed in relation to human-centred ISD.

DIFFERENT LEVELS OF UNDERSTANDING

This study merges with the principles of phenomenography, which is a qualitatively oriented method of empirical research for investigating the different ways in which people experience aspects of reality (Marton, 1981; Marton & Booth, 1997). Essentially, phenomenography is about individual meaning construction, which results in a conception. The primary focus is on the structure of the meaning of conceptions, which are seen in the light of the phenomenological notion accord-

Figure 1. The analytical distinctions of an experience (Marton & Booth, 1997)

ing to which person and world are inextricably related through a person's lived experience of the world (e.g., Husserl, 1995; Merleau-Ponty, 1962). Our intentionality is seen as qualitatively varying foci on the horizon of our life worlds. While experiencing the world, individuals form conceptions, including qualitative dissimilarities, which are inherent in the intertwined referential and structural aspects of an experience. Different levels are due to the way the structural aspect and the referential aspect merge with each other. Then an experience is specified by the analytical distinctions of a structural aspect and a referential aspect (Figure 1). The structural aspect denotes how a particular phenomenon is both discerned from its environment and how the phenomenon's parts relate to each other as well as to the whole phenomenon. That which surrounds the phenomenon experienced, including its contours, is its external horizon. The parts and their relationships, together with the contours of the phenomenon, are its internal horizon. The referential aspect signifies the meaning of the conception. These two aspects are dialectically intertwined and occur simultaneously within an experience. Thus, people create conceptions with respect to the structural aspect's external and internal horizons of a phenomenon that are dialectically merged with the referential aspect of that particular phenomenon.

On the one hand, conceptions differ in terms of content, and on the other hand, they differ in terms of the extent of the form that a certain phenomenon is experienced, as a part of that phenomenon, or more as a whole. When detached parts of a phenomenon are the focus of thought instead of relating the parts meaningfully to the whole phenomenon, the meaning of the phenomenon is understood in a way that refers to a more narrow view. Respectively, when the focus of thought is more comprehensive regarding the whole meaning of a phenomenon instead of on separate parts of it or even the surroundings of the phenomenon, the more explanatory conceptions are. Further,

the more explanatory power conceptions have, the better they support competent action with respect to the phenomenon in question (Sandberg, 2000). Based on these differences, conceptions form a structure of meaning, which incorporates a continuum of levels from more limited understandings to more comprehensive notions. The qualitative variation in the ways that IS designers conceptualise users reflects their different conceptions of users, and simultaneously forms different levels in the designers' understandings, reflecting variations of their situated, practical knowledge as forms of thought. These forms of thought, in turn, suggest different levels of competence in humanising IS, because the subjective conceptualisations of IS designers refer to their intention of action (Säljö, 1994).

The interview method is accomplished with respect to phenomenographic principles. To promote multiple interpretations within individual designers, first, opening questions with varying perspectives into the different phases of ISD, such as planning, design, implementation, use and maintenance, was incorporated in the interview framework. Second, to sustain the connection between the designers' reflection and the actual work within ISD phases while the in-depth interviews aimed at achieving mutual and authentic understanding that proceeded from the interviewees' expressions. The interviews were taped at the designers' workplaces to maintain the work practice orientation and to facilitate the expression of the connection between the respondents' immediate experiences and the subsequent conception. Second, the respondents represent a variety of geographical location, age, gender, educational background and work experience. They came from various different application areas of IS practice, such as e-commerce, tele and media communications, groupware, health care systems, office automation and insurance systems.

The analysis of the interview data was carried out against the phenomenographical theory. Since

phenomenography does not offer grounds for defining the content of conceptions within data, a coding paradigm was developed from the data in order to facilitate the identification and categorisation of meanings in the data (Glaser & Strauss, 1967; Tesch, 1990; Strauss & Corbin, 1990). The development of the coding paradigm was based on the phenomenographical principle regarding the intentionality of conceptions. Conceptions are context-dependent and every experience is described in content-loaded terminology (Säljö, 1994.). That is, the descriptions are carried out in terms of the nature of the situational experiences in question. Consequently, the meanings are to be found in accordance with the underlying assumptions concerning the intentional nature of ISD. In addition, since it is assumed in phenomenography that the meanings of the respondents' mental acts exist in the data and are constitutive of the data (Walsh, 1994), the way meanings are understood in this study should also be in accordance with the types of intentionality existing in the data. Thus, the coding paradigm was finalised by bracketing away any preconceived ideas of what the IS designers' views might be like (Francis, 1993), and letting the analysis be informed by the underlying assumptions of intentionality in ISD.

First, the data includes utterances that describe various actions and objectives concerning ISD. These expressions indicate intentionality as defined by Hirschheim et al. (1995, p. 16). They state that "IS development is intentional, to the extent it reflects a planned change. It is based on developers' intentions to change object systems towards desirable ends", and go on to say that (1995, p. 17) "intentions in systems development are expressed by objectives. These are related to general value-orientations and represent what 'one ought to do' or 'what is good'." From this it can be concluded, in the first place, that intentionality in ISD is expressed by intentional action. That is to say, IS designers' descriptions of the actions and means they are involved with when developing an

IS reveal the meanings they give to the phenomena they deal with concerning ISD. This notion is in accordance with the principle of contextuality in phenomenography, which denotes that people's conceptualisations are not detachable, either from their context or the content of the task at hand. This stance also reinforces the interpretative nature of phenomenographical analysis in that the researcher must see the designers' action as inherently meaningful (cf. Schwandt, 2000). In the second place, as Hirschheim et al. (1995) point out, intentions are expressed by objectives of ISD. Consequently, it is an appropriate way to define that the way the IS designers understand the human user of an IS is revealed through descriptions in which the respondents' focus of reflection is on the objectives of ISD. That is to say, in addition to the actions and means the designers refer to, the IS designers' intentions to change object systems toward desirable ends reveal the meanings they give to the phenomena they deal with concerning ISD. These desirable ends or objectives represent the things that are regarded most important in ISD. In this way, the IS designers' descriptions of action, means and objectives also implicitly indicate value orientations included in the process of ISD. Therefore, the described actions and objectives represent the things that are regarded important, and thus reveal the referential aspect in terms of intentionality as an implied value orientation. This means that the initial referential aspects of conceptions may be found in utterances in which the designers refer to their way and means of building systems and the objectives of their actions.

Second, the data includes descriptions in which the respondents' thoughts are attached to human objects. These descriptions of people indicated human features and also value orientations toward people. Often these descriptions also included expressions which indicated emotionally toned reactions. These kinds of expressions within the data indicate intentionality that is in accordance

with Uljens (1991), who states that the process of qualitative individuation of a mental act has been done when an object and a psychological mode, referred to as an attitude, is shown. In other words, how a particular object of thought is experienced denotes the respondents' attitudes toward the phenomenon that is being reflected on. In brief, the inherent meaning of an utterance may be seen as the correlation between the what- and how-aspects in that they are not detachable from each other, but are interrelated in a particular logical way, indicating what a particular phenomenon is, in what it is revealed, and what kind of values and attitudes are related to it. As described above, the search for the meanings in the data, data analysis, was initiated by establishing a coding paradigm, which suggests that the meanings in the data are found in utterances in which the designers refer to their actions, means, and objectives concerning ISD, as well as to human characteristics.

The subsequent analysis procedures followed the idea, firstly, of iterating between the meaning (referential aspect) of single statements, their surrounding statements, and the data as a whole, and second, iterating between the features that reveal different levels in these meanings (structural aspect). The analysis appreciates the phenomenological notion of "Lebenswelt" in that the continuum of levels from more limited forms of thought to more comprehensive understandings reflects associative connections within the designers' conceptions rather than direct, law-like logical relations between them (cf. Husserl, 1995). The analysis revealed the designers' conceptions as different levels of understanding, which appear as the separatist, functional, and holistic forms of thought. These forms of thought reveal three different levels of understandings incorporating both context-centred and human-centred notions. In the descriptions associated with the context-centred conceptions, the designers' focus of reflection is on technology, work, and business. The human-centred conceptions deal with knowledge, emotions,

and the designers' selves. The following description delineates the specific contents of the conceptions as parts of the three forms of thought by highlighting some exemplary conceptions.

THE SEPARATIST FORM OF THOUGHT

The most partial way in which the IS designers conceptualise humans is through the separatist form of thought. It demonstrates how IS designers see humans within the affordances and constraints of contemporary IS and their development as separated from fluid and coherent interactions. Within this form of thought, the user is positioned outside the IS designers' awareness through objectivist conceptualisations. An objectivist pattern is evident in the context-centred separatist conceptions, which reflect understandings according to which reality exists independent of humans and can thus be understood independent of humans (cf. Lakoff, 1987; Orlikowski & Baroudi, 1991). In this case, when discussing human-centred issues of ISD, the designers' focus of reflection is directed to technology, job titles, and market mechanisms. For example, within the conception of "*the human being displaced by technology*" IS designers refer to humans in terms of technology:

R: What are these requirements and wishes like? Could you tell me more about them?

D16: Well, because it is a question of – let's say – a feedback channel that our company offers as a product to its clients, it means that if the client purchases, for instance, a datanet-based customer network, they have datanet and router accesses through which they operate between their networks and use the whole telecommunication network. Then there are a lot of this kind of usability issues, response times and load percentages, or in a way, how it (telecommunication network) sort of behaves, what happens there.

In the above interview extract, the designer considers the customers' needs as a piece of software—"a feedback channel"—and the main point that emerges is how this item of software works with the functions of a telecommunications network. The designer's train of thought becomes focussed on technology instead of human-centred issues and needs, such as how the software is built in regard to the humans that will be using it. In the same vein, within the conception of "*the human being as a market*" the designers make use of expressions which show their intention is to build products that are profitable and, therefore easy to sell. Yet they do not base their intentions upon human features, such as spontaneous and mood-related online behaviour that could be a prerequisite for selling their products (e.g., Hoffman & Novak, 1996; Bellman et al, 1999):

D5: It is more reasonable to develop a mass product which has a lot of users. The point here is that then it can be copied and sold.

In contrast to notions that emphasise understanding human consumption behaviour, the IS designers adhere to the idea that humans are simply a featureless mass of consumers who form a market for IT products. Because the above conception does not incorporate any human characteristics, but refers to a mass market, it is thereby making a clear distinction between the market and the features of the people assumed to form that market. For this reason, the conception appears as objectivist. This conception also implies a predisposition according to which the current development of IS as an industry is that of a rational institution which produces mass culture by reducing humans to members of a mass (cf. Slater, 1997). Furthermore, humans become separated attitudinally from IS and their development due to a presumed lack of technological knowledge, and thus are forced to encounter disparaging attitudes. The separatist human-centred conception of "*the technology-illiterate human being*"

produces accounts according to which the most distinct characteristic of humans is that they are ignorant of technology, specifically computers, software and ISD methodologies. In particular, this illiteracy is seen as a contrast to the literacy of the IS designers:

R: Have you ever wondered why people behave in that way — that they cannot say what they want from the system?

D17: I think that it's because they don't know how these [IS] are defined. If one doesn't know these methods, one can't do it. That is the biggest reason, not that they aren't willing to say what they want but they don't have the know-how.

Beath and Orlikowski (1994) report similar findings in their analysis of a relatively new representative of the ISD methodologies' rationalist tradition, information engineering (IE). According to the analysis, the IE text creates and sustains both implicitly and explicitly a dichotomy between users and IS designers by characterising the users as technologically ignorant in regard to the use of technology. When operationalised, these characterisations are likely to generate nonviable and unsatisfactory interactions between users and IS designers. It seems also that the designers do not consider the weaknesses in users' knowledge and thought as an issue that deserves to be taken into account in design. However, when humans are included in the design considerations, the weaknesses in people's thinking should be understood as natural flaws in human cognitive behaviour that can be appropriately guided, or even prevented by adequate design (Kirs, Pflughoeft, & Kroeck, 2001; Norman, 1989; Robillard, 1999). The idea then is that designers should have awareness of and be able to recognise these erroneous tendencies in users in order to carry out IS planning and design with the express aim of preventing people from committing faulty actions during computer use, rather than conceptualising users as technologically ignorant.

Moreover, negative emotions and physical stress symptoms have the effect of separating humans from IS. The conception of “*the computer anguished human being*” reveals views acknowledging that IS cause negative emotional arousal in users. These reactions are manifested as negative attitudes, resistance, fear and discomfort in situations where people are confronted by plans for the future use of computers or in situations in which individuals are using computers:

R: How in your mind do people learn to use software?

D6: ... I have also met users who have so much fear of the user interface that they don't dare to explore or try anything, they just do what is familiar and safe.

These conceptualisations are consistent with statements concerning the widespread existence of technophobia (Brosnan, 1998a). Besides being an obviously unpleasant and undesired experience, negative emotions, such as anxiety and fear, make people's behaviour withdrawn and elusive by narrowing their action (Fredrickson & Branigan, 2001), as well as decreasing the quality of their performance (Brosnan, 1998b).

In brief, within the separatist form of thought, the human being becomes separated from viable interactions with both the IS designers themselves and IS. This is due to a tendency to an objectivist conceptualisation, which blurs the designers' thought to such an extent that people are no longer recognised as humans. The overall narrative style of this form of thought is reminiscent of the style of a nomothetic science reflecting technical, strategic views aiming at controlling the IS-related social system with the technical system (cf. Deetz, 1996). Further, people become separated from the development of IS due to disparaging attitudes inherent in designers' assumptions that users are technologically ignorant. Moreover, this form of thought brings to the fore human characteristics,

such as negative emotions, which are seen as an obstacle to a viable IS-user relationship.

THE FUNCTIONAL FORM OF THOUGHT

The functional form of thought consists of conceptualisations in which humans are seen to act in an insubstantial manner, adapting to the external functions of technology, work tasks and the way the IS designers themselves use computers. Within this adaptive response, positive emotions are required in order to create and sustain viable interactions with IS. In this way, the IS-user relationship is seen as functional: the action of people is seen as determined by their external environment, and the role of human emotion is to facilitate this process. The different conceptions that build up this form of thought reveal a behaviourist understanding of the human being.

For instance, the conception of “*the invisible human being*” denotes humans as using IS in an insubstantial manner. Typical of this conception is the belief that there is a user who uses an IS. Yet the user is not characterised further but is assumed just to use the system:

R: If you think of a situation where you are creating an application, who do you think you're making it to?

D16: Hm.....

R: Do you think of certain types of people or how does it show that you are making it for people?

D16: I don't think of particular types of people but I think that the human being is in some sense always a part of the system. If it is a system that has a user interface so there must be somebody who uses it. Even if it is a system that runs by timer initiation, there must be a user interface, too, for setting the timer parameters in the system, so there must be somebody to use it, too. To my mind there is always someone using the systems, they (systems) are not fully automated.

A functioning relation between people and IS is thus acknowledged, but this does not include any features originating from the mental, social or cultural human modes of being. In other words, humans and their behaviour are understood as purely physical-organic responses to technology, as established in the tenets of Skinnerian behaviourism (Skinner, 1938, 1991). Similarly, the IS designers' conception of "*the human being behind the process of work*" denotes humans in conformity with behaviourist thinking. Within this conception individuals are seen in terms of their work tasks or organisational work processes. Characteristic of these conceptualisations is that the people performing the tasks are not portrayed further, but are assumed merely to use IS according to the external task flows:

R: How would you define users' needs?

D8: They consist of the utilising organisation's needs at all levels, beginning with what the people need in order to continually do their work tasks, and ending with the things that the organisation expects from the system, what can be abstracted from the process and be used to develop and control action.

Here, human action is seen as a series of direct responses to external work tasks issued to people. Zuboff's (1988) well-known distinction between "automating work" and "informating work" highlights the difference between implied behaviourist and nonbehaviourist assumptions concerning human action in computerised work (pp. 9-10). Automating work refers to deploying technology in ways that increase the self-acting and self-regulating capacities of technical systems, which are expected to minimise human intervention. Because human intervention is minimised and machines perform the work tasks, interactions between individuals and computers become determined by the structure and sequence of computerised workflows to which, in turn, humans are supposed to respond. Zuboff's term

of automating work, thus, implies a behaviourist assumption of humans and their behaviour.

Quite the opposite is suggested by the term informating work, which adds to the automating view of work in that information technology can be used to automate, but at the same time, it has the ability to translate the automated activities into a form that renders work processes, objects, events and behaviours visible, knowable and sharable for people (Zuboff, 1988). That is to say, within the interaction of humans and computers, people actively observe, interpret and share the information which is mediated to them by IS. They do not just respond like marionettes to the information offered by IS, but actively construct their own conceptions of the computer-mediated tasks they are given and act according to their own interpretations of the particular situation. Thus, in order to accomplish fluid and coherent interaction designs between humans and computers in regard to particular tasks, the users' mental models, especially those concerning the tasks submitted to them, should also be designed (Norman, 1989; Preece, 1994).

Also typical of the functionalist form of thought is that the role of human emotion is to facilitate people's adaptation to technology. Within the conception of "*The techno-enthusiast human being*" the designers depict positive emotions, such as enthusiasm, as essential features in humans:

R: Do you think there are common features in those people for whom you have built systems?

D17: Well, at least during very recent years, it has been enthusiasm.

In particular, positive emotional reactions in people are seen to be induced by technology. Positive feelings are especially seen as a prerequisite for the successful use of IS. These conceptualisations reveal a functional understanding of positive emotions. Whereas negative emotions are associated with specific tendencies,

such as an urge to escape or to avoid disquieting things, positive emotions seem to spark changes in cognitive activity in addition to producing behavioural tendencies (Fredrickson & Branigan, 2001). Therefore, the IS designers' accounts of positive emotions as a prerequisite for the use of computers imply an understanding of the role of human emotional features in promoting successful functioning.

To sum up, within the functional form of thought humans and their behaviour are understood from a behaviourist stance, which renders human substance only as physical and organic by nature, denoting that the movements of people can be explained by the laws of mechanics (Wilenius, 1978). However, this form of thought adds to the previous separatist way of thinking in so far as humans are actually depicted as performing tasks with computers, whereas in the separatist form of thought the conceptualisations either totally omit human features or humans are seen as unable to use computers. In addition, the human emotional feature that is recognised in this form of thought appears as positive — even though functional — in nature. This way of thinking acknowledges humans as users, and therefore is more developed than the previous separatist form of thought.

THE HOLISTIC FORM OF THOUGHT

The most developed form of thought by which the IS designers conceptualise humans as users of IS is the one characterised as holistic. Its holistic quality is revealed in several ways. First, unlike the preceding forms of thought, the designers recognise a number of human characteristics. Second, these observed human features are often seen to coexist or intertwine with each other. Third, these conceptualisations suggest that the relationship between users and designers, as well as the IS-user relation, is a reciprocal process, including characteristics typical of human behaviour.

To begin with, the conception of “*the human being reflected in technology*” reveals the specific goal of constructing computer interfaces with human-like features: the interaction between people and computers is then envisaged as enriched with dialogues conveying both the rational and emotional meanings of the information in question (e.g., Nakazawa, Mukai, Watanuki & Miyoshi, 2001). Respectively, the depictions of various human features in technology reveal understandings suggesting human features built into technology render the interaction between users and IS as resembling the interplay of cognitive, emotional and social aspects that occur between humans:

R: What kind of user interface do you think that people would want to use?

D4: I strongly believe that 3D interfaces are coming. They could offer kind of human-like facial features as agents, which would bring a human sense to the systems. The third dimension could also be utilised so that interfaces become tangible and accessible.

Further, the context-centred conception of “*the human being as an organisational learner*,” which highlights people as organisations which learn about their own work processes, refers indirectly to learning, which stresses both cognitive and social human features. Collective cognitive features are referred to as an organisation's ability to form new insights into its work processes and to guide the deployment of IS effectively (Robey, Boudreau & Rose, 2000). A social dimension is also implied when it is assumed that people learn as an organisation:

D8: Needs are prone to change rapidly, especially after the implementation of the system, because they teach an organisation a lot about itself, and an organisation's self-knowledge increases and usually needs change in a more clever direction. Then there very quickly happens a sort of 'learn-

ing leap', which is often experienced as if the system is not valid at all although it is a question of the organisation's increased knowledge of its own activity.

Within the conception of “*the knowledge sharing human being*” the designers open up their view of learning by specifying mutual understanding between users and designers as essential. “*It is important to be able to explain things so that we understand each other.*” The capability of taking another’s perspectives into account form the core of this conception, which highlights knowledge sharing as a particularly important instance within the processes of organisational learning. Knowledge sharing is the link between individual and group learning, and signifies the expansion of individuals’ cognitive maps into shared understandings (Crossan, Lane & White, 1999). In particular, the ability to take the perspective of others into account is an indispensable prerequisite for knowledge sharing (Boland & Tenkasi, 1995). Buber (1993) ascertains that, in order to be able to take others’ perspectives into account fully, one has to treat others as equal human beings and respect the current circumstances of others. In these kinds of relationships positive emotional features, such as care and joy, need to be acknowledged and combined with cognitive and social abilities (Fredrickson & Branigan, 2001)

Moreover, the conception of “*the emotionally coping human being*” refers to an ability to regulate in a successful way both negative and positive subjective feelings in computerised situations. In this way, the designers see emotional coping in the light of positive outcomes (cf. Folkman & Moskowitz, 2000, pp.648-649):

D8: ... a skilful user always has such peace of mind and attitude. She or he kind of has a better tolerance for stress, and an ability to cope with contradictions in a better way than others. For some reason this kind of attitude leads to a par-

ticular resourcefulness and an ability to utilise the system in a more natural way, compared to a person who has some negative emotional features, fear or hostility towards the system, and who then ends up having difficulties with the system due to her/his heavy attitude.

A cognitive aspect is seen as inherent in emotional coping in that it requires that individuals’ recognise their different emotional experiences. However, in addition to these internal cognitive-affective features, emotion regulation refers to the external social and cultural factors that redirect, control, and shape emotional arousal in such a way that an individual is able to act adaptively in emotionally activating situations (Pulkkinen, 1996). While ISD is often seen as a stressful process which requires an ability to endure changing emotional experiences, such as interest and frustration (Newman & Noble, 1990) in recurrent situations of failure and subsequent success (Robey & Newman, 1996), it is understandable that the designers regard people who are able to regulate their emotions successfully as skilful.

Briefly, the holistic form of thought is comprised of conceptualisations that regard humans as cognitive, emotional, social and cultural creatures. The conceptions belonging to this form of thought embody similar basic human modes of being, as shown above. However, the aforementioned basic modes of being emerge in these conceptions as different behavioural affordances. The cognitive mode of being is seen as intellect, reasoning, learning, reflection, understanding and awareness of something. Similarly, the emotional mode of being is conceptualised as empathy, stress, tranquillity, commitment, contentment and a feeling of mastery. Further, the social mode of being is referred to as a need for communication, group learning, interpersonal power and connection, as well as knowledge sharing. These behavioural affordances are seen as incorporated in technology, appearing between humans, or within the interaction of humans and IS.

THE FORMS OF THOUGHT IN ISD

The IS designers' forms of thought revealed in the results of this study are regarded as important tools for ISD, and are seen to have implications for the ways that humans are taken into account as users within the different situations of ISD. These different situations refer to the phases of ISD such as planning, design, implementation, use and maintenance. The phases are cyclical and intertwining (e.g., Beynon-Davies, Carne, Mackay, & Tudhope, 1999). Planning refers to initiation and requirements analysis actions, including client contacts and definition of user requirements. During this phase the greatest degree of interaction occurs between users and designers (Newman & Noble, 1990). In order to accomplish requirements analysis, the designers should understand many human issues in addition to technical ones (Holtzblatt & Beyer, 1995). Design denotes procedures where requirements are refined and turned into specifications and finally software. Then technical reliability and maintainability of the system, user interface's applicability for the intended purpose of the system, as well as the aesthetical appearance of the system, are designed (Smith, 1997). Winograd (1995) emphasises that, in addition to technical requirements, the properties of a user interface should meet with the social, cognitive and aesthetic needs of people. Especially within new ubiquitous technological environments, the design of IS-user relationship should focus, in addition to social and cultural features, on individuals' perceptual, cognitive and emotional space (Stephanidis, 2001).

How would the designers then perform according to their forms of thought? The strength of the designers utilising a separatist form of thought would be technical knowledge, especially the ability to fluently conceptualise issues of design in accordance with objective definitions, a skill that is needed in creating formal specifications. However, the validity of objectifying design issues is dependent on the focus of such definitions. From

a human-centred perspective, valid definitions would require being theoretically sensitive to human activity and deriving second-order conceptions from that activity (see Walsham, 1995), rather than creating objectivist conceptualisations, which overlook humans and their behaviour. An obvious disutility would be a tendency to treat users as technologically ignorant, which implies incompetence in social relationships with users.

The designers embracing the functional form of thought possess technical knowledge, and value such knowledge in users. They tend to focus on formal job descriptions, external work tasks and individuals' task productivity. A deficit from a human-centred perspective would be the tendency to overlook human issues and to focus instead on the functional purposes of IS; that is, external task information regarding an organizations' process improvements. Often such conceptualisations are regarded to yield Tayloristic designs, which underestimate the social context. However, they possess competence in functional and technical systems design. Their strength would be increased social competence to fulfil the demand for mutual understanding, which is regarded of utmost importance in ISD (cf. Heng, Traut, & Fischer, 1999).

The designers building upon the holistic form of thought emphasise clients' satisfaction, which ensures sustainable customer relationships and regard mutual understanding during ISD as essential between users and designers. Their strength would be increased social competence fulfil the demand for mutual understanding, which is regarded of utmost importance in ISD (e.g., Klein & Hirschheim, 1993; Lyytinen & Ngwenyama, 1992). It seems also likely that they have competence in IS planning which aims at the improvement of organisational processes and are identified as functional, such as sales and purchasing processes, and emphasise mutual understanding. Also, they understand how to maintain customership instead of just visioning economic gains or focusing on people's task productivity.

Besides possessing technical competence, these holistic designers would be able to consolidate definitions of formal and external work tasks into human issues. A particularly significant capability would be to understand the process of organisational learning, which is essential in order to adjust the evolving requirements during the process of ISD. Moreover, they value balanced emotional behaviour, and thus intuitively grasp the possible dangers of relying on superfluous emotional behaviour.

With respect to the humanisation of IS, a holistic conception is required in ISD. It is then assumed that the human being is actualised in intertwined physical, cognitive, emotional, social and cultural qualities, and that these qualities are fundamentally different. Without the simultaneous existence of all of the qualities, it is not possible to consider a creature as a human. Yet the qualities cannot be reduced from one quality to another, but rather need to be understood as a whole (Rauhala, 1983). Considering the human being as an actor, as a user of an IS, the whole of a human being is understood as an active subject adjoining to IS. Then the IS-user relationship consists of human action involving explicit and tacit affordances that emerge dynamically in the interaction between humans and IS. In other words, the static characteristics of humans and technology take on a new form within their intertwining activity, which is shaped according to the affordances that, on the one hand, the human substance embodies, and which, on the other hand, the properties of IS support or ignore. Consequently, understanding humans and their behaviour as users of IS requires insight into these emerging human experiences appearing within the affordances and constraints of contemporary IS and their development. Especially at present when the IS are no longer merely tools for personal and professional instrumental productivity, but also (re)constituting and mediating different social structures and practices (e.g., Orlikowski, 1992; Orlikowski, 2000), IS acts as social spaces that are

important growing social and cultural reference points for users and, thus also for IS designers. Design that takes into account the consequences of the form and functions of IS to users' social qualities, such as self-identity, is indeed and necessary if contemporary IS development aims at high-quality and usable systems (Greenhill & Isomäki, 2005).

In summary, the resulting forms of thought indicate three different but associated levels of intellectual competence in conceptualising humans as users of IS. The separatist form of thought provides designers predominantly with technical perspectives and a capability for objectifying things. However, it is worth noticing that the validity of objectifying design issues is dependent on the focus of such definitions. From a human-centred perspective, valid definitions would require being theoretically sensitive to human activity and deriving abstracted conceptions from that activity rather than creating objectivist conceptualisations, which overlook humans and their behaviour. The functional form of thought focuses on external task information and task productivity, nevertheless, with the help of positive emotions. The holistic form of thought provides designers with competence of human-centred ISD, even though all the aspects of the richness of the human condition are not revealed. It seems the designers are intellectually more oriented toward designing IS for objectified, streamlined organisational processes consisting of external work tasks, and that this orientation challenges the human-centred orientations.

Chapter 2.13

A Method to Quantify Corpus Similarity and its Application to Quantifying the Degree of Literality in a Document

Etienne Denoual

ATR—Spoken Language Communication Research Labs, Japan

CLIPS—GETA—IMAG, Joseph Fourier University, France

ABSTRACT

Comparing and quantifying corpora are key issues in corpus-based translation and corpus linguistics, for which there is still a notable lack of standards. This makes it difficult for a user to isolate, transpose, or extend the interesting features of a corpus to other NLP systems. In this work, we address the issue of measuring similarity between corpora. We suggest a scale between two user-chosen corpora on which any third given corpus can be assigned a coefficient of similarity, based on the cross-entropy of statistical N-gram character models. A possible application of this framework is to quantify similarity in terms of literality (or, conversely, orality). To this end, we carry out experiments on several well-known corpora in both English and Japanese and show that the defined similarity coefficient is robust in terms of language and model order variations. Compar-

ing it to other existing similarity measures shows similar performance while extending widely the range of application to electronic data written in languages with no clear word segmentation. Within this framework, we further investigate the notion of homogeneity in the case of a large multilingual resource.

INTRODUCTION

Be it in corpus linguistics or data-driven automatic translation, statistical or example-based, corpora not only are useful tools but key elements of the discipline. Paradoxically, little work has been done on automatically characterizing such sets, and attempting a meaningful comparison is often a perilous task. Typically, we will read that such corpus is made of “casual speech transcripts,” “mildly spontaneous utterances,” or “highly

scenarized oral language.” However, such tags will be of little use to the user seeking to better understand how his or her system performs and how to transpose its specific features to another task.

In the following work, we try to fill this void with a method to position a corpus relatively to two others, which we use as references. As an experiment, we apply this method in particular to measuring the literality (and, conversely, the orality) of a corpus. First, we examine the notion of corpus similarity, and then we suggest an information theory-based measure of similarity using statistical N-gram character models. Our framework is then tested on the particular case of evaluating the literality of several corpora.

CORPUS SIMILARITY

We are regularly provided with a wider range of corpora to use as tools in analysis or machine translation, and while we get more data every day, it becomes harder to quickly grasp the nature of what we study. Kilgarriff (1998) and Killgarriff and Rose (2001) investigated the similarity and homogeneity of corpora and pinpointed the need to find appropriate measures for them, without which it is difficult to discuss the relevance of one’s findings or port them to another domain. They then proceeded to compare Known Similarity Corpora (KSC) using perplexity and cross-entropy on words, word frequency measures, and a χ^2 -test, which they found to be the most robust. However, as acknowledged in Kilgarriff (1998), using KSC requires that the two corpora chosen for comparison are sufficiently similar so that the most frequent lexemes in them almost perfectly overlap. Whereas intuition would hint at this being true for very large corpora, Liebscher (2003) shows by comparing frequency counts of different Google group corpora that it is not the case. Furthermore, while this measure gives us an idea of the similarity of such corpora to each other, it

does not rank several corpora in similarity (i.e., it gives us no idea of the distance in similarity between them. Measuring similarity by counting word/lexeme frequencies introduces further difficulties; this assumes that the word is an immediate, well-defined unit, which is not the case in Chinese (Sproat & Emerson, 2003) or Japanese (Matsumoto et al., 2002), for instance, where word segmentation is still an unsolved issue.

How do two corpora relate to each other? Perhaps it would be easier and more intuitive to answer the following question: If I define a scale between two reference corpora, where in between does this third corpus fit? Biber (1988, 1995) identifies a set of seven dimensions by counting linguistic features in text samples and shows that a document of text can be assigned a score on any dimension. We will use this property along with information theory to define a scale of similarity between two corpora on which any given third corpus can be assigned a similarity coefficient, with no need of prior linguistic feature selection.

QUANTIFYING SIMILARITY

N-gram Cross-Entropy

Entropic measures performed on characters have the obvious advantage of being blindly applicable to any electronic data without the use of any prior linguistic knowledge (thus eliminating the bias of segmentation errors in languages where the word unit is not clearly defined). In this study, we turn our attention to cross-entropy in terms of N-grams of characters. Dunning (1994) showed the interest of character-based models for language identification in a way that the required training and test sets are surprisingly small in order to achieve good results, achieving a 99.9% accuracy in identifying English from Spanish with only 50K bytes of training and 500 bytes of test text. He further shows that the accuracy of classification only improves with longer test data.

The cross-entropy $H_T(A)$ of an N-gram model p constructed on a training corpus T , on a test corpus $A = \{s_1, \dots, s_Q\}$ of $s_i = \{c_1^i \dots c_{|s_i|}^i\}$ sentences with a sentence of $|s_i|$ characters is:

$$H_T(A) = \frac{\sum_{i=1}^Q \left[\sum_{j=1}^{|s_i|} -\log p_j^i \right]}{\sum_{i=1}^Q |s_i|} \quad (1)$$

where $p_j^i = p(c_j^i | c_{j-N+1}^i \dots c_{j-1}^i)$. The recurrent idea in this work is to construct several N-gram character models using reference training corpora and then use these language models to estimate the cross-entropy in terms of bits per character (bpc) needed to encode a test corpus.

A Coefficient of Similarity

Definition

More than just categorizing or clustering corpora, we wish to quantify similarity. We therefore define a scale of similarity between two corpora on which to rank any third given one. This is done by letting the user select two corpora— T_1 and T_2 —which the user chooses to be his or her references, and use them as training sets to compute N-gram character models. We estimate their cross-entropies on a third test set, T_3 , which we will respectively name $H_{T_1}(T_3)$ and $H_{T_2}(T_3)$ according to the notation in Equation 1. We also estimate both cross-entropies of each reference for each model according to the other one (i.e., $H_{T_1}(T_2)$) and $H_{T_2}(T_1)$, $H_{T_2}(T_1)$ and $H_{T_1}(T_2)$ in order to obtain the weights W_1 and W_2 of references T_1 and T_2 :

$$W_1 = \frac{H_{T_1}(T_3) - H_{T_1}(T_1)}{H_{T_1}(T_2) - H_{T_1}(T_1)} \quad (2)$$

$$W_2 = \frac{H_{T_2}(T_3) - H_{T_2}(T_2)}{H_{T_2}(T_1) - H_{T_2}(T_2)} \quad (3)$$

After which we assume W_1 and W_2 to be the weights of the barycentre between our chosen references. Thus, we define:

$$I(T_3) = \frac{W_1}{W_1 + W_2} = \frac{1}{1 + \frac{W_2}{W_1}} \quad (4)$$

to be the similarity coefficient between reference sets one and two, corpus T_1 and corpus T_2 , respectively.

Meaning

Given the previous assumptions, $I(T_1) = 0$ and $I(T_2) = 1$; furthermore, any given corpus T_3 then will be awarded a score between $I(T_1) = 0$ and $I(T_2) = 1$. Here we consider two corpora that are similar when one of them can be completely predicted given the knowledge of the other one (i.e., given a language model constructed on the other one). This idea is extended to three corpora, two of them being references, the third one being studied.

Figure 1. Method overview: Dashed lines show coefficient equivalences (0 is oral, 1 is literal)—the point ⊗ will be explained in “Statistical Aspects” section

Degenerate Cases

As can be seen on the schematic representation in Figure 1, $I(T_3)$ may take but three values (0,1/2,1) when the size $n - l$ of the models history length gets close to infinity. Let B be the standard value in bits needed to encode a character in a chosen coding system, then:

- If T_3 tends to be most similar to T_2 and most dissimilar to T_1 ; that is, if with a long history length, $n - l$, T_3 is completely determined by a language model trained on T_2 , but is completely undetermined by a language model trained on T_1 , then:

$$\lim_{n \rightarrow \infty} H_{T_1}(T_3) = B, \lim_{n \rightarrow \infty} H_{T_2}(T_3) = 0 \quad (5)$$

T_1 and T_2 are assumed to be dissimilar, therefore:

$$\lim_{n \rightarrow \infty} H_{T_2}(T_1) = \lim_{n \rightarrow \infty} H_{T_1}(T_2) = B \quad (6)$$

In the same manner, a model used to predict the very corpus it was constructed upon will yield a null uncertainty for long history lengths:

$$\lim_{n \rightarrow \infty} H_{T_1}(T_1) = \lim_{n \rightarrow \infty} H_{T_2}(T_2) = 0 \quad (7)$$

We can therefore simplify the expressions of W_1 and W_2 :

$$\lim_{n \rightarrow \infty} W_1 = \lim_{n \rightarrow \infty} \frac{H_{T_1}(T_3) - H_{T_1}(T_1)}{H_{T_1}(T_2) - H_{T_2}(T_2)} = \frac{B - 0}{B - 0} = 1 \quad (8)$$

$$\lim_{n \rightarrow \infty} W_2 = \lim_{n \rightarrow \infty} \frac{H_{T_2}(T_3) - H_{T_2}(T_2)}{H_{T_2}(T_1) - H_{T_2}(T_2)} = \frac{B - 0}{B - 0} = 0 \quad (9)$$

Consequently, if the size $n - l$ of the history length gets close to infinity then:

$$\lim_{n \rightarrow \infty} I(T_3) = 1 \quad (10)$$

- Conversely, if T_3 tends to be most similar to T_1 and most dissimilar to T_2 ; that is, if, with a long history length, $n - l$, T_3 can be completely determined by a language model trained on T_1 , but is completely undetermined by a language model trained on T_2 , then:

$$\lim_{n \rightarrow \infty} W_1 = 0, \lim_{n \rightarrow \infty} W_2 = 0, \lim_{n \rightarrow \infty} I(T_3) = 0 \quad (11)$$

- If T_3 tends to be as much similar to T_2 as it is to T_1 :

$$\lim_{n \rightarrow \infty} H_{T_1}(T_3) = \lim_{n \rightarrow \infty} H_{T_2}(T_3) = H \quad (12)$$

Therefore:

$$\lim_{n \rightarrow \infty} W_1 = \frac{H}{B} = \lim_{n \rightarrow \infty} W_2 \quad (13)$$

$$\lim_{n \rightarrow \infty} I(T_3) = \frac{1}{1 + \frac{H/B}{H/B}} = \frac{1}{1+1} = \frac{1}{2} \quad (14)$$

We have shown here that when the size $n - l$ of the history length gets close to infinity, then I may take only one of the three values (0,1/2,1).

A Word on Corpus Homogeneity

Comparing non-homogeneous corpora, for instance, concatenated texts of various sources or corpora of different sizes could seem vain, for as of this date, we do not know of a satisfying definition of corpus homogeneity nor of any influence of homogeneity on computation. Intuitively, however, a corpus made of a collection of software manuals should be more homogeneous than one gathering mixed sentences from both telephone transcriptions and literature pieces (Kilgarriff & Rose, 1998).

In our first approach, in order to bypass this problem, we first ensure that our corpora individually originate from the same background (i.e., one is a collection of newspaper articles only; another is a collection of telephone transcripts only). We thus divide each reference corpus in n randomly selected blocs of equal size, compute cross-entropies using these blocs as test-sets, and average the results, a process usually referred to as “ n -fold cross-validating,” which ensures that results are not artifacts of accidentally selecting unrepresentative testing data (Charniak, 1993).

In our second experiment, we will specifically address the issue of homogeneity in the case of a large multilingual resource.

QUANTIFYING LITERALITY AMONG CORPORA

Training and Test Data

An experiment was carried out on both English and Japanese, with the hope of distinguishing and ranking similarity irrespective of the language used. In order to validate the previously described framework, we chose to set up a scale of literality between two corpora of contrasting origins:

- As a reference for orality, we used for both English and Japanese the SLDB (Spontaneous Speech Database) corpus, a multilingual corpus of raw transcripts of dialogues described in Nakamura, et al. (1996).
- As a reference for literality, for the English language we used a part of the Calgary¹ corpus, familiar in the data-compression field, containing several classical and contemporary English literature pieces², and for the Japanese language, a corpus of collected articles from the Nikkei Shinbun newspaper³.

Test data was chosen in both English and Japanese with the hope of measuring the literality of

two corpora originating from the same domain but having a hearsay reputation of differing slightly in terms of orality. Those two multilingual corpora are the C-STAR⁴ part of an aligned multilingual corpus, the Basic Traveller’s Expressions Corpus (BTEC⁵), and the Machine-translation-Aided bilingual spoken Dialogue corpus (MAD). Both collections of sentences are from the tourism and travel domain, with MAD being a collection of realistic but clean transcripts of dialogues and BTEC being a collection of sentences from travel handbooks. MAD has the reputation of being more oral than the BTEC. This is precisely what we wanted to measure.

To further validate our measure, we also wished to test it on other corpora from specific backgrounds:

- For the English language, the TIME⁶ corpus (a collection of newspaper articles of *Time* magazine from the 1960s) and the corpus of Spoken Professional American-English⁷ (SPAЕ), a collection of transcripts of meetings and interactions in professional settings.
- For the Japanese language, a corpus of collected articles from the *Mainichi Shinbun* newspaper (MAINICHI) and a corpus of clean transcripts of broadcasts from the NHK news.

All corpora are assumed to be already segmented into sentences, represented by successive lines of electronic data. A particular interest in this study is to stress that entropic measures do not require the use of segmentation at a specific level to be applied. By shifting to a larger unit, this study also could be performed on unsegmented paragraphs or even completely unsegmented documents, although the amount of data required to train the language models undoubtedly would rise in the process. To limit the quantity of required data, calculations were performed independently on each line and averaged.

In the following section, we outline for each corpus basic statistical figures and then compute cross-entropies and the derived literality coefficient.

Statistical Aspects

Statistical aspects for each corpus are shown in Figures 2 and 3 for English and Japanese respectively. Three corpora — SPAE, TIME, and Calgary, the reference for written expression — have notably superior Words/Sentence ratios than the three others — MAD, BTEC, and SLDB, the reference for oral expression.

Word segmentation ambiguity in the Japanese language has been the subject of intense research (e.g., [10]) and is a complex issue. Therefore, we preferred to focus on character counts here. As well as with English corpora, characters per sentence scores for Japanese language corpora that we assumed more literal (NHK, Mainichi, and Nikkei) are usually higher than the ones we previously assumed to have a more oral content. However, the character per sentence score for SLDB (oral reference) is comparable to the one of the Mainichi, making it difficult once again to reach a reliable classification.

Figure 2. Statistical aspects of several English corpora

English Corpora	SLDB	MAD	BTEC	SPAE	TIME	Calgary
Word/Sent. (Mean)	11.27	9.29	5.94	23.34	23.17	20.21
Word/Sent. (Std.dev)	6.85	5.83	3.25	26.43	15.32	15.18
Char/Sent. (Mean)	64.51	44.86	31.15	126.11	131.74	107.70
Char/Sent. (Std.dev)	35.95	27.57	17.02	140.71	92.38	84.69

Japanese Corpora	SLDB	MAD	BTEC	NHK	Mainichi	Nikkei
Char/Sent. (Mean)	32.61	26.87	14.45	65.39	37.73	44.21
Char/Sent. (Std.dev)	22.22	14.07	7.12	39.16	31.88	28.34
Total Characters	20,806K	290K	2,426K	2,772K	2,740K	2,772K
Total Sentences	84,751	10,612	162,318	66,512	71,647	253,016

Entropy

Language models for N-grams ranging from N=2 to 16 were computed for the two references in each language. Cross-entropy was then computed and averaged on randomly selected, non-overlapping blocks of approximately 250,000 characters for each corpus. Results for the English language are shown in Figure 4 and for the Japanese language in Figure 5.

While N-gram orders of 4 to 6 generally achieve the lowest bits per character ratios (apart from the cross-entropy computed on the training set, for which prediction performance is optimal), all numbers rise and stagnate as the order increases. This is due to the fact that for higher orders, unrecognized N-grams increase exponentially and lead to the familiar problem of training data sparseness. Drawing from the field of data compression, where history length

Figure 4. Cross-entropy against the oral reference SLDB (on the left) and the literal reference Calgary (on the right) respectively, for the English language

Figure 5. Cross-entropy against the oral reference SLDB (on the left) and the literal reference Nikkei (on the right) respectively, for the Japanese language

is an active area of research, we will assume, as in Teahan and Cleary (1997) and Dunning (1994), that a history of 3 to 7 characters gives meaningful results.

Meeting the intuition, the cross-entropy of SLDB against itself is the minimum (the accuracy of a language model predicting the corpus it was constructed on cannot be beat).

It is not necessary for the other reference to yield the highest values. For example, on the left of Figure 3, TIME yields the highest values and, therefore, will be in the situation of point ⊗ in Figure 1. Its projection will be within the interval [SLDB,CALGARY].

A Literality Coefficient

We then compute the literality coefficient for each corpus: Figures 6 and 7 show the variations of this coefficient for different N-gram orders, for English and Japanese language, respectively. According to our choice of references, a score of 0 corresponds to being closely similar to the oral reference, the SLDB corpus, whereas a score of 1 corresponds to being closely similar to the literal reference, the Calgary book corpus for English, or the Nikkei newspaper corpus for Japanese.

Figure 8 shows values for 5-gram character models.

Both MAD and BTEC yield lower literality scores than TIME and SPAE, and NHK and Mainichi in English and Japanese, respectively. MAD indeed yields the lowest literality scores for the English language, which would tend to confirm its reputation of being slightly more oral in content than the BTEC, both being usually referred to as oral corpora. It is not that obvious for the Japanese language, where the figure is less stretched out and where we are hard-put to reach a conclusion on literality.

For the English language, the TIME and SPAE have close values for orders of 3 to 5. However, the TIME seems to have a slightly higher literality score for all N-gram orders superior to 4. We

Figure 6. Literality coefficient for the English language. (0 is oral as in SLDB, 1 is literal as in Calgary)

Figure 7. Literality coefficient for the Japanese language. (0 is oral as in SLDB, 1 is literal as in Nikkei)

Figure 8. Coefficient of literality for 5-gram character models

	MAD	BTEC	SPAE/ NHK	TIME/ Mainichi
Eng	0.22	0.32	0.47	0.51
Jpn	0.38	0.34	0.49	0.49

may assume that, indeed, the TIME's degree of literality is superior to SPAE's, which should intuitively be true, considering that the TIME is made of written journalistic texts, whereas SPAE is made of transcripts of formal, professional conversations.

For the Japanese language, while differences in literality are clear between dialogue transcript corpora such as MAD and BTEC and news corpora such as NHK and Mainichi, we are hard-put to reach any decision at all when it comes to differentiating transcripts of highly scenarized, redactional content (NHK) from pure newspaper articles (Mainichi). We assume that the scale contraction phenomenon in the case of the Japanese language (and, conversely, scale stretch in the case of the English language) is due to the fact that we are unable to use a corpus of contemporary literature in the Japanese language. Classification seems robust to N-gram order variations, and all indexes converge to values between 0.4 to 0.5 for N superior to 14 for English, and as soon as N exceeds 7 for Japanese, according to our discussion about degenerate cases in the third section.

Measuring Homogeneity Inside a Large Multilingual Resource

Having characterized a corpus among others by measuring similarity, we would like to profile a single corpus more particularly. Indeed, if similarity is an intercorpus measure, then intuitively, homogeneity should be an intracorpora one. We want to apply our literality coefficient to subsets of a same corpus to try to characterize its homogeneity in literality. As such, homogeneity will be characterized by the internal variations of the previously defined similarity coefficient.

In this second experiment, we specifically address the issue of homogeneity within a large multilingual resource, the Basic Traveler's Expressions Corpus.

To this end, the resource was cut into a number of subsets, each of which was scored on the previously defined literality coefficient, using the same reference corpora as in the previous experiment (SLDB for orality and Calgary or Nikkei for literality). As we increase the number of subsets (analogically to increasing smoothing

Figure 9. Literality coefficient variation within the BTEC in English and Japanese, respectively, for 10 and 100 subsets. As previously, the coefficient is computed on 5-gram character models.

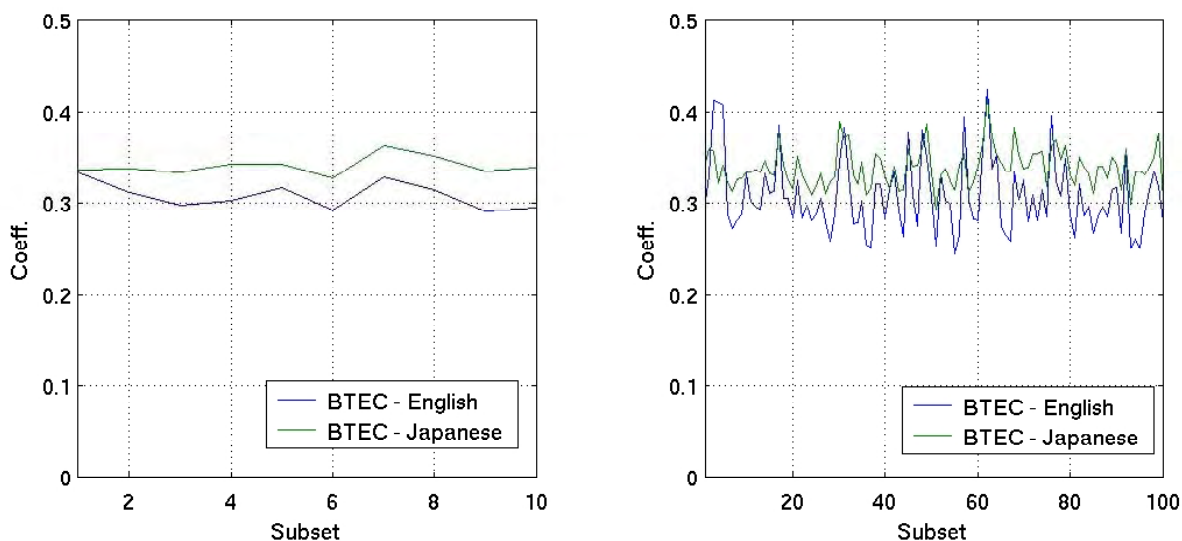

Figure 10. Correlation and standard deviations for an increasing number of subsets

Subsets	10	50	100	500	1000
Correlation	0.59	0.61	0.70	0.69	0.67
Std dev. Eng	0.014	0.031	0.053	0.063	0.075
Std dev. Jpn	0.008	0.016	0.022	0.031	0.037

resolution), we aim at having a better idea of the local variations of the coefficient and of the ideal tradeoff between a high number of small subsets (less smoothed and, therefore, more detailed; less data and, therefore, less significant) and a low number of large subsets (more smoothed and, therefore, less detailed; more data and, therefore, more significant).

The experiment is conducted on the aligned BTEC corpus in both English and Japanese languages. Figure 9 shows the variation of the coefficient for 10 and 100 subsets in both languages. Figure 10 shows the correlation between English and Japanese values, and the standard deviation in both languages for an increasing number of subsets.

Correlation between English and Japanese values appears to rise and stagnate around a moderately high value of 0.7, the optimum being found at an order of around 100 subsets (each subset, therefore, containing roughly 1,600 sentences); which tends to show that, indeed, literality in both languages of the same resource does tend to vary in a similar way, although differences inherent to the languages and their structure rule out the possibility of ever exceeding a certain maximum value in correlation. A more appropriate and accurate subdivision of the corpus remains to be investigated; knowing that the BTEC is a concatenation of sentences taken from various travel phrasebooks, one might assume that there could be differences in style between the various handbooks.

On the other hand, standard deviation provides us with a useful quantification of overall

homogeneity in that it accounts for the average intracorporal variations of the literality coefficient. As predicted, standard deviation increases as the number of subsets increases and their sizes diminish.

A COMPARISON WITH OTHER EXISTING SIMILARITY MEASURES

As mentioned in the second section, a number of similarity measures have been investigated that make use of linguistic feature counts such as the frequency lists of words or lexemes. Such methods assume that the word is a well-defined unit, or they rely on the use of segmenters when dealing with languages in which text is not segmented into words. We wish to compare our method to two measures, based on feature frequency computation, that have been applied previously to English corpora in the past literature: Chi Squared and Log-likelihood. Both measures are symmetric and compare one document to another via their feature frequency lists. The output number is interpreted as an interdocument distance.

Similarity Measures in Previous Works

The Chi Square measure (χ^2), as in Kilgarriff (2001): the number of occurrences of a feature that would be expected in each document is calculated from the frequency lists. If the sizes of documents A and B are N_A and N_B , respectively, and feature w has been observed with a frequency of $o_{w,A}$ in A and $o_{w,B}$ in B , then the expected value $e_{w,A}$ is:

$$e_{w,A} = \frac{N_A(o_{w,A} + o_{w,B})}{N_A + N_B} \quad (15)$$

and likewise for $e_{w,B}$ for document B . The χ^2 value for the document pair A and B is then computed as follows :

$$\chi^2 = \sum_{i=1}^n \frac{(o_i - e_i)^2}{e_i} \tag{16}$$

with the sum over the n features.

The log-likelihood measure (G^2): Dunning (1993) showed that G^2 is a better approximation of the binomial distribution than χ^2 , especially for less frequent events. It was shown to work well with documents of various sizes and to allow the comparison of both frequent and rare events. G^2 is the sum of the log-likelihoods G_w^2 of all n features w :

$$G_w^2 = 2(a \log a + b \log b + c \log c - (a + b) \log(a + b) - (a + c) \log(a + c) - (b + d) \log(b + d) - (c + d) \log(c + d) + (a + b + c + d) \log(a + b + c + d)) \tag{17}$$

$a, b, c,$ and d being defined for each feature by the contingency table given in Figure 11, so that in the end:

$$G^2 = \sum_{i=1}^n G_i^2 \tag{18}$$

Both measures yield a value that is interpreted as the interdocument distance between two documents. Such distances, in turn, can be transposed in the view of our framework so as to define similarity coefficients based on χ^2 and G^2 (i.e., character cross-entropy $H_T(A)$ is replaced in our framework by χ^2 or G^2 measures).

Evaluation

In order to compare our method with the alternative similarity coefficients based on G^2 and χ^2 we use the method of Known Similarity Corpora (KSC) as in Kilgarriff (2001). The comparison will be performed on Japanese, a language without clear word segmentation, so that text data will have to be previously run through an analyzer when using G^2 and χ^2 distances. To allow a fair comparison, our method will be applied on raw unsegmented data. We construct three sets of KSCs with the previously described SLDB, BTEC, and Nikkei corpora; slices of 10,000 words (or their equivalent in unsegmented data) are drawn out from each corpus and randomly rearranged so that each KSC set includes different mixes of one pair of corpora. For instance, the KSC set of SLDB and BTEC includes a subset *s10b0* containing 10 slices of SLDB and zero slices of BTEC (100% SLDB, 0% BTEC), a subset *s9b1* of 9 slices of SLDB and one slice of BTEC (90% SLDB, 10% BTEC), and so forth. Each subset is made of 10 slices and is, therefore, the equivalent of 100,000 words of data, on which we can produce a number of Gold Standard assertions such as “*s10b0* should be ranked with a lower coefficient than *s9b1* because all of its data come from the corpus SLDB” (if we assume that corpora more similar to SLDB get low coefficients and, more similar to BTEC, high coefficients). Each KSC set is made of 11 subsets of 100,000 words of data. The equivalent of 500,000 words of data is left out to be used as references for distance/entropy estimation in our framework. As in [3], frequency lists include the 500 most frequent features in each document (preliminary experiments having shown that best results were achieved for 320 to 640 features).

Once KSC sets have been prepared, they are scored on the three coefficients and ranked accordingly. The ranks are then compared to the gold standard rankings through the computation of Kappa coefficients, and Spearman rank order

correlations. Results are shown in Figure 12.

The KSC method has the following limitations to its validity: first, it does not compare different languages varieties but rather mixes of the same varieties; second, the size of slices may be too small to allow a fair comparison, as one corpus used in a KSC set might include highly heterogeneous parts. All three measures display very high correlations with the Gold Standard rankings. This only tends to confirm their validity as similarity indicators, at least when dealing with mixes of the same varieties of language. The best scores differ, depending on the KSC sets, showing no superiority of one measure on the other two. However, our method could be applied to Japanese data with no prior preprocessing, such as word segmentation, which makes its range of application wider than any measure relying on linguistic features such as words or lexemes.

DISCUSSION AND FUTURE WORK

This work does not state a way in which orality and literality should be defined in an absolute way. It suggests a way to rank corpora in their similarity to each other on a user-definable scale. Ranking is automatic and fast, and does not rely on the counting of any linguistic feature. Classification is only relative to the choice of references and, therefore, should be task-oriented. It is clear that this method of evaluating similarity is not limited to the sole application of quantifying literality. A wise choice of references should prove its capacity to rank other criteria correctly. This should be the subject of a future study.

Different corpora should have similar conventions in their levels of transcription and punctuation to be fairly and impartially compared and to avoid biased results when dealing with transcripts of oral conversations compared to strict written conventions. An approach at corpus homogeneity in the case of a large multilingual resource is proposed here, opening the way to

a future study on the general quantification of homogeneity within a large corpus. Comparing our approach to other existing similarity measures shows similar performance, while extending widely their range of application to electronic data written in languages with no clear word segmentation.

Let us point out once again that it is critical that computational linguistics and corpus-based machine translation have more standards at their disposal for comparing corpora and profiling very large datasets, as we should be able to make a faster and finer link between system performance and corpus features. This is the key to a better understanding of how a corpus-based system behaves and how to isolate and port its qualities to other systems.

CONCLUSION

By defining a coefficient of similarity between corpora and by applying it to the differentiating and ranking of literality, we have both tested and confirmed our assumptions on corpora of contrasting sources, having the reputation of being oral or literal. Ranking is robust to the N-gram model order variations and is more contrasted for values of N between 3 and 7. We have shown here a general way of relatively classifying and ranking corpus similarity with the user being free of choosing his own references. This opens the way to a task-oriented characterization of corpora, allowing a better understanding and porting of corpus-based systems.

Chapter 2.14

Digital Access, ICT Fluency, and the Economically Disadvantaged: Approaches to Minimize the Digital Divide

Ellen Whybrow

University of Alberta, Canada

ABSTRACT

The digital divide is a complex phenomenon inextricably linked to income security and not easily addressed through programs that provide simple solutions of training and access. This chapter details the importance of digital access and fluency as they relate to economic disadvantage and explores a variety of models that are used to address the problem. The chapter argues that programs addressing digital divide issues require a multi-faceted approach to address a variety of needs that exist as a result of the condition. While there may be a clash between community, educational, and employer groups, the chapter proposes an alliance model of stakeholders working towards common goals as well as their own organizational interests.

INTRODUCTION

The rapid increase of information and communication technologies (ICTs) has irrevocably changed the nature of educational and work environments in Western countries in the past decade. As recently as the mid-1990s, the use of technology in most post-secondary programs was limited to the use of PowerPoint for instructional delivery and word processors for assignments. In a few short years, ICT tools such as course management systems, synchronous capability, the Internet, and wireless devices, have provided students new conditions with which to obtain, manage, communicate, and construct knowledge. Graduates of educational programs bring these skills to the workplace, making access to emerging technologies and the cultural capital needed to be fluent in

their use a prerequisite for academic, social, and future vocational success (Wilhelm, Carmen, & Reynolds, 2002; Pew Research Center, 2002).

A continuing dilemma in the field of adult education is the issue of access and equity for students from economically disadvantaged backgrounds. Levine and Nidiffer (1996) found that post-secondary enrollment rates have improved in the previous half-century for all students with barriers to education, with the exception of those students with economic barriers. ICT is constantly evolving and continues to be costly for students who are economically disadvantaged and, in many cases, have had limited or superficial access to these tools (Statistics Canada, 2003; Wilhelm et al., 2002; US Department of Commerce, 2000). As proficiency with ICT is increasingly linked with job and income security (Krahn & Lowe, 2002), becoming proficient beyond the basic use of these technologies has become a key requirement for economically disadvantaged adults to realize vocational and therefore economic aspirations. How educators and the society that they serve accommodate the economically disadvantaged is a key question to those who consider the accessibility of education to be a core value.

Education has long been viewed as a means to equalize social and economic disparity within society. Access to and equity in education are the characteristics that facilitate such equal opportunity. However, educational organizations are limited in tackling such a complex problem. Instead, the answer lies in alliances of various organizations—both public and private—working towards common goals while fulfilling their own organizational interests. The focus of this chapter is to explore the relationship between economic restructuring, the economically disadvantaged, and the need for ICT fluency in this new and ever-changing environment. The chapter will review quantitative and qualitative data describing the phenomenon and will synthesize various approaches developed in response. Finally, the

chapter will suggest directions for program response and areas for further research.

BACKGROUND: DEFINING THE POPULATION AND ACCESS BARRIERS

One of the challenges in undertaking a review of this nature is defending its relevance. Colleagues see technology ubiquitously in use throughout educational institutions and know that student loan programs and scholarships open doors for the disadvantaged to obtain an education, which increases job opportunities once completed. The solution is simple: if you are poor, get an education and the technical skills you will need to get a job. What is less obvious is that there are links between technology and economic restructuring happening at national and global levels which impact personal job and income security for the poor and increasingly the middle class.

What is evident from the literature is that there is no clear or universally accepted definition of who is economically disadvantaged or poor. Some countries like the U.S. use an absolute measurement, which defines poverty as a state in which a person is unable to provide even the most basic needs of food, clothing, and shelter. Other countries such as Canada and Britain use relative measurement, which defines poverty at a specific level compared to median income (Dickens & Ellwood, 2003). These definitions come under criticism from various factions; absolute measures may indicate that poverty has fallen (Institute for Research on Poverty, 2002) or been eliminated (Sarlo, 1992), while relative measures indicate an increase (Dickens & Ellwood, 2003). What is easier to identify is that certain groups are at a disadvantage economically regardless of the criteria used; visible minorities, single-parent families, particularly those headed by women, the educationally deficient, and those living in large

metropolitan or rural areas have higher rates of poverty (Institute for Research on Poverty, 2002). Absolute measurements would obviously exclude people who can afford technology access, while relative measurements mean that people can own technology or have home access and still fall within a definition of being poor. For the purposes of this review, relative definitions and the term “economically disadvantaged” will be used from this point forward.

Some futurists have reviewed the progress of other technologies and predicted that the issues of the digital divide will fade away of their own accord as ICTs proliferate everyday life (Sargent & Tucker, 1997). The Pew Research Center (2003) has found that although Internet access has increased for Americans (58% had home access in 2002 compared to 49% in 2000), its growth has been slowing since late 2001; the report draws comparisons to the adoption rate of the telephone which slowed during the Depression. The report’s survey indicates that a sizeable number of people remain offline and Internet cost is a substantial disincentive for some of the offline population. While it is logical to make historical comparisons to other technologies, this chapter argues that ICT differs substantially from previous technologies such as the telephone. ICT, referring to electronic media consisting of hardware and software, and telecommunications technology such as the Internet go beyond simplistic two-way audio connections to allow for place- and time-independent communication, as well as research, knowledge construction, and management functions. ICT tools also differ from other technologies because they are constantly evolving, making the requirements to continually upgrade hardware and bandwidth important. In a previous report, Pew (2000) reports that, while US Internet access had increased dramatically, half of all Americans remain offline and 57% of non-users have no plans of acquiring access. Many of these non-users (39%) cite cost as a disincentive to going online.

It is also important to emphasize that access can mean more than access to hardware. Mitchell (1999) notes that access involves general connectivity that is available in your surrounding community, as well as what you can pay to service your home. It also involves the cultural aspect embedded in software design. The language and relevance of most information is targeted at the well-educated middle class. These features also pose additional access barriers, which are far less quantifiable than variables such as ownership or home Internet access, but important to note nevertheless.

ICT AND ECONOMIC DISADVANTAGE: THE POLARIZATION OF THE WORKFORCE

Not being online or technically proficient has economic consequences. The obvious is that information, such as job postings, is increasingly available exclusively online. However, there are other reasons related to the restructuring of Western economies that make being a technology “have-not” significant. Technology has produced patterns of work that “deskill” or eliminate human labour (Shalla, 1997). Krahn and Lowe (2002) have analyzed computer use, income, and working patterns that exist within the Canadian economy and have arrived at the succinct label of “Good Jobs/Bad Jobs.” This is a condition in which companies, in efforts to compete globally, have increasingly moved to a structure revolving around a small core group of highly paid workers who are supported in their creation, communication, and management functions by a periphery of part-time or contracted unskilled, semi-skilled, and even skilled workers. Highly paid staff are more likely to use computers and use them in advanced ways. Their use of computers means that they are more likely to be

developing transferable skills. Peripheral workers, although many may use computers, tend to use technology to process data, rather than to create or manage information. This raises the issue of enskilling and deskilling (pp. 289-292). Those who use computers in advanced ways along with other advanced skills improve their employment prospects, while those whose use of technology is marginal or automated find their career prospects limited. This polarized workforce is increasingly a worldwide phenomenon. In the US, Goode and Maskovsky's (2001) collection of ethnographic studies note the effects of this polarized workforce and the corresponding decline in wages and job security for low or semi-skilled people.

The polarization described above can affect a broad spectrum of people including many in the middle class (Ehrenreich, 1990). Lack of technology access, a problem more prevalent among the economically disadvantaged, makes the problem more acute because there are fewer chances for self-directed study. It can be argued that providing access through schools, libraries, and community centres provides a remedy for deskilled or unskilled workers. To a certain extent this is true. If we examine studies of disadvantaged and at-risk children, special programs to provide technology home access are associated with increased school performance; the question remains whether it is logical to assume that similar programs for adults increase skills important for work. A.T. Kearney's (2002) study of children's technology access and its relationship to career preparation for technology-related careers shows that access is only part of the issue. In a workforce survey of youth in the Silicon Valley, it was found that while school (99%) and home (86%) computer and Internet access were very high, youth from lower socioeconomic backgrounds were much less interested in obtaining the education needed to take advantage of the region's major economic activity. As with other characteristics, social networks were extremely important in determining

the educational and career path of youth. It is reasonable to assume that adults seeking retraining to improve economic prospects also have the same influences and limitations.

EXPERIENCES OF DIGITAL "HAVE-NOTS"

The connection between technology literacy and economic security was well-entrenched in the minds of many participants in a qualitative study of economically disadvantaged adults pursuing post-secondary education (Whybrow-Howes, 2000). For those most concerned with changing their economic circumstances, it was important not only to be computer literate, but also to study in a computer-related field to take up a more secure role in the knowledge economy. Interviews with the participants—most of whom were disadvantaged by relative and not absolute measurements—indicated that adult students planning to go back to school were able to save for technology purchases and did not find the cost unreasonable. Those students who were not able to purchase computer systems relied primarily on institutional labs or other community services. Access was most difficult for non-computer owners in highly technologically intensive programs. Since many in the study were, at best, recent computer owners, they often perceived their literacy as substantially behind the literacy of fellow students. As with children, social networks were important in filling in access and literacy gaps, although these networks were not always reliable in achieving these goals.

Stanley (2003) notes the psychosocial issues of relevance, fear, and self-concept that hinder the acquisition of computer literacy. Cost was, in many cases, a minor issue that was used to justify rather than explain one's lack of computer literacy. Some participants in her study put off ICT purchases because they did not see it as relevant to their lives

and lacked an understanding of the potential of ICT to expand social, educational, and economic opportunities. Many did not “see” themselves as computer users, who were perceived as not part of their culture or sub-culture. Many participants did purchase ICTs only to avoid their use because they did not want to appear incompetent or not being able to learn in front of their families or partners. Her research indicates “ownership does not always accurately reflect computer literacy” (p. 409).

SOLVING THE PROBLEM

For many educators interested in social justice issues, the problems associated with the economically disadvantaged, the phenomena of a polarized workforce, and the need for ICT proficiency remains difficult and, at times, seemingly unsolvable. While action at the individual level is always important, in general, complex problems require multi-faceted solutions and a coordination of efforts on the part of individuals, educational institutions, communities, and governments. A review of the literature indicates three general models with which to address ICT and the economically disadvantaged. All models have strengths and weaknesses, and these will be reviewed. Finally, a fourth model will be proposed which builds upon

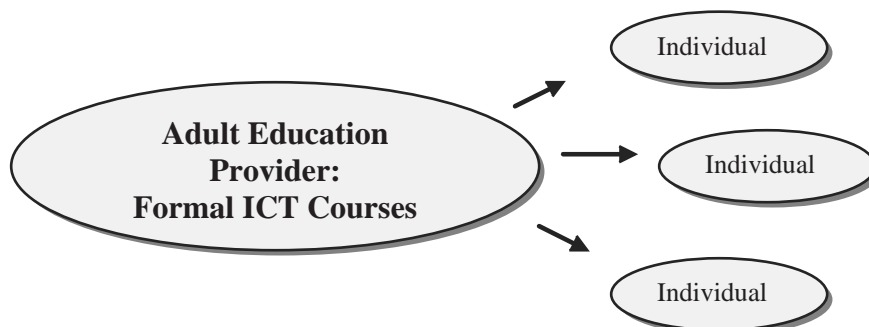

the strengths of all models to provide multiple partnerships, formal and non-formal educational opportunities, and the ability to produce more meaningful changes.

Formal Education: The Computer Course Model

The most basic and easily categorized response is the “computer course.” It is a unit that is easily described, scheduled, and delivered to clients. The service provider may be a community college, non-profit organization, or adult education centre. The “course” is usually marketed to individuals, and its successful completion leads to either more courses, certification, or both.

The blueprint of the course is curriculum. A variety of curriculum responses to the phenomenon of ICT and the economically disadvantaged have been proposed and implemented through the years. Early pre-“Internet” literature focused on the notion of computers as keys to equity, access, and quality (Congress of the US, 1993; Guthrie, Garms, & Pierce, 1988). This point of view states that information technologies provide low-cost learning opportunities, which, in turn, lead to greater educational access for all, and increased equity for those most marginalized in education through expanded individualization and interaction. Computer programs that address a wide range

Figure 1.

of instructional and remedial needs allow students to work at their own pace until mastery of concepts is achieved. However, literature of the day also suggests substantial evidence that students in low socioeconomic schools receive inferior computer instruction, which emphasizes drill and practice, transmission methods, and lower-order thinking skills, while students from high-income schools spend more time making judgments, inferences, and evaluation of the content. "Affluent students are thus learning to tell the computer what to do, while less affluent students are learning to do what the computer tells them" (Watt, as quoted by Resta, 1992, p.122).

The traditional view of technology as a transmitter of knowledge is still very prevalent. Features of this approach are skill-based modules to acquire technology skills, carefully packaged Web-based, or CD-based materials to learn other content and traditional tests. An example of this approach is the European Computer Driving license, which has been widely adopted in the European community and is being used through programming in some countries to certify "the skill level achieved by socially disadvantaged people" (European Centre for Development, 2001, p. 17). Payne (2002), in his review of work-based skills, notes national and international political support for these easily understood approaches, but also notes the approach leads to a decontextualization of learning without specific relevance to the learner. While a computer driving license provides an easily recognizable qualification, it is this writer's viewpoint that it will not fundamentally change the economic conditions in which people find themselves.

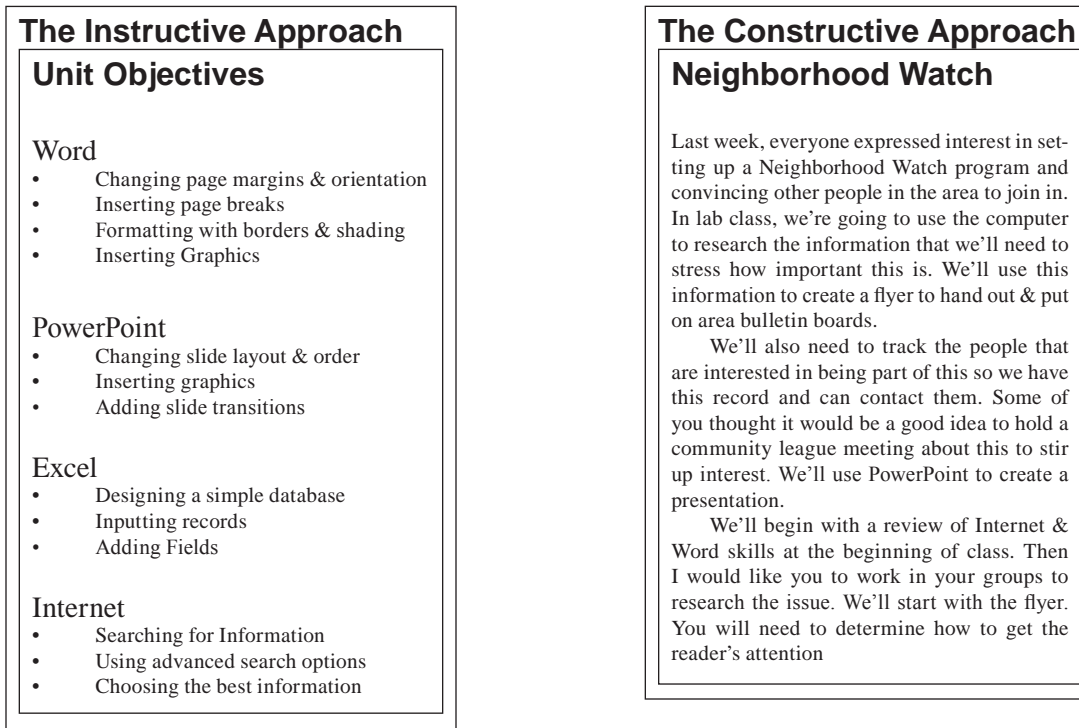

Kozma and Wagner (2003) have noted the features of instructive and constructive curriculum approaches to ICT and the economically disadvantaged. Instructive approaches, which emphasize direct instruction, allow explicit progression, frequent feedback, and coverage of basic skills. Instructive approaches are often packaged as

computer-assisted instruction and can frequently be purchased off the shelf or from publishers, which provides an easily incorporated resource for adult education programs. This approach meets the formal academic and linguistic needs of the disadvantaged by providing early success, obvious mastery of skills, and frequent assessment. These features of the instructive approach are useful, but limited to basic skill development. If we define ICT fluency as the development of advanced skills to create, communicate, and manage complex problems, then the instructive approach has boundaries in terms of creating these opportunities for learning.

Constructive approaches provide skills acquisition by rooting learning in real-world problems. Students work individually or in teams on projects that require the acquisition and use of ICT skills to solve problems that are meaningful to them. Constructive approaches build on ill-structured learning projects to encourage the application of ICT to problem solving. This in turn encourages "higher-level skills, such as the ability to search for information, reason with models, analyze data, and communicate ideas" (p. 12). Constructive approaches address not only specific academic and linguistic needs, but are more suited to addressing the social dimension important to working with the disadvantaged. Kozma and Wagner identify the need to create supportive learning communities through collaborative projects, as well as the need to connect learners with "outside community resources" (p. 9). A comparison of the instructive and constructive approaches is detailed in Figure 2. Both approaches cover the same skills.

There are definite advantages to the instructive approach. Students and instructors know what is being covered, instruction is provided in a manageable and step-by-step approach. More importantly, the curriculum is also easily understood by funders, employers, and the students themselves. However, it is the constructive ap-

Figure 2.

proach that provides a more memorable learning experience by focusing on task-oriented learning experiences. Skills are covered through working towards solutions of real-world problems. This poses obvious planning and instructional challenges, and a learning environment in which the instruction and goals are continuously negotiated. The lack of linearity is somewhat disconcerting to instructors and students alike. Students may finish a course without a clear understanding of what they know. If their goal in enrolling is to improve employment prospects, this is an additional disadvantage. Despite its disadvantages, the constructive approach holds numerous advantages. Studies at the post-secondary level that use a problem-based, interactive approach show positive outcomes in increased student learning (Springer, Stanne, & Donovan, 1999). It is reasonable to assume that the same holds true with non-traditional learners. The approach also provides a community learning experience,

which may reduce anxiety about acquiring new skills and provide learners with a social network of computer users within their culture. In this sense, it is the approach that most likely can be used to fulfill the social needs identified by Kozma and Wagner (2003, pp. 18-20). The authors note that both approaches can be blended to maximum effect; a constructive approach can be the primary methodology, with a regular checklist review and conventional mastery-based testing to keep students focused on what they are learning. Linking to external standards or testing is an important feature to build into an ICT program, as it provides benchmarks for students to aim for as well as a recognizable certification.

Non-Formal Education: Post-Secondary/Community Centre Partnership Model

While the delivery of formal courses is appealing to many economically disadvantaged individuals, the onus still remains on the individual to seek out and enroll in formal offerings. This may leave out those with scheduling, transportation, and childcare barriers. Others may be intimidated by or simply uninterested in enrolling in courses if they perceive themselves as not fitting in with the culture of the other students. Stanley (2003, p. 414) notes that local community centres can play an important role in educational delivery by minimizing barriers. They can also create learning experiences that extend beyond the formal confines of the course structure to a learning environment that provides a range of non-formal opportunities that embed technology literacy in the heart of the community. Partnerships between adult education providers and community centres allow each entity to build on its expertise and expand the opportunities available to people beyond what one service provider can deliver.

As with the Computer Course model, the partnership model may also market formal education to low-income communities. A limited example of this is the approach certain educational organizations have taken in marketing their programs in low-income areas. Roach (2000) reports the efforts community colleges in the Washington area have taken to become more visible to economically disadvantaged communities. Some have established satellite campuses or restructured curriculum to provide less theory and more practical training to

suit the needs of employers in the area. Minority student groups provide support and networking opportunities for low-income students once admitted to these programs.

These efforts, however, do not constitute a true example of a partnership. The efforts are still conventional educational organizations marketing formal course-based learning opportunities to individuals in these communities. Such efforts will provide opportunities to those who are already motivated to change their circumstances, and have academic and personal skills, as well as the support to reach long-term goals. In some communities, this may only be a few individuals. The problem still remains of the larger community. How do we ensure ICT access and meaningful educational opportunities that will minimize economic disparity and maximize social mobility?

The partnership model, in its truest form, implies reciprocity between partners. The educational institution that provides ICT expertise receives opportunities to research or to provide its on-campus students real-life experiences in civic participation rather than theoretical academic review. Partner low-income communities receive ICT hardware, software, ICT expertise, and a variety of educational opportunities, which range from formal course offerings to less-structured opportunities. Educational opportunities flow both ways (Figure 3).

The Chronicle of Higher Education (2002) reports “service-learning programs” that are run from Florida’s Miami-Dade Community College, whose faculty and students have contributed 280,000 hours to various agencies in South Florida. This commitment has led to the

Figure 3.

development of a Technology and Learning Center in the low-income community of Overtown, and provided computers and Internet access, computer literacy courses, and a variety of after-school or summer camp opportunities. A key component to this project is an understanding that the educational institution does not solve problems for the community, but sees itself as creating “problem-solving capacity” with its partner organization.

Not all educational/community partnerships are of a front-line nature. MIT (Schön, Sanyal, & Mitchell, 1999) has been supporting the work of community activists since the 1970s through a Community Fellows Program (CFP). Each year, 12 to 15 activists and organizers from urban low-income communities come on campus for a year to reflect and reorganize work in their respective communities. Since the 1990s, the CFP has become increasingly focused on technology as an educational, organizational, and income-generating tool within their communities. MIT realizes many benefits from this program such as research opportunities, meaningful engagement experiences for its Department of Urban Studies and Planning, and dialogue with its CFP fellows.

One result of MIT’s commitment to community engagement is the Computer Clubhouse concept (Resnick, Rusk, & Cooke, 1999). The clubhouse seeks not only to teach basic computer skills among low-income youth, but also to provide conditions in which participants become producers rather than consumers of ICT. Radical

constructivist principles of learning are central to this mission. Developing learning communities where youth and adult mentors collaborate with others on projects of interest is a key feature of the clubhouse. Roles are not set. A youth participant may become a mentor on certain projects where he or she is the clubhouse expert. On other projects, the youth or adult mentor may become the learner in this dynamic environment. Curriculum is negotiated through “design experiences” (pp. 268-271) that encourage creative expression and problem solving. Sample projects include online art galleries, robotics, or programming computer games. Such projects engage youth in ways formal education fails to do and provide a deeper learning experience that is interdisciplinary by nature.

While the computer clubhouse focuses on youth, another MIT initiative encompasses the entire community to engage empowerment and activism. Shaw and Shaw (1999) report the results of a computer network system placed in a low-income community by the MIT media laboratory. The effect of simultaneous chat and discussion board forum, which was leading edge at the initiation of the project, demonstrates the capacity of low-income communities to use ICT for community improvement. Parental involvement in schools increased, community projects were organized, and dialogue around a variety of topics exploded among residents who largely did not know their neighbors in a decayed and dangerous urban environment.

Figure 4.

Employer Recruitment: The Job Training Model

Non-formal education is a possible solution to pull back disadvantaged youth from the hinterland of unemployment, poverty, or worse. Other partnerships keep ICT available and meaningful for the larger community. However, certain adults require more direct and quick intervention. These may be individuals who are already motivated. Others may be those from the middle class who have fallen on hard times and need a helping hand to get back in the workforce. In these cases, the partnership model may not adequately meet immediate learner needs. Stanley (2003, p. 9) also notes that although economically disadvantaged people would benefit from an ICT curriculum that creates “pathways” to careers, many service providers dealing with this group are not equipped resource-wise or through their own social networks to provide these opportunities.

An obvious context within which to structure ICT approaches for the economically disadvantaged is to link technology skills to current and emerging workforce needs. There are compelling reasons to do this. Khirallah, McGee, and Goodridge (2001) report the need for IT workers; 77% of 500 US companies surveyed see the digital divide as a key issue. Some companies such as Hewlett Packard and Cisco Systems have digital divide programs in place to encourage science and technology interest among children and see this as a long-term strategy to influence education to fill future needs. Adults are more immediately focused on career aspirations, so initiatives that promote economic relevance are important. Other types of linkages are employment initiatives that connect the disadvantaged to minority workforce associations or minority-owned companies. Roach (2000) reports employer interest in recruiting minorities into the IT industry. Associations of IT-based companies have actively recruited minority applicants and created summer internship programs through advertising in low-income

communities or specialized recruitment programs. Other companies work with African-American colleges to offer “internships, workshops, scholarships, and seminars.” Some employers have banded together to form their own partnerships to sponsor training for the disadvantaged. Finally, minority-owned companies can play an important role by providing role models of success in the IT industry, mentorship, and an avenue for networking.

Holistic Initiatives: Multiple Alliance Model

Employer initiatives to recruit and train economically disadvantaged individuals provide immediate solutions, particularly to those who become employed as a result. As noted above, these initiatives meet the needs of some but not others. These types of projects are geared to industry needs and are dependent on the health of specific industries. It would appear that these initiatives are primarily in effect where the IT industry is predominant and experiencing a labour shortage. This has the effect of making large initiatives specific to a geographical region or cycles of economic activity. This also leads to questions about long-term benefits of such programs. A crucial question is whether the training and subsequent employment enskill or deskill the individual. Selwynn (2003, p. 8) notes the “narrowing of adult education...around business and industry-friendly skills and competencies...” and calls for emancipatory goals for ICT adult education that provide learners with opportunities to use ICT to their own advantage. However, programs of an emancipatory focus or those that stress critical pedagogy can lose momentum among participants and funders if they fail to create recognizable certification, employment, or change.

In the previous models, the various service providers and potential employers of economically disadvantaged individuals are restricted to offering disparate pieces. Missing from these

disconnected opportunities are the motivations and goals of the economically disadvantaged, both as individual participants and as members of their respective communities. Each of the players in previous models brings its expertise to the problem. Adult education and post-secondary institutions provide ICT expertise and formal courses, and seek enrollment in these. Employers provide immediate job opportunities and want a pool of qualified workers from which to draw. Both surround the larger hub of the community centre, which provides access to a community of learners and potential employees. Yet each of these entities is limited to a certain extent to these domains. Linking through formal alliances allows each to build on the strength of others. More importantly, an alliance allows momentum toward political solutions.

Conservative policies towards digital divide issues as exemplified by the Bush administration focus on market force correction rather than social programs (Powell, 2001). However, others debunk the power of market forces and call for government intervention to address disparities. To a certain extent, the mixture of educators, community groups, and industry are an unlikely alliance. Selwynn (2003, pp. 13-14) notes, "It is naïve to imagine the effective development of ICT-based adult education without the involvement of the IT industry and other private sector actors..." but acknowledges the clash between "private interest and public good." Kozma and Wagner (2003, p. 25) see the involvement of "national, state or provincial and local governments..." that provide focused job training as well as resources that address larger

issues of "community environments." This may involve direct funding to special needs programs, but may also involve indirect incentives such as tax credits to encourage industry involvement. Industries that sell IT infrastructure have a vested interest in such initiatives and can be recruited as partners. Khirallah et al. (2001) report certain IT industries have either developed educational programs or installed infrastructure at partner schools and homes. Such industry involvement, if harnessed and encouraged to the larger community, has reciprocal benefits to business and the general public. An alliance model allows each player to contribute its specific expertise and in so doing, meet some of its own objectives.

CONCLUSION

It is unlikely that any of the models described will be successful without leadership from the economically disadvantaged themselves. As a group, they exist without any unifying characteristics other than their disenfranchisement from the mainstream. Some are from the middle class and have fallen on some hard times and simply need some support to re-establish themselves. The situations of others is more dire, and it is debatable whether educational assistance of any kind is really helpful beyond programs that focus on children or youth. The extent to which the cultural capital of technology is a barrier to the educational and vocational aspirations of those on the wrong side of the digital divide is not entirely clear, and descriptions of economically disadvantaged adults'

Figure 5.

experiences in this changing environment are not extensively detailed in the literature. Research of a qualitative nature could more extensively inform program development. Extensive long-term quantitative evaluation of the success of formal education ICT courses and job training initiatives to produce long-term economic improvement is needed, as well as the evaluation of the impact of non-formal community-based initiatives.

While post-secondary institutions can provide services and formal courses, they are unable to completely respond to such a complex problem. It remains the role of community leaders to organize their constituents and network with service providers in education, the government, and industry sectors to make a case for action. Ultimately, all players have an interest in working towards the goal of economically healthy communities.

Chapter 2.15

Delivering More Effective Community Consultation and Support for Regional ICT Programs

Lynne De Weaver

Southern Cross University, Australia

Allan H. Ellis

Southern Cross University, Australia

ABSTRACT

This chapter looks at the role of language and the community consultation process in overcoming the digital divide by facilitating the uptake of information and communications technologies (ICT) in small regional communities in Australia. It focuses on one of the ‘telecentre’ programs funded by State and Federal governments in Australia—the Community Technology Centre at New South Wales (CTC@NSW) program. The authors look at some of the key issues that emerged in communities that applied for CTC@NSW grants when a more culturally relevant consultation process, based on Maslow’s Hierarchy of Needs, was developed and implemented. This consultation process was successfully used in tar-

geted regional communities to build social capital, facilitate regional economic development, and empower communities through the use of ICT. The chapter also includes projects that demonstrate the diversity of ICT usage in the communities that received funding to establish a CTC.

INTRODUCTION

Federally funded programs in Australia, such as Networking the Nation, have provided millions of dollars to Australian regional communities to help them gain access to a range of ICT products and services. The Community Technology Centre at New South Wales (CTC@NSW) was one such program, with grant funding being made avail-

able to communities in partnership with the NSW State Government. A new consultation model was developed by De Weaver in order to increase the understanding and uptake of information and communications technology (ICT) products and services in small regional communities in New South Wales. Using the CTC@NSW program as a case study, the chapter will focus on this consultation process and how it was used to achieve successful outcomes for some of the communities that participated in the program. It will also highlight underlying language and technology issues that arose when small rural and regional NSW communities applied for CTC@NSW grants.

One of the major challenges of facilitating effective community consultation at a statewide level was in presenting information about the benefits of ICT products and services in a way that was relevant to all communities. In many instances, 'Communities don't know what they don't know'. This proved to be the case in many of the communities that sought grant funding through the CTC@NSW program. A recent report from a regional research forum (2004, p. 8) stated, "...regional development policy in Australia is 80 years old, but despite this, and the research issues in the last 40 years in particular, what we know is substantially less than what we don't know." Hearn et al. (2004, p. 7) identified lack of ICT knowledge in regional Australia as a further complicating factor and states, "Advocates of ICT projects can mis-specify and under resource the social and human infrastructure required. It is necessary that citizens are able to not only access that technology but that they also possess the skills to use and the resources to access them."

Finally, the chapter looks at the consultation process and methodology used by De Weaver, in her role as regional coordinator for the CTC@NSW program, in achieving successful ICT strategies and outcomes for the regional communities in which she worked. It also highlights the importance of using 'plain English' in the consulta-

tion process and in dealing with the underlying resentment that may exist in various stakeholder groups when their needs are misunderstood or inadequately addressed.

BACKGROUND

The CTC@NSW began its operational phase in March 2001. Its original charter, as shown on its Web site (July 20, 2004), was "...to establish up to 55 Community Technology Centres (CTCs) in regional NSW communities, with populations of less than 3000, to help them gain access to a range of technology services for local businesses, students, community organizations, individuals, and identified special groups within these communities." The specific goals of the CTC@NSW program were to:

1. Assist local communities to establish a network of sustainable CTCs across rural and remote NSW
2. Promote community development and networks of interests in rural and remote NSW
3. Encourage community demand for information technology (IT) services in rural and remote communities
4. Encourage existing telecentres to join the CTC support network

By June 2003, the CTC@NSW program had achieved its goals with a total of 83 fully funded CTCs serving over 100 NSW communities. The CTC network included 50 newly funded CTCs with a further five CTCs in the planning stage, plus 33 telecentres that had been funded by an earlier federal government program. The momentum for establishing CTCs came from the communities themselves, and involved a lengthy community consultation process. The first step in this process was to help communities determine their eligibility through the preparation of an

expression of interest (EOI). Following approval of an EOI, a regional coordinator was assigned to the 'approved' community so work could commence on their application. CTC applications were for seed funding rather than an out right grant. Communities had to determine how much they could apply for *after* they had completed their 3 year business plan. This plan was also the key component against which applications would be evaluated by the Canberra based CTC Funding Panel that met three times a year. Consultation with communities usually lasted from 4 to 6 months, although for some, it was an even longer process if their first application proved unsuccessful.

A wide range of motivational factors needed to be incorporated into the community engagement and consultation process in order to ensure the best possible outcomes for applicant communities. However, as Pigg and Crank (2003, p. 25) stated in their paper, which looked at similar programs in rural American communities, "Community capacity to successfully capture the advantages engendered via the deployment of ICTs is not particularly unique to the technology. Key agents of change must work together with local residents to actively support and engender an atmosphere for collective action towards improvement for their rural communities." Maslow's five-stage Hierarchy of Needs, as re-framed by Chapman (2002, p.1), provided an excellent model to promote collective action as his concept of self-actualization related well to the challenges and opportunities that ICT presented to the small, regional communities involved in the CTC@NSW program. It was this reframing that provided the conceptual framework for the new Hierarchy of Community Needs and offered the structure, understanding, and the methodology by which collective action could be taken to meet the identified ICT needs of individual communities as they sought funding for a CTC.

While there are many definitions for the term 'community', the authors have used the definition given by the American Society of Association

Executives (2001, p. 2), that defines communities in two related ways:

- Community as social glue—providing 'stickiness' or connection
- Community is also what people do for each other—to create a Web of social relationships.

De Weaver used Action Research (AR) as her methodology throughout the 2 years of fieldwork she undertook as the Northern Rivers Regional Coordinator for the CTC@NSW program. It was the cyclical nature of AR, for example, planning, action, and review that enabled her to achieve better outcomes in each of the communities in which she worked, as she was able to build on the insights gained from the critical reflection component of AR when she commenced work in new communities. Action Research was especially effective in this regard because as Dick states (2001, p. 21) "Action Research... pursues both action (change) and research (understanding) outcomes. It achieves change through its participative approach often in conjunction with other change processes."

THE HIERARCHY OF COMMUNITY NEEDS CONSULTATION MODEL

Although much has been written about community consultation per se, when the consultation incorporates explaining the benefits of ICT, identification of needs, and dealing with technical usage issues, a whole new dimension of complexity is added to the process. Aslin and Brown (2004, p. 3) state:

Good community engagement can be achieved by using a wide range of tools and techniques, not by applying a simple recipe or prescription applicable to all situations... The engagement process is part

of furthering another process: decision-making for a particular purpose.

This proved to be the case in the process of applying for a CTC grant and it was Maslow's Hierarchy of Needs in its re-framed five-stage model that formed the basis of the new consultation model that evolved. Maslow's 'Needs', as explained by Chapman (2002, p. 4), consist of:

Biological and Physiological needs including basic life needs. Safety needs including protection, order, etc. Belongingness and love needs including work groups. Esteem needs including status, responsibility, reputation and self-actualization including personal growth and fulfillment.

While Maslow's theory is often closely linked to pedagogy or psychology it also has important applications in understanding what motivates communities to apply for capacity building grants such the CTC@NSW program. This view was reflected by Chapman (2002, p. 6), when he stated that:

Abraham Maslow developed the Hierarchy of Needs model in 1940-50's USA, and the Hierarchy of Needs theory remains valid today for understanding human motivation, management training, and personal development...we must satisfy each in turn, starting with the first, which deals with the most obvious needs for survival itself. Only

when the lower order needs are satisfied are we concerned with higher order needs.

However, for community consultation in the CTC@NSW program to be effective, it was necessary to reframe Maslow's model while adhering to his core values so that it became a new hierarchy of community ICT needs consultation model as shown in Figure 1.

Just as in Maslow's Hierarchy of Needs, the most basic need in many small regional communities is for survival itself as banks, businesses, and governments withdraw services from them in the name of economic rationalism. These communities are then faced with the need to explore alternatives and find out if ICT has a role to play in helping them build capacity and overcome the loss of face-to-face and shop front services that have had such a negative impact on their quality of community life. While Plowman et al. (2003, p. 135) believe that:

Governments have started to respond to the strong expressions of dissatisfaction of rural people concerning the decline of social and economic fabric in rural communities attempting to develop programs for the reversal, or at least the amelioration, of the observed trends....governments are increasingly calling on the presumed self-help capacities of rural communities for them to become 'partners' with government in developing and delivering programs for rural communities...however the

Figure 1. Hierarchy of community needs consultation model (Derived from De Weaver's unpublished monthly progress reports prepared in her capacity as regional coordinator for the CTC@NSW program from 2000-2002.)

depth and breadth of resources, particularly the human and social capital, may not be sufficient to allow communities to respond to, and participate effectively in, such programs.

ASSESSING NEEDS REQUIRED INFORMATION IN PLAIN ENGLISH

It is important to consider how a community's ability to access government funded programs to satisfy its most basic 'survival' needs is often challenged by the bureaucratic and technical nature of the language used in grant applications. De Weaver and Lloyd (2005, p. 4) noted that "...applicant communities had to come to grips with the technology driven and corporatized language of ICT applications, a 'literacy for technology' issue emerged that needed to be addressed." They also needed to understand how access to ICT funding could help their communities survive in a global marketplace. In one community, when a survey was circulated to determine the type of ICT services that residents required, some of the answers gave a clear indication that they first had to deal with a 'literacy in technology' issue. For some, ICT meant being able to have public access to a facsimile machine in order to fax in their benefits claim forms while for others it meant having a public pay phone outside the general store or being able to get mobile telephone coverage. But, for the more sophisticated, access to high-speed bandwidth was a key driver because it meant more cost effective access to national and international markets for their products and services.

In order to understand the implications of what ICT might offer a community, members of that community had to be able to articulate their needs. Wolstenholme (1995, p. 27), provided insight into this stage when she stated, "Action and interaction by members of a community in the pursuit of shared interests is probably the strongest force within a community. It is a way of achieving things for the community...Com-

munity action is the important source of power for any change which is likely to promote the well-being of a community." Information about the CTC@NSW program was therefore imparted and gained in a variety of ways including: media releases, community surveys, free information sessions to explain how the Internet worked, how small businesses could take advantage of online services to do their banking, pay taxes, seek regulatory assistance, and more. The use of the Internet to help high school and tertiary students with their studies by providing access to a vast array of information databases was often seen as a highly desirable outcome for applicant communities. The aim of all these activities was not only to raise awareness of greater access to ICTs but also to explain ICT features in terms of consumer benefits using plain English.

The importance of using plain English to empower people was expounded by Fairclough (Cope & Kalantzis, 2000, p. 163) when he stated, "We are living through a period of intense social and cultural change which is pervasive and universal in its global, national, and local effects...these fundamental changes are changes in languages, different dialects, different genres, and different discourses." Fairclough believes that the language issues of marketization and globalization also arise out of these changing discourses. He also says (Cope & Kalantzis, 2000, p. 164), "The processes of marketization are in part linguistic in nature: they involve a marketization of language, in the sense that the language of areas like public services are being colonized by the language of the market."

It was also interesting to look at the language issue from the perspective of social researchers. In this aspect, Carson and Gelber (2001, p. 5) commented on the community consultation process by stating that, "The achievement of the specific goal of achieving better communication and participation faces a number of obstacles, on a range of levels. At a macro level, those who decide which services should be provided are not

the same people who actually provide the service.” This was indeed the case in the CTC@NSW application, as it was written by bureaucrats who operated in a different paradigm than that of the communities. This implies that the language used in these applications often posed a significant challenge for the communities. In fact, of the 26 communities in the Northern Rivers region of NSW that had initial meetings with regard to the preparation of an EOI, only 7 went on to apply for grant funding, all the rest indicated that they either did not feel that they had the skill or time to deal with its complexity and that they found the wording in the documents too confusing.

For communities that went on to apply, not only did they have to deal with ‘literacy’ issues in order to apply for a CTC@NSW grant but they also had to deal with technical literacy issues as well. Luke and Gilbert (1993, p. 5) provided insight into this when they stated, “To refer to ‘technology’ in association with ‘literacy’ can signal a number of discourses concerning literacy, technology, and various combinations thereof...technology *for* literacy, literacy *for* technology, literacy *as* technology, and technology *as* literacy.” For example, in the technology section of the CTC application, those communities that wanted to use Apple Macs had to deal with information such as:

It is recognized that there is a strong rationale for using Apple Macs particularly in the multimedia field...In recognition of this, and the fact that most CTCs will be running PC based infrastructure, the question then becomes how to integrate the Macs into a PC based network. Although there are a number of ways of doing this, and this has become somewhat simpler since the release of OS 10.1, we still recommend the Macs only be linked to the network via an IP address...

The above was perhaps one of the more glaring examples of the complexity of the language used in a CTC application. It was also one of many such instances. The authors concur with the findings of

Shepherd (1998, pp.19-20) about other Australian regional development programs, “Project documents are peppered with buzzwords...required by financing organizations that must account for their spending or lending in the most up-to-date or fashionable terms. Buzzwords are often used by people with little understanding of what they might mean so they take on a hollow, artificial tone...language can also easily prevent understanding. Frequently outsiders and insiders think of a phenomenon in quite different ways. If the outsider has power to impose his or her thinking, unfortunate consequences many follow.” All of which tend to impede a community’s path to actualization and empowerment.

The culture of communities was also a major variable in achieving successful outcomes. In working with some of the applicant communities in Northern New South Wales, it was found that coastal communities, that had recently experienced an influx of well educated ‘sea changers’ had the greatest propensity to successfully complete their applications. On the other hand, many of the more rural, in-land communities that had been undergoing a steady outward migration of their younger, better educated, more productive citizens, for a variety of reasons, did not even complete their EOI. This outcome reflects Shepherd’s earlier work (1998, p. 204), when he stated:

The likelihood is that the rich and non-marginalized will always be more articulate and dominant in any community or grouping. So outsiders can play an especially critical role in creating space for poor people, economically and environmentally, in terms of rights, access to services, and control over assets and services which the poor can provide to the rest of the community; and politically, by ensuring their inclusion in associations, helping them build networks and coalitions which will protect positions gained.

Effective community consultation needs to give people who live in rural and remote regions

not only a voice but also the capacity to deal with issues arising out of inappropriate communication which can fuel misunderstanding and misinformation in these communities and prevent them from gaining access to the resources they need to ensure that their basic community needs for ICT are met.

IDENTIFICATION OF STAKEHOLDER GROUPS AND MEETING THEIR NEEDS

The establishment of a truly representative ‘application committee’, one that could speak for all the various stakeholder groups was another challenge for applicant communities. Unfortunately, it was found that the groups that had the most to gain were often the most inarticulate. Luke and Gilbert (1993, p. 43-44) spoke of this when they wrote about literacy issues in an Australian context and said “A group without access to literacy in our society is relatively powerless, unless trusted “brokers” exist to act on their behalf. By examining literacy pedagogy in cross-cultural contexts, it is possible to see a new approach emerging that challenges both traditional and progressivist theory and practice.”

The consultation practice employed in applicant communities also needed to build trust so that communities were able to identify their needs in a non-confrontational, safe environment to enable them to move up to the next stage in becoming empowered. However, needs varied considerably from one community to the next, and the key to unlocking those differences was in identifying and engaging all the relevant stakeholders as well as building on their strengths. This view also reflects the earlier work of Wolstenholme (1995, p. 15) when she stated:

While traditional rural identity remains largely intact, there appears to be a move away from idealizing the more Spartan existence of tradi-

tional country life. People were questioning their rural ideology and comparing their lifestyles with those in the city. They wanted access to more resources ...

In this context, identifying the strengths of an applicant community as well as its key stakeholder groups posed a great challenge. But the greater challenge was in finding members from these groups who could work together as a committee to complete the application. This idea was also put forward by Aslin and Brown (2004, p. 4) in another regional Australian project, when they stated, “Recognizing that a wide range of stakeholders exists means facing the likelihood that local and more distant interests may be in conflict, as local communities often have to bear the personal and immediate consequences of decisions being made...Done well community consultation can feel real, committed, integrated, and influential.” At the same time, further consideration must also be given to meeting the needs of all the various stakeholder groups so that linkages can be established to identify *their* needs in order for them to be integrated with those of the community at large. Furthermore, it is not enough to say that ‘youth needs’ should be met if they are not represented on the application committee. They need to be given a voice along with other stakeholder groups. The formation of sub-committees enabled diverse groups to have their own meetings and report back to the main Committee on a regular basis thus keeping applications on track.

It is of interest to note that Collits (2000, p. 30) also reminded that, “Communities have finite resources at their disposal for economic development projects and some difficult choices.” This was evident in the CTC’s final report, as those ‘finite resources’ extended to the skills and commitment of the people in the communities that participated in the CTC@NSW program. The CTC program’s final report (2004, p. 3), highlighted, “Lack of available time from community members and other local issues, such as drought, often hindered

progress with the application for seed funding and the development and establishment of Centres.” It was the people from the various stakeholder groups that provided the membership of the CTC Application Committee and it was their skills and vision that ICT could serve as a catalyst for growth in their communities that proved to be the most significant determinant in the success of an application.

BUSINESS PLANNING AND IMPLEMENTATION SKILLS

The selection and composition of the CTC Application Committee and its sub-committees, proved to be the critical factor in achieving successful outcomes. While these committees needed to include people from the various stakeholder groups, they also had to have members with the requisite business acumen, marketing and computer skills as the business plan portion of the application was a complex spread sheet full of macros to reflect various equipment requirements and usages scenarios over three years. However, the committees that achieved the best outcomes all had a ‘Dorothy’ as a member. Dorothy said at the onset of the application process in her community, “I don’t know much about ICT but I know how to make a good cup of tea, get people to attend meetings and do what they said they’d do.” She was certainly right. What was Dorothy’s motivation in wanting to get a CTC into her community? She wanted to do something to help keep the young people in her community from drifting away to Sydney or Brisbane and she saw ICT as a means of slowing their departure.

However, committees needed to prepare sound business plans and have access to the skills that would enable them to run a community owned and operated business. They needed to understand the implications of cash-flow on their business and what ICT could and could not deliver in their community. They also needed to take advantage

of the many products and services that the CTC@NSW program could offer through its technical and business support staff. The right balance of skills on these committees enabled them to stay focused so that they could gain access to the ICT products and services needed in their communities

ACCESS TO IDENTIFIED ICT PRODUCTS AND SERVICES

The ICT products and services sought by the various communities varied significantly from one community to the next and were dependent on what had been identified in the consultation process. The other major variable was the actual delivery of broadband services to these communities as this was often limited by geographic location. This was also supported by Hearn et al. (2004, pp. 4-5), “...market failure occurs, especially in rural, regional, and remote areas where the costs of setting up and maintaining ICT services can be very high. These factors make government support of ICT initiatives necessary...in the current policy context, government funds are limited. Consequently, greater financial responsibilities are being foisted onto local communities.” However, when a community decided to build on its identified strengths, it was far more likely to achieve its goals even with limited funding.

In a discussion paper produced by the Australian Government, *The Role of ICT in Building Communities and Social Capital*, (2005, p.1) it states:

As the use and impact of ICT increases, so does the prospect that ICT can play a role in shaping the nature of community development and contributing to the building of social capital...There is a greater variation in the needs and demands of communities and the role of ICT in meeting these.

However, this also suggests that, if government policy-makers determine that building social capital and community capacity should be seen as major outcomes of the uptake of ICT in small rural communities, why is ongoing federal funding and support so hard to come by? Communities will only remain empowered if their basic survival needs are met, because empowerment equates to greater social capacity with the flow-on benefit of diversity and innovation through the uptake of ICT. The following projects reflected the diversity of community needs that were met through the establishment of CTCs in several Northern Rivers communities.

Project One

Alive and Driving project was a program that one CTC initiated for learner drivers in its community. During the application process this community had identified lack of public transport as a major issue compounded by the fact that many young people were not very safe drivers. Moreover, there had been a horrific road accident that claimed the lives of three young people from this community that galvanized them into action. The CTC Committee instigated a driver-mentoring program that could give learner drivers access to a car and supervisor so that they could gain the 50 hours of driving experience they needed to sit for their NSW driving test. Learners paid a \$50 membership fee for the first 10 hours access to a car as well as petrol costs during their driving session. After this they could pay a further \$50 that enabled them to access as many hours as required until they got their license. This project was supported by funding received from the Australian Government under its regional partnership program, the Myer Foundation, and through partnerships with organizations and volunteers from the local community. But all the research to gain access to this funding was done using ICT, something that would not have been possible prior to the opening of its CTC.

Project Two

Another Northern Rivers community wanted to use the equipment in its CTC to create a virtual museum. They wanted to gain access to the technology that could assist them in preserving their community's rich and varied history. They used their funding to acquire the equipment they needed to scan and digitize old photographs and documents, record and preserve interviews with World War Two veterans. They also wanted to be able to catalogue and map the graves at the local cemetery and provide facilities for local residents to research their family histories. Currently they are seeking accreditation with museums Australia. Their virtual museum is now fully functional and they continue to work hard to enrich the content in their virtual museum.

Project Three

In early 2005, another CTC in the Northern Rivers was awarded a grant from the NSW Premier's Department Office for Women to conduct a training course specifically designed to help women learn filmmaking, computer, and marketing skills. The project, "Reeling in Women's Stories," saw 16 women of all ages create a 'Short Bytes Film' based on stories relating to womanhood. The participants undertook 14 free workshops to learn new computer and film making skills that included story boarding, filming, producing, and editing and marketing techniques. At the conclusion of the course, they held a movie night at the local cinema to showcase their combined efforts. The event was well attended by people of all ages from the local community.

Project Four

The Australian Taxation Office (ATO) has also worked with a number of CTCs to help deliver its regional and remote service delivery program. The online ATO products and services that are

available through this service are designed to minimize time spent managing tax affairs as well as enable businesses to gain access to information regarding taxation by learning how to access information from the ATO Web site.

A Few Other Projects

CTCs also provide free access to the NSW government portal, which has been designed as a one-stop entry point for accessing information on a variety of government services as well as a place to pay bills to government departments.

During 2005 Senior's Week, 50 CTCs across NSW worked in partnership with the NSW Department of Ageing, Disability, and Home Care (DADHC), and the Country Women's Association of NSW to promote and organize activities for Seniors Week. The 'TechnoSeniors' project was designed to promote the use of ICTs by seniors throughout the week at participating CTCs, these activities included, amongst other things, beginners and intermediate computer classes. This partnership with DADHC saw nearly 3000 participants attend Senior Week activities at the CTCs and 'TechnoSeniors' is now set to become an annual event.

Although not all CTCs have access to videoconferencing facilities, many of those that did participated in youth week celebrations in 2005 through a *young people and work videoconference* sponsored by the Office of Industrial Relations and Work Cover. This Videoconference provided an opportunity for young people in rural communities to have their say on issues affecting them, such as work safety, pay, and conditions. Additionally, many CTCs also host a range of school holiday programs where kids can learn new computer skills, create videos and sound files, and access the Internet in a safe environment.

The CTC Association Web site, <http://www.ctca.net.au> can provide additional examples of other ICT based programs that are helping

communities in the CTC network to remain empowered.

COMMUNITY ACTUALIZATION: SUCCESSFUL ICT OUTCOMES

While the communities mentioned have achieved only some of the goals articulated in their CTC applications, they all have built greater social capital in their communities through their CTC. Their CTCs have also played an important role in their ongoing regional economic development initiatives. The achievements of these communities are representative of what other small NSW communities have achieved through their continued participation in the CTC network. They also highlight the social implications of what access to ICT can facilitate in small regional communities. Hearn et al. (2004, p. 14) state, "...local needs and interests must be addressed...It can be extrapolated that success in attaining these goals necessitates the community having effective opportunities to be involved in deciding on the project(s) to be pursued...it is essential the community 'owns' the initiative.... the strengths and resources of the community should be identified and be used effectively to advance the community." This has also proved to be the case in many of the CTCs located throughout regional New South Wales.

ISSUES ARISING

In the chapter, *The Role of ICT in Building Communities and Social Capital* (2005, p. 4) published by the Australian government, it states; "ICT has a use in the development of community engagement and building social capital. Communities are at different stages of this process and do not always recognize the vast potential of ICT. When it is recognized, barriers may exist in the form of financial support, leadership, professional facili-

tation, technological development, and support and vision.” It continues (2005, p.7) “Governments and communities have committed major resources to ICT projects and programs to foster community development and to assist with networking across groups. However, there has been comparatively little research in Australia of the actual and potential use of ICT as an enabler of community and social capability.” An inhibitor of such research may be linked to the 3 or 4 year government funding cycles of ICT programs, like the CTC@NSW. This has been the case in the communities that were successful in their CTC applications, and are now expected to be able to manage their community owned and operated businesses, even though many of those staffing the CTC are volunteers. However, it is worth noting that if their original cash flow projections were not accurate, the first thing they usually cut is the salary of the CTC manager, and from that point onwards business productivity goes into decline and the long term viability of the CTC becomes a major issue. Although Plowman et al. (p. 8) states, “...No town has a ‘right’ to survive. To survive a town needs to be flexible and adaptable, to provide amenities and services to its members and to those outsiders which interact with it. Atrophy or decline awaits those towns that are not innovative or adaptable.”

However, becoming or remaining an innovative town is a very big challenge indeed, as many observers and writers have pointed out, homogeneity; conservatism, and conformity exert a constant pull. Towns that strive to be innovative in their use of ICT need to be supported, and as shown in the previous examples from the CTC@NSW program, non-traditional uses of ICT can go a very long way towards building greater social capital in these communities. Gray and Lawrence (2001, p. 206) stated, “...new initiatives in telecommunications, transport, health, education, culture, and the environment alongside eliminations of the forces depleting social capital as they bolster inequality...will also be achieved by identifying

mechanisms which aid and reward regions in their quest for sustainability.”

SOLUTIONS AND RECOMMENDATIONS

It is important that successful communities remain empowered, as well as funded, if they are to obtain ongoing access to the many products and services that ICT can deliver. It also means remaining focused on the many challenges of running a small business, including cash-flow, meeting consumer demand and expectation, and building a loyal base of customers. In many cases, it may also mean seeking further assistance with funding not only for a CTC manager who can continue to work with all community stakeholders, but also to assist in upgrading equipment as technologies and applications change.

More creative funding strategies need to be implemented at every level of government because building social capital is not a one-off project, but something that needs to be continually nurtured. The whole process of applying for grants and/or additional ‘top-up’ funding should be re-thought with wider, more community oriented criteria applied because as Gray and Lawrence (2001, p. 112) stated, “It has been acknowledged that regional telecommunications users are disadvantaged. Service providers are reluctant to invest outside the more profitable metropolitan markets and existing government policies to redress this problem are not working.”

Unfortunately, a creative opportunity was overlooked when the federal government’s launched its *Clever Networks* program on August 31, 2006. The following was downloaded from the DCITA Web site (November 30, 2006), “The *Clever Networks* program, part of the \$1.1 billion ‘Connect Australia’ package, will deliver innovative broadband services to communities in regional, rural and remote Australia. *Clever Networks* will fund broadband applications and

leverage broadband infrastructure to foster innovative service delivery for communities. Broadband development activities will complement the delivery of these services by assisting communities to enhance their understanding and use of broadband. Delivering innovative broadband services to Australian communities will encourage economic growth, increase productivity, foster innovation and increase quality of life.”

However, nowhere in the *Clever Networks* application is there opportunity or encouragement for ‘top-up funding’ from communities that had received earlier grants from the federal government to establish the CTC@NSW, and other similar state-wide programs such as the Western Australian Telecentre Network (WATN) and the Tasmanian Communities Online (TCO) program. The Western Australian Telecentre Network is the oldest of these networks and commenced operation in 1991 and is still growing. While the TCO Program, which was funded in 1998, continues to provide significant economic and social benefit to the 64 regional communities it serves.

Programs such as the CTC@NSW, TCO, and WATN could provide ideal venues for demonstrating broadband delivery of ICT. Federal funding, if cleverly used, could also promote the cross-fertilization of ideas and programs that use broadband delivery to facilitate the use of ICT in new and challenging ways. More importantly this type of ongoing funding would encourage small communities to continue broadening their approach to the uses of ICT.

Additionally, government funding should be delivered based on innovation and thus reward communities that continually strive to remain empowered through being innovative. Once communities become empowered by using ICT as a means of meeting their needs, they should be given the opportunity to share their ideas and programs with other ‘networked’ communities through a ‘building on success’ type program

FUTURE TRENDS

There will be continued erosion of face-to-face services in remote and regional areas due to the economic rationalist policies of government brought about by the range of forces associated with globalization. This means that there will be an ongoing demand by people living in regional areas to increase their skill base, so that they can have more equitable access to a greater range of products and services delivered via ICT. It also means that communities that have access to the latest ICT have the potential to become catalysts for regional growth and those communities that have the drive, as well as the capacity to survive, will be empowered and enabled to do so.

Empowered communities will continue to build on the strengths that lie in connecting communities to technology and information dissemination. They will continue to work with governments as well as explore and develop new e-business solutions for their communities. They will also explore opportunities to work with and support the micro and home based businesses that are a growing economic force in many regional and rural areas. CTCs in these empowered communities will continue to secure venue hire from both government and commercial enterprises in order to meet local needs. CTCs will also continue to promote and support computer literacy programs and serve as a one-stop shop for the delivery of more and more local, state, and federal government programs. New and innovative uses for ICT will come from these empowered communities as they use ICT to meet their needs, and at the same time remain connected to wider national and international communities.

CONCLUSION

Preliminary research indicates that a whole of government approach is essential if ICT is to serve as a catalyst for regional economic growth as well as

assist in the building of social capital. De Weaver and Ellis (2006, p. 9) state, “Governments need to leverage the investment they have already made in programs such as the CTC@NSW if they are to pay more than just ‘lip service’ to the goal of regional economic development...”

It is also important to consider that while there are significant stages involved in delivering effective community consultation, it remains an ongoing challenge to ensure that communities that have become empowered as they gained access to ICT products and services will remain committed to what they can achieve as an empowered community. In order to do this, the CTCs in each and every community must be run as financially sound businesses with management committees that can continue to provide the skills and support required to keep these community-owned and operated businesses viable. The long-term success *and* empowerment of communities that are part of the CTC and other similar Networks will also be predicated on continuing to build on the social capital that they have achieved to date.

Additional research undertaken by the authors will again use Action Research to assess whether or not the communities funded by the CTC program have remained viable.

FUTURE DIRECTIONS

The authors are also exploring the experiences of other communities in establishing similar ICT based programs.

Preliminary research has shown that as various government agencies and departments in Australia have rolled out other ICT programs designed to promote regional economic development in rural and remote communities through access to information and communication technology (ICT) programs, the language used in the documentation that supports these programs has often put up unnecessary barriers in the targeted communities and inhibited them from applying for funds.

How rural and remote communities actually engage in, and undertake, the process of applying for these programs is, to a large extent, dependent on their language and business skills. Not only are there social and political implications to be considered by governments in the design and roll-out of these programs, there are also technology and communications issues that need to be addressed in order to achieve more equitable access to these programs.

We believe that:

- The documentation that accompanies ICT based programs designed to deliver services in rural and remote areas should be written in plain English and be devoid of technical jargon. Where acronyms are used they should be clearly defined and examples given.
- Applied sociolinguistics principles need to be introduced and employed in all government grant applications programs for targeted populations.
- Glossaries of terms, which include appropriate examples, should be included in all documentation for funding programs that deal with services and/or products that are outside the usual frame of reference of people who live in rural and remote areas.
- Applications and documentation written for programs designed to build capacity in rural and remote communities should be trialed in selected communities, via focus groups or a similar consultation process, before programs are rolled out.
- All such programs need to be supported by field facilitators who understand the needs of targeted communities and who can provide appropriate support and assistance.
- Programs that promote regional economic development in rural and remote communities also need to include an element of education and/or training in them in order to empower the community and allow members

- to deal affectively with grant applications.
- Outcomes should incorporate community expectations as well as that of government funding bodies.

Chapter 2.16

Developing a Global Perspective for Knowledge Management

Martin A. Schell
New York University, USA

ABSTRACT

Localization of a document or other product requires tacit knowledge of the target language and culture. Although it is promoted by many activists, localization is becoming increasingly inadequate as a strategy for disseminating knowledge on the World Wide Web (WWW). The 21st century has already seen dramatic rises in the numbers of Internet users in nearly every country, making it unlikely if not impossible for any translation effort to accommodate all of the 347 languages that claim at least 1 million speakers. The best way to maximize the accessibility of Web content is to make it more explicit, not more tacit. This means developing a global perspective and writing English text clearly so that nonnative speakers can easily understand it. Global English is characterized by simpler sentence structure, less jargon, and no slang, thereby making it a viable global language for countless Web users whose native language is not considered important enough to merit a localization effort.

INTRODUCTION

A key issue in economic and regional development (ERD) is the applicability of one region's successful program of development to another region. Although general solutions to universal problems (literacy, environmental awareness, AIDS prevention, sanitation, roads, etc.) can be designed by nongovernmental organizations (NGOs) or other global entities, their actual implementation needs to be adapted to local culture and conditions, ideally with grassroots stakeholder participation.

In addition to the traditional top-down approach of applying general principles to local situations, there is increasing recognition of the importance of a bottom-up approach in which one region's developmental success is seen as a potential model for other regions. The generalization of a locally successful program into an exemplar that can then be adapted to other localities poses a major problem in communication, or rather two

problems: The local knowledge must be articulated, and then it must be disseminated.

The implementation of information and communication technologies (ICT) has made huge strides in the first five years of the 21st century, and the number of people who have access to the Internet is now over 1 billion. In order to optimize ICT as a means for knowledge dissemination, it is necessary to have something to disseminate—specifically, knowledge that has been articulated. Therefore, the development of ICT needs to be accompanied by the development of human infrastructure, especially the ability to express oneself clearly to audiences who do not share one's cultural background.

This chapter explains how English can be written more clearly so that it functions better as a global language, not only between native and nonnative speakers but more importantly between nonnative speakers from diverse linguistic backgrounds. The explanation extends into a discussion of how to streamline Web content. Thus, the chapter addresses a point of intersection between the two issues of articulation and dissemination, which are essential to the sharing of any region's success so that it can benefit more of the world's people.

BACKGROUND CONCEPTS

It is often said that human beings learn in three general ways: by hearing or reading words, by seeing images, and by doing. Although students, teachers, and other people who engage in a lot of verbal communication tend to consider the first of these three methods to be the most important, learning by doing has primacy in the sense of developing earliest in an infant. As noted by Nonaka and Takeuchi (1995), "A child learns to eat, walk, and talk through trial and error" (p. 10).

Learning by doing involves empathy and intuition, as well as trial and error. When a child learns to tie shoelaces, for example, these pro-

cesses enable him or her to acquire a skill that is rarely if ever learned through words, images, or a combination of both. Such *tacit knowledge* can be contrasted with *explicit knowledge* (Nonaka & Takeuchi, 1995, p. 8), *focal knowledge* (Sveiby, 1997), *codified knowledge* (Stiglitz, 1999, p. 11), or *formal knowledge* (Jarboe, 2001, p. 2). All four expressions of this fundamental dichotomy in human knowing are derived from the theories of Polanyi (1962, 1966).

Jarboe (2001) observes that learning by doing is facilitated by the "web of relationships and connections" that constitutes social capital (p. 3). This type of learning often involves imitating other people—not only family, friends, and coworkers, but also strangers within one's community (who may, for example, unintentionally teach a person how to get on an escalator without hesitating). Learning by doing can also happen without guidance, which is how most video games and computer simulations are played.

Tacit knowledge can be operationally defined as knowledge that is demonstrated but not explained; it tends to be absorbed rather than grasped. It is acquired through learning by images and words, as well as learning by doing. For example, while growing up, people learn how to tell which colors will match acceptably when selecting a blouse and skirt (or jacket and pants) combination. Another example: Most gold shops in southeast Asia do not sell any items that are less than 18 karat (75% pure); the lack of a market for such items is not because customers in this region crave greater value or purity than Europeans or Americans do, but because they have tacit knowledge that higher karat gold looks better on darker skin.

In *Aspects of the Theory of Syntax*, Chomsky (1969) describes how native speakers tacitly understand their own language in ways that they often cannot explain:

Obviously, every speaker of a language has mastered and internalized a generative grammar that

expresses his knowledge of his language. This is not to say that he is aware of the rules of the grammar or even that he can become aware of them, or that his statements about his intuitive knowledge of the language are necessarily accurate. Any interesting generative grammar will be dealing, for the most part, with mental processes that are far beyond the level of actual or even potential consciousness; furthermore, it is quite apparent that a speaker's reports and viewpoints about his behavior and his competence may be in error. Thus a generative grammar attempts to specify what the speaker actually knows, not what he may report about his knowledge. (p. 8)

For example, people who are fluent in English know that *Clifford is a big red dog* is correct but *Clifford is a red big dog* is incorrect. If a student of English as a foreign language (EFL) asks a native speaker why the second sentence is wrong, the latter will realize how difficult it is to turn syntax into an explicit form of knowledge. He or she may even devise an erroneous rule such as "The color adjective always comes last," which fits *long black hair* but not *blue suede shoes*.

Complementarity and Conversion

In comparing his ideas to those of Polanyi, Sveiby (1997) notes that we can recall the meaning of a message after reading it, but we rarely remember its exact words. Sveiby explains:

The focal and tacit dimensions are complementary. The tacit knowledge functions as a background knowledge which assists in accomplishing a task which is in focus. That which is tacit varies from one situation to another. For instance, when reading a text, words and linguistic rules function as tacit subsidiary knowledge while the attention of the reader is focused on the meaning of the text. (Tacit and Focal Knowledge section, para. 2)

With a moment's effort, anyone who is literate can shift between subsidiary awareness and focal awareness while reading. This happens when an unfamiliar word catches one's attention, prompting a pause to search a dictionary; alternatively, one can simply stare at an individual word, letter, or numeral. The process of learning to read involves familiarizing oneself with the shapes of characters and then recognizing combinations of them as words until one achieves the ability to scan a sentence without focusing on them. Becoming literate basically means converting explicit knowledge into tacit knowledge, a process that Nonaka and Takeuchi (1995) call *internalization* in their socialization, externalization, combination, and internalization (SECI) model (pp. 62-70), which is summarized in Table 1.

Tacit knowledge has been defined in diverse ways in knowledge management (KM) literature, leading to ambiguous KM terminology and confusion (Bouthillier & Shearer, 2002; Sveiby, 2001). Researchers seem to agree that a major goal of KM programs is to convert tacit knowledge into explicit knowledge in order to share it throughout an organization. Nonaka and Takeuchi (1995) call this type of conversion *externalization* and see it as the key to knowledge creation. Tacit knowledge can often be made explicit by articulation: drawing a map to guide a guest to one's home, or telling an audience how to sell successfully.

There is a tendency in KM to conflate *unarticulated* with *hidden*, as Jarboe (2001) does when he exhorts economic development organizations to use information technology (IT) and "knowledge creation tools" that can "capture ... knowledge hidden within the organization" (p. 2). However, uncovering a seed of knowledge which can be disseminated does not prove that such knowledge was tacit. Suppose a project leader discovers that a team in another department recently developed some software which can expedite the leader's project. The project leader will rejoice in finding a hidden resource (hidden from his or her viewpoint, that is) but the team who coded

Table 1. Four modes of knowledge conversion (After Nonaka & Takeuchi, 1995, pp. 70-72)

Mode	Conversion	Trigger (Input)	Process	Contents (Output)
Socialization	Tacit to Tacit	Building a Field of Interaction (Self-Organizing Team)	Share Experiences by Empathy and Intuition	Sympathized Knowledge (exchange of technical skills and mental models)
Externalization	Tacit to Explicit	Dialogue or Collective Reflection (Brainstorming)	Articulate by Metaphor and Analogy	Conceptual Knowledge (creation of new knowledge)
Combination	Explicit to Explicit	Linking New Ideas with Existing Ones (Networking)	Systematize by Analyzing and Organizing	Systemic Knowledge (crystallization of ideas into new system, service, or prototype)
Internalization	Explicit to Tacit	Learning by Doing	Embody by Applying Documents and Procedures	Operational Knowledge (implementation of policy or mass production as routine)

the software already articulated those ideas into explicit knowledge. Such a “discovery” is a good example of networking, but not knowledge creation; Nonaka and Takeuchi (1995) would label it *combination*.

Tacit knowledge can be disseminated very widely by *socialization* (Nonaka & Takeuchi, 1995) without ever being articulated into explicit form. For example, charcoal is nearly always used as a base for growing orchids in southeast Asia. Perhaps this technique was discovered intuitively or accidentally by someone in Thailand, which has long been famous for its orchids. Countless amateur horticulturists adopted the technique by imitation (“It works!”) without ever receiving an explanation about why charcoal is better than soil. An explicit reason could be codified or formalized by a botanist, but it is not necessary for the propagation of the idea.

Data, Information, Knowledge, and Wisdom

As NCR Corporation’s overseas market expanded in the 1970s, their headquarters began receiving complaints from customer support representa-

tives about confusing terminology that resulted in mistaken translations of end-user manuals. NCR had the foresight to accumulate the complaints and assign a senior technical writer, Charles “Ted” Brusaw, to look for patterns and provide guidelines.

Brusaw (1978) traced the translation errors back to misunderstandings caused by word choice in the original English text. He and his team identified a large number of common English words that have multiple meanings which are tacitly understood by native speakers but can easily confuse nonnative speakers. The team compiled the *NCR Fundamental English Dictionary*, consisting of 1,175 clearly defined root words printed in boldface plus hundreds of problematic words interspersed alphabetically in regular font (each followed by a suggested substitute in parentheses).

Although NCR’s database about language problems predated the concept of KM, one could say that their knowledge repository belonged to the *IT track* in the KM model formulated by Sveiby (2001). The information technology track is characterized by seeing knowledge as quantifiable objects (e.g., a list of specific words that have been mistranslated), in contrast to the

people track which views knowledge as processes (e.g., general awareness of how ambiguity results in mistranslation).

Sveiby (2001) emphasizes the differences between the two tracks in order to highlight the need for investment in intangible assets, especially human infrastructure, but the two orientations are complementary. In the NCR case, the back-and-forth flow was like this: Accumulation of specific mistranslation incidents led to an awareness of general patterns, which led to the production of a list in a tangible book, which was distributed to employees as an informal training tool to increase their awareness.

Quantification facilitates digitalization, which has become the preferred method for recording, storing, and transmitting huge amounts of data without loss or distortion. Information and communication technologies have been developed and implemented to handle the technical aspects of information management (IM). While ICT strives to preserve the integrity of data and IM organizes it into information, KM operates at a higher level of abstraction. KM creates, combines, and communicates expertise (tacit knowledge) and ideas (explicit knowledge).

An underlying assumption in the collection and transmission of data is that it is worth retaining and disseminating. The maxim *garbage in, garbage out* (GIGO) applies here: “If invalid data is entered into a system, the resulting output will also be invalid. Although originally applied to computer software, the axiom holds true for all systems, including, for example, decision-making systems” (Jupitermedia, 2001). Therefore, when making economic and regional development decisions, it is essential to have confidence that one’s data is reliable.

Although completeness is an important characteristic of data integrity, it can be a drawback at the level of information. In describing how the Internet can be used for ERD, Jarboe (2001) mentions online databases that link small businesses to “a myriad of sites” which provide information

about finance, accounting, marketing, and so forth (p. 13). However, a Web site that contains dozens or hundreds of links can be time-consuming and even bewildering to navigate. It can also become a source of frustration if many of the links lead to sites that do nothing more than list links. As Jarboe himself notes, “There is an enormous need to be able to quickly distinguish between what information is relevant and what is irrelevant” (p. 2).

When the level rises from information to knowledge, the concept of GIGO becomes even more complex because subjective aspects must be taken into account. Instead of garbled data resulting from signal noise, or extraneous information manifesting as circular Web links, distortion becomes a matter of inaccurate reporting due to selective perception. For example, a TV camera can only record the scene that it is focused on. If a crew is filming a riot, the camera cannot show whether people who live a couple of blocks away remain undisturbed, unless the person behind the lens decides to seek a broader perspective.

At the level of wisdom, we recognize that our mental models may prevent us from determining what is useful and what is not. Nonaka and Takeuchi (1995) affirm the subjective nature of innovation, insisting “The key to knowledge creation lies in the mobilization and conversion of tacit knowledge” (p. 56). Development of a new idea, method, or invention means we are creating something that does not yet exist—the creative process has an intuitive element that leads us beyond what we already know. Therefore, no aspect of tacit knowledge should be rejected in advance as irrelevant, because no one can say for certain what the articulation of that aspect might bring (or help come into being). This state of receptivity is acknowledged in KM’s *people track* with phrases like “build environments conducive to sharing of knowledge” and “create innovation enhancing environments” (Sveiby, 2001).

INHERENT WEAKNESSES OF THE IT TRACK

The quest for quantifiable “knowledge objects” characterizes the IT track of KM, which focuses on capturing and distributing discrete items that are considered to be essential components of expertise. The act of counting objects assumes that they are identical members of a set (e.g., *one tree, two trees, not a mahogany tree, a teak tree*); consequently, the quantification of knowledge has an inevitable tendency to overlook diversity. As T. S. Eliot (1952) lamented, “Where is the wisdom we have lost in knowledge? Where is the knowledge we have lost in information?” (p. 96).

Imagine, for example, a man walking into a building. An observer from the U.S. Federal Bureau of Investigation (FBI) photographs him and records the location, date, and time, thereby producing data. By noting that a meeting of the Communist Party is being held in the same building, the FBI observer creates information with a certain context. The FBI then builds a dossier for the man, which includes the knowledge that he is probably a Communist. With the wisdom of hindsight, it is easy to see how this “knowledge” is fraught with unproven assumptions that facilitated the transformation of a single observation into a supposed pattern of behavior.

New software and hardware have enabled a vast acceleration of the tendency to see people as statistics rather than as lives, an abstraction process that has been used by administrators of large populations for millennia. The proverb “You can’t see the forest for the trees” can apply to economic development in a literal way: Logging a rainforest is often justified in terms of providing jobs. Data about annual income is presented, analyzed, and evaluated, thereby producing economic information about the people who dwell in the forest, which in turn leads to the knowledge that they are benefiting from the removal of its trees.

However, as the proverb warns, focusing on details can prevent a person from seeing the whole picture. Awareness of the indigenous knowledge (IK) possessed by the forest people would lead the development specialist to look at tradeoffs. How many people have been gaining sustenance from the rainforest, for how many generations? How many people will be earning money from logging, and how many years will those jobs last? How will logging impact renewable resources (foods, medicines, and other materials) that indigenous people currently can obtain without using money?

The limited context of the original analysis would then be expanded to recognize long-term sustainable processes of obtaining food based on indigenous techniques of agroforestry, such as those outlined by Grenier (1998, p. 3). This broader perspective would lead to the collection of data that counts cashless providers (tacit income) as well as paid workers (explicit income). The new economic information would describe livelihoods, a concept that is more inclusive than jobs. Thus, the initial claim by government officials that they “know” that logging’s benefits outweigh its drawbacks would need to be revisited, and perhaps exposed as erroneous.

Of course, the IT track provides many benefits, too. Initiatives on the Web include the Computer Systems Policy Project (CSPP), the Virtual Souk (<http://www.southbazar.com>), and the ICT Stories Project that was started by infoDev and the International Institute for Communication and Development (IICD). CSPP (1998) offers a 23 question online assessment to help communities gauge their readiness for electronic commerce. The Virtual Souk (Hazan, 2002), developed in Egypt with NGO assistance, is itself an e-commerce project that connects local artisans and shopkeepers in North Africa with global markets. The Virtual Souk’s story is one of the regional successes that are recounted at the ICT Stories Web site in order to facilitate their global dissemination (IICD, 2003).

Nevertheless, the rapid growth of the IT track (Sveiby, 2001) calls for criticism of its assumptions about KM before they become too ingrained. The remainder of this chapter challenges some IT-track ideas about producing and distributing documents, particularly on the World Wide Web. Respective sections address how assumptions about language, infrastructure, and culture impact the dissemination of knowledge. The author offers suggestions for expanding one's awareness to a global perspective, which hopefully will lead the reader to attain a greater degree of wisdom about how to manage ERD knowledge so that it becomes available to everyone on our planet.

The Limits of Localization

Most Web sites that aim for multinational audiences *localize* their content by translating it into languages spoken by major groups of Internet users: Spanish, Chinese, Russian, and so forth. The Switzerland-based Localization Industry Standards Association (LISA, 2005) defines *localization* as “taking a product and making it linguistically and culturally appropriate to the target locale (country/region and language) where it will be used and sold.”

In August 2003, the software developer Mas i Hernández (2003) tallied the presence of several dozen languages on the Web to determine the relative standing of his native Catalan. By inputting keywords specific to each language, he found that English was the dominant language of the text on 1,280 million pages, followed by German (182 million), French (100 million), and then a cluster of four languages in the 65-70 million range: Japanese, Spanish, Chinese, and Korean. As the president of a Web translation agency, Hopkins (2002) agrees with the principle of multilingualism. However, he recognizes that localization is not needed on each page because most Web content is global information that can be translated directly without adapting it to the

audience's culture (What is a Multilingual Website? section, para. 3).

Localizing every page of a Web site is not only “too much” but also “too little.” By itself, localization can never succeed in reaching a worldwide audience because its purpose is to serve specific groups of users. Adding up a handful of regional groups—or even a few dozen local groups—does not equal a global audience. There are presently 6,912 living languages, including 347 that have over 1 million speakers each (Gordon, 2005d). It is not feasible to localize content into all of them. How often do you see sites that offer the option of viewing pages in *Bangla* (Bengali), Gujarati, Marathi, Panjabi, Telugu, or Vietnamese, each of which has over 40 million native speakers?

A common explanation for excluding these languages from Web site localization efforts is that they are spoken in areas that “do not have enough users to make localization worthwhile” (Nielsen, 1999, p. 315). However, the number of Internet users nearly tripled worldwide during the first five years of this millennium: from 361 million at the start of 2001 to 1,018 million at the end of 2005. Doubling or tripling occurred on every continent and in nearly all countries that began the 21st century with only a small fraction of the population having Internet access (Internet World Stats, 2005c).

The rapid increases in Internet penetration worldwide suggest that localization is a short-term strategy for global dissemination, because its coverage of the world's online population will become less complete as time goes on. The number of Internet users who speak “minor” languages is rising, making a comprehensive localization effort more costly and unwieldy. During 2005, Internet penetration reached 13.9% in Turkey, 12.8% in Thailand, and 11.3% in the Ukraine (Internet World Stats, 2005c), each of which has a national language that is spoken by over 40 million people.

In developing countries, many people who lack a computer at home access the Internet via cyber

cafes. This sharing of hardware is analogous to older forms of pass around readership, such as joining a library or renting a video instead of buying it. Statistics about total Internet users in such countries are often based on multiplying the number of Internet service provider (ISP) accounts by a sharing factor.¹ Because this factor is only an estimate of the actual situation, one should view user statistics (as well as most other statistics related to the Internet) with some skepticism.

Nevertheless, the shortage of Web pages in many languages is obvious to people who are native speakers of those languages. If a Web site does not consider their language important enough to merit localization, these users are likely to access the English version of the site.² At cyber cafes in Indonesia, for example, a few people will gather around a single user whose English is fluent enough to comprehend Web pages in that language. He or she will provide impromptu translation for the others while they surf as a group.

And there is evidence that people who speak English as a second language sometimes choose the English version even though the Web site offers pages in their native language. A survey conducted by Research & Research found that only 8% of Hispanic American Internet users prefer Spanish-language Web sites but 41% prefer English-language sites. The remaining 51% said they are bilingual and read Web content in either English or Spanish. In other words, 92% of Hispanic American Internet users feel comfortable with English-language Web sites, despite the fact that 63% of this market segment were born outside the United States (Romney, 2000).

A Census 2000 brief (Shin, 2003) lists the top 20 languages other than English spoken in the U.S. in 1990 and 2000. The category “all other languages” accounted for about 10% of “total non-English” in both years, rising to 1.7% of the total U.S. population in 2000 (p. 4, Table 1). In other words, a localization effort that includes the top 20 languages would exclude about 4.5 million speakers of “all other languages” (1.6 million of

whom speak English less than “very well”).

The incompleteness of localization is even more dramatic in the global arena: Translating a document into each of the 83 languages that has more than 10 million speakers would fail to serve 20.5% of the world’s population (Gordon, 2005d). In terms of the world’s Internet users, 20.4% would be neglected by a localization effort devoted to the top 10 languages spoken by the online population (Internet World Stats, 2005a). Clearly, using a global language is an essential part of worldwide outreach.

Using English Globally

LISA (2005) defines *internationalization* as “generalizing a product so that it can handle multiple languages and cultural conventions without the need for redesign” and calls this process the “forerunner of localization” (question 3) because internationalization is often implemented by editing a document before translation. Another way to express the complementarity of the two processes is to say that internationalization aims to make text as explicit as possible for a global audience, while localization aims to evoke a local audience’s empathy by appealing to tacit aspects of their culture.

Among the major languages of the world, English is the closest to being a global language. In *The Future of English?* Graddol (2000) lists 12 “major international domains of English” including international organizations and conferences, scientific and technical publications, global advertising and mass culture, aviation and maritime communications (“airspeak” and “seaspeak”), international tourism, universities, and the Internet (p. 8, Table 2). More than 60 countries publish at least some of their books in English (p. 9, Figure 2). And the vast majority of German scientists in eight fields reported that they use English as their working language, ranging from 72% of the scholars in sociology and in medical science to 98% of the physicists (p. 9, Table 3).

It certainly seems that producing a document in English is the best way to reach a global audience. However, the English spoken by Americans, Canadians, British, Australians, New Zealanders, Indians, Nigerians, Singaporeans, Jamaicans, and others is not itself a global language. Each nation speaks and writes its own variety, full of local idioms and slang: American English, Queen's English, and so forth.

In order to serve a worldwide audience (as in *World Wide Web*), it is necessary to use *Global English*—English which is written in such a way that it can easily be understood by nonnative speakers, as well as by native speakers in diverse parts of the planet. Global English lacks slang; it also has simpler sentence structure, less jargon, and fewer idioms than the English that is typically spoken and written in the “inner circle” (Kachru, 2005, pp. 13-14) of countries that were settled by the British.

It is well known in the field of international development that a communications gap is likely to arise between bureaucracies (or stakeholder groups) and the public “when the decision-making process is either surrounded by secrecy or obscured in technical language” (Reinicke & Deng, 2000, as quoted in Waddell & Allee, 2004, p. 4). In this light, LISA's (2005) promotion of “techspeak” such as the abbreviations *G11n*, *I18n*, *L10n*, and *T9n* for the terms *globalization*, *internationalization*, *localization*, and *translation*, respectively, seems misguided. It is not obvious that each abbreviation's embedded numeral indicates the number of omitted letters; therefore, everyone needs a brief initiation when encountering this alphanumeric jargon for the first time. A more serious problem is that the abbreviations tend to confuse the reader's eye because the numeral *1* is similar to uppercase *I* or lowercase *l* in many fonts.

The NCR dictionary produced by Charles Brusaw (1978) was one company's early attempt to encourage its writers to globalize their English in order to make “technical documents easier to

read and use by NCR employees and customers around the world.” One category of words found to be problematic for translators was “jargon that was understood only by the initiated few” (p. 1). Idioms were discouraged and slang was strongly discouraged.

Eliminating the use of slang in written documents and online content is more than a matter of improving readability for a global audience. A report by Stanford University's Persuasive Technology Lab (Fogg et al., 2002) listed “writing tone” among the top 10 factors that users mentioned when describing the trustworthiness of a Web site. “People generally said that sensationalism or slang hurt a site's credibility, while a straightforward, friendly writing style boosted credibility” (p. 43).

It is also important to avoid the use of idioms and slang when participating in an online discussion. This may seem counterintuitive because chatting is a way to open up and express oneself with few restrictions. Indeed, instant messaging can be so fast and fluid that it seems like speech instead of writing. However, it lacks the nonverbal clues of face-to-face chatting (or even phone conversations), and so it is prone to misinterpretation, especially when participants are from diverse cultural backgrounds.

The moderator of an online discussion group should remind members that clarity is important. Pointing out incomplete sentences and gently discouraging the use of the latest slang may slow the action, but such emphasis on explicit language will make a multicultural discussion more inclusive. Although casual Internet English is great for communicating with friends, relying on tacit linguistic habits is too parochial for a chat room, Web site, or blog that aims to attract a worldwide audience.

How to Write Global English

Besides its lack of slang and scarcity of idioms, Global English is characterized by the avoidance

of jargon and buzzwords. All four of these types of diction hinder inclusiveness by making it harder for uninitiated people to read a document. Consider the following sentence that ends a paragraph promoting an online clothing store:

Which is just the right feature for users who want what works.

This type of colloquial English is easy for a native speaker to understand. However, the incomplete sentence can confuse nonnative speakers, many of whom would expect the sentence to end in a question mark.

Changing the initial *which* to *this* might decrease the sentence's trendiness in the American or British market, but it would greatly increase the number of people who could understand the sentence in the global market. In addition, the word *just* and the idiom *what works* should be modified, resulting in:

This is exactly the right feature for users who want efficient online shopping.

The "coolness" of Web content often depends on using the latest buzzwords and slang. However, many nonnative speakers became fluent in English while studying or working in the U.S., UK, or Canada 20 or more years ago. After they returned to their native countries, they retained their fluency but their tacit knowledge of English slang eventually became outdated. For example, they might not know that an expression like *It sucks* is now inoffensive enough to appear in mainstream media and dictionaries.

Colloquial usage is not the only tacit aspect of language that can undermine successful global communication. Many of the words that anglophones consider ordinary have multiple meanings (and even different parts of speech) that can create ambiguity in a reader's mind, particularly if he or she is less than fully fluent in English.

Ambiguity makes a translator's work harder, slower, and less accurate (N. Hoft, personal communication, September 6, 2005; G. Fletcher, personal communication, September 9, 2005). Writing the original text in Global English means making every paragraph, sentence, and word as explicit as possible. This process includes internationalizing the document so that it is "as culturally and technically 'neutral' as possible," which will save time and money when the document is translated from English into one or more other languages (LISA, 2005, question 3).

Here are two examples of ambiguity that most native speakers of English would read without hesitation. However, a nonnative speaker might become confused by them. And even a good translator might render one of these words into a phrase that is ambiguous or incorrect in the target language.

The word *once* can be confusing as a conjunction, because some readers might misinterpret it as an adverb meaning "one time." For example:

Once the prompt appears, enter the course title.

Some people might think the prompt appears only once, regardless of the number of course titles. It would be better to write:

After the prompt appears, enter the course title.

A similar type of confusion can occur if *since* is used as a conjunction, because it can be misinterpreted as an adverb or preposition meaning "after":

Keep a log, since the use of this device can produce momentary fluctuations in the supply of power to other electrical equipment in the room.

Someone might think that the log does not need to be started until a fluctuation occurs. To remove the ambiguity, use *because* as the conjunction:

Keep a log, because the use of this device can produce momentary fluctuations in the supply of power to other electrical equipment in the room.

After finishing a document's final draft, the writer or editor should reread its entire text, seeking points of ambiguity. Any words or phrases that could hinder comprehension or translation should be replaced. However, the writer or editor cannot anticipate everything that might seem unclear to the document's readers or translators.

A people-track approach to removing ambiguity is to build redundancy into one's writing. This does not mean reiterating each sentence with a subsequent one that starts with *In other words* or a similar phrase. It is not necessary to be that blunt. Simply write in a way that provides some overlap between sentences, so they support each other and create a clear context for all of the paragraph's ideas. For example:

We recommend the purchase of this factory because it is a good medium-term investment. If our company buys the manufacturing facility this year, we will be able to upgrade it by the middle of next year. After we modernize the equipment, we will have additional production capacity to help us meet the increase in demand for our products that is expected two years from now.

Note the repetition of concepts in this example: *purchase ... buy, factory ... facility, upgrade ... modernize*. In addition, the time frames are in chronological order and support the use of *medium-term*.

Although some redundancy can be useful, most writing can be improved by making it more concise. A lot of writers repeat themselves unnecessarily and use extraneous phrases. Corpo-

rate and economic development reports tend to use double negatives and hedges that cloud their meaning. Here is an example of verbosity:

The other day, during our annual meeting, when most of us were thinking about the company's future, we heard, for the first time, some forecasts which, you will agree, were not discouraging.

The meaning could be made a lot clearer by splitting this run-on sentence into two shorter ones, such as:

Most of us were thinking about the company's future during our annual meeting. We heard new forecasts that were encouraging.

In "Standards for Online Content Authors," McAlpine (2005) emphasizes conciseness and clarity. She recommends that writers aim to limit sentences to a maximum of 21 words and paragraphs to 65 words (Style section, bullets 4 and 5). Indeed, it is generally less tiring to read sentences that have fewer words, as well as paragraphs that have fewer sentences. When a writer simplifies a document's syntax in order to achieve these targets, the content usually becomes clearer, too.

The principle that smaller "bundles" of information facilitate reader comprehension also operates at the level of document design. In *Designing Web Usability*, Nielsen (1999) advises keeping Web pages short so that they are "optimized for online readers who frequently scan text." If a topic contains a lot of information, the primary page should be narrowly focused and "secondary information relegated to supporting pages" (p. 15).

Streamlining a text in all of the ways mentioned in this section will not restrict one's writing style much, but it will greatly expand the document's potential audience by making the content easier to understand. Many people who are not completely fluent in English can read the language

more easily than they speak it. They can also reread a written document or Web page at their own pace with a dictionary, but such review is very awkward while engaging in a conversation or listening to a lecture.

LOGISTICAL CONSIDERATIONS

After knowledge has been articulated in Global English, the next consideration is: How can it be shared to the widest possible extent? If one chooses to use the World Wide Web to maximize the dissemination of economic and regional development knowledge, it is necessary to think about the logistics of Internet access before uploading the Web content.

Although digital subscriber line (DSL), cable, wireless, satellite, and other fast connections have become well established in industrialized economies, a significant fraction³ of users rely on older ways to access the Internet. Many Web site visitors are likely to use an integrated services digital network (ISDN), or even 56 Kbps modems. Connection rates and speeds can be low, particularly during business hours in their countries when heavy Internet traffic overloads local ISPs. Therefore, it would be a mistake to design a Web site that only works smoothly when it is accessed via a broadband connection.

In addition, it is important to consider that Internet time is often charged by the minute, as is telephone time. People who visit a Web site might be paying their ISP and telecom company a dollar or more per hour for online access. Local utility costs can severely impact the success of a site that aims to disseminate knowledge globally.

Therefore, streamlining the online content is a key to reaching and retaining a worldwide audience. It is wise to reduce the loading time of every page on a Web site in order to make access smoother and cheaper. The site's Webmaster can provide feedback about page-view failures and also advise how to make pages easy to re-access

if a visitor's connection unexpectedly fails.

In the "Response Times" section of his second chapter, Nielsen (1999) describes three thresholds of attention span:

1. A delay equal to 0.1 second is the limit for most users to feel that the system is reacting "instantly."
2. A delay of 1 second is the limit for feeling that one's flow of thought is uninterrupted (for example, after clicking on a link to read another page of text).
3. A delay of 10 seconds is the maximum for keeping a user's attention on the display screen while a page is loading.

Allowing for a half-second of latency in the system's responsiveness, Nielsen (1999) cautions that the 10-second limit for maintaining a person's attention on a Web page is reached with only 34 kilobytes (KB) for modem connections and 150 KB for ISDN connections (p. 48). Any page over these limits is likely to seem slow when loading on the screen, thereby becoming an unintended test of the user's patience.

Connection speed does not matter much for text-rich Web pages, which rarely exceed 10 KB. However, the Web designer needs to be careful about delays in loading time due to the inclusion of photos, music, or animation on a page. A digital photo in .jpg format is likely to exceed 34 KB, and a .wav file of instrumental or vocal music is typically 5-10 KB per second of playing time.

When planning a Web page, check the size of every multimedia file that will be part of it. Take all moving images off the page by providing a link to their .mov file ("Click here to see the video") instead of embedding the file in the page itself. Reduce the use of sound and carefully consider the visual quality of each photo in relation to its file size. A page that totals 500 KB is likely to take more than half a minute to appear on a user's screen if it is accessed via an ISDN connection, and longer if via a modem.

One should make the text as independent of the images as possible, even when it refers directly to a photo. Here is an example of dependent text that forces the reader to wait until the image loads:

Look at the photo on the left.

By adding a few words to describe the photo, one can make the text independent of it and free the reader to scan past it if he or she cannot see it immediately. For example:

Look at the photo of a traditional village in Africa (left).

It is also a good idea to ask the designer or Webmaster to insert the ALT attribute in the HyperText Markup Language (HTML) code for each page that includes an image. This attribute enables the display of descriptive text in the box that outlines a photo while its image is loading on the user's screen.

Tables and graphs should be planned carefully to accommodate their translation into other languages. German, for example, typically expands the length of the equivalent English text by about 30% (Nielsen, 1999, p. 318). Therefore, localization can cause problems in a table's appearance if the Web designer neglects to make the column widths flexible enough.

TRANSCENDING CULTURAL PREFERENCES

Articulation and accessibility are not enough; knowledge must also be acceptable to local stakeholders so they become motivated to adopt and adapt it. Allee (2000) emphasizes the importance of community participation in Web-based knowledge dissemination projects. "People usually don't follow a process or formula or steps. They want to tweak it or put their own spin on it. People, however, will support what they help create"

(Experts are Everywhere section, para. 2).

Relating this aspect of KM to ERD in general, Stiglitz (1999) agrees that local "doers of development" need to adapt knowledge and "make it their own" when adopting it. He then notes that this type of active learning promotes self-reliance and supports group identity. "It is not just a matter of being 'open' or 'closed' to outside knowledge; it is a matter of being open to outside knowledge in a way that reaffirms one's autonomy" (p. 9).

Web pages and other documents that accompany ERD efforts should be conducive to autonomy, or at least not undermine it. Recall that LISA's (2005) definition of internationalizing a document includes the goal of making it "culturally neutral" (question 3). Removing cultural biases before producing a globalized document streamlines the subsequent localization process (if any) and reduces the possibility that the content will alienate some readers. The following examples reveal a few ways that we can broaden our minds to accommodate other worldviews.

In 1986, I edited a speech by a Japanese businessman who asked, "Why does the term *classical* always refer to Europe? If we want to refer to the traditional arts and culture of other regions, we must insert an extra adjective: classical *Japanese* music, classical *Indian* dance, classical *Chinese* calligraphy." Although two decades have passed, the unqualified term *classical music* still refers to a period in European history, and *Classics* is the name of a field of study that focuses on ancient Greece and Rome.

One cannot anticipate every point of sensitivity, but a little research can go a long way toward reducing the intercultural friction that might accompany a document's publication. For example, it would be unwise to refer to Hinayana Buddhism when discussing the role of religion in economic and regional development in southeast Asia because *Hinayana* is a pejorative term coined by self-declared Mahayana Buddhists in order to contrast themselves with Theravada Buddhists (Lie, 2005).

People say, “History is written by the victors,” but there are exceptions to this cliché; Genghis Khan never lost a battle but his reputation is not good. If a country wins a war of independence, its people date their sovereignty from the year of declaration, not the year of the subsequent peace treaty; for the United States, it is 1776 rather than 1783. However, most Western history books ignore the August 17, 1945 declaration of independence by Indonesia and refer to The Hague conference late in 1949 instead.

The national languages of Indonesia (*Bahasa Indonesia*) and Malaysia (*Bahasa Melayu*) are often combined into *Malay* in lists of the world’s largest languages (Graddol, 2000, p. 8, Table 1; also, p. 27, Table 7). When tallying speakers who have Internet access, the online marketing company Global Reach (2004) states, “Malay is the same language that is spoken in Indonesia” but indicates that most of this market segment lives in Indonesia (footnote 26). A reader in Jakarta might therefore wonder why this “single” language is not called Indonesian instead of Malay. The confusion is due to the conflation of modern Malay with the older language of the same name, which gave birth to it and its sister Indonesian (Gordon, 2005b)—a situation analogous to combining Romanian and French into *Romance language speakers* and then saying “Romance is the same language that is spoken in France.”

Other cultural assumptions are unrelated to artistic, religious, political, or linguistic favoritism; they lead to embarrassment or confusion without arousing national pride. In his chapter about designing Web pages to serve a global audience, Nielsen (1999) shows a banner ad for Apple Computer that asked users to turn on a virtual light switch by clicking it. However, the switch was in the down position, which is the “on” position in many countries. Nielsen says the variation of this type of tacit knowledge is rarely mentioned in guidebooks that tell how to internationalize software or Web sites, but it can be discovered by testing the image on a sample

of users overseas before uploading to the World Wide Web (p. 315).

The Rise of Mandarin

Is another language likely to replace English as the global language? When the British Council published the first edition of Graddol’s *The Future of English?* in 1997, the mass media began sounding an alarm that English was being surpassed by “Chinese” (Lovgren, 2004). Graddol (2000) divided English speakers into three categories: those who speak it as a first language (native speakers, or L1), those who speak it fluently as a second (or third, etc.) language (L2), and those who are learning English as a foreign language (EFL) but are not yet fluent in it (p. 10).

Graddol (2000) estimated that there are 375 million L1, 375 million L2, and 750 million EFL speakers of English (p. 10, Figure 4). Although this rounded L1 figure is well above his estimates for Hindi (316 million) and Spanish (304 million), it is very far below the 1,113 million for “Chinese” (p. 8, Table 1). The popular press echoed these estimates without asking why the separation of L1 and L2 speakers was being applied to English but not to “Chinese.”

Most linguists do not recognize a monolithic language called “Chinese” that is spoken as a first language throughout the People’s Republic of China (PRC). “Chinese” consists of several large languages that have a common system of writing but are mutually unintelligible when spoken (C. Hurd, personal communication, December 5, 2005). In linguistic classification, it is considered a subfamily within the Sino-Tibetan family (Columbia, 2001; Gordon, 2005a). However, due to “social, cultural, or political factors,” (Gordon, 2005c, The Problem of Language Identification section, para. 1), politicians tend to displace linguists as the authorities who determine whether two or more languages are equivalent (thereby promoting national unity) or distinct (thereby promoting ethnic identity).

Mandarin is the official language of the PRC and the standard language of instruction in its public schools. In these respects, it is analogous to other national languages that were created to unify diverse populations (e.g., Filipino in the Philippines and Indonesian in Indonesia). In its *Ethnologue* encyclopedia of world languages, SIL International (formerly the Summer Institute of Linguistics) states that 70% of the people in China speak Mandarin as their native language (Gordon, 2005a), which would yield an L1 of 910 million among the present population of 1,300 million.

However, in May 2005, the PRC's Xinhua news agency reported a survey by the National Language Commission which found that only 53% of the population can speak Mandarin, and many of them "are not frequent Mandarin users, preferring their local dialect" ("Half of all Chinese," 2005). This yields a combined L1+L2 of 689 million. If one adds in all of the L1+L2 Mandarin speakers among the 23 million Taiwanese and 34 million (Liren, 2002) to 55 million (Seagrave, 1996, p. 14) overseas Chinese, Mandarin's total probably comes within the margin of error for Graddol's (2000) combined L1+L2 estimate of 750 million English speakers.

In *Asian Englishes: Beyond the Canon*, Kachru (2005) suggests a much higher L1+L2 total for English, based on estimates that one third of his native India uses English, as do 200 million people in the PRC, yielding 533 million L2 speakers in those two countries combined. However, these figures assume that people who have had only three years of English instruction in school are "users of the language" (pp. 206-207). When I lived in Tokyo, I frequently encountered Japanese who had studied English for six or more years and were reluctant to speak it; however, they had the potential to become L2 speakers. After conversing with many Japanese of varying levels of English fluency during 1984-1987, I observed that those who were L2 generally had lived at least six months in an L1 country such as the U.S. or UK.

Regardless of the numbers, there are two solid reasons why Mandarin will not become popular as a global language: It is hard to speak and hard to write. Tones in speech and ideograms in writing make it virtually inaccessible as a second language to the majority of the world's people. Adults whose native language is a tonal one such as Thai, Lao, or Vietnamese sometimes learn Mandarin by overhearing conversations or watching movies, but speakers of non-tonal languages have a lot more difficulty doing so and need twice as much time in an immersion setting such as Automatic Language Growth (J.M. Brown, personal communication, 1990). Learning enough ideograms to read a newspaper requires a long-term diligent effort.

One benchmark of a global language is whether it is used as a lingua franca between two nonnative speakers from separate countries, neither of whom knows the other's L1. For example, a Japanese who is working on a development project in Mozambique would be likely to use English to communicate with a Swede working on a project in Laos. This example is basically an extension of Kachru's (2005) definition of "a 'standard' English-knowing bilingual" in south Asia (p. 215), applying it as a touchstone for anglophones throughout the world. That is, a Global English speaker is someone who is intelligible not only to native speakers of English but also to nonnative speakers from diverse backgrounds.

Although Mandarin is used as an international lingua franca, its scope remains regional; people outside Taiwan, Singapore, and other Chinese-majority areas study the language primarily to communicate with citizens of the PRC. Its recent rise in popularity as a language for international commerce has been at the expense of Cantonese (Yue), not at the expense of English. One impulse for the shift was the reabsorption of Hong Kong in 1997. In addition, Mandarin language schools began to operate openly in Indonesia after the dictator Suharto resigned in 1998.

The Future of Global English

Graddol's (2000) report contains much more than a tally of speakers at various levels of fluency. He suggests that English will remain globally dominant but it will be influenced by nonnative speakers, leading to "new hybrid language varieties" (p. 36). A harbinger of this hybridization is Singapore, which has four official languages: English, Mandarin, Malay, and Tamil. English is the default language when two Singaporeans of different ethnicity make each other's acquaintance, earning it an L2 (p. 11, Table 5). This L2 "Singlish" is flavored with words and structures from three non-Indo-European language families, making it a notable variety despite its narrow geographical range.

In addition, Graddol (2000) foresees "migration toward L1 use of English" by middle-class professionals and university students who use it "as a primary means of social communication" in L2 countries (p. 58). Such migration has been going on for more than half a century in India, where the large anglophone sector supports the creation of literature in their own variety of English, dating back to the 1938 publication of Raja Rao's pioneering novel *Kanthapura* (Kachru, 2005, p. 137).

It is widely recognized that the globalization of American movies, music, and fast food make English trendy among millions, even billions, of people who are not fluent in it. This "wave" of popular culture is augmented by a socioeconomic "wave" in developing countries, some of whose governments now require English to be taught as a foreign language in primary schools. It remains to be seen whether the critical mass of L1+L2 speakers attained by Singapore and India will be replicated by dozens of other countries, each of them thereby developing its own variety of English.

To test the ability of anglophones to understand each other's varieties, Smith (1992) recorded conversations between five pairings of fluent speakers

from the U.S., UK, China, India, Japan, Taiwan, the Philippines, Indonesia, and Papua New Guinea. He played the audiotapes to three groups of anglophones who were studying in Hawaii in 1986: 10 Japanese, 10 Americans, and 9 people of various nationalities (mostly Asian L2). Smith found that the L1 British and American speakers were not always the most easily understood (p. 88). Graddol (2000) cites this finding to support his speculation that an "Asian standard English" (p. 56) may someday codify the similarities that already exist among the varieties of English spoken in east Asia.

A related finding of Smith's (1992) pilot study has a more immediate implication. Smith saw the skill of the listeners in the group of mixed nationalities as "evidence that familiarity with several different English varieties makes it easier to interpret cross-cultural communication in English" (p. 83). Both findings support this chapter's call for action: When used as a global language, English should be spoken in a way that is recognizable to anglophones all over the world; and Global English needs to be neutral enough to accommodate the phonologies and lexicons of all varieties of English, not only those in the traditional L1 countries that were settled by the British.

Kachru (2005) describes the interaction of diverse forms of English in terms of *pluricentricity*, the concept that "world Englishes have a plurality of centres" (p. 18). These centers provide norms and models for English language acquisition, regional codification, and literature. He places Singapore, India, Sri Lanka, and the Philippines in the *norm-providing group*, distinct from China, Taiwan, Japan, South Korea, and Thailand in the *norm-dependent group* (p. 19).

If the reader will permit a coinage, I propose the term *colingual* (analogous to *coworker*), which refers to people who *speak a language with each other*. People who converse in a common language are colinguals in that language. Although two native speakers of a language are colinguals in their

L1, they might not be colinguals in a shared L2. For example, two Japanese could both be colinguals in English with their American acquaintance but not with each other, because Japanese people tend to speak English only when communicating with non-Japanese. However, Singaporeans are likely to be colinguals in English with each other, even if they have the same L1.

This neologism is helpful for understanding Kachru's (2005) separation of anglophone countries into norm-providing and norm-dependent (p. 19). His division correlates with the answer to a question that tests the internal colingual level among an L2 country's English speakers: Do compatriots communicate with each other in English when no foreigners are present? In the norm-dependent group, the answer is "rarely;" however, in the norm-providing group, the answer is "often enough to create a critical mass of colinguals that generates its own norms."

Although Kachru (2005) makes an excellent case for a regional variety called South Asian English that is spoken in seven countries, he says nothing about the extent to which norm-providing Singapore has radiated its lexical influence to Malaysia and Indonesia (e.g., the coinage *handphone* to refer to a mobile telephone), nor whether the Philippines has provided syntactical models to Vietnam or Thailand. So, it is unclear why the Singaporean and Philippine varieties of English should be called centers rather than national varieties. Regional codification of the kind seen in South Asian English has yet to be evidenced in southeast Asia (Crystal, 2003, p. 57).

Given that the number of national and regional hybrid Englishes is likely to increase, what is the future of mutual intelligibility? A Japanese acquaintance told me about an experience she had while teaching her native language to Indonesians in North Sumatra. One day, the students invited her to go hiking, pronouncing the word in Japanese fashion (*haikingu*) as part of a Japanese

sentence. Etsuko was confused when they said everyone would gather in the evening, because she understood *haikingu* to be a day trip on level ground or in low hills. Instead, the students trekked up a small mountain, arriving at the peak in time for sunrise. In Indonesian, the borrowed word *hiking* refers to an activity that Japanese think of as mountain climbing.

This anecdote illustrates how the expansion of English as a global language may undermine itself. To preserve mutual intelligibility, we should recognize common ground, not repress diversity. Therefore, Global English will become more essential in the future, as a way for speakers of divergent forms of English to communicate with each other. In this light, the implementation of ICT requires the development of human infrastructure as well as physical infrastructure. We must learn to express ourselves clearly to audiences who do not share our cultural background and the concomitant tacit aspects of our speech and writing. In addition to making English more explicit on the Internet, we should promote the use of Global English in education and business.

Graddol (2000) uses a pyramid diagram (p. 12, Figure 6) to explain how the expansion of an Indian citizen's viewpoint from home to village to state to nation is accompanied by shifts in language. At the base of the pyramid are local languages used within families and learned by infants as L1. A step higher are languages of wider geographical scope, which are used in media broadcasts and primary schools. Another step higher are state languages (e.g., Malayalam in Kerala), which are used in government offices and secondary schools. At the top are Hindi and Indian English, which are used nationally and in universities. I propose that Global English is a step beyond the top of this pyramid, serving as a lingua franca for international communication and online education (e-learning).

CONCLUSION

Localization is very important in marketing and other fields that rely on tacit knowledge of a target language and culture. However, it is incomplete as a global strategy because it can never accommodate everyone. The limits of localization are becoming more apparent in the 21st century, with over 1 billion people now having access to the Internet and numbers increasing dramatically in virtually every country. Localizing a Web site into all 347 languages that each claim at least 1 million speakers is not a feasible approach to the global dissemination of knowledge.

To make the Web truly a worldwide medium, it is necessary to write English text in an explicit way that can be easily understood by nonnative speakers: simpler syntax, less jargon, fewer idioms, no slang. Writing a Web page or other document in Global English is the best way to ensure that people from all linguistic backgrounds have a reasonable chance of comprehending it. Global English will become more important in the near future, both online and in hardcopy; it may prove to be essential for maintaining English as a lingua franca if the growth of anglophones leads to a proliferation of new varieties of the language in diverse cultures throughout our world.

ENDNOTES

¹ The International Telecommunication Union (ITU, 2003) explains how the total number of Internet users is estimated: “Countries that do not have surveys generally base their estimates on derivations from reported Internet Service Provider subscriber counts, calculated by multiplying the number of subscribers by a multiplier” (p. 4).

ITU’s World Telecommunication Indicators database shows that these were some of the multipliers used in 2004: Myanmar 2; Argentina, Bahrain, Bangladesh 3; Nepal 4; El Salvador, Syria 5; Costa Rica 8; Latvia 9; Honduras 10; and Uganda 25 (E. Magpantay, personal communication, December 13, 2005). Other countries had more complex estimation methods, with the sharing factor sometimes varying even within a single city (E. de Argaez, personal communication, December 11, 2005).

The multiplier attempts to compensate for undercounting that results from several members of a household sharing a single Internet account. Internet World Stats (IWS, 2005b) reports various standards for tallying children, including “The ITU subscribes to the definition of an Internet user as someone aged 2 years old and above, who went online in the past 30 days” (Internet Usage section, para. 2).

However, the multiplier exacerbates overcounting that is related to an individual having more than one account (e.g., at work or school, as well as at home). Even so, the growing popularity of cyber cafes, which have extremely large ratios of users to accounts, probably outweighs the distortion that is due to multiplication of overcounts.

² Compare the estimated 750 million people who speak English as their first or second language (L1+L2) in Graddol’s (2000) report (p. 10, Figure 4) with the estimated

1,125 million who access Web pages in English more often than pages in other languages (Internet World Stats, 2005a). Internet World Stats assigns only one language to each person, based on the following method: “The keywords they search for determine the language they use to surf” (E. de Argaez, personal communication, January 22, 2006).

³ For most of the 21st century, South Korea has had the world’s highest proportion of Internet users who subscribe to broadband. According to ITU figures for the country, 11.9 million of 31.6 million Internet users subscribed, resulting in a penetration of less than 38% at the end of 2004 (W. Yasandikusuma, personal communication, May 27, 2005).

However, “broadband penetration” figures are calculated in different ways, showing perhaps the greatest variance of all Internet statistics. The term *broadband* is sometimes applied to speeds less than the ITU minimum of 256 kilobits per second in both directions (V. Gray, personal communication, May 26, 2005). For example, the Federal Communications Commission (FCC, 2005) of the United States defines *broadband* as a connection that “enables the end user to receive information from and/or send information to the Internet at information transfer rates exceeding 200 kilobits per second (kbps) in at least one direction” (question 5).

In addition, the term *penetration* is defined in several ways. Some surveys divide a country’s total number of broadband subscribers by the total number of inhabitants. Although the United States had the most broadband subscribers as of December 2004, the ITU (2005) ranked it only 16th globally on the basis of 11.4% penetration of its general population, compared to 24.9% for South Korea.

Other surveys divide the total number of households or users who have broadband capability installed (but might not actually subscribe) by the total number of “active Internet users.” For example, over 69.4 million American households had the capability as of December 2004, yielding a penetra-

tion of 54.7% for home users according to Web Site Optimization (WSO, 2005). The inflated WSO figure is exaggerated even more in the “Face of the Web 2004” study by Ipsos-Insight, which claims that 68% of the entire world “accessed” the Internet via broadband in October 2004 (Ipsos, 2005).

Chapter 2.17

Deconstructing the South African Government's ICT for Development Discourse

Sagren Moodley

Human Sciences Research Council, South Africa

INTRODUCTION

The post-apartheid South African government has placed ICTs at the centre of the national agenda for social and economic development (Mbeki, 1996, 2002b; Presidential National Commission on the Information Society and Development (PNC on ISAD), 2003a). The question of whether the application of technologies to improve information and communication access can increase the capabilities of disadvantaged and poor people is central to whether the new ICTs (particularly the Internet) will support or undermine real development. Technology appears in the South African government's ICT for development discourse as a politically neutral force with the power to develop, and without which people are classified as *information-poor*. As Wajcman (2002) cogently argues, "governments everywhere legitimate much of their policy in terms of a technological imperative" (p. 348). One effect of this discourse

is to render poor people passive and dependent, as objects to be developed, rather than as active agents of development. Failure to address these assumptions may lead social scientists to become complacent in distracting attention away from the very *real* global economic, social, and cultural inequalities, to *virtual* inequalities, which merely hide an unwillingness to address the core failings of the development paradigm.

The paper attempts to meet the challenge put forth by Robert Wade (2002):

The current campaign to promote the uptake of information and communication technologies (ICTs) in developing countries and to get aid donors to redirect their aid budgets needs devil's advocates to challenge what John Stuart Mill once called 'the deep slumber of a decided opinion.' (p. 443)

BACKGROUND

The real test of the success of ICTs in development efforts is whether they ultimately contribute to reducing poverty and inequality, thereby improving the lives and livelihoods of the poor. Two important questions emerge from the debate: (1) Who will have access to ICTs and the networks formed? and (2) Who will have control not only of the technology and its application, but of data gathered and processed, and of information exchanged via different modes?

The paper makes the following assumptions: (1) technology is *socially shaped*; and (2) the direction and nature of technological development does not necessarily follow some inevitable trajectory, but rather is a component of a complex, multi-dimensional system of social, cultural, political, and economic change. Further, the paper is premised on the belief that: (1) technology, in and of itself, is neither positive nor negative (Kranzberg, 1985), what Heidegger (1977) refers to as “the ambiguous essence of technology” (p. 33); and (2) the deployment of ICTs is the consequence of human choices which are themselves constrained and shaped by social context. Simply put, ICTs are context-dependent (i.e., they are contingent on uses and applications in particular contexts).

Developing at the end of the 19th century in an era of rapid capitalist industrial expansion and the rise of powerfully intrusive states, Touraine (1988) maintains that the social sciences have been overly preoccupied with positivistic explanation and unduly shaped by an emphasis on order and control. This has left little room for human agency and on the individual actor in social science theories. To regain relevance and validity in the social sciences, Touraine (1988) urges social scientists to become *participant-observers*.

The author has been a participant-observer in numerous government ICT forums (e.g., the Government Information Technology Officers' Council (GITOC), the knowledge and information management (KIM) sub-committee, the Universal

Services Agency (U.S.), the Presidential National Commission on the Information Society and Development (PNC on ISAD), the Department of Communication's electronic commerce discussion process and various discussion colloquia on telecommunications, ICT convergence policy, etc). Collectively, these experiences have been a rich source of data gathering for the paper. By operating as a reflexive critic and a participant-observer, the researcher is well positioned to question the highly problematic set of assumptions underpinning the South African government's ICT for development discourse.

TECHNOLOGICAL DETERMINISM

The benefits of ICTs for the poor are seen as intuitively, self-evident, and universally valid by the South African government. It is clear that government has invested a great deal of faith in the power of ICTs to fast-track development (Matsese-Casaburri, 2002a, 2003; Zuma, 2002). The optimistic view of government focuses heavily on technology potential rather than on adapting appropriate information systems to meet the real needs of poor communities in different environments. Further, this rose-tinted view of technology fails to adequately deal with the constraints for accessing and applying ICTs by the poor. What is urgently needed is a more integrated framework for understanding both information and ICTs in relation to poverty alleviation and development.

The optimistic view of the South African government needs to be tempered in the light of evidence showing that learning is a critical feature of technological change (Bell & Pavitt, 1993; Giuliani & Bell, 2005; Lall, 1992). Further, the importance of ICTs for addressing the real information needs of the poor has tended to be overstated and there is a danger of the policy debate becoming too strongly focused around the capabilities of emerging technologies.

It would appear as if government is underplaying the constraints that make it difficult for the poor to access, assess, and apply information through ICTs. These include lack of human capabilities (i.e., literacy, English language skills, and technical computer competence); urban/rural inequities; gender inequalities; affordability; and lack of relevant information content. Further, it takes time for people to comprehend the potential benefits of ICT-mediated information, or to be willing to trust information that does not derive from personal networks.

The information needs of poor households, communities, and small-scale enterprises should be understood in advance of proposing ICT-based solutions. Significant “financial opportunity costs” for poverty alleviation strategies are likely to arise, since large amounts of limited resources are being diverted to poorly conceived ICT-related investments that might not have a direct impact on the needs of the poor. There is also the risk that introducing digital information systems may supplant existing systems that may be more appropriate and more cost effective in terms of access and coverage. Moreover, over-emphasis on technological solutions can have the effect of drawing attention away from the underlying causes of poverty such as inadequate health and educational facilities.

As part of an integrated development strategy, ICTs can contribute to socio-economic development, but investments in ICTs alone are not sufficient for development to occur. ICT applications are not sufficient to address problems of rural access without adherence to principles of integrated rural development. Unless there is minimal infrastructure development in transport, education, health and social and cultural facilities, it is unlikely that investments from ICTs alone will enable rural areas to cross the threshold from poverty to growth.

Government has over-enthusiastically embraced the application of ICTs to address the pressing needs of the poor (Fraser-Molekete, 2002;

Naidoo, 1998a-c). The major problem is that there is a widespread misunderstanding about how substantial benefits can be derived from ICTs for the poor. Persistent poverty, at both an individual and societal level, has deep and systemic roots. Chronic poverty, limited growth, and inequality are primarily the result of uneven access to material and financial resources.

The material deprivations of the poor are compounded by their lack of access to education, information, and knowledge; their lack of voice in the institutions and societal processes that shape their lives; and their inability to communicate effectively their needs, hopes, and expectations to those who have control over them. These deprivations are mirrored at the societal level by institutions and markets that function poorly, that are often unresponsive to the needs of the disadvantaged and disenfranchised, and that are all too frequently captured or are excessively influenced by economic, social, or cultural elites.

Government's discourse on ICTs for development is couched in the upbeat “we will all benefit from this” language (Mbeki, 1996, p. 1). There are times when it would seem as if government regards ICTs as the technical solution for poverty and underdevelopment (Mbeki, 2002a-b). The technological utopianism of government maintains that the digital world of the new ICTs holds the potential for breakthroughs in resolving the social problems of poverty and inequality in South Africa. The isolation of the poor can be ended and radical new approaches to poverty and social inequality can develop directly through the cyber-world (Ministry of Communications, 2001). The digital space holds potentials for conferring enormous economic benefits on society as a whole and its low-income segment in particular. It is for these reasons that government sees exclusion from the digital world as disastrous for those excluded.

There is a distinctive view in government that technology determines the nature of society (Matsepe-Casaburri, 2002b, 2003). ICTs have become

idolised as a force that can “fix” the economy, raise the general standard of living and human well-being in the country, and deliver on poverty alleviation (Zuma, 2002). For government, the transfer of technology to poor communities is seen as unproblematic (Universal Service Agency (U.S.), 2002). It is not realised that such a transfer would depend not merely on technical elements, but on social and cultural factors as well. Technology is seen as neutral, not as an instrument for the creation of cultural and social orders. The understanding of technology, as part of a wider socio-economic system, is particularly important when the technology is adapted within environments very different from those for which it was originally intended (Schumacher, 1973). When technology is transferred from one society to another, it reflects the social values, institutional forms, and culture of the transferring country.

Since the outcomes of ICTs are open-ended, we have no reason to expect the emerging socio-technical system built around ICTs to remedy social inequalities in our society or to relieve the plight of the poor, any more than other major socio-technical changes have had such effects in the recent past. The three previous “communication revolutions,” for example, have had significant impacts on society but failed to deliver the optimistic predictions first hoped for. The railway was believed to spark the *dictatorship of the proletariat*, the telegraph to engender world peace and the television to revolutionise education. It is highly unlikely then that ICT alone will end global poverty. In the long-term widespread adaptations to the new technological system will likely take place, just as broad social adaptations have been made to other socio-technological shifts (e.g., railways, automobiles, and electricity). But these adaptations are unlikely to remedy the fundamental, structurally based inequality between the poor and the well-to-do. Structural inequalities can be solved only by attacking them within the larger historical, cultural, and socio-economic matrix that generated them.

It would appear that the South African government is driven by a deterministic perspective on social development: technological innovations have a direct impact on social processes (PNC on ISAD, 2003a-b). This can be detected at all levels of discussion, both descriptive and predictive. There is no space for reflection on the myriad of complex ways in which technology and society are dialectically linked. The fact that technologies almost always have unintended and unplanned consequences is ignored. As much in its development as in its application and use, technology is intrinsically shaped by its economic, political and social environment (Williams & Edge, 1996).

There is a widespread approach in government that seems blinded by the “newness” and novelty of digital ICTs, and which, by emphasising the “revolutionary” character of the Internet and related technologies, tends to become (either deliberately or by negligence) ahistoric. To conceptualise technology and technological change outside of any social, economic, political, or cultural context can have several consequences. The first is that the approach becomes one of technological determinism, in which the technology is seen to act as an autonomous agent that has a direct effect on other social systems. Following MacKenzie (1984) and Winner (1993), Edge (1995) defines technological determinism as:

a belief...which holds that technical change is a prime cause of social change, and that technical innovations are themselves “uncaused”—in the sense that they arise only from the working out of an intrinsic, disembodied, impersonal ‘logic’, and not from any “social” influence. (p. 4, emphasis in original)

Such accounts ignore the social shaping of technology and the fact that technologies and social life are interconnected (Groper, 1996; Schmidt, 2001). These approaches disregard the political, social, and cultural processes that necessarily accompany the development of any technological innovation,

not least in the form of values, judgements and interests in operation that help structure Internet access and use (MacKenzie & Wajcman, 1999). Technological development comes to be seen as autonomous and self-generating. Technologies, however, are always situated within circuits of human action which provide their context and shape their direction.

THE “SOCIAL SHAPING OF TECHNOLOGY” APPROACH

Edge (1995) critiques traditional approaches to the social analysis of technical change, emphasising the extent to which such approaches “imply a *technological determinism*, use a simplified *linear model* of the innovation process, tend to treat the technology as a ‘black box,’ and are preoccupied with the ‘social impacts’ of a largely predetermined technical ‘trajectory’” (p. 14, emphasis in original). At a lecture entitled *The Question Concerning Technology*, delivered in 1955 in Germany, Martin Heidegger (1977) made the following prescient remark:

[W]e are delivered to [technology] in the worst possible way when we regard it as something neutral; for this conception of it, to which today we particularly like to do homage, makes us utterly blind to the essence of technology. (p. 4)

That said, we should not replace technological determinism with social determinism. The view we subscribe to is that the “social” and the “technological” cannot be separated. New technology is as much a social product as the shape of society is a technological product. There is a constant interplay between “technology” and “society” (Loader, 1998; Lyon, 1988, p. viii).

The technical attributes of the new ICTs increasingly dominate explanations of contemporary change and development. There is a discernible tendency to understand or conceptualise these

technologies in terms of technical properties and to construct the relation to the sociological world as one of applications and impacts. The challenge for social scientists is not so much to deny the weight of technology, but rather to develop analytic categories that allow us to capture the complex interweaving of technology and society.

It would appear that the “social shaping of technology” approach is beginning to take root in the social sciences (Klein & Kleinman, 2002; Kling, 2000; Pinch & Bijker, 1987; Rip, 1995; Sassen, 2002; Werle, 1998; Woolgar, 1991).

Following Heeks (2002), a reconceptualised “social shaping of technology” approach to ICTs is one which is:

- Centred on information rather than technology
- Integral to its environment
- Integrated with development objectives
- Indigenised

Such an approach potentially has the power to:

- Restore the agency of those rendered passive in the ICT for development arena
- Reorient technology to socially embedded, local uses
- Break down the binary of developed/underdeveloped, recognising poor people’s knowledge and experience, and so opening up the possibility that “we” can learn from and with “them”

It cannot be assumed that the ICT-based information system will be beneficial or harmful without understanding the local social dynamics and how the technology will be used. This is especially the case since communities are complex and dynamic. ICT will be best used where it is embedded in existing social relations, and where it serves to extend the capacity of people to perform tasks they would wish to do, *even in the*

absence of ICT. Moreover, from the literature on technology transfer (Archibugi & Michie, 1997; Archibugi & Pietrobelli, 2003), the role of local adaptive assimilation and learning is seen as key to successful implementation of technology in new settings. Learning, however, will not come about simply by local control of the technology. A level of technical competence and an understanding of the technology's potential are also required before local learning can take-off.

CONCLUSION

The post-apartheid South African government has embraced the ideology that ICT represents modernisation; and it is seen as a key technology for alleviating poverty. The theoretical heritage of this perspective is linked to the modernisation school, which assumes that social change is unidirectional, progressive, and moves society from industrial (or pre-industrial in the case of least developed countries) to post-industrial with modern ICT as the engine. In much of government technicist rhetoric we find an implicit belief in an unproblematic causal progression from ICT innovations to social change (Fraser-Moleketi, 2002). Technological complexities, complex social processes, and independent human agency are not seriously considered.

It seems that the South African government is attracted to the neutral, instrumental view of technology, which is why it builds an increasingly central role for it in its vision of an "information society." Government has taken the technological configuration of the new ICTs as a "given" or prefigured system that needs to become more widely diffused to citizens. Hence, government rhetoric forecloses an assessment of the need for greater variety in the deployment of ICT configurations. The challenge, however, is to reorient this technology to socially embedded and locally-led development that affirms and makes use of the

information, knowledge, and experience that poor people have.

There is clear evidence of technological determinism, which is steeped in a modernisation discourse arranged around political rhetoric and informed by a discursive power which rests on the universalisation of a particular, interpreted, theorised, and valorised regional (i.e., Western) experience. The imposition of policy legitimacy in terms of linking formalised systems of ideas with a recognised interpretation of a dominant Western experience formed within relations of power is set down in a hegemonic tradition (*pace* Gramsci, 1971) and widely accepted as proven and universally applicable.

By and large what emerges from a reading of government's ICT policy documents is a very optimistic view of the benefits to be harnessed from ICTs for poverty alleviation in South Africa.¹ This is surprising, given the recency of ICT developments and the paucity of solid empirical investigation of trends and impacts to date. Very little attention is paid to the costs, risks, and constraints that ICT diffusion is likely to entail. The fact that the poor face multiple barriers both to ICT utilisation and to benefiting from that utilisation, since they have little to spend on communication; live in areas where the Internet is costly and complex to provide; have low rates of education and speak languages that are not very well represented on the World Wide Web, tends to be played down in policy debates. At best, this selective reading of ICTs for development oversimplifies a complex reality; at worst it is likely to result in wasted resources, poorly thought-out projects, and unrealistic expectations.

ICT for development programmes have a better chance of success if the poor are seen as autonomous agents of action and if they define a social process of change in terms of the growing role of independent autonomous action on the part of dominated groups. Such an exercise will, of necessity, entail a *self-analysis* that requires the active participation of social actors engaged in a

collective struggle concerning political and social issues. It is imperative that we move away from the “heroic scenarios” and “intoxicating visions” (Bellamy & Taylor, 1998, p. 170) characterising much of government’s discourse on ICTs for development, and attempt to re-conceptualise the complex and multi-layered relationship between ICT, poverty, and development.

Contrary to the South African government, the key to integrating ICTs in the fight against poverty, then, is not to begin with ICTs, nor to posit them as an essential need. Rather it is to determine the impediments to poverty alleviation and to reducing inequality in society and, thereafter, to ascertain the information, communication and knowledge components of these impediments. In the light of this, the task is to: (1) assess, on the basis of global experience, how ICTs, broadly deployed and properly adapted, could help address these impediments; and (2) to develop and implement a strategy for encouraging and supporting the deployment of ICTs, in support of, and subordinate to, a national poverty-reduction strategy.

Government needs to move away from analytical perspectives that are techno-centric and determinist, that focus on historical discontinuity (i.e., the “information revolution”), and that make unwarranted claims about the future impact of ICTs on the lives of the poor. Much more useful is the “social shaping of technology” approach, which puts the dynamic interaction between social forces and technological innovation into the forefront. This approach calls for proactive policy-making, since it stresses the imperative that *the technological solutions must be shaped to match the vision of a preferred future*. ICTs will not by themselves change existing institutional settings. The use of ICTs within the conventional social and institutional framework not only hampers these technologies full potential, but may also cause many frustrating social problems.

KEY TERMS

Dictatorship of the Proletariat: In Marxist theory the dictatorship of the proletariat refers to the ideal of proletarian supremacy following the overthrow of capitalism and preceding the classless state.

Discourses: The public or outward expression of (usually) unstated or implied ideological positions. Discourses connote values and these values are often assumed to reflect general endorsement. It is characteristic of discourses that they occur as self-evident truths or facts and therefore act to occlude oppositional or resistant discourses.

Information and Communication Technologies (ICTs): Reflects the technological convergence between digital computing, telecommunications, and broadcasting. Whereas computers were largely focused on the processing of information, ICTs undertake *both* processing and communication of information.

Information Revolution: Underscores a notion of historical discontinuity. The emphasis on historical discontinuity runs the danger of underestimating the continuities involved in the process, as much in the technological innovations as such as in their adaptation in the economic, social, and political contexts. Further, the term “information revolution” tends to imply that the technological discontinuity goes hand in hand with a revolutionary discontinuity in social and political relations. The empirical evidence does not live up to the proclaimed epochal dimensions of change. This then raises the question of what should change, thus opening up a wide field for ideological preferences of all sorts.

Information Society: Though as a heuristic device, the term information society has some value in exploring features of the contemporary world, it is far too inexact to be acceptable as a definitive term. In fact, the further one moves from grand national ICT plans and from futuristic forecasts of conditions prevailing within the information society, and the nearer one gets to actual social analysis in which technology is not perceived as a quasi-autonomous force acting upon society, the more questionable the concept of an information society appears.

Social Shaping of Technology: Technical change is no longer seen as autonomous or external to society, but as influenced and shaped by its societal context. Technology is inflected by the values, cultures, power systems, and institutional orders within which it is embedded. Thus, the social

shaping of technology approach serves as a needed corrective to technological determinism.

Technological Convergence: ICTs are based on a long list of technological innovations and evolutions that took place earlier. Effectively, ICTs are characterised by a complex process of technological convergence between microelectronics, telecommunications, computing, and broadcasting. Thus, there is no single historical moment that can be named as its starting point

Technological Determinism: The notion that technological development is autonomous of society; it shapes society, but is not reciprocally influenced. In more extreme varieties of technological determinism, the technology is seen as the most significant determinant of the nature of a society. The reality, of course, is that technologies do not, in practice, follow some predetermined course of development. Also, although technologies clearly have impacts, the nature of these is not built into the technology itself, but varies from one culture to another, depending on a broad range of social, political, and economic factors.

ENDNOTE

- ¹ Government sees an array of positive developments emerging from the information society, with increased productivity and better quality employment, decentralised and increased access to political decision-making and potential for e-government and e-commerce to improve the lives of the poor (Centre for Public Service Innovation [CPSI], Department of Public Service and Administration [DPSA] & The State Information Technology Agency [SITA], 2003).

Universiti Malaysia Sarawak, Malaysia

ABSTRACT

This chapter highlights an initiative by a group of researchers² from Universiti Malaysia Sarawak (UNIMAS) to connect villagers in the remote and isolated village of Bario to Information Communication Technologies (ICTs), which include computers, telephones, the Internet, and VSATs. This project has eased the information flow in and out of Bario, affecting the well-being of the people by providing a means to keep in touch with friends and relatives in urban areas. The response of the Bario community has been positive, but the objective of the e Bario project is more ambitious than to just provide access to the Internet, com-

puters and other related technologies. The main objective is to identify opportunities for remote and rural communities in Sarawak to develop socially, culturally and economically from the deployment of the technologies. The results of the initiative are expected to demonstrate the many ways in which ICTs can be used to improve the lives of marginalized groups, specifically, here, the rural and remote communities in Malaysia. However, to ensure that the objectives will ultimately be met, the team has had to search for an appropriate methodology that will ensure the full benefits of the initiative to the community. This chapter describes and discusses the approaches adopted, emphasizing the benefits of

a close association between the researchers and the community as well as the adoption of suitable participatory methods for engaging with the needs and opportunities that were discovered.

BACKGROUND

The imbalance of access to Information Communication Technologies (ICTs) is claimed to be linked to other forms of poverty and inequality. Drastic efforts are necessary to provide rural communities with access to computer mediated information and communication services or facilities³. This is particularly significant, as ICTs are widely accepted as new social and economic forces in the world economy today. In fact, some scholars (for example, Barr, 1998) suggest that a close correlation exists between telecommunication and economic development, whereby efficient telecommunication facilities foster economic development. As such, telecommunication access for remote and rural communities is now generally accepted as an appropriate goal to foster economic development in developing countries (Barr, 1998). And, especially for rural areas, advanced telecommunication access is expected to not only provide opportunities and means for rural communities to have access to the same services as urban areas in the field of business, but holds a promise to promote their social, economic and cultural conditions (Enberg, 1998).

Furthermore, it is thought that the remoteness and isolation of rural areas should be compensated by efficient telecommunication services. In this context, the rural populations need information and communication facilities as much as, if not even more than, densely populated urban communities. In fact, it is argued to be crucial for the betterment of life in rural areas where getting connected can mean so much. The ICTs can provide opportunities to obtain a wider range of information that can be useful to make better and more informed decisions (Paisley & Richardson,

1998). Besides providing access to sources for health and other categories of information, these technologies are an important means to keep in touch with distant friends and relatives. Fortunately, today, provision of this access is eased by advances in networking technologies that can enable rural communities to have the same benefits of connectivity as urban people.

However, the greater challenge for any initiatives to provide access to ICTs for rural communities is to ensure that “these services are efficiently and effectively deployed in these areas” (Barr, 1998). This is a great challenge, judging from past experiences with earlier technologies where their application in certain areas generated not merely disappointment, but even negative consequences. In a sense, technologies just by themselves do not guarantee benefits for the local people. As such, the challenge is to ensure not only the success of the technology itself (meaning that the technology runs and functions well), but also that the people benefit from its application. And, how do we ensure that there are benefits to the people? This is a question that the team continues to grapple with as we labor through the e Bario project.

THE CONTEXT

The e Bario project was described as “one of the most notable of Malaysia’s Internet development initiatives” by the International Telecommunications Union (ITU, 1998). The project was initiated at the same time that the Malaysian Government aggressively adopted ICTs for national development in its quest for a future knowledge-rich society⁴. In fact, ICTs form an important component of national development policies and the aspiration to be a fully developed nation by the year 2020 (Mahathir, 1991). This is significant for developing countries like Malaysia since the world is seen to be moving into an information age where wealth creation and accumulation are increasingly dependent on high technology for

the exchange of data, information and knowledge (Omar Abdul Rahman, 1993).

Like many other developing countries, Malaysia has large areas with undeveloped infrastructure and a widely scattered population. These can be enormous challenges for using ICTs for development, and especially for Sarawak, Malaysia's largest state. About 60% of Sarawak's total population of 2.027 million people live in rural areas. Many have no access to good roads and have access to only meagre; or worse still, have no access to telecommunication services⁵. The absence, in most rural areas, of an infrastructure includes the lack of both telephone lines and of a non-24 hours continuous supply of electricity. These deficits pose challenges for any ICT initiative in rural areas and remote communities of Sarawak.

Conscious of these challenges, the group of researchers took an ambitious step to begin with Bario, due to it being so highly isolated and remote⁶. Bario therefore exemplified the disconnected portion of the digital divide, and presented a challenging environment in which to test the idea of rural Internet connectivity in Malaysia. The team had to deal with many technical constraints including establishing an effective means of telecommunication with no telephone lines available, finding an appropriate and continuous source of electricity and determining a network configuration that is supported by other forms of power supply and via satellite.

But more challenging is to ensure that the rural communities will benefit. The team was made aware that this requires a shift in outlook from looking at technology to looking at people. The focus has to be on the people and on the process rather than on the technologies themselves (Anderson, 1998; FAO, 1998). The focus must place equal importance on understanding the context of the social, economic and political systems of the community in which the technology will be deployed, and the technology (Garcia & Gorenflo, 1998). This stems from the belief that a clear understanding of local communication patterns

and processes can ensure appropriate applications of technologies and content to the local situation. This is crucial since the success of the ICT's application largely depends on its integration with the local communication networks (Anderson, 1998).

Bearing this in mind, the team adopted the Participatory Action Research (PAR) model⁷ as the research methodology, in that it was deemed necessary that:

- The researchers should learn about life in Bario from the community;
- The community should learn about ICTs from the researchers;
- Community members should perform major portions of the research;
- The researchers should be able to identify with the community;
- As a team, the community-researchers should be capable of critically reflecting upon iterative cycles of action in order to achieve mutually beneficial outcomes from the project;
- Useful information systems will be embedded in the needs of the community;
- Specific actions are required by both the researchers and the community in order to articulate those needs;
- Methodologies for designing and implementing useful information systems will emerge from participatory action-oriented research activities; and,
- Data would be obtained using a combination of surveys, direct interviews, workshops and discussion groups.

Within the PAR framework, the researchers have engaged community members directly in the process; for instance, to conduct surveys, perform interviews and focus group meetings, and have held community gatherings for decision-making and to direct the conduct of the research. A system of close consultation between the project team and the rural users has been developed so that

their needs are realistically assessed. A survey was conducted of 140 (out of 242 households in Bario) household heads to get indicators of the levels of literacy and education, and of the state of the telecommunication infrastructure.

Learning from others, like Richardson (1998) and Anderson (1998), the team adopted the idea of analyzing the needs of the people in rural communities. Firstly, a questionnaire was circulated that listed types of information that had been found to be of interest in other rural communities (Hudson, 2001). The questionnaires were completed by enumerators in interviews with heads of households. The enumerators were drawn from the Bario community. Respondents were asked to indicate their level of interest for each type of information, the extent to which they currently received such information and the level of interest in receiving more of each type of information. Additionally, information was obtained regarding their existing communication patterns.⁸ This effort has helped to identify opportunities, for example information provision and training opportunities (skills and knowledge) that exist within the community, and this was used to inform the selection of content and hence the technology to deliver the content. Information gaps and skill gaps were revealed by integrating information delivery opportunities with an understanding of existing communication patterns and channels of information flow, and by knowing the profile of potential users of the technology and their awareness perceptions, attitudes, and usage of technology.

The Bario community today consists of 78% Kelabit, with the others being Penan, Kenyah, Bidayuh, and Malays (11.5%), Chinese (1.6%) and some Indonesian immigrants (8%). Within the past 30 years, many Kelabit have moved away to pursue further education and obtain better job opportunities. Today, there are only about a thousand out of approximately 5,000 Kelabit who remain in the Highlands. Until recently this has been the elderly and the very young.

As a result of their diaspora, there has been a

need to bridge distances between the Kelabit in the Highlands and those living outside. This was helped initially with the construction of airstrips, and especially by the new concrete airstrip which was completed in 1996. This eased the movement of people in and out of the Highlands. Until recently, for many people in the Highlands, the airport is their closest link to the outside world (Bala, 2002). As people move in and out of the Highlands, the travelling Highlands residents, as well as outside visitors, become important sources of information.

Results from the survey suggest that the community is highly interested in IT, about which approximately 90% of respondents said they would like to receive a lot of information, although the majority (99%) of the respondents had not heard of the Internet. The significance of this emerges from the context that even though many have heard about (81%) and seen (74%) a computer, about 91% have never used one. A few have used a computer, but mainly for word processing (7%), and less than 1.5% have surfed the WWW. The data revealed that almost nobody receives any information about agricultural practices whereas around 90% of respondents would like to receive a lot of information about them, and 68% of respondents currently receive no information about information technology but about 98% would like to receive a lot. Delivering more information about information technology would appear then as potentially more popular than delivering more information about agricultural practices (Harris et al., 2000). Information about information technology appears to be the largest information gap, in terms of the amount of information and the number of people with interest, that was identified from the survey.

DISCUSSION

From this, the researchers concluded that the Bario community has shown a progressive

readiness and enthusiasm for technology-induced improvements in their communication resources. From one perspective, it can be argued that the Internet represents a logical extension of a trend towards technology that the Bario community has experienced in the development of its communications capability. This is further strengthened by the community's willingness to take risks and embrace new learning experiences. This is evident from Pemanca Ngimet Ayu's (the Paramount Chief of the Community) comment when addressing the council of elders on the intent of the project. He said,

"Kira-kira 30 laak nuk puun malem, edtah enu beruh mediting ngen tauh iah ineh enu Kristen – tauh maya' Tuhan Alla. Lun Merar tauh dih pelaba doopian la'maya enu beruh sineh kadikuh idih mare ulun doo ngen tauh. Perapu ngen ineh medting meto' sekulah dih. Sineh peh pelaba the useb tauh la ngalap sekulah dih kadikun tauh kekali, sekuleh ineh teh kereb ngiuk anak tauh dih lem ulun dedih. Kadi' neh tauh perihda'at mated anak tauh dih me sekulah. Edto kinih mula' anak tauh nuk doo ileh dih. Mula ideh uwan kerja dita. Kinih nih neh edtah teknologi beruh medting. Doo tauh terima idih, ni'er kepah tauh kareb pakai idih, paad tauh na'am ketedtan let ngen lun mula' dih."

(About 30 years ago Christianity, a new faith came to us which is Christianity — we are following the Lord. Our parents were very excited to embrace the new faith because it gave us good life. With the new faith, the school also came to us. We were also very excited to embrace the school because we foresaw that the school could help our children. Therefore we sacrificed to send our children to school. Today many of our children are doing in school. In fact, many nowadays are in high positions. Again, today a new technology has arrived in our midst. Let's embrace it and see how we can use it in order not to be left by the rest of the societies." Their capacity to take risks

is prevalent in their history as a people, such as when today's Kelabit forefathers embraced formal education and Christianity about 30 years ago in view of the potential benefits they had to offer) (Harris, R.W. et al., 2001).

Today, the Kelabit see the opportunities provided by the ICTs as a new tool to empower them with information that can allow them to compete in the world, or at least be electronically connected with each other and the rest of the world⁹. This is obvious from a statement made by one of the respondents. He said, "...we cannot not try this technology. We need to be part of the change that is taking place, otherwise we will be lagging behind technologically, and continue to find it difficult to communicate with the rest of the world."

Emerging from the focus group discussions, interviews and survey, the community and the research team were able to develop a joint research and development agenda that represents a prioritised set of information provision objectives that each supports a community development endeavour. We have adopted the following definition of community development developed by the United Nations: "Community development is the process by which the efforts of the people themselves are united with those of governmental authorities to improve the economic, social, and cultural conditions of communities and to enable them to contribute fully to national progress. This complex process is made up of two essential elements: the participation by the people themselves in efforts to improve their level of living, with as much reliance as possible on their own initiative; and the provision of technical and other services in ways that encourage initiative, self-help and cooperation" (Silverman, Anglin, & Sangha, 2001).

One event had a significant contribution to the development of the agenda. It took the form of a two-day symposium to which members of the Bario community were invited, along with influential members of the Kelabit diaspora living

elsewhere in Sarawak. Several members of the Kelabit people who had moved from the Highlands to the towns for education and employment retain strong links to their families in and around Bario and carry some degree of influence in decision making relating to local development. As many are highly educated and occupy senior management, professional and administrative positions in Sarawak society, they are well placed to advise the local community and the project team with regard to making effective use of ICTs in Bario. The two day symposium took the following format:

- Presentations on similar projects elsewhere;
- Outline of the research findings to date with regard to information channels and desires in Bario;
- Discussion on information opportunities so far identified;
- Consensus drawn on potential information areas;
- Break-out groups for each information area to expand with more detail, assign responsibilities and propose activities;
- Plenary presentations from each group for community consensus building and allocation of priorities for development activities and associated information provision.

The research and development agenda is shown in the Appendix, and it relates to information delivery that supports education, culture, commerce, agriculture, health, community, technology and human resource development. Each of these proposals was arrived at in a participatory style, in joint consultation with the researchers facilitating the community to develop these agendas themselves. This indicates a number of opportunities and potential applications of ICTs for the Bario community. As an example of actioning one of the identified areas, the team is now implementing a scheme for e-commerce in support of community-based tourism in Bario. The intention is to raise local incomes by using

the telecenter and the Internet for the promotion and sale of tourism in the Kelabit Highlands to overseas markets. Community-based tourism involves local communities in the management and provision of tourism products and ensures they derive reasonable financial returns whilst preserving the natural physical and cultural assets that they value. Operating tourism as a form of e-commerce disintermediates the tourism value chain and directs a higher proportion of incomes to product and service providers at the point of delivery.

Before the opportunities for development in the research agenda can become viable, there are issues specific¹⁰ to Bario that need to be solved. These issues were identified through the survey and interviews conducted and they include:

1. Literacy Level

About 87.9% of the respondents are able to write, although in Kelabit. All the respondents speak Kelabit, while 91.4% speak Malay, but only 75.7% can write in Malay. About 37.1% can speak English, although only 35% can write in English. Other languages spoken and written are Iban, Penan, Murut and Bidayuh. The language of the Internet is largely English, with as many as 65% of the Malaysian sites being written in English. This presents a challenge to the attempt to build local capacity through the implementation of ICTs.

2. Computer Literacy

Education-wise, most (30.7%) of the respondents have completed upper secondary education, 20.7% completed lower secondary school, 19% received primary school education, 0.7% received tertiary education, while the remaining (28.6%) never went to school. From these figures, it can be seen that while a majority of the people completed a basic level of education, it is an insufficient preparation for conducting an electronic business. However, as many computer experts are self-trained, a higher level of educa-

tion is not necessarily needed to become literate in computer use.

3. Management Capability

In fact, there are not enough people in Bario who have the necessary skills needed to keep up the basic maintenance of a computer system. This is mainly because anyone with a sufficient degree of education has moved away from Bario for higher paying jobs outside. This exodus of skilled personnel has left Bario without the necessary man or womanpower to engage in the application of the technologies. In order for ICTs to be successful, an extensive training in management will be needed.

Despite these challenges, especially the low level of literacy and computer awareness, the team found that the progressive readiness and enthusiasm of the Bario community for technology-induced improvements in their communication resources were favorable indicators for a systematic introduction to ICTs. Members of the community are capable not only of learning new knowledge, skills, ideas and roles, but also have the capacity to integrate new knowledge with their existing knowledge and build something permanent and of value upon this base. The team's experience suggests that technology cannot function successfully without the community's aspirations and readiness to improve its own well-being. When a community has aspirations, whether economic or cultural, most likely members will be willing to learn new skills, ideas and roles. The Bario community has done just this with embracing formal education, and is confident it will do the same with ICTs. The willingness of the Bario community to participate in the project, fundamentally, is one reason why Bario was chosen for the initiative.

In fact, it has been the close working organisation of the multi-discipline project team and the harmonious relationships it has had with the Bario community that facilitated progress

towards the project's goals. And this was made possible by the participatory approach that was adopted, which helped to facilitate flexibility and adaptability among both the community and the implementation team, contributing, it is argued, to the prospects of sustainability. In addition, the Participatory Rural Appraisal (PRA) techniques were found to offer helpful insights in identifying the potential role of information in community development (Chambers, 1997). It encouraged the team to anticipate what it found: that development solutions and their applicability to their local context would be highly specific, localised, contextual, complex, diverse, dynamic and unpredictable.

Bearing this in mind, the team embraced new methods of working, and flexible approaches that could help in the application of ICTs to improve rural life in Sarawak. Some of these are non-ICT related activities, but can provide guidance that is more useful than was initially expected. Some of these approaches include:

- Acknowledging anthropological and ethnographical contributions to Informatics;
- Designing information systems that are appropriate to community-bounded, as opposed to business-bounded, contexts;
- Adopting social analysis that is appropriate for loosely organised communities, as opposed to tightly organised hierarchical organisations;
- Cultivating sensitivity to the cultural contexts and variations of technology deployments;
- Aggressive focus on those social impacts of technology that can generate community empowerment.

This differs greatly from common approaches to the implementation of information systems within organisations, known as systems design and analysis, which often failed to render effective guidance for the identification of the community's information needs. Additionally, the

team concluded that pre-and post-implementation measures based on quantification of benefits, which is a common form of ICT impact assessment, would fail to capture the full effects of the technology in the setting under study. All these require institutional adaptability, co-ordination of multiple agencies, aggressive focussing on targets, balancing of multiple viewpoints and skilful management of relationships.

CONCLUSIONS

This experience indicates that application of ICT-based development efforts at community levels demands new skills and approaches from a variety of professions, some of which challenge traditional practices in several disciplines. As project implementers and promoters, the team encountered a huge range of skills, disciplines and professions during its regular operations. Besides having to adopt multiple roles in advancing the aims of the project (for instance, handling transportation of equipment, power supply, and language, accommodation of people and equipment, and familiarisation of beneficiaries), members had to be capable of associating and dealing with illiterate farmers, local administrators, technicians, small businessmen, officials, local and national community representatives, senior government officers and government ministers. Since the information solutions span education, health, commerce, agriculture and culture as well as communications, there is no single agency that carries responsibility or authority for community development by means of ICTs. Instead, a range of agencies needs to be mobilised and co-ordinated for full benefits to flow to the community.

Considering how the e Bario project is progressing, it is obvious that successful implementations of rural ICTs within contexts similar to Bario remain challenging and highly experimental. Nothing like it had been known to exist in Malaysia; therefore the participants had few

yardsticks against which to measure or compare their activities. Replicated implementations by government or other agencies will undoubtedly encounter a similar set of challenges that will have to be overcome in order to achieve desirable results.

The experiences gained by the team seem to offer methodological guidance for future professional practice. In the first place, community empowerment by means of information is unlikely to emerge as a result of merely implementing technology. Participatory forms of analysis in which community aspirations and development activities are moulded and tracked in a cyclic manner are more likely to achieve desirable results than are technology implementations that are predicated on fixed expectations and inflexible assumptions of what outcomes should look like. Secondly, this finding has implications for post-intervention evaluation. If assessments are based on predicted outcomes, and much of the outcome is not predicted, then the assessments will be clouded and the value of real benefits underestimated. These lessons will be usefully carried forward into wider scale implementations by no longer needing the intensive research attention given to the e Bario project. Simple to use and replicable methodologies thereby contribute to accelerated technology diffusion, allowing larger numbers of people to enjoy the benefits of access to ICTs.

ENDNOTES

- ¹ The e Bario project is coordinated by Universiti Malaysia Sarawak (UNIMAS) and is financially supported by the Demonstrator Application Grant Scheme (DAGS) and Canada's International Development Research Centre (IDRC).
- ² The team is highly inter-disciplinary, and includes researchers with backgrounds in Information Systems, Anthropology, Cognitive Science, Community Development,

Education, Electrical Engineering and the like. Members include Prof. Khairuddin Ab Hamid, Associate Prof. Dr. Peter Songan, Dr. Alvin Yeo Wee, Mr. Al Khalid Othman, Dr. Ngu Bing Hiong, Soubakeavathi Rethinasamy, Jayapragas Gnaniah, Noor Shah Mohd Salleh, Dr. Roger Harris, Elaine Khoo Guat Lien, Ms. Poline Bala and Jacqueline Bulan (Research Assistant).

³ This discrepancy, often known as “digital gap” or “information gap”, can exist between the rich and the poor, between developed and developing nations, and also between urban and rural populations. According to Hudson (1998), the latter is far more significant since about 80% of the population in the poorest countries live in rural areas. Moreover, most telecommunication infrastructures in developing countries are found in the larger cities and are almost non-existent in rural and remote areas.

⁴ During the period of the project, the government has been promoting the advantages of the “K-economy” in which dependence on physical resources will give way to the exploitation of knowledge resources in the future development of the economy. Dr. Mahathir Mohammad says, “In our pursuits towards developing the K-economy, knowledge has to replace labour and capital as the key factors of production in our economy. The challenge for Malaysia is to develop this knowledge amongst our citizens so that our success will be due to the contributions of Malaysian talents and knowledge workers” (NST, April 4, 2001).

⁵ It is estimated that the distribution of telephones throughout the state is in the ratio of seven phones for 100 people. The number is expected to increase to 15 phones for the same number of people in 2005 and 25 phones for the year 2020 (Sarawak Tribune, April 22, 1999).

⁶ Bario is located in the Kelabit Highlands, close to the border between Kalimantan and Malaysia in the Miri Division of Sarawak prior to World War II, little was known of the Kelabit and their surroundings. The Kelabit’s only means of communication to the closest town was by foot, climbing mountains, following the mountain ridges, and crossing and re-crossing rivers and valleys on a journey that took several weeks. Nowadays, flying to Bario, the main Kelabit center, is the only practical way to get there. There is no road, and a land expedition requires a river journey plus an additional weeklong trek across forested mountains (Bala 2002).

⁷ According to Robert Chambers (1997), PAR is an encompassing method that combines action, reflection, participation and research. Here, PAR has been employed for the purpose of actively involving the people themselves in generating knowledge about their condition and how it can be changed. The impact of the research process then is assessed based on what action people take in response to knowledge that has been accumulated and disseminated during the course of the research process, and the extent to which change takes place, and in what direction the change occurs among the research subjects (Mikkleson, 1995).

⁸ This approach is highly recommended by the World Bank (1998) as a systematic approach to the application of IT to rural communities. In order to support IT adoption that will contribute to rural development, it is essential to begin with the needs of the rural community. As a first step, a feasibility study is required in order to: identify the needs and priorities of rural communities in such areas as agriculture, education, commerce, natural resource management, health, etc.; determine the types of information needed to help meet those needs, including information gathered from the rural population and

transmitted to policy-makers and project designers, and information shared among rural communities; determine the gaps between the information currently available and what is needed; and determine how the use of ICTs can close those gaps and build valuable synergies by mobilizing information across sectors.

⁹ This is obvious from a statement made by one of the respondents. He said, "...we cannot not try this technology. We need to be part of the change that is taking place, otherwise we will be lagging behind technologically, and continue to find it difficult to communicate with the rest of the world" (Harris, Bala, Songan, & Khoo, 2001).

¹⁰ And also are highly different from those faced by highly developed areas in Malaysia, for instance the Klang Valley, where the main issues are security, contractual and financial issues, lack of IT skilled personnel, privacy, deception problems, issues of globalization, ownership, lack of computers, and issues of censorship.

APPENDIX

Potential Areas for Social and Human Development through ICTs in Bario				
Broad Topic Area	Narrow Topic Area	Project Area	Envisioned Scenario	
Education	IT – Based Teaching and Learning	Evaluation of IT-based teaching materials	A significant proportion of the school curriculum is taught using computers. The teachers develop some of their own software for teaching mainstream subjects, as well as adopting pre-written software. All teachers are familiar with the software tools used for creating teaching software that can be used by pupils in the classroom or individually.	
	Effectiveness of the IT Literacy Programme	Measuring the pace of growth of IT literacy among school staff and pupils	IT literacy is embedded into the school curriculum. All pupils are familiar and skilled with computers. They regularly use computers for projects and classroom work and for self study.	
	Attitudes and Intentions, Pupils and Staff	Tracking the attitudes towards technology and the intentions to use it.	Computers are the first choice for getting things done, both for teaching and learning and for school administration. Using the computer is no big deal. Everyone understands that computers are the natural choice for achieving their informational and knowledge-based goals.	
	Distance learning	Distance learning in school	Distance learning in school	School pupils regularly enrol on courses from distant institutions, in a range of co-curriculum subjects. They are awarded certificates of competence from those institutions.
		Distance learning out of school	Distance learning out of school	Non- pupils regularly enrol on courses from distant institutions, in a range of co-curriculum subjects. They are awarded certificates of competence from those institutions.
Culture	Genealogy	Networked language skills learning and building	Pupils at the school engage with software-based learning that originates in distant institutions for the purpose of building language skills.	
		Recording genealogical data in the computer	A comprehensive Kelabit genealogy is recorded on a computer that is connected to the internet and which can be accessed and updated from any computer that is similarly connected. Family trees are documented and photographs of individuals are included. Family life-histories are recorded, including dates and locations of major events.	
	Oral Traditions	Recording and classifying oral traditions	Oral histories are recorded and/or transcribed and maintained in a database on a computer that is accessible via the internet. Traditions are recorded along with what is known of their origin.	
	Indigenous Knowledge	Assembling, classifying, recording and disseminating indigenous knowledge	Indigenous Kelabit knowledge that relates to local history, natural history, the environment, economics and culture is maintained in a database on a computer that is connected to the Internet.	
		Assembling, disseminating and contributing to sources of religious support and intra-denominational communications.	The church community, through its own Web site, regularly communicates with equivalent communities world-wide and augments its local activities as a result.	
	Telecentre design	Adoption of local cultural symbolism in the design of the telecentre and the imagery used.	The custom-built telecentre manifests the local cultural engagement between itself, technology and the outside world.	

APPENDIX CONTINUED

Commerce	Tourism	Developing tourism potential through internet outreach and local tourism resource enhancement – highland trekking	Tourists from the world over are able to book trekking and cultural encounter vacations directly with operators in Bario. Bario becomes a world-class location for such activities, on a par with Nepal.
	Trade	Developing opportunities for trade in local handicrafts Developing opportunities for trade in Bario rice	Local craftsmen obtain a good living from e-commerce for their products. Local farmers obtain a good living from e-commerce in Bario rice. The amount of land given over to rice production increases and unit production is increased as a result of improved methods. Bario rice becomes a trademark product with a premium value, and quality standards are maintained.
Agriculture	Agricultural Practices	Digital trade in digital images – the Bario image bank	Photographs of local culture, geography and agriculture are regularly traded over the Internet, with revenues going to individuals whose images appear in the pictures.
		Assembling, classifying and sharing relevant information relating to rice production Assembling, classifying and sharing relevant information relating to pest control	Rice production greatly increases through access to government extension programmes as well as farmer-to-farmer networks and exchanges. Pest control information is readily available and sharable as soon as pests become a threat.
Health	Upper respiratory illness	Assembling and disseminating relevant information relating to the avoidance and relief of upper respiratory illness	Upper respiratory illness ceases to be the main health complaint in Bario.
	Telemedicine Health care	Opportunities for telemedicine IT Based training in health care	Medical information, including heart beat audio recordings, is regularly exchanged across the internet between medical staff in Bario and doctors in Miri, Kuching and beyond. Community members regularly attend health care programmes presented across the Internet.

APPENDIX CONTINUED

	Attitudes and Intentions	Attitudes and Intentions towards IT	The community is able to express its own needs for information, to develop its own information sources and to obtain access to the information resources it needs in support of the development programmes that it has decided upon for itself. IT becomes the principal vehicle for achieving community development.
Community	Community Empowerment and Well-Being	Development and testing of an appropriate index	The community is able to measure its own advancement and to assign the degree to which that advancement has been achieved as a result of improved access to information and to ICTs.
	Gender Relations	Assessing the influence of IT on gender relations	Women perceive themselves as enjoying improved status and income and are able to attribute a defined proportion of that to their involvement with information and with ICTs.
	Social Communications	Assessing the value and need for improved facilities for social communities	Communications between distant family members become daily commonplace events. Anyone can send or receive an e-mail to anyone they know who has an e-mail account anywhere in the world.
	Telecentre Sustainability	Developing a business model for community ownership.	The community telecentre becomes a self-sustaining entity, free of institutional support, a going business concern.
	Wireless Networking	Wireless networking over a LAN	All computers within a given radius from the community telecentre are potentially able to connect to the local network and to obtain access to the internet.
Technology	Local area cell phones	Applying cellular telephony in a remote local area.	Individuals are able to use local cellular phones to communicate within the Bario district, and possibly to connect to the wider national public telephone service.
	Satellite internet access	Evaluation of satellite internet access	The limitations and potential of access to the internet via satellite are well known by the researchers and by the community.
Human Resource Development	Training in IT and Information Literacy	Effectiveness of methods for achieving IT Literacy	The community develops methods for achieving IT literacy that are appropriate for their own use of IT. It becomes a demonstrably IT literate community.

Chapter 2.19

ICTs and the Communicative Conditions for Democracy: A Local Experiment with Web-Mediated Civic Publicness

Seija Ridell

University of Turku, Finland

ABSTRACT

In this chapter, the contribution of new information and communication technologies to enhancing democracy at the local level is articulated as a practical and empirical question that pertains to the locally established patterns and practices of public communication. It is suggested that in order to realize the democratic potential inherent in ICTs, the compartmentalized, hierarchical and one-way practices of both administrative-political machinery and the mainstream media must be exposed and challenged through concrete action. The article draws upon a participatory action research project in which alternative, dialogical and citizen-oriented forms of web-mediated public communication were created and maintained in close collaboration with grass-roots civic actors and groups. In the experimental project, specific efforts were made to enable and encourage online encounters between those local stakeholders that

rarely meet in the discursive public spaces of mainstream media.

PUBLIC COMMUNICATION, ICTS AND DEMOCRACY

It can be argued, following the American pragmatist philosopher John Dewey (1927), that society exists in communication. In other words, organized social and communal life is not possible without communication. At the same time, the ways in which communication is structured materially and functions socioculturally reveal what kind of society we are talking about. There thus is, as formulated by Lewis Friedland (1996) a “fundamental relationship between communication and democracy” (p. 187).

Starting from this view, a prerequisite for a democratic society is the existence of communicative “spaces,” which enable people not only to get

relevant information about the social world but also to participate openly and on equal terms in the public definition, discussion, consultation, and debate on commonly shared but often controversial and problematic issues. Ideally, these public spaces of communication also allow for and foster interaction between “normally” separate social actors. Currently, the prime (re)producer of the public sphere, the media, and especially the professional institution of journalism, perform poorly in enabling and arranging dialogical relationships in their spaces of publicness.

The new information and communication technologies (ICTs), and above all, the Internet have been endowed with high hopes and deep fears as regards the democratic reinvigoration of the public sphere (see, e.g., Tsagarousianou, 1999; Tsagarousianou et al., 1998). Optimists see the Net as remedy to the elitist and monological ills of mass-mediated public communication. The pessimists, in contrast, fear the Net will annihilate any possibilities of open and equal public sphere. What is problematic in the utopias and dystopias of the digitally mediated public sphere is that they are often not only abstract and normative but also at least implicitly deterministic, explaining sociocultural issues with positive or negative technological causality.

Rather than speculating with ICTs’ impact on the future development of the public sphere, it is more useful to approach the new technologies’ contribution as an empirical question. We should examine, for example, whether ICTs allow citizens to behave and engage publicly in ways that the traditional media do not enable (Coleman, 2001, p. 118); or assess how ICT applications are utilized in electronic democracy projects to promote two-way communication between citizens, public officials, and politicians (Tsagarousianou, 1999, p. 202).

From a pragmatic starting point, one cannot separate ICTs’ public potential from the issue of material democracy. It is hard to imagine how digitally mediated communication could function

democratically unless everybody, regardless of his or her material wealth, social status, and cultural competencies, has access to new communication and information technologies as well as opportunities to obtain adequate computer literacy and navigating skills (cf., Wilhelm, 2000). The challenge of material equality is made even more pressing by the fact that computers are becoming basic tools of daily life. This intensifies the disconnection from the rest of society for those without access to new technologies.

Moreover, the dominant economic trend, boosted by strong industrial players, is toward increasingly interpersonal and privatized uses of new communication technologies as providers of symbolic consumer products at the same time as the Net is increasingly being used as a commercial marketplace (Dahlgren, 2001, pp. 74-75). The economically formatted spaces of the Net only remotely contain the aspect of public communication, even less of democratic public communication. As Wilhelm (2000) asked, “can any of us any longer point to a noncommercial space where the interests of the public are articulated and vocalized in a sustained and deliberative manner?” (p. 4). Similarly, Coleman (2001) pointed out that “it is hard to think of a single site specifically dedicated to public discourse” (p. 120).

In terms of social agency, the Net’s increasingly commercially shaped topography prioritizes the role of individually selecting customers and prevents people from recognizing themselves as actors with a public identity. Thus, apart from equal entry to new technologies at the infrastructural level and the level of technical skills, people also need to be challenged in their privatized customer role as well as be offered stimulation and reasons for using ICTs for public ends.

Given economic and other structural conditions, it is clear that the democratic potential of network technologies does not actualize by itself but requires active involvement in communicative processes. This then, not only poses challenges to the media as the institutionalized (re)producer of

the public sphere. Academic research also needs to problematize its working assumptions about public life, its own role in relation to other social practices, as well as the seemingly noncommittal outsider position of academic subjects implied in the professional identity. As London (1999) pointed out, it is not enough that people within the academy speak across disciplinary boundaries; they should speak across social roles. The need for self-reflexivity is not lessened by a cultural climate hostile to critical assessment of the self-evidence of market conditions (cf., Tsagarousianou, 1999, p. 200; Wilhelm, 2000, p. 114).

In this chapter, the question of ICTs' democratic potential in the processes of public communication is analyzed from a critical media studies perspective and in the context of municipal democracy. Drawing upon a local experiment, this chapter assesses whether ICTs can be employed to introduce other than top-down ways of public debate and participation, contributing, in this way, to new forms of Web-based publicness (Tsagarousianou, 1999, pp. 20-2-203).

The local experiment was conducted in 1998-2000 at the University of Tampere, as part of the Journalism Research Centre's research project *Locality in the Global Net*.¹ The project assumed a participatory action research approach, challenging the dominant idea that scholars' role is to merely provide expertise or extract information from the people they study (London, 1999). Rather, the project wanted to align itself with civic interest and experiment with ICTs in creating a locally based communicative space that would enable people to position themselves as participating publics in relation to the social world.

This chapter starts from a more general context by assessing how the ongoing economic trends condition the media's performance and, related to this, what is the current role of ICTs in the production of journalism. Attention is then

focused on the local level by looking at the practices of public communication and the utilization of ICTs in the context of municipal democracy. Here, our example is the second largest town in Finland, Tampere, which has set itself a "bold and dedicated" objective to become not only the leading Finnish municipality in the use of ICTs but "a global leader in the research, development and application of issues related to the Information Society."²

Then, the discussion in this chapter moves on to describing and assessing the local experiment in Web-mediated civic publicness. During the experiment, an online gathering place — a civic Web forum — was created and sustained in close cooperation with local grassroots citizen groups. By assisting already active groups in furthering Web-mediated public discussion on locally important and often controversial issues, the project aimed to problematize the locally established patterns of public communication.

The focus of the experiment was twofold. Attention was paid not only to ICTs' potential in citizen-government interactions but also to the central role the media play in orchestrating and portraying local public life, which is usually ignored in electronic democracy projects. On the civic Web forum, specific efforts were made to encourage public interaction between those local stakeholders that rarely meet in the mass-mediated spaces of publicness.

The experiment clearly showed that a prerequisite for ICTs' use for more open and dialogical practices of publicness is the tackling of the communicative hierarchies and power structures of local governance, on the one hand, and the challenging of the conventionalized strategies with which journalism frames locally important issues and mediates the relations between local stakeholders, on the other.

PUBLIC LIFE IN CRISIS

Erosion of the Mass-Mediated Public Sphere

In (post)modern societies, it is the institution of mass media, and within it, most notably, the professional practice of journalism, that has specialized in producing and sustaining the public sphere. It is more pervasively — and at the same time seemingly unproblematically — the mass-mediated (journalistic) representations that define and present for “all of us” what is real and relevant in the social world (cf., Hall, 1985). Or, to put the point more generally, societies are increasingly held together by cultural, mostly mass-mediated, representations. In (re)producing these constitutive symbolic links, especially news journalism has established a more or less self-evident status as the transparent discourse of the real (see Ridell, 1998).

Within media studies, the way news journalism performs its cultural task has faced mounting criticism over the past few decades. Critical media scholars have problematized the privileged and unquestioned status of news as the primary definer of social reality. Contrary to professional proclamations and common sense assumptions concerning the mission of the genre, they claim that through its conventionalized working practices, elitist choices of topics and accessing of protagonists as well as strategies of presentation news not only provides flawed information about the social world but also suppresses public discussion concerning it. One of the most important reasons for the latter is seen to be that news denies ordinary people serious entry into the public sphere and instead positions them into a mute, passive, and helpless onlooker role.

Another major drawback of the news genre, especially on television, is its constant, nearly 24 hour rolling out of disconnected bits and pieces of information. In the news, events and happen-

ings pop up haphazardly, unrelated to previous events and social developments and without being linked to their contextual background. This flood of chaotic details makes, as Justin Lewis (1991, p. 143, p. 204) puts it, the specificities of history, of causes and consequences, disappear completely, engendering in this way a deeply historical view of the world. Or, as John Dewey (1927, p. 180) noted decades ago, the triviality of news can be ascribed to the way it reports events as isolated from any connections.

What is noteworthy in this context is that the properties of ICTs and the Net, such as the basically unlimited space and interactivity, have not been taken advantage of in renewing the journalistic working practices and strategies of representation. News journalism, as it currently actualizes on the Net, is largely based on the forms and contents familiar from the older media, circulating material already published in other media outlets and, as a result, perpetuates the genre’s fragmented view of social reality and its one-way relations to the audience. This, of course, can be explained by the fact that, contrary to the idealistic self-image of the profession, the production of journalism in the digitally mediated environment is also conditioned by the largely privately owned media industry. Its commercial logic directs Web-journalism toward a “broadcast model, aimed at aggregating and attracting viewership to key online sites in order to please advertisers” (Wilhelm, 2000, p. 144). According to the critics, the commercial media logic with its concomitant forms of representing social reality is most pervasive in the United States, but it is increasingly becoming a general tendency worldwide (see, e.g., Moog & Sluyter-Beltrao, 2001, p. 48).

The intensifying concentration of ownership and the acceleration of competition within the media industry have already actualized in the way news journalism increasingly uses melodramatic, personalized, and scandalous elements. They are calculated to ensure the effective selling of news products to the largest possible audience in a mar-

ket situation, where the “general” audience is split into segmented subgroups. In terms of representing public life, the economically rational logic of production amplifies the voices of those already prominent in the journalistic public sphere. At the same time, however, political actors who wish to attain public visibility are forced to adapt their actions and strategies to the logic of the media, and especially that of television as the dominant institution of the mass-mediated public sphere (Dahlgren, 2001, p. 84).

As regards the future of the public sphere, the media industry’s current developments are about to render obsolete the idea of collective civic arenas for information and discussion on socially relevant issues and substitute it with the idea of a shopping mall. The commercially formatted environments also on the Net implicate a model of social agency within the confines of which the primary interest is directed to fulfilling privatized needs according to differentiated tastes and habits.³ In this actor role, participating in collective conversation is framed by consumerist interest. The spaces currently constructed by digitally mediated news journalism conform to this commercial logic. Rather than constructing virtual sites for democratic public interaction, Web-mediated journalism offers tailored news commodities for private consumption via different distributional platforms.

To summarize somewhat bluntly the critical views, news journalism, the prime guarantor and buttress of public life in democratic societies, has long been in a state in which it, instead of promoting democracy, actually prevents democracy from functioning. Moreover, as Moog and Sluyter-Beltrao (2001) noted, current “media practices threaten to undermine not only public faith in the political process, but the status of the news media as well” (p. 48).

Focus on the Local: Government, Media, and Public Communication

Regarding the media’s role in contributing to the viability of public life in a municipal context, the situation looks, at least at first glance, more nuanced. At the local level, journalism is even making attempts to reform its established patterns of gaining and conveying information and, in this way, improving its public performance. In Finland, some newspapers have also, in cooperation with academic journalism research, followed the American public journalism movement’s example and tried out more reader-oriented ways of producing and designing news stories, such as arranging local citizen juries (see Kunelius, 1999a, 1999b; Heikkilä, 2000). These experiments have been successful, but it remains to be seen whether they will result in more profound changes in professional identity and daily working practices. As regards local journalism on the Web, the interactive potential inherent in the network technology has not as yet been exploited from the starting point of public journalism.

There are two major problems in the way journalism currently mediates local public life. First, problematic are the conventionalized strategies of presentation that journalism uses in portraying locally important, often controversial, issues and actors connected to them. Instead of arranging discussion and debate around these issues, journalism typically gives concerned parties access to its representational space separately. Thus, in one story of a local newspaper, there is, say, a city manager or a town planner, telling about this or that land use plan that has been initiated or is in the process of being carried through in a specific part of the town. In a subsequent story, voice may then be given to residents who are seen, more often than not, to resist the plans. Furthermore, the plans are often presented by the media as already being finally prepared within the municipal planning

and decision-making machinery. This also holds for cases that, in terms of actual decision making, are still at quite a preliminary stage. In this way, the media contribute to an impression that major changes in daily environment are planned and executed with apparent disregard for people who are directly affected by the changes.

Second, in the cases where the media make active residents and city representatives “meet” in their discursive spaces, the encounters are typically framed by antagonism. Pitting these two groups against one another is part of a larger presentational strategy, on the basis of which journalism makes the interests of these parties appear as inherently and irreversibly confrontational.

The strategies of separation and antagonism exclude the possibility of shared or negotiated interests, not to mention collaboration between residents and local government. By routinely employing these strategies of presentation, journalism mediates local public life in a way that breeds and exacerbates hostilities between stakeholders.

Problematically enough, at least in Finland, municipalities have traditionally relied on local media in their communicative relations with the residents. Not only have the media been the major public platform for official announcements, they have also been used as the main channel for introducing more significant plans to the citizenry. Thus, rather than, for instance, mailing a release or a newsletter to households, local governments delegated the task of public information delivery to the media. The media-dependent communication strategy is considered the cheapest way to reach the majority of residents at the same time as the professional mediation of journalism is believed to lend credibility to the city’s plans.⁴ Here, ICTs already changed the situation somewhat and will probably change it more, as municipalities can utilize the Net as a platform for directly informing residents, for example, about future projects and plans.⁵ However, given the uneven access to ICTs, the local media’s role as a public intermedi-

ary between residents and local government will, in all likelihood, remain central in the future as well.⁶

An additional feature of the locally established practices of public communication in Finland is that people in local government, both elected and employed, tend to avoid communicating with residents in public arenas. In our example town, Tampere, city officials and politicians have traditionally attended other than government-initiated public meetings rarely, even when specifically invited to participate, ignoring in this way the explicit plea and demand, presented by residents in many different occasions, that city representatives should engage in public interaction with the citizenry. Especially problematic is that the city representatives’ views of citizen participation in municipal decision making are presented through the local media instead of being communicated more directly to the people. The refusal of open contact with the residents on public forums, accompanied with reliance on the media as the intermediary agency, deepen the possible suspicions harbored by the latter about the alienation of the professional political and administrative class from people’s everyday priorities and problems.

In many Finnish municipalities, the established patterns of public interaction between local government and active resident groups are now deadlocked in a situation where the interests of a vocal minority, both on the side of residents and on the side of local government, clash time and again. Our example town Tampere is, due to, among other things, the protracted cooperation between social democrats and the political right in leading the city,⁷ as well as the problematic role of local media, an especially illustrative case of the “pathologies” of public communication.

As to the active residents in Tampere, the institutionalized antagonism is actualized in the way residents feel that their needs and expectations concerning, among other things, sustainable environment, are not met in town planning, and

that their views are deliberately ignored in the decision-making processes. The civic distrust is deepened by media coverage that keeps residents and the representatives of government apart, at the same time as it portrays the latter as a partner with powerful economic actors. Moreover, the tendency of the media to generalize the points of view of big corporate players as the only alternative available in given situations, strengthens citizens' perceptions that local government advances, despite claims to the contrary, specific and exclusive interests instead of representing more general interests that would encompass the residents' viewpoints.

Correspondingly, suspicions arise and pre-judgements are reinforced in the direction of city representatives, too, who let the residents' views and opinions be mediated to them through the journalistic filtering. This positions especially active residents into a role where they solely and stubbornly oppose any changes in their environment. The mass-mediated controversy is expressed, for example, in the way leading city officials repeatedly label active residents in the local newspaper as "the vocal minority," giving to understand that the "silent majority" either does not care about or is happy with the current practices of local governance.

The civic discontent and mistrust with the local government, also more generally, in the Finnish municipalities, echo findings of studies that explore what ordinary Americans think about the political system in the United States. Hacker (1996, p. 216), for one, summarized these findings by pointing out that, against conventional wisdom, people are not indifferent to politics but rather feel that ordinary citizens are excluded from government and have no role whatsoever in defining public issues and policy choices. According to Hacker (1996), people perceive political decision making to be a process run by the professional political class, lobbyists representing economic and industrial powers, and journalists. The deep-rooted sense of civic powerlessness in the United

States and elsewhere is also reflected in low voter turnouts in political elections. A similar development has been witnessed in Finland, where the turnout in municipal elections has been in decline for more than a decade, reaching a historical low of 55.9% in the most recent elections (year 2000). In our example town Tampere, the turnout was even lower, 53.6%.

In the United States, it is precisely the erosion of representative politics and professional journalism — something that with good reason can be conceived of as a widespread crisis of the central institutions of modern public life — that has given rise to the public journalism movement. Its advocates within academia and the institution of journalism aim to "rescue" the quality of public communication and public life by carrying out joint projects where the points of view of ordinary people are given priority on journalism's agenda.⁸

LOCAL DEMOCRACY AND ICTS: LESSONS FROM TAMPERE

Proclamations and Promises

As statistics tell, Finland ranks among one of the world's leading nations in terms of the diffusion of new ICTs. Sales of mobile phones, for instance, have shown strong growth in recent years. The number of home PCs and network connections has also steadily increased. One of the densest Internet penetrations in the world bolsters feelings of national pride among many Finnish proponents of an information society. In Finland, 64% of inhabitants (in the age group 15-79) have, according to a survey conducted in 2001, used the Net during the last three months, and 31% of them said that they visit the Web at least five times a week. In Tampere at the end of year 2001, 68% of inhabitants owned a computer, and almost two thirds of inhabitants had a Net connection from their homes, workplaces, or schools.⁹ In actual

practice, however, home network access in Finnish municipalities is concentrated in the more affluent households¹⁰ (cf., Wilhelm, 2000, pp. 54-55, pp. 62-65 for the situation in the United States).

Notwithstanding the still uneven diffusion of ICTs and Net connectivity, the interactive properties of computer network technologies have given rise to hopeful expectations with respect to the functioning of public life and democracy at the local level. The most optimistic prognoses suggest that the new technology will, by making possible direct provision of information and two-way communication between ordinary citizens and the representatives of government, contribute to solving the problems of local governance (cf. Bryan et al., 1998, pp. 1-3). In the background looms the straightforward assumption that wider access to technology and data will somehow automatically enhance participation.

Currently, almost all 432 (in year 2001) Finnish municipalities created a virtual existence for themselves and operated a Web site. Even though many invested a considerable amount of effort in offering government-related information and services online, the more interactive properties of ICTs have thus far been utilized modestly by the municipalities (Ruusula, 2001; Ridell, 2002). This, in fact, also seems to be the case elsewhere (see, e.g., Tsagarousianou, 1998; Hague & Loader, 1999; Richman, 2004).

The city of Tampere started developing its Web pages in 1994, and at the moment, considers itself as one of the leading, if not the leading, municipality in Finland in the use of ICTs and the provision of online governmental services. In 2001, the city launched, in collaboration with local businesses, the University of Tampere, and the Tampere University of Technology, an ambitious eTampere program that aims to make Tampere “a key city within the global Information Society” by the year 2006.¹¹ The program consists of seven modules, one of which is named Infocity and involves developing Tampere into a model of an information society in terms of online

public services, citizens’ access to the Internet, and network skills.¹²

As for online content, the city of Tampere’s Web site offers government-related information quite comprehensively, including contact information of different departments and elected officials; most recent meeting agendas and minutes; maps; planning reviews; statistics; press releases; information on social, health, school, day care, cultural, and traffic services; and so on. The amount of services available electronically is ever increasing. Moreover, it is possible to search from the meeting documents¹³ and other data on the city’s server as well as give feedback by submitting an online form, by sending e-mail to city officials, or by giving an opinion on the city’s virtual discussion section. There are also regular questionnaires and opinion polls online for finding out what residents think about issues that relate to the city’s field of activities.

During the past couple of years, the city of Tampere has started to take advantage of the Net’s interactive properties by complementing its Web site with more innovative two-way applications. To name one, an “interactive survey application” is the town planning game that wishes to offer residents an entertaining way to give their opinion on where additional buildings should be located in specific neighborhoods (for more details, see Seppälä, 2000).

In the development of the city’s online services, the role of the local university, on the one hand, has been stimulating as, for instance, a virtual “Citizen Kiosk” (where residents can ask city officials focused questions and get answers within a few days) was introduced after discussions between the *Locality in the Global Net* project and the city’s Information Office. During the project, the idea of the city council’s votes map was also introduced by the Project (see Ridell, 2001). The Information Office put the idea into practice in 2002.¹⁴

On the other hand, the gradually enhancing interactivity of the city’s Web site cannot be

separated from the attempts by public administration (also in Tampere) to react to the bottom-up demands from active resident groups. In the long run, these pressures may result in real “e-participation services,” where ICT applications are designed by starting from the communicative and participatory needs of citizenry.

Practical Lessons

Both the “bold and dedicated” information society rhetoric and the promises concerning its actualization make the city of Tampere appear as an exemplary model for employing ICTs for the purposes of local democracy. As regards to assisting citizens’ equal access to the Net, the city has also taken many concrete actions in recent years. For instance, the number of free-access terminals in public locales has increased, and the city organizes courses in basic Net skills (here, for instance, the Internet bus called *Nettynysse*¹⁵ has been important) and sponsors third-sector actors who offer computer courses. In terms of enabling and encouraging materially active local citizenship, however, not much has been done so far. The public terminals are meant only for surfing and otherwise “consuming” the Net, and places where residents could learn how to produce their own materials on the Net and also take part in the production are lacking.

The picture changes even more, if we relate the official proclamations to the locally established practices of public communication and ask whether the city of Tampere used ICTs for enlarging the political process by fostering alternative ways to communicate and participate. In this connection, it is especially important to examine whether residents are allowed new ways of behaving and engaging publicly.

In Tampere, a major part of the city’s online services consists of giving wider access to governmental information, even though, as mentioned, ICTs are used in different ways to collect residents’ opinions about the city’s field of activities.

The value of governmental information for the local citizenry cannot, of course, be ignored, especially when we talk about public documents that are parts and products of actual planning and decision-making processes. In these cases, the usefulness of online data relates to the way they expose and make intelligible these processes. Currently, the city of Tampere’s Web site presents the official documents quite statically, screening from view the more dynamic aspects of government. For example, board meeting records merely report the decisions made and refer only briefly, if at all, to discussions and debate on issues taking place during the meetings. The possibilities of hyperlinking are not utilized.¹⁶ Moreover, the layout of Web records resembles that of paper minutes in their user-unfriendliness, with thick rows and narrow margins. This practice of public documentation keeps up the perception of municipal decision making as a monolithic professional institution in the functioning of which the involvement of local residents is not welcome.

The closed appearance of local government is created at the city Web site’s main interface. Its structure follows the departmental headings, reflecting the information-seeking behavior of the municipal service provider rather than organizing the information offered according to the needs of end users.

Furthermore, some features of the new technology, such as the Net’s visuality, are currently employed in a way that actually amplifies the one-directionality of information provision. This is the case, for instance, when persuasive maps are used to present the professionally selected and manufactured scenarios of specific planning areas. Here, we are talking less about employing ICTs for offering the residents a possibility to canvass alternative plans than about convincing them through the one-way dissemination of information.

Apart from the distribution of information, the city of Tampere uses ICTs for mapping, among other things, people’s use of the Internet

and their opinions of the priorities of the city budget. One problem with the city's Web polls is that the questions have been structured, as is typical of surveys, in a way that predetermines the parameters of opinions. Thus, a survey on the city budget follows the established organization of the city's fields of activities, leaving the citizens with no possibility of commenting on, criticizing, or making proposals on the hierarchy of preferences already implicated in the selection and formulation of the questions.¹⁷ In terms of widening the democratic process, however, it is the process of coming to topics of importance that is essential and should be opened to the citizenry. The pre-closing of the agenda also holds for the more two-way applications, such as the town planning game, where the options offered and the end results the player can obtain are fixed in advance (according to the city's official land use policies and plans).

The discussion section also makes rather poor use of the interactive characteristics of ICTs. The submission of opinions and questions is premoderated, and the city uses software that supports the expression of separate opinions instead of that which encourages formation of threads of topical conversation. Moreover, few of the elected and employed officials figure voluntarily in the "discussion." City representatives, especially officeholders, seem to prefer personal phone or e-mail contacts with the residents instead of coming out with public comments and answers. This communicative strategy directs people to adopt the position of a client or a customer in relation to local government, instead of encouraging them to assume a publicly participating citizen role. As such, the increasingly customer-oriented ethos among public officials intertwines interestingly with the more traditional, paternalistic conception of democracy. What is noteworthy is that both notions refuse the needs of alert and questioning citizens interested in participating in local public life and motivated to be treated as parties in the processes of local government.

As a whole, our example town Tampere has thus far developed its Web site in a way that prioritizes the administration's professional and organizational needs. The properties of network technology have been accommodated to the prevailing one-way, top-down structures of public communication rather than being used for involving citizens in a meaningful way or opening new forms of public interaction between residents and local government.

Most tangibly, the effects of existing communication practices are actualized in the narrow position constructed for local citizenry in the city of Tampere's Web site. Residents can retrieve the offered governmental information, use the services available, give feedback, and register their opinions on specific, previously supplied topics within a framework determined beforehand by the city as professional machinery. They are not, however, encouraged to initiate public discussion with city representatives, to problematize the officially established agenda of government, to make value judgements of the way the city is governed, or to submit proposals on how the town should be run. In other words, as official netizens, the residents of Tampere are provided with ample, and sometimes even entertaining, opportunities to react, but negligible opportunities to act. Thus, in terms of public agency, the introduction of ICTs by the city has, instead of renewing or enlarging the democratic process, amplified its established mode of operation.

PROMOTING LOCAL DEMOCRACY THROUGH A RESEARCH PROJECT

Challenging Local Journalism: The Premises of Manse Forum

In the *Locality in the Global Net* project,¹⁸ the existing practices of public communication in Tampere were conceived of as a prime condition for the democratic employment of ICTs. The proj-

ect proceeded from the conviction that unless the communicative pathologies are explicitly tackled, no technological application can possibly be of use in enhancing the viability of local democracy.

The starting point of the project was to problematize through practical action the antagonistic frame that governs public relationships between active residents, city officials, and politicians in Tampere and is effectively sustained and often also intensified by the local media. The Internet's interactive properties were seen to offer new possibilities for opening and facilitating direct connections between local stakeholders and, through this process, for challenging local journalism to improve its mediating performance.

In the background of the project, there was the more general promise of the Internet's potential as a locally grounded space for open and citizen-oriented forms of public communication. A more theoretical framework was offered by the notion of Web-mediated civic publicness that can be seen to actualize in specific citizen-oriented genres. The notion of civic publicness is based on the view that citizens should be able to assume an active and creative role as participants in and as (co)producers of the public sphere, allowed to take part in the definition of the domain and agenda of public discussion. The civic Web genres that would enable this kind of public behavior, however, are something that do not exist as yet but must be initiated, created, and stabilized as parts of locally rooted activities and struggles.

In order to experiment with the Net's relevance as a local public sphere, the project established a virtual space — Manse Forum — that served as an arena for encouraging dialogical relationships among city representatives, politicians, residents, and economic actors as well as an arena for trying out citizen-oriented forms and contents. Moreover, in accordance with the participatory action research approach (cf., Whyte, 1991), the project's researcher entered into close cooperation with some local grassroots citizen groups, regularly attending the groups' meetings and offering her

time and the project's resources to group members for producing materials on Manse Forum and for getting mainstream media coverage for the issues the groups considered important.

By collaborating in this way with grassroots groups, the Locality project assumed a more radically citizen-oriented stand than is typical in so-called public journalism experiments. In the latter, the partners are usually journalistic enterprises or specific editorial offices, the primary aim being to solve journalism's problems together with the professional actors. Thus, whereas the advocates of public journalism want to raise citizens' concerns in the foreground of the agenda of public communication without compromising journalism's role as the privileged intermediary of public life, on Manse Forum, the purpose was to circumvent the self-evident primacy of journalism as the producer of the public sphere, and instead attempt to more directly realize — with the help of ICTs — citizen-oriented forms and practices of public communication.

With respect to mainstream journalism, there are at least two levels at which the notion of civic publicness challenges its conventionalized practices, also problematizing the political commitments implicated in professional proclamations.

First, the collaboration with grassroots actors and groups raises to the public agenda issues and points of view that are often excluded from the journalistic public sphere or are framed there as troublemaking from the viewpoint of the rational functioning of society. By providing an outlet for those alternative opinions that tend to be marginalized by journalism, citizen-oriented publicness wishes to widen the circle of actors and groups having the right to a public voice.

Moreover, for journalism, while rhetorically endorsing civic interest, a practical alignment with grassroots actors is a despicable transgression of the highly valued norms of impartiality and neutrality — it signals taking an opinionated stand, which is strictly forbidden to the specialized producers of the public sphere. The professional

proclamations, however, ignore the fact that journalism is, in actual practice, far from nonpartisan. With its elitist source relations and patterns of accessing, it promotes actively and effectively the viewpoints of those with economic, political, or other forms of power. Thus, in reporting assumedly objectively what takes place in the social world, journalists implicate that, in terms of power structures and relations, everything is as it should be. In other words, in journalism, the limits of public communication — and at the same time the parameters of acceptable thinking and action — are drawn in a way that affirms the *status quo*. The alignment with the powerful is so deeply embedded in the working practices of journalism and so internalized by journalists that it appears to them as unbiased and natural.

Second, in terms of civic publicness, it is not enough to enable the multivoicedness of the public sphere at the representational level. What is essential is to arrange dialogical relationships among all relevant parties on issues that concern many people or are perceived as important by them. This, then, requires deliberately crossing over the power-related boundaries of established social roles — something that journalism cautiously avoids doing — for discussion between differently positioned stakeholders does not come about by itself.

In contrast to journalism's affirmative logic of mediation, the notion of civic publicness stresses the importance of such discursive forums that allow not only interaction and consultation among participants but, ideally, also enable an open and public treatment of controversy. Understood in this way, public dialogue exceeds the associative uses of conversation and may serve as a vehicle for facing together and exploring and solving collaboratively complex issues in which values and interests of actors differ and conflict.

Manse Forum in Action

The guiding principle in realizing Manse Forum was the assumption that dialogical and deliberative public discussion does not arise and progress automatically, but it requires active involvement in communicative relations.¹⁹ Therefore, systematic efforts were made to engage in dialogue all those actors seen to have a relevant connection to given issues. Here, the researcher and her assistant, together with some active citizens, encouraged concerned parties to take part in discussions. For instance, responsible city officials were asked to comment on the points put forward on Manse Forum or to provide answers to questions presented there. Economic actors were also urged to take part in discussions and answer questions that concerned them.

Another basic line of operation was to focus on topics that were considered by active residents and grassroots civic groups as important issues in the Tampere region. A major part of these issues concerned shared physical spaces that residents perceived as a common good instead of being primarily a target for private profit making, exploited under the guise of proprietary secrets.

In practical terms, the production of Manse Forum was linked to the activities of three grassroots groups in Tampere. These groups manifest, in the Finnish context, a new locally based citizen activism that in recent years has arisen in different parts of the world, especially (though not solely) in bigger cities (see, for instance, Richard, 1999). Typical of this urban activism is that it gathers together people who feel dissatisfied over the party-based representational politics and who wish to tackle more directly plans that are seen to deteriorate the quality of near environs or risk the standards of municipal services. Also characteristically, the wish to cooperate in order to defend against the perceived threats, exceeds

the ideological differences the participants may otherwise have among themselves.

One of three grassroots citizen groups was the local town forum, *Tampere-foorumi*, which has been active since 1996, defining as its main goal to initiate and arrange diverse and constructive public discussion on locally relevant issues between political power holders, economic actors, and city residents. Rather than being an interest group, *Tampere-foorumi* represents in itself a form of civic publicness, its activities ranging from the arrangement of live public meetings to publishing a leaflet. The researcher, and later also her assistant, regularly attended the meetings of *Tampere-foorumi*'s planning group and participated actively in its work. In comparison to two other groups, the collaboration functioned at a different level, and, related to this, the Manse Forum Web site presents itself as *Tampere-foorumi*'s virtual counterpart. Even the Web site's graphical symbols refer to town forum activities, and there is also contact information of people active in the planning group, the forum's mission statement, and the records of public meetings arranged by *Tampere-foorumi*.²⁰

The second group consisted of active residents who took part in the process of outlining a draft for the city of Tampere's sustainable development policy program under the banner Local Agenda 21. The initiator of the process was the city's environmental department, within which some progressive officials invited groups of concerned residents to brainstorm, during Fall 1998 and Spring 1999, ideas for the sustainable development policy text. The researcher attended the meetings of the *Local Agenda 21 planning culture group* that focused on producing ideas for opening the processes of town planning in Tampere and improving communication between city representatives and residents.

The third group was a grassroots movement *Mältinranta-liike* that has been active since 1997, aiming to problematize, on globally and locally based environmental grounds, the city of Tam-

pere's plan to build a motor bridge in the middle of town. The movement demanded, among other things, that a municipal referendum be arranged on the issue, and it collected almost 10000 names to back up its initiative. The researcher attended *Mältinranta* movement's meetings and gave the group members technical assistance in using the Net, in participating in the discussions, and in producing other materials on Manse Forum. She also helped the group in its efforts to get its viewpoints acknowledged in mainstream media.

In the discursive space of Manse Forum, several issue-based sections were created to address questions considered important by the collaborating groups. Thus, a section was established for the disputed bridge case and another for following the planning of the area that was the focus of interest of the Agenda 21 group. There are also sections that frame their topics more generally or in terms of everyday activities, such as "Dwelling," "Traffic," "Democracy in Tampere," and "Sustainable consumption." Members of *Tampere-foorumi*'s planning group acted as coordinators and facilitators in most of the sections.

Each topical section has a front page with a short, regularly updated presentation of the issue at hand, also containing related background material and hyperlinks to pertinent information on outside pages, such as to meeting agendas and minutes on the city of Tampere's Web site. A central part of each section is an actively facilitated discussion arena.

Regular discussion-oriented contents²¹ on Manse Forum are also public queries to city representatives and, less regularly, to significant economic actors. The *Mältinranta* movement has made several queries to city council members and members of the technical board on the bridge issue. *Tampere-foorumi*'s planning group, for its part, carries through follow-up queries to different stakeholders after its public meetings. What is noteworthy in these queries is that they are closely linked to offline activities, utilizing the Web in a complementary way to advance the

public treatment of given issues, especially by drawing into collective conversation those parties that choose not to take part in face-to-face gatherings or are not “disturbed” by the producers of the mass-mediated public sphere. Moreover, in contrast to the online surveys and polls by the city of Tampere, on Manse Forum, it is the citizens who formulate the questions and pose them to the representatives of local government.

Linked to the activities of Agenda 21 group, a monitoring system for citizens’ initiatives was created on Manse Forum. The group submitted an official proposal concerning direct citizen participation in a significant planning project, followed actively the treatment of the proposal by the planning and decision-making machinery, and documented its phases throughout the process. The year-long monitoring produced public records that enable those interested to follow the process and get a many-sided and dynamic view of a locally important case. In the long run, this kind of online monitoring can be seen to form permanent traces of collective civic memory.

Additional citizen-oriented forms on Manse Forum, to mention here just two, are an open bulletin board and a public participant’s guidebook. The bulletin board is meant for posting announcements of events and issues by local citizen groups and associations, and the city’s notices are picked there by the facilitators when directly relating or otherwise pertinent to issues under discussion on Manse Forum.

The guide for public participants, for its part, offers easily accessible information about local residents’ legal rights, such as the early and continuous citizen comment and participation, stipulated as a necessary part of significant land use projects in the national building act. The guide also gives down-to-earth advice concerning, among other things, the possibilities of defending one’s rights and fighting one’s case (both as a citizen and a consumer) or taking action against

plans that threaten to destroy one’s environment or deteriorate its quality. People are also invited to give examples and tell their own experiences as well as participate in developing the guide by offering critique and making proposals for improvements. The interactivity of the guide could be increased by complementing it with an online service where people can submit questions to legal experts.

All contributions on Manse Forum are meant to be dialogical, wishing to make visible the interactional aspects of all public communication. Thus, not only discussions and queries but also, for example, the online monitoring, intends to alert city representatives to realize that residents are interested in local issues and are motivated to be engaged more directly in their planning. At the same time, the point is to demonstrate that enhanced interactivity of public communication increases the diversity and relevance of information. For instance, by following Manse Forum and attending discussions there, the citizenry and city representatives can be directly informed about each others’ views on specific issues. In the long run, the dialogical forms of Web-mediated civic publicness accumulate into a wealth of case-related civic information that provides a more nuanced and contextualized picture of local reality than is possible by relying only on traditional media coverage of issues.

Moreover, by giving active residents and resident groups a prominent role in producing Manse Forum, the Locality project wanted to challenge journalists and public administrators to rethink their own roles as currently defined within the power-related structures of public communication.

Struggling for Civic Web Genres

From a wider sociocultural perspective, the forms created and maintained on Manse Forum, together

with local grassroots groups, can be viewed as embryos of Web-mediated civic genres: as alternative cultural models that enable, formalize, and stabilize citizen-oriented communicative action. The importance of civic genres lies in the fact that through them, people can recognize themselves and act as participants of public discussion and public life instead of being positioned — as by administrative and most media genres — into the role of spectators, whose activity is restricted to expressing individual preferences and reacting to or choosing from given alternatives.

A key question in reforming local democracy with the help of ICTs concerns the design of such Web-mediated genres that allow and encourage people to assume a publicly participating citizen role. This, of course, is more easily said than done. Namely, genres are cultural artefacts that codify the processes of public interaction in a way that fits into the established patterns of social activity and communicative relations in communities. In other words, initiating alternative genres is a potentially subversive action, as it means, to slightly rephrase Agre's (1998, p. 98) point, intervening in the communicative relationships and problematizing the values and power relations they reflect.

A major cultural obstacle that stays in the way of realizing alternative Web genres and of contributing, in this way, to virtual civic publicness, is the taken-for-granted attitude of mainstream media. The self-evident pervasiveness of media in people's everyday life makes it difficult to challenge with civic forms of public discourse and action the "audiencing" genres that the current trends of media industry ever more efficiently produce and distribute.

During the Locality project, a major stumbling block was that the network technology appeared more or less alien to many grassroots actors, who, as such, were highly motivated to engage in public interaction and willing to raise public discussion on local issues. In the background, there was primarily the fact that most of the activ-

ists, especially in the Mältinranta movement and Agenda 21 group, neither had, for economic or other reasons, ready access to the Net nor skills to use it. During the subproject, the researcher also witnessed these active citizens' serious doubts about their possibilities and abilities to learn the required technical skills as well as their skepticism — partly due to unequal access to computers and telecommunications capabilities — of the new technology's civic potential.

Another major obstacle in the course of the project was the apparent reluctance of city representatives and especially of officeholders to interact openly with active residents and grassroots activists on Manse Forum. It is noteworthy that many of those officials who gave reasons to facilitators for their refusal to participate in discussion or to answer questions directed at them, pleaded to lack of time because of other, more pressing tasks. The workload of city servants is real, tracing back to insufficient human resources, and it may even risk the Internet's potential as an interactive medium in public administration.²² However, the stressing of importance of other duties compared with using one's work time for "associating with residents on the Net,"²³ also reveals that the Internet is not as yet considered an appropriate channel for communication between citizenry and local government.

The unaccommodating attitude of city representatives discouraged Manse Forum's facilitators, undermining their motivation and, as a whole, frustrating their attempts to organize and coordinate diverse and dialogical public discussion. As such, the shunning of officeholders from open interaction with the citizenry is a familiar phenomenon from other electronic democracy projects. Schuler (1996, p. 124), for instance, referred to early experiences from Santa Monica, where government officials, according to him, were unwilling to participate in public discussion and debate on an equal footing with residents (see also Schmidtke, 1998; Tambini, 1998).

WEB-MEDIATED CIVIC PUBLICNESS AND THE FUTURE OF LOCAL DEMOCRACY

To summarize, the observations made during the Locality project are, first, in line with those views that stress the importance of equal entry to the computer network technology, including physical- and skill-based access for all residents, as a basic requirement for a democratic information society. Without providing the material means to enter and participate in the public forum, the democratic hopes attached to new technology in the theoretical cyberutopias and in the official information society rhetoric will come to nothing.

Enlarging public connectivity by setting up free-access terminals at libraries, social service agencies, employment offices, senior and youth centers, and other public locales is a good start. This, however, needs to be complemented with the establishment of new physical locations with computer and telecommunications facilities, where training and technical assistance are provided. Wired civic centers of this kind would make it possible for people to engage in local public life as its active stakeholders — by not only enabling their participation in discussion offline and online but also by encouraging them to take part in initiating public activities and in producing paper and Web publications.

Realizing the material requirements would mean making a public policy choice that defines municipal online services as a community asset and sees residents as its co-owners. Moreover, it would mean developing these services as public cybercasting or as an integral part of the public library system (cf., Grundner, cited in Schuler, 1996, pp. 281-282).

Second, in order to tap ICTs' democratic potential and to actualize genres of Web-mediated civic publicness, it is at least as necessary to problematize and alter the locally settled communicative conditions by tackling their pathologies. Providing citizens with universal access and network skills

remains empty staging, unless these are linked to actual possibilities to communicate meaningfully with the representatives of local government. Moreover, neither the amount of governmental information and services available online nor the technical sophistication of applications will enhance the viability of municipal democracy, if local government does not respect residents' informational needs, communicate with citizenry in public, and open its processes to more direct citizen participation. In other words, innovations in local democratic practice are a prerequisite for the designation of truly interactive online services and the introduction of Web-based participation tools.

In many respects, ICTs' democratic potential in the local context boils down to power, the essential question being who is allowed in municipalities to take part in the processes of defining and implementing democracy. One can argue that a system of government is entitled to call itself democratic only after its policy choices are negotiable and open to public scrutiny. Thus, to be truly democratic, local government should encourage open public discussion and debate on the nature and premises of its agenda.

Traditionally, in Finnish municipalities, citizenry has not been allowed an active and creative role in delineating and deciding the public agenda and policy choices. Our example town, Tampere, is an illustrative case, as there the strategic lines of operation have been strictly in the hands of leading city officials and the leaders of the two biggest party groups.²⁴ In Tampere, the relations between active residents and city representatives have also been exceptionally poor. Rather than perceiving grassroots actors as knowledgeable experts of their environment and as potential partners in town planning processes, public administrators tended to treat them as rivals or even enemies who need to be shown time and again where the actual power resides.

Even though recent reforms in legislation are forcing Finnish municipalities to open their

processes of land use and urban planning,²⁵ and there are even signs of a gradual opening of strategic planning processes, it will take time and a long series of environmental and other struggles before local government is viewed, not to mention practiced, as a joint project, where public officials, politicians, residents, and other stakeholders together envision possible futures and try to innovate solutions to problematic issues. An additional factor in the development is the professionalized, increasingly customer-oriented ethos that is currently pervading public administration and perceiving citizens as consumers of democracy instead of as democracy's coproducers.

Obviously, given the rigidity of local public communication practices, the ICTs will change nothing. However, when connected to the intensifying bottom-up pressures from the grassroots level and the experiments in public journalism and civic publicness, the interactive properties of ICTs will definitely have a transformative effect on the asymmetrical distribution of power that currently structures public communication in municipalities. Namely, as Hacker (1996) pointed out:

...interactive communication creates a symmetry of communication between leaders and citizens. This shifts the balance of power and is a threat to leaders who wish to remain elitist in their administration. Interactive approaches to political communication expand the public sphere and decrease the elite sphere of power and influence. (p. 224)

In assessing the communicative conditions of democratic information society at the local level, one should not bypass the local media. To start with, their role is superior when talking about the cultural image of ICTs and the possibility to locate their deployment and use more generally in the public interest agenda. If the media keep framing the meaning of new technology predominantly in market-defined terms, this will suppress in

people's eyes the Internet's potential as a public and democratic resource, effectively marginalizing its civic uses. Thus, one challenge for the media is to give room, in their representations of the development of the Net, also for the significance of civic interest instead of strengthening the iron hold of consumerism.

A major challenge, especially for mainstream journalism, offline and online, concerns its capabilities to organize public communication in a way that makes possible dialogical and deliberative public discussion. As was argued in this article, the routinely employed journalistic strategies of separation and antagonism keep local stakeholders apart, effectively preventing any real interaction across the established social roles and boundaries of power relations.

The conventionalized strategies of journalistic representation have profound social consequences, as they construct for people a role as helpless onlookers without possibilities to have any real impact, even on the local reality. Thus, the challenge posed for journalism in terms of public agency is whether the profession is able to develop such strategies that do not represent local government as a priori closed from the citizenry but rather emphasize its dynamic nature, making visible those points in the long-lasting processes of planning and decision making that contain officially constructed and self-defined places for citizen involvement. In this way, journalism would enable people to recognize and assume a publicly participating citizen role, rather than suggest a fatalistic attitude to its audience.

As regards developing the space of local journalism toward a dialogical sphere of publicness, an essential requirement relates to exposing the imbalances of material and structural positions of different stakeholders. Rather than implicitly endorsing *status quo*, journalism should extend public dialogue to involve power relations and collision of interests. In practical terms, this would demand engaging not only political but

also economic power holders as participants in public interaction and, in this way, making visible the latter's integration in the local social web as publicly accountable actors. This, for its part, would make it possible to problematize the dominance of economic values and reevaluate the self-evident priority of corporate interests and profit-making, currently so prominent in the mass-mediated public sphere.

³ A parallel development is the erosion of physical public space by the colonization of commercialization and the increasingly privatized needs of transportation (see, for instance, Kressel, 1998).

⁴ Personal communication and e-mail communication with the Head of Information, the City of Tampere, Spring, 1999.

⁵ In Tampere, for instance, the Net was recently approved as an official platform for the city's announcements and notices.

⁶ Though, it should be remembered that not everybody can afford or even wants to subscribe to a newspaper. For instance, in Tampere, with a history as a workers' town and with a monopoly newspaper with a right-wing history, the ideological reasons for not subscribing to the local newspaper should not be underestimated.

⁷ See Laine and Peltonen's (2000) description of the "companion in arms axis" that was formed between social democrats and the right-wing party after World War II, having since been a structural element of local governance in Tampere.

⁸ See, for instance, Charity (1995), Merritt (1995), and Rosen (1991, 1994, 1996).

¹⁰ It should be noted that the amount of homes being connected to the Net does not mean that the problems of access would be resolved. A two-tiered system seems to be speedily developing on the teleoperator and the Internet operator market, meaning that with more money, you get faster and more effective connections. As Bryan et al. (1998, p. 15) pointed out, "even the Internet has a fast lane and a slow lane," thus reproducing, like the old media, social exclusion.

¹³ The usefulness of electronic records, however, is lessened by the fact that agendas and minutes are available online only for two years. It is possible to get hold of the older documents by going to city hall and asking to see them or by getting a chargeable copy.

¹⁴ See <http://inter2.tampere.fi/aanestys/> [30.12.2002].

¹⁵ See <http://www.tampere.fi/kirjasto/nettinsysse/english.htm>. [30.12.2002].

¹⁶ The hyperlinking of agendas and minutes with, for instance, dynamic geographical information would offer an interesting direction in terms of developing ICT applications that serve citizens' information needs and increase the public transparency of local government. For more on the participatory potential of geographical information systems (GIS), see, for instance, Craig (2002), Craig et al. (1998), and Sarjakoski (1998).

¹⁷ From a democracy perspective, an initial problem with polling, as formulated by Neil Postman (1993, pp. 132-136), is that people do not exactly “have” opinions but are, rather, involved in “opinioning.” Thus, in aggregating presumably finished and measurable opinions into public opinion, polling hides from view the complex and culturally mediated processes of thinking that go to the heart of democratic society.

¹⁸ *The Locality in the Global Net* project was conducted from 1998 to 2000 by the Journalism Research and Development Centre, University of Tampere. The project created an umbrella Web site named Manse Square, with three independent but interrelated sub-sites. All Manse Square Web sites are still active, providing a virtual space for local neighborhoods (Manse Communities), a place for civic discussion and public debate for all inhabitants of the city of Tampere (Manse Forum), and a platform for the production of local news and stories for the university’s journalism students (Manse Media). See the final report of the project at <http://mansetori.uta.fi/report/default.htm> [30.12.2002]. For more information about Manse Forum, see Ridell (2001).

¹⁹ Moreover, as studies on Usenet’s political newsgroups and other virtual forums show, public interaction on the Web seems to follow a dynamics that is more or less inimical to thoughtful and sustained public discussion and debate. Rather than listening to other participants’ viewpoints, reflecting on the merits of their arguments, and reevaluating their own positions in relation to new information, discussants voice their own preferences and use other messages to amplify their views. Wilhelm’s (1999, 2000) conclusion of the Web as an arena for public discussion is quite somber. According to him (2000, p. 98), the way virtual forums are

currently designed and used may expand the self-expression and monologue, while doing little to solve social and political problems (see also Dutton, 1996; Hill & Hughes, 1998; Docter & Dutton, 1999).

²⁰ See <http://manseforumi.uta.fi/Mission-E.htm> [30.12.2002].

²¹ The grassroots activists produced other, more self-expressive contents on Manse Forum, such as poems and photo exhibitions.

²² Let it be noted that even people in Tampereforumi’s planning group, despite their commitment to arranging public interaction, were often too busy to participate other than sporadically.

²³ Research interview with a municipal official, the city of Tampere, Spring, 2000.

²⁴ This is reflected, for instance, in the rhetoric and argumentation employed in official strategy and policy documents of the city of Tampere. As Eriksson and Lehtimäki (1998, p. 296) noted of the Tampere City Strategy text, it “convincingly reproduces the top hierarchical position of the strategy maker(s),” constituting other actors primarily as “followers or subordinates who need to adopt the vision and to join the City Management in realising it.”

²⁵ There are several laws that have been reformed significantly during the 1990s in Finland, such as Municipal Act, Planning and Construction Act and Constitution, to mention the most important. In all reforms, the role of more direct citizen participation as a complementary element of the representational government has been stressed.

Chapter 2.20

The Creation of a Commercial Software Development Company in a Developing Country for Outsourcing Purposes

Sam Lubbe

University of KwaZulu-Natal, South Africa

ABSTRACT

SDC has financial services knowledge with cross-industry technical skill capabilities. Their emphasis is on advanced development techniques and tools. The model they used is proving to be successful for all parties and the growth process had provided them with invaluable experience and expertise in the HR transformation. The lesson they have is that they need to ensure that they have a strong presence in the market.

INTRODUCTION

Some case studies are qualitative while some are not. Custom also has it that not everything is a case,

but firstly having established the criteria for case studies, it was therefore decided to subsequently follow the case study method. This was also done because the authors felt that the creation of a software development company (SDC) justified a case study. This was further motivated because there has been a growing interest in the use of qualitative techniques in the administrative sciences and the case study could do justification to research.

This case study will therefore report on the creation of a software development company (SDC) in South Africa using a detailed description of interrelationships between perceptions of what is happening in developing countries and what is happening in developed countries. The case describes the scenario and contributions stemming from the methodological point of view. The case

study also illustrates points such as the value of following a structured method of establishing a methodology for starting such an SDC. The need is discussed for context specific measures of the characteristics for an SDC and the reporting of process measures while establishing an evaluation of the SDC that is being created. Also the need to explore the necessary relationships between the clients and the systems that are created and the perceptions of the clients are discussed. This is because the unidirectional assessment of the SDC can impact on the users and user characteristics and on computer software implementation. Despite the normative nature of the SDC the most important conclusion is the desirability for a variety of approaches to studying SDCs. No one approach to SDC research can provide the richness that information systems research needs for further advancement of the skills in a developing country.

INFORMATION SYSTEMS IN SOUTH AFRICA IN CONTEXT

South Africa is a medium sized country, 471,000 square miles at the southern tip of the African continent with a population of some 43 million people. Relative to the rest of Africa, South Africa is substantially industrialised. The Republic of South Africa is a wealthy country from an industrial and agricultural point of view and computers have been actively in use in South African business and industry since the early 1960s when both IBM and ICL opened offices in Johannesburg. Today South Africa employs computers in every aspect of industry, business, and government, as well as having a relatively high percentage of home computers among the middle class. All the major vendors are present and there is considerable interest in hi-tech.

The business and industrial sectors in South Africa are as sophisticated as anywhere in the world in the use of information systems. South

Africa leads the world in deep level mining and supports this activity extensively with computer systems. The country also has a substantial financial services sector that has won international recognition for its excellence in information technology. For example, the First National Bank (FNB) of South Africa was named one of the world's top 100 computer users by *ComputerWorld Magazine* in May 1995 and in July 1996; the same bank also won the prestigious Smithsonian Institute prize for the innovative application of biometrics in their information technology.

Background

Information systems play an important role in the survival of a country and its organisations. Coupled with the lower costs, increased processing capabilities of hardware, and cost conscientiousness of many CIOs and CEOs, it becomes a vital source of deriving efficient and cost effective solutions for organisational problems. A good manager using a well-organised information system enhances any organisation's ability to compete favourably and it minimizes the assumptions and presumptions in decision making that could lead to bad performance and eventually the downfall of the organisation.

In many organisations, information technology (IT) (especially software) also shapes the process of product development. Organisations that are able to adapt new software technology into their development process have often seen increased productivity and improvement overall in product quality. This is why so much emphasis is being placed in South Africa on the correct procedure for software development. This has provided the motivation for many organisations to strive to become a software development company (SDC).

The cost of software development systems, like information systems, stems directly from the cost of resources required to provide and support the functions of systems. The decision to outsource development to SDCs can be a serious strategic

change. Therefore, before managers can support software engineering, these SDCs must have a realistic understanding of the viability and of the costs and benefits of the tools. Cost benefit analysis usually can mean continuous reaching of goals (Lubbe, 1997). Benefits must usually exceed costs to justify the expense and this is another reason why organisations will look at SDCs as an alternative to developing software in-house.

The economics of software engineering has often focused on software cost estimation. Essentially this is a consideration of the costs related to single development projects. First world sophistication, which is in demand, requires worldwide growth of the use of information technology. However, a worldwide shortage of information technology skills exists. The high level of South African skills (business and technical) consequently causes an alarming rate of loss of top skills and thus a shortage of quality human resources in the IT sector.

Motivation for Starting a Commercial Software Development Operation

The external business pressure causes conversions and downsizing of industry sectors. This in turn causes a trend towards more efficient, focused business SDCs. The increasing competition in the global market place and new entrance is another motivation for starting a new commercial software development operation. The demand for faster and more cost-effective software systems delivery causes better local content as well as flawless production services, which can also be another motivating factor.

Some of the internal IT pressures such as skill shortages, the need for incentives to retain IT staff, perceived lack of professionalism, better productivity, delivery speed, quality, and clear career paths could be a very good motivating factor for starting an SDC.

Further motivation for starting an SDC in developing countries could be to stop the outflow of South African talent by creating job opportunities for new graduates. The worldwide dispersion of these talents could be prevented, ensuring a nucleus of software developers.

For all software developers, recruitment opportunities would be created, thus enabling a contracting option and keeping their talent for the newly proposed SDCs. The SDC should ensure retraining of these people—ensuring interest, loyalty, and the driving force to succeed in the company. Creating the previously mentioned nucleus of software experts makes it easier for customers to rely on excellent solutions and maintenance of the completed products. The solution could be a result of a mixture of the right professionals leading to applicable end products.

Creating a Commercial Software Development Company

Background to Starting a New SDC

The vision of the SDC company is to become the leading SA systems integrator for speed of delivery, quality, and value, using the most advanced tools and techniques, and to be the most appealing IT employer in SA.

One should keep in mind that to start a large-scale software development company, some projects, such as high-volume commercial transactions processing systems, require advanced analysis, design, and development techniques. This will also entail doing an evaluation of the SDC's software development process in respect of the capability maturity model (CMM). Currently a minimum of CMM Level 3 has been targeted. This will ensure that a standard system development process is integrated throughout all development activities of the SDC. As a result, of this a degree of certainty in the quality of the software products will be guaranteed. Furthermore, this will also allow

The Creation of a Commercial Software Development Company

the SDC to benchmark its development process against international standards.

The present SDC company has signed and completed more than 1700 maintenance requests in their first year of operation. On the other hand, they have finished 99 projects in the first year and the following figures were provided in respect of the attainment of their goals:

- Of 78 projects with planned end dates:
 - 18% were delivered ahead of time.
 - 44% were delivered on time.
 - 27% were delivered within one month of the planned dates giving them a completed figure of 89%.

An issue of concern is that they did not speak about the 11% that were needed to complete a 100% record. Of the 60 projects with initial costs estimates:

- 52% were delivered under estimate.
- 28% were delivered on estimate.
- Only 20% were delivered slightly over.

The 20% delivered slightly over, needs to be defined but they declined the offer to clarify this.

The company was created in the late 1990s by combing an established existing organisation and some key staff from the present organisation in the ratio of 3:2. The organisation presently has nearly 200 staff members and is based in one of the harbour cities of South Africa. Their future aim is to expand into international markets. They have some academic connections with one SA university since 1990 and had recruited some of the IS graduates from this university. They regard this as a long and mutual friendship.

The managing structure of the company starts as a normal hierarchical organisation with a managing director at the top and directors for various departments. The operations director controls the following sectors: strategy and architecture,

software factory, business intelligence, systems maintenance, support and renewal, project office, and network infrastructure (see Figure 1).

The company identified the software manufacturing industry in South Africa as a situation of concern. They identified the current outputs of the IT industry as of a low standard and regard this as a future challenge for the success of the SDC. Their strategy is basically to prevent high staff turnover and to keep abreast of dramatic changes in the software manufacturing business.

Services and Operations of the SDC Company

The company's services include items such as strategy and architecture, software factory, business intelligence, systems maintenance, and support renewal.

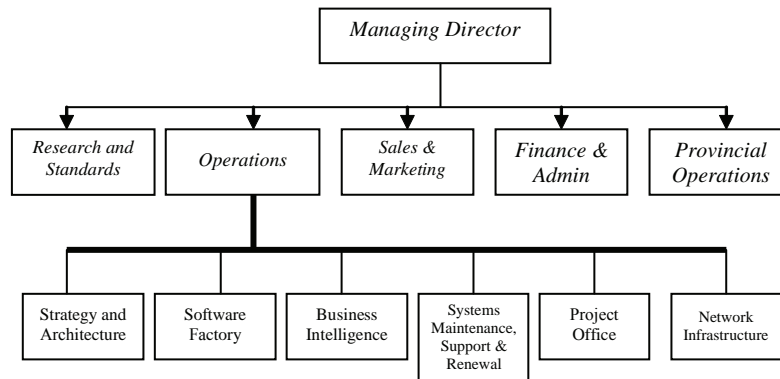

On the strategic architecture side of the SDC, IT enabled business transformation consulting for this newly established organisation consists of project definition, planning, and management. Analysis is an important aspect of any SDC and for this specific SDC that had been set up.

The design of processes, applications, and technology are important factors for managers of SDC and the organisation. Business migration and development coordination is an aspect that should be kept in mind by the managers when they want to develop a new system or application and development of technology.

All of this ensures business change and proper development coordination. The SDC can evaluate packages on behalf of any organisation and look at gap analysis in order to ensure that all variations are within all acceptable norms.

Project management is an important facet of systems development. The SDC would, however, struggle to do some systems integration if they are not an integral part of the company. The SDCs staff however, needs some training in order to ensure a successful implementation.

Figure 1. Organogram for SDC

On the other hand, business systems development is the main thrust for the company that had been selected as part of the case study component. They specialise in enterprise systems groups and the distributed systems for any organisation. Their approach is an engineered, model-driven approach with tight project definition, management, and control. They feel that this approach would enable them to satisfy requirements from organisations that approach them. They implement changes and new systems with a minimum disruption to any organisation.

The problem they face is that as an organization, they have only six years component-based developing experience. However, overall the combined experience of the staff might be several years. They specialise in applications such as GEN (Sterling), Microsoft, DB2, SQL server, and Oracle.

The business intelligence section of SDC entails the formulation of a data warehouse strategy for the organisation by designing, developing, and helping to implement the data warehouse. They regard their duties as including the following: data analysis and DB design, data sanitisation and transformation, data warehouse development, and metabase management. The important aspect of this part of their duty includes data distribution, data mining, information reporting, and decision

support. Here they use software such as SA.S, BO, DB2, and the SQL server.

The systems maintenance, support, and renewal sectors include some of the following duties:

- Service level agreement
- Production maintenance, running, and control
- Help service desk
- Request logging and work tracking
- Change control and management
- Production management, support, and standby
- Optimisation of platform
- Legacy renewal via internet enablement and component wrapping
- They use software such as COBOL, IDB2, IDMS, ADS/Online, MS, and Delphi.
- The strong point of the SDC is whole personal finance solutions. The system entails personal insurance (life and risk), employee benefits, and medical aid thus ensuring a well-developed financial package that ensures that the human resources section of any organisation is well run. In this regard, they use an EB2000/Dataaway.
- Their customer base expansion strategy includes the EB centre (retirement funds,

The Creation of a Commercial Software Development Company

life insurance, properties, healthcare, and investments) while they work across industry into telecommunications, transport, utilities and manufacturing.

- Their approach to systems development

They use a twin track type of development. This entails the following:

- The first step is the usual application requirements gathering, analysis, and design. During requirements gathering and analysis, the underlying philosophy is centred around in-depth identification of business needs. It is recognised that these phases of development are as crucial in terms of final product quality, as is the choice of development technology and actual construction. Therefore, the deployment of good analysts with sufficient experience in the client's business area is given a priority.
- Thereafter, development is split in two different tracks along a component based development timeline.
- The first track entails component design and operation specification and the specific development of components. They release the component and the two tracks meet each other.
- During the first track's process they also release the component interface release to the second track developers.
- The second track entails the application interface prototyping, building the application and application integration testing. There is communication between these two tracks all of the time in order to ensure that the timeline is honoured.
- The last combined step is the application release builds whereby the application is installed and tested in the organisation.

The important step for SDC is the tactical delivery approach that the organisation follows. They follow the European approach whereby code and older software is re-used. If this approach is not applicable, they would investigate. If it is not better to buy, they build the application. If this is not applicable, then build for re-use would be their suggestion to their clients. Their target market is existing systems in the open market but their conceptual approach might differ. They keep a stock of component objects they can re-use. During the development process, they adopt an approach such that the end product is the application that can be generalized and used for other companies as well.

Taxonomy of Components

Their taxonomy could be divided into two sections. The first section is the technical section and deals with the following aspects:

- The security aspect has eight entities in the component and more than 30 public operations. The ADPV is a purchased component as well as the audit part of it. They do registration of all the parts they develop and install.
- The main taxonomy of components can be found in the business side of the organisation. They have 40 FIC applications and 19 public operations.
- The important aspect of their business is the client environment (69 entities and 11 public operations), investment applications (12 entities and 2 public operations), contribution applications (14 entities and 3 public operations), annuity costing basis (11 entities and public operations), EB event (1 entity and 3 public operations), client agreement role (68 entities and 14 public operations), fees (12 entities and 2 operations), Notation (5 entities, 2 public operations), annuity calculations (2 entities), global operations

(no entities or public operations), agreement applications (40 entities, 11 public operations), portfolio applications (34 component entities and 5 public operations), and some investment switching applications which they have finished but nothing is sold yet.

- Components in the developing pipeline entails issues such as EB late pay limits, EM membership fixed property, EB bonus rates, EB commutation limits, and global tax rates and limits.
- The results of the joint venture are that they had a successful HR transformation ensuring that they do not lose too many of their employees (8% vs. 25% previously). Their productivity is 100% better and therefore they can deliver systems faster. There is an international demand for their products.

Broad Requirements for Sustaining SDC Development

In order to succeed, an aggressive government plan is needed. Industry and regional initiative need to be coordinated and correlated. The important aspect is free movement of information and skills. This means the elimination of inflow barriers for high-tech skills. To reach this goal, the government needs to do aggressive international marketing. Furthermore, the government needs to offer incentives for sustaining the growth of SDCs. Some ideas could be tax holidays for new start-ups, facilitation of international links, and knowledge exchange programmes, and so forth.

Sustaining the Generation of SDCs

Companies need to copy examples of the growth of a national software capability that will ensure survival. This would require a prototype roadmap for the growth of a software centre. A lesson can be learned from the government of India: The Indian government has drawn up some software companies contracts with multi-nationals to send

Indian programmers to work in the USA or Europe at the client's site or under direct suspension of clients' technical managers.

Indian companies set up development centres in India where development and maintenance was done under Indian managers. Typical projects were systems maintenance, software test development, and execution as well as software components. Furthermore, some value adding is required while companies are building their research and development capabilities. This would require:

- Highly developed project management capabilities
- Quality by decision
- Extensive employee training
- The highly evolved practise of process engineering and relationship management

The South African software industry and the SDCs need extensive domain knowledge in banking, insurance, and financial services. They also need to create new technical capabilities and products to sell overseas.

For all of this, SDCs in developing countries need a highly educated work force, low cost of labour, highly developed information and telecommunication infrastructure and business modules consisting of:

- Pilot project
- Larger scale development
- Dedicated development centres
- Own development units

The success factors of countries such as India and Ireland need to be copied. South Africa and other developing countries would like to educate a young, highly educated workforce with strong technical and business skills. These workers need to be highly effective and efficient.

SDCs need full government support for the industry, with both financial and nonfinancial industries for both indigenous and overseas com-

The Creation of a Commercial Software Development Company

panies. This would make these countries an ideal gateway to the international markets.

To summarise some patterns:

- A well-educated work force is mandatory.
- Do not start building independent products.
- Take advantage of regional markets.

CONCLUSION

They have strong financial services knowledge with strong cross-industry technical skill capability and an emphasis on advanced development

techniques and tools. The model they are using is proving to be successful for all parties and the growth process had provided them with invaluable experience and expertise in the HR transformation. They think they are well positioned for significant growth.

Chapter 2.21

The Information Society in Ukraine

Serge S. Azarov
Lucky Net Ltd., Ukraine

INFORMATION SOCIETY DEVELOPMENT IN UKRAINE

In order to assess the prospects for the development of the information society in Ukraine, there is a need to consider the possible directions or approaches that such development might take. In *The Diversity within Unity*, Etzioni (2001) states:

Two approaches are to be avoided: promoting assimilation and unbounded multiculturalism. Assimilation—which entails requiring minorities to abandon all of their distinct institutions, cultures, values, habits, and connections to other societies in order to fully mesh into the prevailing culture—is sociologically difficult to achieve and unnecessary for dealing with the issues at hand, as we shall see. It is morally unjustified because of our respect for some normative differences, such as to which gods we pray. Unbounded multiculturalism—which entails giving up the concept of shared values, loyalties, and identity in order to privilege ethnic and religious differences, presuming that nations can be replaced by a large number of diverse minorities—is also unnecessary. It is

likely to evoke undemocratic backlashes, ranging from support for extremist, right-wing parties and populist leaders to anti-minority policies.

Taking into consideration Etzioni's recommendation, there is a need to search for an intermediate approach. However, this raises at least two questions. First is when to precisely commence a movement towards a synthetic approach to the construction of the information society, taking globalization into consideration but preserving the local identity. The second question is who—a leader, a certain group, a class, elite, or a society, in general,—should become a “key executor” of such a grand plan? In other words, the first question calls for an answer regarding the time of the “moment of truth” when ephemeral social illusions give way to specific financial and economic plans and programs.

Toraine (1997) stressed that the “moment of truth” being sought should be understood as the last step-wise stage between the industrial and post-industrial eras. This is a result of the gap appearing between the international economy and a nation-state leading to the destruction of such a

model of a society that unites instrumental rationality and cultural identity. Researching the new social movements at the end of the 20th century, he developed a so called “action sociology” which he used to state that it is “new and diverse social movements, not political or state institutions” that are the true driving force of progress.

The foregoing sets the boundaries for the answers to the questions posed above. This article now analyzes the social and economic conditions in the development of the Ukrainian civil society in order to expose any “gap between the international economy and the nation-state” as well as the existence of “new social movements.”

In such an analysis it is not useful to be overly enthusiastic since it was the Marxist classicists who were the first to write about “the new social movements” and state that “when an idea grips the masses, it becomes a material Force” (Marx, 1848). Of course, what they meant under the notion “the masses” was a new social force; an oppressed class of worker formed during the first stage of capitalism in the process of re-appropriation of added value (peasantry is the capitalism’s heritage from feudalism). That is why, bearing in mind Marx, we must ask:

- In what way are “the new social forces” being formed in the post-industrial society?
- Amongst which social strata existing in today’s society should we look for the “blessed springs of the information society”?

These questions are the key to exposing the productive and cultural identity of both a person and social environments. On the one hand, these form the new information society. However, on the other hand, they are themselves being formed from the “old” social groups including “workers and peasants,” a notorious “middle class,” a ruling elite and even the bearers of the incomprehensible “national idea.”

IDENTITIES AND THE INTERNET

In examining these questions, it is useful to examine the writings of Castells (1997) in *The Power of Identity* which provides a basis to not only to answer these questions but also to begin discussing a notion of “identity.” Castells dedicates his book precisely to the effects of the emerging phenomena of the information society on the new social movements, state policy and the *personal reactions* of the people in the world to globalization and “sprinter” technological development. Castells’ principle propositions are as follows (Castells, 1997):

- The most important feature of the information society is not its dominance of knowledge but in the change in direction of the use of knowledge which displaces previous forms of both personal and property dependency typical of industrial capitalism;
- Globalization gives rise to a tendency to increase identity which can help an individual withstand the external world since the new social structures being formed are networked communities;
- With the beginning of the information era, relations between “society” and the person not only harmonize but become more intense;
- Social and biological traits of human beings, which lock them in the narrow forms of “old communities,” are juxtaposed with the global traits that incorporate them into the new world structures;
- The essence of the networked human identity lies in the fact that for the individual, the process of self-identification becomes self-sufficient. Identifying the value orientations of activities of such self identification based on a specific cultural identity, excludes the necessity to address other social structures;

- There are three types of network identity and each of them can play a key role as a driving force of social progress; they are as follows:
 - legitimizing identity, which is typical of industrial society and corresponds to a system of values of a traditional civil society and nation-state;
 - resistance identity, which is typical of a period of transition when a new value system, recognizing the significance of local communities, is formed; and
 - project identity, that is the based upon a personality that is shaped in the information society;
- A role of the new social movements based on the resistance identity and the project identity protests against the existing social structures;
- Whilst the protest identity is destructive, it is a key source of energy to progress from the industrial to information structures; and
- Technology *does not determine* either historical evolution or social changes but is a potential resource for the development of society and provides for different models of social change.

Thus, according to Castells, the new social forces in the post-industrial society are formed during the processes of searching for both personal and group resistance identities in order to form a new project identity in the end. Of course, this approach cannot be expressed by means of unified social and political, or economic rules of behavior or recommendations, since the globalization process is not regionally homogenous. For instance, certain regions, such as the Pacific region, appear to be actively involved in the global economy while other regions including certain African and Asian countries, are prejudiced against or hostile to concepts of globalization.

Whilst acknowledging the role of the Internet in formation of the information society, Castells

nevertheless stresses that network communication is not a universal means of communication and is not likely to become one in the near future. He considers that:

new electronic net media do not depart from traditional cultures: they absorb them. Social and cultural differentiation leads to the segmentation of multimedia users. It also increases social stratification among the people. The multimedia public will be populated by two separate populations: the interacting and the interacted and it is critical for all kinds of social effects that there should be the development of an open and horizontal network of communication instead of exclusive and closed on-demand media services. The significance of the multimedia increases tremendously in a system in which reality itself (that is, peoples material/symbolic existence) is entirely captured, fully immersed in a virtual image setting, in the world of make believe, in which appearances are not just on the screen through which experience is communicated, but they become the experience. (Castells 1997, pp. 372-375)

Castells contrasts the old forms of national, religious, class and ideological identity with the new networked identity. It is well accepted that national identity in the nation-states historically determined the legal relations between the state and its subjects. Identity based on formal citizenship plays the same role in the multinational states. However, separatist movements based on the notion of national identity exist even in such developed countries as Canada or Spain.

Today, a religious identity is a base for many Muslim countries. But even in such countries there are contradictions derived from different interpretations of religious principles or Confessions of faith. The same can be said about class and ideological identity which, it can be argued, was never fully employed in any country.

In the early part of the 21st century all other forms of identity, including the impacts of such key factors as culture, traditions, history and language, play a role of symbolic interpretations of the national identity in many countries, since they only play a system-forming role in the period of military encounters.

One other dichotomy in the domain of labor division in industrial society is a division between urban and rural cultures. A specific feature of urban culture and identity is *event intensity in the complexity and the tolerance in the decision-making process*. This is not a “gift of heavens.” It is nothing else but a manifestation of the instinct of self-preservation in places with high-density of population without which personal and group collisions would hamper development. In 1900 one in ten people in the world lived in a city, in 1994 every second person lived in a city, while in 2004 the number of city-dwellers exceeded 87% in developed countries. At the beginning of the 21st century, megapolices appeared, and their management is becoming a key problem for the 21st century. On the other hand, devotion to traditions and conservatism, which are also derivatives of a specifically rural way of life and agricultural production, called “idiocy of rural life” by Marx (1948), are typical of rural culture.

At the first stage of development, the information society inherited all features of urban culture of the industrial society and reflected them on the Internet. To a great extent, the Internet was a manifestation of urban culture and active Internet users in the cities were the first representatives of the networked identity. A networked identity, an Internet function, “given to us in sensations,” provides both an individual and virtual communities with a possibility to “resist the external world” (not symbolically but actively). It can also “incorporate” in the emerging new world structures without the blessing of either the state or other subjects of a dominating national or religious identity.

In other words, in the situation when network communications are open for free access, it is easier for individuals, who do not have any particularly strong national, religious or ideological reflections, to find themselves a comfortable “refuge” on the Internet in various old social groups. Moreover, in the information society *a networked person practically does not need direct contact with the old power or social structures.*

In the process of self-organization, based on personal or group experience in the sphere of the formation of networked identity, a departure from a legitimizing identity which is peculiar to the industrial society and nation-state resistance identity, takes place. But all these “departure” phenomena *should not be regarded as destruction of identity as such but as the destruction of the old forms of identity and the formation of new forms of identity.* It upon this base that social movements and forces, aimed at the formation and development of the information society, will be formed.

Finally, it is useful to consider the views of the Russian scientist Inozemtsev’s paper “Senselessness of Questioning”:

posing a question like which forces, personal and individualistic or communal and state-oriented, can determine progressive development of Russia is fallacious. Today any state is objectively incapable of controlling key resources of public development which are now information and knowledge... Russian state is an intellectual and moral bankrupt that is attempting at presenting its surface polish for an evidence of solvency and conceals its scandalous failure to offer any appealing development strategy to the nation by the slogans of struggle for stability. In no country in the world community-type consolidation promoted liberation of capacities and potential of each individual... In the Russian situation, absolutization of a community development principle is inevitably leading to the state bureaucracy. (Inozemtsev, 2004)

PROBLEMS AND PROSPECTS FOR UKRAINE

In spite of the fact that many wanted to avoid the loss of identity in the process of globalization, its preservation, according to Castells, is in any situation doomed to failure since legitimizing identity sooner or later transforms into resistance identity. However, in Ukraine we still have not made it clear which aspect of identity we are talking about, whether it is national, religious, class and ideological, urban, or rural. We are a multinational state and that is why it is complicated to discuss a national identity. On the other hand, religious, class and ideological identities are hardly topical in the development of an information society.

In spite of the fact that in 2004, 67% of the population lived in the cities, Ukraine still had a typical representation of a rural identity. The matter at hand cannot be adequately represented by statistical figures alone but requires examination through the *chronological dynamics of the migration of generations*. In 1991, Ukraine had only entered into the third stage of the five-stage Gibbs model of urbanization (Gibbs, 1963), and in this stage the increase in the urban population is provided not by birth rate, but by migration from a countryside.

In 2004 the majority of elite representatives still originated from the rural areas, either first or second generation. In such a situation it becomes difficult for these representatives to learn to think in the moral, ethical and intellectual terms required of urban culture and to tolerate their opponents in order to perceive the information society as a development factor. Due to this rural-communal bias towards conservatism and a communitarian model of the civil society, there is a tendency to simply copy and disseminate negative features of the socialist command-administrative system. This is generally elitist. But there is also the concept of a ruling elite to be considered. Power can be considered to be an obtrusion of the will of certain subjects upon others using

physical or symbolic violence. Fortunately, there are reasons to believe that the sad times where physical violence to impose power have sunk into oblivion in many situations. However, what is left in its place is a symbolic violence in the form of threats, regulation of behavior, both personal and business, playing out the traditional identities of Orthodoxy or Roman Catholicism and obscure propaganda of values of some sort of integration, for example Euro Atlantic integration. That is why it is difficult to look for the new social forces amongst our ruling elite and is probably, a waste of effort. Such new social forces are more likely to appear within civil society. It is the resistance identity, which will play a regulatory role during the period of transition from an industrial to an information society. This will appear in the sphere of goals, alternatives, and activities, which are most likely to be the system-forming factors of the civil society.

In this context, the resistance identity either of society as a whole or as a fragment of it, will take the shape of civil identity. This implies a certain level of identification by an individual with the information society, a readiness to exert influence upon the formation processes and to bear responsibility. In short, this implies “good old ethical norms.”

It is nevertheless necessary to approach the spontaneous manifestations and “germs” of the civil society with particular care, barring excessive “freedom” euphoria. Since many of the initial approaches still bear the features of “democratic centralism” and totalitarianism whilst their leaders, under a civil society slogan, often still act with personal, selfish or power-seeking motives behind their efforts.

Same caution should also be taken when approaching the state sector. The concept of an authoritarian state, of course, will not disappear easily. However, if it is to survive, the state will increasingly need to rapidly adapt and transform in the direction of the civil society. Given the entrenched nature of the state systems, it is unlikely

that this will occur synchronously but most likely lag a generation behind. Such a situation can be clearly seen in divergence between the implementation of external policy of the sovereign state in building international partnerships and internal policy in which there is a decentralization of power to regions. Such decentralization involves the delegation of certain functions from central bodies to the regions and NGOs in order to form network distribution of authorities.

Any phenomenon, be it globalization, identity, or information society, is in reality a process. Developed as a speculative theory, the notion of the information society naturally reflected all specific features of the age of industrialism just as Marx' communist theory reflected the features of the capitalism of the middle of the 19th century. Therefore it is clear that the information society in the middle of the 21st century will remind us of Bell's (Bell, 1973) or Toffler's models (Toffler, 1987) in the same way the USSR reminded us of the Manifesto of the Communist Party. The "Manifesto of the Communist Party," of course promised, that "the proletarians have nothing to lose but their chains. They have a world to win." However, a "proletarian identity" did not rescue toilers from slavery, and the communist bureaucracy became the true winner.

Nevertheless, there are a number of key issues in information society theory, just as in the theory of communism there was "no private ownership of productive tools" and "the dictatorship of the proletariat." In the notion of an information society, the equivalent unshakable principles are "open society" and "freedom of communication and personality." If these principles are maintained, then no social or economic phenomena will be able to dissolve any form of identity which will emerge from the legitimization of a civil identity. It is the national identity of the country that will undergo few alterations. Since historical practice has demonstrated the stability of this form of iden-

tity (only tribal identity is more ancient than this one) and it will accompany our life for centuries to come. However, it is the nations themselves that will undergo changes in similar fashion to the way a national identity of "Roman" gave way to "Italian."

KEY TERMS

Globalization: This term was first applied to the world economy, which under conditions of global information and communication network can basically operate as a unified system in the real-time mode.

Identity: According to Inozemtsev (2004) and authors of the WSIS 2003 Declaration *identity* is *originality*. Overall, identity can be understood as a system of factors that make it possible for a human being or a community to relate to another. Selecting certain factors as dominant in this system, the researches arrive at certain types

of identity—personal, group, national, class, cultural, professional and so on, as far as “fan-group” identity.

Information Society: The 2003 WSIS “*Declaration of Principles - Building the Information Society*” states that the information society is the society where anyone can produce information and knowledge, have an access to them, use and share them in order to provide individuals, communities and nations with a possibility to fully actualize their potential, securing their sustainable development and improving the quality of life, on the basis of the goals and principles of the UN Charter and fully abiding by the Universal Declaration of Human Rights.

Chapter 2.22

Telecommunication Problems in Rural Areas of Armenia

Gevorg Melkonyan

Internet Users' Society of Shirak, Armenia

BACKGROUND

The Synergy Project “Priorities in the Development of Telecommunications Sector in the South Caucasus” (2003) has the task of modernising the telecommunications system:

- Creation of conditions for free information space;
- Establishing the market of information and knowledge as a factor of production;
- Ensuring informational security of individuals, society, state, and establishing an effective system of free and equitable receiving, dissemination and use of information as a key condition for democratic development;
- Increasing the level of education of the population, the scientific-technical and cultural development of the society by expanding the opportunity of information exchange on an international, regional and national level and, consequently, increasing professionalism and creativity;
- Forming new structures in the public administration, economy, business, culture and social spheres based on massive use of information technologies, computer technologies and telecommunication; and
- Effective use of information resources in the activities of government bodies.

In the rural areas of Armenia during the Soviet authority, the telephone communication system was based on analog stations and a linear network. After many years of operation, the analog telephone stations are worn out, and the linear network is damaged and in the most part is completely destroyed. In spite of the fact that in recent years the infrastructure of telephone communication of the country was considerably improved, one can still see non-uniformity of development of infrastructure between various regions, urban and rural infrastructures of telephone communication, and also between city and other regions of the country and in particular remote villages.

A four-year project of ArmenTel, the telecommunication company with the monopoly in

Armenia, aimed to provide 800 villages with a digital telecommunication technology until 1997, but this promise remains unaccomplished. As a consequence, the majority of villages in the country are now suffering information isolation. Add to this, the terrible condition of rural roads, which have not been reconditioned for 10-15 years, and the image of the majority of villages of Armenia in this aspect will be clear. The only communication facility with the external world is television.

Under these conditions, some public and charitable organizations have undertaken their own research on telecommunication problems and on satisfaction of villages' information need. For example, in 2000, as part of the 3PN (2004) within the framework of the "Narod" network project (NNP, 2004) at school #1 of Akhuryan village, we tried to organize an Internet centre which could also be used by small groups of school children from the neighbouring villages, but owing to absence of telephone communication, this idea was not realized. In the same year, with the support of the Bureau of Educational and Cultural Affairs of the U.S. Department of State, the Armenian School Connectivity Programs (<http://www.ac2k.am/>) (AC2K, 2004) began as part of the Program "Project Harmony" (<http://www.projectharmony.am/>) and many villages, including Akhuryan, obtained access to such services as e-mail, distance learning and e-commerce. The program creates centres connected to the Internet at schools in rural regions using a basic radio-modem connection, which in the absence of linear telephone communication is the only option for rural areas.

RIGHT DIRECTION OF DEVELOPMENT POLICIES

It is necessary to note, that the creation of a telecommunication network in rural regions by the creation the Internet centres at schools is the

right strategy for closing the digital divide as the experience in many countries shows. Despite different socio-economic conditions, in all countries there are similar problems and difficulties:

- Low and insolvent demand of telecommunication services due to small density of the population;
- Significant distances of the villages from the regional centres and truncated relief (sometimes by natural barriers—mountains, gorges, bogs);
- Absence of necessary technical and financial assets; and
- Absence of the highly-skilled specialists.

Irrespective of the development level of the country, the problems of providing telecommunication services in rural areas are similar, and similar solutions are possible—differing in their application, means and fundraising strategies for the necessary resources.

The decision to use the village high school as the telecommunication center was because it is a uniting factor in a village community and is the institution for the preparation of the young generation most receptive to new information technologies. In the present socio-economic environment, the village school is disadvantaged in comparison with urban schools, for example, highly-qualified teachers and specialists do not find rural life attractive. Therefore, a regional computer network for rural educational institutions will be particularly useful for the school-children, the teachers and for the whole rural community. Access to the Internet is a valuable educational information resource for the village school children and teachers, which helps them to prepare for competitive examinations, and is an irreplaceable communication facility that enables dialogue about common projects with colleagues world-wide.

The transformation of villages to be convenient and attractive places to live, is strategically impor-

tant for the sustained development of the country, and so one should expect effective participation and support by the appropriate state structures and, most of all, by the national government. In particular, the government of Armenia has already decided to sanction local and regional networks of the data transfer in a range of frequencies from 2.4 up to 2.5 GHz in all territory of the country. Henceforth, use of radio-modems and wireless network access in this range of frequencies will provide rural Internet centers with the high-quality Internet services. As the base scheme of regional network development, it is expedient to use the network of TV towers—previously having coordinated this with the TVR Committee. Such a concept for the development of telecommunications in rural region was offered in October 2000, at the international seminar “Conversion potential of Armenia” organized by the International Scientific and Technical Centre in Yerevan (<http://www.sci.am/istc2000/>).

After the successful development of new communication facility application processes, information and telecommunication technologies can become not only one of the factors ensuring competitiveness of the economy, but also a basis of active regional cooperation between communities and the formation of a uniform economic space in the region.

ACHIEVEMENTS, THE PROBLEMS AND FUTURE TRENDS

Many rural schools in Armenia are supplied with modern computers donated by different charity organizations and private persons. For schools that do not benefit from such initiatives, the organization “Project Harmony” offers an alternative solution: to equip a bus with computers. However, given the condition of our rural roads, we must note that with this equipment (at a cost of US\$80,000-\$100,000) will not solve the problems. The author believes that it would be more effec-

tive to locate computer and telecommunication equipment where it can be in constant use. And for schools deprived of Internet access, training can be offered by means of multimedia programs on CD-ROMs simulating a real Internet network - offering selection from the most popular sites on a disk and using it as one of computers of a server for the local network. This technique was successfully used at the childhood-youth centre “Meghvik” (<http://users.freenet.am/~meghvik/>) in Gyumri, Armenia.

An acute problem for Internet centres in rural communities (community telecentres) is shortage of expertise. Because of its absence, the directors of schools, being aware of computer breakage and the failure of the programs, often lock away the computers, and then later the computers are obsolete and no longer suitable for work with the new versions of the programs. Carried out by Open Society Institute (<http://www.isoc.am/>), IREX (<http://www.irex.am/>), ACCELS (<http://www.accel.s.am/>), “World learning” (<http://www.worldlearning.am/>) and “Project Harmony” preliminary courses have eased this problem a little, but further courses are necessary.

Recently, the Open Society Institute of Armenia (<http://www.osi.am/>) has developed a community telecenters creation program in rural regions of Armenia, which should help considerably with the problem of information provision in rural communities, thereby reducing the digital divide between the urban and rural population. For this purpose, the Open Society Institute has given a grant to the Armenian association of users CDS/ISIS (<http://www.distancelearning.am/>), which has chosen NGO “Internet Society” of Armenia (<http://www.isoc.am/>) as the partner. The grant was stipulated to prepare the personnel for work at the telecentre - managers, network administrators, operators, and also specialists in training and creation of the programs for training. In addition, a Web-portal for a telecentres network was to be created which all telecentres of the country would use. In the early phase of

the grant, there have been approximately 40 telecentres organized in schools. Forty students have completed training on WebCT™, and also use of the Internet for searching for educational resources.

The Internet training was conducted on the basis of a site <http://www.teachers.ash.org.au/shansen/wow/>. Equipment for the preparation and duplication of a video course was acquired. A Web-portal (<http://www.telecentres.am>) was prepared on which courses on the preparation of the managers, network administrators, links to the telecentres of the world, and also a list of the telecentres of Armenia, in particular, are published. The level of training and availability of the highly qualified specialists in the sphere of telecommunication defines the quality of telecommunication services delivered to the community.

Another important problem for rural telecommunications in Armenia is the unreasonably high price of the main channels of communication, that is caused by an exclusive condition of the telecommunication market in Armenia. But encouraging changes are planned: After lingering discussions and negotiation of authorities with the management of ArmenTel company, the monopolist in sphere of telecommunications of Armenia, the government decided to cancel from July 2004, the exclusive license of ArmenTel company on the international channels of communication. This means the liberalization of the telecommunications market with new operators in the telecommunications market, the gradual improvement of quality of communication channels offered, and a decrease of the price of telecommunications is expected. All these changes create the preconditions for successful development of regional telecommunications and general application of new information technologies, including in the remote rural communities.

CONCLUSION

For effective functioning of community telecentres, it is necessary to analyze the social, economic, educational, cultural and technical factors in the life of rural community, to find and to develop further expedient ways of development, providing interactive harmony of all the participants and sustained development of the community (RTTF, 2004).

Effective interaction in solving the problems of telecommunication sector can influence the development of the telecommunications infrastructure, including in rural areas. Here it is necessary to pay special attention to liberalization of the telecommunications market and further improvement of the legislation in this important part of the economy (NRRI, 2004).

The main problems include: the improvement and closing of tariff regulation and price calculation, improvement of effectiveness of operator activity, regulating of mutual payments, reforming of the sector management, improvement of the statistical base, assistance in the further development and perfection of the market relations in the telecommunication sector.

KEY TERMS

Communication Technologies: The branch of technology concerned with the representation, transfer, interpretation, and processing of data among persons, places and machines.

Distance Learning (Teletraining): Training that in which usually live instruction is conveyed in real time via telecommunications infrastructure, that may be accomplished on a point-to-point basis or on a point-to-multipoint basis, and may assume many forms, such as a teleseminar, a teleconference or an electronic classroom, usually including both audio and video.

E-Commerce (Electronic Commerce): Business transactions conducted by electronic means other than conventional telephone service, e.g., facsimile or electronic mail (e-mail).

E-Mail (Electronic Mail): An electronic means for communication in which usually text is transmitted, operations include sending, storing,

processing and receiving information, users are allowed to communicate under specified conditions and messages are held in storage until called for by the addressee.

Information: In intelligence usage, unprocessed data of every description which may be used in the production of intelligence.

Linear Network: The specific physical, i.e., real, arrangement of the elements of the network.

Mobile Adviser: The highly-skilled expert, voluntary or on a contractual basis, maintains the regional network of the telecentres and helps the personnel by providing advice and necessary programs.

Network: An interconnection of three or more communicating entities.

Rural Area: Residence of a not urban type.

Synergy Project: A team-developed project.

Telecommunication: Any transmission, emission, or reception of signs, signals, writings, images, sounds, or information of any nature by wire, radio, visual, or other electromagnetic systems.

Telecommunications Infrastructure: The aggregate of equipment, such as radios, telephones, teletypewriters, facsimile equipment, data equipment (computers, modems and other equipment), cables and switches, used for providing telecommunications services.

Telecommunications System: A collection of individual telecommunications networks, transmission systems, relay stations, tributary stations, and data terminal equipment usually capable of interconnection and interoperation to form an integrated whole. The components of a communications system serve a common purpose, are technically compatible, use common procedures, respond to controls and operate in unison.

Chapter 2.23

ICT as an Example of Industrial Policy in EU

Morten Falch

Technical University of Denmark, Denmark

Anders Henten

Technical University of Denmark, Denmark

INTRODUCTION

A substantial part of the economic growth that has taken place within the past 2 decades is related to information and communication technology (ICT). First, the ICT sector itself has achieved very high growth rates. Second, productivity gains in other sectors have been achieved, to a large extent, through implementation of ICT-related innovations. It is, therefore, no surprise that ICT plays an important role in virtually all industrial policy programs. Policies stimulating e-government are one of the ingredients in such programs.

In 2000, the leaders of the European Union (EU) adopted the Lisbon strategy to make the EU the most dynamic and competitive knowledge-based economy in the world (CEC, 2000). ICT was seen as a key component in achieving these goals¹, and a special program—eEurope—has been designed to realize the Lisbon goals in the ICT area. This program is, however, also a con-

tinuation of a wide range of ICT initiatives taken by the EU Commission since 1984.

BACKGROUND

In the eEurope program, the Commission mentions three types of benefits stemming from ICT:

1. The ICT sector itself accounted for 6% of employment in the EU in 2000
2. ICT improves productivity in other sectors
3. ICT boosts citizenship and quality of life (CEC, 2004a).

Although the third point may, in part, be outside the scope of industrial policy, as it does not directly address the economic sphere, the three points reflect very well the dual aspect of the EU

ICT policy, which has been inherent from the early beginning:

- **International Competitiveness:** Telecom is considered to be a high-tech sector of strategic importance with regard to the generation of employment and economic growth. In addition, telecom is a sector in which the EU has a relatively strong position compared to the United States (U.S.) and Japan.
- **The Information Society:** Telecom networks constitute an essential infrastructure for the information society. Cheap and ubiquitous access to advanced telecom services is, therefore, important for the generation of employment and economic growth in any industry.

The first point is typical for sector-specific industrial policy. The objective is to strengthen an industrial sector deemed to be of particular importance to maintain or even improve the EU position in the international division of labor. The major reason is a high growth potential with regard to employment and contribution to GDP.

The second point is somewhat more related to horizontal industrial policy aiming at improving the business environment in general. Here, ICT is seen as a part of the overall infrastructure used by all industries. It should be noted that this distinction is not completely clear-cut. The argument for industrial policies directed towards a specific sector will often be that a particular sector possesses important spillovers to other industries. For instance, one of the arguments used as justification for the support to the agricultural sector is that agricultural production generates employment in food-processing industries.

The telecom sector itself has often used its importance for the entire economy as an argument for support. This argument has also been widely used by other sectors if they had an interest in affecting political decisions. However, with

regard to telecom, there has also been a strong pressure from users—in particular, business users—depending on access to more advanced communication services.

A strong ICT sector may support the development of an information society, and an advanced information society will benefit the ICT sector as it stimulates demand and innovation of ICT products and services. Still, the two objectives are addressing two different groups—users and producers of ICT—and these groups often have contradicting interests.

THE EU RESEARCH PROGRAMS

The first initiative taken by the Commission was the introduction of a number of European-wide research programs. The ESPRIT program supporting IT research was commissioned in 1984 and the first phase of the RACE program, supporting telecom research, was commissioned the year after. Both programs offered support for so-called pre-competitive research. In this way, any accusations of industry subsidies could be avoided, and it was easier for competing companies to exchange information. The core of the RACE program was to develop technologies for developing a broadband in Europe (a distant goal at that time), and the focus was mainly on providing the basic infrastructure, although very few applications justifying the need for huge investments in optical networks were available. An important objective of the program was also to create an international forum for discussions and cooperation between European telecom companies to establish a common vision for the future European telecom networks and, thereby, facilitate integration of a market fragmented along national borders.

The RACE program was extended and followed by a series of other telematic research programs. However, there has been a gradual shift in focus from development of basic technolo-

gies towards development of applications. This reflects a trend towards more application-oriented research as well as a shift towards more focus on the demand side. Also, the kind of participants in the research programs has changed. From the beginning, telecom operators were very active in the programs, but following a reorientation of the telecom operators towards more commercial—and more limited—research and development activities, they have restricted their participation. On the other hand, a large number of small- and middle-size consultancy firms and information technology (IT) companies have engaged in the programs.

STANDARDIZATION

A related activity was the establishment of a European standardization body, ETSI. The creation of this body moved a part of international standardization from ITU into the European framework. In addition, it enabled a more direct involvement from industry partners in the standardization process. Many of the EU-funded research projects participate directly in ETSI so that the research made through cooperation between European industry actors can result in common European standards.

The establishment of a European-based standardization body is not only a way to contribute to the development of a common internal market within the EU. It also contributes to strengthening the role of the EU-based industries in the formation of global standards, and thereby it contributes to an improved international competitiveness of the European telecom industry.

SECTOR REFORM

Another line of EU policy has been related to the market reform of the telecom sector. This reform was initiated by the Green Paper issued in 1987

(CEC, 1987) and followed by a series of directives that have been revised a couple of times. The latest major revision was made through the issuing of the new telecom framework directives in 2002. The vision behind the market reform is to change the telecom sector from being a public utility provided by publicly owned—or at least publicly controlled—monopolies into a “normal” industry sector, where private companies compete for market shares and without any sector-specific regulation.

Although the sector reform should be seen in the context of an ongoing reform of public sector activities in general, the primary objective is to initiate a more dynamic development of the telecom sector itself through a complete restructuring and to remove barriers set by former public involvement. It should, however, be noted that the objective of “normalization” of the sector was not clearly defined from the beginning. The first step, which was suggested in the Green Paper, was the liberalization of terminal equipment, creating a common market in this area. The Green Paper of 1987 also suggested a liberalization of other telecom services than telephony, while telephony, which at that time was by far the most important service, as well as the physical network, should be reserved for the incumbent monopoly operators.

A further point is that not all member countries agreed on the proposed liberalization. In particular, France, together with countries from Southern Europe, were very reluctant to liberalize the telecom market, and many countries were concerned about how their own incumbent telecom operator could survive in a liberalized market. A good example of this is Denmark, where the market was divided between four regional operators in limited geographical areas. The Danish government wanted to create a strong Danish actor on the telecom market and merged all operators into one (Tele Danmark). In addition, a substantial part of the revenue raised through the subsequent privatization was given

to Tele Danmark, enabling the company to invest in telecom companies abroad.

A more recent line of policy actions is related to the stimulation of demand and development of content. These types of initiatives dominate the eEurope program initiated for realizing the goals set by the Lisbon agenda with regard to ICT. The objectives of the program do not include anything about the ICT sector itself, but focuses on making ICT available to everybody and stimulating entrepreneurship.

eEUROPE

The eEurope program was initiated in 2000 as a Commission initiative for the special European Council of Lisbon (ECE, 2000). The program has later been followed by the eEurope 2005 program (CEC, 2002a), and the successor of this program—i2010—has just been announced (CEC, 2005).

The eEurope plan 2000-2002 had three overall objectives: Cheaper, faster and more secure Internet, investment in people and skills and greater use of the Internet. In the eEurope 2005 plan, these aims were replaced with: Modern online public services, dynamic e-business environment, widespread availability of broadband access and secure information infrastructure (CEC, 2003). Both plans include actions stimulating network as well as content development.

This dual perspective is most clearly formulated in the 2005 plan, where the mutual dependence between network development and content development is recognized and public action is recommended to correct this market failure: “Funding more advanced multimedia services depends on the availability of broadband for these services to run on, while funding broadband infrastructure depends on the availability of new services to use it. Action is, therefore, needed to stimulate services and infrastructure to create

the dynamic where one side develops from the growth of the other” (CEC, 2003, p. 2).

This is the typical market failure argument used for implementing industrial policy: To achieve the most favorable development, it is necessary to help the market to take the right decisions.

Both plans include a large number of action points, but none or very few of these points include initiatives that would be termed as industrial policy in the supply-oriented, traditional sense. However, they include the development of a wide range of e-government applications, such as e-learning and e-health, and the provision of broadband access to public institutions. Development of such applications enables both cost saving and service improvements in the public sector. But maybe even more important is the impact on other sectors. Development of e-government services stimulate development of similar service in the private sector and lead to further growth in the demand for infrastructure facilities, such as broadband. eEurope also includes a large number of initiatives involving the private sector. These initiatives include support to research and development in telecom networks as well as applications like e-business. The objective of many of these initiatives is to develop pilots, which can inspire other parts of the private sector. Finally, the plans include a continuation of the telecom reform process and measures for improvement of legislation to facilitate e-business.

Although the 2005 plan states the importance of the supply side, the only really new initiative, in addition to a continuation of the telecom reform process, is a suggestion to finance network development in less favored regions; for example, by the use of structural funds. This initiative is maybe the one most in line with the old-type industrial policy subsidies.

In addition to initiatives at the EU level, most member countries have defined their own national broadband strategies as a part of eEurope. National programs within the ICT area are far from a new phenomenon. In the early 1990s, it became fashion

for each country to develop its own plan for how it could become global champions in ICT (Henten, Falch, & Skouby, 1995).

The national programs fit very well with the EU programs, as they basically use the same type of remedies: Support for research and development and pilot projects, e-government initiatives, and demand stimulation through demand from public sector institutions. Very few countries have discussed direct subsidies for network development. Sweden has had programs for public funding of broadband networks, and in Denmark, broadband access receives substantial taxation subsidies, as companies are allowed to offer broadband connections to their employees as a tax-free fringe benefit.

FUTURE TRENDS

The eEurope and iEurope programs tend to emphasize more on content development and stimulation of demand than previous ICT programs. The same trend can be observed in other countries; for example, in the Japanese U-Japan program. One reason for this is that the major parts of telecom reform now have been implemented and the supply of network infrastructure no more is seen as a major bottleneck for development of the information society. Therefore, more attention is given to development of content. In this context, e-government plays a major role, as development of public content can stimulate development of content in the private sector as well as the demand for ICT network facilities, such as broadband.

CONCLUSION

During the process of creation of the EU internal market, it has been important to remove all barriers for international trade between member states. This includes national subsidies as well as other measures favoring domestic industries. On the

other hand, it has been important to ensure development of the European industry in competition with the U.S. and Japan. This has led to a strategy with policy goals that are not very different from those set by traditional national industrial policy; but at the European level, many of the traditional remedies are replaced by a new set of initiatives with focus on stimulation of ICT-based innovations and applications. In this context, e-government plays a crucial role, as development of public e-services stimulates the overall use and demand for ICT. The impact of such policies on the entire economy is difficult to assess. But there has been a clear, positive impact on the penetration of ICT technologies in the countries being most active in this policy area. In particular, policies securing more competition on national ICT markets led to a much faster introduction and higher penetration of new ICT services, such as broadband access and mobile communication.

KEY TERMS

eEurope: The eEurope program was initiated in 2000 as a part of the Lisbon Process to ensure that the EU will fully benefit from opportunities of the information society. The objectives are to make communication services including broadband widely available, to stimulate content development and improve e-literacy—all in a way that strengthens social cohesion.

ETSI: ETSI is a European standardization body established following an initiative set by the European Commission. ETSI prepares common standards for telecommunication systems for fixed and mobile networks and services, TV broadcasting as well as for information technologies. Both European and non-European companies can be members. Today it has 688 members from 55 countries.

EU Research and Development Programs in ICT: European research activities are structured around consecutive 4-year programs, or so-called Framework Programs. The Sixth Framework Program (FP6) sets priorities—including the information society technologies (IST) priority—for

the period 2002-2006. While the first cycles mainly focused on the basic technology, later programs include a wide range of applications as well. The current program includes a project line on ICT research for innovative government.

Industrial Policy: State policies conducted with the aim of strengthening the industrial base of a country or region. General macroeconomic stabilization policies are not considered part of industrial policies; however, industrial policies can encompass a broad range of supply-and-demand-oriented policy initiatives.

International Telecommunication Union (ITU): An international organization within the United Nations system where governments and the private sector coordinate global telecom networks and services.

Lisbon Process: At a summit in Lisbon in March 2000, European leaders set the goal of

the EU becoming “the most dynamic and competitive knowledge-based economy in the world” by 2010. The target was a 3% average annual economic growth and the creation of 20 million jobs by 2010.

Telecom Sector Reform: A reform that has transformed the telecom sector from national monopolies controlled by governments to a sector with competition and private ownership. The telecom market was in principle liberalized in 1996 within the U.S. and in 1998 within the EU, although public ownership of telecom operators still persists in some European countries.

Chapter 2.24

Information Literacy for Telecenter Users in Low-Income Regional Mexican Communities

Antonio Santos

Universidad de las Americas-Puebla, Mexico

INTRODUCTION

The purpose of this article is to propose a methodology to increase information literacy among people who attend telecenters in low-income communities in Mexico. The Mexican government created telecenters, or community technology centers, as part of a national project under which adults lacking basic education who are isolated and living under economically and technologically marginal standards are granted access to educational materials and work training in the form of printed, audiovisual, and electronic media (CONEVyT, 2001). Our research group evaluated the Mexican telecenter program as part of a nationwide qualitative diagnostic study, which represented the initial stage of a three-year research project conducted by the Information and Communication Technologies for Education and Community Development research group at the

Universidad de las Americas-Puebla in Mexico for the National Institute for Adult Education. The results of this study combine with the concepts of information literacy and socioconstructivist pedagogy to form the basis for the present proposal.

This article is organized in three parts. The first is centered around a discussion of current literature treating technology for social development, including the aforementioned diagnostic study on telecenters, or *plazas comunitarias*, as they are called in this Mexican project. The purpose of the second part, which is to explore a different perspective on the subject at hand, is developed during a discussion of information literacy and social constructivism. The third part fleshes out ideas broached in sections one and two and proposes a methodology for technology community centers, as the *plazas comunitarias*, under which information literacy and personal development are promoted.

BACKGROUND

In this section, the traditional view that access to technology leads to social development is analyzed and criticized. This view may be considered limiting as it might hinder potential benefits from reaching users of technology; to illustrate this point, results of the diagnostic study on the *plazas comunitarias* project in Mexico will be presented and discussed.

Technology for Social Development

In most developing countries, providing access to information and communication technology (ICT) to low-income populations—that is, bridging the digital divide—is a high priority since it is widely believed that ICT can be a tool “for social action and positive social change” (APC, 2003, p. 12) as well as a facilitator of “more productive and rewarding lives” (McNair, 2000, p. 9). However, in developing countries, the ICT revolution remains an unfulfilled promise to low-income populations due to obvious access inequalities and the conviction of developing societies that access to technology implicitly leads to social development (Moghaddam & Lebedeva, 2004; Curtain, 2004). It makes perfect sense then that most efforts made by these governments are dedicated to supplying the technology with the expectation that this is enough to decrease the digital divide.

According to Hewitt (2001), these expectations are simply too high, and it is an overstatement that just giving people access to the Internet broadens their employment opportunities and improves their chances at achieving sustainable economic growth. In the same vein, León (1999) accepts the importance of access to information and communication technology, but agrees with Hewitt that this alone does not constitute entrée into a new stage of social development. During an OECD roundtable discussion of ICT and the digital divide, participants commented that the gap is not digital, but rather educational, and they

stressed the need to empower people with educational, cognitive, and behavioral skills instead of just supplying them with equipment (OECD Secretariat, 2000). Steyaert (2000) adds to this list the need to develop information skills in order to become fully information literate. And finally, in a 1996 UNESCO report, Delors worries about the high hopes for social change that are imposed on technology. He declares that the so-called information and communication revolution is not purely technological and that it is important to situate it in a greater social and economic context, a comment that touches on one of the chief criticisms directed at the supply of technology in an effort to diminish the digital divide.

A Diagnostic Study on Plazas Comunitarias

A prime example of a project under which a one-dimensional, causal relationship is asserted between technology and social development is the *plazas comunitarias* project in Mexico. To clearly understand how this linear view prevents users from exploiting the full potential of ICT, the results of the diagnostic study conducted by our research group are explained here (for the full research report see Salinas, Porras, Santos, & Ramos, 2002).

Problem Statement

The *plazas comunitarias* are being opened nationwide to allow low-income populations the opportunity to: 1) attend literacy and non-formal basic education programs; 2) receive continuing education; and 3) become technology literate.

However, due to lofty aspirations on the part of the government at the project's outset, the *plazas* were opened at a hectic pace. Thus, the Institute did not have time to develop a basic model that would aid them in integrating the objectives they hoped to achieve. Understanding the need for such a model, the Institute contacted

our research group to aid in the development of an educational model.

Research Design

The main objective of the qualitative study was to diagnose how the *plazas* were functioning during their first year in operation. It was an exploratory qualitative study done in a sample of 17 *plazas* in six Mexican states over a six-month period. Researchers employed observation and in-depth interview as data collection methods as well as a number of informational sources. To encourage inclusion and expand the sample's variability, the *plazas* were selected using purposive sampling. Questions asked during the study included: How do students learn? How are ICT being used? How are all its physical areas being used? How are the *plazas'* services being promoted? How are the *plazas'* personnel performing their job tasks? And how are the *plazas* relating to their local communities? All observations were recorded in research journals. Finally, the constant comparative method of inductive data analysis was used to identify patterns that might help us understand how the *plazas* were functioning.

Results

1. Although the *plazas comunitarias* project was something new for the Mexican population, it was not entirely an educational innovation as the project lacked a systemic perspective and failed to consider many of the complexities of the social system related to the *plazas*.
2. The *plazas* were operated as traditional schools, not as center of adult education. The opening of the *plazas'* buildings caused employees and adult students to feel that they were in a formal learning environment, and technological materials were used in the same way as in traditional schools. That is, ICT served only as a vehicle of information and not as a mind-tool (Jonassen, 1996).
3. Telecenter users frequently engaged in cognitive processes of the lower orders. In fact, most observed teaching, learning, and utilization of technology practices were focused on the memorization of content for answering multiple-choice exams. Therefore, these adults were not developing higher order skills that would improve their everyday lives, such as learning to learn, problem-solving capabilities, and collaborative learning methods.
4. The role of ICT in the *plazas* was basically to teach its users the essential functions of the equipment and how to manipulate it in order to extract information. Thus, there was no clear understanding of the potential of ICT to improve quality of life or teach life-long learning skills. For the *plazas*, using technology meant only the rote learning of software applications, so ICT was not really perceived as part of the whole knowledge construction process.
5. The *plazas comunitarias* are not decreasing the social inequalities and exclusion of the poor because the people that need these services most are not stepping forward to become telecenter users. They do not recognize any link between the services offered at telecenters and their own personal needs. On the contrary, individuals with more education and belonging to a higher socioeconomic class go to the *plazas* without outside encouragement since the benefits of ICT are more obvious and credible to them. Thus, traditional economic and social inequalities and exclusions are simply replicated at the *plazas* rather than decreased (Steyaert, 2002).

A DIFFERENT PERSPECTIVE

The literature previously cited in this article suggests the employment of an alternative perspective on the use of ICT for social development. To this end, the notion of information literacy and the epistemological and pedagogical concepts of social constructivism are discussed in this section.

Information Literacy

Access to technology is not enough to effect a real difference in the quality of life of socioeconomically disadvantaged populations. Physical access to technology is not as critical as developing information skills, that is, becoming information literate (Steyaert, 2000, 2002). Possessing such skills is a central factor in dealing with social inequalities and exclusion since too little attention is currently paid to developing individual knowledge-acquisition skills, which aid in the satisfaction of individual needs and interests.

The American Library Association (1989) defines information literacy as “the ability to know when there is a need for information, to be able to identify, locate, evaluate, and effectively use that information for the issue or problem at hand.” This definition is dynamic because it states specific skills and actions that would allow a person to solve a problem and, at the same time, become information literate. It is important to note that this person’s goal is to solve a significant, personal problem and not to become information literate. In this regard, Dewey (1938) addresses the importance of acquiring skills as “means of attaining ends which make direct vital appeal” (p. 6).

Social Constructivism

In contrast to traditional objectivism, which assumes that knowledge is “out there” and that it can be transferred to the person, social constructivism takes the view that knowledge is a process more than it is an object, a process through which

individuals develop higher cognitive abilities and construct knowledge through social interaction (Driscoll, 2000). In this social constructivist vision, “knowing is not a static disposition of actors, but rather an on-going social accomplishment” (Orlikowsky, cited in Rowland, 2004). Moreover, the social constructivist posture contends that knowledge is closely related to action and with the context and situation within which it is constructed and used (Brown, Collins, & Duguid, 1989). According to this epistemological perspective, social constructivist pedagogy strives to build learning environments focused on problem solving, where the sharing of knowledge is encouraged through collaborative learning to allow for free meaning development and negotiation. Within one of these learning environments, ICT must be dynamically integrated into the social processes so that people can actively and collaboratively use ICT as a mind-tool (Jonassen, 1996), instead of learning passively from ICT equipment as sheer carriers of information.

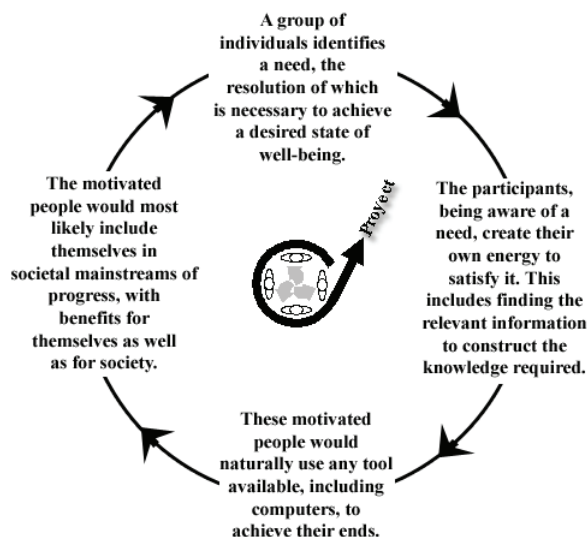

METHODOLOGY TO FACILITATE INFORMATION LITERACY

Drawing from ideas presented in the last section, our research group designed a methodology for the *plazas comunitarias* to promote social development by integrating the use of ICT. This methodology is based on information literacy and social constructivist pedagogy.

The Methodology’s Goal

As Figure 1 demonstrates, the methodology’s goal is to engage the *plazas’* users in a “virtuous cycle” (that is, the opposite of a “vicious cycle”), within which they experience a dynamic process that leads them to a higher state of well-being. The energy that drives a virtuous cycle comes from within the participants themselves; it is generated when a decision is made to act collaboratively and

Figure 1. "Virtuous cycle" of ICT integration

become motivated to satisfy a significant need. To organize these collaborative actions, users develop a group project—that will eventually satisfy the previously identified need—by performing a series of activities.

The premise is by getting involved in a significant activity, the person develops the necessary intrinsic motivation to seek out relevant information and make critical decisions to solve his or her problems. These motivated people would naturally use any tool available, including computers, to achieve their personal ends. In this way, ICT becomes a problem-solving mind-tool instead of being an end in itself. The hypothesis here is that motivated people would most likely include (rather than exclude) themselves in societal mainstreams of progress, producing benefits for themselves as well as for the community.

Project Development

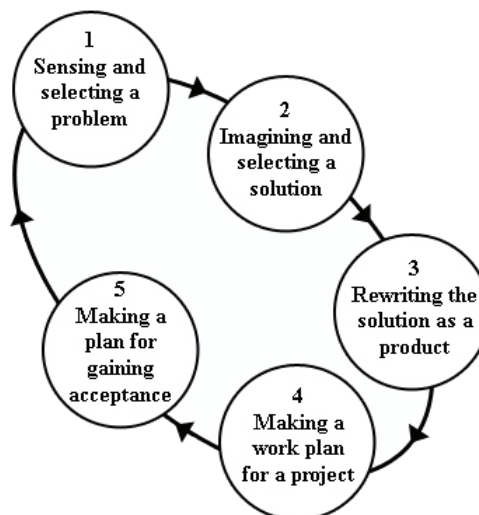

The heart of a virtuous cycle is the set of activities in which users participate in the development of a group project. This process starts at any *plaza comunitaria* when one of its educational advisers invites a group of users to initiate a group project.

The process may be carried out with one person alone, but two or more are preferred as the methodology attempts to exploit the proven benefits of collaborative learning. Then, the adviser and the group complete five different activities, as shown in Figure 2. Selecting a problem (defined as anything that interferes with the satisfaction of a need) as a team and then developing a project to solve it is the first step. The adviser then asks the participants to share their life circumstances with the group and identify problems to which a solution might improve the quality of their lives.

Once each person has expressed their life circumstances to the group and has identified at least one problem, the adviser begins a process of discussion, consensus, and action with the group with the goal of selecting the problem to be solved. The decision is based on which problem is more closely related to their community, taking into consideration their local values and culture, and how much knowledge they already possess with respect to each problem.

Next, the group repeats the process of discussion, consensus, and action, but now with the purpose of imagining possible solutions and selecting one for the chosen problem. The selec-

Figure 2. Activities to develop a group project

tion is made based on such criteria as pertinence, available resources, cost, and time. Then, in order to avoid lengthy discussions and to focus their efforts, the adviser asks the users to imagine a product that they could develop to embody that solution. This product becomes the ultimate goal of the project.

To systemize the group's actions, adviser and users construct a work plan to develop the identified product. This is done by listing all the possible activities and sub-tasks that must be accomplished to reach the project's culmination. Once they are listed, the adviser writes them down in a table format using the following columns: "Task Description"; "What information do we need?"; "What do we need to learn?"; "Which media might we use?"; "Who will do it?"; and "How much time is required?" Finally, as part of the work plan, the group discusses a strategy and makes a list of activities that it might do to achieve community acceptance of its solution-product.

Once the work plan is established, activity begins and users—whose goal it is to complete the project and not to learn certain technology—start to naturally integrate ICT as a mind-tool and develop the information literacy skills needed to accomplish their goals.

CONCLUSION

This article has presented a different way of using IT for social development, one where the individual, his community, and his local culture become the center of all activities. The methodology proposed here has now been tested in the field, and its results will be presented in a future publication. However, there is still much work to be done in this area; we need to develop more research and development projects with a systemic perspective if we want to understand the use of ICT in complex social contexts. In such cases, a phenomenological view seems to be much more powerful for understanding how

a socioeconomically excluded person could improve his quality of life by having access to, for example, the Internet. The qualitative paradigm and the related methodology introduced in this essay appear to be the right choice in experiencing and comprehending the myriad relationships that are cultivated inside a telecenter. Once inside, we might, together with the local players, inductively construct the knowledge necessary to propose broader solutions to the issue of facilitating social development and equality through the implementation of technology.

KEY TERMS

Cultural Function of a Telecenter: Set of processes that a telecenter as an open social system carries out to strengthen grass-root values and identity. ICT should facilitate multiculturalism instead of pursuing the standardization of society.

Distributive Function of a Telecenter: Set of processes that a telecenter as an open social system carries out to foster the egalitarian distribution of its benefits and ICT growth and integration into the community's social dynamics.

ICT as a Cognitive Partner: Traditionally, ICT is used as a vehicle of information, but when used as a cognitive partner, it collaborates in the thinking processes of humans by performing actions such as changing a graph instantaneously or supporting a person to build his ideas when designing a concept map.

Information Literacy: The ability to collaboratively know when there is a personal or communal need for information, to be able to identify, locate, evaluate, and effectively use that information for the issue or problem at hand. (This definition is based on that given by the American Library Association (1989), however, here a social construction of knowledge dimension was added.)

Pedagogic Function of a Telecenter: Set of processes that a telecenter as an open social system carries out to foster social construction of knowledge and the development of cognitive and collaborative skills in ICT users; using ICT as a cognitive partner to empower people instead of as a vehicle of information.

Socio-Organizational Function of a Telecenter: Set of processes that a telecenter as an open social system carries out to strengthen and

support the natural social groups and organizations that exist in its local community.

Telecenter: An open social system where people interact among themselves, with technology and with their context, exchanging information, materials, ideas, feelings, and so forth. The purpose of a telecenter is to maintain this flow by: (1) carrying out cultural, pedagogic, distributive, and socio-organizational functions; and (2) providing access to the necessary technology.

Chapter 2.25

Gender and ICT Policies and Programmes in an Indian State

Malathi Subramanian

Anupama Saxena

Guru Ghasidas University Bilaspur, India

INTRODUCTION

The development and use of information and communication technologies have stimulated huge changes in the life of people globally, leading to a process of transition from the industrial to the information society. The ultimate aim of the information society should be the empowerment and development of all its citizens through equal access to and use of information (Goulding & Spacey, 2002).

BACKGROUND

Unfortunately, despite the potential ability of information to empower disadvantaged groups and the massive investments in information and communication technologies, the information society has remained largely silent on gender issues (Jansen, 1989). There is evidence of a gender imbalance in the use of ICT that threatens to restrict women from being equal partners and beneficiaries of the emerging information society, thus creating a gender-based digital divide.

Decades of experiences have shown that without explicit attention to gender in policy, gender issues are not considered for implementation (Hafkin, 2002). Policy making in technological fields often ignores the needs, requirements, and aspirations of women unless gender analysis is included (Marcelle, 2002). If gender issues are not articulated in ICT policy, it is unlikely that girls and women will reap the benefits of the information age (Hafkin). Closing one's eyes to this fact can entrench inequality and even enlarge the gender gap, making ICT a "gender-negative" technology (United Nation's Development Programme [UNDP], 2003).

Thus, the issue of mainstreaming gender into ICT policies and programmes in the context of India becomes important, as here the ICT policy and programmes have been viewed by national and state governments largely within neoliberal macroeconomic frameworks of gross domestic product (GDP), employment, and competitiveness (Gurumurthy, 2003) rather than as issues of development or empowerment as well. Moreover, as in most of the developing countries, ICT education in India is largely confined to cities as the institutions

that offer ICT education are urban based. While there may be a marginally increased enrollment of women in technical institutes in the last two decades, this has not resulted in more women in ICT-related careers or at decision-making levels. Women are vastly underrepresented in government, business, and social and political institutions even in the urban context. Men still hold most of the management and control positions in ICT-related employment and policy-making bodies. In the ICT-related employment sector, males account for 70 to 75% of the workforce. It has been held that even in the urban context, in the period following education, mobility or a lack of it is a crucial factor that affects the access to ICT and networking capacities of women, which is reflected in the extent of the presence of women in this sector (Pichappan, 2001). Women in India are considered to be the most socially excluded group, and a lack of access to information is being identified as one of the most important reasons for their exclusion (Hooper, 2003). This lack of access to information has added to their alienation from mainstream development activities and empowerment, resulting in increased social exclusion and economic and political marginalization, especially of rural, tribal, and other socially disadvantaged women of India.

A Brief Profile of the Indian State of Chattisgarh

Chattisgarh is a newly formed state of India that came into existence in the year 2000. It is a state richly endowed with natural resources but also marked with severe poverty, backwardness, illiteracy, and ignorance: 79% of the state population lives in rural areas, 32.55% of the population is of scheduled tribes (STs), and 12.22% is of scheduled castes (SCs). During 1999 to 2000, the state was third in share of the rural poor in India, with 11.35% of the total poor. Its low position in social and economic infrastructure and development is well documented (Dev, 2004; Kannan, 2004). The

state has been ranked second to last in the list of all Indian states for telecommunications density (report of the Ministry of Communications and Information Technology, <http://www.trai.gov.in/dld1.html>).

Women in Chattisgarh

Women in Chattisgarh are visible in every walk of life, be it in agriculture, in the collection and processing of the state's rich forest wealth, or in construction and wage work in urban areas. Contrary to the situation in many parts of India, Chattisgarh enjoys a comparatively favorable position in terms of women's population as reflected in the sex ratio, which is 990 females to 1,000 males (census of India, 2001, <http://www.censusindia.net/>). However, in terms of infant mortality rates, its record is 97 girl deaths out of 1,000 infants, which is the highest in India (Rustogi, 2003). Furthermore, during 2000 to 2001, the school dropout rate (Class I-VIII, i.e., grade one to grade eight in schools in India) in Chattisgarh was 47.15%. This rate was higher among the SC (49.95%) and ST (63.68%) categories. Also, the female dropout rates were much higher than those of males (social infrastructure document, <http://chhattisgarh.nic.in/opportunities/Social%20Infrastructure.pdf>).

ICT Policies and Programmes

Nevertheless, with the formation of a separate state for its people, the state is aspiring for the prosperity and growth of its people (state vision document, <http://chhattisgarh.nic.in/vision/new/Chp%205%20-%20Unlocking%20Natural%20Wealth.PDF>). Expressing its commitment toward the development of its woman population, the state has envisaged a very ambitious and comprehensive women's policy (<http://chhattisgarh.nic.in/wcd/womenpolicy.PDF>). Realizing the importance of ICT, Chattisgarh also has a very comprehensive and ambitious IT policy (<http://chhattisgarh.nic>.

in/policy/IT%20Policy.pdf). After its emergence in November 2000, the state government launched a number of ICT-related schemes and programmes for the benefit and development of its people, which are listed as follows:

1. **Bhuiyan:** All land records are computerized under this scheme. By paying only rupees, anyone can get a copy of the land records. Implemented in all Tehasil (Block) headquarters of the state, it is also planned to be extended to the villages at a future date.
2. **E-Sangwari:** This scheme is implemented with the objective of providing seven services to common citizens and was launched in the Bilaspur district only: (a) death certificates, (b) birth certificates, (c) caste certificates, (d) Form 16, pertaining to income tax, (e) khasaras (land records), (f) income certificates, and (g) domicile certificates.
3. **E-Kosh:** This scheme started in December 2004 to computerize all treasury transactions of the district headquarters.
4. **E-Panchayatas (Local Self-Government Units):** This programme was launched on January 26, 2005. It is executed through janpad panchayatas (local self-government units). Each janpad panchayata is given two computers that will be linked by satellite. The total cost of the project is over 9 million rupees, excluding the cost of software and satellite linking. It is sought to be an informative programme aimed at informing the rural people about the development and welfare schemes, and making available forms online. It is expected to be interactive in the future.
5. **Videoconferencing:** This programme was launched in January 2001. The heads of various government departments answer the questions asked by the common people through videoconferencing. It is being operated daily, and according to the officer in charge, 8 to 10 questions are asked daily.
6. **Feedback:** Most of the departments of the government are on the Web with the facility of a feedback system. Any citizen of the state can register any complaints or suggestions related to any of the schemes or programmes of the state government through the Internet. The complaint or suggestion is directly sent to the concerned department or official online. The status of the application or complaint can also be ascertained online.
7. **Wireless Loop-Line (WLL) Telephone:** Bharat Sanchar Nigam (the central agency providing telephone and Internet services all over India) has provided at least one phone to each village under this scheme with a 50% subsidy of the total bill. At some villages, Internet facility is also being started through this.

The ICT-related schemes listed attempt to make administration more citizen friendly in that earlier, obtaining these services involved visits to the offices concerned, often requiring a lot of time and effort. Making these schemes available on the Internet has also made it possible to obtain feedback from the public at the users' end, which was not easy earlier. The use of the Internet in administration in that sense is aimed at collapsing the distance between the officials and the public. In the Indian context, since before the ICT-based administrative schemes were introduced, it has been primarily men rather than women who often come into contact and interaction with officials (also mostly male) in administration. This is an activity in the public domain, which is traditionally male dominated, and is also considered largely the responsibility of the man in male-headed Indian families. The use of the Internet in administration could put the schemes within the reach of women without them having to move from their locales. However, this has not happened as assumed with the ICT-related policies and programmes, which aim at bringing administration within the reach of every citizen.

ICT Programmes and Women in Chattisgarh

Field surveys show that while it is generally assumed by policy makers (mainly male) that ICT policies and programmes will benefit men and women equally, the ground reality is that there is a vast difference in the availability, use, and access of ICT facilities for men and women. Hence, it is necessary to examine the gender perspective in the ICT policies and programmes. The ICT policies, programmes, and schemes in Chattisgarh seem to bypass the question of women's capacity building and empowerment. The impact of these policies at the user end for women is one of exclusion due to various reasons that need to be addressed urgently to avoid the digital gender divide superimposed on the already existing gender disadvantages for women arising from sociocultural factors (Nadamoto, 2003). Without a gender perspective, the low participation of women in accessing and using the ICT-based facilities may not be noticed. This is the case in the Chattisgarh region where even in urban areas, as compared to men, a very low number of women use the Internet-based facilities and services such as videoconferencing with public bodies; accessing Internet-based services like e-sangwari for obtaining records regarding births, deaths, or land; or using local government-information kiosks for obtaining information under the e-panchayata scheme. In fact, very few women have telephones registered in their own names. Similarly, in the educational sphere, there is low enrollment, retention, and visibility of women in ICT-related courses of study. Thus, in the Indian context, where women are already less visible in the public spheres due to sociocultural factors and men already dominate, ICT schemes are more available and accessible to men. This is also because ICTs have masculine connotations due to the traditionally larger presence of men in technological disciplines. Such is the picture in urban areas in Chattisgarh where more women

are literate, are aware, and face comparatively less sociocultural constraints. Even if these programmes and facilities based on ICT are made available in the rural areas, women would still find it difficult to benefit from them due to the already existing limitations of a male-dominated society, especially those in areas dominated by the scheduled castes and tribes, who have been recognized as disadvantaged and who suffer from severe poverty, illiteracy, and backwardness, added to by the domination of patriarchal values, traditions, and attitudes.

While the state government of Chattisgarh is using the Internet in publicizing its various policies and programmes, advertising tenders and contracts, and making available the application forms of various schemes, in the absence of any capacity-building measures for women using ICT, at the operational level it is difficult for women to benefit from these schemes as they are unable to access the schemes due to various reasons located in the sociocultural milieu in which women are already disadvantaged. Traditionally, the households in India, whether in the urban or the rural sector, are male dominated, with the sphere of functions and activity related to the household clearly demarcated for women, which restricts their mobility in the public domain. This is reflected in women's choices of courses of study, the fact that very few are opting for and remaining in IT-related courses, and women's low presence in decision-making structures, even in urban areas where most of the ICT-related educational and training centres are found, where ICT-based programmes and schemes are being implemented, and where more women are educated and aware. In the rural areas, particularly in the backward areas and where socially disadvantaged sectors already exist, the digital divide accentuates the existing disparities both for men and women. For women who are situated in a rural backward area, it is doubly accentuated in that the well-intended ICT programmes and schemes do not reach them due

to the urban bias in these programmes, and also because of the already existing gender disparity in the sociocultural milieu.

As ICT is becoming a popular and powerful tool for opinion formation through the dissemination of information, women's voices remain unheard while the men continue to dominate the common public discourse and opinion. The increased use of ICT in business is also benefiting mostly men as that sphere is also male dominated in India. In this sense, it could be said that the ICT-based services could further accentuate the dominance of men even though it may be intended to benefit all citizens. The ICT-based services, instead of being a means of empowerment and development of women, may in fact help in perpetuating the existing male-dominated gender patterns and biases in the society unless the issue of capacity building and empowerment of women is addressed.

FUTURE TRENDS

It is obvious from the foregoing analysis that without including the gender perspective into ICT policies and programmes, the potential benefits of ICTs may bypass girls and women, leading to a gender-based digital divide accentuating the preexisting gender imbalance. Access to and use of the new technologies may be directly linked to the social and economic development of women. In the Indian context, for instance, after the death of their husbands, without death certificates, many women face difficulties in getting the family pensions or rights over the properties of their husbands. Likewise, because of the lack of access to land records, it becomes difficult for women to sell or buy land without the help of a male. Similarly, as the videoconferencing facility is available only in the district headquarters, it is almost impossible for rural women to visit the site without the male members of their families. Thus, if women do not have access to and control over

these technologies, it may result in their further marginalization from the economic, social, and political mainstream. Indian rural women comprise a social group that is already disadvantaged in the predigital society, and there is a threat that when it comes to the prospect of participating in and benefiting from the emerging information society, they will again find themselves doubly disadvantaged.

CONCLUSION

Technology has actually been historically and culturally construed as masculine. There has been a tendency toward the division of disciplines into masculine and feminine. For instance, arts, literature, languages, social sciences, and teachers' education are viewed as feminine. On the other hand, professional disciplines such as engineering, agriculture, medicine, commerce, and law have been traditionally perceived as masculine. More women are enrolled in the so-called feminine disciplines. As a result, women are conspicuously absent from the decision-making structure of ICT policy and programmes, resulting in the absence of the gender perspective in ICT policies and programmes.

Women's organizations, the office bearers of women's wings of different political parties, and other gender-focused organizations do not consider ICTs as a development concern or as an advocacy or political issue.

There is sometimes the problem of conceptual clarity regarding the modalities of gender mainstreaming among policy makers, those who implement them, development workers, and even among the academia. This lack of clarity or awareness, either conceptually or in operationalization, of gender mainstreaming and the resultant uncertainty have often led to nothing being done substantially apart from the mere use of some new words without much change in intentions or consequences for women

There is often a common tendency in India among policy makers and among those who implement them to treat some areas as gender neutral, and this is the case with the ICT policies and programmes in Chattisgarh.

The patriarchal character of society and the well-entrenched patriarchal attitudes creep into the formulation and implementation of the ICT policies and programmes.

Unless a gender perspective is mainstreamed into policies and programmes, ICT is likely to remain a male-centric technology benefiting mostly men and depriving women, especially those who live in rural areas and those who are already socially disadvantaged as in Chattisgarh. There is an urgent need to ensure adequate measures in this direction to ascertain equal benefit and use of ICT for women.

KEY TERMS

Digital Divide: The digital divide is defined as the disparity between individuals with and those without access to a computer and the Internet. The divide is applicable to all population sectors encompassing both adults and children, but the focus of much attention has been on segments of the population seen as underserved: people in low-income, rural, and multicultural areas, and women.

Gender: Gender refers to socially constructed rather than biologically determined roles of men and women, as well as the relationship between men and women in a given society at a specific time and place. These roles and relationships are not fixed but can and do change in the light of evolving needs and opportunities.

Gender Mainstreaming: Gender mainstreaming was defined by the United Nations Economic and Social Council in 1997 as a strategy for making women's as well as men's concerns and experiences an integral dimension of the design, implementation, monitoring, and evaluation of the policies and programmes in all political, economic, and social spheres so that women and men benefit equally, and inequality is not perpetuated.

Gender Neutral: Gender neutral means a policy or programme that purports to, or is assumed to, impact men and women in the same manner. (It could also mean a lack of gender awareness or even "gender blindness," i.e., not conscious about the ground reality about the position of women in a particular society.)

ICT Policy: An ICT policy is an integrated set of decisions, guidelines, laws, regulations, and other mechanisms geared to directing and shaping the production, acquisition, and use of ICTs. Because the ICT sector is heterogeneous, extending beyond traditional classifications of industrial or services sectors, and because the production and diffusion of ICTs are of equal importance, policies in the ICT sector intersect with a number of other areas of policy making: technology, media, industrial, and telecommunications policy, and so forth.

Primitive Tribes: The most backward groups of Indian tribes.

Scheduled Castes (SC): The socially disadvantaged section of the Indian society on the basis of the caste system, identified for affirmative action by the Indian constitution.

Scheduled Tribes (ST): The indigenous people of India, the forest dwellers commonly known as tribes, identified for affirmative action by the Indian constitution.

Chapter 2.26

Crossing the Digital Divide in a Women's Community ICT Centre

Clem Herman

The Open University, U K

INTRODUCTION

This article examines the role of community-based training initiatives in enabling women to cross the so-called digital divide and become confident users of ICTs. Drawing on a case study of the Women's Electronic Village Hall (WEVH) in Manchester, United Kingdom, one of the first such initiatives in Europe offering both skills training and Internet access to women, the article will illustrate the impact that community-based initiatives can have in challenging and changing prevailing gendered attitudes toward technology. Gendered constructions of technology in dominant discourse suggest that women must also cross an internal digital divide, involving a change in attitude and self-identification, before they can see themselves as technically competent. Learning about technology is intimately linked to learning about gender, and the performance of skills and tasks that are culturally identified as masculine can be an empowering step for women, successfully challenging preconceived gendered relationships with technology.

The WEVH occupied a unique position, acting as a model for other women's ICT initiatives and influencing the development and proliferation of other community-based ICT access projects. There were two main motivating forces behind its setting up in 1992. The first was a shared vision of the potential for ICTs to be used as a tool to combat social exclusion. The second was a feminist commitment to redressing the inequalities and underrepresentation of women in computing. Both these perspectives formed an important backdrop to the growth and development of the organisation and have continued to inform its strategic plans.

BACKGROUND

The Digital Divide

The context in which the WEVH was set up in the early 1990s was the first wave of initiatives concerned with tackling the so-called digital divide. During the decade that followed, there

was a proliferation of initiatives driven by both British government and European policy aimed at ensuring that the emerging information society was inclusive of all citizens including specific measures for the participation of women.

While the personal ownership of PCs (personal computers) and home-based access to the Internet has increased at a rapid pace in Britain since the early 1990s, it is still the case that significant sections of the population do not have access to computers or the Internet. Moreover, those who are digitally disadvantaged often do not have the skills to take advantage of the potential that ICTs have to offer¹ (Office of National Statistics, <http://www.statistics.gov.uk>). Community-based ICT facilities to tackle the so-called digital divide were seen as one of the key strategic tools in community development and urban regeneration that was reflected in policies at the local, national, and European level.²

During the first wave of measures to tackle the digital divide in Europe in the early 1990s, women were considered one of the primary target groups for ICT training and access. The emerging Internet at that time was predominantly used by “techie” men, designed and implemented without the perceived need for inclusive strategies, and immersed in a strongly male-identified culture. At the time of its creation, the WEVH was therefore responding to a clear need to tackle gender inequality, an issue that was considered self-evident to all concerned. Over a decade later, following the transformation of user interface design and the creation of the World Wide Web, Internet access reached the majority of the British population, and there is now only a small difference in usage between men and women (Citizens Online, 2005).³ While this is certainly an improvement, this simple analysis of Internet usage ignores the realities of women's continued underrepresentation in the IT industry, from their lack of influence on content and applications development to widespread inequalities in women's employment opportunities in IT. Yet it seems that the increase

in women's access to the Internet and basic ICT skills has seen a reduction in public commitment to resources for women-specific ICT initiatives, which had historically been justified by the statistics of Internet usage.

While quite rightly addressing important social-exclusion issues, the notion of the digital divide as it has been used in British policy debates is somewhat limited, assuming a one-way process in which access to a computer and the Internet enables individuals to cross over and join the digitally empowered. However, there are significant numbers of ex-Internet users or refusers, that is, those who have stopped using the Internet either by choice or because they no longer have access: “It is clear ... that overall growth patterns of Internet usage conceal significant changes in usage by different sub-populations, including some evidence of drop off by particular groups” (Woolgar, 2000, p. 5).

Community ICT Access

The creation of the WEVH was part of a growing movement of community ICT initiatives that were developed at the local level both in Britain and elsewhere in the early 1990s. All of the initiatives had the common aim of providing “supported access in a location other than work or home” and “access to ICT in a social context” (Liff, Watts, & Stewart, 2000, p. 2-3). They have been known by a range of names including e-gateways, telecottages, telecentres, electronic village halls (EVHs), ICT learning centres, cybercafes, telework centres, community teleservice centres, and so on.

The idea of the electronic village hall was based directly on a model pioneered by Lars Qvortrup in Denmark, and was influenced by a growing counterculture in the USA of online community networks and bulletin boards such as The Well (Rheingold, 1995). The creation of urban electronic village halls was part of a vision for the city of Manchester that combined community grassroots involvement with a local-

authority public-information service known as the Manchester Host, an e-mail and bulletin-board system that local people could connect with and use to communicate with each other that would have shared community space as well as online databases supplying information. A cornerstone of the vision was that local people who did not have access to computers in their homes would be able to use these services at community access points: There were already some examples of these kinds of community centres operating successfully in rural Scandinavia. The concept of an electronic village hall in Manchester was a deliberate attempt to adapt the concept of a rural telecottage into an inner city context (Leach & Coppitch, 2005). The name implied that the centres would function as cozy, friendly local meeting places where technology could be made accessible and simple to use. In 1990, there was no World Wide Web, just text-based, command-line interfaces, so it was imperative that there were people to enthuse and support new users who might find the technology intimidating. The centres would be staffed by enthusiastic “telemateurs” who would raise awareness and act as missionaries within the communities. This was very important: The projects were not responding to expressed needs, but were proactive in trying to create those needs and a critical mass of users on the Manchester Host. As well as the WEVH, two other electronic village halls were set up in geographical neighbourhoods, providing services to spatial rather than virtual communities. The EVHs were charged with wide-ranging social and economic aims, including a regeneration agenda supporting and encouraging the development of local communities and businesses through the use of ICTs.

Women and ICT: Finding a Space

While this political context in the city of Manchester was one strand in the WEVH story that

informed its strategic and financial development, it was the feminist agenda of empowering women through the use of technology that formed the core of the organisation's vision. In looking at how the experience of the WEVH connects with theories about gender and technology, it is possible to trace a changing awareness and perspective within the organisation during its historical development, which reflected changes in external environments and political climates within what might loosely be called the women's movement in Manchester.

The original proposal for the WEVH was to house the project in a women's community centre, a building that had been home to the famous Pankhurst family. (Emmeline Pankhurst and her daughters were leaders of the British suffragette movement in the early years of the 20th century, and their house became an important focus for the women's movement in Manchester in the 1980s.) However, differing perceptions and attitudes toward technology resulted in the project being located elsewhere. Existing workers at the centre who had been immersed in the political struggles of the 1980s adopted what could be described as an ecofeminist position: They saw technology as something to resist rather than embrace and were afraid the project would take over the work of the centre. There was a level of technophobia that sprang from a tradition of radical feminism in which technology was to be resisted as part of the patriarchal, military, industrial complex, a biologically determinist viewpoint advocated by writers such as Susan Griffin and Adrienne Rich (Grint & Gill, 1995). The 1980s women's movement had been characterised by peace and antinuclear protests, the emergence of green and environmental causes, anticapitalism, and a celebration of women's creative diversity. The new information and communication technologies were seen to be associated with masculine values and were perceived as a threat to hard-won women's space.

Equality of Opportunity

In fact, from its inception, the WEVH can be seen to have subscribed to a liberal feminist agenda in relation to technology (Henwood, 1993) in that the aim was to get more women into technology by increasing the supply of skilled women. Women were identified as lagging behind in their involvement with new technologies, and the new centre would help them catch up by offering special programmes of training. This approach came through the conviction that providing opportunities for skills development would bring about change and was consistent with the dominant equality-of-opportunity discourse current at that time. This was an approach prevalent in women's training centres throughout Britain, which provided access to training in nontraditional skills. This agenda was also overtly highlighted in the criteria of funding agencies. Many of the training and research projects were funded by the European Union and were based on the underlying justification that there were skills shortages in a particular industry (in this case IT) and women were underrepresented in these occupational sectors. The solution was to increase the number of women in these sectors by encouraging them to develop skills and enter work in ICT. Training was carried out within a culture of nurturing and supporting women, which drew on traditional feminist pedagogical methodologies—peer support group, personal growth and consciousness raising, a celebration of the hidden achievements of women in history, and so on (Ellen & Herman, 2005).

While individual women certainly achieved personal success, not surprisingly, very little change was brought about to the gender balance in the IT industry as a whole. Although women consistently found employment directly after their training (<http://www.wevh.org.uk>), only a handful of women went into areas of IT that were highly gender segregated such as computer networking. Those women who went on to study computing or IT in higher education mainly went into so-called

“soft” or hybrid degrees, not into the traditionally male-dominated subjects such as computer science. This is hardly surprising given the scale of the problem: The equal opportunities or liberal feminist agenda, the “women-into” approach, has not generally been successful in achieving the large-scale restructuring of gendered occupational segregation in technology (Ellen & Herman, 2005). In fact, any attempts to rectify the unequal gender balance in segregated occupations without tackling underlying cultural norms seem destined to remain marginal in their impact.

Cultural change is necessary at both the macro and micro level. Parallel to the discourse of equal opportunities and the liberal feminist analysis of gender and technology, the WEVH can be seen as having the more subversive strategy of challenging the perception of “technology as masculine culture” (Wacjman, 1991, p. 137). Understanding technology as culture (both as the work environment in which technology is used as well as the artefacts and hardware themselves) has enabled the organisation to challenge attitudes that women had about themselves and their own expectations. Women experienced participation with technology as an appropriate activity rather than a transgressive act to be resisted. An environment in which trainers and technical staff were all women and learning was experienced in an all-female group provided a stark contrast to the cultural norm of technology as masculine. The women-only training environment was crucial to success: It allowed skills to be acquired in a gender-neutral way without having to refer to dominant cultural assumptions of gender-appropriate knowledge.

Empowerment and Cultural Change

Even within a small-scale environment such as the WEVH, it has been possible to challenge deeply held cultural attitudes. One of the key strategies was to ensure that women had hands-on experience of touching technology, which has often

been a taboo activity for women. Throughout all training provision, an emphasis was placed on giving women the empowering experience of handling pieces of technological equipment and to see this as fun and enjoyable. In introductory courses, women had to assemble their own PCs by plugging in the correct leads; in the networking course, women were installing motherboards and fitting new cards, crawling under tables to connect wires. All trainees were taught to carry out routine maintenance and troubleshooting procedures.

These experiences are empowering not only because they develop useful skills, but also precisely because they are transgressive and not what women would have expected of themselves. These women were not performing gender in the way in which they had been used to, and by doing so, they were subverting received notions of gender-appropriate behaviour or performance (Butler, 1999). This empowerment was something that women could transfer to other areas of their lives, and many expressed how they had become more confident and increased their own self-esteem. One woman says, "the training I received at the WEVH has had an incalculable effect on my life...I learnt about the logic behind computer systems which set both my capabilities and my imagination free" (Dyson, 1999, p. 78). By challenging internal stereotypes about the type of knowledge and skills considered appropriate for themselves as women, they could then apply this knowledge to other situations.

A final perspective through which this process of bringing women into a self-confident engagement with technology can be viewed is that of Haraway's (1991, p. 149) notion of the cyborg. As women acknowledge and develop their own relationships with technology through the acquisition of skills, they gain an understanding of and positively embrace the role that technology does and will play in their lives. They recognise that they "are all hybrids of machine and organism...are all cyborgs," and see technology as part of their own

future rather than something external to them: "[The WEVH provides] the right atmosphere for any woman, of any background, to attain her best. It made us feel positive about the future, new technology and picture ourselves in it" (Dyson, 1999, p. 75). Opening up opportunities for women to positively use and shape technology has been the ultimate goal for the WEVH; as much as skills and knowledge, it is attitudes that must be changed for this process to succeed.

FUTURE TRENDS

It is clear from this case study that community-based women's training centres such as the WEVH can play a vital role in supporting women to become skilled and confident users of ICT and cross over the digital divide. During the rapid expansion of Internet usage since the late 1990s, the WEVH and similar centres have been important in ensuring gender equality in access to ICTs and pioneering new approaches to empower women in their use of technology. Yet, while Internet usage has now reached the majority of the British population and is relatively equal in terms of gender, there is still a need to support those who are digitally disadvantaged. The lack of Internet access and ICT skills is closely correlated with other indicators of economic disadvantage such as educational achievement, ethnicity, age, and employment status. Thus, for the foreseeable future, there will continue to be a role for women's centres to provide support and empowerment for a significant minority of women who would otherwise not have the skills or confidence to use ICTs. And while the prevailing culture of the IT industry as a whole continues to be male dominated with significantly fewer women employed in this sector, it is important that women's ICT initiatives continue to offer spaces that are free from mainstream gendered constructions of technology, and a basis from which to campaign for change.

CONCLUSION

The original aims and objectives of community ICT initiatives have been clearly tied to an agenda of local democracy and participation. In the case of the WEVH, the fear was that ordinary women would be excluded from participating in the new information society and therefore it was imperative to provide public access points for those without access to equipment at home or at work. But it was always clear that democratisation included not only the means of participation (i.e., hardware and connectivity), but also the skills and attitudes needed to effectively make use of these. For women in particular, there were internal messages and cultural barriers that also had to be overcome. This vision has remained but has had to adapt to a wide range of changes. Technological developments and the wider ownership of PCs have altered the role from one of advocacy and awareness to that of fulfilling expressed needs.

The WEVH has been a unique example of a vision that has survived and grown despite the changing agendas of funding agencies and politicians, a vision of a centre where women can become confident users of technology. Above all, it has played a unique role as a place of personal change and transition for women, an inspiration for other community ICT initiatives, and has created a culture of women using and shaping technology.

KEY TERMS

Cyborg: Originally used to describe human-machine hybrids and commonly found in science fiction, the term was adopted by Haraway (1991) to advocate women's involvement with rather than rejection of technology.

Digital Divide: The division between those who have access to ICTs (particularly the Internet) and those who do not, implying that those without access are disadvantaged. It is used to describe both local and global inequalities.

Electronic Village Hall: A centre providing computers and Internet access for local people or people from a particular community or group. It is also known as a cybercafe, community technology centre, telecentre, or telecottage.

Empowerment: Development of the capacity (either of an individual or a group) to act independently and be able to make and influence decisions and choices affecting one's own life.

ICTs (Information and Communication Technologies): The convergence of computerised information systems with communications technologies, generally used to mean all forms of electronic communication including computers, mobile phones, and other devices.

Information Society: A society in which information and knowledge are central to economic and social life, in contrast to industrial or agricultural societies. The term was widely used by British and European policy makers in the 1990s.

Liberal Feminism: Feminist theory focusing on equal rights and emphasising the removal of barriers to ensure equality of opportunity for all regardless of gender.

ENDNOTES

- ¹ In February 2005, 35% of adults in the United Kingdom had never used the Internet. Of these, 42% had no Internet connection, and 37% felt they lacked the knowledge or confidence to use it. (Office of National Statistics, <http://www.statistics.gov.uk>)
- ² For example, the UK Online initiative in 2000
- ³ The Office of National Statistics (<http://www.statistics.gov.uk>) estimated that 64% of men and 56% of women had used the Internet in the 3 months up to September 2005.

Chapter 2.27

Developing Regional Tourism Using Information Communications Technology

Dean Carson

Southern Cross University, Australia

INTRODUCTION

Tourism and hospitality industries are heavily reliant on the effective exchange of information between suppliers, intermediaries, regulatory and marketing agencies, and consumers (Sheldon, 1999). Many technologies may be employed to facilitate this exchange, with the selection of the most appropriate technologies in any given circumstance depending on issues such as the proximity of agents; the extent to which information is dynamic; and the application of information as part of business or decision-making processes.

In regional tourism [i.e., that which occurs outside major capital cities, domestic source markets, or international tourism gateways (Kelly, 2003)], suppliers, intermediaries, facilitators, and consumers are likely to be highly dispersed (Carson, Sharma, & Waller, 2003). Information is likely to be dynamic, as tourists respond to seasonal changes in product offerings. A lack of critical mass of products and consumers in regional areas (Carson, Richards, & Rose, 2004) heightens the importance of effective information exchange, as businesses have fewer opportunities to draw on

local markets to make up for any market instability that may result from poor communication.

Information and communications technologies (ICT) and, specifically, online technologies, offer potential for improving communication effectiveness, which may be defined to include accuracy, reliability, timeliness, and accessibility of information exchange (Carson & Sharma, 2002). While these technologies may be employed by businesses operating in regional destinations, it is important to recognize that regional destinations tend to operate as tourism systems (Leiper, 1995), with close connections between organisations in the private, public, and community sectors required to take advantage of the economic, social, and environmental benefits of tourism while minimizing the negative consequences. As an ICT issue, then, the question is not simply how can tourism businesses best employ the technologies for their individual sustainability, but how can regional tourism systems as a whole effectively employ ICT (Carson & Richards, 2004)?

Despite the substantial potential, and the growing role played by ICT (particularly online technologies) in the regional tourism destination

development, Alford (2004) provided strong evidence that many systems have failed to meet expectations. Project costs, particularly in the implementation phase, have been poorly assessed, and there has been a high rate of project failure. Alford suggests that technology-driven approaches to decision making have a poor record of success and proposes the use of critical theory to increase the understanding of ICT issues. This approach recognizes that technology inevitably interacts with “the real world” and that real-world constraints are more important to the outcome of technology projects than their technical merits.

This article is concerned with proposing a framework that may assist regional tourism destinations to incorporate some real-world thinking in making decisions about what types of ICT to implement and support. It also describes some of the broad international trends in ICT and tourism that may influence the adoption of technology. The article is based on a five-year research program in Australia that has included case studies of technology adoption by a variety of organisations that participate in regional tourism systems in Australia (see, for example, Carson, Taylor, & Richards, 2003; Carson, Sharma, & Waller, 2003; Sharma & Carson, 2002), and a review of the international literature addressing tourism and ICT adoption generally. The article argues from the standpoint that regional tourism systems and their component organisations need to make careful decisions about what technologies to implement, and how these may best be employed. Furthermore, substantial barriers to technology adoption persist in many regional areas, and these will need to be addressed to allow tourism to reach its potential as an economic driver, particularly in developing countries and depressed rural economies (Kelly, 2002).

A FRAMEWORK FOR REGIONAL TOURISM TO EMPLOY ICT

Throughout the late 1980s, researchers such as Buhalis (1998, 1997), Sheldon (1999), and Werthner and Klein (1999) suggested that ICT and, in particular, online technologies, would become more widely depended upon by tourism businesses, consumers, and intermediaries to manage relationships between these agents. ICT may therefore facilitate relationships between business and consumer, business and business, and business and government. There are additional relationships between government and government and consumer and consumer (for example, chat rooms) that have been facilitated by ICT but are not considered in this paper. Likewise, consumer and government relationships have been enhanced through initiatives such as Australia’s Electronic Travel Authority System, which allows for online processing of visa applications for many international visitors (Sustainable Tourism Cooperative Research Centre, 1999).

Carson and Sharma (2001, p. 121) proposed an online architecture as a guide for tourism businesses in assessing their ICT needs, and then matching tools and applications to those needs. The online architecture suggests that organisations (primarily, but not exclusively, private firms) need to consider their information exchange needs in relation to communication, research, promotion, product distribution, and management functions. The online architecture emphasizes that technology can only be effective if its use enhances the ability to perform business functions. The best technology is not necessarily that which is newest to market or that which contains the greatest number of features. The best technology is that which most closely matches the business needs of the purchasing agent. The online architecture provides a framework for assessing that match.

Figure 1. Influences on the online architecture

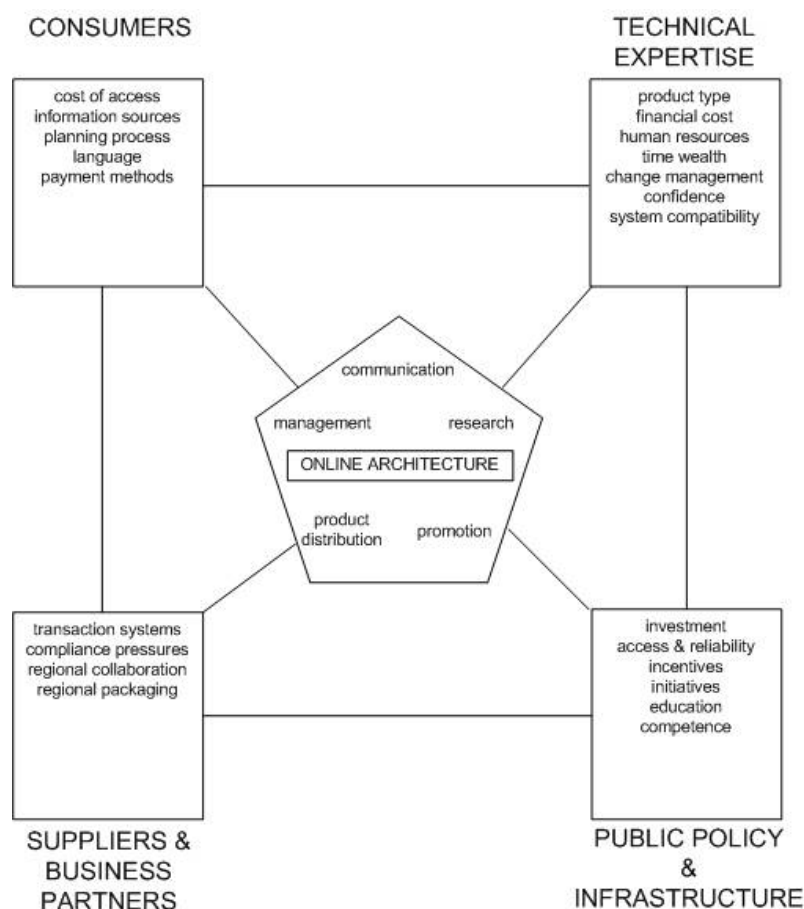

Figure 1 is a refinement of the online architecture proposed by Carson and Sharma (2001). It encompasses the five components of technology application described by Carson and Sharma, and also includes a set of influences on the specific technology mix for an enterprise or, in the context of this article, a destination. Four influences are identified as being consumers, technical expertise, public policy and infrastructure, and suppliers and business partners. Within each influence are conditions that act upon the capacity for regions to choose an online architecture. Conditions may include financial, human, and time costs (technical expertise), public investment and access to infra-

structure, the nature of regional collaboration, as well as the preferences of consumers.

It may not be that each of the four influences described in Figure 1 have equal weight in implementation of a regional online architecture. Some of the conditions (for example, access to adequate infrastructure) may be prerequisite, while others (such as the compatibility of online systems of business operation with offline systems) may exert degrees of influence. While the framework in Figure 1 may assist regions in scoping their general online architecture requirements, decisions about specific technologies, applications, and management approaches are driven by the cues listed as follows:

Communication

- What networks require maintenance through communication?
- Who are the targets?
- How often and when do I communicate with them?
- What is the format of the communication?
- What technologies do my targets have, and what technologies do they plan to use?

Research

- What information do I need?
- When do I need it?
- What costs do I incur currently in getting that information?
- Is the information available online?
- What are the costs of getting this information online?

Promotion

- Who is the intended audience?
- What is the message?
- What action do you expect the audience to take having received the message?
- Can they take this action online?
- How do you measure the impact of the message?

Product Distribution

- What am I selling?
- Who am I selling it to?
- When is it normally paid for?
- What are the costs of accessing e-commerce models (in-house, outsourcing, etc.)?
- What inventory management systems do I have?

Management

- What management functions do I need to perform (banking, recruitment, staff training, compliance, etc.)?
- How often do I perform them?
- Are there resources online?
- What is the cost of accessing them compared to the current cost?

The research by Sharma and Carson (2002) showed that businesses that undertook a formal or informal program of ICT planning that considered each aspect of the online architecture were more likely to persist with technology implementation, and to self-assess their ICT strategies as highly effective for their businesses. Those who used a more technology-driven process of planning (based on “what was possible” rather than on “what was required”) tended to perceive more barriers to implementation, and to suffer greater rates of withdrawal from their ICT tools and applications. Of course, all elements of the online architecture are essentially concerned with communication, and in a regional setting, may contribute to the maintenance of networks and relationships both within a region and between a region and other elements of the tourism system.

The Australian research described by Sharma and Carson (2002), and a review of key international literature in the field, has identified a range of ICT tools and applications that have been developed specifically for tourism or that have found particular application in regional tourism destinations. Table 1 identifies some of these initiatives to provide a sample of the ways in which ICT has been employed to facilitate regional tourism development. Initiatives marked with an asterisk are described in brief below the table.

Developing Regional Tourism Using Information Communications Technology

Table 1. Potential ICT responses to an online architecture for regional tourism (Sharma & Carson, 2004; Carson & Richards, 2004; Knoblock, 2004; Christou et al., 2004; La Micela, Roberti, & Jacucci, 2002; Maidche & Staab, 2002; Flouri & Buhalis, 2004)

- **AFTA WebMAIL:** WebMAIL is an online information management system for travel agents in Australia (AFTA is the Australian Federation of Travel Agents). WebMAIL collects and collates product offerings and announcements from participating industry

suppliers across Australia, and provides a single point of access to these for registered travel agents. The system has been instrumental in assisting travel agents in managing the high volume of daily information (special deals, new packages, etc.) they have

received by fax and individual e-mail in the past (Sharma & Carson, 2004).

- **Decipher:** Decipher is an Internet-based “one-stop shop” for tourism research and business intelligence aimed at the Australian tourism industry. It stores publications, tables, maps, and other information packets in a central location and provides access to these through a series of knowledge products (such as business planning and marketing tools) and search functions (Carson & Richards, 2004). Decipher has similar aims to technologies under development or currently implemented in Austria (Woeber, 2003), Canada (Waksberg, Stevens, & Vales, 2000), Spain (Navaro & Rubio, 2000), and in the state of Illinois in the United States (Gretzel & Fesenmaier, 2002).
- **Business Entry Point:** The Business Entry Point is an online information service for small firms in Australia. It provides assistance with licensing and accreditation requirements, and assists in business planning and compliance.
- **Australian Tourism Data Warehouse:** The Australian Tourism Data Warehouse is one example of a national-level tourism product database used for online promotion purposes. The Data Warehouse brings together state and regional product databases using a common data structure and ontology.
- **GDS:** Global distribution systems are used by airlines, travel agencies, and other intermediaries to manage product inventory and to sell tourism products and packages. In the past, these have been dedicated line electronic services, but virtually all of the major GDSs (Amadeus, SABRE, Galileo, etc.) have migrated to online systems.
- **PICO:** PICO is the *Project of Innovation by means of Cooperation* that has used ICT applications in destinations in northern Italy to create a series of forums and information-exchange vehicles to assist local tourism

organisations to work together as a single virtual tourism organisation (La Micela, Roberti, & Jacucci, 2002).

CONCLUSION: DEVELOPING REGIONAL TOURISM DESTINATIONS USING ICT

It is clear from Table 1 that there is a wide range of ICT applications that have either been specifically designed for tourism or that have substantial use among tourism organisations. Many of these have clear advantages for enterprises and intermediaries involved in regional tourism, as they help address issues of isolation, geographic dispersal, lack of critical mass of enterprises and consumers, and management of dynamic information. Carson, Richards, and Rose (2004) have argued that for regional tourism destinations to gain a competitive advantage, they need to work collaboratively. One feature of that collaboration may be the sharing of ICT resources and infrastructure to achieve common purposes, such as accessing markets, maintaining relationships with suppliers and tour packagers, managing customer relations, or accessing business intelligence and research.

A review by Sheldon (1999) indicated that the larger enterprises, particularly airlines and accommodation chains, have been at the forefront of ICT adoption in tourism. The increasing reliance on applications such as GDS by these sectors has then flowed down to other sectors, most notably, travel agents and other intermediaries. Regional destinations tend to have fewer large enterprises and have therefore lacked the technology demonstrators and lead users that may facilitate adoption. In some countries, including Australia, government programs have attempted to address this issue by offering incentives and education for regional tourism enterprises and organisations to encourage technology uptake (Sharma & Carson, 2002). In some cases, these programs have clear ideas of how regional tour-

ism enterprises should use technology, and these ideas are often formed from experience in metropolitan areas or the claims of ICT manufacturers and distributors. Experience suggests (Carson, Sharma, & Waller, 2003) that regional enterprises often find their own ways of using ICT that may be different from those envisaged. For example, there has been a relatively low rate of uptake of Web-based commerce by Australian regional tourism enterprises if that commerce is assessed in terms of the number of enterprises with their own, e-commerce enabled Web sites. Instead, smaller regional enterprises have engaged collaboratively with private-sector e-commerce portals such as *wotif.com.au* and *lastminute.com*. Engaging in this way has reduced the individual costs of adoption and helps to manage the ongoing issues of poor ICT infrastructure in many regional destinations around the world.

ICT has proven to be an effective tool in assisting regional tourism destination development. The employment of a decision-making framework such as the online architecture described in this paper may contribute to ongoing innovation in ICT use. Significantly, while there may be a focus on individual enterprises selecting and implementing ICT, the collaborative aspect of regional destinations must also be considered. Many ICT applications offer collaborative solutions to the communication, research, promotion, product distribution, and management needs of regional tourism enterprises and destination managers. Effective implementation of online architecture, however, requires attention to the needs and resources of consumers, enterprises, policy makers, infrastructure providers, and business partners. Alford (2004) recommended a communicative and collaborative approach to planning implementation projects for ICT in tourism, and the online architecture offers some cues for managing that communication.

KEY TERMS

Accommodation Management Systems: Integrated software (desktop, network, or Web-based) to assist a variety of functions for accommodation establishments. This may include reservations, room maintenance, banquet booking, finance, and customer relationship management.

Destination Marketing Organisation (DMO): Public-sector organisations charged with the promotion of a destination. They may operate at local, regional, or national level, and often include membership from private-sector organisations.

Destination Marketing Web Site: Web site featuring information about individual products and generic information about a local, regional, or national destination. These sites may be purely for promotion or may include e-commerce facilities for booking and purchasing product. They may be managed by DMOs or by private firms or industry associations not affiliated with a DMO.

Event Management Software: Integrated software (desktop, network, or Web-based) to assist a variety of functions for event managers.

This may include venue booking, delegate registrations, speaker requirements, transport, and accommodation management.

Global Distribution Systems: Global distribution systems are used by airlines, travel agencies, and other intermediaries to manage product inventory and to sell tourism products and packages. In the past, these have been dedicated line electronic services, but virtually all of the major GDS (Amadeus, SABRE, Galileo, etc.) have migrated to online systems.

Intermediaries: In the tourism and travel sectors, intermediaries are those organisations that package or on-sell product. These include travel agents, tour packagers, inbound tour operators, and destination marketing organisations. The Internet has led to the emergence of electronic intermediaries that offer their services entirely online.

Online Architecture: An organisations' online architecture demonstrates the range of functions they perform, or intend to perform, using online or other information technologies. Functions may pertain to communication, research, promotion, product distribution, or enterprise management.

Regional Tourism Systems: The combination of organisations and institutions with an interest in the management of tourism in a given destination. Regions may be defined by administrative boundaries or by communities of interest.

Smartcard: Card system that allows visitors to prepurchase products or product "credits" and to use the card at venues and attractions (such as hotels, theme parks, tours, etc.) in lieu of direct payment.

Victoria University, Australia

ABSTRACT

This chapter provides an overview of tourism ontology and how it can be used for developing e-tourism applications. The Semantic Web is the next generation Web; it uses background knowledge captured as an ontology and stored in machine-processable and interpretable form. Ontologies form the core of the Semantic Web and can be used to develop intelligent applications. However, generating applications based on ontology still remains a challenging task. This chapter presents a framework that provides a systematic process for developing intelligent e-tourism applications by using a tourism ontology.

INTRODUCTION

Tourism is one of the most successful and dynamic industries in the world, and it is constantly evolving because of technological advancements. Information technology is being used to enhance tourism services such as travel bookings, itinerary planning, destination marketing, and informa-

tion sharing. These services use dynamic Web applications.

The current tourism applications rely on static information sources such as Web sites to create tourism products and services. These applications lack intelligence; for example, an itinerary planner in the current scenario will allow the tourist to make bookings, but it cannot suggest an itinerary based on the travellers preferences. A Semantic Web application using an ontology, generic profiling, and semi-structured query tools can overcome the technical limitations of the current systems, and help build intelligent e-tourism tools, or applications.

This chapter discusses the purpose of developing a tourism ontology and proposes a model to develop intelligent tourism applications based on the same. The second section presents the background knowledge, followed by a proposed model for developing e-tourism applications, the following section demonstrates the working of an itinerary planner, and we finish with the conclusions.

The main objective of this chapter is to present a framework for developing ontology based

e-tourism applications. The specific foci of the chapter are:

- To provide an understanding of the Semantic Web and ontologies
- To introduce various existing travel ontologies and applications based on the same
- To describe a process model for developing e-tourism applications
- To present a case study using an intelligent itinerary planner

BACKGROUND

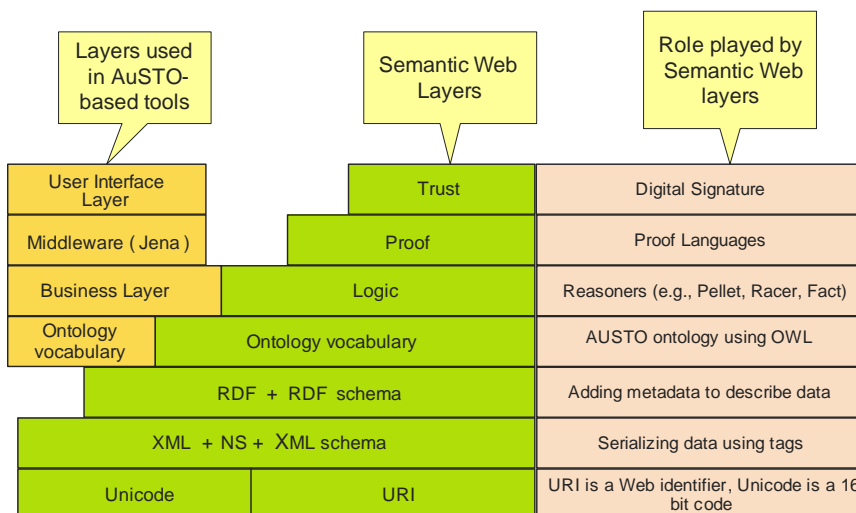

Semantic Web

The Semantic Web was thought up by Tim Berners-Lee as a mesh of information linked up in such a way so as to be easily processable by machines. It is not intended to be read by people, as it describes relationships between data that software will interpret (Palmer, 2001). Figure 1 represents the Semantic Web stack which has a layered architecture, it is based on a hierarchy of languages, each language both exploiting the features, and extending the

capabilities of the layers below (Butler, 2003). A brief introduction to the Semantic Web layers is presented in the following:

- **Uniform resource identifier (URI):** The Web naming and addressing convention, like the strings starting with “http” or “ftp”; they are short strings used to identify resources on the Web. Anyone can create new URIs. Example: <http://melba.vu.edu.au/roopa.txt>.
- **Unicode:** A replacement for the older ASCII code and can cope with multiple languages. It is a 16-bit code that can be used to represent the characters in most of the world’s scripts.
- **Extensible Markup Language (XML):** A standard format for serializing data using tags; XML file can contain data like a database, it is derived from Standard Generalized Markup Language (SGML) and is somewhat similar to Hypertext Markup Language (HTML). XML schema is a schema language used for describing XML data as well-defined schemas or data models. XML namespaces (NS) is an extension to XML for managing a collection of names identified by URIs.

Figure 1. The Semantic Web stack, and its layers covered in this chapter

- **Resource description framework (RDF):** This allows users to add metadata to describe the core data; RDF Schema is a language for describing RDF vocabularies (Bray, n.d.); in other words, RDF schema provides a way of organizing a large set of RDF vocabulary.
- **Ontology vocabulary:** A data model that represents the terminology used in a domain; it also is used to reason about the objects in that domain and the relations between them. Web Ontology Language (OWL) and Darpa Agent Markup Language + Ontology Interchange Language (DAML+OIL) are some of the languages used to describe ontologies.
- **Logic:** The Logic layer allows carrying out reasoning on a set of data, based on pre-defined rules, in order to draw conclusions. Inference engines or reasoners (Inference Engine, n.d.), such as, Racer, Fact, and Pellet work at this layer.
- **Proof and trust:** The proof and trust layers are still nascent. In most applications construction of proof is done by using some rules, the other party can use these rules to see whether or not a statement is true. Trust layer allows the creation of digital signatures for authentication and encryption.

What are Ontologies?

An ontology is a data model that represents a domain; it can be used to reason about the objects in that domain and the relations between them. Ontologies represent knowledge about the world or some part of it, they consist of: classes, collection of objects; attributes, properties an object can have and share; relations, represent the way the objects are related; and individuals, which are instances of the class (Chandrasekaran, Josephson, & Benjamins, 1999).

An ontology can be a domain ontology and theory ontology (Swartout, Patil, Knight, & Russ, 1997). A domain ontology models a specific

domain; it represents the particular meanings of terms as they apply to that domain, for example, tourism. A theory ontology provides a set of concepts for representing some aspect of the world, such as time and space.

Need for Tourism Ontology

Ontologies are especially useful where multiple entities such as researchers and organisations are active in the same domain, but each entity uses their own data model for that domain. For example, in the tourism domain, different entities such as travel agents, hotel chains, national, and regional tourism organisations have their own way of representing their services to the consumer (accommodation, events, attractions, services, etc.) using different data models. Furthermore, these data models maybe represented using different software technologies. This leads to interoperability problems, that is, software developed for one system cannot access data on another.

If tourism entities need to communicate with one another, a common data representation is needed. This common representation needs to represent both the concepts in the domain, and the relationships between these concepts. In addition, it should be possible for each tourism entity to map its data models to that used in a common ontology.

Having an ontology is very useful in this situation; as it models the domain in a structured manner, all entities will be able to use the ontology to communicate with all other entities, by mapping their source data model to the common ontology and then using the existing mappings between the ontology and the other destination data models (Clissmann & Höpken, n.d.).

Another benefit of ontologies is that they make it possible to carry out reasoning on the domain, they also act as back ends for intelligent applications, that is, they provide the ability to derive domain knowledge for developing intelligent applications. These applications, with the help

of a reasoner, can infer facts from the domain ontology. Creating an ontology for tourism will allow knowledge sharing between different tourism organizations, and also will allow for the creation of intelligent e-tourism tools such as search engines and tour planners.

Travel Ontologies

A variety of tourism ontologies have been developed to date. In this section we give an overview of a number of tourism related ontologies. The Harmonise ontology is not only a minimum standard ontology, but also a means of reconciling various ontologies.

OTA Specification. The Open Travel Alliance specifications have been designed to serve two purposes, namely to act as a common language for travel related services, and to provide a mechanism for information exchange between travel industry members (The Open Travel Alliance, n.d.). It is possible to view the OTA specifications as a comprehensive ontology, defining concepts such as AirSchedule, GolfCourseReservation, HotelContentDescription, HotelPreferences, and so on. The OTA specification has already been utilised in a travel related project called Agentcities (Gordon, Kowalski, Paprzycki, Pelech, Szymczak, & Wasowicz, 2005).

MONDECA. MONDECA's tourism ontology defines tourism concepts based on the World Tourism Organization (WTO) thesaurus (MONDECA, n.d.). These include among others, terms for tourism object profiling, tourism and cultural objects, tourism packages, and tourism multimedia content. MONDECA has created a proprietary system called the Intelligent Topic Manager (ITM) that is used to manage its travel ontology.

TAGA Ontology. The Travel Agent Game in Agentcities (TAGA) is an agent framework for simulating the global travel market on the Web. Its purpose is to demonstrate the capabilities of Agentcities (Agentcities, n.d.) and Semantic Web

technologies. TAGA works on the Foundation for Intelligent Physical Agents (FIPA) compliant platforms within the Agentcities environment (The Foundation for Intelligent physical agents, n.d.). In addition to the FIPA content language ontology, TAGA defines two domain ontologies to be used in simulations. The first ontology covers basic travel concepts such as itineraries, customers, travel services, and service reservations. The second ontology is devoted to auctions and defines different type of auctions, roles the participants play in them, and the protocols used. TAGA ontologies are limited in their usability, and are rather unrealistic due to the nature of the TAGA simulations.

Harmonize Ontology. Harmonize is an attempt at ontology-mediated integration of tourism systems following different standards (E-Tourism, n.d.). Its goal is to allow organizations to exchange information without changing their data models. The Harmonize project also involves sub-domains that are partially related to the world of travel: geographical and geo-spatial concepts, means of transportation, political, temporal, and gastronomy, and so forth. These sub-domain concepts can be used within the travel system.

Numerous ontologies have been developed for the domain of tourism. Defining and agreeing on the right ontology is a difficult task. One could argue that the choice of the right ontology is purely subjective, because the meaning of various terms differs across domains, users, and situations. Each of these ontologies have been developed with a specific task in mind and specialises in a particular aspect of the tourism domain; for example, a tourism ontology that specialises in tourism events can be used to develop an event planner. Most of the ontologies have been developed with a tool in mind, and their scope is limited to that tool. We have developed an abstract ontology called the Australian sustainable tourism ontology (AuSTO) which covers all the general concepts used in tourism, both from the customer perspective and from the enterprise perspective;

subsequently several intelligent tools such a tour planner, search engines and travel recommender systems are planned for development based on the AuSTO ontology.

Applications Based on Travel Ontologies

A number of intelligent applications such as search engines, tour planners, and location-based tour guides have been developed using ontologies. These applications help the traveller as well as tour operator to plan trips and find information about destinations. In this section we describe two such applications and their usage.

On Tour. On Tour can be considered as an intelligent search engine. The main objective of the On Tour system is to connect isolated pieces of information, that is, to assist the user in finding information from a variety of sources, and to allow individualized use of the same (Daniel, 2005). As a search engine, On Tour allows for the querying of distributed data as well as considering the semantics of discovered concepts and instances. It allows the user to specify preferences like maximum budget and minimum comfort, and define further constraints such as personal schedule. This system helps the user to plan a vacation from the beginning to the end. In later phases of development On Tour will act as a recommender system by giving advice on best restaurants, venue for musicals, and so on. It also will provide support for mobile devices. On Tour approach is to extract pieces of information from structured Web pages and conduct constraint based reasoning for the integration of multiple information sources.

Talea. Talea is a platform aimed at supporting the development of Web-based tourism applications (Levi, Vagliengo, & Goy, 2005). This software was designed and developed within the Diadi 2000 (Dissemination of Innovation

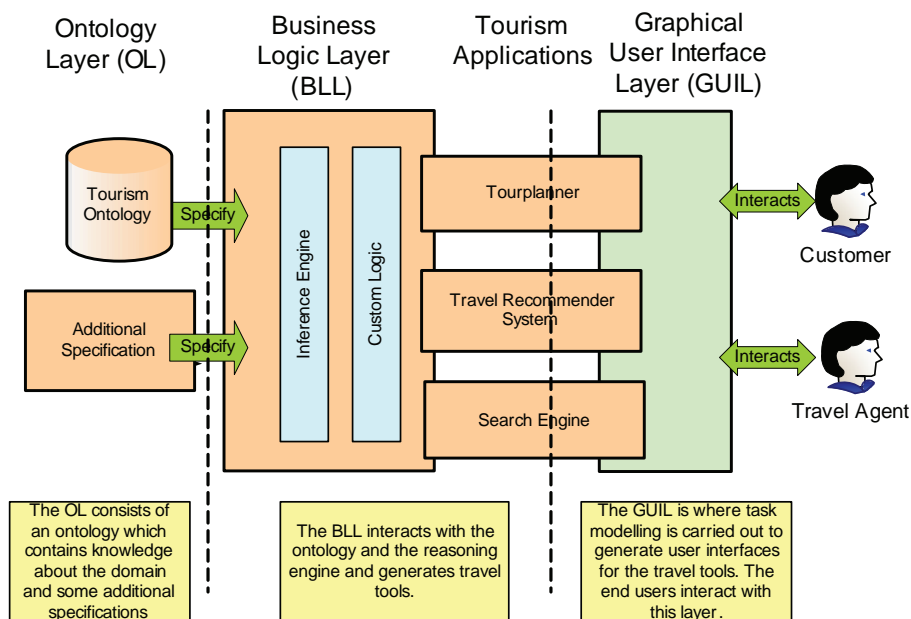

in Industrial Decline areas) project. The Diadi 2000 project aims at applying ICT technologies to small and medium enterprises (SMEs) to increase the value of their businesses. Talea provides for multi device access, where customers and suppliers can use PDAs or smart phones to buy and offer tourism services. This software acts as a matchmaker by matching service provision with request; tourism suppliers can advertise their services such as room availability, car rentals, and so on, and customers can perform a search for a particular service.

Dynamic Packaging System. An important type of e-tourism application that has evolved in recent years is a dynamic packaging system (Cardoso, 2005). It is used by airlines, hotels, tour operators, and travel agencies to create customised packages for individual consumers. Dynamic packaging can be defined as the combining of different travel components, bundled and priced in real-time, in response to the request from a consumer or a booking agent. They have created an e-tourism ontology that allows interoperability through the use of shared vocabulary and meanings for terms. Semantic mediators are used to support a virtual view that integrates semantically annotated e-tourism information sources. Final dynamic package processes are created using conditional planning ranking and selection. Once the dynamic package processes are evaluated they are presented to the tourist and the tourist can select the package that he finds most appealing or suitable according to his preferences.

TOURISM APPLICATION GENERATOR ARCHITECTURE

Figure 2 presents the underlying model for generating ontology based e-tourism applications; called the e-tourism application generator architecture (e-TAGA). The e-TAGA model consists of

Figure 2. A tourism application generator architecture (e-TAGA)

three layers: the ontology layer (OL), the business logic layer (BLL) and the graphical user interface layer (GUI). The OL provides persistence for the tourism ontology; the business logic layer includes two common components and parts of the tourism applications themselves. The two common components in the BL are the inference engine (IE) and the custom logic (CL). The GUI layer includes the graphical user interface (GUI) components of individual tourism applications and some common GUI elements.

Ontology Layer (OL)

The ontology layer consists of the ontology which embodies knowledge about the domain and some additional specifications. This layer is the core of all Semantic Web systems. We will use the AuSTO ontology to exemplify the operation of the various layers.

Tools for Ontology Development

In any ontology development project one needs to begin by selecting an ontology development tool. In the AuSTO project three different tools were compared in order to decide which one of these would be most suitable for our tourism ontology development. The three tools considered were Protégé 2000, Ontolingua, and OntoEdit free. This comparison was based on ontological aspects and usability aspects. Our study indicated that Protégé 2000 is far superior in usability and ontology aspects as compared to Ontolingua and OntoEdit free (Jakkilinki, Sharda, & Georgievski, 2005), hence Protégé2000 was selected. Protégé2000 (Protégé, n.d.) comprises an open architecture that allows programmers to insert arbitrary components into the tool. This feature can be exploited during the development of Semantic Web applications based on the ontology. An additional benefit of Protégé 2000 toolkit is

developers can package the implementation of the application as a Protégé plug-in and test how the system behaves in response to any changes in the ontology.

Methodology Followed to Develop AuSTO Ontology

Ontology development methodology includes tools, techniques and process followed in order to develop the ontology. The methodology followed to develop the AuSTO ontology is as follows (Jakkilinki et al., 2005).

1. **Identify the purpose behind ontology development:** The pertinent questions are listed here, along with their answer for AuSTO development.
 - Why is the ontology being built? In the case of AuSTO, the ontology is being built to describe the tourism domain.
 - What is its intended use? AuSTO ontology will be used as a knowledge base to develop intelligent tools such as an itinerary planner.
 - Who are the users? AuSTO will be used by operators in tourism domain, such as the tourist operators, tourism vendors.
2. **Ontology capture mechanism** consists of three different stages:
 - **Determining the scope of the ontology:** This involves identifying all the key concepts and relationships in the domain.
 - **Selecting a method to develop the ontology:** The method we followed to develop AuSTO is the top-down approach.
 - **Defining the concepts in the ontology:** This involves taking closely related terms and grouping them as classes.
3. **Coding the ontology:** Coding refers to representing the ontology in some formal

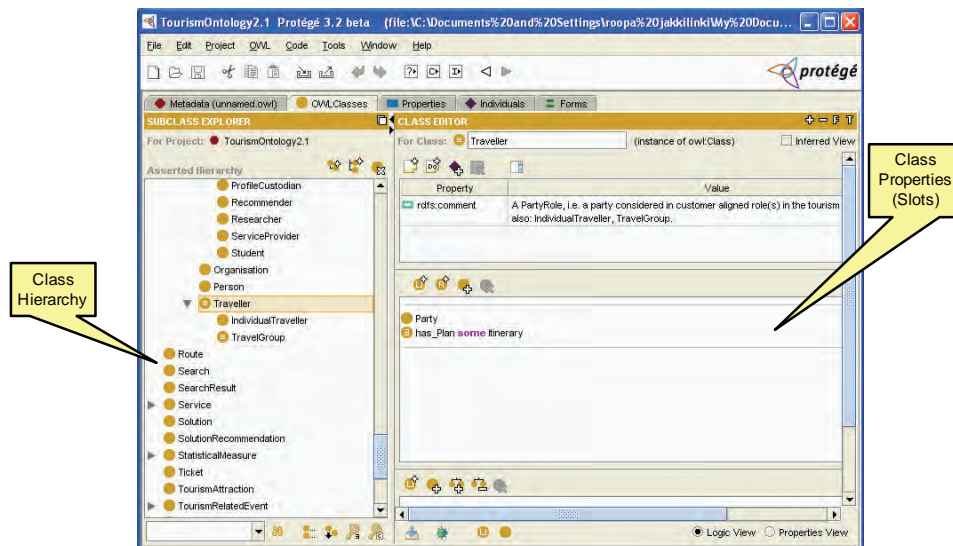

language. A suitable ontology editor has to be selected, in the case of AuSTO the ontology editor used is Protégé. Once the ontology editor is selected the classes have to be entered as concepts and their attributes are entered as slots.

4. **Refinement:** This consists of two phases, namely intra-coding refinement and extra-coding refinement. Intra-coding refinement refers to the refinement done during the coding phase, whereas extra-coding refinement refers to the changes made to overcome the errors uncovered during the testing and maintenance stages.
5. **Testing:** The testing process uncovers any defects in functional logic and implementation. Testing should be carried out during all stages of development.
6. **Maintenance:** This can be corrective, adaptive or perfective. Corrective maintenance involves correcting the ontology to overcome the errors discovered by users while querying the ontology. Adaptive maintenance involves modifying the ontology to fulfil new requirements. Perfective maintenance involves improving the ontology by further refining it, in order to enhance its functionality (Pressman, 1997).

Brief Description of Classes in AuSTO

Creating an ontology involves delineating concepts into a class hierarchy. Three important approaches to develop class hierarchies are top-down, bottom-up and a combination approach (Uschold & Gruninger, 1996). In the top-down approach the development process starts with the definition of the most general concepts in the domain, followed by specialised concepts. In the bottom-up approach the development process starts with the definition of the most specific classes, which form the leaves of the class hierarchy tree, with subsequent grouping of these classes into more general concepts. The combined approach

Figure 3. A screen shot of the AuSTO ontology

uses a combination of top-down and bottom-up processes. The approach followed for AuSTO is the bottom-up approach. This approach is usually driven by the need for having a workable vocabulary quickly and then enhancing it as the project progresses. AuSTO is written in OWL (Web Ontology Language), Figure 3 is a screen shot of AuSTO ontology in Protégé. The AuSTO ontology consists of a class hierarchy shown on the left, each class has properties and one can create individuals, or instances of a class, using the instance tab in the Protégé interface.

AuSTO being tourism ontology it contains classes from the tourism domain. Following list gives some of the important classes in AuSTO:

- **Involved party** can be traveller, vendor, operator, and so forth.
- **Requirement** refers to travel requirements
- **Offering** includes travel products and services.
- **Solution** refers to systems outputs such as itineraries.
- **Resource** can be reserved or rented items.
- **Specification** allows for both offering specifications and requirement specifications

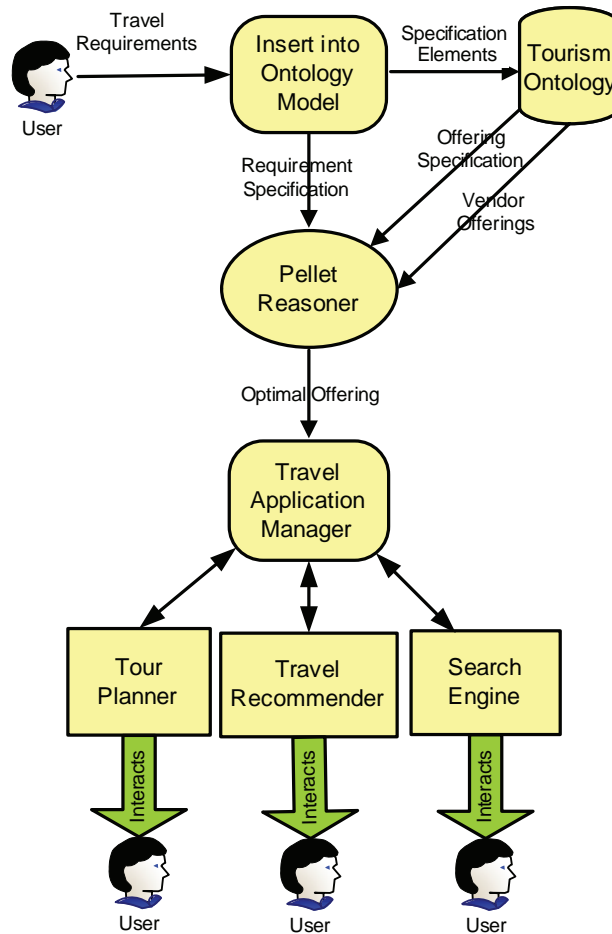

- **Preference** includes traveller’s preferences such as date, time, location, or price range.

Each of these classes can represent a plethora of tourism information. For example, requirement represents diverse travel requirements such as accommodation, entertainment, transport, and offering represents the wide range of travel products and services that vendors make available to the traveller, often as part of a packaged solution.

Business Layer

The business logic layer (BLL) uses an inference engine and custom logic, and is responsible for generating outcomes; that is, it returns results based on user interactions. Figure 4 describes the BLL for the applications based on AuSTO. A user specifies his travel requirements in the ontology and the tourism vendor advertises his offerings which are tourism services in the ontology. The offerings and requirements are loaded into the ontology model of the Jena subsystem. Pellet reasoner matches the travel requirements to the vendor offerings and sends it to the travel application manger. Travel tools such as tour

Figure 4. Architecture for the business layer

planners can query the travel application manager and produce the travel solution, which in this case is an itinerary.

What are Reasoners?

The reasoner is a software that applies logic to the knowledge embodied in the ontology for arriving at some conclusions (*Inference Engine*, n.d.). We generally recognize two types of inferencing, namely forward chaining, and backward chaining. In forward chaining one proceeds from a given situation towards a desired goal by adding new assertions along the way; whereas, in backward

chaining one starts with the desired goal and then attempts to find the method for arriving at the goal. A number of reasoners are available, such as Racer, FaCT, Pellet, and F-OWL. Pellet is the reasoner used in the AuSTO project, it is an open-source Java-based OWL DL reasoner developed by the Maryland Information and Network Dynamics Lab Semantic Web Agents Project (Mindswap, n.d.).

Role Played by Jena

Jena is a Java framework for building Semantic Web applications, it is open source and has been

developed by HP (Hewlett Packard) Labs. Jena acts as a middleware which connects the ontology, reasoner and the user interface. In Jena all operations are done by manipulating the Jena model. Therefore, to manipulate an ontology it needs to be loaded into the Jena model first. Jena has four subsystems: query engine, database interface, reasoning engine, and ontology management. Jena's architecture allows external reasoners to be plugged into the Jena models.

User Interface Layer

One of the most difficult aspects of building an application is designing the user interface. User Interface design is the design of the graphical elements on the computer screen with which a user interacts to conduct application tasks. The user interface is as important as the functionality of the application, and plays an important role in the success of any product. User interfaces accomplish two fundamental tasks: communicating information from the computer to the user and communicating information from the user to the computer.

The benefits of a good user interface design include: lower training costs, less user stress, consistency in application usage, increased ability to recover from errors, better user control, less clicks to find information, ability to store more information per screen, easier to use the software, selection amongst many choices using limited space, see all selections at all times, better understanding of the software, save screen space, and higher data entry speed (Miller, n.d.).

Task analysis and modelling techniques are increasingly being used in designing user interfaces, they form an important part of user interface design process and help design more intuitive interfaces.

What are Task Analysis and Task Modelling?

Task analysis involves the study of a system functionality as a collection of tasks. Generally the systems function is divided into a set of top-level tasks, and each one of these is further divided into sub-tasks, and so forth to develop a task-tree. This process can be used to guide the design of new systems beginning with user requirement capture. One of the most important applications of task analysis is designing user interfaces, in which menus are based on the task trees. The top level menus can be labelled after the top level tasks and the sub menus after the next level tasks (Dix, Finlay, Abowd, & Beale, 1998).

After an informal task analysis where the main tasks and their attributes have been identified, task modelling is used to understand the relationships among the various tasks in order to better address the design of interactive applications.

As task modelling is used to model the behaviour of a system from user's perspective, it captures the system requirements and actions defined as a set of tasks, and models the behaviour of the system as a scenario of tasks. This allows the designers to improve the human computer interaction aspects when designing a system's operation (Georgievski & Sharda, 2003). Although task models have long been considered in human-computer interaction, only recently have user interface developers and designers realized their importance to obtain more effective and consistent solutions (Giulio, Paterno, & Santaro, 2002). Task models play an important role because they represent the logical activities that should support users in reaching their goals, and knowing the tasks necessary to attain a goal is fundamental to any good design (Paterno, 2002).

There are two types of task models: user task model and system task model. A user task model

states the problems to be solved by the system, and thus consists of overlapping user scenarios (Georgievski & Sharda, 2003). Actors involved in a user task model are generally human; however, it may include external systems and the environment. A system task model forms the basis for specifying a solution in the form of system requirements. Actors involved in a system task model are generally subsystems, interfaces, and, at times humans.

Tools for Task Modelling

One of the main problems in task modelling is that it is a time-consuming and sometimes tedious process. To overcome this problem interest has been increasing in tools that support task analysis and modelling. However, current tools are outcomes of research projects, and are used mainly by groups that have developed them.

The concur task tree environment (CTTE) is a Java Applet based tool developed by Human Computer Interaction Group – ISTI (Pisa). CTTE provides the ability to build task models from a visual perspective where the user can define and structure the tasks in a logical fashion using the graphical editor provided in the tool. CTTE enables the user to focus on the activities of their model and thus allowing the user to identify the requirements of the model and organize them into a logical hierarchy of task and subtasks (Georgievski & Sharda, 2003).

The main features of the CTTE tool are (Giulio et al., 2002):

- **Focuses on activities:** Allows designers to concentrate on the activities that a user has to perform, rather than programming details.
- **Hierarchical structure:** Provides a wide range of granularity allowing large and small task tree structures to be developed and reused.

- **Graphical syntax:** Facilitates easy interpretation of the logical task structure using graphical representation.
- **Concurrent notation:** Provides rich set of possible temporal relationships that can be used to specify the relationship between the tasks.
- **Distinct task representations:** Uses distinct icons to represent user task, application task, interaction task, and abstract task

CTTE provides the ability to build two types of task models: single user task models and cooperative task models. Single user task models are used to represent systems that a single user controls. A cooperative task model is similar to a single user task model; however it includes tasks executed by two or more users.

Other useful features of CTTE tool are model comparison, reachability analysis, and interactive task model simulator (Giulio et al., 2002).

Itinerary Planner Case Study

In this section we describe the task model created to represent the user interface for the itinerary planner. This task model guide the development of the user interface by focusing on the various functions the user interface needs to perform.

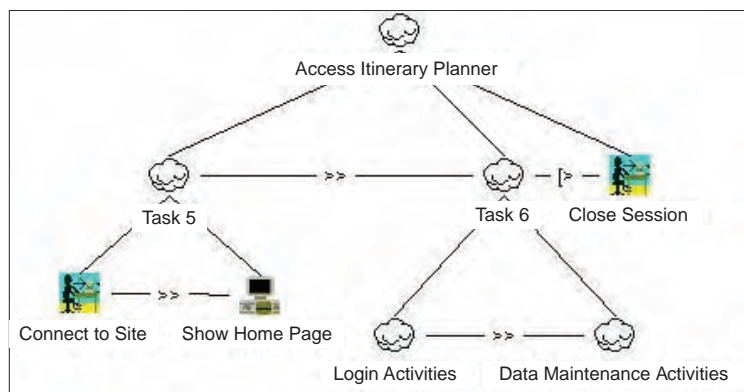

CTTE allows the following types of tasks to build the entire task model:

- **Abstract tasks** define a set of subtasks to be performed at a conceptual level
- **User tasks** denoted the operation/tasks executed by the user
- **Interaction tasks** represent tasks that carry out communication between entities within the task model.
- **Application tasks** are of tasks executed by the system or application entities in the process model

Table 1. Temporal operators used in CTTE

Syntax	Notation	Description
$T1 \square T2$	Choice	A choice between two or more tasks
$T1 \gg T2$	Enabling	T1 enables T2 when T1 is terminated
$T1[\square] \gg T2$	Enabling with Information Exchange	T1 provides some information to T2 besides enabling it
$T1 \triangleright T2$	Suspend/Resume	T2 can interrupt T1, and when T2 is terminated T1 can be reactivated from the state reached before the interruption
T^*	Iteration	Tasks performed repetitively

Figure 5. Itinerary planner abstract model

CTTE uses transition notations to describe the temporal relationships between tasks and the execution sequence for the task model. The temporal operators used in CTTE are described in Table 1.

We have implemented the task model for itinerary planner as a single user task model that represents the overall function of the user interface from a user perspective. We represent these tasks as tree diagrams in Figures 5 to 11. In the task tree diagram we define the execution sequence for each task using the temporal operators described in Table 1.

Figure 5: This shows the itinerary planner abstract task model. It illustrates the tasks the user can perform on connecting to the itinerary planner Web site. Task 5 consists of connecting to the Web site and viewing the home page. Task

6 involves logging into the Web site and then carrying out the data maintenance activities. Figures 8 to 13 expand on these activities.

Figure 6: This shows the task model that expands the Login Activity task. Login Activities describe the tasks to be performed for the user to login, it allows for an existing user, as well as new user.

Figure 7: Data Maintenance Activities task tree, which provides a choice between four abstract tasks: Preference Maintenance, Requirement Maintenance, Itinerary Maintenance, and Offering Maintenance.

Figure 8: Preference Maintenance Activities task tree, which consists of the tasks involved in maintaining the preferences of the traveler. Here preferences refer to what of the traveler likes, with regard to various facilities such as accommodation, transport, and so forth.

Figure 6. Login activities

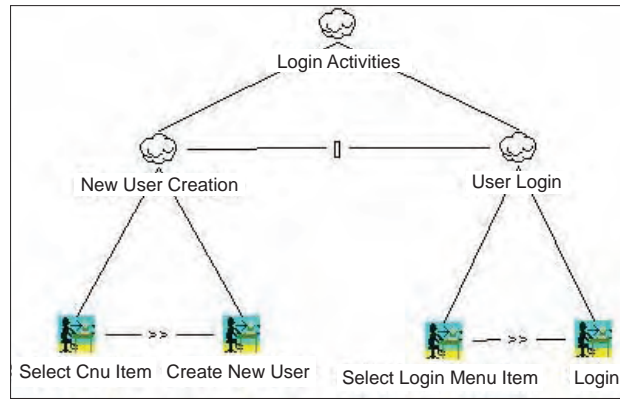

Figure 7. Data maintenance activities

Figure 8. Preference maintenance activities

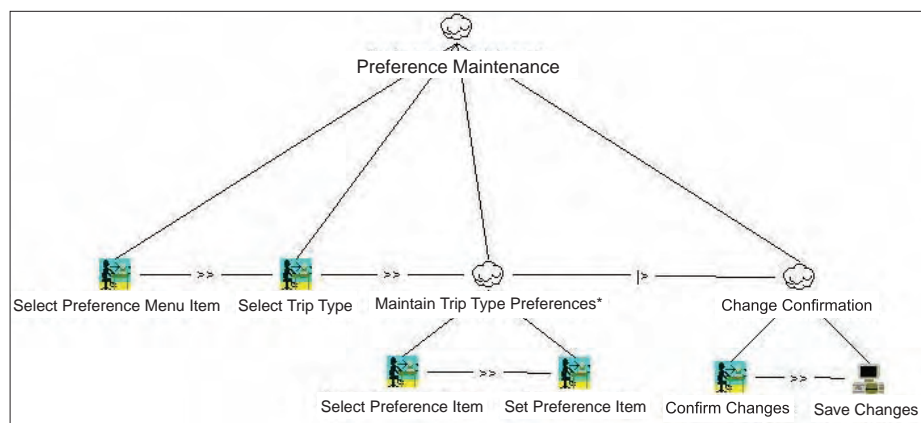

Figure 9. Requirement maintenance activities

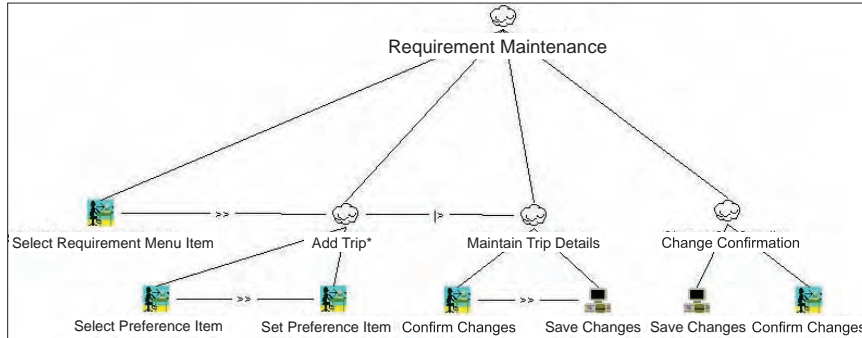

Figure 10. Itinerary maintenance activities

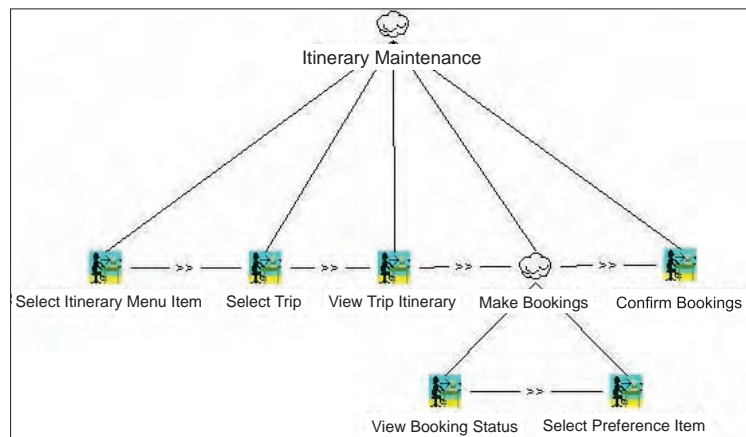

Figure 11. Offering maintenance activities

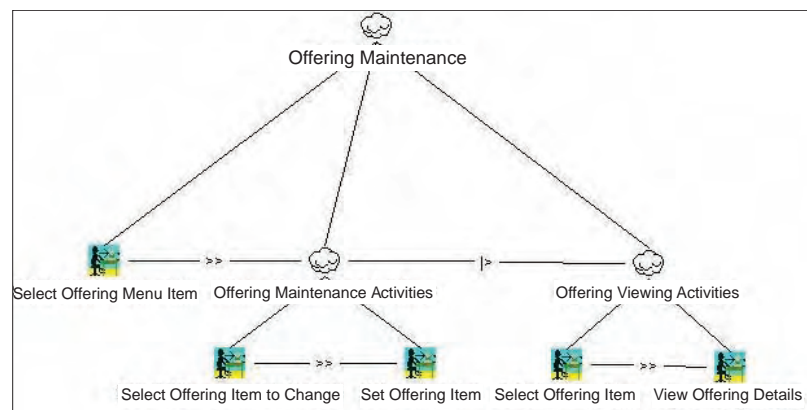

Figure 9: Requirement Maintenance Activities task tree, which describes the tasks involved in maintaining the traveler requirements. Requirements refer to the travelers demands for the tour, for example the traveler may want 5-star accommodation and a business class flight.

Figure 10: Itinerary Maintenance Activities task tree, which describes the tasks involved in creating an itinerary for the traveler. An itinerary is generated by matching the traveler's requirements with the offerings available.

Figure 11: Offering Maintenance Activities task tree, which describes the tasks involved in maintaining the offerings being provided by various travel vendors. Tourism vendors can advertise their services such as room availability, tickets availability through this option.

Working of an Itinerary Planner

In this section we describe the operation of a travel itinerary planner; this itinerary planner has been developed based on the application generator framework. It consists of AuSTO ontology, a user interface created using ASP.net, and a business logic layer, which acts as a connector between the ontology and the user interface. The AuSTO ontology is populated by a tourism domain expert, the application allows tourism operators to advertise their offerings in the offerings page, and the offerings are stored in the ontology. The end user or the tourist can specify his requirements in the requirements page, these requirements are stored in the ontology, and the tourist also can specify his preferences which also are be stored in the ontology. The itinerary planner matches the requirements with the offerings, and produces an itinerary; the end user can either reject the itinerary offerings or accept these and confirm bookings in the itinerary page. The user interface for the itinerary planner has been developed based on the task model described in the previous section. This application is explained in some more detail with the help of screen shots in the following.

Figure 12: This shows the new user screen, which allows the creation of a new user. It is necessary to have an account in order to use the application.

Figure 13: This shows the user login screen where an existing user can login into the application. Once the user logs in, he has access to facilities such as storing preferences or specifying requirements.

Figure 14: This shows the requirements screen where a tourist can enter his requirements for a trip. Once the requirements are entered the tourist clicks the Add Trip button and a new leg can be added.

Figure 15: This shows the itinerary screen, the tourists' requirements are matched with the vendor offerings and an itinerary is produced. The tourist can accept offerings in the itinerary with the help of the checkboxes, and make booking by clicking on the Make Bookings button and then confirm bookings.

Figure 16: This shows the preferences screen, which allows the user to store his preferences for accommodation, transport facilities and other such services. Different preferences for different kind of trips can be stored, such as family trip and business trip.

Figure 17: This shows the offerings maintenance screen, tourism vendors such as hotels or transport providers can advertise their offerings on this page. For example, hotels can advertise their room availability, and transport providers can advertise their vehicle availability.

CONCLUSION

There is a need for standardisation of definitions and concepts in the field of tourism; the solution is to develop travel ontologies. Number of travel ontologies have been developed in recent times, each with an application in mind; we have developed an Australian sustainable tourism ontology (AuSTO), specifically for the Australian

A Framework for Ontology-Based Tourism Application Generator

tourism sector. This AuSTO ontology reuses the knowledge from some of the existing ontologies. Ontologies enable the development of Semantic Web applications, but ontology driven application development is still a nascent field. We are developing an intelligent travel application generator based on the AuSTO ontology. The application generator framework enables the production of different intelligent travel tools such as Itinerary planners, and recommender systems. We are building an itinerary planner by using this framework, and this intelligent itinerary planner can match the user requirements specified in the ontology with vendor offerings specified in the ontology and produce an itinerary as a solution. This chapter presented an overview of the Semantic Web, introduced different tourism ontologies and some applications based on tourism ontologies, and describes in detail a framework for developing e-tourism applications based on ontologies.

ACKNOWLEDGMENT

We would like to thank Sustainable Tourism Cooperative Research Center (STCRC), Australia, for the funding this research. We also would like

to thank Henk Meijerink and Paul Mohinyan for their help in this research.

Chapter 2.29

Developing Visual Tourism Recommender Systems

Mohan Ponnada

ABSTRACT

Tourism recommender systems (TRS) have become popular in recent years; however, most lack visual means of presenting the recommendations. This paper presents ways of developing visual travel recommender systems (V-TRS). The two popular travel recommender systems being used today are the TripMatcher™ and Me-Print™. Tour recommendation using image-based planning using SCORM (TRIPS) is a system that aims to make the presentation more visual. It uses SCORM and CORDRA standards. Sharable content object reference model (SCORM) is a standard that collates content from various Web sites, and content object repository discovery and registration/resolution architecture (CORDRA) aims to locate and reference SCORM repositories throughout the Internet. The information collected

is stored in the form of an XML file. This XML file can be visualised by either converting it into a Flash movie or into a synchronized multimedia integration language (SMIL) presentation. A case study demonstrating the operation of current travel recommender systems also is presented. Further research in this area should aim to improve user interaction and provide more control functions within a V-TRS to make tour-planning simple, fun and more interactive.

INTRODUCTION

Recommender systems have become popular with the advent of e-commerce. The development of this technology is being strengthened as more people start using the Internet for making purchases. Recommender systems are used by

Amazon.com (Linden, Smith, & York, 2003) to recommend books, and movies are recommended on MovieLens (Miller, Albert, Lam, Konstan, & Riedl, 2003). In recent years there has been much work done to improve recommender systems. With increasing Internet adoption, business transactions on the Internet are likely to grow substantially; this encourages vendors to add recommendation capabilities to their Web sites (Peddy & Armentrout, 2003). Tourism is one of the most successful and dynamic industries in the world, and is constantly evolving with continuous technological advancements that include Internet based systems. One such advancement is visual travel recommender systems (V-TRS).

Travel recommender systems (TRSs) are increasingly being adopted to support the tourism industry, some examples of this include Triplehop's TripMatcher™ (Delgado, 2001; Starkov, 2001), and VacationCoach's expert advice platform Me-Print™ (VacationCoach, 2002). A TRS allows tourists to access an informed recommendation for travel planning via an artificial intelligence-based engine. However, current TRSs do not provide tourists with the facility to visualise their complete holiday itinerary, integrating location, transportation, accommodation, attractions, and entertainment. The tourist has to browse through individual Web pages to build a mental picture of the planned tour. In this chapter we introduce the concept of a visual TRS, which can overcome this limitation.

The main objectives of this chapter are:

- To understand recommender systems
- To provide an insight into current application of recommender systems in the tourism industry
- To gain an understanding of services provided by TRS systems, their benefits and limitations
- To present the framework of a visual travel recommender system

- To present a case study demonstrating the operation of current travel recommender systems
- To discuss the future trends in travel recommender systems

BACKGROUND INFORMATION

Recommender Systems

“Recommender Systems are an attempt to mathematically model and technically reproduce the process of recommendations in the real world” (Berka & Plößnig, 2004). Recommender systems are being used by e-commerce Web sites to make suggestions to their customers (Schafer, Konstan, & Riedl, 1999). These recommendations can be made on various factors such as demographics, past buying behaviour of the customers, and prediction of the future buying behaviour.

Recommender systems enhance sales in three different ways (Schafer et al., 1999):

- **Browsers to buyers:** A good Web site can turn visitors of the site into buyers by helping them find the products they wish to purchase.
- **Cross-selling:** Well linked Web pages can improve cross-selling by suggesting additional products for the customer to purchase.
- **Loyalty:** Recommender Systems can improve loyalty by creating a relationship of trust between the Web site and the customer.

Classification of Recommender Systems

The process of recommendation varies depending on the application and the system in question. However, the general concepts underpinning rec-

ommender systems are the same. Recommender systems can be classified into four recommendation paradigms (Stabb et al., 2002), namely:

- **Content-based recommender systems**
- **Collaborative-filtering recommendation systems**
- **Knowledge-based recommendation systems**
- **Hybrid recommender systems**

Content-Based Recommender Systems. In content-based recommender systems, the users express their needs, desires and constraints. The recommender system makes a recommendation by matching the user profile with the product information, using information retrieval techniques. The system understands the user's desires and preferences based on the characteristics and ratings provided, and by looking at past user preferences.

However, this system has a number of limitations (Balabanovi, 1997; Shardanand, 1995):

- Firstly, the "new user problem" comes into play since the user has to rate a sufficient number of items before a content-based recommender system understands the user's preferences.
- Secondly, the number of features associated with an item influences this type of system. To extract sufficient features, the content must be in a text form, or features should be assigned to items manually. Such feature extraction is difficult for graphics, audio and video streams.
- A third disadvantage is that a content-based recommender system recommends items that match against the user profile, this provides little opportunity to the users to experience the item being recommended (Shardanand, 1995).

Collaborative-Filtering Recommender Systems. Collaborative-filtering recommender systems are the most widely used recommender system, where user feedback, reviews and rating given by other users are relied upon to recommend an item (Hill, Stead, Rosenstein, & Furnas, 1995). For example, suppose if a user is looking for a book on the Java language in an online book store, the system recommends books which have high ratings based on the feedback from readers who have read various Java books. These systems work well if there is a large volume of ratings for each item.

Reliance on these types of systems is problematic for the recommendation of new items or where the number of reviews is low. Also, it does not account for divergence in preferences between new and previous users. Pazzani (1999) suggests one way of overcoming this limitation via the use of a hybrid recommender system, that combine collaborative, content-based, and demographic filtering approaches.

Knowledge-Based Recommendation Systems. Knowledge-based recommender systems combine the knowledge about the user and the products and services on offer to make a recommendation. If a user visits an online book store, the system recommends other books in related topics. The system knows what the user is looking for, and based on this the system recommends additional products (Burke, 2000). These systems do not need extensive knowledge about an item to make a decision, but like the content-based recommender systems, they require knowledge about the user and his/her buying patterns, which can be acquired by a series of queries.

Hybrid Recommender Systems. Hybrid recommender systems combine two or more recommendation methodologies. These systems were developed in order to overcome the limitations of each of the individual systems. Most often, collaborative-filtering is combined with some other

methodology. Decisions are made by combining two or more techniques, including artificial neural networks (Pazzani & Billsus, 1997), information retrieval techniques (Hull, 1998), and Bayesian classifiers (Mooney, Bennett, & Roy, 1998).

In the modern Internet world, recommender systems have the ability to act as key tools that influence the success of a business. “Recommender systems are changing from novelties used by a few e-Commerce sites, to serious business tools that are re-shaping the world of e-Commerce” (Schafer et al., 1999), these systems are supporting many Web sites that help customers find the right product.

Current Travel Recommendation Systems

Since the mid 1990s, tourism Web sites have flourished, allowing users to plan and view their holiday locations online. As tourists began using online tourism information, TRSs were developed to recommend holiday locations and activities. The two most popular recommender systems for tourism and travel presently in use are TripMatcher™ (Delgado, 2001; Starkov, 2001) used by Ski-Europe, and Me-Print™ (VacationCoach, 2002) used by Travelocity.

TripleHop’s Trip Matcher™. Traditionally, when a person wanted to go on a holiday, they visited a travel agent and had a counselling session. After having analysed the requirements and specifications of the customer, the travel agent made recommendations as to what would be an ideal place for them to visit. TripleHop’s Trip Matcher™ tries to mimic the counselling scenario by allowing the users to search for advice on available destinations. The technical process behind the system is designed so that when the user specifies his/her requirements and constraints, the system matches the specified preferences with the services and items on the catalogue, or the database. This system is being used by Ski-Europe.com.

Ricci (2000) explains, “TripleHop’s matching engine uses a more sophisticated approach to reduce user input. It guesses importance of attributes that the user does not explicitly mention. It then combines statistics on past user queries with a prediction computed as a weighted average of importance assigned by similar users.”

The system then advises users about potential destinations they may book, based on their interest and browsing pattern. The software learns about user preferences by remembering navigation patterns each time he/she browses through the Web site, enabling it to provide useful recommendations. From an algorithm perspective, it uses contextual filtering and attribute-based collaborative filtering.

VacationCoach Me-Print™. Me-Print™ relies on three important components to give personalised travel advice, namely, intelligent profiling, expert knowledge base, and robust advice engineering. Me-Print™ uses profiling of users to categorize them. It exploits user profile such as their unique lifestyle and leisure preferences in relative terms. For example, if a user likes golf, the algorithm considers user’s preference for golf in comparison to other sports such as tennis, or swimming. These multiple preferences are used to provide advice based on priorities and interests.

Services Offered by Current TRS

A travel recommender system allows users to choose their holiday while sitting in front of a computer. A simple user interface provided by the recommender system offers an interactive and simple means of communicating with the system. These systems aim at making the interaction time brief, by reducing the time needed for visiting various Web sites to gather information. At times the system has to deal with issues relating to under, or, over specification of user requirements. The system suggests appropriate repair actions such as “constraint relaxation” if the user has over-specified the requirements, and “tightening,” if

details have been under specified. The framework for this system is based on case-based reasoning (Ricci, 2002).

The system has the ability to formulate queries and offer various examples to users if they are not experienced enough to come up with a proper query. Ricci (2002) states that an effective TRS should not only support active preference construction, but also should allow users to explore the different options available.

Benefits of Integrating TRS in Today's Business

A TRS system can be very helpful in tourism business, as it displays a list of products retrieved by a query to the system, and allows the user to make an informed selection. After the choice has been made, the initial query is saved along with the selected destination, this enables the system to identify and suggest a better set of products in the future. An information feedback technique such as Rocchio's method (the relevance feedback technique) is used to add new terms and constraints into the original query based on the selections made (Ricci, 2002). Research shows that an accurate recommendation, even if not taken up by the customer, can increase the user's trust in the system, which is necessary for future recommendation acceptance.

Some TRSs interact with the users in multiple stages and pose a sequence of questions, each question raised as a result of previous interaction. If these systems are designed to manage the human-machine interaction effectively they help to grow the business, as the users are not expected to be familiar with the system to begin with. This draws in more potential buyers who need help in making decisions.

Limitations of Current Travel Recommender System

Recommendations from a TRS aim to help the tourist in making informed decisions about their

travel plans. However, current TRSs deal only with the first stage of planning a trip, that is, destination selection. Present TRSs are unable to generate a complete travel itinerary which includes information such as accommodation and tourist attractions. Furthermore, a tourist is unable to visualise the planned holiday by using the current TRS technology. New information presentation models are required to increase user's confidence in the selected destination, such as providing the user a view of his/her trip, and allowing comparison between different options on a given trip.

Visual Travel Recommender Systems (V-TRS)

Visual travel recommender system (V-TRS) is a TRS that uses visual information, along with audio, to enhance the presentation of the recommendations made to the user. Two models aiming to develop the V-TRS are presented in the following.

Tourism Recommendation Using Image-Based Planning (TRIP)

Most of the TRSs available today don't provide a complete itinerary, but rather focus solely on the destination selection. This forces travellers to spend a lot of time browsing the Internet, looking for different attractions at their chosen destination. In addition to the suggestions provided by the recommender system, there can be a number of factors that effect the tourist's decision. Generally, tourists seek a second opinion from their acquaintances (relatives and friends). Often, many changes, and some backtracking is required before a travel itinerary is finalised. All of these factors make travel planning a complex undertaking.

As more people rely on the Internet to book their travel plans, it is important for travel Web sites to not only provide textual information, but also visual information. This will further help

travellers in their decision-making process. A recommender system with more visual presentation and reasoning enables tourists to get a feel of the destination. The tourism recommendation using image-based planning (TRIP) proposed by Kimber, Georgievski, and Sharda (2006) aims to achieve this.

TRIP Overview. Before booking a holiday package, the traveller would want to have an idea of what he/she is going to experience on the trip. “How am I going to organize my trip?” and “How can I get the maximum value for my time and money?” are the major questions that occur at that point in time. Most of the time, it is difficult to find the right details about the trip, and one has to go through the time-consuming process of visiting Web sites, gathering chunks of information and then sorting the details. The TRIP system aims to overcome this drawback by presenting the details visually. The presentation can be customised based on the user’s requirements. This will enable the user to have a clear idea as to what he/she is going to experience on the trip. The presentation provided by the visual travel recommender system will include details about the user’s selection such as hotels, the services offered by the hotels, the places that he/she is going to visit, and other major activities.

Tour planning is influenced by experiences, thus, the recommender system should provide the tourist with visual clues to assist them in decision making. Planning a complete tour involves various components and decisions, which can be categorised into travel, accommodation, interesting places to visit and hospitality considerations. Some hindrances to decision making can be the time required to gather and analyse information about the destination, balancing schedules with other activities, and ensuring that the travel experience is satisfying.

Keen and Rawlings (2004) have proposed a system which facilitates the decision making process by using a visual language. Their prototype demonstrates tourism products available in

Northern Tasmania, Australia. Users are provided information on a wide range of tourism products in the form of images and videos. As the user explores the information, the system keeps track of their browsing pattern, and a logic-based statistical profile is constructed. The profile building is a continuous process—the more the user uses the system, the better the profile becomes. This profile influences the system’s interaction with the user in the future and any information of interest to the user is stored in an electronic scrapbook (e-scrapbook).

The e-scrapbook is a personalised area in which the user can place information about items of interest. Typical information could be travel schedule, accommodation booking, and recreational activities. The user can place different products in the e-scrapbook, for example, cost of accommodation at various hotels. The user can easily delete items from the e-scrapbook, and also save items in it for future use. This gives flexibility to the user, and helps in gathering information over a period of time.

The system also allows past users to post their e-scrapbooks on a Web site, thereby allowing new searchers to import partial or entire e-scrapbooks from experienced users. This facility gives new users a demonstration of how to plan a trip, and gives valuable feedback. Once the user is happy with all the information in the e-scrapbook they can purchase the products. This method of travel recommendation using image-based planning helps user to narrow their choices until they are satisfied, and, at the same time, provide a graphical overview.

Tour Recommendation Using Image-Based Planning with SCORM (TRIPS)

In the present Internet environment, tourists have to visit a number of Web sites in an attempt to visualise their tour. The proposed tour recommendation using image-based planning with

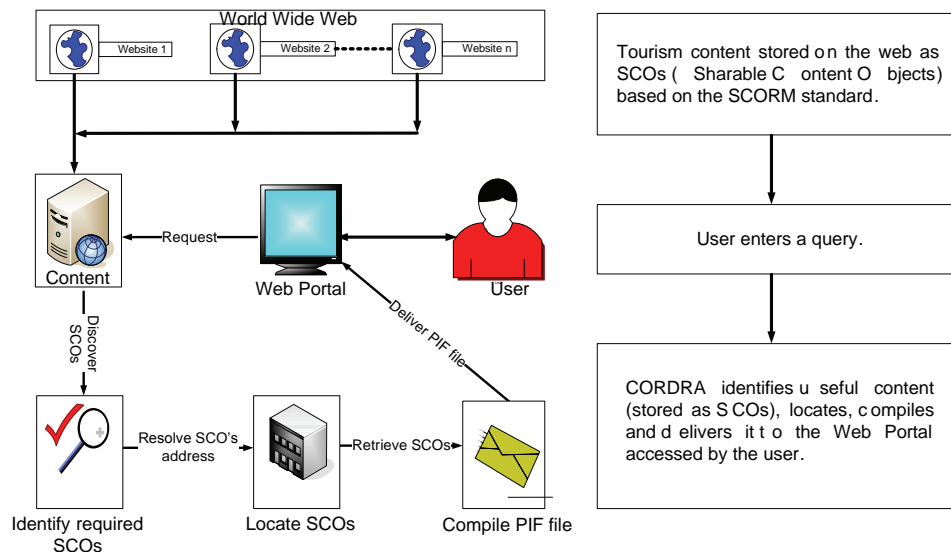

SCORM (TRIPS) system, will allow tourists to visualise their entire vacation by collating content from various Web sites. TRIPS uses the sharable content object reference model (SCORM) to store tourism information on various Web servers. If tourism Web sites post their information based on the SCORM standard, the proposed system could assemble relevant multimedia content from different sites and present it to the user to create a virtual experience. The SCORM standard has originally been developed as a reference model for Web-based e-learning technology. It is possible for us to adapt this standard for creating a visual experience generator for tourists.

The SCORM standard was proposed by The Department of Defence (DoD) and Advanced Distributed Learning (ADL) laboratories in 1997 to standardise the format of e-learning contents on the Web. The SCORM model aims to improve performance and reduce costs of e-learning systems. It was created by collating various e-learning specifications used by the Institute of Electrical and Electronics Engineers (IEEE). The main objectives of SCORM standards are to define

reusable learning objects and to develop content and assessment models. SCORM, as an e-learning standard, enables portability of learning contents, thereby allowing content to be used across different courses. In addition to SCORM, an extension is being developed to enable content registration and resolution of all relevant information throughout the Internet, this is called the content object repository discovery and registration/resolution architecture (CORDRA).

CORDRA. The CORDRA model also is an undertaking of the Department of Defense (DoD) and Advanced Distributed Learning (ADL), and aims to extend the current SCORM standard. This model is being developed so that one can locate and reference SCORM repositories throughout the Internet. Figure 1 presents a conceptual model of how CORDRA will achieve this. CORDRA searches the World Wide Web, much the same way current search engines do. Once the required resources are discovered, their location is resolved; making the resources accessible to SCORM based systems as the sharable content objects (SCOs). Even though SCORM and CORDRA standards

Figure 1. Finding and delivering content as SCOs

have been developed for e-learning systems, these can be used to create visual TRSs. If the tourism Web sites store information using SCORM, then based on a user query, the CORDRA system can collate all related information from the Web. However, the collated information needs to be combined into presentations that the user can view in a controlled manner.

Visual Tour Planning Using TRIPS. The TRIPS system uses sharable content objects (SCOs); these are Web information objects such as pictures, videos, and descriptions of places. Once a traveller's destination is finalised, further options need to be explored. For example, if a traveller is travelling to Melbourne (Australia) in January, options could include watching the Australian Open (tennis), visiting beaches, cruising over the Yarra River, or visiting historic sites. Depending on the number of days available, the tourist can visit all the places mentioned, or visit a selection of places based on priorities. The TRIPS

system contains information about the tourist's destination and their interests, and gathers SCOs related to the tourist's interests. Once the tourist finalises his/her selection, TRIPS can create an activity tree of the itinerary, and deliver the useful content (SCOs) as a package interchange file (PIF). The PIF contains an XML file (imsmanifest.xml) with all control files and resources referenced in the contents pages. The PIF, therefore contains information about the activities available to the tourist, structured in a hierarchy.

Conversion to Flash Movie. Next, the TRIPS system needs to provide options for delivering content in a user-defined sequence. This enables the user to control the sequence of on-screen displays. The Melbourne tourist may want to consider visiting the Australian Open on the first day and then take a half-day wine tour of the Yarra valley, and relax on a beach in the afternoon, followed by a dinner cruise on the Yarra River. SCOs with information relating to these activi-

Figure 2. Conversion of PIF file to Flash movie file using ActiveSWF software

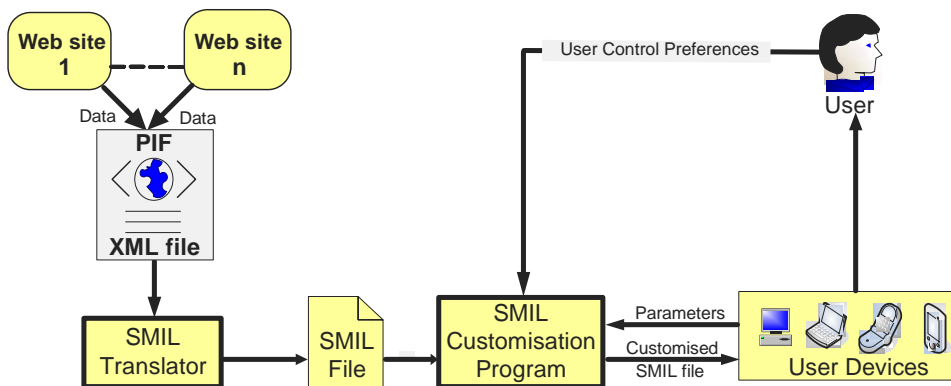

Figure 3. Conversion of PIF file to SMIL file using a translator

ties will be collated in the PIF file. The aim is to present to the tourist a short presentation of the travel itinerary being considered. One way to do this is to convert the imsmanifest.xml file to a format compatible with ActiveSWF (Activeswf, 2005) tool which can convert an XML file to a Flash movie. The duration of the movie can be selected by the user bearing in mind the number of options to be viewed. Figure 2 shows the conversion of imsmanifest.xml file to swfmanifest.xml (ActiveSWF readable xml file), and then to a Flash movie.

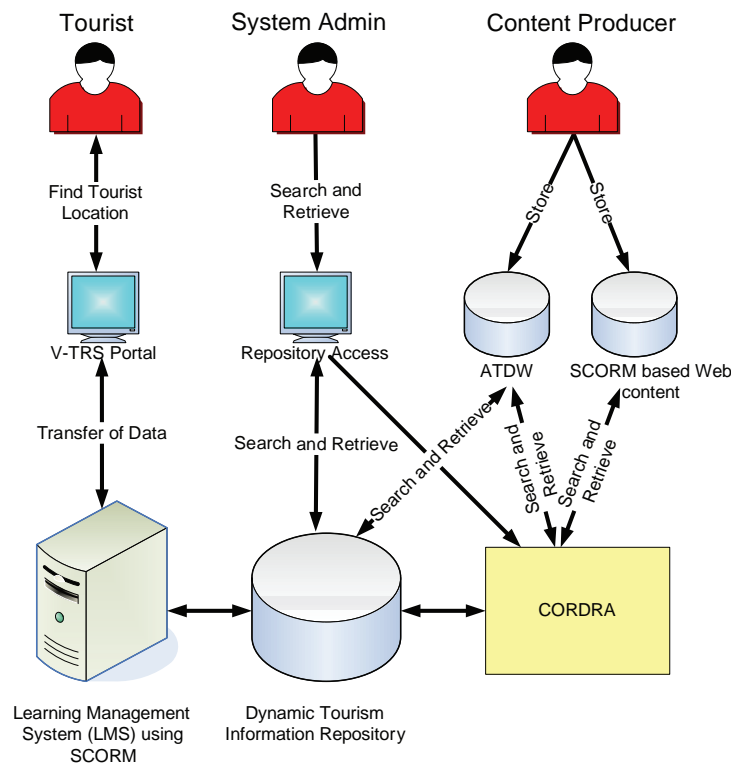

Conversion to SMIL Movie. The conversion of PIF file into a presentation also can be achieved by using the SMIL standard, as shown in Figure 3. The synchronized multimedia integration language (SMIL) is a W3C recommendation that makes use of XML for creating descriptive multimedia presentations. It defines different mark-ups such as timing mark-up, layout mark-up, anima-

tions, and visual transitions. The translated SMIL file can be sent to any user device, such as a Web browser on a computer, or on a portable device. The program checks for parameters such as screen resolution, bandwidth, and customises the SMIL presentation to match the system parameters. This process can optimise the presentation suitable for display on the specific user device.

As shown in Figure 3, SCOs from various Web sites are collected and stored into the PIF file, this file is sent to a translator which translates the file into a SMIL file, and the SMIL file is then sent to a customisation program which checks the parameters on the user device. The SMIL file is modified according to these parameters and then sent to the user device for viewing.

TRIPS Architecture. Based on the characteristics of SCORM, a new model has been developed for creating the TRIPS system. This new model allows tourism information to be converted into

Figure 4. Tour recommendation using image-based planning with SCORM (TRIPS) model

reusable content packages. These packages will be searchable and accessible through the local SCORM repositories, as well as through the CORDRA enhancement. The advantage of this is that all information stored using the SCORM standard will be more interoperable, accessible, reusable, maintainable and adaptable. The overall architecture of the TRIPS system is shown in Figure 4.

The process of converting `imsmanifest.xml` to a presentation file (`swfmanifest.xml` or `.smil`) takes place on the server-side. On the client-side, a graphical user-interface is used to browse potential destinations and their components.

The TRIPS architecture can be broken down into five main components: visual-TRS Web portal, learning management system (LMS) using SCORM, dynamic tourism information repository, repository access, and CORDRA. This system has three types of users: tourist, system administrator, and content producers.

V-TRS Web Portal. The tourist interacts with the system via the V-TRS portal. This portal works with a SCORM-based learning management system (LMS).

Learning Management System (LMS). As SCORM is a standard designed for e-Learning, the system designed to use it are called learning management system (LMS). The TRIPS system can use any of the standard LMSs available, and adapt it to work as a V-TRS.

Dynamic Tourism Information Repository. Dynamic tourism information repository is a central storage system. This repository can be set up as a single server or a network of shared resources. The primary function of this repository is to store all the sharable content objects (SCOs) that will be used for tour visualisation.

Repository Access. Repository access is a console or a portal used by the system administrator to access the information within the repository. Unlike the tourist, who gains admittance through the LMS, the system administrator accesses the

SCOs in their raw format and can even modify these, if required.

Role of CORDRA. CORDRA, though currently under development, already shows great promise when considering the possibility of incorporating it into the TRIPS model. CORDRA will pave the way for a far superior search facility due to its access to the World Wide Web, which is an ever expanding resource of tourism information. Currently, the Australian Tourism Data Warehouse (ATDW) stores tourism product and destination information that relates to Australian tourism (ATDW, 2005). In order to implement the functionality promised by CORDRA, the ATDW's expanding database could be included. The data from various databases, when combined with information on the Web, creates a huge data source that can be accessed by TRIPS. This provides TRIPS the opportunity to become a universally accessible V-TRS.

FUTURE TRENDS

How Visual TRS Can Enhance the Current TRS

Even though the current travel recommender systems make quality recommendations to the user, these recommendations are not presented in a way that lets the user visualise the entire trip. Future recommender systems will make use of audio-visual media to provide an in-depth view of the user's trip, where, the human-computer interaction is made more interesting by using audio and video in innovative ways. Dynamic text will be displayed along with the images to provide a description of each destination. Narration of this text in different languages also will be possible. TRIPS can be used in a distributed environment using CORDRA. If all tourism related Web sites are SCORM and CORDRA compliant, then information from any Web site can be retrieved

and used to recommend a complete holiday plan, including travel, accommodation, and other activities. Tourists will then have an easy and effective way of planning their personal or business travel. This also will improve the credibility of the World Wide Web as an effective vehicle for travel planning.

Case Study

Current recommender systems are not very interactive in terms of presenting the details of the tour. Even though the recommendations that they make are of a good quality, their presentation is more textual and rather unappealing. The system output does not give a feel of what the user is going to experience on the trip. In other words, the current recommender systems give a simplistic description of the different available destinations and offers.

For the purpose of this case study, we have developed a Web site that emulates how current TRSs work and make suggestions based upon user's choices and other criterion. We discuss

this system and present screen shots of its user interface.

Figure 5 shows the input screen for the recommender system. First, one must answer some questions, such as the region, budget, desired length of vacation, type of vacation and other such preferences.

The user input is analysed and the system makes recommendations with brief details of different packages which match the user's preferences. In this case, if the user wants to know what is included in each package, he/she needs to visit different Web links. Figure 6 shows a screen capture of how recommendations are often displayed.

To some extent, recommendations made by such systems are useful; however, they fail to hold the user's attention. Our aim is to present these recommendations in a more appealing and attractive manner. We want to make the process of making recommendations more fun and interactive, by changing the way information is presented to the user. Rather than displaying the recommendations in the form of text, we are in-

Figure 5. Input screen of the travel recommender system

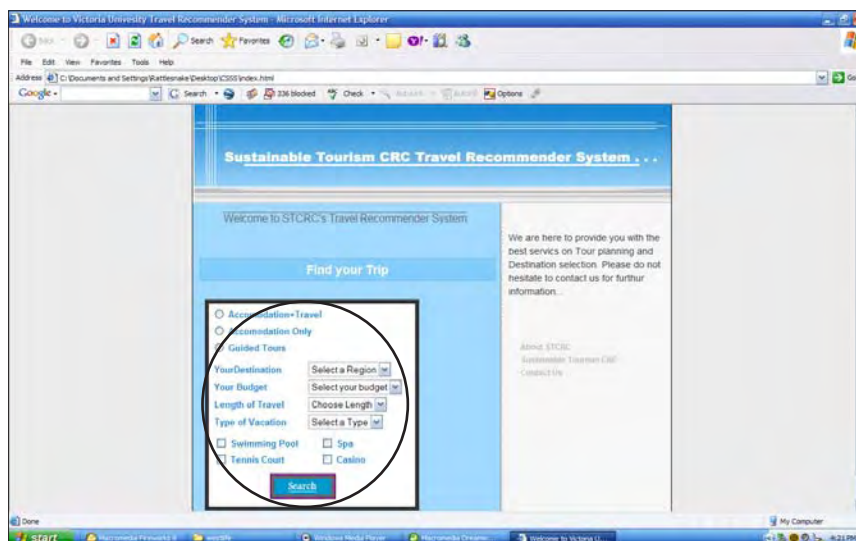

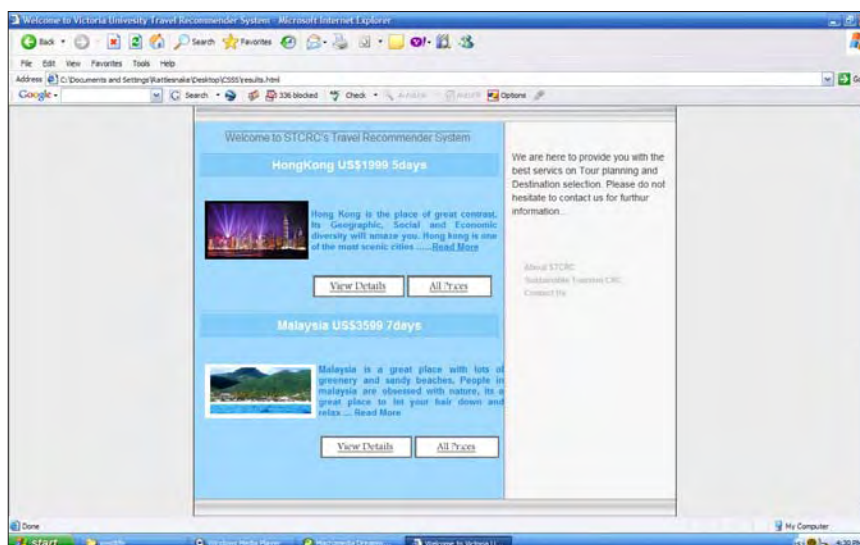

Figure 6. Screen showing the recommendations made by the system

roducing audio, video and text narration, thereby taking the concept of travel recommender systems to the next level.

CONCLUSION

The technology of recommender systems is improving constantly as more people use the Internet for making purchases. Vendors all over the world are encouraged to add recommender capabilities to their Web sites to attract more online business. This chapter discussed how the limitations of current travel recommender systems (TRS) can be eliminated by using visual travel recommender systems (V-TRS). Recommender systems are classified as content-based, collaborative, knowledge-based and hybrid. The most widely used travel recommender systems today are the TripMatcher™ and MePrint™. Current TRSs only deal with the first stage of tour planning, that is, destination selection, and are unable to provide a visual presentation of the entire tour. The proposed V-TRS aims to save time, while making the systems more interactive, and providing a visual

presentation to give the tourist a feel of the entire trip. In this chapter we have proposed a sharable content object reference model (SCORM) based architecture to visualise the tour, and suggested ways to use the content object repository discovery and registration/resolution architecture (CORDRA) enhancement.

Two different ways can be used to generate a video presentation from the data in XML format:

- Convert the XML file into a Flash movie
- Convert it into a synchronized multimedia integration language (SMIL) file

Further research in this area should investigate the user interface and control functions of the V-TRSs to make the task of tour planning, fun, easy, and more interactive.

ABSTRACT

The globally observed recession of mobile services market has pushed mobile network operators into looking for opportunities to provide value added services on top of their high cost infrastructures. Recent advances in mobile positioning technologies enable services that make use of the mobile user location information, offering intuitive, attractive applications to the potential customer. Mobile tourism services are among the primary options to be considered by service providers for this new market. This chapter presents the key concepts, capabilities, and considerations of

infrastructures and applications targeted to the mobile tourist, covering data and content delivery, positioning, systems' interactions, platforms, protocols, security, and privacy as well as business modelling aspects.

INTRODUCTION

During the last decade of the 20th century, wireless data networks have invaded everyday life and have gradually started taking over areas traditionally considered as being only suited to wired applications. Due to their versatility, wire-

less telecommunications systems have become a widespread standard, leading to hardware price drops and radical quality increases. Today there exist a bunch of technologies that allow the delivery of information to mobile or wireless devices and their users, all presenting different characteristics in performance/ quality, autonomy and cost. These technological advances accompanied by the reach of the saturation level (Ellinger, Barras, & Jackel, 2002; Gruber, 2005; Gruber & Verboven, 2001) in the mobile telephony market pushed hardware vendors and network and service providers into looking for new business opportunities. The needs of tourism-related information provision and services were amongst the first to be considered for new applications in the field of communication devices.

In traditional fixed systems, the location of a terminal and its user was a part of its identity and remained constant for a long period during its lifetime. In this new mobility era, this observation no longer holds: the physical position of the user might be highly variable, introducing a whole new range of issues and opportunities to be taken into account. The use of intelligent systems that exploit the positional information of the client, accompanied by the ability to provide feedback over a wireless medium, can lead to the provision of innovative highly intuitive services that were not available in the near past (Grajski & Kirk, 2003; Kakaletris, Varoutas, Katsianis, Sphicopoulos, & Kouvas, 2004; Rao & Minakakis, 2003; Staab & Werthner, 2002; Yilin, 2000).

But, although mobile telephony networks offer maximum mobility, they are not the only means for providing location-based services (LBS) for tourism. Local fixed wireless networks in their various forms are another of the modern and popular technologies facilitating relevant services. In addition to telecommunication systems and from a technological perspective, there are a wide range of other systems such as global positioning system (GPS) (Dana, 1994; ETSI, 2006; GARMIN, n.d.), or ID tags (Bohn & Mattern, 2004;

Tarumi, Morishita, & Kambayashi, 2000) which might have a significant role in the development and deployment of e-tourism applications based on location information.

This chapter presents the technological concepts associated with the provision of location-aware tourism-related services under a service-oriented approach capable of supporting open value chains and to lead financially viable open and powerful communication systems. The rest of the chapter is organised as follows: The “Background” section presents the technological and business background of location-based services; the “Technology Overview” section gets into details of the technological aspects and issues raised in the domains of positioning and data/content delivery, which are fundamental elements of the examined class of services; the section on “Mobile Tourism Services” captures the specific needs and opportunities in the specific application area and presents issues and considerations with respect to integrating the various parts into an open system capable of delivering such services. In the “Conclusion,” technology and market conclusions and trends are presented. Finally, due to the large number of acronyms and the frequency of their appearance, a table of acronyms is provided at the end of the chapter in order to ease reading through it (see Appendix).

BACKGROUND

The application of the above-mentioned technologies and concepts in tourism gave birth to the ubiquitous tourism¹ concept (OTC, 2003), which refers to the existence and access of tourism related services at any place, any time. Although tourism-related services are mostly related to content provision, more applications can be identified. In its entirety, content provision for e-tourism covers a large number of thematic areas: culture, urgencies, transportation, events, and so on. Thus, content might be both temporally and spatially

labelled (LoVEUS, 2002; M-Guide, 2002). In addition, information seeking and avalanche-like content provision might guide the user to areas quite outside her/his initial focus areas.

The information technology (IT), the Internet and the mobile telecommunications revolutions of the last decades of the 20th century made it possible for enterprises to enable massive access to their applications and data. Users are able to access applications and information through a variety of integrated “channels” including the Internet, mobile telephony, and voice interfaces and thus bring forward the concept of multi-channel architectures. Consequently, multi-channel content delivery and media-independent publishing have emerged in order to address the demand for personalised content that can adapt to the end-user device capabilities. Devices, such as PDAs, cellular phones, smartphones, and television set-top boxes, introduced the need for additional channels for publishing content. The approach of maintaining independent content sets per channel proved to be highly inefficient in terms of maintenance, until the wide adoption of eXtensible Markup Language (XML) and related technologies, such as eXtensible Stylesheet Language / XSL Transformation (XSL/XSLT), offered a standard solution to this challenge.

Technology is not the sole reason behind the emergence of the ubiquitous tourism concept. The existing 2/2.5G² mobile market has reached saturation as analysts have predicted, but its effects have only been acknowledged lately, due to the high expectations of the emerging 3G³ markets. The costs of licensing (Andersson, Hulten, & Valiente, 2005; Katsianis, Welling, Ylonen, Varoutas, Sphicopoulos, Elnegaard, et al., 2001; Yan 2004) and deployment of 3G networks led mobile network operators⁴ (MNOs) into a global recession era and a global pessimism for their adoption which actually reflects user attitudes towards the new standard. In order to confront that, business opportunities based on existing mobile and wireless networks have been further

investigated (Katsianis et al., 2001; Varoutas, Katsianis, Sphicopoulos, Loizillon, Kalhagen, & Stordahl, et al., 2003). The provision of value added services over 2.5/3G networks not only allows providers and users to make the most out of the existing infrastructures, but also encourages usage and drives expectations for the next generation of mobile networks (Varoutas, Katsianis, Sphicopoulos, Stordahl, & Welling, 2006). To provide such services, the integration of various components and base-services is required, which breaks the current status of most MNOs that have traditionally been formed as almost monolithic self-contained service(s) providers.

This need for integration of various market stakeholders in complex business models aiming for the provision of high quality services has been indicated not only by mobile market analysts but also by information systems architects. The service-oriented approach (Brown, Johnston, & Kelly 2003; Colan, 2004), a whole new IT perspective which is rushing into the industry, underlies the concepts and offers the guidelines that render possible such complex collaboration schemes. In the LBS domain, mobile positioning protocol and mobile location protocol (Ericsson; OMA, 2002) already exercise concepts in-line with current service-oriented architectures (SOA) common practices. Nevertheless, the design of services, such as location-based ones, will always have to face domain specific challenges concerning technical, economical or even ethical and social factors of the service application (Daoud & Mohan 2002).

Nowadays it is possible and desirable to build open systems that can support the delivery of tourism-related location-dependent content to an end-user on top of the technological and business background already described, allowing:

- Seamless interoperability of systems and content provided by several market stakeholders towards providing a large range of high-quality location-based content delivery

services, through standards and loosely coupled elements

- Exploitation of state-of-the-art and future technology in positioning, mobile devices, and network infrastructures
- Compliance with requirements and standards for personalisation and quality of service (QoS)
- Low-cost implementation and upgrade road-map from 2/2.5G to 3G and other current and future mobile and wireless networks
- Guarantees of privacy

As already mentioned, provision of tourism-related content can be shown that covers a large portion of the information that is usually delivered through location-based services. A number of studies already exist that focus on various aspects of technologies, architectures and business models of this area (Devine & Holmquist, 2001; EMILY, 2002; M-Guide, 2002). This chapter presents the design aspects of such services in a generic way, capturing the needs of many location-dependent services since it assumes a highly heterogeneous network infrastructure leveraged by the Internet protocol (IP) layer. In this way, dealing with the details of mobile or other wireless network infrastructures is avoided yet interoperability and integration issues are been identified and investigated.

TECHNOLOGY OVERVIEW

In the following sections the technologies involved in the provision of mobile tourism services are introduced. Connectivity, which essentially allows delivering data to a device, and positioning, which is the ability to locate a device and consequently its user in space, are the fundamental enabling technologies for the provision of location-based services. Assuming these, tourism related information could be delivered to devices capable of presenting it (e.g., mobile phones), with a multitude

of options (quality, depth, size, etc.), derived from exactly the same content that would drive traditional applications (Web sites, printed elements, etc.). The driving force behind these is modern software platforms and system architectures that facilitate the creation of the various nodes of a complex structure of collaborating service elements.

Wireless and Mobile Data Services

Since the last decade of the 20th century and the beginning of the 21st, the mobile user has come to enjoy the provision of many technologies and services that were hard to even imagine several years before (Lin & Chlamtac, 2001). Besides voice, some of the most common ones are:

- **Information services** (News, Directories, Weather, Athletics, Financial, etc.)
- **Entertainment** (Chat & Flirt Services, Guess who, Alerts, Horoscope, ringtones, etc.)
- **Communication tools** (SMS, MMS, e-mail, instant messaging, etc.)

Apart from these common services, a series of other, more complex ones are being offered to the user like navigation, local news, SMS vote, microbilling, and so forth. Enabling these services is achieved through various means the most important of which being the Web, SMS, and MMS. These higher-level information exchange media are based on lower level communication channels offered by an infrastructure provider. The most important ones are briefly described below:

- **Global system for mobile telecommunications (GSM)** refers to 2nd generation mobile telephony networks (Mouly & Pautet, 1995), which although digital, was designed with voice communications in mind, thus giving data rates of 9.6kbis/s, which is rather slow for multimedia applications. Additionally

data transfer is not packet switched thus not optimised for computer type communications requiring circuits to be allocated even if no data are exchanged. Since its initial appearance, several enhancements were proposed as side-by-side technologies that enable higher performance data transfers (Korhonen, Aalto, Gurtov, & Lamanen, 2001).

- **General packet radio services (GPRS)** is a wireless communication protocol based on the same modulation as GSM, designed to be provided as a complementary medium to facilitate data transfers over GSM networks. It is packet-based and delivers data rates of approximately 40kbps⁵ (Korhonen et al., 2001; Pahlavan & Krishnamurthy, 2002; Patil, 2003; Tisal 2001). It supports continuous connection to the Internet for mobile equipment users. Since GPRS radio resources are utilised only when devices have data to exchange, its end-user cost is lower in both terms of money and power consumption. Packet switching allows more users to be simultaneously connected to the Internet, yet performance drops on high load and no strict guarantees can be given.
- **Enhanced data rates for global evolution (EDGE)** facilitates high-speed mobile data transfer over which can reach a peak rate of 384kbps and is aimed to mobile network operators that might not be able to obtain UMTS (further information is provided below) spectrum but would not like to be left out the modern high speed data services (Halonen, Romero, & Melero, 2003; Rysavi 2005). Even higher speeds may be available in good radio conditions. EDGE provides the same benefits of GPRS (e.g., packet switching, always connected) however by using a different modulation schematic achieves much higher speeds.
- **Highspeed circuitswitched data (HSCSD)** overcomes the limitation of GSM circuit switched data, which supports the allocation of one user per channel per time slot and allows multiple channels to be virtually merged thus offering higher data rates (Halonen et al., 2003; Korhonen et al., 2001). However the allocation of multiple channels raises the connection cost of the end-user, rendering the service rather inappropriate when compared to other modern techniques.
- **Universal mobile telecommunications system (UMTS)** utilises WCDMA (wide-band CDMA) over a 5MHz bandwidth thus allows speeds the increase of mobile network speed in order to allow high-speed transfers. UMTS is one of the five types of 3G radio interfaces specified in the ITU⁶'s IMT-2000 recommendation. It allows various classes of service, ranging from more than 100kbps for a fast moving user up to a 2Mbps for a fixed client "lab" speed (3GPP, 2002; Lin & Chlamtac, 2001; UMTS, n.d.).
- **High-speed downlink packet access (HSDPA)** is deployed as an upgrade to UMTS networks and captures the observation that most end-user high-bandwidth demanding applications require one-way high-speed communications, downstream (i.e., towards the end-user). On-demand video, TV and data downloading are some applications that expose such a transfer pattern thus can benefit quite significantly from the speed offered by HSDPA which is up to 3.5 times faster compared to the maximum rate of 14Mbps of today's 3G UMTS (Holma & Toskala, 2004; Kaaranen, 2005; Rysavy, 2005).
- **Wireless fidelity (WiFi)** is a term that in general refers to the 802.11 family of wireless network protocols (Muller, 2003; Smith, 2003). A variety of protocols (e.g., 802.11b, 802.11g) that operate in 2.4GHz and 5GHz bands, being the most popular ones, belong to this family, offering nominal speeds of up to

108Mbps (802.11.Super-g). WiFi networks are fixed, local-area, wireless networks thus do not offer the mobility capabilities provided by mobile networks. Additionally, although they can operate without an infrastructure (e.g., on a computer-to-computer way), yet another (usually fixed) connection to the Internet is required in order to obtain worldwide access.

- **Bluetooth (IEEE 802.15)** is a short-range, relatively low performance communications protocol. It is designed so that it allows low power consumption and it is very simple to implement so that it can be easily adopted by “dummy” devices such as headphones, computer mice, keyboards, and so forth. (Bluetooth.org, 2001; Miller & Bisdikian, 2002; Morrow, 2002; Muller, 2001; Xiao & Pan, 2005).

Location-Based Services

Location-based services are an entire class of mobile services that utilise positional (mostly geospatial) information of the mobile user in order to provide intuitive, easy access to content and tools. The term covers a quite large group of services since it can range from global scale services to highly spatially constrained ones (within a room or a building, such as a museum or a conference center).

One of the main aspects of location-based services is positioning, that is, the estimation of the user position, a topic to be covered in detailed sub-subsequent sections. Depending on the service class, the mobile equipment and the infrastructure, different approaches and accuracy levels can be applied (Dao, Rizos, & Wang, 2002; Northstream, 2001). In this chapter, the focus is on global scale services, but the elements and concepts presented are not restricted to this particular class of services (Kakaletris et al., 2004). Most location-based services can be categorised into four main business applications:

- **Tracking services (with two sub categories):** emergency services and fleet management services. In the case of emergency services (such as the E-911), the network has the ability to locate persons who are in danger or missing (with special interests for kids) and give them the necessary protection (Reed, Krizman, Woerner, & Rappaport, 1998). Emergency services are first priority for USA (FCC, 2001) and US companies focus on these class services. Road assistance and tracking of stolen equipment (cars, boats, etc.) are other similar services (Fritsch & Scherner, 2005). Fleet management services cover scenarios such as radio-taxi coordination, transportations, delivery, and so on, and in the general case, require high accuracy (Feng, Zhu, Mukai, & Watanabe, 2005; Iwasaki, Kawaguchi, & Inagaki, 2005).
- **Information services:** In this category of services content relative to the location of the user is provided to him/her. However in global scale services the focus is not on the accuracy of user’s position acquisition but rather on the content and the way it is presented (Taylor & Ryan, 1995). Local news, cultural information, events highlighting, or even advertising are some of the applications of this category. Such services may be provided near sightseeing or within museums (Zimmermann, Lorenz, & Specht, 2003). In high granularity services (e.g., within museums) positioning has to be accurate and in many cases highly sophisticated since it might even need 3-dimensional location of the user and directional clues (Pateli, Giaglis, & Spinellis, 2005).
- **Fun and entertainment:** Player position-aware games are a new opportunity for service providers and the first flavors are already out. Despite the criticism, chat and flirt is another very popular type of service. In this area, location-aware systems will have

Table 1. Typical wireless and mobile data networks

Technology	Typical Performance ⁷	End-user relative cost	Scope	Compatibility
GSM	9.6Kbps	High	Global	Very high
GPRS	40Kbps	Medium	Global	High
HSCSD	64Kbps	Very High	Global	Low
EDGE	115Kbps	Medium	Global	Low
UMTS	220Kbps	Medium	Global	Medium (in deployment)
HSDPA	750kbps	Medium	Global	Low
WiFi	11Mbps ⁸	Low	Local/indoors	High
Bluetooth	500Kbps	Low	Indoors	High

the opportunity to refine partner matches within a certain distance (Gratsias, Frentzos, Delis, & Theodoridis, 2005; Karagiozidis, Markoulidakis, Velentzas, & Kauranne, 2003; Lee, Prabhu, & Park, 2002).

- **Billing:** Billing also can adopt location-aware schemes. Creating attractive options such as allowing users to exercise cheaper communications when in certain hot spots (such as home, etc.) is a possible scenario of location-based billing (Gratsias et al., 2005; Koutsopoulou, Panagiotakis, & Alonistioti, 2005).

Positioning

Location-based tourist information requires positioning of the mobile user with a variable accuracy (Kakaletris et al., 2004; Yilin, 2000). Yet this does not imply that automated acquisition of positional information is always required or desired in order to consume such a service, as when checking available information by forehand, not being physically present in some area. It is obvious that locating the user requires that one is equipped with a module that has some kind of connection to a fixed infrastructure. However the elements of this composition might vary:

- **Equipment** can be a PDA, a 2G or 3G mobile phone, a personal computer, an ID tag, an IR Scanner, a GPS receiver, and so on.
- **Connection to the infrastructure** can be unidirectional or bidirectional utilizing systems such as WiFi, GSM, GPRS, UMTS, satellite antenna/receiver, IR receiver/transmitter, and so on.
- **Infrastructure** can be mobile or fixed network such as a satellite system, a mobile telephony/data network (GSM, GPRS, UMTS, etc.), a set of WiFi or Bluetooth access points, installed RF tags, fixed IR scanners, and so on.

Positioning can be categorised under two main classes:

- **Active:** The client is the only one responsible for the computational load of the position estimation.
- **Passive:** The client (user/mobile equipment) is being located without adding any logic to positioning by itself. Infrastructure obtains simple to extract information from client and calculates the position.

Hybrid methods also are very popular, allowing for high accuracy and availability systems. Exploitation of the positional information also can vary quite significantly:

- In **self-contained systems**, such as GPS enabled PDAs, the content might be already present on the mobile equipment and a local piece of software acts on them, thus no further connection to the outside world is required. The range of location-based services to be supported in this case is limited, navigation being the most popular one.
- In **always-connected systems** a medium for exchanging information with the infrastructure and usually the world (the Internet) is required. This can be done in order to acquire the position, or exchange information that will allow position estimation, or access the core service/content.

The rest of this section presents the details of some of the most important positioning methods, their requirements, and their characteristics. There are a number of ways for obtaining user's position

and the following sections describe some of the current applied automated methods:

The GPS

GPS positioning (ETSI, 2006; GARMIN, n.d.) is based on a network of 24 earth orbiting satellites. It was originally designed and implemented to cover the needs of the US military forces, however since the 1980's it has been used for wide spectrum of applications ranging from civil engineering to recreational systems. Communication is one-way; consequently clients only receive signals, thus guaranteeing privacy. A GPS client/device receives signals from several satellites with at least three satellites needed for 2-dimensional coordinate estimation (latitude, longitude) while four are required for three-dimensional positioning (latitude, longitude, and altitude). Signals are time-tagged, enabling the client to calculate distance from each satellite using the send/receive time difference. Accurate position estimation requires combining the aforementioned distances for multiple satellites. Bookkeeping of coordinates is a way to calculate the speed and direction of

Figure 1. GPS operation

moving GPS devices, a facility provided by almost all modern receivers. In such systems end-user devices are quite small and due to low power consumption tend to be highly autonomous.

Civilian GPS satellite signal is low power (i.e., less than 50 watts in 1575.42 MHz). It penetrates glass and plastic, but cannot go through metal, ground or concrete, effectively preventing indoors GPS usage. Dense urban use also can be problematic in some cases. Additionally, the GPS signal is vulnerable to signal travel time errors that lead to false distance estimation. Reflection of signal on solid objects as well as other orbital/stratospheric phenomena can result to wrong time estimations. Utilizing more satellites is a way to deal with such problems.

One of the strongest points of GPS however is accuracy, which can range from 1 to 15 meters for civilian systems. This fact, accompanied by the simplicity of the relevant devices and the availability of the service which can be utilised at no cost (apart from equipment) makes it capable of driving major successful commercial applications, such as navigation for tourists. As already mentioned, GPS is controlled by the U.S. Department of Defence, nevertheless it is expected that the European Galileo system will be competing with it by 2008 (Di Fazio, Mocci, Rossini, D'Angelo,

Lorelli, & Jarosh, 2004; El-Rabbany, 2002; Prasad & Ruggieri, 2005). GPS has to be accompanied by a supplementary network in order to drive interactive on line systems where satellite coverage is unavailable. Pseudo-GPS systems emulate the existence of satellites for indoors use without requiring any additional equipment, yet they are not widely adopted solutions (Schmid, Neubauer, Ehm, Weigel, Lemke, Heinrichs, 2005).

GSM-Positioning

GSM positioning (ETSI, 2006; Mao & Douligeris, 2000; Spirito, 2001; Zhao, 2002) is a facility potentially provided by GSM mobile network operators. Its operation is based on the fact that there is always some type of raw information on the location of a certain GSM mobile device in order for the network to be able to deliver information to the user. Since it can be originated from the network, it is raising serious privacy and security concerns, which can be overlooked for emergency purposes but not without risk of misuse.

GSM positioning is always available in some form, as long as network coverage is provided. However depending on the network infrastructure and method utilised its accuracy might vary quite significantly ranging from 100m to more

Figure 2. Cell ID/Cell ID + TA

than 500m (even several kilometers) (Caffery & Stuber, 1998b; Drane, Macnaughtan, & Scott, 1998). Although due to this low level of accuracy GSM positioning is of little use for high accuracy demanding application, it is accompanied by a bidirectional communication channel (voice or data) thus enabling interactive applications. Its network-side activation, whenever applicable, makes it ideal for some special emergency and tracking cases.

- **CellID** is a location technology that utilises the well-known location of fixed network elements, that is, the base station transceivers (BTS), to identify the mobile equipment location (Figure 2). It can be easily combined with timing advance (TA) in GSM networks and round trip time⁹ (RTT) information in WCDMA networks in order to improve accuracy. TA is a technique that utilises the timing advance information applied by the GSM network to determine the approximate distance a MS is from a base station.
- **Enhanced-observed time difference (E-OTD)** is a more complex method for calculating device position (Caffery & Stuber 1998a, 1998b). It requires location measurement units (LMUs), a type of device used to provide precise timing information for asynchronous networks. Although this method can increase accuracy, it also increases

infrastructure cost and it still suffers from issues with network density in rural areas. E-OTD and time of arrival (TOA) methods are very similar to GPS positioning already described. The location of mobile devices is calculated using the signaling time from two or more stations (see Figure 3).

Typically GSM-positioning would not always be enabled, since this requires significant resources from the operator's side. In the typical usage scenario, the user has to ask for locating him/her, either through an SMS or through a request over the standard Internet protocol (IP). Due to its privacy risk, GSM positioning is usually surrounded by rules of activation and bureaucratic procedures/agreements, which can be even harder to overcome in cross-MNO cases unless a standard user-driven mechanism is utilised. Unfortunately despite the existence of specifications, in mid 2001 decade there is still no standard for GSM positioning that is widely adopted by operators. A final restriction on its use is its cost, which can vary quite vastly depending on the level of consumption of the service.

WLAN

Wireless local area network (WLAN) positioning (Wang, Jia, Lee, & Li, 2003) is a local type of positioning usable within range of WLAN

Figure 3. E-OTD operation

hot spots, which is mostly restricted indoors or in quite constrained areas (e.g., building blocks, etc.).¹⁰ It is the primary candidate technology for big buildings like airports, museums, market places and other sites where radio interference is not an issue and it should generally be accurate enough to guide a visitor through the coverage area. Positioning is very similar to GPS and GSM positioning, thus it uses the time difference between the signals from some known positions. This information can be corrected and improved with site calibration, a method which also can be utilised in some GSM positioning cases but not without significant difficulties. In the WLAN positioning case, information about the physical structure of the target area (walls, obstacles, etc.) is of crucial information in order to obtain reliable results.

According to systems' vendors, WLAN positioning can be quite accurate (one meter indoors according to Ekahau, 2006) yet site calibration is definitely required for such accuracy. Its cost is

quite reasonable since infrastructure and equipment are quite cheap and it is well suited for interactive on-line applications since data network coverage is implied.

Other Methods

Despite its peculiarity considered in the context of the e-services described above, observation accompanied by a traditional map (i.e., paper-printed) also could be a useful method of information dissemination for tourists even in the electronic age. This does not suffer from service unavailability, privacy, mobility, and autonomy issues, and its price is usually low. Using an electronic map instead of a printed one would add in detail and in some cases reduce in size while posing some restrictions on autonomy, however if not accompanied by a positioning system it would still require observation and manual operation in order to consolidate other information.

Positioning through mapping addresses to geographical coordinates is very similar to using maps

Table 2. LBS summary of performance, implementation, and cost trends (Sources: EMILY, 2002; Hightower & Borriello, 2001; Moureu, 2000; SnapTrack, 2001)

Metric	CELL-ID + TA	E-OTD	GPS	A-GPS	Hybrids
Accuracy	100m 10km	100m 500m	10m undefined	10m 100m	1m 100m
Kick-off time	Low	Low	High	Very high	Very high
Dimensions	2	2	3	2/3	2/3 (+direction)
Mobile Equipment Requirements	None	Low	High	High	High
Applicability	Good	Poor	High	Medium	Good
Infrastructure Cost	None	High	None	None-to-high	High
Best area applicability	Dense urban	Urban / Dense urban	Suburban	Suburban, urban	Outdoors, Indoors
Coverage	High	High	Partial	High	High
Overall Quality	Poor	Medium	High	High	Excellent
Compatibility	Medium	Poor	Full	Medium	Poor

Figure 5. LBS technologies services and accuracy¹³

since it requires observation and manual utilisation of information. However the location is obtained through lookups in appropriate databases, such as geographical information systems¹¹ (GIS). It is quite usable in urban areas and roadsides of rural areas and it can be both electronic and traditional (maps with indices).

There are several other methods, like local sensor networks, ID tags based on infrared or radio frequencies (IR or RF), gyroscopes, and statisti-

cal models (Hightower & Borriello 2001; Nellen, Bronnimann, Held, & Sennhauser, 2004; Spratt 2003). Out of these one could expect low-cost gyroscopes to be the most attractive mechanisms for mobile travelers in the future (whenever it becomes possible to build lightweight, low-cost gyroscopes) since they could drive the most fascinating classes of applications. For example taking into account the direction of sight of the user could even further enhance the simplicity of

interaction with a service, especially in complex (with respect to location and quantity of content) environments such as museums or exhibitions. Further issues and opportunities can be found in the section on “Mobile Tourism Services.”

Summary

Each method presented has advantages and shortcomings. It seems that GPS is currently the primary means of reliable positioning when global positioning comes into play, however hybrid positioning (i.e., by blending of different location technologies) utilizing GSM and WLAN methods could be optimal. In the rest of this chapter “hybrid” will refer to combining GPS with other location techniques.

There are several whitepapers, guidelines, studies, and surveys showing the details of each positioning approach (Caffery & Stuber, 1998b; Hightower & Borriello, 2001), however a higher level evaluation of the ones applicable to tourism as it appeals to mobile network operators will be introduced below. Other types of systems like personnel/patient tracking in hospitals (Dao et al., 2002; Douglas, 2004), information delivery in museums (Sparacino, 2002) or emergency related ones (FCC, 2001; GSM, 2002) generally require more sophisticated means for delivering their services.

When designing an open infrastructure then, positioning should not have any strong relation to the implementation of services for the mobile traveler. Realisations of different services should leave methods of getting positioning information open, allowing the end-user to choose among them: GPS, GSM and map outdoors, WLAN and GSM inside. Services should be prepared to receive coordinates as bunches of numbers in the three-dimensional + direction space accompanied by definition of coordinate-standard and accuracy.

Such an approach would leave all possibilities open for the user. Also this method would keep

service providers’ monetary costs down, because service provider can leave all costs of positioning to be decided by the traveler.

When building services for the mobile traveler, designers should ideally therefore forget the actual positioning method and provide a service in a way that it would be able to cope with any degree of accuracy or availability of positioning information. Obtaining the position would then be a task to be carried out by external parties such as equipment manufacturers or infrastructure providers, both of them working on low details of the software that manages the “networking” hardware.

Positioning Standards

An attempt to standardise positioning has been carried out during the past few years. Solutions and best practices have been proposed by vendors, associations and individual researchers (Adams, Ashwell, & Baxter, 2003; GSM, 2002; Rao & Minakakis, 2003). As a consequence the terms mobile positioning center (MPC) and gateway mobile location center (GMLC) systems emerged in order to label the entities of the infrastructure that were used in order to extract positioning information and estimate end-user locations. The mobile location protocol (MLP) is an application protocol developed by the location interoperability forum (LIF) that specifies the messages to be exchanged over standard Internet technologies in order to obtain coordinates from a positioning center. It is focusing on network based positioning and has its origin in proprietary commercial protocols. OpenLS (OpenGIS location services [OGS]) defines the interfaces to an open location-based services platform, such as the GeoMobility server. Utilizing XML for location services (XSL) defines the data exchanged in the interactions with the geographic information system (GIS) for various classes of services that capture facilities such as routing (navigation), position extraction, lookup (directory), map drawing (presentation), and so on.

Popular, yet proprietary protocols such mobile positioning protocol (MPP) (Ericsson) also can be an option since many existing systems support these.

Content Technologies

One of the major aspects of mobile tourism services is the delivery of content to the end-user. This in the general case involves identifying the content to be displayed, (optionally) moving it to the device¹⁴ and presenting it. In the following paragraphs focus is given on the case that content is passed to the device upon request, that is, does not reside pre-installed on the device.

Delivering content of location-based services to the end-user is not as simple as it seems at first sight. There is a multitude of devices that content can be delivered to and a number of media through which it can be transferred, all of them presenting different capabilities and shortcomings. Typical examples are SMS, MMS, and WAP:

- **SMS** market penetration is significantly higher than the penetration of WAP. The majority of the location-based systems implemented by MNOs, use the SMS for exchanging data. However presentation and interaction facilities are severely limited over this transport medium; furthermore SMS can be extremely expensive per byte of data exchanged
- **MMS** significantly increases the quality of presentation and reduces the price per byte of exchanged data. Yet its penetration is significantly lower than SMS, it suffers the same interaction restrictions and finally its cost can be significant over SMS for simple text information exchange
- **WAP** adds to presentation and interactivity quite significantly. However its penetration is quite limited and it is not expected to be widely adopted unless significant convergence to Web technologies is achieved

Research on service types show that the SMS/MMS solution might be more appropriate, while WAP/Web is the only way for others (Bennett, 2001; Heijden & Taylor 2000). Taking into account that current end-user mobile terminals have limited displays and end-users are not accustomed to consuming interactive services through the mobile phone interface, SMS/MMS may be a commercially viable solution for a wide range of location-based services. Special sub-sections of tourism related services such as directory lookups can be ideally served through simple SMS exchanges.

Positioning also is influenced by device capabilities. The majority of mobile phones are not equipped with GPS devices, which could have a significant impact on their autonomy, size, and weight since the cost of a GPS receiver is insignificant compared to the cost of the rest of the device. Even PDAs or laptops do not usually come out of the box accompanied by GPS receivers, making it a requirement to purchase one separately. The primary option is a Bluetooth GPS device that can be easily connected to portable computing devices such as latest mobile phones, PDAs, or laptops; however despite the small size of these devices this scenario requires that the user carry one extra component.

Mobile Terminals That Support LBS

The development and full deployment of high quality location-based services for tourists assumes the existence of terminals with extended capabilities in battery capacity, processing power, main memory, application capabilities, size, and weight. Such devices may be categorised according to an incremental rating of the applications they can support. Today, four categories of terminals can be found in market:

- **Standard GSM mobile terminals**
- **GPRS/UMTS phones:** There are two categories of GPRS/UMTS phones. The WAP

based and the HTML based ones. The former category offers facilities for consuming WAP information sources (WAP sites) while the latter one exchanges information in Web standard formats such as HTML, JPEG, etc. They require a Web server, which will host the mapping applications and will be responsible for routing requests to external systems.

- **PDAs/Smartphones:** Smartphones are latest generation mobile phones equipped with enhanced displays, more powerful processors and capabilities of carrying out tasks that were formerly responsibility of computer systems. PDAs are devices in some extent similar to the smartphones, stressing on presentation and application capabilities rather than communications. Latest generation devices are usually equipped with an HTML browser able to interface with standard Web sites. PDAs offer built in or expandability options for GPS, GSM, WiFi, and so on.
- **Laptops with communication facilities:** These offer all the advanced options of computers in terms of computational and storage capacity, yet they have limited mobility features.

Multi-Channel Content Delivery

Multi-channel content delivery is a very important aspect of the content provision system. Infrastructure and content should be suitably constructed so that they allow delivery of information through various media and means, be it SMS message exchanges, GPRS, or fixed networks connections, computers/PDAs/phones, and so on. Nowadays there is a whole suite of technologies and a large number of systems that enable multi-channel content delivery, under the *author once—publish many* approach, where the same source content is used for several targets ranging from printed media to mobile devices.

Nowadays the most widely applied solutions for this approach are based on a set of standards and tools build around XML, a simple text language developed by the World Wide Web Consortium (W3C) that has its roots on SGML. XML can be used with a wide range of applications, such as authoring tools, content display engines, translation tools, and database applications (Anderson 2000; Bosak 1998; Bosak & Bray 1999). However, its major use in the context of mobile tourism services is for structuring the tourism related content in a form that it becomes meaningful for a series of software elements and operations. More precisely, the various parts of a document are labeled in a special manner (tagged) so that can be extracted by various applications to fulfill their own needs (Anderson, 2000). A relevant technology is the well-known HTML which uses a somewhat similar tagging mechanism yet it neither enforces structure nor allows for application specific labeling that would facilitate a customised use of the document. HTML uses a fixed set of tags and describes only formatting instructions for the Web. On the other hand XML is completely extensible since it does not have predefined tags, unless it explicitly conforms to a schema. Various schemas exist in order to capture industrial and domain specific needs and as long as two systems comprehend the same schema they can use XML documents to exchange information. News Industry Text Format (NITF) and News Markup Language (NewsML) are two examples of markup languages that could be of some use to tourism related services, since they enable the sharing of syndicated news articles from alternative news providers.

In addition to XML, the combination of XSL/XSLT is one of the fundamental parts of the described content delivery chain. A stylesheet is a declaration that describes how to display a document and XSL is a language for expressing stylesheets for XML documents. By keeping content and its presentation information separate in the XML document and the XSL stylesheet

respectively, display of the same original document on different media and preferences sets is achieved by simply modifying the stylesheet.¹⁵ However modifying presentation might not be enough in several cases; transformation of the source document might be required and this is where XSLT comes into play. Although XSLT transformation was originally intended to perform complex styling operations, like the generation of tables of contents and indexes, currently it is often used as a complete general-purpose XML transformation language. In that manner it is the standard means for transforming the source XML document (e.g., tourism content) into presentable forms such as HTML or WML¹⁶ pages, or other XML schemas or even into other more complex formats.

Apart the content structure, a number of features are exploitable in the context of establishing advanced, reliable multi-channel content delivery services, such as mobile tourism related ones:

- **Security**, in order to authenticate users and authorise access to sections of the system and potentially charge usage, required in order to safeguard mobile user's privacy and content/service providers resources
- **Session management**, in order to drive stateful applications driven by a series of user actions, a feature required for almost every type of modern interactive Web application
- **Automated device/channel detection**, in order to enable adaptation to device capabilities, with minimal user intervention that drive better application experience
- **Client and/or server form processing and validation** that allows meaningful interaction with the system while minimizing message exchanges
- **Content rendering**, that adapts to the device capabilities and user preferences (personalisation), required for delivering content to a multitude of heterogeneous devices

- **Support for off-line operation of devices**, able to drive different application and connectivity scenarios, especially useful in several forms of application in the mobile tourism area¹⁷

Unfortunately, it can be shown that with today's applied technologies, depending on the device/channel, almost all requested features have to be achieved by a different set of technologies and interactions each time. Approaching this problem through the Model-View-Controller design pattern (Gamma, 1995) offers a potential design solution to the challenge, by breaking an application into modules so the logic can be dealt separately from the interface. This allows developers to maintain a single code base for all channels and face each device/channel as a different view for a given transaction. The Model-View-Controller pattern can have as many views as desired and isolates the request handler (aka the Controller) and enterprise system (the Model) from any knowledge of the view. Achieving the desired features (e.g., security, session management, form validation, and content rendering across all devices and channels) is case/device/channel specific.

In the proposed multi-channel approach considering the Web as the primary channel allows an all-in-one solution for already established Web content provision services. The value of a multi-channel content delivery enabling platform is that it provides to the hosting enterprise a single interaction model for all external systems or users and leverages security, session management, and content rendering.

Commercial, freeware and open source software markets offer a wide range of tools that relate to the multi-channel content delivery process. One can easily locate a series of software tools that transform rich content into tailored formats mainly for adopting Web content to mobile devices or vice versa, or systems that offer some degree of support for multi-channel content delivery.

These systems mostly belong to one of the following categories:

- **Content management systems (CMS)**
- **Authoring and publishing tools**
- **Wireless application gateways (WAG)**

Platforms such as enterprise portals and e-commerce suites also might be offering some degree of support for multi-channel content delivery, however they are considered of rather little use in the case of rich mobile tourism services by themselves, since they are capturing this aspect under the perspective of their specific application domain. Such facilities also can be offered by application servers, however at a much lower level. Currently there is no product that provides a full solution that can take raw content and transform it automatically to multiple formats for any requesting device taking into account all the aspects of multi-channel content delivery referenced in the previous section.

Content Types

There are various types of content that can be delivered and displayed by end-user devices. Text is the easiest to handle, however it is relatively

less attractive compared to the others due to its nature, which only uses vision through the channel reading. On the opposite side, rich multimedia content such as Flash¹⁸ (Against the Clock [Firm], 2002; Kozak, 2002) is highly attractive, however its current support by mobile devices is not global, yet it is expected to increase in the near future, as convergence of technologies dictates. Direct execution of “binary” code on the devices through industry standards also can be referenced, however support is relatively limited and minimal or no cross device compatibility is provided.

The Semantic Web

The Semantic Web (W3C, 2001) comes into the scene in order to cover, among others, many of the issues met in the multi-channel content delivery area. It is led by W3C and provides a whole framework so that data obtain a well defined meaning and can be reused under different cases potentially leading to quite different end-user experiences and content compositions. The key-enabling concept is the resource description framework that is heavily dependent on XML contracts. The Semantic Web can be considered as the next step of the current World Wide Web (Berners-Lee & Hendler, 2001; Berners-Lee et al., 2001).

Table 3. LBS content types (Source: M-Guide, 2002)

Content class	Compatibility	Features	Size	Power	Sample technologies
Text	Very high	Poor	Very Low	Very low	HTML, Plain text
Audio	High	Medium	Low	Medium	MP3, MIDI
Image	High	Medium	Low	Medium	JPEG, WBMP, GIF
Video	Medium	High	High	Very high	MPEG, 3GP ¹⁹ etc
Integrated interactive multimedia	Poor	Very high	Medium	Very high	Macromedia Flash
Executable entities	Very poor	Very high	Medium	Very high	Applets / ActiveX Components

Software in Control

All of the above mentioned technologies are provided through software elements which might be either proprietary, bound to a specific device and/or case or generic enough to fit several scenarios or even totally irrelevant services. Commercial or open source platforms do exist that can support almost all of the stages of mobile tourist content delivery, with little or even no need for integration development.²⁰ Nevertheless, provisioning of custom services will most probably demand explicit development of custom software elements.

In scenarios that several market players are involved for the provision of a rich service, such as the case of mobile tourism ones, the traditional component oriented architecture, which modularises software in order to be reused among various cases, needs to be enriched by concepts that allow independence among the various stakeholders.

The concept of service-oriented architecture (SOA) captures architectural style that aims to achieve loose coupling among interacting software entities (Erl, 2004, 2005; Newcomer & Lomow, 2005). In this context a service is a unit of logic and data provided by the service provider that is assigned to provide the appropriate results for its consumer. In this framework the provider and consumer are both software agents that act behalf of their owners. As a concept SOA is quite abstract and can be utilised both for B2B and B2C interactions. Typically lots of protocols and operations fall under its meaning, however in mid-2001, more concrete forms of service oriented paradigms are being applied, accompanied by relevant protocols and enabling platforms.

The model of publisher/subscribers, assisted by a directory service over a transport consisting mostly of XML and Internet based protocols is the current roadmap for applying the SOA:

- **Service publishers** (might) announce their characteristics in a directory service (e.g., UDDI, 2004).

- **Service consumers** can either look in the directory service and locate the service that meets their requirements and obtain a reference to the access point of the service or they directly obtain this through other media.
- **Consequently consumers** use the access point reference to directly communicate with the server.
- **SOAP over XML over HTTP** (i.e., TCP/IP) are the most common protocols for consumer/provider interaction, yet message details are service dependent.

Recent extensions of the initial concept of Web services for the SOA approach add state management, thus allowing a standardised way to access resources hosted by suppliers (Czajkowski, Foster, Ferguson, Frey, Graham, & Snelling, 2004; Foster, Frey, Graham, Tuecke, Czajkowski, & Ferguson, 2004; Huber & Huber 2002; Snell, Tidwell, & Kulchenko, 2002). Typically consumers have no internal knowledge of the operation of the service provider and a particular service in question. The provider might revise implementation, as well as other characteristics of a service without explicitly notifying clients.²¹

One level below the overall software architecture is the software technology, which in the case of location-based services has two facets: infrastructure and client. Developing on the infrastructure side is facilitated by numerous technologies and platforms and is of little interest from the mobility perspective. All Web service enabling technologies, assisted by technologies to deliver reach content are quite applicable for the purposes of tourism location-based services. Dozens of open-source free or fully commercial platforms exist in the today's software market, making it available for anyone to adapt its infrastructure to their own needs and capabilities. However, due to its relatively recent appearance, development on the device has somewhat limited options. For the time being, the most common

platforms for mobile device development are the two described below and come from commercial software vendors, however they are both freely available to the development communities:

- **The micro edition of the Java 2 platform** is the port of Java to portable devices that have minimal capabilities of processing and storage. It is a runtime environment that provides on one hand a subset of the facilities offered by the typical desktop Java engines, yet it provides microdevice-specific capabilities access, potentially assisted by vendor specific libraries. J2ME is very common in latest 2G and 3G mobile phones as well as non PocketPC PDAs (SUN).
- **The Microsoft .NET compact framework** is a subset of the Microsoft .NET framework, the Microsoft technology for desktop and Web application on the Windows platform. Although meant to be platform independent through standardisation (ECMA²²), currently .NET compact framework is only available for PocketPC and other flavours of the Windows platform. Due to its requirements it is not suitable for current low-end devices, yet its performance is very promising in addressed devices (Microsoft).

MOBILE TOURISM SERVICES

“Tourism-related” content refers to any content that might be of interest to the visitor of a location (Beatty 2002; Kakalettris et al 2004; Karagiozidis et al 2003; Kim, Kim, Gautam, & Lee, 2005). This content, be it static (e.g., maps, routes), of low refresh rate (e.g., scheduled or periodic events), highly dynamic (e.g., traffic), cultural (e.g., museums, exhibitions, local historical info), informative (e.g., weather, local news) or commercial (e.g. restaurants, commercial fun parks, etc.), has an increased degree of interest to the “consumer”, especially when he/she is in

particular locations. The term “location” is a varying-“size” descriptor which might range from the actual spot where one is standing in a room, to just a rough approximation of a country. In this context of course, the term “tourist” is very loosely related to the typical “tourist” and mostly fits the definition of “mobile equipment user”. It is obvious that a very large number of services related to content delivery fit this definition, such as map delivery, archaeological information delivery, events announcements, emergency, or health services, transportation information acquisition, even in-doors museum exhibition presentations. These are all forms of this type of location-based tourism-related content delivery service.

When designing an infrastructure able to support such services, requirements that have to be met come from various sources:

- **Technical issues** that have to be exploited and addressed in order for it to be applicable
- **Regulatory and social/ethical restrictions** that have to be met in order for the supplied services to be publishable
- **End-user expectations and requirements** that have to be considered in order to achieve successful commercialisation, and so on.

The requirements presented here arise from a careful study of the 2/2.5G and 3G mobile network technical specifications, location-based services related whitepapers and applied paradigms (Laitinen, 2001; Ludden, 2000; Northstream, 2001; Searle, 2001), modern IT system architecture concepts (Varoutas, Katsianis, Sphicopoulos, Cerboni, Kalhagen, Stordahl, et al., 2002; Varoutas et al., 2006), regulations & standards (FCC, 2001; GSM, 2002; IST-REPOSIT, 2001; LIF-IOT, 2002), and finally, market and end-user surveys (Beatty, 2002; Dao et al., 2002; Katsianis et al., 2001; LoVEUS, 2002; M-Guide, 2002). This comprehensive study led to the identification of the following key points that require careful con-

sideration when implementing a location-aware service that aims to provide tourist information content:

- **QoS in quantifiable technical terms** (response time, throughput, availability, scalability, coverage, accuracy, etc.)
- **QoS in non-quantifiable terms** (quality of content e.g coverage, depth, media, multi-linguality/multiculturality, etc.)
- **Integration capabilities** (relevant services support and integration capabilities)
- **Security** (authentication, authorisation, privacy, etc.)
- **Service related procedures** (e.g., activation /de-activation, billing, pricing, personalisation, stakeholders interoperability, etc.)
- **Service specific features** (e.g., notification, positioning triggering)
- **Content related issues** (e.g., ontology)
- **Present and emerging technology capabilities** (positioning, presentation, mobile networks, etc.)

Having carefully examined alternatives and the potential impact of decisions on the above-mentioned key points, several interesting conclusions can be identified as referenced below. Although technology enthusiasts would think otherwise, end-users are not generally amazed by high accuracy positioning mechanisms or very high data rate demanding services. The already referenced user surveys show that they rather prefer low cost intuitive services that will satisfy their expectations, within reasonable quality limits. In the same context, widely used equipment lacks high interactivity capabilities (i.e., means of passing information to the service and presenting content to end-users). Although emerging devices are expected to vastly improve this particular aspect, average users are not enticed by such capabilities.

High accuracy in positioning is not always a real concern either. For example delivering some

sort of transportation information or providing a local directory service, requires only a rough approximation of the position. On the other hand, presenting information in an actual exhibit, which the visitor is looking at, requires not only precise position as to where one is located but also information about the direction of sight, and even that detail of information may not be adequate. At this point, the conclusion is that “less accuracy” does not render LBS useless but rather restricts the range of services that can be provided. Therefore, although almost identical content might be available for presentation to each end-user visiting a museum or an open archaeological site, equipment differentiation (e.g., display capabilities, channel usage, positioning mechanism, and capabilities), can drive a completely different degree of content exploitation.

Another issue is that some requirements, for example accurate positioning and enhanced content, come with some extra “cost” to the end user. Cost is not only in financial terms, which are mostly obvious, positioning accuracy (e.g., through a GPS module) and advanced display capabilities for example, might have a severe impact on device autonomy and size. Enhanced content (video, virtual reality representations, etc.) will require more bandwidth and even more powerful equipment (having indirect impact on autonomy and size).

When to locate a user is yet another confusing issue. User-requested positioning requires an extra step to be taken by the end user, who actually has to request to be located or explicitly state his/her location at the moment. Alternatively, the user can be continuously located (tracked) by the system. Continuously positioning the mobile user is not usually required, even in the case when the undoubted demand it implies in terms of infrastructure and equipment resources is not a problem. A typical example is a highly mobile user who is accessing some location-based directory of content, related to a specific position he/she has been some time earlier. While the

user may be attracted to these particular sites of interest, mobility might cause the delivery of quite different content in subsequent requests for information, which could come to be quite irritating. Thus the user should have the possibility to allow either continuous or on-request triggered positioning. A good practice would be to totally avoid automatic positioning instead of temporarily ignoring new position information, however certain applications could require two positional indicators (“live” position and “querying” position). The issue of delay also needs to be taken into consideration when locating the user. In on-demand positioning schemes, the system

might introduce quite significant delays due to high load or computational issues which might render some applications rather unattractive.

Finally, a very important observation that guides the proposed approach is network convergence; xxML/HTTP/TCP/IP “stacks” tend to provide a uniform roadmap for offering a very large range of services to each-and-every consumer oriented device type.

System Concepts

In the rest of this chapter various concepts of an open architecture, capable of providing rich mobile

Figure 6. Example of layout of LBS system (Based on Kakalettris et al., 2004)

tourism services, are pointed out. Although an architectural approach is introduced, the intention is not to propose a single solution that could be identified as the best in one way or the other for the tourist; the purpose of the analysis to follow is rather to position the enabling technologies and identify the issues, shortcomings and strong points of various approaches. Depending on the particular application one has to provide, different roadmaps can be followed. An hypothetical structure of an LBS provision system targeting tourism content delivery is shown in Figure 6. In this scenario, the elements are separated in three conceptually different clusters:

- **End-user devices**, be it mobile or fixed ones. For simplicity, it will be considered that mobile ones have some sort of positioning capabilities either on their own (e.g., GPS) or network assisted/provided.
- **Network infrastructure**, which is either a mobile network or a fixed wireless local area network, or a combination of both. In case of mobile equipment that lack positioning capabilities, it is necessary that the network provide the ability to locate the user through connection information, spatial information and potentially the user's previous behavioural data. The network might provide various means of submitting information to the user, such as MMS/SMS (GSM, 2003).
- **Service infrastructure**, which relates to the systems that delivers information and facilities to the user utilizing as one of its implied inputs, the positional information of the user.

The mobile/wireless network details such as access points, MSCs, VLRs, HLRs and so forth are almost totally hidden and only interactions of higher-level components are being referenced. Additionally SOA constructs which obey to specific patterns are omitted (Brown et al., 2003; Colan, 2004; UDDI, 2004). The following sections high-

light important structural and operational aspects of such a system.

Service Interactions

In the presented architecture, the main element is the "service" (i.e., to tourists). Under the modern understanding of realizing a service-oriented architecture, services are implemented under the WebServices paradigm, utilizing in almost 100 percent of the cases the SOAP/XML - HTTP - TCP/IP route. Thus messages are exchanged in a very standardised manner which can be found to be fully supported by vendors' major server systems (content management systems, relational database management systems, runtime environments, etc.), and mobile/client systems as stated by the leading technologies of the area (provided by Microsoft, SUN, IBM, etc.). Under this architecture, the system elements such as services are loosely coupled and can be even dynamically composed upon interaction/request by using SOA enabling systems such as the UDDI registry.²³ Composition can be entirely left to the servicing side, thus the service access point (SAP) and its delegates, however exploring mobile equipment capabilities allows that this task also can be performed at the client side through the same standard mechanisms.

Service Access Point

In the proposed scheme the concept of a service access point (SAP) is introduced, which is responsible for accepting customer (i.e., tourist) requests for a bunch of services. This is not required to be part of an MNO infrastructure, but in the case that the full Webservice approach is followed this element is a Web service hosting server, accessed by the client devices through typical WS addressing constructs. In case typical World Wide Web (WWW) interactions are performed through a browser then this server would be a normal Web/application server. A unifying approach

can be that both servers exist (even in the same system) in the provider's infrastructure and the Web server redirects incoming calls to the same SAP that the Webservice consuming capable clients access. This point can be responsible for a series of actions, which among others include:

- Authenticating end-user even beyond typical username/password challenges by utilising sophisticated network provided authentication mechanisms
- Orchestrating service interactions in an application specific scenario when an end-user delivered service requires invocation of a series of services
- Providing facilities for dynamic service composition allowing the end-users, devices or services to seek and locate suitable content and service provided that match their needs with regards to quality, cost, availability, and so on; delegating lookups to registries such as UDDI is performed at this level
- Providing a repository for open-schema persistent end-user profiles that can be selectively partially offered to subsequent request handlers. Alternatively a distributed profile schema could be used however this would raise interoperability issues and would increase the risk of compromising user privacy. Updating profiles could be triggered by users and other services to the extent allowed by their role in the system
- Providing a "service-side triggered" positioning acquisition point, in case end-user equipment is incapable of autonomously handling positioning which is the main the case when SMS/MMS channels are utilised. In this case requesting services would address this element in order to obtain user position upon and special security concerns have to be handled
- Providing a mechanism for content lookup in registered content providers acting as a content broker, so that content that meets

specific minimal structural requirements can be delivered to end users without additional processing nodes

- Maintaining session state on top of stateless protocols
- Acting as a front-end for non-IP network connected channels, such as SMS/MMS ones, to coordinate requests and replies between channel gateways and content/sub-service providers
- Providing presentation transformation layer to adapt content to client device/channel needs

Optimisation features as a caching of aggregated content are application specific ones that can be considered as part of the SAP. Advanced value added services on top of positioning such as movement prediction also can be considered however they should preferably be implemented as a typical Web service to be accessed on demand.

Homogenisation of Positioning

Examining the details of user positioning, be it network driven, client driven, or even manual, shows a significant heterogeneity not only in the area of the actual position estimation, but also in the process of obtaining this information which is a rather quite important aspect of the system design. Even the relatively simple case of manual positioning might have various implementations: manually supplying the coordinates of the location or indirectly acquiring them out of location information (e.g., road intersections, etc.). The following graph shows various potential interactions among equipment, software, and data that could be utilised to drive user positioning.

It is desirable to hide as much as possible of this heterogeneity from the ASP point of view. A potential solution would be as to separate positioning into three distinct layers as follows:

Figure 7. Positioning interactions (Based on Kakaletris et al., 2004)

- One layer is concerned with the actual calculation of the position. This layer is quite different in each and every implementation, not only due to the various alternatives of positioning mechanisms but also due to differentiation to details of the actual algorithms and infrastructures. Very little can be done in order to unify this layer other than defining the appropriate interfaces
 - The second layer is the SAP positioning layer, which has to provide the actual end-user position to the application layer. This layer is separated in a server-side and a client-side part (components to extract device data where applicable) and its purpose is to determine the actual position supplier and
 - extract information data, or provide a means for manually identifying position
 - The top-level layer is the application layer, which has to determine whether new positioning is required, reuse of previous information is adequate or actual position is known (e.g., within query), forward a request to SAP layer and ultimately return location information back to the end-user (within response)
- The aforementioned layers might make use of components (e.g., coordinates translators) or services (e.g., GIS). A subset of the previous interactions, through eliminating the direct message exchange of the positioning server and SAP

could potentially minimize the risk of building privacy holes in the system.

Push & Pull Services

There are two ways one can consider delivery of content to the end user. In both cases, it is assumed that the user has posed a request for content and they are not entirely network driven, since this would raise several regulatory issues. In each case the user interaction pattern is somewhat different:

- A **pull** service is the one that delivers request to the user upon his/her explicit request within a reasonable interaction time;
- A **push** service is one that submits information to the user when special criteria are met and there seems to be no explicit binding of a request to a response in the form of interaction. These criteria could be location, time or more advanced ones like matched lookups for information and so on.

Over the typical HTTP/TCP/IP stack found in advanced mobile equipment one can consume such services by various mechanisms. The simplest approach would be by periodically polling through a proprietary client for any kind of pushed information to be presented to the user. Triggering polling by identifying significant positional change also could be considered for appropriate devices. This solution introduces network usage even when no information is to be delivered to the user, and is actually a mixture of pushing and concepts services. Traditional mobile devices could be contacted through typical gateways (SMS/MMS) whenever network-monitoring procedures decide that interesting information is available. Push services on location criteria can however become a potential scalability and performance threat for an LBS infrastructure, because of the computational and bandwidth demands required for scanning vast collections

of data on each and every end-user move.

User Authentication and Identification

A very important part of the service is user identification, authentication, and authorisation (Gajparia, Mitchell, & Yeun, 2005; Soppera & Burbridge, 2005). The SAP is proposed for taking over the responsibility of authorizing end-users. Authentication is actually optional since it is considered that just identifying the user can be quite enough in several application scenarios, such as free-of-charge information delivery. Simple identification might be utilised for some personalisation facilities. A basic scenario for authentication would be based on a username/password challenge scheme, which will be verified against a user directory. Client certificates are a more advanced option. Using secure channels for performing authentication is required to avoid common security penetration cases, yet not all devices might be capable of all common types of secure information exchange. SAP is responsible for maintaining the user directory where users (via their credentials) are mapped to unique identifiers and authorisation information.

Authentication is of crucial importance when positioning takes place under a network provided positioning mechanism. Acquiring end-user's location relying on simple username/password challenge opens a wide opportunity for service misuse. Taking advantage of the "spying effect,"²⁴ an unauthorised user can attach a typical mobile device related to a specific user account on a person to be "watched," and request positioning information through a secondary device (e.g., fixed PC or other mobile equipment [ME]) on behalf of the above-mentioned account. If no network session data are being used, location information will potentially be delivered to the "spy". This might be a well-accepted feature of some implementations but the typical perspective of privacy forces counter measures for avoidance of such

situations. In the SMS/MMS channels case this information is being incorporated in the state of the gateway/SAP session that is being established to fulfil a client request. On the TCP/IP typical channel the situation is a bit more complicated. Since the client is requesting position over an HTTP request, the MNO typically receives the request for locating the user by the SAP. Thus some user identifier must be presented (other than the username). Fortunately, the SAP already has the TCP/IP session information (source address/port) that is being used in order for the user to be serviced. Typically end-user mobile equipment is behind a NAT gateway and this address is not a real one, thus the port number must also be used in order for the related MNO to locate the correct user. The SAP can select the correct MNO either by the internal directory service (the source address of the request directly or indirectly identifies the MNO) or by the end-user information record being used. The MNO can therefore identify the actual user through NAT layer information and GPRS IP address assignment records.

Nevertheless a highly secure approach could be restricting positioning information exchange internally to the MNO infrastructure, by having positioning servers to replying only to requests raised internally by MNO subscribers, and more specifically only by the mobile device being located. In this scenario, the client device acts as an autonomously positioned piece of equipment, at least as this can be understood from the SAP point of view.

Content Structure

Limiting delivered content to “tourism” related categories might not be a significant restriction for the location-related content to be provided, but certainly poses some requirements on the structure this content must meet. There exist rich schemas for describing “tourism” content (TourML 2003), which attempt to fully capture

the corresponding ontology. However from our point of view forcing “over” structuring of content is usually a source of problems for the content producers and providers. It is a strategic decision that content providers expose content compliant with a minimal set of requirements. These requirements could include position information (in various forms, e.g., rectangles, series of points, etc.), language identifiers, labels, multiple classifications in a two level hierarchy (though not a hard constraint) and a content rating scheme. Content classifiers are open to extension by CPs and are being aggregated by the SAP. The first level is mainly proposed to be a means to define end-user content selection preferences, but a more sophisticated scheme can make use of a free hierarchy. Content rating is being required in order for free of charge, simple or rich content to be differentiated by the SAP, in order for it to be delivered to various clients, although the actual content manipulation is to be performed by the content provider (CP). Internally CPs might realise a more complex structure, but the SAP is concerned only about the above-mentioned tags. Usage of extra tags can be handled by additional user preferences, for which an extensible mechanism should be provided.

Presentation

A final, but quite important issue is that eventually data must be presented to the end-user. Presentation can be realised by a wide series of equipment, which might range from high quality multimedia laptops to simple SMS capable mobile phones. As already mentioned the XML/XSL/XSLT set of standards and related tools provide a powerful mechanism for implementing an *author-once-publish-many* times scheme, capable of covering a wide range of end user preferences and equipment. At this point, it can be identified that these are two level transformations in order to achieve maximum content reusability:

- The first level is internal CP transformation and renders original data into a form that will comply with the SAP required minimal structure;
- The second level of transformations is the one that will transform the content in a way that it will fully exploit the capabilities of the end user device and user preferences. Such rendering can result into simple text fragments to be posted over SMS, MMS fragments, WML, HTML, DHTML pages, and even advanced SMIL²⁵ presentations.

Presentation transformation should not be considered as a Web-only requirement; even if data are accessed through proprietary Web service clients such transformations would be of use.

Application Gateways

The assumed infrastructure of these models of service delivery is heavily based on the assumption of a homogeneous underlying network—on HTTP/TCP/IP layers. It is obvious that this is not a realistic assumption especially when mobile networks come to play. In order to hide the diversity of the underlying infrastructures, gateways are required that allow for the translation of non-SAP native requests to be fulfilled. These gateways receive client requests and deliver them to the SAP in a form they can be understood. At this point it is obvious that in order for uniform interaction to be achievable by all CPs, translation of requests is being handled by a specific reception point of the gateway that analyses the content of the incoming message and forms the appropriate request to the SAP. When requests are being replied, the data are being appropriately packaged and delivered to the actual network operator infrastructure components that will push it back to the requesting equipment through the appropriate “channel.” Typically channels that require gateways are the SMS, EMS, MMS ones, while the functionality of

such gateways also is significant for implementation of alerting services.

Pricing/Billing

Authorizing users is not only required for enabling access to the services and content authentication but also for charging and billing. When requests and responses are being exchanged among the various parties, the SAP user identification is being utilised in order for the CP or application service provider (ASP) to authorise and charge the appropriate subscriber. Alternatively ASPs or CPs perform no user identification and deliver data on behalf of the SAP, which is the actually charged partner. This would cover the CP/ASP/SAP part of the service usage. On the other hand the network operator will charge network usage, potentially posing a premium on top of the traffic which is being delivered to specific ASP/CPs/SAPs, and so on. Another scenario is that ASPs/CPs might vary the charges depending on user location or user preferences (such as content quality, type, or location-based advertising allowance), thus allowing for quite complex pricing/billing schemes.

CONCLUSION

Making use of standards and protocols (e.g., LIF, XML, and HTTP), avoiding proprietary solutions and limiting interoperability requirements to a minimum renders architecture capable of integrating various stakeholders with limited cost and implications. The technologies being proposed allow interoperability and redirection among various sub-service providers and the integration of services in order to provide a homogenous application to the end-user.

Although the proposed solution for tourists has been tested²⁶ on a single network operator elsewhere, support for location-based services is not restricted to a single network provider, even when

positioning is performed by the mobile network operator. Despite its “tourism content delivery” orientation, the infrastructure in this testbed can be made capable of providing more complex services with minimum impact on service providers, by making use of state-of-the-art client equipment features, such as Java, DHTML, and so on. In this regard, utilizing a directory service under a standard protocol, within the SAP, is mostly adequate for creating a totally uniform platform for indoors and outdoors LBS and quite heterogeneous positioning methods and capabilities (e.g., RFID, wireless access point identification, etc.). Since the motivation behind location-based services is its potential beneficiary commercial exploitation, a preliminary technoeconomic evaluation based on hypothetical deployment and commercialisation scenarios has been attempted by the authors and can be found in M-Guide (2002). The study presents basic financial indicators that showed the viability of the proposed solution as well as a full description of the evaluation scenarios and results. The details of the methodology used in technoeconomic evaluation can be found in IST-TONIC (2000).

There are various aspects of the presented approach where potential improvements will lead to further benefits for the end-user and the content/network providers. These largely involve standards identification and adoption, as well as refinements of current implementations. An essential improvement would be to fully fit the design discussed here to the open service-oriented architecture initiative, thus providing dynamic service discovery. Introducing the attributes and rules that will enable the creation of a universal directory service to support each and every relevant information and service lookup is a step that should be made.

Although business-to-customer (B2C) information interchange is sufficiently faced under our perspective, business-to-business (B2B) is partially dealt with. B2B data exchange is limited to areas where information is essential for servicing

a particular user request, for example, positioning, authentication, and so on. However B2B collaboration can be further exploited in subjects such as content modifications due to relocation, caching, restructuring service organisation, and so on. Further work on this area would potentially enhance scalability of “push services,” another area that has not been fully exploited.

Work also needs to be done on roaming-user scenarios in order for the infrastructure to fully comply with market requirements, since handling and network positioning of roaming users is currently performed inefficiently. Moreover, a more detailed technoeconomic study is needed, based on specific deployment scenarios, taking into consideration up-to-date technological and financial data in order for a more precise profit/loss prediction of relevant service deployment to be made possible.

ACKNOWLEDGMENTS

A part of this work has been performed with the support of the E-Content M-Guide Project, which was partially funded by the European Union. The authors would like to acknowledge the support and contributions of their colleagues from M-Guide project, namely Exodus SA, Vodafone-Panafon SA, University of Athens, Municipality of Athens, Adaptia and Iternet. The authors would also like to thank the two anonymous reviewers for the fruitful comments.

ENDNOTES

- ¹ Being redefined for the electronic era.
- ² 2nd generation (2G) of mobile telephony is widely known as GSM, while the term 2.5G is used for the 2G networks with data and Internet access capabilities mainly based on GPRS.
- ³ The 3rd generation of mobile telephony is mainly known as UMTS.
- ⁴ Also labelled as “operator” when no ambiguity is introduced.
- ⁵ Speed might vary upon device capabilities, reception quality, network load, and so forth.
- ⁶ International Telecommunication Union whose standardisation sector is ITU-T, known as CCITT up to 1993 (CCITT originates back to 1865).
- ⁷ Performance highly varies upon network load, infrastructure specifications, reception and mobile equipment capabilities.
- ⁸ Nominal speed varies from 11 (802.11b) to 108Mbps (Super-G).
- ⁹ The time required for a signal (or minimal data element) to be send by the source, transmitted back by the target and received back at the source.
- ¹⁰ Outdoors WLAN access is becoming more and more popular since year 2005.
- ¹¹ Basic geographical information systems are data repositories that offer storage and retrieval facilities suited to the type of information in focus (geospatial) accompanied by appropriate management and visualisation tools.
- ¹² Source: Derived from Searle (2001)
- ¹³ Source: Derived from Searle (2001)
- ¹⁴ There are cases that content might be pre-installed on a device.
- ¹⁵ The XSL Formatting Objects (XSL-FO) vocabulary is designed in order to facilitate content display on a wide variety of media such as screen, paper, or even voice.
- ¹⁶ Mark-up language technologically similar with HTML for use with WAP and 2G/2.5G Web-enabled mobile phones.
- ¹⁷ In advance downloading of the content to the mobile device and consequently displaying it to the tourist by utilizing combined user-interaction and equipment (such as a GPS device) provided information.
- ¹⁸ Flash technology (introduced by MacroMedia Inc. in 1996) is mainly used for creating interactive multimedia presentations on the Web.
- ¹⁹ 3GP is a format defined by 3GPP as a simplified version of MPEG-4 Part 14 for multimedia objects exchange and playback on 3G mobile phones.
- ²⁰ Development effort required to achieve systems’ inter-working when no sufficient configuration/customisation capabilities exist in the involved software entities.
- ²¹ Special concerns apply to this assumption.
- ²² An initially European standardisation organisation, currently named as ECMA International.
- ²³ The UDDI registry is essentially a “yellow pages” like service for locating Web services capable of serving a particular request.
- ²⁴ The term has been proposed by Antti Damski, Adaptia Ltd. in M-GUIDE Project (M-Guide, 2002)
- ²⁵ A markup language of similar technology to HTML that allows display and playback of interactive multimedia content adding special features for synchronisation/presentation, partially supported by some of the well-known Web browsers.
- ²⁶ The solution has been developed and tested as part of the M-Guide Project, which has been partially funded project by EU under the eContent initiative, during 2002-2004.

APPENDIX: ACRONYMS

Acronym	Description
2 G	2 nd generation mobile telephony (e.g., GSM)
2.5 G	2 nd generation mobile telephony (e.g., GSM + GPRS)
3GPP	3G Partnership Project
A-GPS	assisted GPS
AOA	angle of arrival
ASP	application service provider
B2B	business to business
B2C	business to client
BS	base station
BTS	base transceiver station
CCITT	International Telegraph and Telephone Consultative Committee
CDMA	code division multiple access
CMS	content management system
COO	cell of origin
CSS	cascading stylesheet
DHTML	Dynamic HTML
ECMA	European Computer Manufacturers Association
EDGE	enhanced data GSM environment
E-OTD	enhanced observed time difference
GIS	geographical information system
GMLC	gateway mobile location center
GPRS	general packer radio service
GPS	global positioning system
GSM	global system for mobile communication
HSCSD	high speed circuit switched data
HSDPA	high-speed downlink packet access
HTML	Hypertext Markup Language
HTTP	hypertext transfer protocol
ICT	information and telecommunication technology

Chapter 2.31

Collaborative Commerce and the Hotel Industry

Michelle Rowe

Edith Cowan University, Australia

Alfred Ogle

Edith Cowan University, Australia

ABSTRACT

This chapter proposes a framework to consider the application of collaborative commerce (c-commerce) in the hotel industry. C-commerce and some general characteristics of the hotel industry are examined, followed by a discussion on the likelihood of c-commerce adoption by hotels. A case study of two five-star hotels located in Perth, Western Australia is considered in light of the framework. Corporate structure, information technology (IT) and its importance to organisation strategy, the role and attitudes of the general manager of each hotel to IT as well as the social identity of the hotel to c-commerce emerge as issues critical to c-commerce. This area of study is in its infancy and further research is required to more fully consider the issues.

INTRODUCTION

Hoteliers are notoriously secretive and have been reluctant to share information and ideas with others, especially their rivals, due to a “fear of information leakage” (Chung, Oh, Kim, & Han, 2004, p. 429). This paranoia manifests itself in the dearth of literature on strategic alliances in the lodging sector (Dev & Klein, 1993). But what if hoteliers saw themselves in a different light—sharing information and ideas—from a perspective of co-opetition (competitive co-operation) or collaboration? This chapter poses this question and probes the likelihood of hotels seeing themselves in this light. This issue will be considered in the context of collaborative commerce which will firstly be defined and explained.

Collaborative commerce (c-commerce) is the use of Internet-based technology that promotes

collaboration in business. The emergence of c-commerce reflects a shift of focus to relationships between firms, not just transactions (Sheth, 1996). Network behaviour, which underpins inter-organisational relationships, is of interest to tourism and hospitality operators. The premise behind the formation of networks is the realisation that a single organisation is incapable or unwilling to cope with environmental conditions (Cravens, Shipp, & Cravens, 1993) and does not possess the skills and expertise needed to compete in that environment.

This chapter overviews the concept of c-commerce and investigates the relevance of this concept to the hotel industry generally by way of a case study of two five-star rated hotels located in Perth, Australia. Although collaborative strategies of international hotel chains have been explored (Fyall & Spyriadis, 2003), the authors seek to investigate the phenomenon with respect to a framework that considers c-commerce and its antecedents. To understand factors necessary for and to explain adoption of c-commerce, the domains of MIS, management and an industry perspective are all relevant—hence a multidisciplinary approach is taken.

The influence of the manager and ownership structure of the hotel are thought to be important factors in the adoption of c-commerce. Using case studies of Perth hotels, the chapter also raises the questions of what motivates general managers (GMs) to enter into relationships with competitors, the nature and extent of these relationships and the role of information technology (IT) within the organisation and in such relationships. These issues have not been widely researched, however, and are considered here.

WHAT IS C-COMMERCE?

C-commerce is the use of technology, especially Internet-based technology, that promotes collaboration amongst businesses. It consists of all of an

organisation's IT bases, knowledge management and business interactions with its customers, suppliers and partners in the business communities in which it interacts (Gartner Group, 1999; McCarthy, 1999). C-commerce can occur horizontally involving co-opetition, being a sharing of resources and information amongst competitors, or vertically along a supply chain.

C-commerce is the coming together of firms, including competitors, to exploit opportunities that arise. As global competition intensifies many organisations are forming partnerships as an expeditious way to keep up or to access unique or "pioneering" resources (Ring & Van de Ven, 1992, 1994). As stated, collaboration around IT is a response to an increasingly complex and dynamic market (Cravens et al., 1993). Increasingly it is argued that firms, especially small and medium enterprises (SMEs) must enter into such partnerships to survive in globalised marketplaces. Most tourism enterprises worldwide fall into the SME category and are known as small and medium tourism enterprises (SMTEs) (Buhalis, 1996).

What are the Benefits of C-Commerce?

C-commerce is concerned with obtaining sustainable competitive advantage from the maximisation of value adding benefits obtained by working collaboratively with others via IT. The adoption of IT has been identified as a possible source of strategic competitive advantage (Yetton, Johnston & Craig, 1994) as well as a potential generator of innovation resulting in further competitive advantage (Ryssel, Ritter & Germunden, 2004).

C-commerce enables firms to "grow" their assets and access markets (Bitici, Martinez, Albores, & Parung, 2004; Ring & Van de Ven, 1992). Internal efficiencies can be generated by the sharing of information via IT within inter-organisational relationships (IOR) (Ryssel et al., 2004). It can be argued that collaborative enterprises or networks "create new and unique value propositions by

complementing, integrating and leveraging each other's capabilities and competencies" (Dyer & Singh, 1998, p. 676). IT/ICT are critical drivers of integration and cooperation since they enable businesses to integrate activities and functions otherwise not possible (Joo, 2002).

Collaboration generates "relational rents" or "supernormal profits jointly generated in an exchange relationship" (Dyer & Singh, 1998, p. 662) that cannot be achieved individually. These authors contend that the competitive advantage of these partnerships requires the presence of four factors: relation-specific assets, knowledge-sharing routines, complementary resource endowments, and effective governance. For these relational rents or benefits to arise these elements are required. Often the question is if they are in place. Firms need to adopt a different approach to strategic planning and management to allow the creation of networks and associated infrastructure based on shared resources with other organisations (Chi & Holsapple, 2005). This requires strategic thinking, trust and a realization of the importance of co-opting rather than competition which typically exists amongst individual firms. Again these issues need to be considered generally and specially in relation to the hotel industry.

The Hotel Industry

When considering the adoption of c-commerce, the industry context needs to be borne in mind. The ownership and corporate structure as well as management of the hotel, including the expertise, perceptions and influence of the GM and the role of IT in the property or chain are important factors influencing c-commerce adoption.

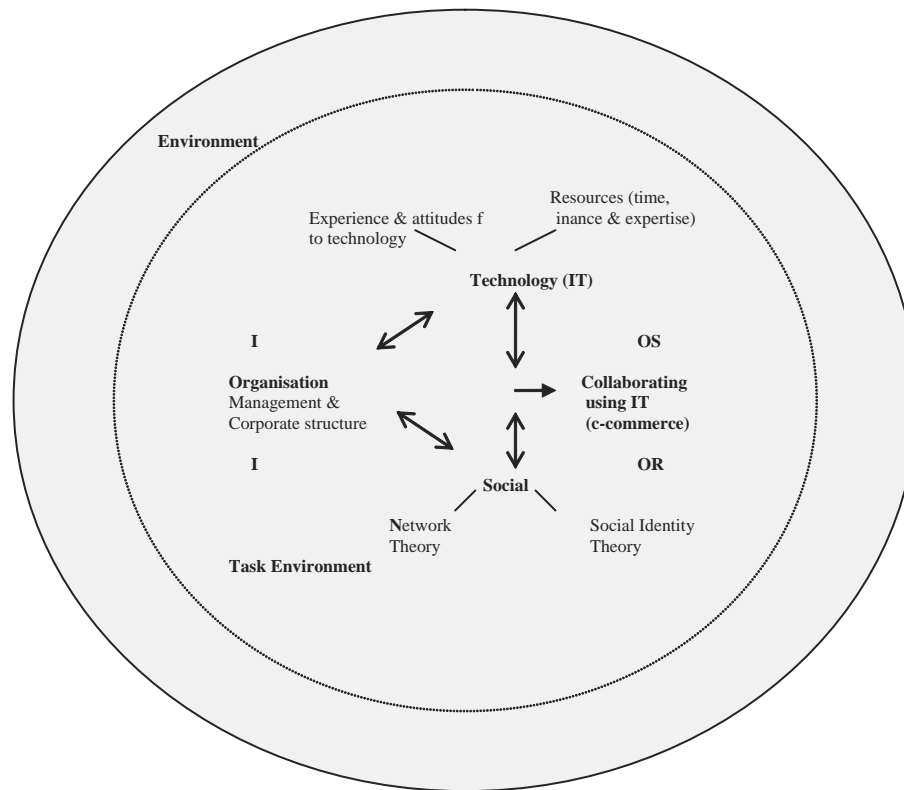

Inter-organisational systems (IOS), of which c-commerce is one type (see Chi & Holsapple (2005) for a more complete discussion), have been facilitated by electronic commerce. The tourist industry was one of the first industries to adopt information and communication technologies (ICT) (Garzotto, Paolini, Speroni, Proll, Retsch-

itzegger, & Schwinger, 2004).

In the past, electronic data interchange (EDI) and electronic funds transfer (EFT) have been the technologies to enter into IOS. The standards required for EDI and its high set up costs have tended to act as a barrier for SMTEs to enter into IOS. This potentially is overcome by the Internet. It is possible for hotels to take advantage of the Web via collaboration around the net as a way to deal with excess capacity and increase occupancy rates quickly. This is the case within many chains as the role of online intermediaries has expanded dramatically, especially since 9/11 (Starkov, 2002). Individual hotels are better able to compete in an increasingly dynamic marketplace via the exploitation of the advantages of the Web (Grover, Teng & Fiedler, 2002) as evident in the widespread participation in "distressed Web sites" such as needitnow.com, Travelocity.com; wotif.com and participation in innovative distribution services such as auctions and disintermediation (Connolly, 2000).

Chains of hotels generally have in place integration of the property management system (PMS) with the corporate central reservation system (CRS) and global distribution system (GDS) systems although in the past SMTEs appeared to have been under-represented in most mainstream CRS and GDS (Go, 1992). CRS integration allows for individual properties to benefit from the extensive reach of the chains marketing network and to allow for cross selling amongst properties within the chain. A view held in the late 90s was that via seamless distributions channels, untapped opportunities could be availed to firms (Stern & Weitz, 1997). That view is validated with Internet-enabled GDS integration that allows chain properties to extend their reach beyond that of their chain marketing network whilst simplifying and streamlining the booking process, thereby enhancing customer service (Connolly, 2000) and creating competitive advantage. In some instances independent or non-chain properties subscribe to a non-affiliate reservation network which enables

Figure 1. Holistic view of the factors necessary for c-commerce adoption

independent operators to obtain many of the benefits enjoyed by chain-affiliated operators (Kasavana & Brooks, 2001). This interoperability of systems is an example of c-commerce, especially the CRS which has been the most commonly used wide area network (WAN) application in hotels (Brooks, 1999). However, GDS provide hotel bookings only for major hotel chains (Dogac, Kabak., Laleci, Sinir, Yildiz, Kirbas, & Gurcan, 2004)—excluding small independent operators. Web service technology would overcome the advantage afforded to top tier players, however this is beyond the scope of this chapter.

What about sharing of information between rivals in a location? Is this likely? Given that many hotels are part of a chain, interoperable systems are in place which facilitates the flow of information within the organisation. This may

mean individual hotels do not need to collaborate with hotels in situ. Where strong information flows occur within the organisation (effectively c-commerce between hotels making up the chain) the need for and hence adoption of c-commerce between competitors in one location is negligible and may not be necessary.

Factors Considered Critical to C-Commerce Adoption

A review of the literature concerning c-commerce, IT, and inter-organisational theories as well as from the hotel industry perspective has been undertaken. In summary, c-commerce requires firms to develop a strategy, both short and long term; adopt appropriate business models; develop and sustain appropriate collaborative cultures engendering trust; invest in

IT to facilitate information and knowledge sharing; and set in place appropriate organisational structures to enable collaboration (Kalakota & Robinson, 1999).

A framework depicting critical factors underlying c-commerce adoption is set out in Figure 1. The nature of management and management's attitudes to IT and risk taking as well as the corporate structure of the hotel are important factors shaping attitudes towards c-commerce. To understand networking or the c-commerce relationship, consideration needs to be given to two broad groups of theories: network or inter-organisational relationships theory and social identity theory.

DISCUSSION OF PROPOSED FRAMEWORK

Organisation

Decisions to adopt IT are made by management. This can either reflect corporate policy, as is the case for chains, or, where management is autonomous such as is the case for independents, organisational decisions. Attitudes to and experiences of management tend to influence subsequent decisions and predispositions (particularly from the perspective of traditional decision making techniques—see Fulop, Linstead, Lilley, & Clarke, 2004) and this is the case with respect to IT.

Issues concerning ownership, management structure and degree of centralisation of decision making, including IT, come into play here and influence attitudes to IT and collaboration. These are important to the hotel industry as discussed.

Technology (IT)

Firms make IT decisions either to generate cost savings or to enable a value added strategy to be pursued. Cost savings tend to be the strategy adopted where IT is peripheral to the business and

where management's experience of IT is limited. The concern is for efficiency and systems to be in place to help achieve this. A value added strategy is appropriate (Levy, Powell, & Yetton, 2001) due to strategic necessity or where management is seeking growth and understands the connection between IS and added value.

C-commerce requires a strategic decision to invest in and collaborate around IT with others. Without a strategic view of IT c-commerce cannot arise and certainly would not be considered. Where a strategic view of IT is adopted the benefits flowing from investments in IT (including c-commerce) are likely to add value and generate potential competitive advantage as discussed earlier in this chapter. Responsiveness to the market and latest technologies available which customers may demand could be a driver for IT adoption. In such case IT is seen to provide a "strategic opportunity" to improve business performance and potentially generate competitive advantage rather than merely be an operational tool to increase efficiency.

Resources

Resource based theory of the firm (Caldeira & Ward, 2003; Feeny & Willcocks, 1998) suggests that firms are characterised by a set of competencies or skills and capabilities that are important to enable it to achieve a sustainable competitive advantage. IT is part of that resources set. Important to c-commerce is the availability of resources dedicated to its implementation and also to adaptation of systems with "partners." These resources include time to plan and focus on future directions, rather than operational issues, financial resources to invest in software and hardware, and expertise of management, IT advisors or an IT "champion." SMEs have limited resources and generally do not possess the technical know how or resources to, for example, maintain effective Web sites (Gonzales, 2004). A coming together or collaboration is a means to overcome such limitations as access

to scarce resources, including skills, information and knowledge is facilitated (Macpherson, Jones, Zhang, & Wilson, 2003).

Social Network Theory

Network theory refers to cooperative IORs that include strategic alliances, partnerships, coalitions, joint ventures, franchises, network organizations and c-commerce. A variety of motivations underpins the formation of cooperative relationships such as access to new technology, markets, development of economies of scale and complementarity of skills as well as risk sharing (Powell, 1987; Ring & Van de Ven, 1992).

The literature indicates that IT is not the driver underlying c-commerce, rather relationships precede any collaboration around IT (O'Keefe, 2001). This indicates social bonds should be created first before c-commerce is possible. The development of informal connections via networking is critical to subsequent c-commerce. Some assert that once a relationship exists the use of IT within that relationship encourages a commitment to the relationship, thereby enhancing the relationship (Grover et al., 2002).

Without the cultivation of relationships, firms are not able to capture the full value of technology (O'Keefe, 2001). Such a coming together will only occur if the shared benefits are acknowledged and are deemed to be worthwhile. Perceptions of these benefits and a willingness to engage in c-commerce are influenced by attitudes to and experience of IT as well as the availability of resources able to be dedicated to c-commerce.

Whilst technology is central to c-commerce, it is the willingness to share information rather than the technology per se that potentially can constrain the relationship (Mason, Castleman & Parker, 2004; O'Keefe, 2001). Attitudes to knowledge and the willingness to share information with others are critical. Knowledge is seen as a source of competitive advantage. The sharing of this knowledge though potentially undermines

this advantage since the knowledge gained by cooperation may be used for competition (Levy et al., 2001). This can only be overcome through the generation of trust, commitment to the relationship and an agreement to not act opportunistically, enforced by endogenous systems agreed and adhered to.

Participants in networks are likely to be entrepreneurial in nature—identifying opportunities, mobilising resources, and looking beyond resource limitations. This requires a boundary spanning approach—a willingness to interact with others “outside the organisation so as to obtain valuable information from the task and general environment” (Jones & George, 2003, p.173). Entrepreneurs are more likely to boundary span and network as they recognise the benefits in sharing ideas and information with participants either in similar or different industries. It is a contention of the authors that participants in networks and c-commerce are more likely to be entrepreneurial firms that are growing (Chell & Baines, 2000).

Table 1 summarises factors that are considered to be important to the adoption of c-commerce from a network theory/IOR perspective. Some factors pertain to the individual organisation whilst others relate to the dynamics and interaction between the potential partners and often develop over time as negotiations unfold.

Trust is identified as a critical factor to collaboration—without it there can be only limited mutual obligation between cooperating partners. Trust is a prerequisite for knowledge sharing and is fundamental to the question “to collaborate or not to collaborate.” Whilst trust is difficult to achieve, it is possibly the most crucial aspect for success (O'Keefe, 2001) and is a precursor to commitment (Morgan & Hunt, 1994).

The concept of inter-firm adaptation has been considered in extensive research into IORs (Brennan, Turnbull, & Wilson, 2003). Adaptation (Hallen, Johnson, & Sayed-Mohammed, 1991) is a central feature of a working business

Table 1. Summary of main factors necessary for collaborative IORs/c-commerce

Factors pertaining to individual organisation	Factors pertaining to interaction of potential partners
<ul style="list-style-type: none"> • Commitment and trust • Adaptation • Level of investment in IT within the firm and level of Enterprise Application Integration • Network competence • Willingness to share information/enter into relationship (trust) • Willingness to behave in fair/equitable manner (trust) • Motivation behind co-opting • Personality/values/beliefs of proprietor • Organisation culture/collaborative culture • Reliance on trust/endogenous systems • Goals/vision, for example, growth • Growth of the SME 	<ul style="list-style-type: none"> • Commitment and trust • Adaptation • Congruency • Track record with partner (trust) • Motivation behind co-opting • Reliance on trust/endogenous systems • Goals/vision, for example, growth • Interaction/dynamics and negotiations between parties

relationship. It requires combined investment by both parties to the relationship, especially to shared IT systems in the case of c-commerce. This creates durable economic bonds between the partners. The willingness to adapt behaviour or to be flexible, for example, via adaptation to overcome difficulties experienced in an IOR, is important in generating trust.

Whilst trust and commitment and other characteristics depicting relationship quality are necessary for c-commerce, the lack of participation in collaborative ventures may reflect a weaker identification with social groups outside the organisation. This is what social identity theory argues.

Social Identity Theory

Social identity theory (Tajfel & Turner, 1979) identified the importance of the social self which contrasts with the individual self. Cooperation

(Kramer, 1993) with other decision makers, and so willingness and propensity to enter into c-commerce, is a function of the strength of one's personal identity viz that of a collective identity. When personal identities are salient, the focus is on personal goals and outcomes. For cooperation with others to occur then, the salience of one's collective identity needs to transcend one's personal identity. Motives of decision makers are more complex than ego (Axelrod, 1984; Kramer, 1993), with self-interest being one variable explaining cooperation. This has implications for c-commerce adoption in that the benefits of collaboration and the importance of a collective view preceding such cooperation need to be considered.

This is supported by other authors (Terry, 2003) who assert that individuals seek to improve their social identity and are motivated to belong to high status groups. This has implications for establishing c-commerce.

Consideration Regarding the Hotel Industry

A number of these issues are now considered in relation to the hotel industry. The hotel industry is characterised by corporations or chains and independent operators. The benefits from c-commerce are considered to be greater for independents since they tend not to have the critical mass associated with top tier players (i.e., chains) and because they do not have in place strong collaborative arrangements, which exist internally within chains.

Interoperable systems already exist in chains, but do not exist amongst independents. Independents appear to resort to subscription to affiliate reservation networks that allow non-chain properties to participate as overflow facilities (Kasavana & Brooks, 2001) rather than network amongst themselves. This reliance on existing intermediaries potentially may be a barrier to c-commerce adoption. However it presents itself as a way for “independents to maintain their individuality and distinctive methodology, while still benefiting from the economies of scale that an affiliation with a larger group of like-minded properties can offer” (Travel Impact Newswire, 2004).

Where a hotel is owner managed and therefore has greater autonomy to determine policy, the GM is more likely think strategically and boundary span and so consider collaboration and initiate relationships fundamental to c-commerce. C-commerce though requires interoperable systems and the development of relationships, so may evolve over time, reflecting a typology of IOS developed elsewhere (Chi & Holsapple, 2005). Softwares that are available to facilitate such sharing of information as well as the Internet and the semantic Web are means by which this difficulty can be overcome. These issues fall outside of the scope of this chapter.

In relation to issues of size and resources, while medium sized hotels may *prima facie* employ more than 200 employees (the upper limit of medium enterprise in Australia) (Australian

Bureau of Statistics, 2002) according to full time staff equivalent figures (FTSE) many fall into the category of a medium size employer. However, the context of the hotel in relation to an international corporation needs to be considered. Secondly, whilst many hotels use IT in a comprehensive and integrated manner in their operations and indeed within the chain (if this is relevant), much of its application is operational rather than strategic in nature.

CASE STUDY

Many of the issues discussed can be illustrated by the experience of two five star hotels located in Perth, the capital city of Western Australia.

Hotel A is a franchisee of a world renowned chain of hotels, the reputation of the chain and the brand generating its competitive advantage. There is a reliance on corporate policy and IT decision making. Built in 1973, this purpose built CBD hotel has 390 rooms and overlooks the scenic Swan River. Its target market is corporate clientele. Around 70% of its guests are domestic corporates and 10% are international corporates. The international name and its acclaimed loyalty program make this hotel more attractive to international corporates compared to regional chain or independents.

The GM is an industry veteran with 35 years industry experience, with 20 of those years employed in this hotel chain. Commencing as a bartender, he progressed into food and beverage management and then engaged in hotel general management.

Thirty-six percent of room bookings are made via chain-related reservation channels with corporate systems critical to the operation of this hotel. Decisions regarding IT are centralised and little autonomy is given to the GM in this regard. The GM saw IT as being ancillary to strategy and perceived it as being a tool to increase efficiency of the business. This reflects the centralised ap-

proach taken by the hotel towards IT and the longstanding position this GM has had within this chain. Whilst the future application of IT such as self check-in and check-out is recognised, since people and personalised service are at the heart of the business, such technologies are not likely to become reality. Certainly any decision in this area would be made at the Head Office level.

The nature of the corporate structure means that intra-chain networking is critical with a substantial reliance on integration with sister hotels in terms of room reservations. Interoperable systems exist in-house and thus between hotels, with systems determined by the corporation rather than by individual hotels.

This hotel relies on formal networks via Australian Hotels Association (AHA) rather than initiating relationships with external organisations. There is a willingness to participate in the industry practice of sharing information such as occupancy and roomrate figures. The hotel is a stable and mature business, placed third in the Perth market in terms of revenue per available room (REVPAR). Seventy percent of its policies are brand driven and therefore while the GM has the prerogative to cater to the distinct conditions of the individual property, autonomy is restricted.

Hotel B belongs to small regional chain. This particular chain was unique in that each property within the chain is owner managed and independently operated in terms of policies and procedures (P&P). Housed in what was originally the Australian Taxation Office built in 1968, the building was converted into a hotel in 1996 and has 306 rooms affording Swan River views. Located in the CBD, its target market is corporate guests with currently 60-70% of its clientele being domestic corporates. The GM has been in the hospitality industry for 20 years, first as a dishwasher in his family restaurant in Perth, then shifting to food production. Focusing on production, he worked up to Chef de Cuisine, then became interested in the service aspects of the industry taking on a position of Food and Beverage Manager, Ex-

ecutive Assistant Manager and then GM of this hotel in 2002.

The GM had a greater degree of autonomy with respect to IT investments and decision making and indeed strategic direction for the hotel. IT adoption was seen as potentially generating strategic opportunity for the business (Engsbo, Saarinen, Salmi, & Scupola, 2001) and a means to set the hotel apart from the competition. The hotel is the market leader in the Perth market in terms of REVPAR and is growing and innovative. In part this reflects the nature of the GM—younger, more entrepreneurial and who looks to IT as a means by which strategic advantage can be achieved. He is unrestricted by a chain corporate culture and so is less restricted in his decision making. Personal relationships between counterparts are important to this GM, indicating that the synergy between peers within the chain was strong.

The GM tended to take the initiative with regard to networking amongst competitors, was open to changes occurring with respect to IT and is more entrepreneurial and boundary spanning in its interactions with those outside of the organisation to obtain valuable information from the task and general environments (Jones & George, 2003). This was recognised as being a way to increase the quantity and richness of information available to the hotel to aid decision making in a dynamic and competitive environment. This openness to IT innovation adoption is typically not a trait of hoteliers hailing from food production due to the limited opportunities for such adoption in the kitchen area. This GM admits that he is somewhat of an anomaly in this regard.

Attitudes toward technology is a factor that differentiates the approaches of the two hotels and this reflects individual traits such as age, length of tenure, level of entrepreneurship, and background. In addition to these individual factors, corporate culture and decision making practices and degree of centralisation of decision making come into play.

DISCUSSION

Firms engaged in c-commerce do so because they recognize the strategic benefits, however c-commerce demands significant investment in IOS. A commitment to the relationship requiring investment in IT from a long term perspective then is critical. Efficiency no longer is the sole motivation for IT adoption (Levy et al., 2001). This is an important point—one hotel saw IT purely as a tool to increase efficiency and so took a passive role, relying on corporate IT strategy. The other had a more strategic approach generally in their business and towards IT.

In part this reflects the nature of the ownership of the hotel, that is, owner managed as well as the attitudes of the GM to IT and change generally. Whilst the independent hotel recognized the value adding potential of IT, it is not likely that this will extend to c-commerce. This firm had a strong individual identity and whilst acknowledging the benefit in strategic alliances to win business and sharing information such as occupancy rates and possibly REVPAR with competitors, as is generally the case in this industry, evidence of further collaboration is not apparent.

This chapter proposes that organisations must possess certain characteristics for effective c-commerce adoption—these are embodied in the framework set out in Figure 1 and Table 1. The lack of these characteristics and low level of awareness of the benefits of c-commerce would act as an inhibitor to c-commerce adoption. For the hotel industry c-commerce of sorts exists amongst chains anyway and so since relationships are focused inwards within the chain generating a high corporate identity, the drive for relations outside that corporation is less.

From the case study it is evident there is a lack of a social identity amongst players in the industry in situ, other than membership of the AHA provides. Whilst hotels have a track record of adopting IT as discussed it tends not to be strategic. Certainly there is no real evidence

of integration of IT within corporate strategy, reflecting a view of IT as a tool to increase efficiency of operations. The strategic benefits and competitive advantage IT could generate for the business need to be understood for c-commerce to be entered into.

Research is required to determine whether the factors embodied in the framework proposed here are critical antecedents to c-commerce adoption. The relationship between these and or other factors identified by subsequent research needs to be investigated more fully with respect to the hotel industry, both in Australia and overseas.

From the case study the influence of the GM, and management structure and decision making practices of the hotel are significant influencers to potential c-commerce adoption. Hotels that are part of a chain already have interoperable systems that facilitate information and knowledge sharing amongst the chain—this seems to be more important to individual hotels compared with potential collaboration with rivals in a location. This reflects the salience of individual identity viz social identity.

The autonomy of GM is a significant issue. GMs of hotels in a chain are more concerned with operational issues with strategy and policy determined at corporate level, including IT investment decisions such as PMS system and other softwares that are used. Since the GM in the owner managed hotel had a greater degree of autonomy, he is able to determine IT investment decisions which requires a more strategic view.

Investigation of the impact the external and task environments have upon c-commerce adoption in the hotel industry is important especially comparing contexts. Given that the majority of research regarding collaborative IORs and c-commerce has taken place in Europe the impact of the cultural and institutional settings needs to be acknowledged. The influence of parent companies upon individual hotel decision making also needs to be explored.

CONCLUSION

In conclusion, c-commerce is an emerging phenomenon in many countries and industries. Little evidence exists as to its adoption generally, or amongst the hotel industry in particular. This chapter seeks to identify the factors critical to c-commerce adoption. The framework proposed in this chapter requires “testing” in hotels taking into account different national as well as other industry contexts so that validation or refinement can occur.

The notion that ownership structure and management significantly influence the business, its direction and so adoption of IT has significant relevance to the use of IT in the businesses studied here. Where the GM had little interest and involvement in IT the likelihood of innovative uses of IT was less.

Where a strategic view of the use of IT is taken by management collaboration around IT is deemed to be more likely. However this is complicated by issues of ownership structure and centralisation of IT and policy. The case study discussed here would indicate c-commerce is likely to be adopted by the independent sector of the industry where managers have greater autonomy to enter into such partnerships. Chains already collaborate around IT and so share information online and via CRS. Because of this and reliance on centralised IT decision making, individual hotels are less likely to enter into such relationships in situ.

Overall, there seems to be a strong relationship between the attitudes of GM to IT and their strategic vision and the role of IT and likelihood to adopt c-commerce. Where c-commerce exists in-house (that is in large chains) there is no need to consider entering into such collaborative arrangements with competitors. The rate of adoption, should it occur, will be slow until benefits are perceived. The influence of the corporate structure and the role of the GM are factors that significantly influence the likelihood of c-commerce adoption in the hotel industry. Such adop-

tion is not likely at least at this point in time due to the factors outlined here.

ABSTRACT

This chapter begins with an overview of public health in developing regions. From this population-level perspective, we discuss the information challenges in each of the four domains of public health: research, education, health-care delivery, and disease surveillance. We introduce health-related use classes—categories of specific use cases—to provide a structured presentation of health and information communication technologies in developing regions. In this regard, we define and discuss the following six use classes: (a) surveillance and information gathering, (b)

research, (c) provider to provider, (d) provider to patient, (e) education, and (f) logistics. Defining ICT broadly, we argue that the design or selection of technology requires consideration of the cost, ease of use, infrastructure, culture of ICT use, penetration of different ICTs, and population health profile. All of these factors vary among resource-scarce settings, and each factor can greatly impact the appropriate choice in any given setting. We discuss the following three types of assessment, each of which plays a crucial role in project evaluation: systems issues, usability, and health outcomes. Designing ICT for health applications in developing countries requires a deep

understanding of various contextual factors, such as health and ICT infrastructure, disease burden, and sociocultural issues. With this in mind, and with some understanding of future trends in health and ICT utilization, we provide forward-looking recommendations for practitioners, researchers, funders, and policy makers.

INTRODUCTION

Human and societal development without health is not sustainable. The World Health Organization (WHO) defines health as “a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity” (WHO, 1948, Preamble). Public health can be categorized into four domains: research, education, health-care delivery, and disease surveillance. In this chapter, when we refer to public health, we refer to the bundle of health-related activities that fall under those four domains, which have an impact on the individual (e.g., delivery of medical treatment or health education) and the larger population (e.g., health-care infrastructure capacity or tracking HIV infections).

Unhealthy people have difficulty being productive members of their communities, and unhealthy nations cannot be productive partners in the global community (Deaton, 2003; Hancock, 1993). For many developing economies, disease burdens debilitate entire populations and have a significant impact on a range of factors such as economic growth and development (Baldacci, Clements, Cui, & Gupta, 2005; “Health and Wealth,” 2002; Sachs et al, 2002). Poor infrastructure, lack of health systems, lack of access to medical care and medical goods, and financing are major barriers to improving population-wide health and national development. According to the WHO (2004), in 2002 the combined public and private per capita health-care spending in developing countries averaged \$70 per year compared to \$3,055 in high income countries. The global disease burden

comes from a variety of causes such as malaria, HIV, diarrhea, tobacco-induced chronic diseases, poor sanitation, and lack of clean water. The scope and scale of challenges facing such regions is great and requires innovative solutions. This is the context in which information and communication technologies must operate, and in this chapter, our aim is to discuss the promises and challenges of using such technologies to tackle global health problems in low-income regions.

ICT for development has received considerable interest outside of public health for a variety of applications that are discussed elsewhere in this book, such as in education and governmental affairs. While the application of ICT into health care has been on the periphery of ICT innovation, the intersection of ICT and health may be one of the greatest means to positively enhance development. Information access, exchange, and brokering are central to the delivery of health care on both an individual level via clinical providers and a macrolevel via policy makers. Access to information has a significant impact not only on the delivery of health care, but also on increasing equity in health, and thus ICT intervention offers promise in improving health care (e.g., in education, delivery, and clinical outcomes). This promise, however, is tempered by the complex interface of the design, development, and maintenance of ICT, and the nature of public health in developing regions. The application of ICT to improve health similarly depends on access to relevant, reliable knowledge in forms that are appropriate, readily assimilated, and easily applied, whether by a biomedical researcher, a nurse, a doctor, a midwifery student, or a mother.

A range of applications involving ICT for health have been undertaken in recent years. Activities range from the Ptolemy project that links full-text clinical journal access from the University of Toronto with a network of several dozen East African surgeons, to a satellite-based radio feed across Asia with health-education local programming run by Equal Access, a nonprofit organiza-

tion focused on low-cost technology (Beveridge, Howard, Burton, & Holder, 2003; Camaran Pipes, Program Coordinator [personal communication, August 30, 2005]). Various ICTs such as the Internet, radio, and mobile phones can be utilized to build research, training, and implementation capacity. The broad diversity of applications and end users (from surgeons to illiterate patients) in this context presents great opportunity as well as significant challenges and ethical considerations (e.g., access, cost, connectivity, and culturally appropriate content delivery).

The existence of distinct technology use classes or groupings of use cases (e.g., provider to provider, provider to patient, and surveillance) distinguishes ICT for health from other domains. Each use class implies a different set of implementation costs and benefits. Furthermore, much attention has been directed toward the latest Internet-enabled technologies, but public health practitioners have at their disposal a much broader set of ICTs. Public health must focus on the context and goals of health and the capabilities of particular ICTs rather than on being technology driven. Finally, the

infrastructure needed for public health intervention is quite complex, varying significantly over both disease categories and physical context. This complexity creates multiple barriers to technology access from social, economic, and political factors rather than technological ones.

In this chapter, we seek to move beyond the limited focus in much of the literature on ICT and health informatics to provide an integrative and expanded framework and analysis of the role of ICTs in public health. Specifically, we will describe each of the distinct use classes, emphasizing their impact on the design, deployment, and maintenance of ICT. We lay out a comprehensive map between ICT and public health. Moreover, we seek to make explicit the multiple barriers to technology access present in the public health infrastructure. Our specific goals are as follows:

1. Indicate the appropriate roles that ICT can play in improving multiple public health domains, specifically delivery, education, research, and surveillance

Table 1. Barriers to effective ICT utilization in health

Individual	Organization	Population/Society
Experience	Lack of administrative data	Per capita spending on health
Language	Lack of personnel capable of undertaking research	Policies that disincentive research
Economic instability	Human resources	Regulatory framework
Rural location	Incentives	(possibility of getting sued in U.S.)
Distance from points of service	Funding	Policy framework (UK, Canada)
Lack of trained personnel to provide service	Infrastructure	Lack of national funding to document population health
Cultural strictures against receiving service	No educational or training institutions	Organizational infrastructure
Economic inability to access service	Networks	Physical infrastructure
Lack of trainers to educate individuals	Decision making (information over load)	Underinvestment in education
	Capital resource constraints	Policy environment
	Labor constraints	Technology availability
	Information quality constraints	Resource availability
	Human resources necessary for maintenance of equipment, network	Language
	Cultural concepts regarding gender and ethnicity	Education
	Ethical constraints to implementation	Culture
		Politics
		Gender
		Socio-demographic differences
		Ethical constraints to implementation

2. Describe the multiple use classes for ICT, highlighting these with concrete examples
3. Provide recommendations for practitioners, discussing promising applications of technology and meaningful assessment of initiatives
4. Discuss future trends

INFORMATION CHALLENGES IN PUBLIC HEALTH

Much of the discussion of ICT within the sphere of public health in low-income countries has been limited to remote diagnostics and vertical health information systems that report to the central government disease and death events, patient load, and other tasks that fall under medical services and disease surveillance. The discussion of ICT in public health could expand to include health education strategies, effective research tools, and interactive surveillance and response data systems. For many developing countries, the health sector is significantly tied to donor agencies' priorities, which often place a premium on public-sector implementation, individual project reporting, and short-term crisis response.

From a consumer or patient perspective, however, the single largest challenge to public health is access. Low utilization of health services is a function of both underfunded demand and poor supply of high-quality services. ICT can play a significant role in addressing both supply- and demand-side constraints; however, a greater understanding of the barriers to the effective use of ICT in public health applications is needed. Table 1 identifies challenges to public health activities at various levels of social organization. ICT can help overcome those barriers.

Surveillance

Health data are necessary for informed decision making and the allocation of scarce health re-

sources. Disease trends change rapidly, and surveillance systems need to capture those trends to accurately forecast emerging threats to the public's health. The challenges to the implementation of ICT solutions to data collection on population health are exacerbated by centrifugal mandates that devolve power from the central authorities to regional health agencies, and in some cases, to nongovernmental actors. These regional data collection agencies often lack the training, experience, and resources to adequately collect data, much less mount a response to rapidly emerging situations. New surveillance systems should be modular, decentralized, and connect an array of information suppliers on a competitive basis.

Research

Health research essentially is the experimental and observational functions of testing health products, services, and policies. The supply and demand of ICT in health research is inhibited by the same infrastructural challenges facing other public health domains. The ICT challenges to conducting research are exacerbated by ethical quandaries, such as balancing the great need for innovative solutions to pressing public health problems against the protection of communities and individuals in the research.

Fostering the production of health research in developing countries represents a critical challenge of the global public health community. ICT offers a cost-efficient platform for disseminating health research originating from the developing world; however, the cost of dissemination is far from the only barrier. Only 10% of global health research funding is targeted toward 90% of the global disease burden (10/90 gap), which translates into a 1/99 gap for health information (Godlee, Pakenham-Walsh, Ncayiyana, Cohen, & Packer, 2004). It is clear that a significant part of the problem is a result of infrastructure challenges that inhibit both the creation of health research and also the submission of relevant health research into

appropriate forums. A few of these infrastructure challenges can be alleviated by the implementation of certain ICT. For example, wired and wireless Internet systems can bridge problems with inadequate and costly postal systems. However, according to one study, the publication barriers faced by developing-country researchers extend beyond purely poor infrastructure. As Horton (2000) noted, developing-country researchers faced broader challenges to both initiating research and disseminating their results, such as the following:

- Lack of a culture of research, thus little reward
- Absence of a peer group to stimulate debate and review work
- Bias in favor of developed countries from journal editors and reviewers
- Lack of interest from editors concerning diseases that are prevalent in developing countries, but not in the developed countries
- Bias toward high-tech, lab-oriented research

Education

There is the need to improve the quality of health-care information in terms of its reliability, relevance, and usability. One barrier to health education is the lack of information demand. Limited demand is a function of any of the following factors: a poor reading culture, low motivation associated with poor working conditions and poor prospects for career development, lack of awareness of evidence-based health care, long-term professional isolation, and long-term lack of access to information leading to the view that whatever is available is adequate (Godlee et al., 2004).

The lack of demand is related in part to the poor quality of much of the information supply (scientific and technical journal papers, reports,

theses, conference papers, and bibliographic, factual, and full-text information, for instance). Poor supply worsens educational performance, lowers demand, and creates a negative feedback loop (Easterly, 2002; Edejer, 2000). Godlee et al. (2004) see improved electronic access to essential information for health professionals, such as drug formularies and evidence-based handbooks, as critical to improve health services. Information supply challenges include access to the technological tools for information retrieval, such as high-bandwidth Internet connections. The lack of infrastructure at the societal or economic level is a significant handicap. For instance, global communication networks continue to expand, but remain too costly for many low-income communities. Another supply barrier is the lack of clearly evolved educational standards and norms, including the encouragement of research into better ways of teaching that would enhance the ease of use and value of the content often streamed in from high-income countries (Arunachalam, 2003).

Medical Services

Medical treatment is costly in terms of human resources and money. Providing medical services to improve population health requires a highly trained professional corps and a highly productive infrastructure. The reality in most developing countries is an urban core of highly trained medical professionals that treat a wealthy minority in private practices. Underfunded public clinics close at midday so that staff can open shop to private patients in the afternoon. The financially lucrative, yet non-essential treatments and services sold in many private practices appeal to the paying patients but are not the services that would be prioritized if the national health funds were distributed among the entire population (Walsh & Warren, 1980).

The most useful and urgently needed services in any low-income population often are simple and repetitive. They are such because the enormous

costs in treating large numbers require that the service be effective and efficiently provided. Childhood vaccines are classic examples of the type of medical service that is both effective and efficient for large low-income populations (Walsh & Warren). It is a form of triage as those same low-income individuals would benefit just as well from the personalized attention provided to rich patients if they were ever presented the opportunity.

ICT USES AND APPLICATIONS

There is a long history of ICT applications in industrialized countries; telemedicine (or telehealth) dates back to the late 1960s in the United States. Research and implementation from industrialized regions may prove useful to new initiatives in developing countries. At the same time, the unique constraints within developing countries and evolving technologies allow for new uses and applications. The Institute of Medicine defines telemedicine as “the use of electronic information and communications technologies to provide and support health care when distance separates the participants” (*Telemedicine: A Guide to Assessing Telecommunications in Health Care*, 1996).

Telemedicine initiatives in industrialized countries, such as Norway and the United States, have often sought to serve groups separated by distance from medical resources, but distance separating participants is not an essential quality of the applications we will discuss in this chapter. The following retrospective on the failures of telemedicine in its infancy is highly relevant to our current discussion (Bashshur, 1980, pp. 13-14):

Many telemedicine projects begun in the early seventies were discontinued because they were not self-sustaining. Some were hastily conceived, almost assuring their eventual demise.

In some instances this is not surprising since they were implemented without a clear definition of mission, an identification of the specific niche they would occupy in the existing health care system, or the unique contribution they would make to it. Moreover, the serious questions dealing with the economic viability of this mode of practice...were not addressed....[T]hese projects were designed as self-limiting experiments without intention of continuation beyond the experimental stage.

As we review current initiatives and look to the future, it is important to develop a framework for discussing the applications. Perhaps more than other ICT application areas, such as education and governance, health applications involve a variety of users of various backgrounds and technical proficiency. Professional software systems designers often employ use cases, stories describing the detailed use of a system, to determine the functional requirements of that system. The use case has evolved from a concept introduced by Jacobson, Christerson, Jonsson, and Overgaard (1992) in *Object-Oriented Software Engineering* to a fundamental tool in software design.

In this work, we define use classes as groupings of use cases with similar traits. Applications with common human and organizational elements, for example, linking providers to patients, belong together in a use class. It is important to cluster applications into such use classes because, although the use classes themselves are agnostic with respect to the specific technology, the applications within a particular class may utilize some of the same technologies or approaches as one another. This is because of commonalities in the ability of users, physical constraints, and technical requirements.

For ICT applications in health, we define six primary use classes; though these are by no means

exhaustive, they do cover the majority of current and upcoming applications. These use classes are (a) surveillance and information gathering, (b) research, (c) provider to provider, (d) provider to patient, (e) education, and (f) logistics.

A MULTITUDE OF USE CLASSES

Surveillance and Information Gathering

The practice of public health cannot exist under a state of ignorance; however, in many developing societies, this is the predominant condition because of the lack of reliable disease surveillance and other critical health data. The systematic gathering and analysis of clinical, environmental, and behavioral information represents a key user class. This type of information gathering allows public health to move from being reactive to responsive, with an end result of saving and improving lives. The Centers for Disease Control and Prevention (CDC) (2005) define public health surveillance as “the ongoing systematic collection, analysis, and interpretation of health data for the purposes of improving health and safety. Key to public health surveillance is the dissemination and use of data to improve health.”

The key components in the labor- and information-intensive practice of public health information gathering are the following:

1. The systematic and comprehensive collection of information on communicable and noncommunicable diseases, environmental factors, and behavioral and other health-risk factors
2. The integration and analysis of disparate data sources to identify public health events and problems
3. The dissemination of the results to the public health community so that a response can be developed

Perhaps the most well-known type of information gathering is the surveillance of communicable diseases. These types of diseases are of great importance because of the potential for rapid global spread without proper intervention (e.g., severe acute respiratory syndrome [SARS] or avian influenza subtype H5N1). In 2005, the Uige Province of Angola experienced the largest and deadliest outbreak of the Marburg hemorrhagic fever ever. There is no cure or effective treatment for the Marburg virus, but there are techniques for limiting the exposure and spread of the virus. In Angola, these measures were implemented months after the initial outbreak because of poor performance in the technical and social aspects of the national surveillance infrastructure (Ndayimirije & Kindhauser, 2005). A major gap was the lack of a functioning surveillance system that might have generated action reports concerning the existence of abnormal clinical cases. In the end, Dr. Maria Bonino, leveraging her experience, reported potential hemorrhagic fever cases to the government and international agencies with the assistance of the district health administrator Dr. Matondo Alexandre (LaFraniere & Grady, 2005). Months after the first cases, the existence of Marburg was confirmed, allowing for a full-scale response by the collective expertise of the Global Outbreak Alert and Response Network (GOARN) operated by the WHO. This case illustrates serious gaps in the collection of surveillance data. The public health information infrastructure relies on data collected from a variety of sources (Lumpkin & Richards, 2002).

1. Medical data is derived from clinical encounters and includes patient history, physical findings, and clinical tests.
2. Environmental data is derived from ongoing monitoring programs of the environment, for example, tests for the level of air pollutants in a given community, or the capturing of insects, birds, and animals to test for particular diseases.

Peering into the Black Box

3. Survey data is designed to fill in the gaps of the other primary methods of gathering data. Surveys can be conducted via direct clinical intervention, the phone, or other mechanisms. Examples include the demographic and health surveys, or national HIV serosurveys.

Health data collection can be a Herculean task in industrialized regions, but in developing regions, severe resource constraints often turn the best plans of systematic data collection into a patchwork of incomplete data sets and missing information. However, a surveillance infrastructure does exist for certain types of diseases due to significant international attention and intervention. In Angola, the GOARN network, in their response to the Marburg outbreak, used

the existing basic infrastructure for poliomyelitis eradication to aid their efforts (Ndayimirije & Kindhauser, 2005). In Uganda, one innovative method of using ICT to bridge these obstacles is the use of handheld computers and wireless connectivity technologies to allow consistent transmission of health data between rural health workers and the national authorities. Uganda has a poor wired communication infrastructure, but the mobile-phone network offers comprehensive coverage throughout the country; thus, by using technologies from Wideray Corporation (<http://www.wideray.com>), health workers are able to transmit information locally via 802.11b wireless connections to a server (Wideray jack server). Those data are then passed onward to data repositories located in the Ministry of Health in Kampala via GPRS (general packet radio service)

Table 2. Essential sources of health-related information (AbouZahr & Boerma, 2005)

1. A census.
 2. Continuous monitoring of births and deaths with certification of cause of death. Where universal coverage and medical death certification is not feasible, consideration should be given to sample vital registration systems (i.e., registration of vital events in randomly selected samples of the population) coupled with verbal autopsy.
 3. A surveillance and response system focused on epidemic and vaccine-preventable diseases (e.g., cholera, HIV, and polio) as well as emerging diseases (e.g., SARS).
 4. A programme of household surveys designed to measure use of healthcare services and important household or individual behaviors, covering both demographic and health surveys and other surveys that can be used to generate health-related information, such as surveys of living standards.
 5. A system of service generated data derived from facilities and patient-provider interactions covering aspects such as care offered, quality of care and treatments administered.
 6. Mapping of public health facilities and services at national and district levels.
 7. Behavioral surveillance focusing especially on risk factors such as smoking, unsafe sex and malnutrition.
 8. National health accounts.
 9. Financial and management information.
 10. Modeling, estimates and projections.
 11. Health research, including clinical, health systems and operations research.
-

on the GSM (Global System for Mobile Communications) network (Taggart, 2003).

Voxiva presents another approach to bridging the immense infrastructure challenges for data reporting in developing countries. An organization that frames itself as a service provider, Voxiva allows for its partners to collect real-time data from disparate locations using whatever technological means are available (Casas, LaJoie, & Prahalad, 2003; Voxiva, 2005). Furthermore, they enable effective communication using this same strategy, focusing on the use of available technology. Paul Meyer, founder of Voxiva, originally noted that the telephone was a much more widespread, accessible, and thus practical tool than the Internet; based on this, Voxiva began a disease surveillance initiative, Alerta, in Peru in 2002. This enabled better reporting in terms of yield, frequency, and data quality without investment in infrastructure or technology at the edges of the network. Today, Voxiva's solutions continue to allow heterogeneous forms of interaction for data reporting, including the Web, telephone, fax, e-mail, and SMS (short messaging service). Since they operate as a service, their partners (or clients) are not responsible for technical issues or maintenance: simply interfacing with the system as users. Today, Voxiva has international health surveillance initiatives in Peru (Nacer for maternal and child health); Tamil Nadu, India (post-tsunami Health Watch); Andhra Pradesh, India (Acute Encephalitis Syndrome Surveillance Information Management System [AESSIMS] for Japanese encephalitis); and Rwanda (Treatment Research and AIDS Centre [TRACnet] for HIV/AIDS).

Surveillance and information gathering are ultimately concerned with generating knowledge about the state of health in a given area. As has been discussed, the collection of data is critical to this endeavor, but equally important is the proper analysis of collected information to ascertain actionable knowledge. A large part of the analysis equation involves the presence of personnel skilled in epidemiological techniques and data analysis,

but ICTs do have a role in assisting analysis. In particular, geographic information systems (GISs) have been increasingly used to map data to improve analysis and decision making in developing regions. One example is the HealthMapper application, a geographic database, information-management, and mapping application, developed by the WHO to support the surveillance needs of national Guinea worm-eradication programs. As the software was designed for public health needs, it can be applied to numerous disease surveillance applications incorporating surveillance-specific data as well as data relating to population settlements, social and health services, and the natural environment (WHO, 2005). Developed by researchers at the Centers for Disease Control and Prevention, EpiInfo represents a similar effort to create freely available software for surveillance data management and analysis (2005).

Research

Information gaps in health research in developing countries exist in both the consumption and production of research. However, the global public health community often focuses only on the consumption of health research information as the key information gap facing developing countries. Thus, providing access to critical health research through free or reduced-price access to journals is the principal intervention. This point of view neglects that information gaps are often a result of multiple problems, and health research is no different. Journals are often the least valuable information sources for health professionals (Godlee et al., 2004). The focus on access clouds the issue of information needs, and there is often a considerable gap between information and useful knowledge. Being able to select the information that is necessary and appropriate given the particular local context is the critical issue. Access to appropriate knowledge is complicated by two factors: (a) most health information sources are produced and hosted in developed nations, and

(b) there exists scant research on the ecology of information for health workers in developing nations: “Notwithstanding an often rudimentary computing environment, users in developing countries should be empowered to produce digital library collections themselves, not just consume information produced elsewhere...In the developing world, digital libraries represent a killer app for computing technology” (Witten, Loots, Trujillo, & Bainbridge, 2001, p.84).

Applications are needed for analyzing surveillance data, evaluating health interventions and related projects, and conducting analysis of clinical trial data. One thought has been to focus on creating parallel knowledge networks so that developing-country researchers can exchange information amongst themselves, but in many countries of Africa for instance, these initiatives face severe infrastructure bottlenecks. It is often easier and cheaper in many African countries to communicate with Europe using the telecommunications system than it is to connect to their neighbors. As is evident, ICTs have the potential to assist in improving some of the barriers related to the production and consumption of health research, but many challenges are beyond the realm of the technology.

Provider to Provider

The need for health care is universal; however, the quality, availability, needs, and health service delivery mechanisms differ greatly across the world. Health-care providers are the human interface and play a central role in large regional and local health-care systems. Differences in service quality among health-care providers are one of the key distinctions between developing and developed nations. Health-care providers as referred to in this chapter are service professionals or semiprofessionals responsible for delivering some form of preventive and curative care. Health-care providers tend to be differentiated both by specialties and severity of care (e.g., primary,

secondary, and tertiary), as well as the economic model of their affiliate institution: public, for profit, and nonprofit.

Guided by standard health policy and high-income-country precedent, many low-income countries have focused on the development of a distributed public-sector health-care infrastructure based on primary care. However, a substantial portion of health-care services in developing societies are delivered by private providers on a fee-for-service basis (Hanson & Berman, 1998; Prata, Montagu, & Jefferys, 2005). “Private” providers are defined as those who fall outside the direct control of government, and can include both for-profit and nonprofit providers (Hanson & Berman). Many of these private providers tend to be small and independent, for example, individual doctors and drug shops. This informal private sector serves a significant portion of many low-income populations, and could potentially improve the quality of their services through the adoption of low-cost ICT strategies. As AbouZahr and Boerma (2005) note, “ICTs have a significant role to play at the level of individuals and communities, for effective clinical management and for assessing the extent to which services are meeting the needs and demand of patients and communities” (p. 529).

Health-care service providers have two broadly defined information needs. The first area is the collection, processing, reporting, and use of pertinent health information. The second information need is to consult, coordinate, and diagnose across disparate locations, specialties, and levels of care. It is assumed that poor provider service is simply due to a lack of information, but the reality is more complex. Several factors impact the demand and supply of health information, and ultimately the efficacy of provider services:

- **Many actors, many needs, and unequal power:** At inception, the Health Information System (HIS) of Mozambique was heavily centralized, and information policy em-

phasized reporting from the primary levels to the central authority (Braa et al., 2001). Later, Mozambique adopted the WHO-recommended primary health-care strategy, which focuses on the district and local delivery of health care, thus there is greater use of information at these levels rather than through upward reporting. However, local use of information is hampered by two factors: (a) an underfunded local infrastructure and (b) the dependence of Mozambique on foreign donors for a substantial portion of their resources, creating yet a different set of information needs.

- **The lack of capacity to utilize information effectively:** Health workers have little or no training to interpret health data in a useful manner. In the Cuamba district of Mozambique, the health center had cumulative data on each point in the DPT (diphtheria, pertussis, tetanus) immunization campaign; however, those data, if interpreted properly, would have shown a dropout rate of 55% by the last required immunization and only 10% coverage for the target population of 2,500 children (Braa et al., 2001).
- **Infrastructure problems:** Technical infrastructure is handicapped by irregular electricity access, the lack of skilled technical personnel, and the inability to fully implement comprehensive communications infrastructure.
- **Absence of strong provider networks:** Developing societies are characterized by a single public health-care entity and an array of small, independent private providers that account for most health-care contacts. These informal and unregulated health-care markets present both data collection and health policy enforcement difficulties.
- **Lack of a strong health information infrastructure:** The health information infrastructure (HII) refers to the organizations, technologies, and policies responsible for the use of information relevant to health-care services. Due to the lack of financial and technical resources in many developing countries, the HII infrastructure is inadequate or nonexistent.
- **Gaps in data due to intermittent and noncomprehensive data collection:** This is largely a result of failed governance. Developing-country governments are unable to enforce surveillance reporting from the health sector (public and private).
- **Pertinent information and data spread among diverse group of stakeholders:** Essential health information is not derived from one source, but is the responsibility of many domestic and international actors.
- **Lack of agreement on an essential data set:** An essential data set is the most important data elements chosen from all primary health programs routinely reported by health service providers. The essential data set is guided by two principles: (a) The number of data elements should be limited to 100 or 150, and should enable the calculation of 80 to 120 indicators, and (b) the essential data set should integrate the needs of various programs. When building the data set, one must ask two important questions: (a) Why do we want to collect this information? (b) How will we use it? (Shaw, 2005)

Similarly, we also find challenges in the supply of health information:

The need to collect, process, report, and use information is a crucial part of any health-care information system. The continuing improvement in the quality, cost, and capabilities in modern ICT has allowed an entirely new type of information exchange: remote consultation, coordination, and diagnosis. While this type of ICT application is in its infancy, certain applications have showed the promise of ICTs to extend the reach of health

services. While urbanization is accelerating across the developing world, significant populations remain in rural or underserved areas. Though many issues are beyond the reach of technology, many challenges in remote consultation, coordination, and diagnosis are a direct result of deficiencies in the technical infrastructure.

A remote hospital in Yugoslavia received a donated ultrasound unit from Dartmouth-Hitchcock Medical Center (USA) for use in the examination and diagnosis of patients (Dartmouth Medical School, 2005). While there was a definite need for the ultrasound machine, the hospital did not possess the capacity to read the images. A doctor and medical student from Dartmouth Medical School attempted to remove this barrier by designing a system for remote image reading. In their pilot study, 50 images were compressed, transmitted, uncompressed, and reviewed by two attending radiologists, as well as one radiology resident and medical student. In 64% of the cases, the reviewer could not tell the difference between the two types of images. Image compression was critical to the feasibility of the transmission of large images over a slow link; however, increased data compression affects different aspects of image quality, which can be highly problematic for clinical applications, such as radiology. The study found that 67% of the images were suitable for diagnostic purposes, and of the remaining images deemed unsuitable, the machine, rather than the image compression, may have caused the problem.

Another similar example demonstrates the use of annotated images (via a Web-based referral system called EyesTalk) in order to refer difficult ophthalmologic cases to centers of excellence within the Aravind Eye Care System (AECS; Bhandari, Ibrahim, & Sandhu, 2004). For example, a complex case of childhood glaucoma was referred to one of the system hospitals with a pediatric glaucoma specialist; this referral included the referring clinician's comments as well as two digital images of the child's condition. The receiving ophthalmologist reviewed the

information, spoke with the referring doctor over the telephone for further information, and made his recommendations.

In the industrialized world, health-care systems are dominated by strong public and private entities (e.g., National Health Service, United Kingdom). These strong entities are capable of implementing information policies and management both internally and externally; however, as has been shown, many developing societies are entirely different. Small, independent providers in developing countries have an inability to communicate for reasons that go well beyond ICT, but ICT in collaboration with programmatic and policy-level change can have an impact on more effective service delivery, particularly in resource sharing and the sharing of information to improve clinical management and response.

Provider to Patient

Connecting providers directly to patients was a major objective of many of the telehealth initiatives in the United States and other industrialized countries over the past 40 years. In all cases, the aim was largely the same: to connect health-care providers to patients who would otherwise be inaccessible due to distance or transportation. This communication could be used for a variety of services, including the provision of health information, diagnosis, and treatment follow-up. In fact, telephones were first used for diagnosis almost as soon as they were invented, with a pediatrician diagnosing a child with croup over the phone in 1897 (Fosaelli, 1983). Successful diagnosis is more appropriate to some medical disciplines than others; to date, primarily in industrialized countries, these disciplines include dermatology and mental health (radiology also, but that falls under the provider-to-provider use class).

Newer communication technologies include asynchronous modalities (where there is a delay in communication), e-mail, for example. This introduces dynamics into the proposed applica-

Figure 1. An N-Logue kiosk operator demonstrates the remote eye care diagnosis system in Tamil Nadu, India (Copyright A. Bhandari, M. Ibrahim, J.S. Sandhu 2004)

tions that have not been witnessed previously. Synchronous communication technologies, for example, telephones and audio-video links, are largely intuitive for new users, are more comfortable for patients because of direct interaction with providers, and have been used extensively in a variety of medical disciplines. Asynchronous methods have not been used extensively, and bring both advantages and disadvantages.

E-mail as an example makes better use of resources, including bandwidth and the provider's time, making it more cost effective and potentially allowing for consultation with a wider range of providers; with little need for scheduling, and given the lower time investment, consultation with specialists around the world is a possibility (e.g., Graham et al., 2003), but the sustainability and scalability of such a model is still in question. Furthermore, the utility of information that may be conveyed using a combination of text and images is subject to the abilities and/or training of the user or mediator, such as a kiosk operator. Evaluating the health outcomes based on these different modalities in a developing setting would be very useful for planning effective ICT initiatives in the future (see Whited, 2001, for an evaluation of outcomes in a developed setting). Patient satisfaction is another issue that may vary

with differing modes of interaction. Finally, and perhaps most importantly, e-mail incurs a delay in response. Where transportation is costly, as it is for many rural people in the developing world, a delay between medical service events often prevents the patient from following up; in the case of e-mail being used for diagnosis of an ophthalmic condition at a kiosk in a larger village in India, the patient may not be able to return to the kiosk for lack of time and/or funds.

The Aravind Eye Care System, among other ICT initiatives, has experimented with remote diagnosis (see Figure 1). AECS is one of the largest providers of eye care in the world, located in Tamil Nadu, India, and focused on the eradication of preventable blindness in underserved populations. In 2003, AECS partnered with n-Logue, a private company created by Professor Ashok Jhunjhunwala of the Indian Institute of Technology, Madras, to establish rural information kiosks throughout India. The partnership was aimed at providing another mechanism for screening patients and directing them to the hospital for care. Many of Tamil Nadu's residents live in rural settings where transportation to urban centers for treatment represents a significant burden. Much like the eye camps that AECS runs, this initiative was aimed at bringing the diagnosis to the people.

Figure 2. Women in Kunduz, Afghanistan being trained to use Equal Access Satellite Receiver (Copyright Equal Access 2005, reprinted with permission)

Under the supervision of one of the doctors at their Madurai hospital, AECS designated several counselors to deal with requests for consultation made from the n-Logue kiosks.

At present, the system has not met with widespread use due to several factors. The n-Logue wireless technology was good at providing connectivity across distances cost effectively, but bandwidth was severely limited. Each kiosk owner was provided with a bundle of technologies, including a digital camera, but its resolution often proved insufficient for proper diagnosis of anything beyond the most mature cataracts. Furthermore, patients preferred synchronous communication mechanisms such as videoconferencing sessions with the counselors to detailing their problem to the kiosk owner who relays the information via e-mail along with a picture. The bandwidth restrictions of the n-Logue system made it difficult to hold satisfactory videoconferencing sessions, though attempts were made to deal with poor performance. Another problem was the kiosk owners themselves because they served as the key point of contact with the rural communities. If they did not buy into the potential of such services, or were unwilling to provide the assistance necessary to facilitate such contacts, the system was effectively useless. This was the case with many kiosk owners; but in cases where

a motivated kiosk owner existed, positive results were seen by AECS (Bhandari et al., 2004). There exists potential for this system to be used additionally for follow-up care and the dissemination of information (including education), but this potential is yet unrealized aside from some experiments.

Connecting providers to patients, via any modality, must be accompanied by proper support and follow up; training mediators, such as kiosk operators, to assist with diagnosis or screening is critical to the success of such operations. Furthermore, practitioners should realize that this is of more value to some medical specialties than others, and that digital imaging can play a very important role in the feasibility of operations for some of these disciplines.

Education

As we have already indicated, education is one of the major areas of public health. As a use class, education presents more usability challenges than the other classes because of the diversity of end users. Health education can be subdivided into two subclasses: (a) continuing education for medical staff and semiskilled training for paraprofessionals, and (b) direct population education. Each of these subclasses represents a distinct but

diverse set of users with different needs, values, and abilities.

- **Health worker education:** Chandrasekhar and Ghosh (2001, p. 851) indicate the need for “education and lifelong learning that will enable doctors in developing countries to be informed about and trained in the use of advances in knowledge.” Pakenham-Walsh, Priestley, and Smith (1997, p. 90) further develop the need to educate a broader set of health workers: “Providing access to reliable health information for health workers in developing countries is potentially the single most cost effective and achievable strategy for sustainable improvement in health care.” The challenges are in providing that reliable access, but also in allowing for ownership of information, in other words, for health workers and others to actively participate in, and contribute to, the educational process rather than passively assimilate information created in a different context. In either case, ICT has not been adequately used to date to accomplish the task of continual training for medical professionals and paraprofessionals. The end users of such systems have a wide variety of abilities and informational needs, from skilled surgeons to midwives.
- **Population education:** As we have already noted, the goal of health education is to change peoples’ behavior in order to benefit community health. Unfortunately, such health promotion has always been a very difficult proposition, given any medium. Recent trends toward using culturally appropriate entertainment have proved more successful than traditional means of education, such as the presentation of facts (e.g., Brown, 2004; Farr, Witte, Jarato, & Menard, 2005, for HIV/AIDS). ICTs are well-designed for entertainment and are often used for this

purpose across the developing world, so leveraging this in order to develop meaningful health education initiatives is promising.

Equal Access’ educational initiatives use satellite radio to enable community women (see figure 2) to create audio content and broadcast it to a wide geographic area (Bellows & Sandhu, personal communication, 2005). Their system is being used to develop locally created programs that enable health education in Nepal, Afghanistan, and India. Satellite radio as a medium allows them to create their own content at a much lower cost than traditional broadcast radio, and to reach a much broader audience. The drawbacks are the cost of program creation and the equipment cost. In other settings, educational kiosks have been used in urban health clinics in Mexico City to educate women about prenatal care (Langer & Catino, 2003). In direct education of populations at large, the users are highly varied. In many cases, they may not be literate, or they may speak many dialects and languages over a small geographic area, but this is very country dependent. For example, Cuba and Mongolia both have literacy rates of more than 97%, while Nepal’s rate is 45% and Niger’s is less than 20% (CIA, 2005). This makes the development of appropriate educational material difficult. While some technologists approach this problem by developing content (or devices) that communicate in all manners to all people, another approach is to view the community’s collective assets (in terms of both literacy and linguistic ability) as an element of the system (Sandhu, Hey, Newman, & Agogino, 2005). Rather than creating ICT that can communicate with every person, ICT that can communicate with every community can have greater population impact, if designed carefully.

Logistics

Logistical systems form the backbone of the major areas of public health. Logistic systems supply

Peering into the Black Box

not only products, but also health professionals who provide key services. As a use class, logistics has two general subclasses of end users divided into (a) disaster-relief systems for emergency and temporary medical services, and (b) permanent population health services that enhance health systems. Both of these subclasses represent a distinct but diverse set of users with different needs, values, and abilities.

- **Disaster relief logistics:** In the December 2004 Indian Ocean tsunami, there was a need for both short-term disaster relief and long-term systems enhancement. The logistics of relief include collecting immediate surveillance data, funneling resources to set up medical services, creating systems to inform the affected populations about treatment and prevention of contagion, and evaluating the process to continue squeezing more efficiency from future missions. Various organizations specialize in developing the necessary systems and skills for logistics relief programs. The Fritz Institute, for example, focuses on developing and deploying humanitarian logistics software, and addressing the problem of aid delivery, supply-chain management and coordination, and operations research. Such logistical organization of services and goods is critical to both public health relief efforts and health systems in general. As *The Economist* noted:

what is special about this tsunami is the geographical extent of the devastation and the number of countries affected. Earthquakes produce terrible consequences, but normally of a highly localised sort...the damage stretches across thousands of miles and involves millions of people. That produces a huge logistical challenge for international organisations and

aid agencies: how to get relief supplies and, later, reconstruction assistance to so many places at more or less the same time. Much more of the money and planning will have to be devoted to planes, helicopters, trucks and supply lines than in "normal" disasters and relief efforts.

(“Asia’s Devastation: Reflections on a Rare but Terrible Calamity,” 2004, p.9)

The tsunami operation highlighted the complexities of getting relief across borders in the shortest possible time and with maximum efficiency. Humanitarian organizations not only had to cope with damaged infrastructure, they were also dealing with 12 different governments and 12 different sets of customs regulations. Delays in getting aid to those who needed it cost lives (Bannon, 2005). Coordinated efforts via ICT applications such as humanitarian logistics software applications are starting to gain attention. Recent crises demonstrate that ICTs can improve the delivery of health and disaster-management services to poor and remote locations (Chandrasekhar & Ghosh, 2001). However, the opposite is also true, and ICTs should be supported by contingency plans when ICT-dependent operations fail. In the 2005 U.S. Hurricane Katrina relief effort, mobile medical services could not be seconded quickly to disaster areas in part because the communications infrastructure had been decimated resulting in an inability to coordinate human efforts to drive the placement of such extra resources. The service providers and volunteers, however, expected the systems to be ready, and the absence of any effective response system led to immediate criticisms of federal and state inaction (Marchione, 2005).

- **Long-term population health services:** There are a variety of logistical ICT applications that can enhance health systems. The discussion of each would require detail

beyond the scope of this chapter; however, several general examples should be mentioned. Systems to assure consistent medical goods and information supply are critical for every aspect of public health. For example, “stock-outs,” when inventory levels reach zero in the face of continuing demand, are a constant problem for public clinics in many developing countries, and having a basic communications link in place can help alleviate this problem. In another example, effective surveillance and subsequent logistical coordination requires a data supply chain to deliver information to decision makers and resource-allocation centers. Furthermore, health services are only operational if clinical data are accessible by health-care workers. Some other examples of supporting health-care delivery and systems include the implementation of mini medical records via smart-card applications that capture clinical data. Some efforts are being made to have personal health data carried on a card to clinics of the patient’s choice. All of these applications should be designed with two major goals in mind: the enhancement of decision-making capacity and the organization of services for patient care.

A VARIETY OF TECHNOLOGIES

In July 2005, *The Economist* asserted that the mobile phone, not the personal computer, was the key to alleviating the digital divide (“Business: Calling an End to Poverty,” 2005). Even C. K. Prahalad claimed in that same issue, “Emerging markets will be wireless-centric, not PC-centric,” but wireless technologies alone will not offer a means for tackling all problems. Though the article cites a World Bank report indicating that 77% of the world’s population lives within range of a mobile network, this is in fact an optimistic estimate;

60% is more accurate (*Financing Information and Communication Infrastructure Needs in the Developing World: Public and Private Roles*, 2005). Additionally, many of the people in this 60% do not have access to the networks because of the prohibitive handset cost. Furthermore, building mobile networks that will reach the remainder of the population will be difficult as this represents the poorest, most rural populations, and as the quality of access will necessarily be worse. Sharing devices where appropriate will certainly help alleviate some of these problems, but the reality is that heterogeneous methods integrating multiple technologies with more traditional forms of communication will be necessary to achieve the apparent goal of improving lives as Voxiva is now doing with health surveillance in Peru and India. It is important to recognize that a variety of ICTs exist, each with its own set of strengths and weaknesses. Furthermore, the requirements of each use class within the health sector vary greatly, so no single ICT will prove decisive.

A particular ICT activity can similarly be enabled by multiple technologies, depending on the setting; for example, television can be relayed via traditional terrestrial broadcast, via the Internet on a personal computer, or via satellite using a dish. In this television example—in addition to different platforms and broadcast mechanisms—there can also be different applications, such as entertainment, news, or education. Although the end result may be similar, the cost, ease of use, infrastructure, and penetration might be extremely different. These factors can greatly impact the appropriate choice in a given setting.

Assessment

Health ICT involves the intersection of technology, health, and local context and thus requires a multifaceted approach to answering the question of how best to judge these technologies. In other words, an assessment of the technology alone is not likely to yield a sufficient analysis because

without improved health outcomes, the overall benefit will be negligible. These issues of technical and population health performance impact both design and assessment. As health ICT operates at the intersection of several fields, we must clarify what is meant by assessment. Assessment includes systems-level issues, health outcomes (or relevant proxies for health outcomes), usability, and technical evaluation; however, we will only discuss the first three of these as technical evaluation (e.g., reliability, performance, interoperability) is well established. Each of these factors plays a critical role in the successful deployment of a sustainable health ICT solution.

Systems Issues

How do we assess these various technologies? In order to judge any technology one must first ask questions concerning the initiative, project, or intervention. The following are systems-level issues, where systems are comprised of people, organizations, and technology:

1. What are the system goals?
2. What are the needs of the target users?
3. What are the capabilities of this target population?
4. What are the needs of the critical stakeholders (often not the users)?
5. Who has ownership of the technology? Is there sufficient local investment in the initiative to provide for sustainability?
6. What is the duration of the project and how will the system evolve?
7. How will maintenance and support be provided?
8. What are the assumed modes of interaction with the system, and are they feasible?
9. What is the source of financing, what are the real operation costs, and is it economically sustainable?

The answers to these questions should be used during the systems design phase, and should be answered prior to undertaking any initiative. At the same time, these questions can and should be revisited during the progress of such an initiative in order to assess its effectiveness as it is implemented.

Health Outcomes

Different assessment strategies are appropriate for different ICT initiatives in health, both by the nature of the application and the purpose of the project. A one-size-fits-all assessment strategy is not practical and may be somewhat harmful. Why conduct assessment? In some cases, assessment is no more than program evaluation and is used to improve the ongoing processes of an initiative. Beyond this, program evaluation may help others undertaking similar initiatives. In the most rigorous sense, as is often appropriate in a more experimental initiative, formal research methods can be used to elicit intervention effects in order to add to the greater body of knowledge and to plan a strategy for similar initiatives elsewhere.

Randomized control trials (RCTs) of products and even services are the most rigorous means of assessing the potential. The gold standard, double-blinded RCT, may be impractical or unethical in many settings (Smith & Pell, 2003). An intervention might be randomized against a placebo or compared to the current gold-standard product or service in what are called equivalency trials. For example, an equivalency trial might compare in-person cataract diagnosis (the gold standard) against remote diagnosis using e-mail with digital imagery. Randomized intervention trials require the measurement of effects at the scale of an individual, or perhaps a community; as such, this methodology does not lend itself easily to particular ICT applications (e.g., changing from paper to electronic medical records at a particular health center).

Evaluating medical interventions has traditionally considered efficacy and clinical outcomes. Increasingly, there is also concern with cost and effectiveness in the field. For public health evaluators, the ultimate goal is verification of health outcomes: alive or dead, sick or healthy. However, other indicators often suffice to answer questions of program functionality. For example, health education evaluations rely on measuring changes in knowledge, attitudes, or behaviors (in increasing order of difficulty), but do not have time to wait for health events to validate the intervention.

Ethical issues also arise, particularly in the design of RCTs. International standards require prior informed consent of study participants; furthermore, research cannot assign harm to study subjects (United Nations, 2005). Withholding a service that is known to be beneficial from a population when there are sufficient funds to provide the service to this population may be unethical. A more comprehensive discussion of RCT ethics is not appropriate here, but ethical issues should be at the forefront of any research design.

Committees for the protection of human subjects (CPHS), also known as institutional review boards (IRBs), were established in the hope that peer review would reduce the likelihood of abusive research. Community advisory boards (CABs) take research oversight one step further with active community participation in research design and implementation. Community-based participatory research (CBPR) is a loosely defined field in which the community forms an active partnership in, and in some cases leads, research efforts (Minkler, 1997). Rather than limit participation to the CAB, CBPR calls for community involvement from the first efforts at framing the research question to the dissemination and publication of findings. Critics argue that this gradient of increasing involvement from IRB to CBPR compromises the quality of objective inquiry; however, there are compelling counterarguments noting the greater ethical validity of study participants playing an active role

in research design and implementation. Though there are some similarities, CBPR is distinct from the participatory methods that have been used in other development-related work (e.g., Narayan & Srinivasan, 1994).

Usability

Usability refers to the ease with which people can utilize a product or service for a particular purpose. Though the term is often applied to artifacts, it can apply to any designed system, of which technology is often only a part.

Voxiva represents an excellent example of a system that has adequately addressed issues of usability. They circumvented many usability issues by focusing on existing technology: their system users were already familiar with the technology as it was readily accessible and required no further maintenance. However, in the case of other applications, such as electronic surveillance systems, it may be necessary to develop new technology. In such cases, it is imperative to follow systematic usability design and assessment strategies. Good usability alone will not make a project successful, but poor usability of health ICT does not only plague projects, it can actually harm individuals (e.g., see Koppel et al., 2005).

Various methods exist for assessing the usability of products or services, primarily from the fields of human-computer interaction and human factors engineering. A treatment of these methods is outside the scope of this chapter, so for a more comprehensive review of usability, including usability assessment, the reader is referred to Kuniavsky (2003), Nielsen (1994), and Norman (2002). Beyond this, Karsh (2004) provides a topically relevant, comprehensive overview of issues related to technology acceptance.

Design is inherently an iterative process, and integrating systems usability testing into this process leads to more robust, lean, and ultimately useful products and services. The key is to involve

users early and often in the design process, in particular eliciting and addressing their unique needs as system users.

OVERALL CONSIDERATIONS

In the short term, information technologies essentially “introduce new channels of communication and transactions in healthcare” (Demiris, 2004, p. 145). Effective delivery of health services requires a plethora of data. Measuring population outcomes, monitoring service delivery outputs, and managing health systems all require large, often complex, information flows. Technologies that manage information and communication increase the efficiency of information flows, and ultimately save lives and money. The ability to coordinate a health system and delivery of care is predicated on the ability to communicate and have access to information. In the long term, health ICT “refers to a fundamental redesign of healthcare delivery” (Scott, 2004, p.1). Health ICT applications and principles promise to rebuild health industries in profound ways. However, the challenges are significant because emerging economies impose resource constraints on ICT development that are not present in wealthier societies. In addition to resource constraints, there are a number of other very important challenges, including the match between design and cultural context, systems infrastructure, and disease characteristics.

It is necessary for design purposes to know the local context and variety of applications. In one example of the challenges to public health, researchers identified four critical factors in telehealth transfer to Ethiopia: national ICT policies, ICT infrastructure, telehealth implementation factors, and culture-specific beliefs and values and differences in technology cultures between the developers in rich countries and the users in poor countries (Tan et al., 2005). Heeks (2002) highlighted a “design-actuality gap,” which he defined as the match or mismatch between infor-

mation systems designs and local user reality. Two further illustrations make similar points. First, according to Jayasuriya (1999, p. 335):

Factors that led to the failure [of the Philippine computerized information system (IS)] included ambiguity in the organization and in responsibility for the project, lack of capacity to undertake large information systems development projects and inability to retain appropriate staff. However, when the historical and contextual issues were revealed and the interplay between the content, process and context of the change was analyzed it was revealed that the content of the IS was not responsive to the changes in the wider health system. The case study confirms the need to analyze and understand organizational, environmental and cultural issues in adopting models and procedures used elsewhere when managing information systems in developing countries.

Second, according to WHO (2001a):

New technologies hold great potential for improving health care, primarily by increasing the quality, relevance and delivery of information to health personnel. Unfortunately, this potential is far from being realized in many countries, partly because of the financial, technological and infrastructure challenges of the “digital divide,” but also because the real and greatly varying needs of the users are often overlooked.

ICT development, use, and implementation can face infrastructure-level barriers that not only include the lack of a highly skilled work-

force and appropriate financing, but also other factors that fall under the broad umbrella of ICT governance; some examples include issues such as the sustainability of ICT systems, training and management capacity, constant maintenance of software systems, establishing data standards, adequate and appropriate power supply, and privacy and security of particular types of sensitive health data (e.g., pregnancy or HIV test results). In the West, there are regulatory systems in place that guide rule enforcement, and policy initiatives that protect privacy such as the Health Insurance Portability and Accountability Act (HIPAA) regulations in the United States. Innovative solutions must be generated in order to have a high level of ICT governance that also encompasses ethical considerations. Furthermore, because of the lack of health-care infrastructure in many developing regions, product design must be appropriate to the particular context. For example, having robust hardware (e.g., for power-supply issues, having longer life batteries or alternative power options) or proper management is more critical.

In the developed world, various insurance and governmental schemes generally pay for most of health care; however, in the developing world, the individual can bear over two thirds of the cost (Lewinberg, 2003). The lack of third-party payers for medical infrastructure in these regions is a significant barrier. The annual total expenditure per person in the world's developing regions is less than \$75 on all health expenses (Quick, 2003; Trouiller, Olliaro, Torreele, Orbinski, Laing, & Ford, 2002). Since the consumer does not bear the actual cost of substantial portions of health care in developed nations, the demand for medical care and new technologies is very high (Cutler & McClellan, 2001). Clearly, this is not the case in developing nations. However, even if the cost of technology or particular types of care was significantly reduced, the lack of infrastructure would make it very difficult to distribute, administer or use, and properly sustain the use of various medical goods (Hongoro & McPake, 2004). Furthermore,

there are significant indirect costs, including waiting time, transportation costs, lost wages, poor-quality health services, and many others (Melese, Alemayehu, Friedlander, & Courtright, 2004; Russell, 2004). These indirect costs are substantial and are significant deterrents to utilizing health care. These factors will substantially impact any sort of ICT for health initiatives and should be taken into account.

Alternative health finance strategies are being piloted. The World Bank, German Development Bank (KfW), and others are considering a mechanism called output-based assistance (OBA). Instead of using input-based global budgets, which allocate funds for supplies, labor, and other goods and services to the provider, an OBA approach gives patients the means to choose their preferred health-care provider. Patients use vouchers for health services at qualified government and non-government facilities. Providers are reimbursed on a per-patient basis, the clinic's output, as long as quality criteria are met in delivering the service. OBA has been lauded as a strategy to put aid in the hands of those who need it most while freeing service providers to develop competitively priced high-quality health services (Campell, Janisch, Potts, & Bellows, 2005; Sandiford, Gorter, & Salvetto, 2002; Yamamoto, 2004). ICT reporting systems will improve the efficiency and reduce fraud of future iterations of this strategy.

The nature of a particular disease will dictate not only ICT design and health finance structures, but also a host of other factors such as intervention, sustainability, complexity, and costs. In general, the public health community categorizes diseases as either acute (HIV) or chronic (cardiovascular diseases); however, one must go beyond such categories and understand the true natural history of disease and its treatment. For example, an SMS-based (mobile phone) medication reminder may result in very different levels of compliance after several months for tuberculosis patients, who are generally asymptomatic, when compared with diabetics, who can become symptomatic very

Peering into the Black Box

quickly. Also, the course of diabetes is a chronic condition requiring a lifetime of treatment and vigilance.

Major barriers to information-technology access and development include disease characteristics, appropriate accompanying technology, sociocultural considerations, and poor health-care infrastructure. ICT for health projects should be mindful of the overall goals of public health in developing countries, which is to reduce population-wide morbidity and mortality. When building such projects, designers should consider the net impact of any particular ICT implementation on a disease or health issue, and whether extremely scarce resources are being used wisely. Initiatives should also attempt to build in cost-reducing, efficiency-increasing systems for health care, and avoid redeploing an entirely different way of delivering care.

TRENDS AND CONCLUSION

Future trends will be affected by the dynamic nature of both technology and the shifting disease burden. There are several likely stages of ICT utilization for health in developing countries that

will be dependent on the state of the infrastructure available.

In the short term, it is practical to assume that the state of the ICT infrastructure (lack of infrastructure in many cases) will be relatively stable; however, the utilization of the existing infrastructure will be somewhat variable. We anticipate an increase of currently available services: more health worker training, more telehealth applications, improved frequency of data gathering for surveillance, and more sites using information technology for effective management. Skilled medical staff, particularly in urban areas, will gain increasing access to health information, but this will still be tempered by the cost of accessing some of the most relevant content (e.g., health journal research).

In the long term, we expect ICT infrastructure to develop and overcome current bottlenecks. The diffusion of modern ICTs—mobile telephony is the most prominent example today—have allowed many populations to leapfrog older technologies (such as terrestrial telephony) because of the lower access costs. In a similar fashion, we expect mobile telephony, WLL (wireless local loop), WAN (wide area network, including Worldwide Interoperability for Microwave Access [WiMAX]), and other such technologies to enable wider access to

Table 3. Change in the rank order of disease burden for 8 leading causes worldwide, 1990-2020 (Lopez & Murray, 1998)

Rank	Disease or Injury	
	1990	2020
1	Lower respiratory infections	Ischemic heart disease
2	Diarrheal diseases	Unipolar major depression
3	Conditions during the perinatal period	Road traffic accidents
4	Unipolar major depression	Cerebrovascular disease
5	Ischemic heart disease	Chronic obstructive pulmonary disease
6	Cerebrovascular disease	Lower respiratory infections
7	Tuberculosis	Tuberculosis
8	Measles	War

information and communication channels. Thus, we expect a proliferation of the number and type of health services, but this will occur over a time scale that is largely paced by the natural diffusion of the technology.

While economic viability plays a central role in the sustainability of any health ICT initiative, technology itself plays another critical role. Computing and communication technologies—from software applications to mobile phones to networking equipment—are constantly evolving. The highly dynamic nature of technology and the obsolescence of the technology left in its wake are of paramount concern as new technology often requires further capital investment and personnel training. Using older technologies with local support is appropriate as long as the technology is meeting the necessary requirements, and maintenance does not depend on components that can no longer be acquired. Technological sustainability and obsolescence are key concerns because of the often critical nature of health services that may grow dependent on the technology.

We need to understand not only technological change, but also dynamic health issues. The global burden of disease (GBD) forecast for 2020 (see Table 3) provides a gross indication of the changing face of disease and injury. Notably, depression will climb to second on the list in the face of prevailing global stigma and discrimination against those who suffer from it (WHO, 2001b). Road traffic accidents will represent the third highest disease burden, and while health ICT initiatives may serve to improve response to such accidents, prevention will be equally as important. Though these forecasts were compiled by a group of world experts, they were developed with disparate data and many strong assumptions, and are subject to regional differences; however, the importance of this data to our discussion is not the actual changes in the GBD, but that there will be a change, and that ICT initiatives, or the use of ICT more generally, must adapt to these changes.

Health disparities within countries and regions will explode over the upcoming years. For the first time, many health technologies, including ICT, will be available in country, but only to those who can afford them (e.g., Apollo Hospitals in India). It is yet unclear whether having these technologies present in country will have any impact on population health at the national scale, but is nonetheless an important trend to watch.

In order to successfully develop and integrate ICTs for public health applications, it is crucial to approach the process holistically, addressing human factors with respect to organizations, cultural context, and end users. Comprehensive ICT strategies should integrate more “basic” technologies (terrestrial phones, conventional radio, and television) with new opportunities. Multipronged assessment is critical to addressing locally relevant issues as well as to providing information for others who may undertake similar initiatives. All of this ICT development and integration should consider the use classes as a starting point for applying these lessons to research, education, health-care delivery, and surveillance in public health.

Acevedo-Ruiz, pp. 235-265, copyright 2007 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Chapter 2.33

Analysing a Rural Community's Reception of ICT in Ghana

Paula F. Saddler

Association of Certified Fraud Examiners, USA

INTRODUCTION

The Fiankoma Project was a development awareness (DA) initiative run by the Video Educational Trust aiming to link the small rural community of Fiankoma (Ghana) with people and institutions in Brighton UK through Information and Communication Technologies (ICT). People in both settings produced accounts of their lives using digital media that were turned into a Web site for cultural exchange and development education. A parallel research project *Understandings of education in an African village: The impact of information and communication technologies* studied the effects of the intervention on the Ghanaian community, seeking to gain the perspective of rural Africans on ICT and development and particularly education. Ethnographic and participatory methods enabled the research to achieve an unusual perspective on these issues (Thomas & Ahmed, 2004; Chambers, 2003).

The research drew on data collected by Fiankoma Project workers as well as the mostly Ghanaian researchers in the *Understandings* team. "Data chains" were used to make more explicit the moves

from field experience to textual outcomes. Visual material often formed the first link in the chain, prompting reflection on the issues of interest and a stimulus for dialogue in the shape of informal interviews. The chain was continued by discussions between insider and outsider researchers of the previous links, interpreting existing data, and generating narratives derived from researchers' experience and understandings of the context. This linked with other data to guide further lines of inquiry (see Pryor & Ampiah, 2004 for a full methodological discussion).

Fuller accounts focusing on educational issues in Ghana are published elsewhere (Pryor & Ampiah, 2003; Pryor, 2005, forthcoming). This article discusses ICT and development issues, reporting on attitudes before the intervention, describing the approach to using digital media and its effect on attitudes towards community development. This is analysed and placed within an emergent framework for considering how ICT use might impact beneficially on rural people in disadvantaged contexts.

BACKGROUND

Before intervention from the Fiankoma project, villagers had little experience of electronic media, but paradoxically these were having a profound effect. Inexperience was due to the remoteness of the village and its lack of electricity, in itself a point of contention. Some months previously the village elders had proclaimed a levy to bring electricity to village. Any sum of money is difficult to find in rural Africa, but the levy appeared to be well within people's capacity to pay. The researchers conducted a ranking exercise, which confirmed that most people in the village considered electricity to be the one thing that would most improve their lives and bring economic benefits. Nonetheless, many had refused to pay. Interview data suggested that reluctance to pay was due not to poverty, but because of the weak social fabric of the village. Fiankoma is not a community to which its occupants owe allegiance, but a settler community. People live there because from the 1930s onwards, they or their parents left their homes to carve out farms in the forest. Despite many years residence, people felt more connected to their places of origin. Their attitude towards the electricity fund was reflected in their reluctance to contribute to anything locally—including the schools that their children attended. Recent work suggests that this situation is common in Ghana and elsewhere in sub-Saharan Africa with rural-rural migration leading to less stable populations than has been thought the case (Litchfield & Waddington, 2003).

Villagers' most frequent encounter with electronic media was radio mainly used for music. FM reception was poor and AM output did not use the local language. This also confined TV viewing mainly to infrequent Akan language soap operas and soccer matches. In a village of some hundred households up to five TV sets were in use at any one time, run from car batteries that had to go by taxi to be recharged. Nonetheless,

everyone watched TV occasionally, although few had any power over what and when. A traveling video showing Nigerian action-packed blockbusters, high on violence especially towards women, played to quite large audiences. During the project the village elders banned these shows, which were seen as corrupting the young, an action validated by Leach, Fiscian, Kadzamira, Lemani, and Mach-ankanja (2003) who report boys' claims elsewhere in Ghana that sexual molestation of girls took place "to practice things in films" (p. 37).

The village had no telephone, few people had used one, though they knew about them from television, and it was placed very low in the ranking exercise. Computers were unfamiliar, as they did not feature in televised dramas. Although the senior secondary school syllabus includes some "hands on" experience, the few students who attended reported that this had failed to materialize. Very few had heard of the Internet.

Attitudes and understandings are ultimately more important than hardware and infrastructure issues (Leonard & Dorsey, 1996). Villagers' reactions to the project's work yielded important insights about their image of ICT. It had been anticipated that understanding the purpose of the project and the notion of cultural exchange would be problematic, so much effort went into explanations. Nevertheless two misconceptions surfaced.

The first, that the project was to provide development aid, occurred throughout the fieldnotes and was dominant in interviews. Development and its outcomes are familiar concrete ideas, whereas cultural exchange is abstract and unfamiliar. Moreover the very idea of cultural exchange presupposes experiences of a cultural "other," which is difficult to grasp for people whose experience of other cultures is hazy. "Obruni" (strangers, white people) might be benevolent, but that they wished to learn from villagers was incomprehensible. Recognising a power differential between the two parties, where difference in wealth was a

key distinguishing feature, good intentions could only be assured by some material benefit accruing from the exchange (Nelson & Wright, 1995).

Second, screenings of work in progress provoked worry about how the images might be used. Some felt that the "Obruni wanted to make a mockery of the inhabitants of the village."² Another view of malign intent, the idea from animist religion that Obruni would carry away people's spirits, may seem remote from the realities of modern technology, but in some respects it is close to the truth. The tourist gaze does not flatter developing countries, and affords no control to the subjects (Linnekin & Poyer, 1990). Images are created and removed from sight with no "come back." The "spirits" can be edited and used without reference to those portrayed. This "régime of representation" stereotypes the subjects, "classifies them according to a norm and constructs the excluded as 'other'" (Hall, 1999, p. 259). In global news media Africa is largely absent but when covered is usually seen negatively (Hawk, 1992) and Africans' poverty is explained "with reference to their own cultural lack" (Stevenson, 1999, p.138). The media's construction of Africa functions to perpetuate feelings of Western superiority and provides legitimisation for existing relations of dominance (Borgartz, 2002). Until recently this issue only surfaced for Africans who migrated to the North. However, with the reach of media extended to remote villages, people are exposed to a romanticised picture of global culture, yet do not see their own realities reflected.

In summary, although people were passive consumers of electronic media on a very small scale, these were affecting their cultural attitudes. Television and video gave a window into a more sophisticated and attractive urban world, mostly the cities of West Africa (cf., Lewin, 2000; Hall, 1998). ICT development was at best irrelevant for most people. At worst it reinforced the divide between them and the urban elite.

Faced with these problems, the methods used by the Fiankoma Project are significant. A docu-

ment was produced, spelling out the approach in the form of 12 rules (see www.fiankoma.org). The Fiankoma Method recognises that technology is less important than knowing what to do with it and conceptualises this in terms of enabling people to publish their own information and represent their own lives. The Web site was designed with its audience in mind, a process facilitated by having actual partners. A wide range of media, especially low tech, such as drawings and scrapbooks, enabled more people to participate actively. As far as possible, editorial responsibility was given to groups of people to help them explore cultural commonalities and differences. They were encouraged to respond to each other's contributions and find equivalence, so simple reproducible activities were favored. Humor and media conventions worked well and provided a safe context in which to look at problematic issues. Using ICT in development awareness required allocating time for making materials, viewing work from the other community and reflective discussion. The Web site was seen as something to be used rather than just created and the strategy for use included opportunities such as guest books, public events, and competitions.

EFFECT OF THE INTERVENTION ON ATTITUDES TOWARDS COMMUNITY DEVELOPMENT

When the Fiankoma project Web site was running, researchers returned to the village to collect more data and a group of villagers was taken to the city and introduced to computers. The session ended with browsing the Internet, especially the Fiankoma Web site.

Reactions were very positive, especially when people saw their village and themselves on the computer screen. The experience was intended to provoke thought about how computer technology might impact on their lives in the longer term, but it was difficult to get them to think beyond the

immediate experience. Issues of connectivity and access gave the experience a degree of unreality. Some expressed skepticism about the effect of computers, for example, that computers, though very exciting and useful, would emphasise the difference between urban and rural people. Others were more optimistic: a boy who had seen the Web site reversed his decision to drop out of school. The exchange value of school was heightened, as computers were the province of senior secondary school graduates and the use value of schooling via literacy was accentuated, since getting the most from the Web site depended on reading. ICT provided a window onto a world of opportunity, which was linked to education.

The Internet session also alleviated worries about the effect of the project's images. Visibility was now viewed positively: "Before no one knew I existed, now the whole world can see me."

Several months later, the Fiankoma project workers returned to share more UK work. A film was screened and two further Internet café visits staged. At the screenings most interest accrued from participants seeing themselves, especially activities where they had been most active in planning and authoring. The UK sections they were most positive about were those with strong points of connection to their own.

The Internet sessions were particularly targeted at teachers and older pupils. Teachers now recognised great educational potential in the Internet and that more access might enable Ghanaians to catch up, though this was unlikely as lack of resources would always put African countries at a disadvantage (c.f., "leapfrogging" and "marginalisation" in Yates (2002, p.6)).

However, the most dramatic effect of the Fiankoma project happened a few months later. A letter was received saying that the village had resurrected plans to raise money for electricity. The main engine for this was to be community action. The richest man in the village had donated land for a community farm and the village was

organising communal labor. All profits were going towards electrification and the village was now seeking other ways of getting further contributions. The Fiankoma Project responded to this by offering to raise matching funds. Several harvests later sufficient money has been raised and at the time of writing electrification is expected imminently.

The extent to which the Fiankoma project caused this change in attitudes towards community development is obviously open to debate. However, available data suggest that villagers hold it responsible. Whereas previously lack of community spirit generated little "push" towards this development, interaction with ICTs seems to have exerted a strong enough "pull" to counter the lack of community spirit.

DISCUSSION

This was a case study of an unusual eventuality—a cultural exchange project. As such it is difficult to generalise and hard to reproduce these specific circumstances and interventions elsewhere. Moreover, it is difficult to compare its effect on village life with ICT for development projects elsewhere in sub-Saharan Africa. Project reports tend to focus on individual effects and community impact is either unreported or is speculative rather than evaluative in nature (Etta & Warnahui, 2003; Adeya, 2002). More important, this was not a development initiative but a cultural exchange project. Villagers had no expectation of computers coming to the village for a very long time, so they were not demanding electricity to browse the Internet. The key outcome was that the particular form of their interaction with ICT had helped to galvanise a village into taking collective action where there had been very little sense of community; and this testifies to the power of some of the practices used. Analysis of just what was so powerful about these practices

may be useful in pointing to ways in which ICT development projects, especially those in rural Africa might conceptualise their work.

Before intervention, the impact of ICT on people in the village was negative, at best neutral. Radio, television and video appeared to have interrupted some traditional forms of communication, such as story telling. Video was associated with violent and sexually dubious messages, offensive to many adults in the village. Television was a window into a world of material plenty invoking invidious comparisons between urban and rural life and diminishing villagers' sense of dignity. Few could exercise power in their consumption of media, being reliant on neighbors' goodwill and limited by language. Rural people like them were infrequently portrayed and then in a negative way. Access to ICT was limited, passive and unmediated. They were sufficiently involved to be drawn into the periphery of the global media world, but the means of access and the nature of the texts only emphasised their sense of inferiority and exclusion.

By contrast, media access via the Fiankoma project, although still limited, was active/interactive and mediated. These features contributed to the ICT having a much more positive impact. In theorising this, the research identified three aspects that seem to have contributed to the change in attitudes:

- Recognition
- Association
- Appropriation

Recognition works in two ways. First, people were able to see people represented whose lifestyle they recognised. The effect might not be so extreme for people from other villages, but nevertheless, the sympathetic portrayal of "people like us" is a far cry both from glamorised views of urban society and the negative portrayal of village life otherwise available. It was recognisable because rural people had been actively involved

in generating text, rather than just consuming it. Recognition also occurred in the sense that the villagers felt themselves recognised by outsiders and therefore distinguished by being portrayed.

By being on the Internet they experienced association by joining with a wider world. Although the Web site was not accessible in the village, the site was interactive and messages were passed on. Rich and poor can rub shoulders and talk to each other in cyber space and the Internet allowed people to communicate and associate as part of a prestigious global community.

Both recognition and association raised morale and enhanced dignity. Describing the village to a wider audience seems to have given people a sense of identity. A community that was not there before was called into being. This provided the "push," while the idea of the benefits of electrification furnished the "pull" to provoke this community into action.

Appropriation occurred through the active methodology of the Fiankoma project. People could develop skills and actively appropriate techniques only seen passively before, thus developing an enhanced understanding of how media worked. Producing materials via digital media is likely to demystify the process and make the producer a more critical consumer, enabling a meta-perspective and a deeper understanding. When people in the village were making the accounts of their lives, it was clear that they already possessed some media literacy as they used conventions such as those seen in Ghanaian soap opera, but those who took an active part in it had undoubtedly extended this literacy by the end of the project. Sayed (1998), in defining information literacy, identifies two aspects: first, narrow or specific notions, concentrating on mastery and understanding of IT; second, global definitions, emphasising access to, location and critical evaluation of information. Active methods such as those of the Fiankoma project put people in a good position to gain both aspects. Although most of what is available via digital technology fits more easily with fears about

exploitation and mockery, enhanced knowledge to read what was going on and to see behind the techniques can only be positive in combating any sense of inferiority.

CONCLUSION

Much ICT development work has focused on issues of access and hardware. Optimists suggest that increased provision will empower disadvantaged communities (leapfrog) whereas pessimists argue that they will only ever get further behind (marginalisation). The work reported here suggests that whilst addressing issues of connectivity, it is important to think clearly about issues of text and representation. At a practical level the Fiankoma method provides clear guidelines for community developers using ICT and digital media, emphasising active skills such as authoring and editing rather than just passive skills of being able to move around the World Wide Web. At a more theoretical level, the three concepts of recognition, association and appropriation represent an emergent framework not only for analysing electronic media artifacts, but also for appraising the potential impact of development work with ICT, particularly with people in low-income countries and other marginalised groups.

KEY TERMS

Appropriation: The idea that active exploration whilst creating their own texts enables people to appropriate the knowledge that will help them read other texts.

Association: The degree to which participation in global communication confers on participants some of the prestige associated with more glamorous lifestyles.

Development Awareness Projects: Projects aimed at promoted awareness and understanding of international development issues usually with people in high-income countries.

Fiankoma Method: An approach to community working with ICTs emphasising active authorship.

Leapfrogging: The notion that access to ICTs will enable people to skip over stages of technological and economic development.

Marginalisation: The idea that availability of ICTs will serve further to marginalise poor people.

Recognition: The extent to which digital media should both enable marginalised people to recognise themselves and their lifestyle and to feel recognised by their experiences with them.

Chapter 2.34

Factors Motivating the Acceptance of New Information and Communication Technologies in UK Healthcare: A Test of Three Models

Janice A. Osborune
Brunel University, UK

Malcolm Clarke
Brunel University, UK

ABSTRACT

This paper discusses the use of three published models, the Technology acceptance model (TAM), Rogers diffusion of Innovation theory (IDT), and the Triandis theory of interpersonal behaviour (TIB), and attempts to bring them together in an integrated model to better predict the adoption of new information and communication technologies by a cohort of health professionals within UK primary care in an attempt to aid implementers in bringing technology in at an organizational level.

INTRODUCTION

Over the last 25 years, public healthcare delivery has been undergoing continuing changes. This has included the use of new information and communication technologies in a bid to improve services to patients, speed up waiting times, and addressing structural problems in the National Health Service (NHS). These changes have been largely driven by technical competence on the medical side but not matched sufficiently in technical organizational improvements. This article discusses the use of three published models, the Technology Acceptance Model (TAM), Rogers

Diffusion of Innovation theory (IDT), and the Triandis Theory of Interpersonal behaviour (TIB), and attempts to bring them together to assist in the political decision to bring technology in at the organization level too.

PUBLIC HEALTHCARE IN THE UK: AN OVERVIEW

Within the United Kingdom, there exists a plethora of organizations and bodies providing the majority of healthcare in the UK including general practitioners to accidents and emergency departments, and dentistry. These organizations all fall under the National Health Service (NHS), the publicly funded healthcare system of each part of the UK, which in theory is managed by the Department of Health. Services provided under this organization are characterised by free service to all citizens and is divided into two levels of care, primary and secondary.

In the United Kingdom, a patient must first see their own doctor (referred to as the GP) located in close proximity to the patient's home. GP's are the first point of contact for users in the UK. This level of service provided is known as primary care. At present, 90% of all health and social care contacts with the NHS are through primary healthcare (NHS, 2001). Primary healthcare is provided through a combination of general practitioners and community medical workers. Services such as district nursing and child health monitoring are provided by community medical workers. If specialist help is required by a patient, he or she will be referred to a hospital or a consultant by their GPs. This is referred to as secondary care, as self-referral is not allowed and the clinical condition presenting normally cannot be dealt with by a primary care specialist and so is dealt with at this level.

One major problem in the NHS is that of communication between hospital specialists and general practitioners particularly in inner city areas. The written communication between GPs and consultants have been highlighted as being of poor quality (Rowland, 1992) and often having poor educational value (AGHTA, 1996). This problem has led to problems occurring in the outpatient referral system in terms of delays for hospital appointments, leading to frustration by patients (DOH, 1991).

In addition to this, there have been problems with out of hours GP services (Hallam, 1994), which has led to recommendations being made for more access to the healthcare system through entry points such as NHS Direct (Rogers, Chapple, & Sergison, 1999).

The government, in an effort to modernize the National Health Service and to deal with the numerous structural problems, have emphasized in policy initiatives the vision for connecting health policies with the capabilities of new information and communication technologies, which are able to provide new kinds of service that are more responsive to public needs and speed up access to healthcare. *The Information Strategy for the Modern NHS* (1998-2005) was seen as both visionary and relevant to the needs of the NHS. In the *Information for health* policy document for example, removing distance from healthcare was seen as a goal of the innovative technology Telemedicine.

Opportunities in the field of telemedicine will be seized to remove distance from healthcare, to improve the quality of that care, and to help deliver new and integrated services. GP's will be able to send test readings or images electronically to hospital specialists many miles away and in the same way receive results and advice more quickly (National Health Service Executive, 1998)

One of the major programmes, which the government has initiated, is the National Programme for IT for which an overview is provided.

National Programme for IT (Formerly NPfit)

The National Programme for Information Technology (Npfit) came about in 2002 as a result of the UK government's decision to make an unprecedented investment in information technology as essential to its plans for the National Health Service. This programme has been seen as one of the most expensive information technology programmes in the world with costs estimated to run over £18 billion over ten years. (Brennan, 2005).

The programme aims to connect 30,000 general practitioners and 270 acute, community, and mental health trusts to a single, secure, national system to make information available when and where it is needed, including to patients themselves (Hutton, 2004).

In tracing its history, the Npfit programme came about as a result of suggestions made in the Wanless Treasury's report (Wanless, 2002). The report gave reasons as to why previous targets set by the NHS Executive, of all NHS trust having electronic medical reports implemented by 2005, had not been achieved. These reasons included budgets for information technology being used to relieve financial pressures elsewhere instead of locally and an inadequate setting of central information technology (IT) standards.

The Report recommended that the NHS double the proportion of its budget invested in information technology to 4%, to bring it closer into lines with the healthcare in the United States, which has a budget of 6%. They concluded that without a major advance in the effective use of information and communication technology, the health service would find it difficult to deliver the efficient high quality service, which the public will demand. The government's response to this

was to allocate £2.3bn for a new national programme for IT (Doh, 2002). The Primary aim of the programme is **for** electronic patient records to be implemented in all acute trusts by the end of 2007. In 2005, the government established an agency, *Connecting for health*, as the single national provider of IT, which would deliver the National programme ensuring the maintenance, development, and effective delivery of the IT products and services delivered by the former NHS information authority.

There are several products that the National Programme plans to deliver, which includes:

- **A National Care Record System (NCRS):** *Connecting for health* plans to produce holistic records for patients from birth to death gradually, holding a review of the person's health and all his or her health contacts within the National Health Service. This summary patient record called the "spine" will be accessible 24 hours a day, seven days a week by health professionals, whether they work in hospitals, primary care, or community services.
- **Electronic Booking:** This programme, *Choose and book*, will allow GPs and other primary care staff to make initial hospital or clinic outpatient appointments at a convenient time, date, and place for the patient. If the patient prefers, he or she can make their appointment later online or through a telephone booking service.
- **Electronic Transfer of Prescriptions:** This will allow for prescribers to create and transfer prescriptions directly to a patient's community pharmacist and the Prescription Pricing Authority (PPA). It's aim is to reduce reliance on article prescriptions and it is expected to reduce prescription errors and provide better information at the point of prescribing.
- **New National Networking Service (N3):** This will provide the NHS with world-

class networking services, including secure broadband connectivity, from every site where NHS services are delivered or managed

Based on the expenditure of this and similar programmes, we deduce that money is available so the choice is between spending the time to do it well, seeing that the government intends to have information technology playing a central part in healthcare within the very near future, or to do it badly on time. This then leads us to look at external models on which to identify factors, which play a part in technology adoption.

DEVELOPMENT OF RESEARCH MODEL

There have been several theoretical perspectives, which have been used to study the determinants of IT acceptance and adoption across a variety of disciplines including Communications (Rogers, 1995), Sociology (Wejnert, 2002), and Information systems research (Knol & Stroeken, 2001).

Intention-based models and behavioural decision theories have been used to explain usage of information systems (e.g., Agarwal & Prasad, 1997; Davis, 1989) and results further show that behavioural intentions are significantly and positively correlated with actual behaviour. According to these theories, user adoption and usage behaviours are determined by intention to use information technology, which in turn is influenced by beliefs and attitudes about information technology.

Although there are many theories, which can be used to explain intention we have selected three. The technology acceptance model, the theory of interpersonal behaviour, and Rogers innovation and diffusion model. These models will form the basis of our conceptual model.

Technology Acceptance Model (TAM)

The technology acceptance model (TAM, Davis, 1993) is described as the most dominant theoretical model in information technology acceptance (Misiulek, Zakaria, & Zhang) and is an adaptation of the Theory of Reasoned Action (TRA, Fishbein & Ajzen, 1980). The TAM's goal is to provide an explanation of the determinants of computer acceptance that is generally capable of explaining user behaviour across a broad range of end-user computing technologies and user populations (Davis, Bagozzi, & Warshaw, 1989).

The TAM identifies two beliefs perceived usefulness and perceived ease of use, as being of primary importance for computer acceptance behaviour. The model posts that a users adoption of an information system is determined by behavioural intention, which is determined by the user's belief about the system, similar to the TRA. The model differs from the TRA in that behavioural intention is viewed as being determined by the individual's attitude and perceived usefulness. The TAM does not however include the subjective norms of the TRA as it was not found to be significant (Davis, 1989).

The Triandis Theory of Interpersonal Behaviour

The Triandis model (Triandis, 1980, see Figure 1) explains individuals' behaviour in terms of what they have always done (habit), by what they think they should do (social norms) and by the consequences, they associate with a behaviour (perceived consequences). The model also contains aspects that are directly related to the individual, for example attitudes, genetic factors, intention, and behaviour and others that are related to the individual's environment, for example culture, facilitating conditions, and social situations.

Rogers Innovation and Diffusion Theory

The Innovation and Diffusion Theory proposes that an innovation is an idea or practice perceived as new by an individual, group, or organization (Rogers, 1995). Diffusion is described as the process by which an innovation spreads. The individuals’ decision to accept or reject an innovation occurs in the following stages, awareness of the innovation, which leads to an attitude being formed towards it based on the individuals perception of the innovation. The decision to adopt or reject is then made, implementation takes place, and the individual confirms his or her decision. The perceived characteristics of an innovation include its relative advantage, compatibility, complexity, trialability, and observability (Rogers, 1995).

Reasons Behind Integration

Previous models described here can contribute to our proposal of an integrated model in a variety of ways, which are:

Incompleteness

Although strong empirical support for the TAM has been established through numerous studies

(Karahanna, Straub, & Chervany, 1999; Venkatesh & Davis, 2000; Venkatesh, Morris, Davis, & Davis, 2003), the TAM has had several criticisms levelled at it, including not offering sufficient understanding to provide system designers with information needed for creating and promoting user acceptance of systems (Mathieson, Peacock, & Chin, 2001), and its assumption that its use is volitional, which means that in there are no barriers to prevent an individual from using a technology or a system if he or she chose to do so (Mathieson et al., 2001). There may be situations in which an individual wants to use an IT, but is prevented by lack of time, money, or expertise (Chau & Hu, 2001; Taylor & Todd, 1995). Given the fact that the information and communication technologies, including mobile health technologies (described as computing technology, comprising software, hardware, and communications specifically associated with mobility, Zaslavsky & Tari , 1988) are fairly new to health professionals, the possibility exists that they may choose not to use the technology because they may not have sufficient skills or the ability to use the technology, hence the model would not give a complete picture of factors affecting adoption.

Because of the uncertain theoretical status of the TAM, Davis (1989) dropped the subjective norm, which has resulted in studies using

Figure 1. Triandis Theory of Interpersonal Behaviour

the TAM seldom including variables related to the social environment. Technology adoption in healthcare is a current hot topic at the moment and we believe that social pressure plays an important role in explaining reasons behind their use.

Similarities Between the Models

Although these theories focus on different determinants to explain consumer behaviour in the adoption of technology, they have similarities:

1. The TAM and the Triandis model are both intention-based models, which assume that attitudes influence intention, which determines behaviour and the actual use of the technology.
2. Perceived ease of use in TAM is related to the complexity construct of the Innovation Diffusion theory in fact the complexity construct is the exact opposite of the Perceived ease of use construct.
3. Perceived consequences in the Triandis model construct is similar to the construct of perceived usefulness (PU) in the TAM and similar to relative advantage in the Innovation Diffusion theory.

We have divided the technology adoption process into three factor areas, those related to the social environment, those related to the technology, and those related to the individual. We find the Triandis model most relevant for factors related to the social environment; for the technology related section we find the attributes from the diffusion of innovation, which concentrates on both the technology and its compatibility and the TAM more suitable; and for those related to the individual, we find the IDT and the Triandis model more suitable. As these models do not give a complete overview on their own, we find it necessary to combine the three to evaluate adoption.

AN INTEGRATIVE MODEL

Given their complementary nature, a model that integrates the key research constructs from TAM, TIB, and EDT should explain more variance in IT usage intention than either model alone. Such an integrated model is depicted in Figure 3. In this section, we discuss how the assembled model attempts to do the duties assigned to it.

Social Factors

An individual's perception of social pressure to perform or not perform a behaviour affects intention, (Fishbein & Ajzen, 1975). Perception of social pressure refers to an individual's perception of whether individuals close to or important to them think that they should or should not perform a behaviour. Consequently, we view social factors as norms, values, and roles, which influence an individual's intention to adopt medical technology. These values in our context may be conveyed by interaction with patients and peers.

There are varying views on physicians being influenced socially. It has been suggested that general medical practitioners are influenced in their decision-making by medical specialists, who are seen as being innovative and creative. (Blumberg, 1999). Such opinion leaders can activate local networks to diffuse an innovation by facilitating transfer of information (Young, Hollands, Ward, & Holman, 2003).

Perceived Usefulness

Among the many possible influences on technology use, Davis (1989) suggests that two determinants are of particular importance: perceived usefulness and perceived ease of use. Perceived usefulness is the tendency of people to use or not use a technology to the extent they believe it will help them perform their job better.

Perceived Ease of Use

PEOU is the degree to which a person believes using a particular system would be free of effort, and if the performance benefits of usage are outweighed by the effort of using the technology (Davis, 1989). Hence, the more complex the innovation of an information technology, the lower the probability of its adoption will be (Rogers, 1995). Applying this to technology adoption in the NHS, technologies perceived to be user friendly will be more appealing to both patients and practitioners. Perceived ease of use refers to ease of using the technology, sending data electronically as in the case of mobile technology, obtaining the data necessary to proceed with consultations as in the case of General Practitioners.

Facilitating Conditions

Facilitating conditions are the objective factors that make a behaviour easy or difficult. In the Triandis model, facilitating conditions are important determinants of behaviour. Even if intentions to perform the behaviour are high, the habits are

well established and the physiological arousals are optimal, there may be no action/behaviour if the situation or objective factors do not warrant the behaviour (Triandis, 1980). A simplified explanation of this is that facilitating conditions are important in that individuals with the intention of accomplishing something may be unable to do because their environment prevents the activity from being performed.

Triandis hypothesizes that facilitating conditions directly affect the actual behaviour rather than intentions because he argues that one might have the intention to perform a certain act, but if the environment does not support this behaviour then the act will most likely not be executed. We define facilitating conditions as those factors in an individual’s environment that facilitate the act of adopting technology. Empirical investigations have shown that facilitating conditions could also have a significant positive impact on attitude (Chang & Cheung, 2001).

We expect facilitating conditions to have a positive influence on technology adoption.

Figure 2. Integrated model

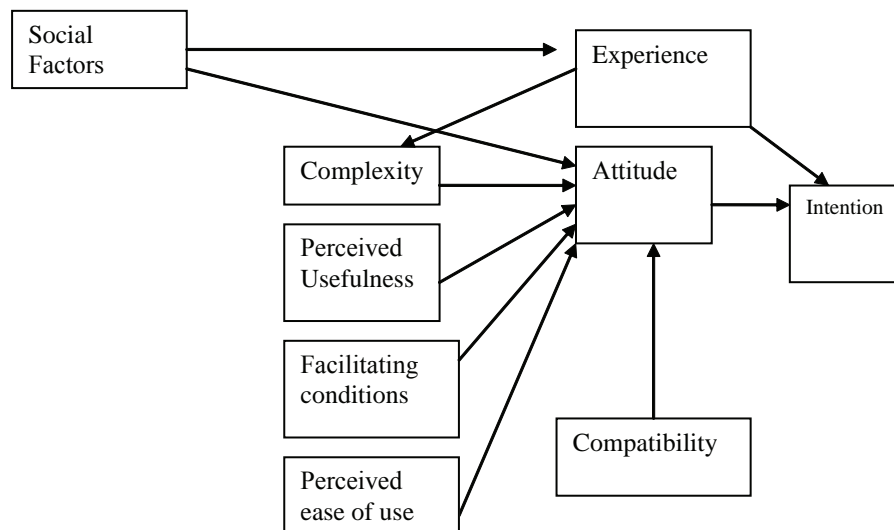

Figure 3. Comparison of the three models

	TAM	TIB	IDT
Variables	Perceived ease of use	Social factors	Relative advantage
	Perceived usefulness	Facilitating conditions	Trialability/ Experience
	Attitude	Perceived consequences	Compatibility
		Genetic Factors	Complexity
		Cultural Factors	Observability

Key:

TAM : Technology Acceptance Model

TIB : Triandis Theory of interpersonal behaviour

IDT : Innovation Diffusion Theory

Perceived Consequences

According to Triandis, each act or behaviour is perceived as having a potential outcome that can be either positive or negative. An individual’s choice of behaviour is based on the probability that an action will provoke a specific consequence.

Relative Advantage

Relative advantage is the degree to which an innovation is perceived as better than the idea it supersedes. Physician perceptions of new technologies affect the adoption of innovation in clinical practice. For example, physician perceptions related to teledermatology suggest that this new technology needs to be quick, efficient, reliable, and easily used (Weinstock, Nguyen, & Risica, 2002). If new technologies are too time consuming or complicated, they may not be widely adopted and used. In a study on the perceptions of GPs towards teledermatology, the results reported a preference for reliable, efficient, and easy-to-use technology (Collins, Nicolson, Bowns, & Walters, 2000).

Trialability/Experience

Trialability is the degree to which an innovation may be experimented with a limited basis. The

more adopters experiment with a new technology and explore its ramifications, the greater the likelihood that the innovation will be used during early stages of adoption (Agarwal & Prasad, 1997; Natek & Lesjak, 2006).

Intention

Behavioural intention refers to “instructions that people give to themselves to behave in certain ways” (Triandis, 1980) or their motivation regarding the performance of a given behaviour. In our model, intention refers to health professionals’ motivation to adopt information technologies.

Attitude

According to Fishbein and Ajzen (1980), “attitude is a learned predisposition to respond in a consistently favorable or unfavorable manner with a given object.” Attitude is directly related to behavioural intention and adoption because people will only intend to perform behaviour for which they have positive feelings (Han, Harkke, Mustonen, Seppanen, & Kallio, 2005; Marino, 2004). We hypothesise that attitude is positively related to the users intention to use new ICTs in healthcare

Compatibility

This construct has not been included in most studies on technology adoption apart from those using the IDT (Cho,). Compatibility refers to the conformity of an innovation in our case new ICTs with the values and beliefs of users and with previously introduced ideas and needs (McCole, 2002). Therefore, the adoption of a new technology depends on its compatibility with existing practices. The importance of technology compatibility with the organization and its tasks has been shown to be a significant factor in successful technology implementations (Cooper & Zmud, 1990). We hypothesise that compatibility is positively related to the user's attitude towards new ICT's in healthcare.

DISCUSSION

The primary objective of this paper was to compare two of the more dominant technology acceptance and adoption models in IT research, namely the TAM and the IDT as well as a less popular model from the social science, the TIB, then extend these models to an integrated model of IT acceptance and adoption.

On their own these models do not fully evaluate the acceptance of technology by individual, however when integrated the weaknesses of the individual models are totally cancelled out by the strengths of the integrated model.

As described earlier, the TAM assumes that there are no barriers to preventing an individual from using a technology if he or she wished. The IDT and the TIB however feature variables, which can affect adoption by the individual, hence filling one of the gaps of the TAM. The Triandis models which attempts to cover all the major component of the individual and their environments with its 34 variables is somewhat difficult to test by virtue of its complexity hence only the variables relating to our study have selected. The

IDT focuses on the process of adoption as well as the, this is complementary with both perceived characteristics of the technology complimenting both the TIB and the TAM

Based on these factors, we believe the integrated model will have better explanatory power of user adoption of technology. However dear readers, as with any cake, the proof is in the eating and as such, we will shortly be conducting an exhaustive study on a cohort of health professionals within a Primary Care Trust given new medical technology as part of a government modernization initiative to see if the model lives up to expectation. We ask that you wait with bated breath!

Chapter 2.35

Information and Communication Technologies: Towards a Mediated Learning Context

Glenn Finger

Griffith University, Australia

Maret McGlasson

Griffith University, Australia

Paul Finger

Griffith University, Australia

ABSTRACT

Teaching and learning in the 21st century should be markedly different from earlier times through the design of new teaching and learning environments. Through the presentation of three models of technology-rich learning environments (teacher-directed, learner-centered and mediated), this chapter provides a case study of the design and delivery of a course called Learning with Information and Communication Technologies (ICTs) guided by a mediated learner approach, using

new approaches to using ICTs and assessment for learning as key course design drivers. That course aims to prepare future teachers who demonstrate strong theoretical and practical understanding of designing and creating effective ICT teaching and learning experiences, and are confident and proficient users of ICTs. We provide an analysis of the implementation of that course through the presentation of the learning stories and reflections of students. Specific discussion is provided about the conceptualization and implementation of an e-portfolio approach to promote deep learning.

INTRODUCTION

Through the presentation of three models of technology-rich learning environments, namely, teacher-directed, learner-centered and mediated (see Trinidad, 2004), this chapter provides a case study of the design and delivery of a course called *Learning with ICTs* guided by a mediated learner approach using new approaches to using ICTs and assessment for learning as key course design drivers. *Learning with ICTs* aims to prepare future teachers who demonstrate strong theoretical and practical understanding of designing and creating effective ICT teaching and learning experiences, and who are confident and proficient users of ICTs. In terms of diversity, the students who undertake this course enter the university with a very diverse range of ICT knowledge, skills and attitudes. This diversity is discussed together with the conceptualization and implementation of an e-portfolio approach to promote deep learning. Therefore, there is a dual challenge here—first, to use ICTs in the design and delivery of a university teacher education course that caters to a diverse range of student needs and strengths, and second, for that course to promote the development of ICT skills and knowledge for those students as future teachers to be able to design and deliver effective teaching and learning using ICTs with their students.

Teaching and learning in the 21st century should be markedly different from earlier times, as Russell and Finger (2005) have argued that teaching and learning is now occurring in an increasingly online world. Since the penetration of computers in educational institutions, in particular during the last two decades, there has been a dynamic increase in access by teachers and students to ICTs through the purchase of hardware and software, ongoing renewal and upgrading of hardware and software, and large ongoing investments in infrastructure that has dramatically improved connectivity. Traditionally, learning environments were restricted to face-to-face delivery or where

distance education was undertaken, delivery was largely characterized by the posting of printed resources, and communication was often slow and cumbersome. However, the move to adopt new and emerging technologies to transform the ways we teach and learn requires improved understanding of how we can best use those new and emerging technologies. For example, Fraser (2003) suggests that, while students spend approximately 20,000 hours in classrooms by the time of their graduation from a university, “educators often rely exclusively on assessing achievement and pay scant attention to the quality of the learning environment” (Fraser, 2003, p. vii). He argues that there is considerable optimism internationally that the integration of ICTs will enable the creation of learning environments, but warns that this optimism needs to be “accompanied by systematic research and evaluation” (Fraser, 2003, p. vii). This caution is echoed in *The Becta Review 2005 Evidence on the Progress of ICT in Education*:

A key challenge for institutions is to develop effective and innovative ways of using ICT to extend learning beyond the boundaries of their organization, and in doing so support practitioners in delivering more learner-focused educational experiences. (p. 5)

BACKGROUND

The use of new and emerging technologies, referred to throughout this chapter as ICTs, has gained many proponents in higher education as a means for opening possibilities for improved delivery of programs with benefits for educators and students. Chambers, for example, identified education as “the next killer application for the Internet” (Chambers, 2001). There is now a plethora of terms, such as Web-supported, Web-enhanced and Web-based modes of delivery, e-learning and flexible learning, to reflect higher education strategies that utilize ICTs, with many universities developing e-strategies.

According to Bigum and Rowan (2004), the enthusiasm of vice chancellors in universities reflects two drivers: "... a perception that flexible delivery is more effective and efficient in terms of getting teaching resources to students, and secondly, that one form of flexible delivery, online teaching, offers possibilities for generating revenue from overseas fee-paying students" (p. 213).

Bigum and Rowan also cautiously note that the status of the term *flexible learning* is reflected in sayings in some Australian universities as being "inversely proportional to the distance you are from the vice chancellor!" (Holzl, 1999, p. 1). There is an inherent danger that teaching and learning is viewed narrowly as a consumer package to be marketed and delivered to students who become seen as customers rather than learners. Bigum and Rowan (2004) caution that "how we frame this work matters" (p. 223), as we need to be aware in our quest for improved teaching and learning using ICTs that particular performances of flexibility "close down what is possible, rather than, as the rhetoric suggests, open up performances of teacher education" (p. 223).

Similarly, Roffe (2004) adds substantially to the conception of e-learning, as he argues that the "e" term should not be seen exclusively as equating to electronic learning, but rather needs to be understood in terms of the human purpose of learning. Roffe proposes that e-learning should be concerned with more human "e"s—engagement of the learner, enhancement of learning, ease of use, empowerment of the learner to control the learning schedule and execution of the learning program (Roffe, 2002). Then we argue that in designing courses for students in higher education programs, which capitalize on the use of ICTs, a design process needs to be driven by the conceptualisation of a model of an ICT-rich learning environment.

DEFINING DEEP LEARNING

Throughout this chapter, we will refer to the term deep learning in ways consistent with the definition provided by Education Queensland's

Productive Pedagogies (Education Queensland, 2002a, 2002b). Deep learning is conceptualized as relating to deep understanding and deep knowledge. For example, students develop deep understanding when they grasp the relatively complex relationships between the central concepts of a topic. Instead of being able to recite only fragmented pieces of information, they understand the topic in a relatively systematic, integrated or holistic way. As a result of their deep understanding, they can produce new knowledge by discovering relationships, solving problems, constructing explanations and drawing conclusions. On the other hand, students have only shallow understanding when they do not or cannot use knowledge to make clear distinctions, present arguments, solve problems or develop more complex understanding of other related phenomena (Education Queensland, 2002a).

Knowledge is *deep* when it concerns the central ideas of a topic or discipline judged to be crucial to it. Deep knowledge involves establishing relatively complex connections to those central concepts. Knowledge is *shallow, thin or superficial* when it is not connected with significant concepts or central ideas of a topic or discipline, and is dealt with only in an algorithmic or procedural fashion. Knowledge is also shallow when important, central ideas have been trivialized by the teacher or students, or when it is presented as non-problematic. This superficiality can be due, in part, to instructional strategies; for example, when a teacher covers large numbers of fragmented ideas and bits of information unconnected to other knowledge (Education Queensland, 2002b). When both deep knowledge and deep understanding are combined, deep learning takes place.

MODELS OF ICT-RICH LEARNING ENVIRONMENTS

Trinidad (2003) notes that in Hong Kong, as with many countries, many leaders and policy makers "correlate the use of technology with pedagogical

changes” (p. 101). However, in many Hong Kong classrooms, even with the introduction of new technologies, “... teachers remain teaching in a transmissive, exam-driven culture (teaching for the test) and the technology is used for lower-level activities, such as teachers presenting lectures via PowerPoint and students’ word processing assignments and searching the Internet” (Trinidad, 2003, p. 101).

Thus, there is the potential for educators to use ICTs to continue to teach with a subject-centered approach using traditional pedagogies. Trinidad theorizes three conceptions of technology-rich learning environments: (1) teacher-directed, (2) learner-centered, and (3) mediated. The following summaries of these models are drawn from Trinidad’s theorizing.

The Teacher-Directed Learning Environment: ICTs Integrated into Existing Approaches

In this model, teaching, learning and assessment reflect a transmissive approach whereby the educator is expert with a specific knowledge base and the student is seen as a passive receptor of the knowledge to be taught, acquired and assessed. The implication of the use of ICTs in this model is to support a teacher-directed approach. Elsewhere, Roblyer (2004) refers to this as a directed or objectivist approach that views knowledge as having a separate, real existence outside the human mind and learning happens when this knowledge is transmitted to people and they store it in their minds. Drill and practice software, and low-level

use of the Internet as a means to obtain information, reflects this approach. Figure 1 provides a visual representation of this model, with the positioning of ICTs as an adjunct resource for educators and students.

The Learner-Centered Teaching Environment: ICTs Transform Pedagogy, Curriculum and Assessment

The learner-centered teaching environment reflects a more constructivist approach, as described by Roblyer (2004), whereby humans construct knowledge by participating in certain experiences that foster creativity, self-analysis and metacognition, and promote problem solving and group collaboration. In this model, according to Trinidad (2004), the educator can be involved in restructuring the learning activities and the curriculum to transform curriculum, pedagogy and assessment. As displayed in Figure 2, adapted from the work of Newhouse, Trinidad and Clarkson (cited in Trinidad, 2003), this learning environment highlights the central importance of a learner-directed approach, and the role of ICTs enables transformation.

The Mediated Learning Environment

Albon and Trinidad (2001) theorize the Mediated Learning Approach (MLA), which “revolves around the learner and the technology, which *drives* the model” (p. 106). Here we see the “e” word’s more sophisticated definition: “There becomes a sense of empowerment and engagement

Figure 1. ICTs and the teacher-directed learning environment (Adapted from Albon & Trinidad, 2001)

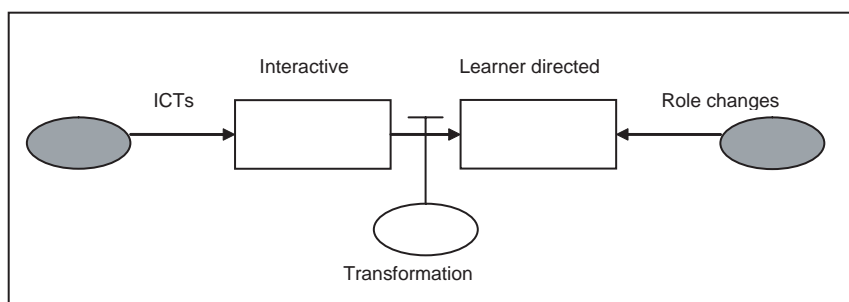

Figure 2. ICTs and the learner-centered learning environment (Adapted from Newhouse, Trinidad & Clarkson, cited in Trinidad, 2003, p. 22)

for the learner ... where they are no longer dependent on the specific and often limited knowledge of their educator, but work within the community of learners mediated by the educator” (Trinidad, 2004, p. 105). In this model, ICTs become the vehicle for communication, collaboration and the framework for mediated learning, which provides for interactions to assist the development of new and self-sustaining communities of learners to exist alongside established, traditional approaches. Subsequently, not only ICTs are utilized, but multiple information sources are used, ranging from traditional text materials in the form of books to the online resources of the Internet. In this model, ICTs are used as interactive technologies that enable learning communities “that transcends the four walls of classrooms but are not restricted by traditional class timeframes” (Trinidad, 2004, p. 106). It becomes essential, then, that educators design courses that provide learning experiences using forms of communication and facilities to access information at a time and place of the learner’s choosing, beyond and in addition to the traditional timetabled face-to-face lectures and tutorials.

In MLAs, the ICTs that drive the design of learning are complemented in the design approach by the assessment *for* learning, rather than assessment *of* learning. Assessment *for* learning, discussed in detail later in this chapter, also drives MLAs. Assessment is seen as more than knowing

the content, but becomes integrally interwoven into stories of learning whereby students collect and select authentic and diverse evidence, drawn from a larger archive representing what a person or organization has learned over time and on which the learner has reflected. Figure 3 builds substantially upon the model developed by Trinidad to theorize the importance of assessment *for* learning. The model overcomes the limitation of the earlier Trinidad model, which presented a self-contained model, whereas the model built in Figure 3 highlights the transformations occurring throughout the learning journeys of students within a course, and also articulates the connections between other formal and informal learning, as well as future learning. Too often, we see courses developed as stand-alone courses within higher education programs. Rather, we need to see ICTs and assessment *for* learning drive course design to assist students to synthesize learning among the courses they are studying within a specified study duration (e.g., within a semester) as well as throughout longer learning journeys (e.g., from learning over 3-4 years of a formal university program to life-long learning).

In addition, the model attempts to acknowledge the learning experiences students bring with them to the specified course. That is, students who enter the university program bring a diverse range of ICT knowledge, skills and attitudes. As displayed in Figure 3, this diversity was captured through the

use of the *ICT Continua* (Education Queensland, 2003), which commences with a *Minimum* phase, proceeds to a *Developmental* phase, and is ongoing through the *Innovator* and *Leader* phases. Most students entering the program were identified as being at a *Minimum* level of ICT knowledge and skills. Some students were best described as being terrified of using computers, while some had advanced ICT skills and knowledge. Consistent with the conceptualization shown in Figure 3, all students were encouraged to adopt the *Learning Journey* metaphor accompanied by an expectation that there would be transformational learning. Assistance and support was provided through peers, online sources and collaborating organizations.

In this chapter, this model is critically important for analyzing the case study presented, as both the ICTs and assessment *for* learning are key drivers in designing the MLA. In the following section, we discuss the use of ICTs and the assessment *for* learning approaches with specific reference to the portfolio process and the development of a learning community through discussion forums.

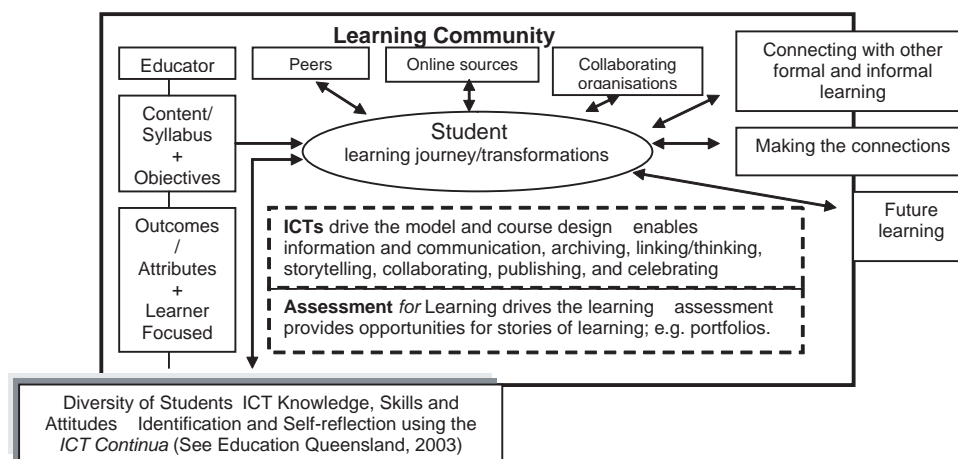

CASE STUDY: DESIGNING THE COURSE *LEARNING WITH ICTS*: TOWARDS A MEDIATED LEARNING ENVIRONMENT

This case study focuses on the design and delivery of the course *Learning with ICTs*. This course is a first-semester, first-year course situated within an eight-semester, 4-year teacher education preservice program at the Gold Coast campus of Griffith University in Queensland, Australia. This course is also delivered from two other Griffith University campuses (Mount Gravatt and Logan), and university policy requires cross-campus consistency in the formulation of the course outline. Semester 1, 2005, was the first time this new course was delivered, due to it being a course within a new bachelor of education (primary) program that commenced in 2005.

The Architecture: Course Design

The course conceptualization was guided by the need for the entire suite of four first-semester courses to have an integrated assessment item so

Figure 3. The MLA

Note: This model builds substantially on the model provided by Trinidad, 2004

students could make connections between the four courses rather than the courses being delivered as four discrete courses. Also guiding the conceptualization of all four courses was a central question: Who are we as learners? Subsequently, the expectation was that students entering their first semester of the teacher education program would undertake personal and group investigations around that central question through the theoretical perspectives, learning experiences, content and assessment of each course, as well as through making the connections among those courses.

The Assessment

For *Learning with ICTs*, three assessable tasks were required: problem set, Web site development and portfolio. Additional activities students were required to do included attending lectures and workshops. The course was Web enhanced through the provision of the Blackboard platform adopted by Griffith University. Students were provided with additional online learning resources in the form of summaries of lectures, Web links to useful Web sites, and a range of tools, such as the discussion forum. The discussion forums were established by the lecturer around key topics related to the central concepts of

the course, and students were expected to engage in these regularly. These were intended to provide students with opportunities to formulate and share ideas with other students in a non-threatening environment and scaffold students into developing more articulate analyses and linkages with theoretical perspectives as they progressed through the course. These enabled informed discussion about the topics posted, contribution of original ideas supported by reference to relevant literature and thoughtful responses to other people's contributions.

The Problem Set

The problem set was undertaken by students using ICTs to formulate their answers to a range of problematic scenarios. An example of a problematic scenario was:

Your school has been expending substantial funds from the school budget to acquire ICTs for some years. However, there are concerns that these ICTs are not being used effectively in classrooms. As an enthusiastic and informed user of ICTs, especially through your deep understandings of learning with ICTs developed throughout your preservice teacher education program, you have been asked to outline a rationale to inform the improved use of ICTs in

Figure 4. Traditional portfolio process: Emphasis is on collection of evidence (Adapted from Barrett, 2005b)

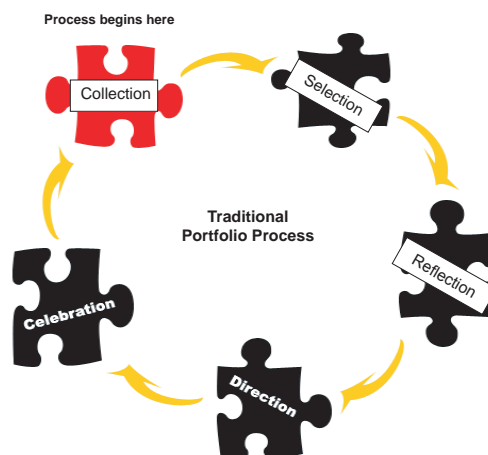

Figure 5. Reflective portfolio process: Emphasis is on reflection (Source: Adapted from Barrett, 2005)

your school to the school's ICT committee. Your rationale for ICT use needs to be supported by reference to learning theories and theorists, especially those associated with directed instruction and constructivism.

Students were scaffolded into the problem sets through their engagement with the textbook, lectures and discussions in workshops, and through the establishment of online discussion forums. The discussion forums were designed using the Blackboard platform, and students were allowed to make new threads and respond to other students' ideas.

The Web Site: Who are we as Learners?

The assessment task directly linked with the other courses and required students, working in pairs, to design a Web site using Macromedia Dreamweaver. Students were provided with the following design challenge:

As a teacher, you will be required to utilize a variety of tools to promote effective communication. This task exploits some of the communication capabilities of the World Wide Web. In the courses Introduc-

tion to Education, Studies in Sociocultural Understandings and Communicative Performance, you have been investigating the question "Who are we as learners?" by investigating your experiences as a learner and your reasons for selecting teaching as a career. You should also have come to realize the diversity that exists between yourselves and your potential students. Your task now is to assemble the discoveries you have made into a series of Web pages. The aim of this task is to use these pages to illustrate the aforementioned diversities and your understanding of your journey, as a learner, to date. Your Web site should also reflect some of the implications of this new knowledge for your professional life as a teacher.

Students created their Web sites around a suggested structure, which included the homepage titled *Who are we as Learners?*, and pages called *Personal Learning Journeys*, *Why Teach?*, *What makes a Good Teacher?* and *Our Professional Futures*. Artefacts in the form of assignments from the other courses, as well as additional information using a variety of media, were collected by students as "assets." The variety of media enabled students to develop interactive multimedia and digital video stories of learn-

ing. Students then selected and organized those assets for inclusion in the Web sites. As well as using *Macromedia Dreamweaver*, students used Macromedia Fireworks, Macromedia Flash, Windows Moviemaker, Microsoft PowerPoint, Adobe Photoshop, Adobe Acrobat and Microsoft Photo Editor to create their artefacts. The design of this assessment enabled the Web site to be a central vehicle for the development of students' personal stories of learning with the portfolio described in the following discussion.

The Portfolio

The Portfolio was conceived initially as a showcase piece to demonstrate basic and advanced ICTs skills through developing samples using a variety of software. However, guided by our move to conceptualize the course guided by MLA, students were encouraged to develop the portfolio more as a personal story of learning through the notion of an ICTs journey consistent with the *ICT Continua* (Education Queensland, 2003) used as a self-reflection tool, whereby teachers—in this case, future teachers—can move through *Minimum, Developmental, Innovator* and *Leader* phases. The ICTs Journey metaphor aligns with the MLA model (see Figure 3).

The portfolio task was established as a foundation for a portfolio students will continue to contribute to throughout the 4 years of their program. Therefore, the self-reflection links with prior ICT skills and knowledge and provides the platform for ongoing ICTs learning by linking with future learning. Students were required to demonstrate an extensive range of ICT skills and knowledge, including word processing, desktop publishing, presentation software, multimedia design, spreadsheets, databases, educational software, Internet use and Web site development. The ICT skills needed to be complemented by descriptions of how each ICT application could be used creatively in teaching and learning environments. The Web site development described earlier was

integrated into the portfolio, and discussion forum contributions were also required to be included. We continue to investigate how the portfolio enhances students' personal learning journeys and how the format supports this process. The following provides insights into the design of the portfolio in terms of moving towards e-portfolios within the context of assisting the development of an MLA using ICTs.

Defining E-Portfolios

There are many definitions for portfolios within education. The literature ranges from traditional portfolios showcasing assessment through to reflective digital portfolios or e-portfolios that support deep learning. Four major types of portfolios can be identified in the literature.

Traditional Portfolios

In 1991, Valencia (cited in Chatel, 2003) stated that a portfolio is a collection of student work that provides the means for “collecting evaluative information formatively as well as summatively” (p. 33), giving it the unique characteristic of always being a work in progress. It is a collection of physical artefacts that reflect a student's development and progress. Figure 4 demonstrates the traditional approach to developing a portfolio as presented by Barrett (2004a, 2004b, 2005), which commences with collection, selection, reflection, direction and celebration. In the traditional portfolio, emphasis is on the collection of artefacts, with the final product usually presented as a paper copy for assessment.

Reflective Portfolios

Barrett (2005b) advocates that a portfolio should be more than just a collection of data and recommends that the role of reflection in the portfolio is important for promoting deep learning. Barrett states:

... an educational portfolio contains work that a learner has collected, reflected, selected and presented to show growth and change over time, representing an individual or organization's human capital. A critical component of an educational portfolio is the learner's reflection on the individual pieces of work (often called "artefacts") as well as an overall reflection on the story that the portfolio tells. (p. 2)

Figure 5 shows that the emphasis is within the reflection phase of the process.

E-Portfolios

Barrett (2005a) notes that e-portfolios, also known as digital portfolios or electronic portfolios, are defined by the National Learning Infrastructure Initiative (NLII, 2003) as:

- A collection of authentic and diverse evidence
- Drawn from a larger archive representing what a person or organization has learned over time
- On which the person or organization has reflected

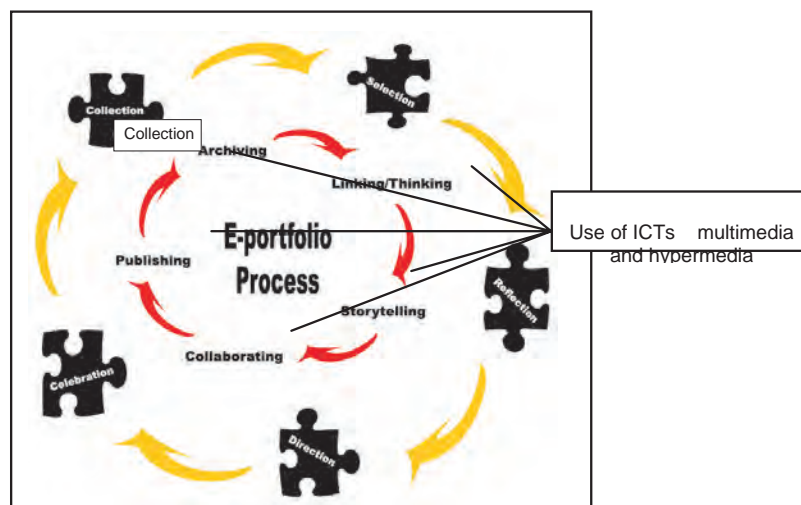

- Designed for presentation to one or more audiences for a particular rhetorical purpose

The traditional process, which involved collecting, selecting, reflecting, direction and celebration, is enhanced through the use of ICTs, according to Barrett (2004a) through the use of multimedia and hypermedia to enable archiving, linking and thinking, storytelling, collaborating and publishing. Figure 6 diagrammatically portrays the enhanced process of creating a portfolio with the added ICT enhancements. This extends the ability to communicate the stories of learning from the restrictions of a predominantly paper or print publication to multimedia, digital stories using video, audio, graphics and text in a Web-based portfolio. The use of hyperlinks through hypermedia can be a powerful means to demonstrate connections and links, rather than being limited to the restrictions of a linear story of learning similar to the teacher-directed learning environment model shown in Figure 1.

Higher Education Portfolios

In the context of higher education, the term portfolio denotes collections of evidence assembled

Figure 6. E-portfolio process: Enhancing the process through ICTs

by students, faculty members or entire institutions to enhance the effectiveness of teaching and learning, assess learning effectiveness and demonstrate competence to external stakeholders (DiBiase, 2002). Several types of academic portfolios have received attention in the literature; however, three have become prominent, according to Ketcheson (2001):

- **Student learning portfolios:** *Purposeful collections of examples of student work annotated (ideally) with students' reflective commentary. Examples may be drawn from assignments associated with a single course, or from curricular and co-curricular activities spanning a student's entire academic career.*
- **Teaching portfolios:** *Consist of course syllabi, assignments, student work and other artefacts, collected by practicing or aspiring teachers with the intent of fostering self reflection and peer review of teaching.*
- **Institutional portfolios:** *Contain examples of [an] institution's activities, programs, and initiatives, each expressing an element of reflection and self-assessment. Through its portfolio, an institution documents how it is achieving its stated mission by examples that speak to the interests of various audiences.* (p. 84)

For this case study, these contexts of designing the assessment *for* learning, defining e-portfolios as a process that is learner focused and using ICTs to enable the use of multimedia and hypermedia for students to collect, select, reflect, direct, publish and celebrate their stories of learning merge to inform the design of the course *Learning with ICTs* to create a mediated learning environment driven by the use of ICTs and assessment *for* learning. The key emphasis in the following analysis is to relate stories of personal learning in that course.

This is consistent with Barrett's theorizing that any portfolio should be a story of learning that promotes deep learning. Her thoughts are that the portfolio needs to incorporate a section within the reflection phase that focuses on storytelling. Moreover, Barrett refers to the work of Paulson and Paulson (1994), who outline the differences between the positivist and constructivist paradigms of portfolios:

- **Positivist portfolios:** *The purpose of the portfolio is to assess learning outcomes, and those outcomes are, generally, defined externally. Positivism assumes that meaning is constant across users, contexts and purposes ... The portfolio is a receptacle for examples of student work used to infer what and how much learning has occurred.*
- **Constructivist portfolios:** *The portfolio is a learning environment in which the learner constructs meaning. It assumes that meaning varies across individuals, over time and with purpose. The portfolio presents process, a record of the processes associated with learning itself; a summation of individual portfolios would be too complex for normative description.* (p. 36)

As the course design and delivery takes place within a university higher education context, there is a need to acknowledge both a positivist and constructivist approach. As an institution, we need to meet both certifications as well as promote personal growth and development of students. Therefore, when developing a portfolio, a hierarchical approach could be used. According to Barrett and Wilkerson (2004), the positivist approach is "the floor below which they cannot fall." The constructivist approach is where we hope our teacher candidates will go above the floor, showcasing the many ways that they are going beyond minimum requirements.

Reflections and Narratives: Personal Stories of Learning

As suggested by Holloway and Wheeler (1996), “Narratives and life histories are stories which individuals tell about their condition, work or life” (p. 59). While these are not new forms of data collection, as there is evidence of the use of these, for example, in the form of autobiographies and diaries, Holloway and Wheeler suggest that previously, “narratives were not analyzed systematically; but more recently, they have found a place in naturalistic enquiry for studying “the phenomena of development and transition in people’s lives” (Josselson & Lieblich, 1993, p. ix). This approach is adopted here to gain access “to the world of participants and share their experiences” (Holloway & Wheeler, 1996, p. 60). This aligns with the *Productive Pedagogies* (Education Queensland, 2002c) reference to the use of narrative in lessons encouraging the use of personal stories, biographies, historical accounts, and literary and cultural texts. In contrast, an expository teaching style places more emphasis on written, non-fiction prose, and scientific and expository expression by both teacher and students. It involves descriptions, reports, explanations, demonstrations and the use of documentaries (Education Queensland, 2002c).

Students’ personal stories of learning were gained from the artefacts collected and selected by them for inclusion in their Websites developed around the focus question *Who are we as learners?*, as well as for their portfolios. A student example of a Web site is provided to illustrate one student’s personal story of learning, and examples are drawn from that student’s e-portfolio to demonstrate the course in action. Students were also required to engage in online discussion forum topics posted regularly throughout the course. This chapter draws upon their responses in the final forum for the course and presents a synthesis of those responses to portray students talking about their learning.

Web Site: Who are we as Learners?

Generally, students were challenged early in the course with the task of having to design and present a Web site. However, after some scaffolding into the construction process, the Web sites were designed and constructed to provide a means for the collection, selection and presentation of student artefacts related to the focus question and the required questions framed for each of the Web pages. Students used a variety of media and created “assets” and “images” folders for archiving their artefacts. A course, *Sociocultural Understandings*, being undertaken simultaneously by students, required them to provide an autobiographical account of an experience in their lives and analyze this through a sociocultural lens. Students included this in their Web sites as a link from their *Personal Learning Journey* Web page. The following is an excerpt from a student example:

Throughout the development of oneself, each individual person is exposed to an individual set of incidents and circumstances, which occur in social institutions that impacts and defines that person’s beliefs and values in a process known as socialization (Holmes, Hughes, & Julian, 2003). A key moment in the development of my beliefs occurred in the event outlined in this account. This very event defined my belief of who I am as a learner: I discovered on reflection of this particular event that society suggests that there are those exposed to advantage in life and those exposed to disadvantage, but our social foundation suggests that the disadvantaged should be supported by the advantaged. (Student sample in Web site)

That Web site included a rich suite of images of the student throughout various stages of learning and growth, together with reflections of his personal learning journeys, key events in his life, including the highs and the lows, the struggles and the achievements, his reasons for wanting

to become a teacher, his thoughts on what makes a great teacher and his vision for his professional future.

E-Portfolio: A Student Sample

The portfolio process as described earlier in this chapter required students to portray their personal stories of learning in terms of ICT skills and knowledge through the creation of ICT samples to demonstrate basic and advanced skills and knowledge using a wide range of software. Figure 7 portrays the homepage of a student with navigation to the samples and stories of learning in his e-portfolio. This e-portfolio presented not only a means for the archiving, linking and publishing of evidence of learning unable to be demonstrated through a single essay or end-of-semester exam, but it provided the means for linking with other assessments undertaken in this course, such as the discussion forum contributions and Web site development, and enabled links with other assessments in other courses being undertaken by the student. As indicated earlier in relation to the Web site, the e-portfolio also enables a powerful means for using it as a platform for linking with future learning. Additional pages can be added,

additional artefacts can be archived and linked, and the currently stored evidence of learning will provide a rich resource for reflection as the student's learning journey continues.

Students Talking about their Learning

Throughout the course, students participated in an online forum discussion that had to be included in their portfolios. Consistent with the MLA model (see Figure 3), and after the course delivery, the assessment *for* learning experiences provided by the problem sets, the Web site—*Who are we as Learners?*—and the portfolio process, the culminating forum was framed by the course convenor as:

This is the final forum for this course. I am confident that students are making the connections required this semester and can make sense of the ways in which this course has been designed, and the ways in which the four semester-1 courses are attempting to make connections. ... I'd like to think that through your activities, you've made several other important connections—connected with the Teaching Team (lecturers and tutors), and con-

Figure 7. E-portfolio homepage (Acknowledgment: This Web page was constructed by a co-author of this chapter)

nected with other students ... these connections are critical to assist your sense of belonging and sense of learning community. Finally, the Web site—Who are we as learners?—encourages you to make links (should I say ‘hyperlinks’?) with the other courses you are undertaking. So ... the final forum for this course asks you to reflect upon your learning journey this semester in terms of the deep understanding and deep learning (the really important personal and professional growth experienced). You are invited to share some of your reflections about that deep learning. Comment, for example, on the challenges, the highlights and the connections. (Finger, 2005)

The following reflections have been synthesized from the student responses provided to that forum topic.

Discussion Forums: Effective for Communicating Ideas

The online facility provided by the discussion forums was perceived as being extremely effective by students. These perceptions tended to be supported by expressions by students that the forums provided a facility for assisting students to gain confidence in articulating ideas required by the problem set assessment task.

- “The discussion forums were a super idea to help with the problem set questions. I enjoyed reading other people’s input, and it also helped me think about other students’ different viewpoints.”
- “These discussion forums are great! There are a number of reasons why I feel this. The first is that it is a non-threatening environment where you can express your ideas . . . The second is that it also allows you to examine other people’s ideas at the same time, ideas that you may not have thought of or that could have been presented in the

lectures or tutorials. There have been weeks when you come into the forums late and see the quality stuff that others have already written and all you can do is just say ‘That’s right.’ It did also open up our thought patterns in preparation for the problem set, again giving us greater understanding and deeper thought before confronting the scenarios in the problem set.”

- “The discussion forums have provided me with opportunities to write, read and think about my own learning journeys. . . I also found that the forum topics complemented the text and lectures very well.”
- “I think that the forums gave us all an opportunity to express our opinions and they really helped me to interact with my peers.”
- “In addition, I liked the forums because they helped me to get my mind around the concepts I had read or learnt in the lectures. They also meant that I had time to respond to the questions asked in the forums and wasn’t put on the spot . . . they were a non-threatening way to communicate ideas.”

Reflections: Who am I as a Learner?

Students reflected that the focus question—*Who are we as learners?*—was effective in linking their learning in this course with the other three courses they undertook during the semester.

- “What a journey. I feel that this course has been very reflective and allowed me to explore who I am as a learner with the help of the other three courses.”
- “The overall theme of who are we as learners really makes you think about why we are here, why we made that choice to be part of the education field, and I’m grateful for having the chance to reflect upon it.”

Making the Connections

Students generally reported that the focus question—*Who are we as learners?*—facilitated the connections between the courses, and some students indicated that the Web site enabled the connections to be made.

- “To me, this course helped me link all the other courses I am doing because of the Web site having grouped all my ideas of who we are as learners.”
- “By looking at the connections between and within each course, I now see that all the courses—despite the different topic areas—are designed to make each of us look at who we are. This course has intrinsically given us a powerful medium for learning.”
- Students also mentioned the connections made between assessment items within the course *Learning with ICTs*, connections with the teaching team and connections with other students.
- “The forum topics, lectures and assessment items have all been directly linked.”
- “The ‘hyperlinks’ between the Web site and our other courses are starting to appear at long last. All of our subjects encouraged us to learn about our attitudes, beliefs and values and then challenge them in a new way. It has been an amazing journey, and I am proud of how much I have learnt.”

The Challenge of Designing a Web Site

Students enrolled in this course came with a wide range of ICT skills and knowledge. Very few had designed and constructed Web sites. The course required students to create a Web site as described earlier in this chapter using Macromedia Dreamweaver to enable the development of a Web-based means for collecting, selecting, reflecting and publishing artefacts related to the central question of *Who are we as learners?* Many responses from students

highlighted the challenge this created, which they overcame, and felt great personal satisfaction with their learning.

- “Week 1 ... What do you mean I’ll be designing a Web page? Are you out of your mind? Only ICT geniuses can do that stuff ... but here I am at the end, having accomplished something I never thought I could, would or should, and I’m really proud of my input and the final result.”
- “For me, this course has been an absolute treasure; I started off thinking, they are kidding right—design a Web site! After cursing and grumbling, we started; we made mistakes; we grumbled some more; we continued; we made more mistakes ... the final design is ready now. But you know, the road I have traveled to get to where I am with my Web design has been the most stimulating, educational experience I have had since starting my degree ... thanks for the challenge and the learning experience; this is precisely why I want to teach, to offer challenge, stimulation and excitement—which you clearly set out and attained with this student.”

Stories of Inspiration to Teach

Powerful stories were presented by many students related to becoming inspired to teach from the learning experiences provided in this course. Underlying these reflections were often messages of the importance of the human dimension in teaching the course and the relationships between the lecturer, tutors and the students.

- “I have learnt that anyone can dictate information to students and say ‘learn this,’ but good teachers inspire deeper learning. They encourage students to explore what they know, explore the unknown and explore what their peers know.”

- “Glenn [lecturer] and my tutor should be commended for their fabulous work and their inspiring stories ... I don’t know what everyone else thinks ... BUT I AM INSPIRED.”
- “What has been the deep learning for me this semester? It has been making the connections with the various course contents, with the tutors and lecturers, the students, and how I can use these experiences in my future role as a primary school teacher. But above all, it has been about connecting with me and the deep personal reasons for wanting to enter the profession.”
- “Glenn, you have been so approachable and friendly, and many of us have spoken of what a great example of what teachers should be you are; you are interested in more than the surface, thank you!”
- “I would like to thank Glenn and Maret [tutor] for their fantastic teaching efforts this semester; your passion for teaching reminds us all of why we chose to study this course and head in the direction we are going, thank you.”
- “Glenn, you mentioned how impressed you were with the tutorial attendance; I think you can take credit for that—your passion and enthusiasm overflowed the lecture theatre and infected all of us.”
- “I could not see how anyone, no matter how gifted, would be able to make computers and keyboards and hard drives exciting. But! All credit to Glenn, he pulled it off marvellously! Not only did he make these mundane electrical pieces seem interesting, but explained in his always polite humor how technology has, is and will affect us. One thing that I constantly noticed throughout the semester was Glenn’s passion for his course. This came through not only in his lectures, but even when greeting me in the hallway. It was great to meet someone who so obviously enjoyed and loved his career with children, and has made me much more aware of my desire to enter this profession, too. So thank you, Glenn.”

Some students suggested that the success was related to the narratives and sometimes the associated humor provided by the lecturer to illustrate theoretical perspectives. The following reflections are indicative that there is a powerful human dimension required to inspire students. The use of ICTs can assist in achieving this, but are insufficient by themselves to ensure success. Passion, enthusiasm, modeling commitment and the building of authentic relationships with students were seen by students as contributing to their commitment to teach.

- “My tutor, Carmel, should be commended on her kind approach to teaching. ... I feel inspired by her and Glenn ... here’s a pat on the back. Your stories have also inspired me ...”

FUTURE TRENDS AND SOLUTIONS: THE JOURNEY CONTINUES ...

Based upon the students’ stories, the e-portfolios provide the platform for the personal stories of learning to continue. The continuing collecting, selecting, reflecting, directing and publishing will continue as students proceed through their higher education program on their journeys as future teachers. The *ICT Continua* (Education Queensland, 2003) will continue to provide the self-reflective device for documenting and guiding that journey.

Continuing research and investigation is needed to theorize e-portfolios to promote deep learning by students in higher education. The case study provided here has provided a sense of a road map that has gone some distance along this journey. However, considerable development

is required to further explore the ways in which students can collect, select, reflect, direct, publish and celebrate their learning. For example, why might students see some attempts at e-portfolio as simply another requirement or assessment of learning.

Similarly, the promotion in this chapter of MLAs requires more theoretical models built to guide and be guided by course design and delivery. There seems to have been some critically important intangibles, almost impossible-to-measure qualities emanating throughout the story provided in this chapter—stories of higher education, humans, humor and stories of passion, challenge, commitment and inspiration. A key challenge is our need to develop improved understandings of the interface between teaching, learning and ICTs. How can ICTs assist in transforming learning in higher education, as Roffe (2002) puts it, so that it engages learners, enhances learning, provides ease of use, empowers the learner to control the learning schedule and assists in the execution of the learning program?

CONCLUSION

This chapter has outlined a case study of the design and delivery of a course for future teachers undertaking a higher education course. The design of that course—*Learning with ICTs*—was guided by a mediated learning approach in which the design was driven by ICTs and by assessment for learning. Through describing the assessment undertaken, complemented by samples, and a synthesis of reflections by students, the chapter has provided some guidance for understanding the importance of the human dimension of technology in higher education. The chapter provided some insights into the potential for the role of e-portfolios theorized as enabling personal stories of learning using multimedia and hypermedia.

Chapter 2.36

Learning–Supported Decision–Making: ICTs as Feedback Systems

Elena P. Antonacopoulou
University of Manchester, UK

K. Nadia Papamichail
University of Manchester, UK

ABSTRACT

The biggest challenge for any organization is managing the disperse nature of knowledge across a diverse set of knowledge carriers. The role of ICTs in supporting and extending the organizational memory is of particular concern. This chapter contributes to our understanding of the challenges the Digital era presents us by proposing a socio-technical framework, which emphasizes feedback as the critical link connecting social systems and technical structures. The main thrust of the framework is the alignment of social structures and social actors in ways that seek to integrate different modes of learning with different models of decision-making. This integration is to be supported by a range of decision-learning structures (in ICT systems), which create different feedback levels. These feedback levels are the main focus of

the chapter which makes a valuable contribution in extending debates of learning, decision-making and their relationship demonstrating the inherent challenges of the digital era in using ICTs as social as much as technical tools.

INTRODUCTION

A trend that is common to many organizations in the post-industrial society (Bell, 1976) is the volume, dispersion and complexity of the information available that has a significant bearing on efforts to ‘manage’ knowledge and support organizational and individual learning to meet strategic objectives. The ‘social life of information’, as Brown and Duguid (2000) eloquently demonstrate is affected by a multitude of social forces such as: economic conditions, international forces,

technology and changing assumptions. While Information and Communication Technologies (thereafter ICTs) are predominantly seen as tools supporting information management, their role in relation to learning and knowing in organizations is still embryonic. A review of the decision support literature, shows that a number of methodologies (predominantly ICT based) have been proposed in an effort to overcome the inherent subjectivity in the process of decision-making. For example, many decision support tools seek to find ways in which objective information can be successfully collected, categorized and distributed to support decision-making. Decision-making can be supported both by ICT-based decision support systems, as well as the dominant assumptions and values that determine the practices of a community of decision makers.

This point is critical in the analysis the chapter seeks to pursue, because it seeks to capture the dynamic interactions between the human and technological dimensions and to highlight the significance of feedback systems as mechanisms that convey powerful cultural meanings that carry collective knowledge in a codified form giving sense to the actions taken in relation to making a decision. Therefore feedback systems reflect the social structures that support information flows in organizations in the way existing lessons learned are codified, stored and distributed among members of a community.

The objective of this chapter, therefore, is to propose a socio-technical framework for supporting decision-making by exploring how learning modes facilitate knowledge transfer and feedback in relation to ICT-assisted knowledge management initiatives. ICTs as feedback systems that act as knowledge codification devices reveal both the sense-making process shaping individual interpretations, as well as the knowledge structures that form part of the organizational memory. Therefore, understanding how decision makers learn to make decisions would be of considerable value, as it would help highlight more forcefully how

the subjectivity in the decision-making process develops and how it can be potentially worked with to enhance the effectiveness of decisions. Essentially learning how to take decisions is akin to saying learning how to learn. This view locates as central to the effort to support decision-making the question of whether learning could be one of the purposes of making decisions and indeed if there is a 'best' way of learning in relation to decision-making.

For the purpose of this analysis decision-making is defined as:

A learning-supported process which is embedded in the learning culture and climate of the social context in which it takes place, has the capacity to evolve through the processing of information and the building of knowledge by developing interpretations based on the evolving organizational memory.

The discussion begins with an overview of the role of learning, knowledge and sense-making in the context of decisions. The analysis then examines the relationship between learning and decision-making by reviewing the three modes of learning that have dominated our understanding of learning in organizations. The way different levels of feedback and degrees of knowledge transfer that shape decision making are then discussed in relation to the ICTs. A socio-technical framework for supporting decision-making and learning is proposed identifying three feedback levels. The chapter concludes with an overview of future trends and challenges in the development of decision support systems in the Digital Era.

DECISION-MAKING AS A LEARNING-SUPPORTED PROCESS

Even though our understanding of the nature of decision-making as a complex process and a multifaceted phenomenon has come a long way

(see for example Langley, Mintzberg, Pitcher, Posada, & Saintmacary, 1995; Mumford, 1999), a persistent issue remains that decisions are based on the information available and the interpretations that decision makers impose as they make sense of the information available. If we accept that decision-making involves a large degree of sense-making (Weick, 1995) then perhaps the challenge is to examine how decision makers learn to make sense of the information they have available, how they use their own knowledge [both tacit and explicit (Nonaka & Takeuchi, 1995)] in formulating the understanding that then guides their repertoire of assumptions, as well as their actions in relation to taking a decision.

The view of decision-making as a learning-based rather than information-based process is relatively unexplored in the existing literature. The only reference to decision taking as a learning process is made by Arie de Geus (1999) and Ackoff (1999), both of who acknowledge that it is important to understand how learning takes place, however, they do not actually examine what is the relationship between learning and decision-making. In this section we make the case for a learning-based view of decision-making by first discussing the main issues and controversies in understanding the role of learning in the context of decisions. From the analysis we also identify some of the principles of a learning-supported approach to decision-making considering also the role of ICT's and other decision support systems. We begin by reviewing the main modes of learning.

Modes of Learning

The development of learning theory over the years has commanded the attention of many researchers and reflects the emergence of a number of 'schools of thought' each proclaiming to have a better grasp of what learning is and how learning takes place. In an extensive review of the learning theories, Burgoyne and Stuart (1976, 1977) identified at least

eight "schools of thought" which they discuss using metaphors in relation to their main principles and applications, as well as, their assumptions about the nature of people. In similar fashion, *Merriam and Caffarella* (1991, p. 138) discuss four main theories of learning — Behaviourist, Cognitivist, Humanist and Social and Situational Learning — and discuss their main principles in relation to their orientation to learning. Table 1 summarizes the main characteristics of each of these theories and the basic assumptions about how adults learn.

Table 1 shows that the orientation of different learning theories over the years has moved from notions of conditioning and indoctrination, towards autonomy and self-direction. Further realization that learning consists of unstructured, discontinuous and often unconscious aspects has generated more interest in the experiences people in organizations encounter and the actions they take (Marsick & O'Neil, 1999). Experiential learning and action learning theories aimed to address this issue by placing importance on the social, cultural and political aspects surrounding the learning process. This view has found more voice in recent contributions promoting a situated view of learning in organizations, integral to the functioning of communities of practice (see Wenger & Snyder, 2000; Lave & Wenger, 1991). These perspectives have also helped bring to the forefront greater consideration of the psychoanalytic, emotional and aesthetic aspects of learning (see Antonacopoulou & Gabriel, 2001; Scherer & Tran, 2001).

The development of learning theory illustrates the difficulty of capturing the complexity and diversity of learning from any one single perspective. This is best reflected in the lack of an agreed definition as to what learning is. Earlier theories considered learning as a change in behavior, which results from the acquisition of knowledge and skills. Many researchers have actually defined learning in these terms (e.g., Bass & Vaughan, 1966). The definitions of learning assume that

Table 1. Learning theories and their orientation

Aspect	Behaviourist	Cognitivist	Humanist	Social and situational
Learning theorists	Thorndike, Pavlov, Watson, Guthrie, Hull, Tolman, Skinner	Koffka, Kohler, Lewin, Piaget, Ausubel, Bruner, Gagne	Maslow, Rogers	Bandura, Lave and Wenger, Salomon
View of the learning process	Change in behaviour	Internal mental process (including insight, information processing, memory, perception)	A personal act to fulfil potential	Interaction /observation in social contexts. Movement from the periphery to the centre of a community of practice
Locus of learning	Stimuli in external environment	Internal cognitive structuring	Affective and cognitive needs	Learning is in relationship between people and environment.
Purpose in education	Produce behavioural change in desired direction	Develop capacity and skills to learn better	Become self-actualized, autonomous	Full participation in communities of practice and utilization of resources
Educator's role	Arranges environment to elicit desired response	Structures content of learning activity	Facilitates development of the whole person	Works to establish communities of practice in which conversation and participation can occur

the change in behavior is relatively permanent and that practice and experience are an important ingredient. Learning defined in these terms is often associated with taking action towards resolving problems (e.g., Argyris, 1982; Thomas & Harri-Augstein, 1985). However, as researchers increasingly recognized that learning is not always a structured, continuous and conscious process, learning has been defined as a process of gaining a broader understanding and the awareness of the

personal meaning of experiences which does not necessarily result from the acquisition of new knowledge as much as a rearrangement of the existing knowledge (e.g., Gagné, 1983; Revans, 1982). Learning has been increasingly defined in broader terms to capture the complexity of thinking, as well as acting and researchers have more recently described learning as a process of reframing meaning, transformation and liberation (e.g., Antonacopoulou, 1998; Kolb et al., 1991;

Schön, 1983). The recognition that learning is a dynamic and emergent process encourages a more integrative framework of interacting variables which arrests learning as a *space* of action, interaction and transaction than simply a means of filling knowledge gaps (see Antonacopoulou, 2002a). From this perspective, learning emerges from the interconnection of various personal and contextual factors. In other words, learning does not only depend on the individual's motivation and personal drive, but on the reinforcement of learning within the environment as well. This point stresses the situated and contextual specificity of learning and signals that different modes of learning allow learners to use feedback from the interaction with the environment as the basis of improving how and what they learn (see Antonacopoulou, 2002b).

The most widely known modes of learning to reflect this point are the distinctions made by Argyris and Schön (1974) between *single-* and *double-loop learning* and (Bateson, 1972) with reference to *deutero* or *triple-loop learning*. These modes of learning are chosen as the focus of analysis because, unlike other types or modes of learning promoted in the existing literature, they have feedback loops at their core. Figure 1 represents diagrammatically the three modes of learning.

Essentially, it could be argued that single-loop learning is predominantly concerned with identifying and correcting a problem and depending on the consequences if the problem persists, because the actions taken failed to address it, then one has to consider alternative actions. Double-loop learning on the other hand, still propounds a problem-solving mentality at the core of learning activity however, unlike single-loop learning it seeks to detect and correct a problem but also modify underlying norms and objectives, which have guided the implementation of the initial action. Finally, deutero (triple-loop learning) is concerned with learning to learn. Learning does not stop when a problem is solved or when new

actions are taken to prevent it from happening again, nor is it enough to review one's assumptions. One must also actively seek to reflect, inquire and develop new strategies for learning. Romme and van Witteloostuijn (1999, p. 439) echo this point when they suggest that while double-loop learning "involves reframing ... [and] learning to see things in new ways," triple-loop learning requires "developing new processes or methodologies for arriving at such re-framings." In triple-loop learning not only are norms questioned, but embedded assumptions of how we think and learn are re-examined.

From this brief overview of learning modes it is evident that the main difference between them lies at the level one seeks to use feedback as a means of rethinking whether one's actions in relation to *why* one learns (e.g., solving problems or taking decisions) are also consistent with *how* and *what* one learns. These issues are perhaps better evident in the role of learning in supporting a range of organizational processes such as decision-making.

The Relationship Between Learning and Decision Making

It is increasingly recognized that a number of key organizational processes have learning at their core. de Geus (1997) propounds the view of planning as learning, while Whittington (2001) explores strategizing as [learning] practice. In this chapter we make the case for decision-making as learning-supported considering that decision-making itself, as others have already argued, entails several learning principles.

Decision-making has been described as a "knowledge-intensive activity with knowledge as its raw materials, work-in-process, by-products and finished goods" (Holsapple, 2001). Yet, to-date we have limited empirical evidence that shows what forms of knowledge constitute the process of making decisions, how such knowledge is produced and utilized, how different stakeholders

Learning-Supported Decision-Making

formulate their knowledge, and what impact the different knowledge they bring has on the process of decision-making. These issues suggest that a key priority in understanding the nature of decision-making is to understand first the way knowledge that serves decision-making purposes evolves as different human, technological and social conditions interact and create conditions that shape the nature of decision-making. Therefore, we need to move beyond the view of decision-making as a step process based on knowledge components, to understand decision-making as a complex process of learning possibilities.

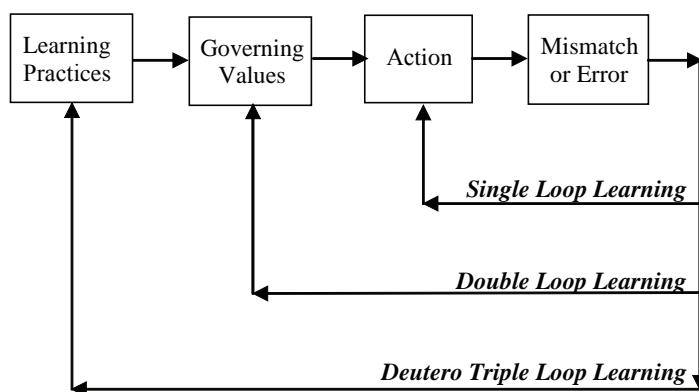

One of the key principles critical to decision-making is feedback. This suggests that at the core of making a decision lies knowledge and insights gained from past and current experiences which can affect significantly the kind of decision made, as well as the way decisions are reached. Beach (1990) supports this view in his 'Image Theory', showing how decision-related knowledge influences how a decision is made. Beach identifies three distinct but related images: the decision maker's values and principles (image 1); his/her goals and agenda (image 2); and his/her plans, tactics and forecasts (image 3) about what (s)he expects (s)he will accomplish from the decision. Therefore, one's mental models are not only restrictive of one's ability to make decisions they are also restrictive of one's ability to learn.

This reveals an intimate relationship between learning and decision-making. In the same way that learning is a necessary requirement for decision-making, decisions have to be made to create learning. This would seem to be at the core of what decision-making as a learning-based process could be all about — namely that decisions are possibilities that are shaped by the *purpose* they seek to address. This means that in the same way learning is contextual and situated, decision-making is particular and idiosyncratic to the actors (people and social dynamics between them) and structures (systems that define the boundaries of interaction between social actors, e.g., technology) involved with shaping the purpose of decision-making. Feedback mechanisms are critical in balancing the known with the unknown. Based on these principles the next section examines how ICT systems can be employed as feedback mechanisms capable of codifying knowledge and conducive to learning-supported decision processes.

ICTs for Supporting Learning-Based Decision Making

Despite the common perception of a decision support system as a particular tool, the widespread view is that “the term decision support system is an umbrella term to describe any and every

Figure 1. Three modes of learning

computerized system used to support decision making in an organization” (Turban & Aronson, 2001, p. 14). The concept has evolved from management information systems in the '60s and '70s through to expert systems and group decision support systems in the '80s to data warehouses, business intelligence tools and portals in the '90s (Power, 2002).

Our understanding of how such technologies are used in organizations has improved over the years. Researchers and practitioners developed frameworks that highlighted the behavioral aspects of decision support technologies and explored the information needs of decision makers (Simon, 1960; Gorry & Scott Morton, 1971; Davis, 1974; Sprague & Carlson 1982). A significant milestone came with the development of expert systems and artificial intelligence tools. These technologies enhanced the knowledge-based capabilities of decision aiding tools (Silverman, 1994).

While the users of traditional decision support systems are usually expert decision makers, the users of intelligent decision support systems that incorporate expert systems technology can be novices. They range from non-experts that need advice or training, to experts that seek the advice of an expert system to validate their own opinion. Only a small number of expert systems replace rather than support decision makers (Edwards, Duan, & Robins, 2000). In decision analysis applications, the intended users of intelligent tools include the facilitator, the actors, and the D.I.Y. users who directly interact with a decision-aiding tool (Belton & Hodgkin, 1999). Depending on their education, training, expertise, beliefs and experiences different decision makers reach decisions and apply actions to different levels of success (Turban & Aronson, 2001). As Marakas (2002) points out there is not currently a bandwidth limitation between a network and a computer but rather between a computer interface and the brain of a decision maker.

A new generation of decision support tools such as data warehouses and data mining was introduced in the '90s. Companies have implemented data warehouses and employed data mining and business intelligence tools to improve the effectiveness of knowledge-based decisions and gain competitive advantage (Heinrichs & Lim, 2003). Other primary decision support systems include OLAP (Online Analytical Processing) and Web-based decision support tools (Shim et al., 2002). Executive (or enterprise) information systems allow managers to drill down into data while offering highly interactive graphical displays (Bolloju, Khalifa, & Turban, 2002). Intelligent agents and strategic decision support systems support the formulation of strategy and improve organizational performance (Carneiro, 2001). Collaborative systems offer facilities ranging from supporting groups of decision makers to coordinating virtual teams (Shim et al., 2002). All these technologies can become available on the Web to reduce costs, allow easy access to information and therefore improve efficiency. In this context, ICTs such as intranets and extranets can be constructed to provide decision support (Power, 2002).

The preceding paragraphs show that decision support systems offer a diverse range of functionalities. They support decision making at different levels ranging from acquisition, checking and display of data to interactive evaluation and ranking of alternatives (French & Papamichail, 2003). The aim of this section is not to provide an exhaustive list of decision aiding tools but rather to illustrate how such technologies can be used to enhance learning in decision processes. Using the same classification of modes of learning given in the previous section, we discuss how different types of decision support systems support the three modes of decision-learning.

Single-loop decision-learning. A wide range of tools can be employed to facilitate the implementation of decisions through better knowledge and understanding of the decision context and content.

Learning-Supported Decision-Making

For example, databases and on-line sources offer easy access to explicit forms of decision-related data. Executive information systems and other business intelligence tools such as OLAP products and visualization packages, provide on-the-fly data analysis so that managers become aware of problems and monitor the implementation of their strategies. Expert systems support control activities such as monitoring, diagnosis, prescription and planning. Data mining techniques (e.g., artificial neural networks, genetic algorithms, rule induction, case-based reasoning) convert raw data into more meaningful and actionable forms of knowledge by finding patterns in historical data and learning from past examples (see for example Bose & Mahapatra, 2001).

Another technology that can facilitate learning through inferences from history is an experience database that contains decision problems or opportunities that ended in failure or success. Such databases can be coupled with case-based reasoning (Shaw, Subramaniam, Tan, & Welge, 2001) or rule-based system tools (Hunter, 2000) to facilitate the retrieval of cases or identify partial matches. Their main contribution is that they allow individuals to learn about past decisions, as well as respond to the challenges of the future without reinventing the wheel or repeating mistakes (Croasdell, 2001).

Single-loop technologies improve actions through access to repositories of explicit knowledge and better understanding of the decision problem. Even though they promise to improve the efficiency and effectiveness of decision-making, it is important to acknowledge their limitations. Walsham (2001) gives the account of the manager of a multinational company who described the intranet of his company as a large warehouse that nobody visits. Organizations need to give incentives and motivate individuals to access repositories and learn about new ICTs.

Double-loop decision-learning. A common decision rule that individuals adopt when they are unable to reach a decision is to get an expert

to explore the decision problem and provide them with a briefing (Janis, 1989). In such a setting, directories of experts or 'people finder' databases can be particularly useful. Eliciting expertise from one or more experts, however, requires interaction (Huber, 2001) and ICTs that support this include e-mail, online chat, mailing lists, newsgroups and on-line conferences.

If experts are not available, expertise is scarce in a domain, or there is the need to elicit and permanently archive the experiences of valued employees then 'lessons-learned' systems should be considered. They differ from experience databases that codify information about a decision problem because they capture expertise and meta-knowledge (e.g., the reasoning behind a decision and the company's agreed values and beliefs that justified a particular decision). Orr's (1990) ethnographic study of Xerox's maintenance engineers is an illustration of this point.

As decision makers are facing time and space challenges, computer-supported collaborative environments promise decision-making teams to perform tasks faster, more accurately, and with fewer resources (Maybury, 2001). They provide services such as workflow management and shared applications, as well as, a variety of facilities including text chat, audio-and video conferencing, shared whiteboard and shared and private data spaces. Such systems enable parallel or serial interpretations of data by experts who interact synchronously or asynchronously to extract, process and disseminate information to decision makers. However, these technologies are platform and software dependent, the users have to enter a specified online place and the group members are not always aware of other participants and their activities, which inhibits communication and group work (You & Pekkola, 2001). Therefore, collaborative environments have not been successful in decision environments that require negotiation and knowledge sharing (Walsham, 2001).

Knowledge that flows from different sources contributes to collective meanings (Croasdell, 2001). In large organizations, it is important to integrate knowledge sources and provide a knowledge map that binds the knowledge components together (Preece et al., 2001). Concept maps, semantic networks and frames (Liaw & Huang, 2002) can also overcome information overload problems.

Single-loop technologies make knowledge retrievable whereas double-loop technologies contribute to learning by making meta-knowledge and individuals with decision-making expertise accessible. Advanced collaborative support tools can increase decision-making interactions. The collective experiences of individuals provide background knowledge for understanding decision-making processes, policies, culture, and practices, and could therefore improve the effectiveness of decision making (Croasdell, 2001).

Deutero decision-learning. Communicating knowledge through an electronic medium does not necessarily improve human communication and action (Walsham, 2001). Online data and knowledge repositories, e-mail messages and newsgroup archives cannot always codify the deep tacit knowledge that is needed for decision-making. Most companies are starting to realize that leveraging knowledge through ICTs is not always attainable (McDermott, 1999). Face-to-face interactions that allow participants to give and take meaning by interpreting a range of verbal messages and nonverbal clues, as well as mentor relationships between new and experienced recruits can enhance the continual inter-subjective communication between decision makers (Walsham, 2001). Electronic media such as video conferencing and on-line chat can be used to create virtual teams and eliminate the need for some expensive face-to-face meetings (Maznevski & Chudoba, 2000). Virtual teams however, cannot outperform face-to-face teams in terms of communication effectiveness and their members report lower levels of satisfaction compared to

face-to-face team members (Warkentin, Sayeed, & Hightower, 1997).

Reaching a consensus in a group of decision makers is often difficult to achieve. Individuals have to convey their thoughts, understand the viewpoints of their colleagues, and interpret other people's mental models. Thus, it can be argued that decision-making is the result of a learning process in which a community of people develops a common language, deals with a context-specific issue, and has a specific purpose and reasons about actions. Organizations ought to acknowledge, support and nurture these 'communities of practice' that encourage knowledge sharing, learning, and change (Walsham, 2001; Wenger & Snyder, 2000). Participants of communities of decision-making practice will share ideas, experiences, and know-how, and will adopt innovative and creative approaches to problem-solving and decision-making. This can prove to be an effective way of sharing deep decision-making knowledge.

From this overview, it is evident that there are a number of well-established ICT tools and approaches that support decision-making by facilitating knowledge transfer and feedback. Therefore, ICTs could potentially play a vital part in stimulating and supporting feedback mechanisms between actors and structures affecting decision-making and learning. Their fundamental contribution perhaps lies less in the codified knowledge they can transfer and more in the momentum they can create so that awareness of learning opportunities can be acknowledged and integrated in the decision-making process. Moreover, ICTs can be a valuable mechanism for capturing and extending the current organizational discourse (Grant, Keenoy, & Oswick, 1998). These points are central to the socio-technical framework of learning-supported decision processes discussed next which emphasizes feedback systems as the social structures that support knowledge flow in organizations.

A SOCIO-TECHNICAL FRAMEWORK FOR SUPPORTING LEARNING-BASED DECISION MAKING

As evident from the review of the three learning modes, the nature of feedback is shaped in relation to the problem-driven approach to learning. Equally it is noticeable that many of the decision-making models are also problem-driven. An example would be Simon's (1960) behavioral model, which is based on the principle of 'bounded rationality' and assumes that decision makers try to be rational, but their rationality is bounded partly by their representation of the decision problem (Barthélemy, Bisdorff, & Coppin, 2002). Sprague and Carlson (1982) have enhanced Simon's model by adding a previously implied 'Implementation' step. This is the final stage of the decision process where the decision makers implement their chosen alternative by taking action, and monitoring performance and effectiveness. If there is a mismatch between reality and a desired state, and the outcome of the action taken does not meet expectations, then the decision process or a part of it is repeated.

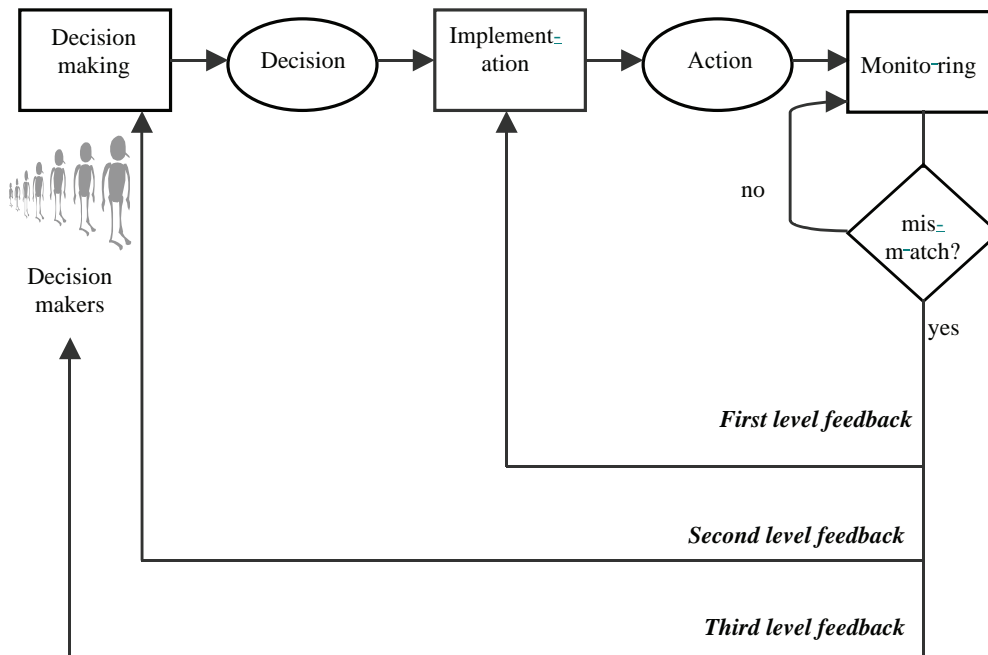

Therefore, the relationship between learning and decision-making reflects that they share a common structure in the way both assume the process of learning and decision-making takes place. This structure tends to be seen predominantly as linear underpinned by feedback mechanisms, which provide a cyclical approach to the way learning and decision-making unfold. The decision-learning model discussed in the previous section however, also shows that feedback mechanisms are dynamic and complex and not simply technological tools (in the various DSS solutions) which act as information depositories. In developing a socio-technical framework of learning-supported decision-making, it is important to capture the dynamic nature of feedback systems

reflecting both the way ICT systems are part of the social structure which allows information to progress from meaningless data to meaningful knowledge and from knowledge to insightful learning. We seek to capture these points in the three levels of feedback, which we argue underpin the socio-technical framework of decision-learning. Figure 2 presents the three levels of feedback diagrammatically.

First-Level Feedback

This first level of feedback reflects a mode of decision-making geared towards implementing a solution to a perceived problem supported predominantly by single-loop learning. By virtue of this rather basic process of decision learning, the role of feedback systems is to extract, process and disseminate basic available *information* to develop an understanding of the perceived problem so that the best possible solution can be reached. While this level of feedback may appear rather simplistic in essence it may well be that the nature of the issue at hand requires only a basic processing of the information at hand. The typical ICT systems that can be used to facilitate this process include data marts, data warehouses, knowledge repositories, OLAP products and executive information systems. Such decision support systems assemble flows of knowledge from different sources and assist decision makers in making sense of the relevance and significance of information to a particular decision problem. Essentially, these ICT systems would be part and parcel of the existing information structure which would reduce decision times and costs to detect and correct problems in a routine setting. Their capability to extract, process and disseminate information is vital in facilitating learning in organizations (Harvey, Palmer, & Speier, 1998) and can be further enhanced using artificial intelligence techniques (Bhatt & Zaveri, 2002).

Figure 2. A socio-technical framework for supporting learning-based decision making

Second-Level Feedback

The mode of decision making at the second level of feedback extends the focus well beyond the decision itself and seeks to explore the decision-making process itself. This implies that decision-makers are concerned to improve not only the decisions they make but the way they take their decisions. Essentially therefore, the focus is to critically reflect on the implicit assumptions that underpin the current decision-making structures and through this process seek to develop new understanding. The double-loop learning process that underpins the focus of decision-making provides a useful feedback platform to translate available information into valuable *knowledge* which feeds back to current decision-making practices critical insights into the values and perceptions which underpin them. Fundamentally, second level feedback to some extent disrupts social structures that support decision-making and learning by bringing to the forth greater awareness of the

actual process of learning and taking decisions. This very approach of looking critically at the way a process takes place can be greatly supported by ICT systems which have the capacity to overcome the inherent subjectivity embedded in learning and decision practices. For example, collaborative support tools (Maybury, 2001) can be used to facilitate interactions with expert decision makers who can provide insight into the content, context and process of decision making. Architectures of decision support systems that codify problem solving strategies in new entities called model marts and model warehouses have recently been introduced (Bolloju et al., 2002). Emerging technologies such as virtual reality could be used to represent experiential rather than formal forms of knowledge (Beynon, Rasmequan, & Russ, 2002). Therefore, second-level feedback encodes rich experiences and expertise, improves the efficiency of decision-making, and contributes to identity formation by reflecting on the meanings decisions made create and not just on the meanings that shape decision-making.

Third-Level Feedback

The third level of feedback, essentially embraces learning as central to both the decision-making and learning process. In other words, it extends the focus of decision-making and learning on the people performing this process by virtue of their actions not just assumptions. Consequently, the focus of decision-making would be reflecting on the process of learning to take decisions rather than the decision-making process itself. This also would extend to the approach to learning which would also be concerned with learning how to learn (Bateson, 1972). The feedback systems therefore, would be concerned with reflecting the social structures that support learning to learn using ICT systems that provide mechanisms for capturing and supporting the learning process. Even though ICTs that enhance discourse and communication can facilitate learning (Robey, Boudreau, & Rose, 2000), they cannot always substitute the importance of face-to-face meetings and informal communication. However, decision practices have changed in the recent years and organizations are now forced to support geographically dispersed teams of decision makers. ICTs such as videoconferencing and group support systems allow the exchange of social cues—in the case of text-based tools the cues are known as ‘smileys’ or ‘emoticons’—and in doing so facilitate and enrich communication (Shim et al., 2002). Such ICTs therefore, could be embedded in the organizational discourse and facilitate communicational exchanges by addressing linguistic interpretations, cognitive representations and reciprocal learning (Barthélemy et al., 2002). The main characteristics of the three feedback levels are summarized in Table 2.

Therefore, it would be idealistic to suggest that learning-supported decision-making would be reflected through deuterio learning, supported by deuterio decision-learning (in the use of ICTs) in an approach that facilitates decision-making based on feedback level three. The socio-techni-

cal framework of decision-making needs to be based on a balanced approach between social systems and technical structures so that different feedback levels can be effectively integrated to support different stages in the decision-making and learning process. ICT systems can form the backbone of different levels of feedback in capturing the dominant discourse and its associated social structures. This point suggests that the socio-technical framework relies on the homogeneity within the heterogeneity of decision-makers which is never settled or fixed but constantly in progress as multiple perspectives given and perspectives taken are negotiated as part of the emerging organizational discourse.

FUTURE TRENDS

The biggest challenge for any organization is managing the disperse nature of knowledge across a diverse set of knowledge carriers. The role of ICTs in supporting and extending the organizational memory is of particular concern. The proposed socio-technical framework discussed in this chapter seeks to address the above concerns by promoting learning both as central to decision-making but also as one of its purposes. At the core of the proposed framework lies the need to seek feedback systems as the point of connection between the way social structures shape the information available into meaningful knowledge and the way ICT systems manage the available information in ways that this is fed to users in a timely fashion and in an actionable form.

The use of ICTs to support knowledge management initiatives can only be of benefit, when the main focus is on supporting the development and communication of human meaning (Edwards, 2001). The challenge is to build tools that recognize the sense-reading (i.e., intelligent interpretation and understanding) and sense-giving (i.e., account of one’s experience) nature of the decision-making activities (Walsham, 2001),

Table 2. The characteristics of three levels of feedback

<i>Feedback level</i>	<i>First Level</i>	<i>Second Level</i>	<i>Third Level</i>
<i>Source of feedback</i>	Knowledge repositories, search engines	Lessons-learned systems, experts	Communities of practice
<i>Type of feedback</i>	Passive	Active	Organic
<i>Attitude of decision maker</i>	Reactive	Reactive/Proactive	Proactive
<i>View of decision making</i>	Atomistic	Group	Social
<i>Focus</i>	Decision content, context, process	Values and assumptions	Decision-making capabilities
<i>Tactic</i>	Make knowledge easily retrievable	Make meta-knowledge and experts easily accessible	Set up and nurture communities of practice
<i>Purpose</i>	Improve decision-making efficiency and effectiveness	Improve decision quality	Improve decision-making capabilities

and address the complexities of the interconnected and knowledge-intensive decision processes of the future (Courtney, 2001).

Therefore, future research that seeks to support learning-based decision-making, needs to address systematically these issues and identify mechanisms that can support the development of learning communities for decision practice. As the socio-technical framework to decision-learning propounds, there is a need to balance personal and collective priorities in relation to learning and decision-making, thus maintaining the critical balance of their situated, contextual and emergent nature (Antonacopoulou, 1999).

Clearly we do acknowledge that in this chapter we lay only the foundations of the socio-technical framework of decision-learning and there is clearly a lot more work that needs to be done to overcome the inherent limitation of the current representation of the feedback systems which does not fully capture the dynamism that emphatically underpins the socio-technical approach that

ICT systems can support. Notwithstanding the limits of representation (at least diagrammatic representation), we feel confident that this framework makes a valuable contribution in extending debates of learning, decision-making and their relationship demonstrating the inherent challenges of the digital era in using ICTs as social as much as technical tools.

CONCLUSION

This chapter contributes to our understanding of the challenges the digital era presents us by proposing a socio-technical framework, which emphasizes feedback as the critical link connecting social systems and technical structures intended to support the transformation of information into actionable knowledge supported by meaningful learning strategies. The analysis presented explored the social life of information in the context of decisions and with an emphasis on the role

of ICTs as key feedback systems supporting a learning-based approach to decision-making. In proposing a learning-supported view of decision-making, the discussion identified some of the key principles of the socio-technical framework. The main thrust of the framework is the alignment of social structures and social actors in ways that seek to integrate different modes of learning with different models of decision-making. This integration is to be supported by a range of decision-learning structures (in ICT systems), which create different feedback levels. These combined, have a bearing on the alignment between decision actions in relation to what, how and why one learns. This alignment however, is acknowledged to be fraudulent, with a number of challenges not the least of which is how one learns to balance personal and collective learning priorities.

ACKNOWLEDGMENT

We would like to thank the members of the GNO-SIS Research Group for their valuable discussions. Special thanks are due to Prof. Simon French and two anonymous referees for their comments on earlier drafts of this chapter.

Chapter 2.37

Reframing Information System Design as Learning Across Communities of Practice

Kevin Gallagher

Florida State University, USA

Robert M. Mason

University of Washington, USA

ABSTRACT

This article frames the requirements definition phase of systems design as a problem of knowledge transfer and learning between two communities of practice: IS designers and system users. The theoretical basis for the proposed approach is Wenger's (1998) framework for social learning, which involves three dimensions: alignment, imagination, and engagement. The article treats the requirements definition task in systems design as a set of activities involving mutual learning and knowledge transfer between two communities of practice (CoP) along these three dimensions. In taking this approach, the article maps the results of past research on the systems design process onto this CoP framework and illustrates that the proposed framework encompasses the same activities used by traditional methods of require-

ments definition. However, this approach focuses attention on the learning that must take place between the two CoPs and thereby helps resolve some of the inherent shortcomings of prior efforts and approaches. The framework provides both a more encompassing conceptual lens for research on improving the requirements definition task and practical guidance for managers who are charged with a systems design project.

INTRODUCTION

Requirements definition is a critical step in systems development that requires the identification of information needs and knowledge of a system's processes (Nelson & Coopriider, 1996; Vessey, 1994). Historically, researchers examined the requirements-definition stage of system design

as a process of inquiry (Boland, 1978; Salaway, 1987). Problems with identification, articulation, and communication of information needs have long been identified with the challenges of information system design (Boland, 1987). There have been different approaches in attempting to meet these challenges, but none has completely resolved the issues.

Land (1998) notes that because systems are so different, a contingency approach—using different methods for different types of systems—is appropriate. Others have suggested more structured analyses of the design process itself, establishing metrics for requirements engineering (Costello & Liu, 1995) and developing tools for each aspect of the problem (Nature_Team, 1996). Some researchers have suggested that the process of design must remain flexible and that a management structure that encourages an evolutionary design process is associated with greater effectiveness (Ravichandran & Rai, 2000). In considering software project risk and software quality, organizational issues as well as technical issues are important (Wallace, Keil & Rai, 2004). Others also emphasize the critical nature of human-intensive dimensions of the process (Tamai, 1993). It also has been noted that evolutionary designs are necessary as complexity increases (Mens & Eden, 2005). Larman (2004) argues that an “agile” and iterative design process is key to software development success.

The approach that we want to explore in this article emphasizes these human-intensive dimensions of the design process. Although the design process involves many actors (Lamb, 2003), we want to focus on two roles: the designer (who has technical knowledge) and the user (who has knowledge of the application and context of use). The conceptual approach is one that considers requirements definition as an instance of knowledge acquisition (Byrd, Cossick & Zmud, 1992).

Recently, organizations and researchers have begun investigating the potential of knowledge transfer (Alavi & Leidner, 2001) to make organiza-

tions more effective when engaging in information intensive work. Such knowledge transfer is necessary because clients are not sure what is possible and are unclear about their needs, and IT designers thus are unable to work toward an outcome that meets clear specifications (as in designing a product for production) (Larman, 2004).

To date, however, conceptualizations of knowledge transfer in software development do not completely capture the complexity and richness of this process by which clients and designers work together. As Polanyi (1966, p. 4) says, “We know more than we can tell.” Regardless of how well we articulate knowledge, it always contains a tacit dimension. Hence, simple inquiry is insufficient for the requirements definition process because it is able to access only explicit, leaky knowledge (Von Hippel, 1994). The information transferred through traditional elicitation approaches is only part of what someone knows, and it rarely includes *how* or *why* they know it (Lanzara & Mathiassen, 1985).

Because of the tacit dimension of knowledge involved in most tasks and processes, it is difficult, if not impossible, for people to articulate exactly what it is that they need prior to design. Even if they can articulate what they need, the system development effort is hampered if the system developers do not understand why and how users need what they need. With an understanding of the why’s and how’s of information, developers can be more innovative in their delivery of requirements. For example, unless developers understand which information is used together and how it is connected, they will be unlikely to find ways to combine and simplify tasks.

If we keep the traditional concept of inquiry as the basis for eliciting requirements, the effort must always be incomplete. The language or metaphor of “inquiry” or “capturing requirements” is part of the problem. The choice of metaphor can inhibit the range of approaches to information systems (Mason, 1991), and recently the metaphor of “engineering” has been questioned as the basis

for approaching software development (Bryant, 2000).

What is needed is an approach that engages users in such a way that they can elucidate not only what they know, but also how and why they know it. In addition, users must learn about how systems in general, and this system in particular, will be developed. An improvement over current approaches is to engage designers so that they really understand what the users are telling them, and to ensure that they effectively share their knowledge of both the systems and the processes for which they are developing technology (Boland, 1978). To accomplish this, both users and developers must share their knowledge and learn from each other (Boland, 1978; Churchman & Schainblatt, 1966). In short, what is needed is a process of mutual learning in which designers and users engage in a process of learning from each other.

In order to work toward such a process, we turn to the concept of a community of practice (Lave & Wenger, 1991). The concept, first used to help understand situated learning, refers to a group of people defined by an interest in a specific subject or problem who collaborate to share ideas and resolve issues common to the group. In this article, we posit that information system (IS) designers and IS users belong to two distinct communities of practice (CoPs) as they work together in a systems development context. The system designers comprise one community and the users for which the system is being designed comprise the other (Churchman & Schainblatt, 1965). The term “users” may cover many roles, including managerial, and in the following we may use “managers” to provide a specific context for the discussion or simply say “users” for the generic situation. The requirements definition phase of IS design requires that these two groups engage in mutual learning both to share knowledge and to develop new mutual understandings of the possibilities as a system design emerges. The knowing of managers (or other users) is formed

by a very different practice than the knowing of IT professionals (Brown & Duguid, 2001), resulting in different ways of knowing (Boland & Tenkasi, 1995). Knowing is not easily shared across these two groups because of their different histories and perspectives.

The article extends Wenger’s (1998) design for social learning within a CoP (p. 236) to learning across two communities of practice. Wenger’s model comprises three dimensions: alignment, engagement, and imagination. We apply this framework of social learning across the two CoPs (i.e., managers and designers) and show that the framework not only is consistent with prior research on the information system design (ISD) process but also suggestive of how the design process can become more effective.

The remainder of the article comprises three sections. The next section, Social Learning, reviews the concept of social learning and distinguishes it from simple knowledge transfer. This section further illustrates why the characteristics of social learning are the characteristics required for an effective requirements definition process.

The subsequent section presents an architecture for social learning. It reviews the three dimensions of Wenger’s model for social learning in a community of practice and notes that factors considered essential to the requirements definition phase of the system development process can be mapped onto these dimensions.

The final section summarizes the application of the model for information system design, outlines issues in implementing the architecture, and discusses the implications for research and practice.

SOCIAL LEARNING

Knowledge and Knowing

Viewed from a social learning perspective, knowledge is social, not individual (Brown,

2002), and is a matter of our competence with respect to some valued enterprise (Wenger, 1998). Knowledge encompasses aspects of experience, action, and the accomplishment of some activity. In this perspective, knowledge is more than stored information, even more than codified and structured information.

It is helpful to distinguish “knowing” from “knowledge.” In common usage, “knowledge” brings with it the context of an accumulation of facts and “know what.” On the other hand, use of the term “knowing” conveys more of a sense of engagement in a process of learning and becoming. Knowing is not only an accumulation of facts, but an accumulation and assimilation of experiences and learning that alter who we are as well as what we know. As we learn *about*, we also learn *to be* (Brown & Duguid, 2001). Levels of participation or nonparticipation reveal a sense of relation, familiarity, and belonging to the situation. These aspects of identity development affect one’s modes of involvement and willingness to engage in activities. The attributes of identity are developed, and reciprocally supported, through the process of learning.

We are constantly engaged in accomplishing activities and we typically become more proficient with experience. Our knowing, therefore, resides in our practice (Cook & Brown, 1999), which is how we accumulate experience and situated ways of knowing. Participation is our “knowing in action,” so a design processes can benefit from participation by those who know the existing process.

Apprenticeship and Communities of Practice

Communities of practice provide a theoretical framework for understanding how the dynamics of social structures influence learning and practice. The origins of communities of practice are grounded in apprenticeship and their ability to support situated learning through social coparticipation

(Hanks, 1991; Wenger, 1998). Understanding how apprenticeship promotes learning within a community can help in understanding how learning can occur across communities. Learning through practice is exemplified in apprenticeship, whereby a community regenerates itself through a process of participation and training. When the transfer of explicit knowledge is supported by sharing the practices in which it makes sense, it is possible to *understand* its meaning in a way that makes it most useful, actionable, and purposeful.

Participation is the key to developing and sustaining communities of practice, but observation also plays a critical role by allowing one to participate on the periphery of a community. While the master remains engaged in the craft, the apprentice learns by means of “legitimate peripheral participation” (Lave & Wenger, 1991), observing the practices and developing the tacit dimension of knowing. By engaging in practice, the master is able to communicate more than what can be said and the apprentice is able to learn more than what can be heard.

The roles of a community’s members are not rigidly defined; however, a key to apprenticeship is that members can engage in varying roles simultaneously. Legitimate peripheral participation supports learning without requiring members to acquire all of the necessary knowledge for full membership in that community. In this way, a member can span the boundary of a community and still be able to observe, understand, and learn. Participation and observation (nonparticipation) together define our levels of engagement as we employ these modes of engagement in attaining knowledge of our own communities and other communities from which we may learn.

To participate on the periphery allows one access to a community through passive modes of observation and similar activities that do not overly dominate or eliminate participation altogether. This is exemplified by active listening. Conversely, marginality is a mode of nonparticipation that stifles participation, as exemplified

by listening in on a conversation in which the terminology is foreign. In both cases, there is exposure to a community of new information. The first situation offers a mode of nonparticipation that facilitates learning. In the second, the learning becomes stifled.

Apprenticeship is offered here as the starting point of a model to use when designing a way for two communities to come together, share knowledge, and learn. In the case of requirements definition, it may be enlightening to consider the IT professionals to be apprentices to the user community (Beyer & Goltzblatt, 1995) and the users to be apprentices to the IT community. Through apprenticeship, the participants learn about practice. To make “know that” useful requires appropriate “know how” that we can only gain through practice in both senses of the word: to do and to improve (Brown & Duguid, 2001). The need to involve users in system design has been a long held belief for requirements definition; however, involving IT in the practices of the users is less established, but has the potential to be quite revealing.

Knowing as a Challenge for IS Design

The challenge for IS design is to enable participation by both users and designers in a process that both conveys knowledge and enables knowing. In any social process, our experience informs our knowing, but the structure of the relevant social arrangement orients and guides our experiences. We develop personal histories from experience, and, through practice, we negotiate and form the meanings we give to things. Identity is how we see our role in the process that then influences our level of engagement.

Both users and designers must be engaged in the process of knowing about the other’s needs and the opportunities afforded by alternative designs. Engagement is a social process, one not naturally emerging nor easily brought about by fiat.

Prior researchers have acknowledged the social aspects of information system design. For example, political arrangements in organizations and dynamics of relative power among design participants can influence the degree to which they feel safe participating in activities (Hayes & Walsham, 2001). Others have noted the importance of the relationship between users and designers in the design process (Beath & Orlikowski, 1994; Hirschheim & Klein, 1994; Ives & Olsen, 1984). Mutual learning can only take place when users and designers are able to engage in effective modes of participation when they are involved in requirements definition activities. Through appropriate modes of participation, requirements are informed both by what the participants know and by how and why they know it

What we want to accomplish in the IS design process is to enable both designers and users to engage in a learning process that enables safe but effective participation in the design activities. The apprenticeship model of social learning in a community of practice, coupled with Wenger’s (1998) architecture for social learning (p. 237), provides a model for such a process.

AN ARCHITECTURE FOR SOCIAL LEARNING

Processes of social engagement differ in their ability to support learning. Figure 1 illustrates Wenger’s (1998) architecture for social learning in a community of practice, showing arrangements for alignment, imagination, and engagement. When engaged in practices across communities, the support of such social arrangements can facilitate a sense of belonging for members that helps to ensure participation and learning. Collectively, the three dimensions enable members of the community to learn with each other. The architecture provides a framework for considering the requirements of the process of IS design, particularly the requirements definition phase of this process.

The three dimensions are interdependent and, in fact, have inherent tensions among them. For example, a structure that assures close coordination for alignment can inhibit imagination and engagement. Conversely, imagination without alignment can result in activities that do not contribute to the overall learning process.

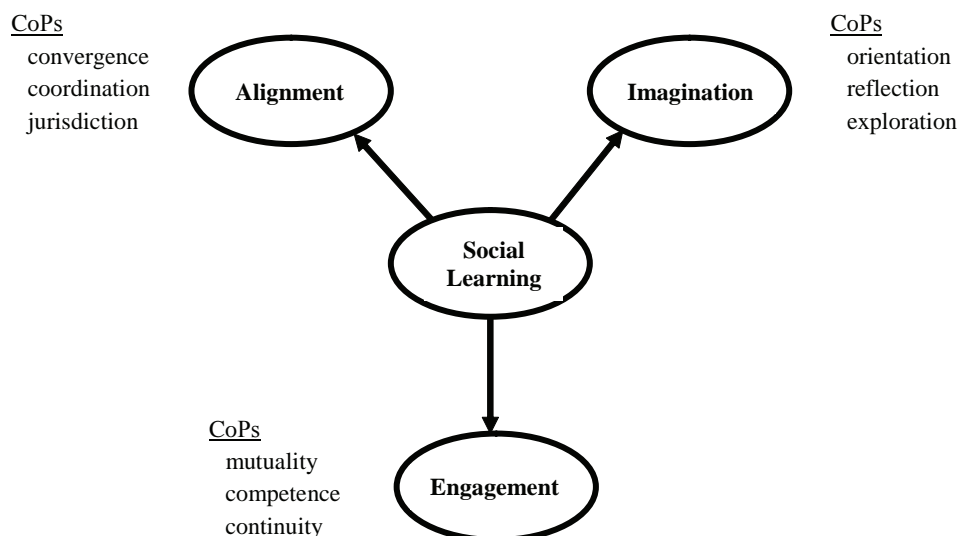

Alignment ensures coordination of the community's activities and resources toward achieving an objective. In the case of system design, this means achieving a fit between the local needs of a business unit and the new design. Learning is important to such a practice, as working through the development of a design raises new questions from which participants can learn about the existing system (Kyng & Morten, 1995). However, there are many ways to establish a fit during design, some of which may inhibit future flexibility (Allen & Boynton, 1991) and lead to rapid obsolescence or an inability to adapt. Alignment alone is not enough to support learning. A community of practice, and perhaps more importantly, the interaction between two communities, must also support what Wenger labels *imagination*.

In Wenger's terms, imagination provides the opportunity to create new possibilities. The ben-

efits of creativity and innovation in the development of systems are well established in the field of information systems (Cougar, 1996). However, creativity without the appropriate information as to the possibilities and constraints of a design or an appropriate vision of the future may lead to poor implementation (Zmud & Apple, 1992). Therefore, a process of mutual adaptation is necessary to achieve an improved design and a successful implementation (Leonard-Barton, 1993). Mutual adaptation can be viewed as an accommodation of both alignment and imagination that can be accomplished through learning.

The third dimension of Wenger's design, the concept of *engagement*, represents active involvement in the negotiation of meaning during the learning process. Engagement requires appropriate modes of participation. Appropriate modes of engagement by participants can ensure a balance between alignment and imagination. By supporting participants' engagement in a social process, it becomes far more difficult for any one set of perspectives or goals to dominate the process. However, engagement is difficult to ensure. Psychologically, individuals must feel it is safe for them to engage in an activity, that it

Figure 1. Wenger's architecture for social learning

will be a meaningful investment, and that the personal and professional resources that are necessary for participation are available to them (Kahn, 1990).

In the apprenticeship model of learning, engagement in practice by the bearers of knowledge will assist in their grasping, articulating, and transferring knowledge to others. Furthermore, peripheral participation by those who are in apprenticeship roles facilitates their ability to appropriate the meanings conveyed in specifications by those engaging in the design process. In sum, engaging in the practice of design can help us to understand and transfer what we know.

The challenge in employing Wenger's design for learning in the IS design process is balancing the tensions inherent in each of the three dimensions (See Figure 2 below.). Traditionally, IT departments have been concerned with alignment. They feel a need to align themselves with business strategy, with user functions, with business processes, and with organizational objectives (Chan, Huff, Barclay & Copeland, 1997; Reich & Benbasat, 1996). They have perceived standardization of systems and control over the design process as the key to alignment (Kirsch, 1996). However, with excessive alignment, imagination is curtailed and success becomes elusive (Baskerville & Stage, 1996). Excessive imagination and creativity, on the other hand, can lead to idiosyncratic designs and unworkable heterogeneity, reducing the ability to share, diffuse innovations, and efficiently develop new systems.

The quest for alignment makes its necessary for IT and users to work together. Yet, mutual engagement in these activities is in direct tension with the development of functional expertise within the organization. It also raises organizational tensions around leadership and decision making, between working together and understanding who has jurisdiction. As many IT scholars have claimed, partnership is key to IS success (Henderson, 1990). Partnership addresses the tension between conflicting power bases in the organization, but a

successful design environment must also address the tension between imagination and alignment. Wenger's design for learning recognizes the need to balance these tensions in the design of a learning environment that will support the appropriate modes of engagement and thereby facilitate and balance the tension between alignment and imagination.

The information system design (ISD) literature is consistent with this three-dimensional framework of learning in a community of practice. The literature on use of methods and controls is consistent with Wenger's dimension of alignment. The need for imagination during system design is supported by the ISD research on learning by doing, performed through modeling and prototyping. Research on user participation and involvement supports the need for engagement.

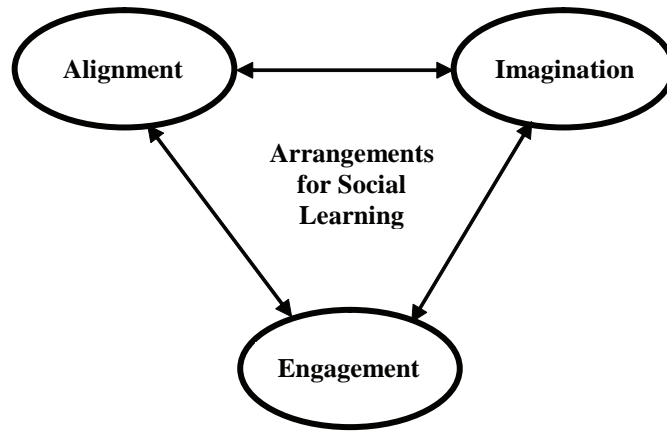

The next section discusses the commonalities between Wenger's framework and the ISD literature, explains further the facilities used to implement the model, and highlights the challenges of applying the principles and balancing the tensions in the ISD setting.

Alignment

In Wenger's model (Figure 1), alignment is comprised of three facilities: *convergence* provides a common focus; *coordination* provides methods and procedure; and *jurisdiction* provides policies and procedures. Similar themes are found in the IS literature, which describes the need to pursue objectives, employ standard methods, and control the design process.

Objectives are defined based on user needs and the possibilities the system affords, negotiated through a social process of mutual adaptation (Leonard-Barton, 1993). Through methods, activities are organized to achieve these objectives. Yet, methods often give primacy to designers over users (Beath & Orlikowski, 1994) or to problem solving over alternative rationalities (Boland, 1979). Thus, formalizing methods serves to structure

Figure 2. Wenger's architecture for social learning adapted for requirements determination

activities, thereby imposing controls that promote and suppress certain behaviors.

The IS design process requires more than obedience to method, it must also be a reflective activity (Iivari, 1987). System design requires iterative and adaptive planning as the acquired experience and learning from each sub phase informs the ongoing effort (Iivari, 1987). Thus, development efforts must recognize the need to balance iterative development with complimentary methods of control.

Control is complicated by the fact that coordination and communication necessary to complete the tasks spans organizational departments (Kirsch, 1997). A complex relationship exists between efficiency and quality. Different strategies of control lend themselves to different situations. Informal methods of control are used when understanding of the process and outcome measures are inexact (Ouchi, 1979) and depend on social strategies (Eisenhardt, 1985). Self-control relies on the motivation of individuals, and in IS it is strongest among personnel who take part in defining work procedures (Kirsch & Cummings, 1996).

Clan is another informal control characterizing a group that is dependent on one another to achieve a common objective (Ouchi, 1980). Boland (1979) distinguishes "control over" from "control with"

in order to distinguish bureaucratic processes from those where shared values and beliefs serve as the basis for coordinated action. Through appropriate selection of members and use of appropriate training and socialization processes, individuals in a group can develop a stronger sense of identity and commitment (Kirsch, 1996). Appropriate activities serve as rituals to reinforce acceptable behaviors. The development of identity and commitment are equally vital components in apprenticeship, where methods of training and socialization are employed to facilitate learning directed toward achieving objectives. In the end, certain modes of control, especially in excess, can have a negative impact on both engagement and imagination.

Imagination

Imagination is comprised of three facilities (Wenger, 1998): *orientation* provides a location relative to the organization; *reflection* provides facilities for comparison and evaluation; and *exploration* provides opportunities for envisioning, creating and testing new ideas. Again, similar themes are found in the IS literature that emphasize a need to understand situational context and explore possibilities through processes that support discovery and innovation.

Systems requirements are the first step in defining possibilities for new information technologies. As previously noted, the development of system requirements is often conducted through inquiry and other elicitation methods, intended to identify user needs. Yet, this step is highly prone to unintended influence through bias and error (Salaway, 1987). In addition, interviewing can close down inquiry, if motivated to solve problems rather than explore the appropriateness of different possibilities for an organizational situation (Boland, 1979).

Another method of elicitation is the use of design tools, such as computer assisted software engineering (CASE) or use cases, which help users describe the organizational situations in which they are involved and convey what they know (Lanzara & Mathiassen, 1985). Such tools help users move from the current situation to the enactment of a new one (Lanzara & Mathiassen, 1985). For instance, redirecting the attention away from the existing system and refocusing on a new realm of possibilities (Wastell, 1999) is one such example. To reframe a situation leads to a discovery of possibilities.

Drawing on theories of action, Lanzara and Mathiassen (1985) are critical of most existing tools. They suggest that better tools are needed to bring the “background into the foreground” by offering ways to make procedure more explicit, thereby relating descriptions to the actual settings. This advances a user’s opportunity to question the appropriateness of existing solutions, challenge their adequacy, and take more responsibility for initiating a more positive action.

Similarly, prototyping enables a common reference point for users and developer, which helps to develop a mutual understanding and draw out and refine user requirements (Alavi, 1984). Reifying what is known helps to reveal what is not fully understood and offers alternative active techniques for articulating and defining existing situations that allow the designs and users to engage in a social process of simultaneous definition, design, and discovery.

To summarize, there is great support in the IS literature for imagination in the design process. There also is great concern regarding the mutual understanding of context among users and designers, which is necessary to define the present situation and to inform an effective process of discovering new possibilities. Furthermore, the tools we have available are limited in their ability to support and encourage these activities. Tools alone are not sufficient without the social and human elements that can encourage and inform their use; engagement provides these elements.

Engagement

Engagement is facilitated by *mutuality* though: reciprocity and interdependence, which provides opportunities to form and share perspectives; *competence*, which supports the occasion for applying knowledge and exercising judgment; and *continuity*, which supports mechanisms of memory, which work as repositories for information created through social encounters. Similarly, IS research has found that the design process and subsequent adoption of a technology benefit from user involvement, which enhances confidence and acceptance of the technology (Hartwick & Barki, 1994; Ives & Olsen, 1984).

Including users in the design process involves more than their presence, however; it also requires overcoming conflicts of interest and effects of authority (Mumford, 1983, p. 31). Often users are given relatively passive roles, despite being required to sign off on requirements (Beath & Orlikowski, 1994). As a result, patterns of user participation vary according to who controls the selection of features and the coordination of activities (Kirsch & Beath, 1996). Participation, therefore, is often token or compliant, rather than shared.

The participative design (PD) movement highlights empowerment of users as important in their ability to influence the overall design process (Hirschheim & Klien, 1994). Joint application

design (JAD) is designed to actively engage users and designers in activities, often away from their usual work settings and organizational roles, recognizing the importance that altering structures has on the dynamics of a design process.

One way that JAD involves users is through modeling and prototyping. Models support the development of shared understanding between users and developers, thereby building confidence in what is established as knowledge during inquiry. Prototypes serve to cultivate user participation and help build credibility and establish good working relations.

As with alignment and imagination, there is great support in the IS literature for engagement as a key component of RD success, but there is concern about our ability to successfully nurture it. The following section discusses the results from several researchers who have provided insight into approaches and tools that may help to overcome some of the most frequently encountered impediments to successful alignment, imagination, and engagement in the RD and ISD processes.

Summary: Designing an ISD Process for Social Learning

Table 1 illustrates the parallels between Wenger’s model of social learning, an apprenticeship model,

and the factors judged important to successful design from the ISD literature. What remains is the construction of social learning processes that enable a project to implement and balance these factors.

Designing Structures for Social Learning

The social process of ISD, whereby users and developers collectively define requirements, is complicated in that participants may differ in their backgrounds, cognitive styles, personality, job characteristics, organizational circumstances, affiliations, or location (Robey & Markus, 1984). As one might expect, this leads to differing interpretation, confrontation, and misunderstanding.

A major concern, therefore, is that the discourse required for an effective process of inquiry is distorted in traditional organizational structures. Altering the structure of a design process through choices regarding the number of participants, the activities conducted, and the role of users and designers can offer greater opportunity for users to raise issues, question the appropriateness of choices, make and demand commitments, and express attitudes and concerns (Hirschheim & Klien, 1994).

Table 1. Correspondence between Wenger’s model and information system design literature

Dimension	Community of Practice	ISD Literature
Alignment	<ul style="list-style-type: none"> • convergence • coordination • jurisdiction 	<ul style="list-style-type: none"> • objectives • methodology • control
Imagination	<ul style="list-style-type: none"> • orientation • reflection • exploration 	<ul style="list-style-type: none"> • context • possibilities • discovery
Engagement	<ul style="list-style-type: none"> • mutuality • competence • continuity 	<ul style="list-style-type: none"> • participation • self efficacy • joint tasks

Nonaka and Takeuchi (1995) show that through organizational design actions enacted through structured mechanisms, knowledge creation is facilitated. Churchman and Schainblatt (1965) note that researchers and managers viewed problem-solving differently and propose a dialectic approach to manager-researcher communication. Boland (1979) found that structuring problem-solving processes in ways that are enabled by differing rationales encouraged participants to share their knowledge and arrive at different types of solutions. Different processes for understanding and applying knowledge are influenced by the controls placed over the process of user-designer interaction.

Altering the structures of user-designer interaction may provide benefits beyond improved specifications or overcoming user resistance. Bringing users into close interaction with designers promotes social sense making (Boland, 1984) and shared understanding (Nelson & Coopriider, 1996). Information analysis, extended to include the context within which data are interpreted, also provides design mechanisms that can support self-reflection (Boland, 1979).

In summary, the IS literature shows support for the notions resident in Wenger's design for social learning. However, it does not explicitly address the tension inherent in alignment, imagination, and engagement. By exploring structures that balance these tensions, the process of system design may benefit, as we demonstrate in the next section.

Resolving and Managing Tensions as a way of Explaining Successes and Failures

In this section, we revisit three previously published studies to illustrate the value that the social learning model adds to the literature in information system design. The studies we examine used three different methods: controlled experiments, field research, and comparative analysis of previ-

ously collected case studies. The authors of each study include in their data and their analysis consideration to all three of the dimensions in our model: alignment, engagement, or imagination. However, in each study, one of the dimensions is used as the primary focus of investigation and therefore becomes a primary explanation for the results and the authors' understanding of what distinguishes effective from ineffective design processes.

For each study, we offer an alternative explanation that encompasses the original differentiating characteristics but offers additional insights into how to manage the process of information systems development. With these insights, the tensions among all three dimensions are included in the management framework rather than emphasizing one dimension of the model over the others. Consequently, this research contributes to the research literature by emphasizing the need to balance the dimensions in the model, and the result is a broader perspective on the practice of managing the system development process.

Boland (1978)

In the first study we examined, Boland (1978) addressed the question of how a user is involved in system design. Employing an experimental research design, "two radically different processes of interaction between a systems designer and a manager were compared in an information system design exercise." The author refers to the first as traditional and the later as an alternative. The first process was conducted by having the designer interview the manager. Afterward, the designer made suggestions for the design. In the second process, there was an initial sharing of information followed by a period of mutual suggestion and critique by each participant.

In the study, the structure (methodology and control) influences the interaction between the user and the manager. Based on how this protocol or interaction takes place, the problem solution is

derived. The author states “the alternative interaction approach produced higher quality designs with important implementation advantages.” From these results, Boland suggests that the protocols “may help to define different problems, and thereby produce different, but equally rational, solutions.” As stated in the article, “the structure of their interaction is defined as the protocols or accepted patterns they follow in punctuating their exchange of messages.” Using the model proposed in this research, the causal direction between the dimensions inferred in this statement is quite clear. Alignment, which includes methodology and control, sets the stage for how users and designers will engage in the process. The author also states, “the structure of their interactions serves as the context for the generation, interaction, and interpretation of ideas between them. The protocols they followed are seen as a source of rationality in the design process, as they guide in bounding the problem space, drawing inferences, and defining an ‘appropriate’ information space.” From the social learning model perspective, the protocol influences design activities, or, in other words, the causal direction inferred is (the words of our model) “alignment affects imagination.”

A richer explanation, employing the proposed social learning model, is that the alternative process resolved tensions in the process and, compared with the traditional process, struck a better balance in what was emphasized as important. Protocols, as a part of a prescribed methodology, served to organize the process or inquiry, but as exhibited in the study, they may not engage users in ways that promote knowledge transfer or afford the ability to imagine the design of an innovative system. The alternative process certainly undertook a different rationality, as the author went on to discuss, but it also undertook a more balanced approach across the three dimensions of the proposed model. By having participants first share information, then describe solutions and discuss pros and cons, both engagement and imagination were enhanced.

Wastell (1999)

In the second study we analyzed, Wastell (1999) also viewed social structure as a vehicle for learning and as a critical element in information system design. The study involved field research and employed an action research approach. Opportunities for design to influence the structure of interactions between participants or the development environment and the way it is managed and controlled are surfaced in the study. Three case studies are described. In each case, the author suggests approaches, and then describes how these changes improved performance. Using a theoretical perspective from psychology, the author proposed that antilearning defenses create difficulties for information systems design.

Stress and anxiety, arising from the group defenses of those involved in the system development effort are at the center of this approach. For example, following traditional protocols allows participants to adhere to prescribed behavior rather than engaging the participants from other groups in a common set of tasks. The approach to improving method and involvement are to reduce stress and defense avoidance behaviors. As prescribed by the author, modeling and other activities of design provide the design process with transitional objects, which facilitate involvement by designers and managers. As a result, the use of these objects promotes a learning environment, or transitional space. Thus, use of transitional objects “can facilitate the change process by providing a source of support through the transition, redirecting the anxieties that could otherwise lead to erection of defenses.”

In this framework, one role of the project manager is to maintain, rather than create, this learning environment. Thus, Wastell places the focus of his investigation, and prescriptions for improvements, on the process of modeling and designing. These concepts are incorporated in the imagination dimension of the proposed model.

For example, in one of three cases the author uses in the article, the company, Acme, is described as exhibiting “overly fastidious attention to notational detail and the aesthetics of diagrams . . . and users complained that they would be presented with large sets of diagrams which they found difficult to understand; one commented that ‘we did not know what we were doing or why we were doing it.’” The author’s diagnosis of the problem was that these methods of design “provided IS professionals with an illusion of control.” Users “drew back from the real job of analysis, of engaging with users in an open and frank debate about IS requirements.”

Using the author’s proposed framework, the causal direction of this theoretical approach is that imagination influences both the engagement of users and designers and the alignment or management of the process by which design is conducted. The prescription offered by the author is that design activities should be used as transitional objects. The use of these objects facilitates the creation of a transitional space. This space is a structure that promotes learning, allowing designer and managers to safely engage in activities. Once created, management must try to support the existing environment, which is quite different from the idea that methods and controls are needed to ensure the effectiveness of a process.

The author sums up the problem in this case as a situation in which “a highly prescriptive methodology is imposed by fiat” compared with an alternative that works better. The alternative, described in a similar case study, is a process in which practitioners create their “own methodological ideas before consolidating these experiences into new working practices.”

Using the social learning framework model, we might explain the findings as one in which there was a shift in emphasis from a strong adherence to an ineffective method toward greater emphasis on both modeling and engagement of users and designers. The emphasis has moved toward greater engagement of users and what

is described as a more “experimental” approach to development, and created a transitional space for those involved in the project. In this social learning explanation, the shift is toward a greater balance between the engagement and imagination dimensions of the model.

Kirsch and Beath (1996)

In this third study, the researchers again analyzed participation in system development projects. Kirsch and Beath (1996) analyzed data from eight case studies as a way to understand the relationships between different modes of involvement, the processes of coordination between designers and manager, and the product of the design effort. The process of user involvement is examined in terms of how involvement is actually enacted, as apposed to how methodologies may be prescribed in the literature. The authors examine this relationship from several directions in discussions at the end of the article, but their initial focus in terms of theoretical direction of causation is that participants will enact a methodology, rather than just following it blindly. The product of design is also examined by looking at who makes the selection of system features.

These authors focus on the effect of involvement, or engagement as defined in the social learning model. The study identified three different patterns of user participation: token, shared, and compliant. Each is shown to have different implications for a set of outcomes: task-system fit of the resulting system and management of conflict among these outcomes.

The authors propose that these patterns (token, shared, and compliant user involvement) vary in terms of who contributes technical and domain knowledge to the project and who controls feature selection. Involvement by users also influences the coordination mechanisms employed, the level of conflict, and how these conflicts are resolved. The data are examined in a number of ways, but the emphasis is placed on understanding how engagement influences the process by which the

project is coordinated (alignment) and by which the system is designed (imagination).

To the first point, the authors state that the “enactment [of user involvement] is as much the choice of the client as it is the choice of systems developers.” This leads the authors to suggest that methods might focus less on the way that designers should try to engage users but more on developing mechanisms to elicit user knowledge. To the second point, regarding the influence of user involvement on the modeling and design process or the effect of engagement on imagination, the authors conclude that high user involvement is not always necessary for task-system fit. The findings show, however, that when the system design features were derived by a process of negotiation between users and designers, the process yielded two of the three highest quality designs in terms of task-system fit.

Using our social learning model, an alternative explanation is that the processes that engaged users and designers took into account what participants do (imagination) and how the learning process is managed (alignment). As a consequence, the engagement process struck a better balance among the three dimensions in the proposed model. Engaging in a complex and often ambiguous process can be troublesome, especially if there is a great deal of conflict. In this study of eight cases, the three cases that had the highest rating overall had the least conflict. And while selection of features plays an important role in determining fit, as pointed out by the authors, feature selection does not have to be controlled by users. But their engagement and participation in negotiating the design process yielded the two cases with the highest ranking overall.

Summary: Additional Insights Using the Social Learning Model

As noted, each of these studies discussed the interaction of the three dimensions in the proposed social learning model. In each study, causal

inference was not the primary object of their investigation, as each study undertook a process perspective in their research approach, which we acknowledge and appreciate. These studies collected and reported rich sets of data and offered thoughtful and insightful analysis, enabling us to revisit them from the perspective of the tensions inherent in the social learning model.

By using these particular studies as a baseline, we are able to explore alternative explanations for the results of each. That is, we can offer different, richer explanations for how the studies unfolded, and more importantly, how the results came about. The studies started with different foci: Boland with control and method, Wastell with modeling and design, and Kirsch and Beath with user involvement. As a result, the three studies examined their data using different theoretical perspectives and thereby derived very different causal explanations of what occurred.

The social learning model does not resolve the conflicting direction of causation implied by these earlier studies. Instead, the learning model provides a “both/and” rather than an “either/or” explanation. Our model shows the relationships between the dimensions in the model as inter-related, with tensions that need to be resolved, rather than the need to optimize any one of the dimensions.

Finally, we note that all three studies demonstrate the need to balance engagement and imagination. While Boland found that more engagement was related to more and better designs, and Wastell found that the activities of design helped to engage the two communities in a more effective social process, Kirsch and Beath found that varying combinations of user and designer involvement has differing effects, dependent on many other factors. As a consequence, simply trying to increase involvement of users does not necessarily lead to better designs. Alternatively, the availability of an innovative or a structured design processes will not insure users’ participation, nor can the design process insure that those users will acquire a sense of involvement.

DISCUSSION AND CONCLUSION

This article has posited that the necessary exchange of knowledge between the designers and the users of information systems during the design process may be viewed as exchanges between two communities of practice. The article further suggests that the apprenticeship model of learning is an appropriate model for this knowledge exchange in which there is mutual learning. In this model, the user is the apprentice to the designer (when learning of technical capabilities) and the designer is the apprentice to the user (when learning of the system requirements and use). Apprenticeship conceptualizes knowledge as constituted in action, so separating the tacit from the explicit is not possible. Our knowledge exists in our competencies to perform or engage in action, and these competencies are formed in our learning through the negotiation of meaning. It is through this mutual apprenticeship process that we can grasp and articulate the meanings of the information we need to transfer. Mutual apprenticeship is a means by which both communities can learn, enabling the sharing of both the tacit and explicit dimensions of each knowledge domain.

Apprenticeship is the most accessible example of the benefits of both participation and nonparticipation and how the evolution of shared histories and development of the roles played by the apprentice and the master bring about the transfer of knowledge. If a master is asked to merely explain certain knowledge to the apprentice, the conversation would be flawed by the misunderstanding arising from the differing interpretations of the words that were used. However, through a process of engagement in a situated practice, development of competencies, and the evolution of identities, knowledge is transferred across communities via the apprenticeship model. The architecture for learning provides focus for balancing the tensions among alignment, imagination, and engagement.

Changes in structure can allow a community to move beyond just transferring “know what” to sharing greater degrees of “know how” and “know why.” By engaging in common practices, communities can understand greater degrees of the tacit dimension that exists in all knowledge (Brown & Duguid, 2001). However, even communities who work at the same practices can have differing ways of knowing. These differences result in knowledge being sticky and difficult to transfer, and they demonstrate the social dimensions of knowledge arising from the situated ways in which practices may develop.

By altering modes of participation in line with an apprenticeship model of learning and by supporting alignment and imagination through each community’s engagement in practice, managers can reduce the difficulties of sharing knowledge across the communities of users and designers. Perhaps of greater value, the knowledge shared across these communities, through altering modes of participation and balancing dimensions of the learning process as defined in Wenger’s model, can result in greater degrees of “know how” as well as “know what.” Furthermore, communication of related practice associated with the knowledge transferred and communication of the historical reasons for the practices used and the meaning appropriated in activities express aspects of a “know why” dimension embedded in the community’s way of knowing. Each of these changes should yield more creative designs and systems that have a greater degree of alignment with the organization’s goals.

We examined several cases of success and failure from the perspective of the causal explanations put forth by the investigators and using the model proposed here. In particular, we found it enlightening to compare the balance among the three dimensions of the model in successful and unsuccessful projects, which showed how the former had exercised a better balance than the latter. Ultimately, alignment, imagination, and engagement must all be supported, but focusing

too heavily on one dimension may disrupt the balance among them. Similarly, the various modes of participation in the apprenticeship model have the potential to benefit a learning process, but their implementation as changes to an overall process may have very subtle influences based on the number of participants and their role in the organization.

The model provides important insights into how apprenticeship and knowing across communities can contribute to the theory and practice of information system design. Through the development of learning environments that span communities and support engagement of practice and appropriate modes of participation, organizations can create, focus, and transfer system knowledge through an apprenticeship model of learning. For information systems researchers, the model provides new opportunities for examining and evaluating requirements definition approaches. All of the issues raised in this article require further investigation. Many opportunities exist for future research to further understand, validate, and extend this work.

For practitioners, the model provides insights into the importance of context in understanding what is known in organizations and the importance of practice in forming the way that we know it. For project managers and executives, creating an environment in which both designers and users are encouraged to be both masters and apprentices may well prove to be a critical factor for project success.

Chapter 2.38

The Transformation Model

Kathleen P. King
Fordham University, USA

ABSTRACT

The journey of transformation is a model of professional development developed, grounded in research of 205 educators, and based on a framework of adult learning begun in 1997. Transformative learning is a theory that describes the experience and cognitive process by which adults critically evaluate previously unexamined beliefs, values, or assumptions; try new beliefs, values, and assumptions to determine the fit for themselves; and then develop a dramatically new perspective of their worldview (Mezirow, 1978). This article describes how the author developed a mixed quantitative and qualitative tool to more broadly gather and analyze data about this experience. The work focuses on two major groups of traditional adult learners: English as second language learners and adult basic education learners. The journey of transformation represents a refinement of the 10-stage transformative learning theory model, one which is dynamic and interactive among the stages. The model emphasizes an environment of support for technology learning and encour-

ages a role for practice and experimentation with technology that recognizes the fluid, nonlinear process of such learning.

INTRODUCTION

The journey of transformation is a model of professional development that has been developed, grounded in research of 205 educators, and based on a framework of adult learning starting in 1997. It was fully presented in the literature in 2002 and 2003 in a two volume book, *Keeping Pace with Technology+* (King, 2002b, 2003).

Origins of the theoretical basis of this model are the adult learning theory of transformative learning (Mezirow, 1978). Transformative learning is a theory that describes the experience and cognitive process by which adults critically evaluate previously unexamined beliefs, values, or assumptions; try new beliefs, values, and assumptions to determine the fit for themselves; and then develop a dramatically new perspective of their worldview. Mezirow's original study was a

small group of adult women returning to college later in life.

King developed a mixed quantitative and qualitative tool in 1997 to begin to more broadly gather and analyze data about this learning experience. From 1997-2002, King focused his work on educators and two major groups of traditional adult learners (English as Second Language [ESL] learners and Adult Basic Education [ABE] learners). The studies of educators extended from not only educators of adult educators, but also k-12 educators and professors in higher education.

King's basic perspective was to "throw a wider net" of data gathering in order to identify broader patterns of transformative learning experiences than in traditional studies in the field that typically numbered 5-15 participants.

The journey of transformation represents a refinement of the 10-stage transformative learning theory model as it is experienced among k-12 educators (volume 1) and professors (volume 2) learning educational technology (King, 2002b, 2003, 2004). This new integrated model has four major stages: fear and uncertainty; testing and exploring; affirming and connecting; and new perspectives.

As an entirety, this experience is not linear; it is one which is dynamic and interactive among the stages. The learning experienced in the model of the journey of transformation is recognized as resulting in fundamental transformations of educators' perspectives and practice of teaching and learning.

The significance of the model includes many dimensions, not limited to the fact that it brings adult learning theory to a place of practical application across educational contexts. The model emphasizes an environment of support for technology learning and encourages a role for practice and experimentation with technology that recognizes the fluid, nonlinear process of such learning.

BACKGROUND

The Research

In the extended study, which grounded the journey of transformation, 205 participants included 155 women and 50 men. These participants had 0-40 years (M=10.53) experience in teaching at k-12, adult, and higher education environments. Their ages ranged from 30-39 years old (King, 2002, 2003).

Analysis of the data revealed that 84% of the respondents had experiences of perspective transformation through this context and followed a distinct pattern of development that emerged as the journey of transformation model (King, 2002b, 2003). This model may be defined as a four-stage integrated model of transformative learning experienced within the context of educational technology learning, resulting in fundamental transformations of educators' perspectives and practice of teaching and learning. The four stages of the journey of transformation are fear and uncertainty; testing and exploring; affirming and connecting; and new perspectives. Frequently having to learn technology or new aspects of technology under pressure served as a "disorienting dilemma" that was characterized by fear and uncertainty (King, 2004).

Research and Theory

The stages of the journey have linkages with Mezirow's (1978) theory of transformative learning. However, the journey's stages do not represent single actions. Instead they are continuums of experience. Specifically in this model, transformative learning is revealed when "educators' learning journeys of *development*, their *disequilibrium* which promotes learning, and their learning that includes *reflective abstraction*, and the construction of *structures/meaning*" (King, 2004, p. 12, italics in original).

In terms of *development*, instead of one single learning moment, this model emphasizes a direction that some educators follow. That is a pathway that leads to perspective transformation, as adult learners engaged in research-grounded professional development in educational technology.

Much like Rogers' (1995) theory of the diffusion *process* of innovations, the model is a journey. In contrast to his theory, however, this model includes *constructions of meaning*, and ways of understanding that go beyond the innovation and is more fully explained through the adult-learning theory of transformative learning.

The journey of transformation is a *reflective abstraction* that starts with a process of questioning, and analysis, and leads to the individuals' development and empowerment. The *disequilibrium* of transformative learning also is evidenced in the beginning stages of the journey of transformation, as educators face their growing confusion and fears regarding educational technology learning.

Understanding educators in these ways can be powerful paradigms and frameworks for those who work with them. Considering that educators can experience these changes in perspective and related practice, developers, instructional technologists, and other educators involved in assisting them can gain new insight into faculty members' needs. Such perspectives of possibilities can change the focus of professional development. Instead of solely focusing on skill acquisition or instrumental learning, the journey of transformation highlights the educator as a self-directed adult learner and professional. This focus sets the stage for emancipatory learning.

The Model's Stages Explored

While full explanations and descriptions of the model and stages are found in the literature, brief descriptions are provided here:

Fear and uncertainty. Learning a new skill set can be uncomfortable for adults, but learning

technology seems to especially generate fear and anxiety. Part of this increased emotion may be due to the high value the general public and business place on technology knowledge. In beginning sessions, the teacher/facilitator may be nurturing and supporting participants' initial efforts to complete guided computer activities. Within this first stage of the journey, learners especially need to build confidence in their facilitator as the one who will provide support and guidance.

The fear-and-uncertainty stage reveals concrete examples of how our technology-based culture can leave the novice emotionally stranded and isolated from solutions. Looking at the emotional, affective side of this dilemma and questioning it confirms that educational technology learning needs to address much more than instrumental learning.

Testing and exploring. Educators gain confidence to pursue more activities and begin to reach an exploration mode. They typically are no longer limited to a script of instructions but explore different functions and applications on their own. Educators begin to see similarities among programs and anticipate how they likely function. As learners explore on their own, they gain autonomy.

Teachers describe the second stage of the journey of transformation as the time when they are engaged in testing, exploring, and gaining confidence with the use of educational technology. Many times they indicate that they were questioning their prior beliefs and ideas about teaching and learning. By increasing their confidence in educational technology, they also begin to explore how they might implement new teaching methods with their students.

Affirming and connecting. During this stage, teachers are acquiring more instruction, planning how to use knowledge, and testing new connections or syntheses, regarding the teaching and learning in which they have been engaged. For example, they may describe how they have realized that the collaborative learning they have

The Transformation Model

experienced can be used in their classes. In addition they begin to realize that using technology should be integrated with and consistent with, rather than separated from, their prior educational knowledge and practice.

In these ways, in this stage, some educators will realize how they can *connect* their teaching experience with technology. That is, these educators use their teaching expertise to apply technology in new ways. Often as educators design classroom materials, they also are implementing them week-by-week within their classrooms. While engaging in developing curriculum that integrates technology, the journey of transformation includes their affirming, connecting, and discussing how they might further develop their teaching practice. Perhaps they begin to look at teaching and learning from a new perspective as this stage opens up new possibilities? Others may affirm and stretch the possibilities for their educational practice or philosophy as they build upon and *scaffold* with one another's experiences.

New perspectives. It is critical to note that the "final stage" of the "journey" may be reached in days, months, or years. The timetable for the journey for every individual is different. Usually at the new-perspectives stage, educators have invested much time and work in overcoming challenges, exploring new technologies, and beginning to develop new instructional and curricular materials.

Many of these educators reach beyond their prior boundaries, both conceptual and curricular, to see possibilities previously unseen. In this final stage of new perspectives, teachers reflect more completely, develop new ideas, evaluate their merit, and perceive learning and meaning in new ways. These educators are carefully and thoughtfully reexamining their grade-levels and content areas to determine where technology can be integrated, scaffolded, transformed, and used to benefit their curricular goals and consolidate their direction.

Like the new school or collaborative classroom, typically the professional development classroom is "noisy" at this point. Teachers are engaged in dialogue, discussion, teamwork, and debate, while they are creating, evaluating, and redesigning interdisciplinary and cross grade-level curriculum that will maximize the benefits of technology. Additionally, they experience freedom in their roles and abilities; this is a manifestation of emancipatory learning. Often empowerment clearly permeates these accounts provided in the reflective journals of the educators.

SUMMARY

This research revealed that while educators are learning educational technology, they can have transformative experiences. These learning experiences may include new visions of teaching and the classroom, transitioning from being a "received knower" to a "constructed knower" in educational technology and interacting with educational technology professional development as emancipatory learning rather than instrumental (Cranton & King, 2003).

Furthermore, it was demonstrated in this research that when educators learn technology and build on their professional expertise, they may experience changes, not only in their personal and professional perspectives of individuals, teachers, and learners, but also as practitioners. That is, they may fundamentally change their educational practice in lasting ways. (King, 2002a, b). For example, in this study, it was recounted how these educators often moved from teacher-centered to learner-centered learning models and expanded their view of the classroom to create more active, constructivist, and transformative experiences. Instead of professional development focusing only on instrumental learning (skills training or theory transmission), these professional development experiences presented learning opportunities for educators to fundamentally change. The changes

they experienced were in their actions of reflection, self-examination, and redefinition of their perspectives, purposes, and practices. This model revealed concrete examples of a reflective practitioner being developed through the adult-learning model of transformative learning in educational technology professional development. In this case, we have a nexus of teacher-education theory and adult-learning theory being demonstrated through this research and articulated in this model.

Main Focus of the Article

The major focus of the journey of transformation has been to further identify the characteristics of adult learners and educators, in particular, as they engage in learning technology for educational application. Cranton and King (2003) provide a solid overview of the background theory of transformative learning, and how it provides for an open-ended, generative, and constructivist approach to professional learning. A chapter within the larger volume by King and Lawler (2003) describes the literature, practice, and trends in professional development for teachers of adults, examining how the learning of technology in this manner provides a different paradigm for researchers and theorists alike.

The significance and implications of this journey of transformation model, the impact on understanding educators, transformative learning, professional development, and future research may be examined. Realizing the potential that changes in teaching and learning resulting from the journey of transformation can have on educators, their students, colleagues, and institutions, those interested in educational reform may find some direction in this model.

This model focuses on the growth and development of educators learning technology. In this way, the research offers the opportunity to understand faculty needs and explore their potential as professionals and individuals in powerful theoretical and practical ways. New possibilities arise with

this model, and the result of these findings may include changes in professional development planning, delivery, and follow-up. However, equally important is that those involved in the professional development of educators need to be prepared for changes in the lives and work of educators.

Solely providing traditional workshops may not lead to radical change; it likely will not be the entire answer. Instead educational organizations should design and develop continuing programs of educational technology learning, where adult learning is anticipated and supported on an ongoing basis (Cranton & King, 2003; King, 2004, 2005).

Future Trends

In regards to research, discussion, and development of multiple points of inquiry, additional research about this model needs to be pursued. Such research could further test the model and provide modifications and refinements for diverse settings. For example, the model may be examined among faculty in community colleges and within different disciplines, such as business, nursing, the sciences, and the arts. The exploration of the relationships between other adult-learning theories (i.e., andragogy and self-directed learning) and the model can be examined to see what emerges as similarities and differences, and how the model fits among these paradigms. The journey of transformation offers a different perspective on educational technology learning that also may be further explored through the variables of learning styles, personality types, and organizational cultures (King, 2005; King & Wang, 2006).

CONCLUSION

Finally, it must be clarified that this model of the journey of transformation is intended to provide an understanding and vision of educators' learning and development. It has never been intended

The Transformation Model

to confine learners to predetermined outcomes or timelines. Instead it is quite the opposite. The model is based on an educational philosophy of radical pedagogy and social constructivism, as is transformative learning, which embraces an open-ended journey: a constructivist opportunity for educators through professional development. It provides a new perspective for our field, a framework for understanding, practice, and further inquiry. Not meant to confine, it supports a perspective that all educators have their own distinct experiences from which to grow.

GLOSSARY

Diffusion of Innovation: The study of how, why, and at what rate new ideas and technology spread through cultures (Rogers, 1995).

Journey of transformation: a model of professional development of educational technology which is based on the adult learning theory of transformative learning (King, 2002, 2003, & 2004).

Radical pedagogy: an educational philosophy that focuses on social change as the goal of education. (See Paulo Freire, Henri Giroux).

Transformative learning: an adult learning theory characterized by 10 stages. It is understood as an experience of critical questioning of beliefs and assumptions as individuals examine the framework from which they have been viewing their world. Originated in the work of Mezirow (1978).

Chapter 2.39

The Influence of Constructivist E-Learning System on Student Learning Outcomes

Thanakorn Wangpipatwong

King Mongkut's University of Technology Thonburi, Thailand

Borworn Papisratorn

King Mongkut's University of Technology Thonburi, Thailand

ABSTRACT

In this article, the study of how a constructivist e-learning system affects students' learning outcomes was explored and a two-phase study was designed. The first study sought to create a constructivist e-learning environment (CEE) and discover how students expected their learning outcomes under CEE. CEE is composed of three constructs, which are exploration, collaboration, and construction. The statistical results showed the high level of student expectation on every construct. Consequently, constructivist e-learning system (CES) was developed. In the second study, CES was used in the actual classroom environment. The purpose was to compare the learning outcomes and knowledge development of students who studied the course using CES with those of students who learned it under a traditional learning environment. A

T-test method was used to analyze the learning outcomes. The results showed that students who used CES had better learning outcomes and knowledge development than students who did not use CES.

INTRODUCTION

E-learning refers to an alternative method of teaching and learning using all electronic media, including the Internet, network, audio/video tape, and CD-ROM. For the past few years, the use of e-learning to conduct teaching and learning in educational institutes has rapidly increased along with the development of information technology. E-learning has an advantage of enabling students to learn from anywhere and at anytime. E-learning also provides a one-stop service for teachers and learners in order to

create and deliver educational content quickly, effectively, and economically (Ong, Lai, & Wang, 2004).

In the past, e-learning researches have focused more on learning objects. The IEEE Learning Technology Standards Committee defines learning objects as “any entity, digital or non-digital, which can be used, re-used or referenced during technology-supported learning” (Shepherd, 2006). However, students may not improve learning outcomes by using only learning objects. Recently, the focus of e-learning has shifted from defining, sharing, and reusing learning objects to emphasizing learning activities based on the concept of learning design, which emerges as one of the most significant recent developments in e-learning (Yu, Zhang, & Chen, 2006). The key principle in learning design is to develop learning activities that are performed by different learners in the context of learning (Koper, 2006). The objective of learning design is also to assist students to effectively learn by creating and managing their learning processes (Pan & Hawryszkiewicz, 2004).

Regarding learning design, e-learning has blended with learning theory in order to try to improve learning outcomes. The learning methods, such as independent learning, active learning, self-directed learning, problem-based education, simulations, and work-based learning are based on constructivist learning theory (Reiser, 2001). The e-learning design in this study, therefore, is based on constructivist learning theory.

This study was divided into two phases. The first phase was to create constructivist e-learning environment (CEE) and to explore the expected student e-learning outcomes on CEE. The objective of this step was to investigate what learning outcomes students might expect by using a statistical method. Consequently, based on CEE, the constructivist e-learning system (CES) was developed. The second phase was designed as an experimental research that focused on the comparison of actual student e-learning outcomes. The

CES was used in the classroom environment. The student learning outcomes between students in traditional classroom environment and constructivist e-learning environment were compared. The statistical method (t-test) was also conducted to test the significance in this study.

REVIEW OF LITERATURE

Constructivist Learning Theory

The constructivist learning theory has emerged as a prominent approach to teaching during the past decade. The research of Dewey, Piaget, Vygotsky, and Jonassen, among others, provides historical precedents for constructivist learning theory. Constructivist learning theory represents a paradigm shift from education based on behaviorist theory to education based on cognitive theory. In a constructivist learning environment, students have better learning outcomes than in traditional learning environment (Parker & Becker, 2003, Tynjala, 1999).

Among many definitions of constructivist learning theory, the most common characteristic is that they all focus on activities and environments rather than on learning objects. Knowledge is constructed by learners and not transmitted by an instructor. Dewey (1938) believes that knowledge emerges only from situations in which learners have to draw them out of meaningful experiences. Piaget (1960) indicates that learners are active and constructive in making sense of their environment. Piaget (1975) believes that learning should be attained through well-defined stages by active participation of a learner. Vygotsky (1978) focused more on learning activities. In addition, Jonassen (1994) suggested that the constructivist learning should emphasize less on the sequence of instruction and emphasize more on the design of the learning environment. He also pointed out that constructivist environments stress situated problem solving tasks. In conclusion, construc-

tivist learning is an educational approach that effectively motivates learners by enabling a more active, explorative and interactive learning process. In other words, through the learning process, learners construct knowledge within a constructivist learning environment.

CONSTRUCTIVIST E-LEARNING ENVIRONMENT (CEE)

Constructivist learning is considered to be the ideal pedagogy for e-learning. First, constructivist learning focuses on a student's learning experience rather than an instructor lead teaching method. In an e-learning environment, an instructor's role is to help students develop their knowledge and give students a degree of choice such as what to study, where to study, and how to study. Students are placed at the center of the learning experience. Second, constructivist learning sees students as an active participant in their learning experience rather than a passive participant. In an e-learning environment, context is also an important part for student learning. E-learning forces students to explore information, make connections, and build knowledge. Finally, constructivist learning sees learning as a social experience.. E-learning easily enables communication among students without the barriers of time and place; collaboration is crucial.

In recent literature, the following constructivist e-learning researches can be found. Chuang and Tsai (2004) studied on the preferences toward the constructivist internet-based learning environments. Zhang, Zhou, Briggs, & Nunamaker (2005) studied the influence of interactive video in constructivist e-learning environment. Zualkeman (2006) designed the framework for developing authentic constructivist e-learning environments using game-based learning as a medium. Moreno, Gonzalez, Castilla, et al., (2006) applied constructivist e-learning to a computer architecture and engineering course using Moodle platform. Puntambekar (2006) developed constructivist, distributed learning environment (CoDE) and used an online graduate course in order to study the process of collaboration.

For constructivist e-learning applications, computer-supported collaborative learning (CSCL) is widely studied. Many systems have been developed based on CSCL and considered to be constructivist learning applications such as CSILE (computer supported intentional learning environments), which functions as a collaborative learning environment (Scardamalia & Bereiter, 1994). CoVis (collaborative visualization) is an integrated software environment that incorporates visualization tools for open-ended inquiry (Edelson, Pea & Gomez, 1996).

Puntambekar (2006) designed the constructivist e-learning environment called CoDE. CoDE uses two main cognitive tools to help students

Figure 1. Constructivist e-learning environment (CEE)

construct knowledge. The first tool is called Reflective Notebooks. Reflective Notebook was designed to help students analyze ideas and write a reflective essay into the system. The other tool is Discussion Tool, which is designed to support group working for students.

This research proposes an alternative design of learning environment called CEE. CEE consists of three constructs which are exploration, collaboration, and construction, as shown in Figure 1.

Exploration is one of the main approaches in the constructivist learning theory (Murphy, 1997, Stager, 2001). An exploration activity can be defined as searching information resources to comprehend the information and to acquire knowledge (Kashihara, Kinshuk, Oppermann, et al, 1998). The exploration activities include search, variation, experimentation, play, flexibility, discovery, or innovation (March, 1991). In a real world situation, students prefer to learn by exploration in the context of a real task. They need to perform, rather than taking time out to work through the documentation in a task-independent manner (Rieman, 1996). Exploration is also a favored approach to encourage students to seek knowledge independently and to manage the pursuit of their goals (Murphy, 1997). Knowledge that is generated by exploration activities is often new knowledge (Katila, 2002). To help in the exploration process, instructors can use hyperlinks to link other useful online resources to allow students to journey on a process of discovery. Search engine is also a knowledge retrieving tool that assists students to construct new knowledge (Liaw, 2005).

Collaboration is also considered to be a key feature of constructivist learning theory. Collaboration is a characteristic of a powerful learning environment which results in active construction of knowledge (Van Merriënboer & Pass, 2003). Through a process of collaboration, students have an active and constructive role in the learning environment (Dewiyanti, Brand-Gruwel, Jochems, et al., 2004). The interaction between individual

and collaborative learning activities is part of knowledge construction (Puntambekar, 2006, Yli-Renko, Autio, & Sapienza, 2001) and contributes to higher learning performance in the learning environment (Wang & Newlin, 2000).

Writing is suitable for tasks where the aim is to foster understanding, change, and develop student thinking skills (Tynjala, 1999). Constructivist learning theory encourages student writing activities in order to reflect on student knowledge development. Therefore, the construction component, in this study, is designed for writing or recording students' reflection.

Reflective learning is another main characteristic of the constructivist learning theory (Jonassen, 1994). Reflection improves the knowledge creating potential of all students. When students have an opportunity to discuss and explain, they improve their learning (Pirulli & Recker, 1994). In addition, reflection helps students establish the linkage between theory, research, observations, and experiences (George, 2001).

STUDY 1: EXPECTED E-LEARNING OUTCOMES ON CEE

Hypotheses

The objective of this study is to understand the student's expectation on their learning outcomes under each component of constructivist e-learning environment. The hypotheses applied to the study 1 are:

- H1: The average value of expected e-learning outcomes on collaboration is greater than 3
- H2: The average value of expected e-learning outcomes on exploration is greater than 3
- H3: The average value of expected e-learning outcomes on construction is greater than 3

Methodology

Participants

Participants were students of an introduction to computer course at Bangkok University. At the beginning of the semester, a random sample of 600 students out of the total population of 4200 received an e-mail that described the study and provided a link to where the questionnaire could be completed. Four hundred sixty three students (77.17%) responded to the e-mail. The size of valid responses conforms to finite population sampling formula (Yamane, 1973), along with a 95 percent confidence level and a 5 percent precision level. The demographic data of these participants are shown in table 1.

Instruments

The data for this study were gathered by means of a questionnaire. The questionnaire included four major sections: (a) demographic information, (b)

expected outcomes from collaboration process, (c) expected outcomes from exploration process, and (d) expected outcomes from construction process.

The participants were asked to determine the range of expected learning outcomes from each construct by indicating 1 as Very Low level; 2 as Low; 3 as Moderate; 4 as High; and 5 as Very High. Mean rating points were then distributed to the following scale classification levels such as Very Low (1-1.80); Low (1.81-2.60); Moderate (2.61-3.40); High (3.41 –4.20); and Very High (4.21 to 5.00). Findings from the questionnaires could determine the current level of expected learning outcome from CEE.

Reliability Assessment

The internal consistency reliability of items in each construct was examined using Cronbach's alpha to confirm the adequacy of the measures for testing the hypotheses. The results in each construct are presented in table 2. The reliability

Table 1. Demographic data of participants in study 1

Demographic Characteristics	Frequency	Valid Percent (%)
Gender		
Male	169	36.5
Female	294	63.5
Age		
17	1	0.2
18	122	26.3
19	227	49.0
20	73	15.8
21	19	4.1
22	12	2.6
23	7	1.5
24	2	0.4
Faculty		
Accounting	5	1.1
Business Administration	175	37.8
Communication Arts	235	50.8
Economics	1	.2
Fine and Applied Arts	3	.6
Humanities	3	.6
Laws	35	7.6
Science	6	1.3
Number of Participants	463	100

Table 2. Cronbach's alpha reliability coefficients

Construct	Cronbach's Alpha	Number of Items
Collaboration	.883	6
Exploration	.781	2
Construction	.853	3

Table 3. Means of expected learning outcomes

	N	Mean	Std. Deviation
Collaboration	463	3.486	.752
Exploration	463	3.893	.886
Construction	463	3.647	.796

of all constructs shows a high level of internal consistency above the recommended minimum level of .70.

RESULTS

Table 3 shows the average expectation of student learning outcomes for each construct. Referring to the hypothesis, the mean value of collaboration construct, exploration construct, and construction construct are 3.486, 3.893, and 3.647, respectively. The results show that the level of student expected learning outcomes is high for all constructs.

One sample t-test was used to test the hypotheses. Table 4 shows the results which indicate that the mean value of collaboration construct is significantly greater than 3 at significant level 0.05. The mean value of exploration and construction constructs are also significantly greater than 3 at significant level 0.001. Therefore, hypothesis 1, 2, and 3 are supported.

STUDY 2: THE COMPARISON OF E-LEARNING OUTCOMES

Research Model and Hypotheses

The results from study 1 show that the level of expected learning outcomes on each construct of CEE was high. This result could imply that students believed the CEE constructs could help them develop their knowledge. Therefore, the constructivist e-learning system (CES) was developed based on CEE as shown in Figure 2.

In this study, CES was used to create the constructivist e-learning environments. The objective was to compare learning outcomes between students who used the CES and students who studied in the traditional learning environment. This study also examined the knowledge development between students who used the CES and students who studied in traditional learning environments. The subject used in the experiment is "Introduction to Computer," which is normally taught in the traditional classroom environment.

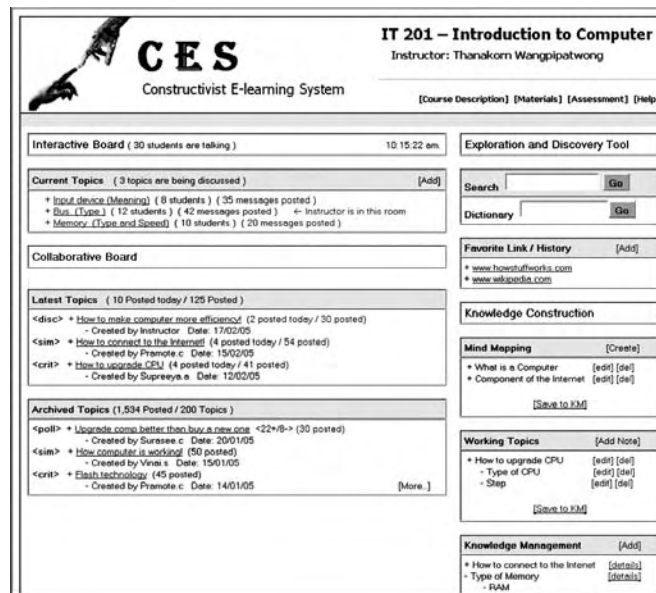

The Influence of Constructivist E-learning System on Student Learning Outcomes

Table 4. Results of one sample t-test

	Test Value = 3.0		
	t	Sig. (2-tailed)	Mean Difference

Construction	6.661	.000***	.247

* $p < 0.05$, *** $p < 0.001$

Figure 2. Constructivist e-learning system (CES)

This subject introduces basic concepts of computer and internet technologies. An instructor in the class was prepared to use CES as a tool, integrating with constructivist learning activities. The instructor was also prepared to understand the concept of constructivist learning theory and how to use the activity in the classroom. The same instructor taught the same content as in traditional classroom environment. The duration of the lecture in both classes was 13 weeks.

The hypotheses applied to Study 2 are:

- H4: Students who use the CES in traditional face-to-face classroom environment will achieve better test scores than students who do not use it in traditional face-to-face classroom environment.
- H5: Students who use the CES in traditional face-to-face classroom environment will achieve better knowledge development than students who do not use it in traditional face-to-face classroom environment.

Methodology

Participants

Two class sections were randomly selected for the research experiment—Section T and C. Section T was taught in traditional learning environment. Section C was taught in constructivist e-learning environment using CES as a tool. Both sections had the same amount of time for lectures. Students who enrolled in the course had no prior knowledge about the teaching method. There were 31 students in section T and 28 students in section C. The demographic data of students in both classes is shown in Table 5.

The average GPA of students from both groups are shown in Table 6. Although the average GPA values from each group are slightly different, the results from statistical analysis (t-test) displays no significance ($p=.434$). Therefore, GPA was considered not to be effective to the research experiment.

Instrument

The independent sample t-test analysis was used to compare the mean values of test results between two groups. There were five tests in this study—test 1, 2, 3, 4, and 5. Test 1 was designed as a pre-test and was administered at the beginning of the semester to measure student prior knowledge. The other four tests were administered in order to measure the learning outcomes. Since the class had two sessions, test 2 was taken at the end of the first session before the midterm examination date. Test 3 was a midterm examination. Test 4 was designed as a post-test and was taken at the end of last session before final examination date. Finally, test 5 was a final examination. The test 3 and test 5 schedules were pre-announced to students before the test date. However, students did not know the test date of test 2 and test 4 before they took the test. The potential test scores ranged from 0 to 100. All tests were closed book and closed notes.

Table 5. Demographic data of participants in study 2

		Section

Table 6. Independent sample t-test of GPA

	Section T (Mean)	Section C (Mean)	t-value	Sig. (2-tailed)
GPA	2.38	2.50	-.788	.434

The Influence of Constructivist E-learning System on Student Learning Outcomes

Test 1 and test 4 covered the general information about computer and information technology. The question types in both tests were similar, but questions in test 4 were more specific and difficult. The questions in test 2 were about how to use Microsoft Word and Microsoft Excel as they were part of the learning objective in the lecture content. Test 3 and 5 covered all the lecture contents of midterm and final, respectively. Table 7 summarizes all test descriptions and schedules.

Results

Table 8 displays a mean score for each test and section. Notice that all mean scores from section C are higher than the mean scores from section T, which means hypothesis 4 is supported. However, regarding t-test analysis, the mean score of section

T from test 1 is not significantly different to the mean score of section C ($p=.429$). Because test 1 is a pre-test, it can be concluded that student backgrounds in computer and information technology of both sections are not different.

An independent-sample t-test was also used to determine if there were any significant mean differences between class sections from test 2 to test 5. As in Table 8, the results showed that test 2 and test 4 are significantly different ($p<.05$). For test 3 and test 5, despite the higher score on section C, the results show no significant difference between section T and C.

Considering the development of student knowledge from pre-test (test 1) to post-test (test 4), the results show significant improvement for both sections ($p<.001$), as shown in table 9. However, the mean difference of student improvement in

Table 7. Description and schedule for all tests

	Description	Schedule
Test 1 (Pre-test)	General information about computer and information technology	Before class started
Test 2	MS Word and MS Excel	One week before midterm exam
Test 3	Fundamentals of computer system, process concept, and storage devices	Midterm exam
Test 4 (Post-test)	General information about computer and information technology (more difficult than test 1)	Last week before final exam
Test 5	Introduction to computer network, the Internet, Web design and development	Final exam

Table 8. Independent sample t-test between section T and section C

	Section T (Mean)	Section C (Mean)	t-value	Sig. (2-tailed)

Test 2	69.301	83.334	-2.157	.036*
Test 3	66.258	70.214	-1.159	.251
Test 4	67.903	80.357	-3.522	.001*
Test 5	58.839	58.929	-0.31	.976

* $p<0.05$

Table 9. Paired sample t-test of test 1 (pre-test) and test 4 (post-test)

Pair T-test Between Test1 and Test4 of	Mean Paired Differences	Standard Deviation	t-value	Sig.(2-tailed)
Section T	-12.419	14.712	-4.700	.000***
Section C	-20.536	9.461	-11.485	.000***

*** $p < 0.001$

section C is much higher. Therefore, hypothesis 5 is supported.

DISCUSSION AND CONCLUSION

This study proposed an alternative design of constructivist e-learning. The two-phase study was aimed at examining the extent of constructivist practices when applied to traditional classroom environment using constructivist e-learning system. According to the literature review, the constructivist e-learning environment (CEE) was designed. CEE is composed of three constructs, which are collaboration, exploration, and construction. Study 1 was conducted in order to evaluate what students expected from each CEE construct toward learning outcomes. The results from study 1 showed that students' expected learning outcomes from each CEE construct were significantly high. In addition, exploration construct had the highest mean scores. This implies that students believe most of their learning outcomes are from the exploration process. Possibly, the new knowledge gained from the exploration process is more obvious than the others. For example, when students needed information in the Internet, they searched and found it. They would feel immediately that they gained new knowledge. Collaboration construct, by the way, has the lowest effect on students' expected learning outcomes. This situation occurs because students may not receive the new knowledge every time they collaborate with others.

To strengthen the value of the research results, the constructivist e-learning system (CES) was developed and used in the actual classroom environment. The experimental research was designed in study 2. Two class sections were used in the experiment. According to the t-test analysis, the average GPA of students between sections were not significantly different. Therefore, GPA was not the factor that affected the study results. In other words, it could imply that the learning outcomes from each section occurred from the learning process.

The pre-test was also administered in both sections in order to evaluate student background knowledge in computer and information technology. The statistical findings showed that there were no significant differences of student background between each group. As a result, we could also eliminate student background on computer and information technology from the factor that affected the student learning outcomes.

The findings from study 2 showed that students who used the CES in traditional face-to-face classroom environment achieved better test scores than do students who did not use CES. However, it is interesting that only two tests (test 2 and test 4) had significant mean difference but the other two tests (test 3 and test 5) had not. Notice that the test date of test 3 and test 5 were announced before the test. It could be possible that students in both sections had a better preparation for test 3 and test 5 before the tests, which, therefore, yielded to closed results between section T and section C.

The significant difference of results between test 2 and test 4 would imply that students who

learned in constructivist e-learning environment had a better knowledge development than students who learned in traditional learning environment. As stated before, student background knowledge on computer and information technology were not different, and student took the test by not knowing the test date. Therefore, students needed to use their knowledge developed from learning process to answer the tests.

The results from statistical analysis of pre-test and post-test also confirmed the previous findings. The results showed that the mean difference of students in section C was much higher than those in section T, although knowledge improvements of both sections were significant. Therefore, it could be concluded that students who studied in constructivist e-learning environment had a better knowledge development than students who studied in traditional learning environment.

Although the research results supported all hypotheses, many aspects should be discussed. First, we found that students were apparently unfamiliar with the constructivist learning environment. The expectation of knowledge acquisition from an instructor was high. However, students had more understanding on the new role as time went by. In fact, students seemed to be happier studying in the constructivist e-learning environment. Second, we found the same result as Puntambekar (2006) that students expected an instructor to take the lead in every discussion and waited for instructor feedback before they continued to other discussions. Therefore, the instructor should understand the facilitator role and encourage students to continue learning in constructivist e-learning environment.

Concerning to the use of the CES, we also found many interesting aspects. First, using collaboration tools in the CES helped students learn not only from their own group but also from other groups. Since the students were capable of seeing all of the ideas within the CES, they could build knowledge from a broader point of views. Second, students who were familiar with the computer and

internet had more fun using and learning by the CES than students who were not. It seemed that they did not have to worry about how to use the CES. They just concentrated on how to study and learn by using the CES. Finally, students seemed to have more focus on studying when using the CES. With a traditional teaching, some students might use the web, or msn when listening to a teacher. These activities did not happen when students used the CES unless they already finished the assignment.

There are some limitations in this study that should be noted. First, the use of student subjects from Bangkok University may limit the generalization of the results. Second, the findings from using the CES in classroom environment were obtained from a single study. In fact, only the Introduction to Computer course is used in the experiment. Therefore, studying CES in other courses may be needed. Caution should be taken before generalizing the findings, as well. Finally, a teacher who intends to use CES should understand the constructivist learning concept in order to utilize the CES tools.

Chapter 2.40

A Wireless Networking Curriculum Model for Network Engineering Technology Programs

Raymond A. Hansen
Purdue University, USA

Anthony H. Smith
Purdue University, USA

Julie R. Mariga
Purdue University, USA

ABSTRACT

Wireless networking is experiencing explosive growth, both in market size and the number of new standards and technologies. Effectively educating students, both at the undergraduate and graduate level, with the abilities to evaluate, implement, and integrate wireless networks should be a key part of any information technology (IT) education program for the foreseeable future. The Computer & Information Technology Department (CIT) at Purdue University is in a unique position to fulfill this educational need

through its wireless networking curriculum. This curriculum currently offers three courses within the network engineering technology program, covering topics from 802.11 networking to 3G cellular, wireless network security and management to WWAN technologies. Each course includes trend analysis of wireless networking in order to effectively prepare students for employment in this area. This paper discusses the existing wireless networking curriculum by providing a brief perspective of previous course content and detailing each current course in the areas of prerequisite knowledge, intended audience, course content, and lecture/laboratory integration.

BACKGROUND AND HISTORY

Constant analysis of material presented in a course is critical for its success. As a market evolves, it is important to monitor, report, and reflect those changes through the course material. In this instance, the explosion of the wireless networking sector provided a wealth of new information. The wireless networking industry has a historical growth rate greater than 10% per year and grew by nearly 15% in 2005. Additionally, the market is expected to increase an additional 35% by the year 2010 in the United States alone (*Wireless Telecommunication Services Industry Profile, 2006*). Since wireless networking has experienced and continues to experience tremendous growth, it was important that the CIT department analyze the existing wireless networking course being offered.

The CIT department currently offers two baccalaureate degrees. The first is a BS in information systems technology (IST) and the second degree offering is a BS in network engineering technology (NET). Each of these degrees accounts for roughly half of the student population of the department, which is currently at 550 students. Additionally, there are several areas of specialization within each degree that allow students to concentrate their studies on a specific focus within the IT field. This breakdown can be seen in below. The students who are progressing towards a BS in NET are the primary audience of the courses detailed in this paper.

In 2002, there was only one course being taught that covered wireless technologies. This course, however, concentrated heavily on wireless communications instead of wireless networking technologies. The course relied heavily on the mathematics and science behind signal propagation and the radio interface, as well as the standards and working groups of the telecommunications industry. While these fundamentals are important for students to understand (Reisman, 2005), a movement towards the applications of these

fundamentals to businesses and industries was needed (Goscinski et al., 2005). Additionally, the laboratory component had very little correlation to the material presented in lecture. The laboratory objectives that the students were completing were not sufficient in providing a solid understanding of wireless networking, and it was not supplying them with the information and knowledge of the emerging technologies of the time. The desire was to move the course away from a largely signal engineering-based course to a network engineering course, in order to equip the students with the necessary knowledge and experience for the current wireless network environment.

The original course has been modified and is now the first of three wireless networking courses that are taught in the CIT department. It is listed as CIT 346—Wireless Networks and is offered as a junior-level course. CIT 346 now provides the fundamentals of 802.11-based wireless networks, basic signaling, and modulation technologies and the importance of proper network design and implementation. Also, the laboratory component is tied directly to the material presented in lecture. The laboratory experience also has been improved by explicitly stating assignment objectives (what tasks are to be accomplished) and requiring responses to “knowledge items” (what knowledge should be gained by accomplishing the specified tasks). This requires each student to be able to directly apply material covered during the lecture to the specific tasks performed during the weekly laboratory assignments. For example, in one laboratory assignment, students are to build a multi-access point wireless network and perform a seamless handoff from one AP to another AP, using a client device, while a second client device runs frame/packet capture software to record the traffic. The “knowledge item” for this exercise is for each student to be able to identify the frames required to successfully complete the handoff and be able to discuss their ordering and what function each frame performs. This exercise ties directly to the lecture material concerning 802.11

Figure 1. CIT degrees and specializations

	CIT	
B.S. Degrees	IST	NET
Areas of Specialization	Database Administration Systems Integration Application Development	Wireless Networking Network Security & Forensics

framing and provides reinforcement on this topic to the student.

An additional undergraduate course was created to concentrate on the topics of wireless network security and management. This course is listed as CIT 499—Advanced Wireless Network Security and Management and is offered to students with a senior-class standing who have successfully completed CIT 346. This 400-level course allows students to focus entirely on topics of wireless security and management, which include focus areas in current security standards, thwarting attacks, and equipment vulnerability testing. This course also presents additional information concerning wireless network management and security techniques. The laboratory portion of the wireless network security and management course allows students to gain valuable experience and knowledge on securing and managing enterprise-class wireless networks by finding flaws and vulnerabilities. The laboratory objectives are defined in such a way as to direct students towards a solution without giving them detailed instructions on how to complete a task. Similar to the CIT 346 laboratory, the CIT 499 laboratory uses “knowledge items” to ensure students are able to directly apply lecture materials to laboratory experience.

Lastly, the CIT department offers a graduate-level course that concentrates on cellular and wireless wide area networking (WWAN) tech-

nologies. This course is listed as CIT 581—Topics in Advanced Wireless Networking and is offered to graduate students and senior-level students. This course examines the evolution of cellular networks in both the United States and abroad, in addition to discussing the emerging WWAN standards and technologies of 802.16 and 802.20. These topics cover approximately half of the semester. Students are required to perform research on a wireless topic that interests them and then present their research/findings to the class. This includes a 15-20 page publication-quality paper as well as a 30-minute presentation and the subsequent discussion.

The creation of the graduate-level course has enabled the creation of the WWAN laboratory on the roof of Knoy Hall of Technology. This WWAN laboratory was begun as a simple wireless backhaul evaluation scenario and quickly grew to an environment for testing and evaluating many different WWAN technologies. The laboratory is ideally suited for testing many different scenarios, due to the diverse landscape surrounding the university. These scenarios include “extending the enterprise,” which utilizes the equipment to replace the wired wide area infrastructure of an organization, to providing rural broadband wireless access, and more. The WWAN laboratory allows the students of the CIT 581 class to complete a semester project that integrates the material covered in the lectures with a hands-on approach to WWAN designs and implementations. This hands-on study also allows students to compare characteristics, such as security, throughput, quality of service (QoS), and reliability, of equipment from different vendor.

What does the future hold for the wireless network curriculum in CIT? It will certainly include the continual examination of the emerging technologies in each of these areas and applying those new technologies to the curriculum to keep students on the leading edge. The future also will include the development of an additional undergraduate course that will concentrate on

the emerging network capabilities of radio frequency identification (RFID), Bluetooth, and wireless mesh networks. This emerging course will include identifying the specific requirements of the micro-sized networks of RFID and Bluetooth, in addition to detailing the LAN and WAN capabilities and interactions of meshed and grid networks and how they differ in function, applicable standards, and performance.

Courses

The following is a discussion of the existing wireless networking courses offered by the Department of Computer and Information Technology in the Network Engineering Technology area of specialization.

CIT 346—Wireless Networking

Prerequisite Knowledge

In order to fully understand the concepts presented in CIT 346, there are two courses that are needed to ensure the student will have a solid foundation of knowledge to build upon. The first prerequisite is the successful completion of CIT 330—Local Area Networking and Systems Administration. This course provides the framework for understanding how LANs function and provides an introduction to systems administration techniques. The second prerequisite is the successful completion of ECET 374—Digital Telecommunications offered by the electrical and computer engineering technology department solely for the CIT's NET specialization. This course provides an introduction to the signaling characteristics, modulation techniques, multiplexing, and appropriate protocols and standards of digital communications. ECET 374 requires the completion of two calculus courses and one statistics course, which are second-tier prerequisites for CIT 346.

Audience

This is a 300-level undergraduate level course for students in the Computer & Information Technology Department, majoring in Network Engineering Technology (NET), who have an interest in the expanding field of wireless networking. CIT 346 assumes no formal education in wireless communications or networking systems. This course is available as an elective for Electrical and Computer Engineering Technology students who have fulfilled the specified prerequisites.

Course Concepts

CIT 346 focuses primarily on the area of wireless local area networks (WLAN). The course initially introduces students to wireless principles, behavior, and theory, propagation patterns of various antennas, performance, and coverage differences between the various standards (e.g., 802.11a, b, and g) as well as basic network architecture. With this basic framework, the course moves to the topics of wire-line network integration, large-scale wireless network design, and wireless network security and management. The course ends with an introduction to cellular technologies. The following list briefly details the progress of CIT 346 through the semester, starting with week one and finishing with week 16.

- Course introduction and overview
- 802.11 MAC
- 802.11 framing
- 802.11 management operations
- WLAN communications
- Basic RF and antennas
- Site survey and deployment analysis
- 802.11 PHYs
- WLAN security and management
- 802.11a and 802.11g
- WLAN challenges, troubleshooting, trends, and future standards

- Introduction to cellular concepts
- GSM, GPRS, and EDGE
- CDMA technologies
- Other WWAN technologies

The laboratory portion of CIT 346 is vital to the success of the students. The laboratory objectives are structured to reinforce the information presented in the lectures by allowing the student to directly observe and interact with equipment to reach a defined set of objectives. The following list shows the topics covered in the CIT 346 laboratory.

- WLAN fundamentals
- Roaming and handoff
- Antenna diversity
- Site survey techniques
- Basic WLAN security
- Network design recommendations
- WLAN management
- WLAN integration

Figure 2 shows the progress of material presented and the correlation between lecture and laboratory materials for CIT 346.

Advanced Wireless Network Security & Management—CIT 499

Prerequisite Knowledge

In order for the student to be able to fully grasp the material presented in lecture and lab, there are

two prerequisite courses for this undergraduate course. First is the successful completion of CIT 346. This course provides the foundation information of how wireless networks operate and provides an introduction to the security and management concepts that will be detailed in CIT 499. Second, the successful completion of CIT 343—Advanced Systems & Network Administration is mandatory. CIT 343 expands on the systems administration knowledge gained in CIT 330 and provides the students with hands-on knowledge of the UNIX and Linux operating systems. This knowledge is vital to the success of the student in the Advanced Wireless Security & Management course because a majority of the tools and utilities used in the laboratory are Linux/UNIX based.

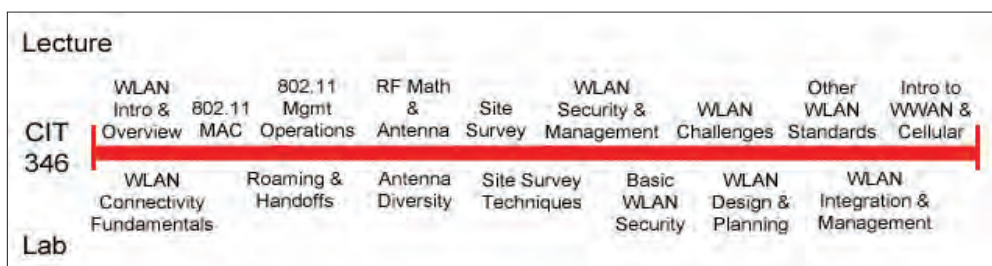

Audience

This course is a 400-level undergraduate course that expands on the security and management topics that were briefly covered in CIT 346. CIT 499 assumes that students fully understand signaling and RF basics, as well as the operations of WLANs as covered in CIT 346. CIT 499 is also available to graduate students who have an interest in the security and management topics involved with operating and maintaining a wireless network in an enterprise environment.

Course Concepts

CIT 499 concentrates on the security and management of WLANs. It starts with a short review of

Figure 2. CIT 346 course topic timeline

A Wireless Networking Curriculum Model for Network Engineering Technology Programs

details from CIT 346 and then immediately delves into the security issues of current WLAN installations. This initial material exposes the inherent lack of security in all wireless systems and then discusses techniques to mitigate those risks. The course then moves to WLAN design and other management fundamentals. The following list shows the basic concepts covered in CIT 499.

- 802.11, basic RF review, and security models
- Antenna design
- WLAN vulnerabilities
- WPA
- 802.11i/WPA2
- EAP protocol and methods
- Authentication servers
- Encryption and key management
- Auditing WLAN/WWAN
- WLAN/WWAN design fundamentals
- WLAN/WWAN policies
- Wireless management standards and protocols
- WLAN, WWAN, and cellular integration
- Legislation concerning wireless networks and communications

The laboratory portion of CIT 499 gives students hands-on experience in the topics covered in the lectures. The objectives of the laboratory assignments are designed to give the students the basic skill set to design, secure, protect, and manage an enterprise wireless network. These labora-

tory exercises correspond to the topics covered in lectures and are shown in the following list.

- Intrusion techniques
- WEP vulnerabilities
- EAP method performance
- EAP method vulnerabilities
- WLAN VPN/WPA/802.11i performance evaluations
- WLAN/LAN integration and monitoring

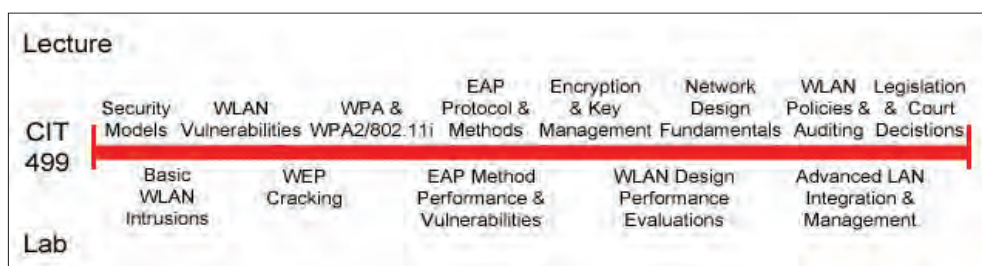

Figure 3 shows the progress of material presented and the correlation between lecture and laboratory materials for CIT 499.

Selected Topics in Advanced Wireless Networking—CIT 581

Prerequisite Knowledge

In order for the student to be able to contribute to the in-class discussions in CIT 581, there are several prerequisites that must be satisfied prior to enrollment in this course. First, a basic understanding of RF and wireless fundamentals is assumed. In addition, it is assumed that students are knowledgeable of IT, in general, and possess an in-depth knowledge of telecommunications and networking. This usually means the successful completion of CIT 346. This course is intended primarily for graduate students, but a select number of senior-level students are allowed to enroll, if they meet two criteria. They must earn

Figure 3. CIT 499 course topic timeline

an overall grade of 80% or higher in CIT 346, and they must receive the signature of the professor indicating that they are aware they must perform at the graduate-student level.

Audience

This is a graduate-level course for students interested in advancements in selected topics of wireless communication systems. CIT 581 may be a selective for students from undergraduate majors in the CIT department, provided they meet the prerequisite requirements.

Course Concepts

CIT 581 concentrates on the cellular industry and its technologies as well as incumbent and emerging WWAN technologies. The course begins with an introduction to cellular systems and their evolution, which leads into discussions on cellular concepts and standards, such as PCS, GSM, and cdma2000. CIT 581 then covers the emerging 802.16 and 802.20 technologies and standards. This portion of the course lasts for approximately eight weeks. The following list shows the topics covered during the initial portion of CIT 581.

- Introduction to cellular technologies and fundamentals
- PCS
- GSM
- GPRS
- EDGE
- cdma2000 & cdmaOne
- EV-DO and EV-DV
- 802.16 & 802.20
- 4G definitions
- Link viability determination

The remainder of the semester is used by students to make presentations on areas and topics they have individually researched. The information presented by each student corresponds to

a 15-20 page publication-quality paper that is submitted to the professor for evaluation. The topics that are presented by the students change each semester as students choose topics that appeal to their interests within the framework of the course. Previous topics that have been presented by students are shown in the following list:

- high-speed handoffs in wireless data networks,
- location-aware wireless devices and applications,
- the feasibility of municipal-provided wireless networks,
- free space optics, and
- RFID applications and challenges.

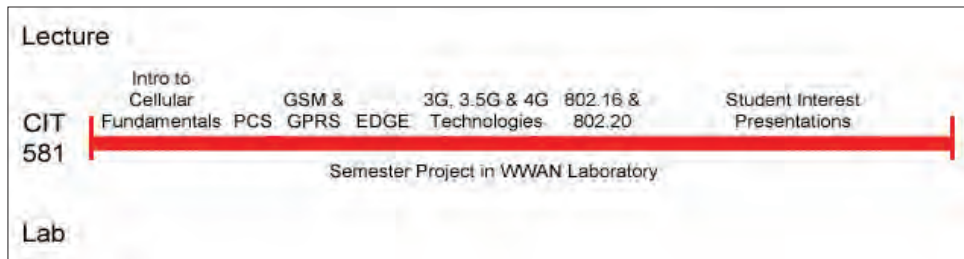

Students apply lecture material to real-world situations through use of the Knoy Hall WWAN laboratory. This allows students to operate and evaluate many different types of WWAN equipment in a diverse set of circumstances. Previous projects have included point-to-point link evaluations, wireless Internet service provider (ISP) simulations, and WWAN integration into an enterprise LAN/WAN.

Figure 4 shows the progress of lectures and student presentation topics throughout the semester for CIT 581 and the corresponding semester project.

SUMMARY

The CIT department at Purdue University offers three courses in the wireless networking field. These courses have been designed to provide students with an appropriate amount of detailed information and hands-on knowledge to benefit them in the workplace. Each of these three courses in wireless networking emphasizes a specific area within that field. CIT 346 covers the introduction to wireless networking and concentrates on wireless local area network technologies. CIT 499 covers

Figure 4. CIT 581 course topic timeline

detailed topics on wireless network security and management in both local and wide area networks. CIT 581 introduces and examines cellular and other wireless wide area network technologies. Each of these courses utilizes a laboratory component to provide hands-on experience with the material covered in lectures. The future of the wireless curriculum is certain to expand through continual examination of emerging technologies and expansion of existing technologies.

Chapter 2.41

Agent-Based Architecture of a Distributed Laboratory System

Hong Lin

University of Houston-Downtown, USA

ABSTRACT

We present a method for designing the architecture of an agent-based e-educational system. We demonstrate the effectiveness of our method by its application in the design of a computational grid built to be an environment for lab activities. An integrated lab package was developed to allow students to utilize the grid services and support the learning process. Our architectural design strategy ensures an outstanding feature of the system: It allows lab modules to be added into the system in an incremental fashion while ensuring the correctness of the system. Students are recruited in our research program to develop lab modules and build the grid. Initial use of the lab package indicates that it allows lab activities to be performed more efficiently and it enhances the learning effectiveness.

INTRODUCTION

Agent-oriented design has become one of the most active areas in the field of software engineering. The agent concept provides a focal point for accountability and responsibility for coping with the complexity of software systems both during design and execution (Yu, 2001). Such a complex system typically cannot utilize the central control strategy, because it consists of loosely coupled self-contained functional units, each with its own mentality and behavior, because they are designed to deliver different services to different groups of clients. This brings unprecedented challenge to software engineering, because the design of such a system must ensure correct interaction among the functional units as well as correct implementation of each unit, probably running on different platforms. The emergence of intelligent agent conceptualization brings forth a modeling

tool deemed to be effective in coping with the issues in developing large-scale distributed systems (Paquette, 2001). In this approach, a distributed system is modeled as a set of autonomous, cooperating agents that communicate intelligently with one another, and interact with human users at the right time with the right information.

A distributed learning system is a typical complex distributed system that involves many dynamically interacting educational components, each with its own goals and needs for resources while engaged in complex coordination. It is very difficult to develop a system that could meet all the requirements for every level of educational hierarchy, since no single designer of such a complex system can have full knowledge and control of the system. In addition, these systems have to be scalable and accommodate networking, computing and software facilities that support a large number of simultaneous users concurrently working and communicating with one another (Vouk, Bitzer & Klevans, 1999). A special challenge in the design of an educational system is that it must be modular while having a distributed nature. Modularity is required so the system can be scaled to accommodate multiple course modules. In this article, we discuss the design of an online learning system that supports laboratory activities for computer science curriculum. The laboratory is performed in an educational grid. We use a multi-agent system (MAS) to design an infrastructure that allows for incremental development of lab modules.

We have studied the implementation of Collaborative Agent System Architecture (CASA) (Flores, Kremer & Norrie, 2001) with the chemical reaction model (CRM) (Banâtre, Fradet & Radenac, 2004, 2005a, 2005b). CASA can catch the interactive and dynamic nature of e-learning systems. Our research results are published in Lin (2005) and Lin and Yang (2006a). Following our existing work on the design methodology of MAS, we exploit this methodology in a project that aims at a grid for laboratory use in under-

graduate education. The new method will provide a solution to current problems in the design of a comprehensive environment to support lab activities in teaching courses on parallel/distributed systems and networks. Although great efforts have been put in the development of software lab packages (for example, the Phil_2000 lab package for introductory computer science courses), most of the labs are still ad hoc activities. Without a central controlling model, available computing resources cannot be effectively utilized. In addition, teachers and students may be discouraged to explore the use of advanced labs to enhance learning effectiveness, because they often have to repeat the same scenarios inefficiently in different labs due to lack of an integrated lab package. The unified model in chemistry-inspired languages will enable formal specification of an evolving system and provide a framework for top-down design of the entire system (Banâtre, Fradet & Radenac, 2004; Lin & Yang, 2006a, 2006b). This design strategy will lead to an architecture that enables incorporating lab modules into the lab package in an incremental fashion.

The organization of this article is as follows. Next, we will give some background that initiated our research project. Then, we articulate the design goal, design ontology and architecture of the designed system. A showcase is described, and the implications of the lab package to the education are discussed afterwards. Then, we discuss some related works and compare our system to other e-learning systems in the literature. Finally, we give concluding remarks and discuss the future works.

BACKGROUND

With the fast innovation of computer and communication technologies, computer curriculum is being adapted to accommodate teaching modules that enhance teaching effectiveness by utilizing frontier technologies. Apart from traditional

computer science curricula, information technology (IT) curricula strive to equip students with modern computer technologies defined by the current industrial desires. The Department of Computer and Mathematical Sciences (CMS) at the University of Houston-Downtown (UHD) is augmenting its computer science curriculum by an IT track. One of the most important parts of this project is designing labs that can be performed through the Internet. Our first step is implementing lab packages for our parallel computing and computer-networking courses in a grid that encompasses lab facilities centered at a Beowulf cluster. We will then extend our lab environment to include other computer science and mathematical courses.

The challenge we face, however, is that we need to build an infrastructure that will accommodate multiple courses in different disciplines. The main problems we are solving are: 1) to define an interface extensible to incorporate more lab modules and customizable to different course structures; and 2) to establish a computational backbone that provides services for various lab activities, such as testing a parallel program, producing network phenomena and analyzing performance. Performing these activities requires coordination among multiple nodes. The architecture of the system requires extensibility and scalability to accommodate multiple course modules.

To address the first problem, we follow the practice we had when we built the lab package for our introductory computer science course. One of the outstanding features of this package is a lab explorer that allows students to browse through lab activities. Another feature is click buttons, which invoke programs through the interface. We adopt the same structure in the lab package we designed for our parallel computing and networking courses.

To address the second problem, we need to build an array of servers that run on a computational grid. A grid is a system of networked computing and storage sources (see *Grid.org*) that allows the

sharing of information and computational powers. The grid is also a platform on which experiments of distributed data processing and computation can be exercised. Services are provided by different nodes of the grid. The design of the grid must meet certain criteria so the incorporation of any unit fits into the long-term blueprint. For example, as mentioned, the underlying infrastructure must support incremental and dynamic addition of lab exercises into the lab package. This is to support ongoing construction of closed labs for courses in parallel computing, computer networking and other courses (Lin & Nguyen, 2005). On the other hand, however, the complexity of the system makes the design of its infrastructure difficult. Our existing research results suggest that the agent model is a powerful tool to solve problems in a distributed system. Therefore, we use agent technology to build the architecture of the grid to manage the coordination and communication among the nodes and handle load balancing issues. We envision that our practice will provide a solution to the problem of immersing current technologies into educational efforts.

THE PROJECT

Goals and Objectives

The barrier in front of us is the integration of various networking technologies into one client/server model to provide a uniform lab environment for different lab activities. Given the targeted use of this solution, we need to define and implement the infrastructure that balances functionality and reliability. This leads to development of an educational grid, which is an integrated environment for resource management, lab module development and lab activity support. The architectural design of the grid should focus on system topology, interactions among system units and dynamic features of the system, without involving proprietary platform information, such as the operating systems

on individual nodes, programming languages for program units and vendor-specific machine features. With MAS modeling, interfaces among system units will be formally specified, and design and deployment of each functional unit, such as a lab module, will not affect other units or cause any revision on the overall system.

As described above, an agent system provides an architectural model for a distributed networking system. As an active research area, the study in agent technology strives to apply intelligent information-processing technologies to complex software systems. Features of an agent system have been summarized in the literature. For example, according to Griss and Pour (2001), an agent shows a combination of a number of these characteristics: autonomy, adaptability, knowledge, mobility, collaboration and persistence. These features exist in different types of MAS, such as collaborative agents, interface agents, reactive agents, mobile agents, information agents, heterogeneous agents and economic agents (Weiss, 2003). The chemical reaction model is a high-level computational model that makes the minimum assumptions on the underlying computing platforms. It has no artificial sequentiality and it has higher-order program composition operations. It can specify the dynamic features of an MAS succinctly without involving any assumptions on proprietary computing platforms. This article focuses on the architectural design of the agent-enabled grid, the integrated laboratory and their impact on the education. We omit technical details about the chemical reaction model (Interested readers can refer to our publications for explanations of our methods). In Lin (2005), a sequence of case studies shows that features of various agent systems can be grasped by the chemical reaction model succinctly. In Lin and Yang (2006a, 2006b), we give comprehensive examples of specifying a course material maintenance system using the chemical reaction model. In addition, part of our work in constructing the cluster is presented in Lin and Nguyen (2005).

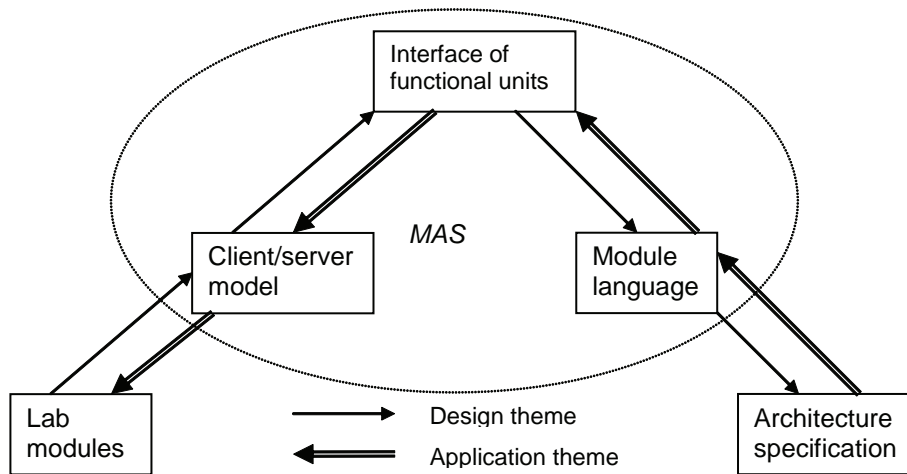

The Design

The project includes a sequence of major steps: grid construction, lab design, client/server model definition, the definition of the interface of functional units and the agent-based architecture construction. Our plan can be described as a pyramid-shaped model, illustrated in Figure 1.

The system is designed using a bottom-up strategy (the Design Theme). We constructed the grid and design lab modules using existing toolkits: Globus Toolkit 4, Java and Apache Server. The services provided by the system are implemented in client/server architecture. A Java-based user interface delivers the services on the Web. A master server forms a gateway to re-direct client requests to other servers. Multiple servers interact with one another through formally defined interfaces to cooperate in fulfilling client requests. In our system, all functional units, including servers, are modeled as an agent. Each agent is then designed in the module language we have proposed for specifying MAS (Lin & Yang, 2006a). The overall system is specified in the chemical reaction model. In Figure 1, we can see the MAS is the conceptual model for implementing grid services, and the interfaces of functional units define the interaction among functional units and are the central part of the agent system. The interface also separates the architectural design from the design of individual functional units.

Adding/deleting services or features in the grid can be done in a top-down strategy (the Application Theme). If a service of a new type is to be added into the system, for example, it is added into the architectural specification. Through an automatic transformation procedure (Lin & Yang, 2006a), the specification is re-written into an MAS in the module language. The actual program that codes the services is then incorporated into the system through the standard interface. Therefore, updating services or lab exercises in the system will not cause any changes in other parts of the

Figure 1. The pyramid model of the project

system, and correctness and reliability of the system can be ensured to the maximum extent.

In the following sections, we give more detailed descriptions of the steps in the design theme.

The Grid

In creating a computing environment suitable for running programs in different disciplines involving distributed processing, we construct a Beowulf cluster and create a grid node from this Beowulf cluster with bus-based communication connectivity and use it as a dedicated computing resource and platform for experimenting parallel computations with regular communication patterns. This makes experiments on various network topologies feasible and, therefore, allows us to evaluate parallel programs on different architectures. The grid is then built by incorporating networked classroom computers using Globus Toolkit 4 software. The grid uses the most prevailing networking technology so that the labs designed for the computer networking course will give the students an image of the operations in the real-world networks. The cluster is virtually incorporated into the grid to provide a platform for experimenting operations in parallel computing and networking, such as dynamic

load balancing, non-uniform memory access and dynamic routing in networks. One of the nodes of the cluster is configured as the master node, which runs the master server. The master server coordinates the services provided by servers on various nodes of the cluster. The Web server with the graphical user interface (GUI) of the lab will run on an up-front Windows machine and the Web server communicates with the master server for any services.

The Lab Package

We set the criteria that guide the development of lab package to achieve effective utilization in teaching the concepts in parallel computing, grid computing and networks. The lab design plays an important part in the system, because it is used as the target application of the methods we are developing. The comprehensive lab package runs on the grid. The lab package includes an interface, written in Java Applets to allow Web access, and a stack of servers running in the background (mainly on cluster nodes) to incorporate services into a unified environment. We have implemented two labs in the above Java framework and will continue to develop more labs. These labs will be used to investigate client/server computing model

and interfaces of functional units, which are the foundations of our multi-phase architectural design methodology. The targeted versatility of our lab package requires the following features:

- **Scalability:** We can add new nodes into the grid or delete nodes from the grid.
- **Extensibility:** The design of the lab environment should make it possible to incorporate other software packages to enhance the functionality.
- **Customizability:** Object-oriented design of the architecture and standardized interfaces of objects should ease lab composition.
- **Accessibility:** The lab software should create an interface for users to control node activities through the Web browser.
- **Robustness:** The client-side component of the lab software should ensure the correctness of the program before loading it onto the grid for execution.

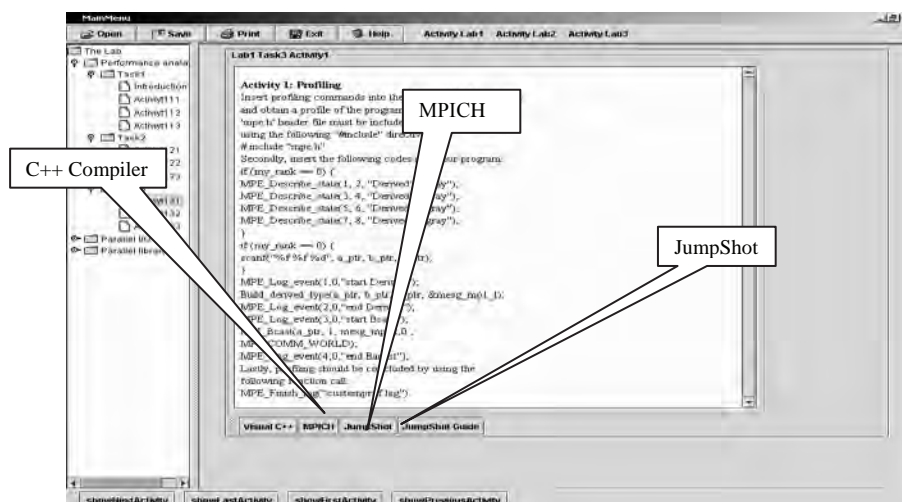

These features impose special requirements on the client/server computing model for delivering services.

Client/Server Model Definition

Each service is implemented in a client/server model. Servers are running in cluster nodes. Different servers may run on different nodes to achieve load balancing. Services are ordered by clicking a button on the user interface. For example, Figure 2 shows a snapshot when a parallel program is loaded onto the cluster. Three buttons are displayed on the bottom of a text window to allow the compilation, execution and profiling of the program.

Since all lab activities are performed in the client/server model, a master server is designed to act as a backbone of the whole lab architecture. Auxiliary servers are designed to perform various network activities, such as database searches, data encryption/decryption and address translation, and are deployed in different nodes in the grid. The lab software allows the students to start, monitor and terminate a program on any particular node of the grid. With this feature, students can experiment service configurations in a distributed system and examine how network features affect the performance of the system. An incorporated node manager provides the students, via GUI, a list of available nodes in the grid where they can

Figure 2. Starting servers through the interface

select a set of nodes for running the program. A separate window can be opened for each node to monitor the activities ongoing on the particular node. Figure 3 shows a snapshot of the node manager. Once a node is selected from the dropdown menu (on the lower left side), a pop-up window (in the center) is displayed to allow configuration of services and monitoring of activities carried out by the servers. Configuration of services on a node is done by clicking the toggle buttons. For security reasons, all services are predefined.

Interfaces of Functional Units

Functional units of the system include servers, clients and resources. Resources in our system are self-contained functional units that serve as information sources. For example, a database is wrapped by an agent that provides basic data storage and retrieve services. Standard interfaces of functional units allow modular design and incorporation of the system and allow information sharing.

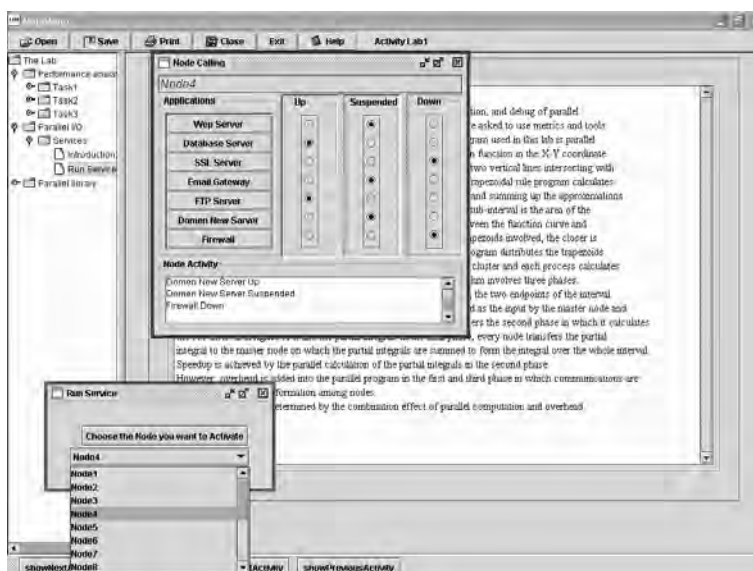

Given the complexity of the system, the definition of interfaces of agents is a critical part of

the system design. The interfaces are defined in the computation model that supports the chemistry-inspired languages, which are employed to specify the agent-based system architecture and facilitate a transformational method to implement the system (Lin, 2005; Lin & Yang, 2006a).

A SHOWCASE

We have laid out a list of labs for our parallel computing and networking courses that have been chosen as the first test-bed of our system. These labs are carefully designed based on the goals of the course set forth in its syllabus and our teaching experience. Lab topics are either typical topics of the area or problems tackled within the course projects. The lab design emphasizes the operability and vividness as well as the manifestation of the basic concepts and typical technologies. We also address the role played by the cluster when we design the labs. For example, one lab allows students to analyze the performance of a parallel program on the cluster. This lab aims to help students understand the metrics studied in the classes

Figure 3. A snapshot of the node manager

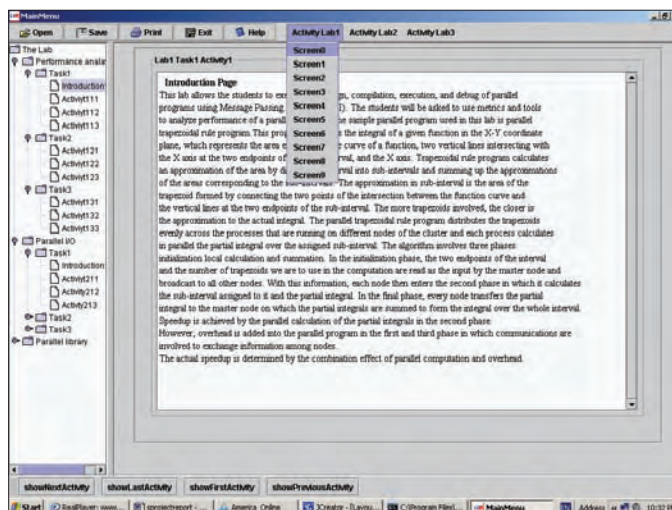

— that is, speedup and efficiency — to measure the performance of a parallel program. Other labs are designed to help students understand the topology of the connection in a distributed system, the use of collective communication operations in scientific programming, the concept of communicators that facilitates structured communications in Message Passage Interference (MPI), the load balancing techniques in combinatorial search and so forth. In the following, we describe the scenario of the lab on the performance analysis of a parallel program.

This lab allows students to use standard metrics to analyze the performance of a parallel program. The students predict the performance of the parallel program they choose, load the program onto the cluster, compile and run the program, and then compare the predicted results to the experimental results. As illustrated in Figure 4, one lab session is organized in a series of tasks and each task into a series of activities. In this lab, students study some standard measurement criteria —that is, speedup and efficiency — for performance analysis of parallel algorithms in Task 1 Activities 1 and 2, and predict the speedup and efficiency of the chosen program given the size of the problem input and the number of nodes

in Activity 3. Task 2 requires the students to load the chosen program onto the cluster and then compile the code. The students can click on the C++ Compiler button at the bottom of the page to compile the code once the loading is finished. Task 2 Activity 1 walks the students through the program loading process; Activity 2 asks students to compile the code. The code is then checked in Activity 3 by a program to ensure its correctness. Erroneous code causes the students to be asked to correct the code until it is errorless. In Task 3, students can analyze the experimental performance of the program by using MPICH JumpShot profiling software and compare the experimental results to the theoretical predicts done in Task 1. In Activity 1, students are required to insert profiling commands into the program and obtain a profile of the program by running it. In Activity 2, students start up the JumpShot program from the program menu to obtain a Gantt chart of the program. The students then calculate the actual performance data by using the logged timing data, and compare the experimental results to the predicted. This is done in Activity 3.

Figure 5 shows some snapshots of the lab activities. Figure 5(a) shows the window that takes the student’s responses to performance

Figure 4. The main window of the lab platform

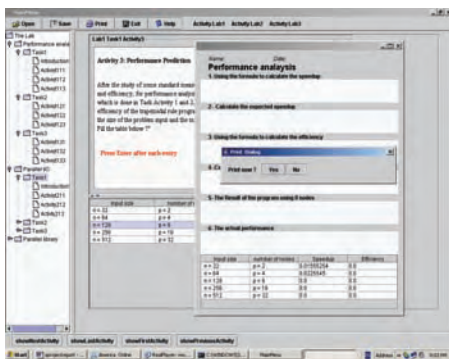

prediction questions. Figure 5(b) shows the moment when the student opens a program through a dialog window and monitors the execution of the program through a pop-up window. Figure 5(c) shows a text window in which the student adds profiling statements into the program.

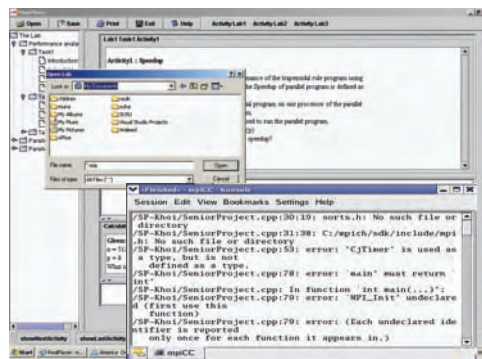

It would be useful to review the problems a teacher may encounter in the teaching process and how the system addresses these problems. Performance analysis of parallel programs is a typical topic of a parallel computing course. An experiment on performance analysis involves the use of several tools; that is, the compiler of parallel programs, a host file to select nodes to run the program, the shell command to execute the program and a profiling program to perform a posteriori analysis. Without an integrated platform, students often spend a lot of time probing the use of these tools instead of focusing on the problem to solve. In addition, since the students

must handle the aspects of the experiment piece by piece, they are given unnecessary access right to the system resources. In our system, all lab activities are performed through a uniform interface and jobs are handled by the client/server execution model. Although students do not access the grid directly, the tools to use are available through the client interface (accessibility). On the other hand, students can only run programs allowed through the interface. This reduces the chances for them to run malicious or malfunctioning programs (robustness). The teachers are given the authority to incorporate a different set of programs into a different lab module (extensibility). A dynamically computed master host list contains the currently available nodes in the grid. The students can choose to use the master host list as the default or form their own host list to test their programs (scalability).

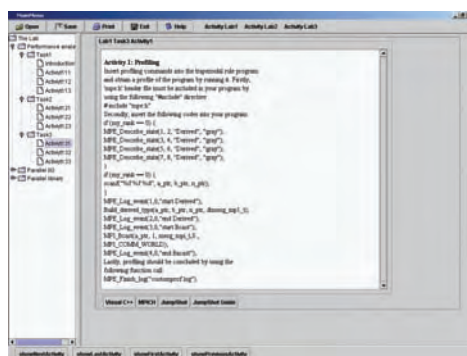

Figure 5. Snapshots of lab – performance

a. Performance prediction

b. Compilation and execution

Perhaps the first benefit brought forth by this system is time efficiency in general. It typically took a whole class meeting for the students to do a closed lab. Except for those well-prepared students — for example, those with prior experience — the students spent a large portion of their time in learning how to use the tools. A lot of students were not able to finish the labs in the end of the class session and had to take the labs as their homework. With the integrated toolkit, the students can basically follow the instructor through the whole lab in one class session. The reason for this is that the software helps the students focus on the main theme of the lab and exempt them from taking care of unnecessary details. For example, when compiling or running an MPI program, the students no longer need to know what command to use and what command options to use. Time efficiency is especially important for a minority serving institution (MSI) such as UHD, which has limited resources and a student body of diverse academic preparations.

It is notable that the lab package makes feasible a lot of experiments that were not easy previously. With the integrated lab platform, it is fairly easy to repeat the experiment without switching between platforms. A problem that recurred frequently in this lab is use of an erroneous program. To avoid spending time in correcting compile-time errors, the students were asked to use a program that was developed and tested in previous course works. We did not allow the students to use a program that came alone with the software package because we wanted the students to be exposed to different behaviors of the system in different application contexts. In the performance analysis lab, the students were required to draw a speedup function curve by analyzing the profile of the first few results obtained by using a sample number of nodes. The function curve was then used to predict the performance of the program on different numbers of the nodes. If there was a significant discrepancy between the predicted result and the experimental result, the students would be asked to repeat the experiment to remove the deviation

caused by temporary problems. Recurring discrepancy would need further analysis by taking the machine features and load balancing features of the program into account, which was usually taken as homework.

RELATED WORKS

Greer McCalla Vassileva Deters, Bull and Kettel (2001) elaborated the lessons learned from several large-scale, real-world deployments of the I-Help agent-based peer-help learning support system. Gavrilova, Voinov and Lescheva (1999) described a project of an intelligent MAS for distance learning using Learner-model approach. Thaiupathump, Bourne and Campbell (1999) investigated the effects of applying intelligent agent techniques to an online learning environment. They created the knowbots that automated the repetitive tasks of human facilitators in a series of online workshops. The findings indicated that the use of knowbots was positively associated with higher learner completion rates in the workshops. Baylor (1999) defined three major educational potentials for agents as cognitive tools: 1) as assistants, managing information overload; 2) serving as a pedagogical expert; and 3) creating programming environment for the learner. All of these works focus on supporting learning models using intelligent agents instead of addressing the complexity of the distributed learning systems.

On the software engineering side, a number of Architecture Description Languages (ADLs) have recently been proposed to cope with the complexity of architectural engineering. These include Rapide (Luckham, Kenney, Augustin, Vera, Bryan & Mann, 1995), Darwin (Magee & Kramer, 1996), Aseop (Garlan, Allen & Ockerbloom, 1994), Unicon (Shaw, DeLine, Klein, Ross, Young & Zelesnik, 1995) and ACME (Garlan, Monroe & Wile, 1997). ADLs provide constructs for specifying architectural abstractions in a formal notation and provide mechanisms for reasoning about the architecture. They focus

on defining architectural elements that can be combined to form a configuration. Few research efforts aim at truly defining an architectural description language for MAS.

Some formal languages have been proposed to address design issues of MAS. They focus on construct abstractions that can capture “social” behaviors of agents, such as beliefs, desires and intentions (BDI). Unfortunately, none of them is a complete formal system based on a finished computation model, and they are still under development. For example, SkwyRL-ADL (Faulkner & Kolp, 2002) is proposed as a BDI-MAS language to capture a “core” set of structural and behavioral abstractions, including relationships and constraints that are fundamental to the description of any BDI-MAS architecture. As it is still striving for a fully defined set of abstractions, it does not clarify the relationship of the architectural model to the underlying computation model and, therefore, does not serve as a language that encourages program design by derivation or transformation. Another attempt for addressing the architectural design of MAS is presented in Kokar, Baclawski and Eracar (1999), where control theory-based architecture for self-controlling software is developed. This model aims at a framework to accommodate formal methods for specification of agent functionality and inter-agent communication. However, no formal language is developed to facilitate the formal design. Instead, the author is attempting to use existing languages such as such as Extensible Markup Language (XML), DARPA Agent Markup Language (DAML), and (Unified Modeling Language (UML) to implement his vision.

CONCLUSION AND FUTURE WORKS

We present a method for designing a computational grid that supports online lab exercises, as part of our IT track of curriculum design. A lab package is designed to support the learning process in

courses of parallel computing and networking. The grid is centered at a Beowulf cluster, which provides a computational backbone of the grid, and services are deployed in distributed nodes of the computing networks and organized by an MAS. The agent conceptualization successfully addresses high-level architectural design issues, such as scalability, extensibility and modularity. We have developed the lab package with a framework that accommodates different lab activities in different courses. Although the depicted system is still in the development phase, the foundations have been established. The approach we use allows us to design the architecture that supports the development of modular components and allows the modules to be added in an incremental fashion.

The system is being developed in different levels of the pyramid model concurrently. We have designed several lab modules and used them in our parallel computing classes. Although the lab packages are not as stable and full-functioning as commercial software, they present the complex concepts in an integrated programming environment and give the students a starting point to acquire more sophisticated design techniques. We continue to involve students in the design and improvement of the lab modules in the form of senior projects and student research programs. The grid has been fully established and is being tuned for the best performance. The peak High Performance Linpack (HPL) benchmark performance of 16 nodes is 18Gflops at this point.

We try to avoid touching hard issues in our lab activities. For example, issues relating to load balancing and network congestion require deep analysis that need other algorithms and tools. We will, however, integrate more tools into the system so that more experiments can be performed.

We will add more lab modules into the system to support experiments on parallel/grid computing, computer networking, security, databases, programming languages and other courses in an incremental fashion. By including more and more lab modules, we envision a new classroom culture

that inspires more practice-oriented learning. With the grid as the computing base, we set our long-term goals at information sharing among multiple institutions and cross-campus collaborations in developing and evaluating course modules as well as research collaborations.

A Project–Based Learning Approach: Online Group Collaborative Learning

Jianxia Du

Mississippi State University, USA

ABSTRACT

A framework for Online Group Collaborative Learning is illustrated in this paper. The foundation of the framework is based on Piaget's concepts of assimilation and accommodation and Vygotsky's theory of social interaction. This paper examines how an online project-based learning approach affected students' cognitive skills development and motivation, and explored factors leading to successful collaborative projects. The results indicated that, in a project-based online group environment, unique characteristics exist for leadership style and individual role, goal setting and project management, accountability and commitment, peer supportive relationships, individual

accomplishment and group accomplishments, and mixed gender and race group preference.

INTRODUCTION

The value of collaborative learning is widely recognized because of its positive effects on social, cognitive, and metacognitive development. One advantage of collaborative learning is that it provides students opportunities for self-reflection and joint construction of knowledge, and this environment frequently leads to higher levels of task-related interaction and behavior (Johnson, Johnson, & Stanne, 1986). When students are able to participate in active learning activities,

they find learning more pleasurable and satisfying than non-participative events.

Small group dynamics have been studied in educational contexts since the 1970s. Research indicates that small groups facilitate learning as compared to individual learning (Bruffee, 1999; Hamm & Adams, 1992; Johnson et al., 1986) and that peer group work has significant impacts on varied learning outcomes in both face-to-face and online learning environments (Bruffee, 1999; Harasim, 1990; Scardamalia & Bereiter, 1996; Uribe, Klein, & Sullivan, 2003). Although much of cooperative learning research initially focused on face-to-face cooperation at the elementary school level, now it is extending gradually into higher education, which is the focus of this study.

Positive interdependence promotes group cohesion and a heightened sense of belonging to a group, which can be achieved through the task, resources, goals, rewards, roles, or environment (Brush, 1998). Individual accountability refers to the extent to which students are individually accountable for jobs, tasks, or duties, and was introduced to counter the free-rider effect (some students would deliberately not invest any or little effort). Both principles, however, relate to the group dynamics phenomena of group cohesion and social loafing (Du & Havard, 2003) and thus apply to any form of small group learning. Bosworth and Hamilton (1994) proposed a process-oriented design method for online group-based learning that focused on fostering the envisioned group interaction that is thought to enhance learning instead of focusing on the formal product of such interaction. This method tends to be the dominant view in most institutions providing higher education and centers on five elements that directly shape group interaction: learning objectives, task type, level of prestructuring, group size, and the technological tool used.

The need for systematic design of online learning is amplified by some observations that exhibit conflict regarding coordination during group interaction. These observations that suggest

conflicts are more likely to occur in asynchronous online settings compared to face-to-face settings, since group members are not present at the same time or place. Also, the lack of presence concerning immediate feedback and face-to-face setting makes asynchronous communication unnatural. Clearly, some support should be designed to help students overcome difficulties in group coordination during asynchronous collaboration.

Group performance effectiveness depends on the group's use of its alternate opinions and on the handling of increased coordination (Shaw, 1981). Roles, stated functions/duties, or responsibilities that guide individual behavior and regulate intragroup interaction (Hare, 1994) can promote group cohesion and responsibility (Boud, Cohen & Sampson, 1999) and thus can be used to foster positive interdependence and individual accountability (Hedberg, 2003). In addition, roles can stimulate a group member's awareness of the overall group performance and each member's contribution. Finally, roles appear to be most relevant when a group pursues a shared goal requiring a certain level of task division, coordination, and integration of individual activities.

Despite the potential benefits of collaborative learning, several studies reveal that collaborative learning does not always lead to the desired outcome. For example, free collaboration does not systematically produce learning (Dillenbourg, 2002), and researchers report large variations in the quality of interaction and learning outcomes (Lehtinen et al., 2000). Other variations may include, but are not limited to, the length of studies, the technology used, differences in research methodology, and the quality of the group processes (Shaw, 1981; Strijbos et al., 2004). Students who have experienced negative online experiences perceived those experiences as weaknesses of online learning. These problems were most often caused by delayed feedback from instructors (Laszlo & Kupritz, 2003), lack of self-regulation and self-motivation, sense of isolation, monotonous instructional methods (Wang, Sierra, & Folger,

A Project-Based Learning Approach

2003), and poorly designed assignments (Hedberg; 2003, Thomas 2000). Problems in collaborative group projects include social loafing, free riding, disorder due to poor leadership and member role identification, low motivation through no common goal, and poor management of tasks.

In this study, we argue that collaborative learning has moved beyond the question whether it is effective in accelerating knowledge construction, but we focus on the conditions under which these type of learning environments were optimally effective. The purpose of this study was to investigate students' perceptions of online group collaborative learning and to examine how an online project-based learning approach affected students' cognitive skills development and motivation. This study will identify specific group dynamics and factors leading to successful collaborative projects.

A THEORETICAL FRAMEWORK FOR ANALYSIS OF THE COLLABORATIVE LEARNING PROCESS

Constructivism is a term used to describe a number of different theories. Two dimensions were focused on in this study; namely, the knowledge construction process of individual learners and knowledge construction as a socially situated process (Driscoll, 1994).

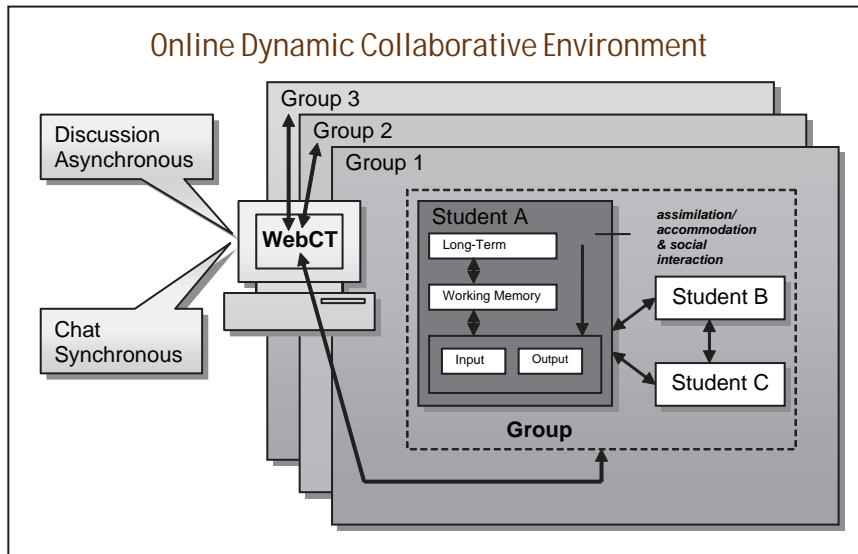

The individual learner constructs knowledge by adapting previously constructed schemes. This view is based on Piaget's theory and the concepts of assimilation and accommodation. This process of schema construction and reconstruction implies the selection of stimuli from the project-based environment; continuous storage; and retrieval of schemas between long-term memory and working memory in order to organize, elaborate, refine and/or integrate these schemas. This overall process is monitored by metacognitive processes. These processes help the learner to be selective in

stimulus selection, storage, retrieval, and response organization (Popolov, Callaghan, & Luker, 2002). The online setting influences this complex of cognitive activities in interaction with the nature of the project-based environment.

The knowledge construction process may also be seen as socially situated. This view is based on Vygotsky's theory of social interaction, where the interaction between people plays an important role. This is where the social part of social constructivism becomes evident. The interaction among learners in the online environment is expected (1) to incite the learner to make explicit the actual level of schema development by writing down his or her ideas, and (2) to demand from the learner an explicit comparison of his or her schema and those of others in order to defend or criticize them. As such, the interaction demands further elaboration and organization of the schema at the point that collaboration enters. This theoretical description implies that learning in the online environment depends on the amount of schema exploitation activities and the amount of explicit comparison and contrasting. The more these activities are invoked, the higher the level of knowledge construction to be expected.

Figure 1 provides a graphical representation of the theoretical base for the present study. This scheme is an extension of the framework used in previous research (Hare, 1994; Kitchner, 1983). It integrates social constructivist principles and concepts derived from the information processing approach to learning (Dillenbourg, 2002). We consider three elements or levels regarding learning: individual processes, group member processes, and group environment processes (see Figure 1). Individual learning is depicted through an information processing perspective with sensory receptors providing input, refined through short- and long-term memory and exhibited through output. Individual input and output are affected and refined through social interaction, where familiar information is assimilated and new information is accommodated. Learning

Figure 1. Graphical representation social constructivist principles and concepts derived from the information processing approach to learning

continues at the group environment level, where group input and output are refined through review and critique by other groups.

FRAMEWORK APPLICATION IN ONLINE GROUP COLLABORATION

The online learning environment for this course was created in WebCT, a database-driven, Web-based course management system designed to support online learning environments (Hutchins, 2001). The database elements available in WebCT enable the instructor to record, manage, and support the activities and interactions of a large number of students. This multimedia design for an instruction course is required of all students enrolled in the Master of Science in Instructional Technology (MSIT) program. Students enrolled in the MSIT program and in this course represent a wide range of diverse backgrounds. They reside throughout the states of Mississippi, Tennessee, and Alabama. Each semester, approximately 30 students are enrolled in this course.

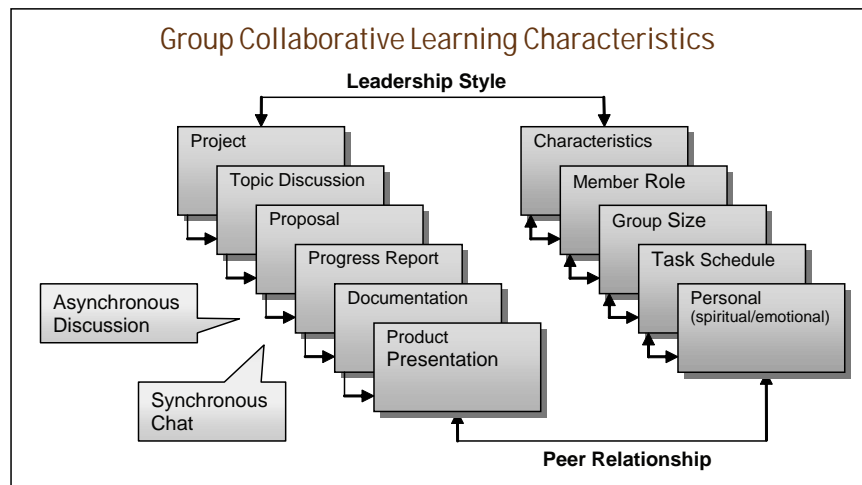

In Figure 2, leadership style and peer relationships have a dramatic effect on the nature and outcome of the final product in a project-based learning environment. Both project and group characteristics are impacted by their related characteristics, leadership style, and peer relationships (see Figure 2). This project is sequential in nature with each phase channeling into the next. Peer relationships and leadership style within a group are interrelated, impacting each phase of the project.

Framework Application

We applied the framework during two semesters of a graduate level multimedia design for instruction course. The purpose of this course was to provide students with an overview of hypermedia/interactive multimedia technology by working with various hypermedia/multimedia tools. Students were introduced to the design and production process of developing multimedia applications and were provided the opportunity to learn various tools, concentrating on different

A Project-Based Learning Approach

Figure 2. Effect of leadership style and peer relationships on the nature and outcome of the final product in a project-based learning environment

aspects of the technology, such as text, graphics, audio, animation, and video. By working with these tools, students were expected to develop the skills and understanding required for the creation of instructional tools for application in education and industrial settings. Students were required to apply design principles necessary for the creation of hypermedia/multimedia in developing multimedia-based applications. Several important aspects about this environment regarding skill development, theoretical and technical issues, and the application skills and knowledge toward the successful development of a comprehensive multimedia instructional product (Popolov, Callaghan, & Luker, 2002; Slavin, 1995) were examined. Through online group communication using the asynchronous discussion feature and synchronous chat available through WebCT, students' skills and knowledge regarding multimedia development were enhanced. The social aspect of the learning environment was critical (Vygotsky, 1978). This required focused attention by the instructor, as knowledge is socially constructed and enhanced through peer-to-peer and instructor-to-peer communication (Boud, Cohen & Sampson, 1999; Kitchner, 1983; Kitchner & King, 1981).

In the multimedia process, students worked in groups and took on different roles. The contexts for learning in this course were primarily interactive, collaborative, multi-disciplinary, and student-centered. Students were required to participate actively in weekly discussions regarding specific multimedia development topics. Assignments on learning different tools were given to assess application skills, and students were required to write a research and reflective paper on hypermedia/interactive multimedia instruction. Group projects for the semester developed and assessed students' ability to comprehensively apply the theoretical and technical requirements for multimedia design for instruction. Students worked together in teams of four or five students to develop an instructional Web site as the final course project. The tools used for project development included Macromedia® Dreamweaver, Fireworks, Flash, and Hyperstudio®. The general target audience for the site included prospective students and teachers. Deliverables beyond the completed Web site included a project proposal, a project progress report, project documentation, and a final presentation of the final product. The project proposal was intended to describe the in-

structional problem, the specific target audience, the instructional or training context, and the objectives to be achieved. The formal project progress report required groups to provide status on their project, including work completed and tasks planned for completion. Project documentation, similar to a detailed design document, revealed details about the product that was developed, justification and use of an instructional design model for product development, audience analysis, formal instructional content, learning objectives, media selection, instructional strategy employed, and assessment. Finally, project documentation concluded with a description of the formative evaluation process and findings. Each group presented its final product to the class. Every member of each group was expected to take an active role in the final presentation.

FINDINGS

Accountability and Commitment

Almost all the students reported accountability, responsibility, unselfishness, commitment, and dedication as major attributes that ensured the success of online collaboration. Students felt that their online collaboration on the project was more successful, because students in their group exhibited these characteristics. If a student had to be absent from meetings, legitimate reasons such as a death in the family or in a friend's family, work, or having to take care of other family obligations were the norm. Being absent did not prevent the student from being accountable. These students returned to the group concerned about what went on during online discussions in which they were absent and what their assignments were without having to be told by other students in the group. Exhibiting these attributes of accountability and commitment seemed to be contagious within the groups. The more one group member exhibited these traits, the more these traits seemed to become

a norm for the behavior of the rest of the group members. There was an unspoken appreciation shown by the rest of the group when members participated with this level of commitment, because the rest of the group members seemed to exhibit the same level of behavior when they had to be absent. Complete commitment to the success of the project was exhibited not just by one but by most of the group members, since leadership with accountability and commitment were practiced.

Leadership Style and Individual Role

Group dynamics were affected by the leadership style of the online group coordinator. Three groups had female coordinators; two groups had male coordinators. The leadership style exhibited in the group that produced the best results came from a leader who coached the team by stepping back and letting team members shine. This leader quietly led them to meet deadlines and goals and to follow the outline of the project, while allowing them to make decisions for the successful completion of the project. The leader allowed the team members to lead, to shine, to be successful, and to feel complete ownership of the finished product, which was not any one individual team member's project, but the project of the committed, concerted efforts of the group. Because group members had ownership in the project and were made to feel the importance of their input, the final project was much more advanced than would have been achieved otherwise. A leadership style that promoted inclusiveness, pride, self-confidence, participation, and understanding created a much more productive and self-reliant team that was able to produce beyond the norm. A leader that was more interested in the performance of the team and the quality of the finished product rather than self-recognition produced the more successful product.

One group leader stepped down at mid-semester due to overwhelming outside responsibilities.

A Project-Based Learning Approach

No one assumed the leadership position, and that group was ineffective for four weeks; without instructor directives, the group would have failed the project assignment. Two groups had young leaders, who were expected to be at risk, but gained momentum as the semester progressed. Both of the young group leaders initially had difficulty organizing and influencing cooperation from the team members, but gradually, with the help of their more experienced team members, the teams became focused. One leader, a manager by profession, seemed to be the most effective and influenced the team to produce the best project in the class. Another team was highly inexperienced in Web skills and had a leader with a lack of course subject knowledge, who was hesitant to lead with firm direction in the beginning. Eventually, this leader pulled the group together to produce a good project.

Individual Accomplishments and Group Accomplishments

Some groups and some leaders experienced individuals who were more interested in their individual accomplishments than the accomplishments of the team. A few individuals with high Web skills quickly developed the vehicle for the final project, but the results were not necessarily compatible with the project goals. Because of existing skills in Web development that some individuals possessed in the group, they may have wanted to take on the design and development of the project without taking into consideration the input of the other team members. Realizing they could produce a product because of their skills did not necessarily mean that their product would excel as much as a product that included the input and talents of all members of the group. The time limitations and the complexity of this project naturally required that it be a group project, thus requiring the talents and input of everyone on the team. Group members questioned and worked through compatibility of design with team project goals, until the design fit the project idea and

theme. Although team members were appreciative of the individual's Web design skills, they wanted their input heard and a finished product that met the guidelines of the project. Team members did not want an individual's accomplishments to overshadow or overrule the accomplishments of the team. Leadership styles definitely affected the group dynamics of each team. These leadership styles included (1) style that produced the best finished product, (2) lack of leadership when one leader had to step down, (3) inexperienced leaders who just needed some practice, and (4) group leadership that required leaders to refocus members who were interested in their accomplishments instead of the team's.

Setting Goals and Managing Team Project

Setting goals and managing the team project assisted the teams in successfully bonding and completing its project. Students reported that setting a common goal and establishing a bonding within the group by dedicated students was critical in the process of team development and achieving success. Due to the complexity of the project and the amount of time required to complete it, students explained that this kind of dedication and bonding was vital to the success of the team and the assignment. In addition, it was important for a team to plan, to manage, and to meet the timeline; it was equally important for the team leader to delegate teamwork in order to accomplish tasks on time. Missing deadlines and not remaining on schedule also caused a much less polished product at the end of the semester.

Accepting responsibility for group assignments and following through in a timely manner with those assignments affected group productivity. Not only were missed or late assignments an indicator of an individual's lack of dedication to the team, but it also indicated the lack of dedication the team member had to the project. A team member without dedication who missed or was late with assignments caused other team members

to be late and sometimes miss their assignments, also. Teams that had definite deadlines and frequent communication were able to build more powerful projects than those who had frequent absences and did not honor deadlines. Teams that worked together to demand participation from each member were also more successful. If a team member was not meeting assignment deadlines and goals, improvement would be gained from pressure by the team leader and the other members of the group. It appeared that no one in any group wanted to be singled out as the unproductive member. Although there were exceptions, the united strength of the team was much more powerful than just a single individual's leadership role.

Most of the groups referred to their project proposal plans and final project guidelines to evaluate their own development stages and notes. Groups who did not practice referring to their project proposal or the project guidelines consequently had project omissions and components that did not relate or fit their design. Often, there were discussions on adding or eliminating parts concerning the project design, and the limitations were not always skill-based. There was a concern that the element did not comply with the project goals or would have to be restructured to fit the project goals. When met with these types of obstacles, the successful groups looked outside the team for advice or help. They either consulted with the instructor, professionals whom they viewed as knowledgeable, online sources, or friends who had experience in a particular area. The successful groups viewed limitations as obstacles to overcome, not as roadblocks for which there was no way around.

Positive Peer Support Spiritually and Emotionally

Peer support served as a positive element in groups and helped to support students spiritually and emotionally through the difficult parts of the

project development phases. Several students mentioned “friendship” and “trust” as enjoyable online collaborative learning experiences. This meant “close friends getting along well” and “giving a helping hand to a struggling member.” Students seemed to draw inner strength and purpose when they felt appreciated and were complimented by their fellow group members. This caused the student to be more likely to seek help when needed and to give help where needed. Developing this type of relationship was a gradual process as the group members worked through the obstacles of producing the final project. Gradually, when one member produced a good idea, another member complimented that member and so forth. This process of positive team feedback helped to make the individual team members more self-confident, thus producing a more self-confident team. This positive peer relationship also enabled the students to openly discuss problem areas and to avoid any potential disagreements. Group members were less likely to engage in disagreements when they had this positive relationship. They could work out any disagreements maturely by openly discussing and agreeing on possible solutions. This positive peer relationship produced group members who were more productive and who engaged in the timely completion of the final project.

Preference for Mixed Gender and Race Groups

Students preferred mixed gender and race groups for their online discussion groups. In one group, the instructor chose a white male as group leader of a predominately African-American female group. Initially, the group leader was apprehensive about his ability to lead this group, as was the group about having him as their leader. When the group of African-American women saw that the group leader was not domineering, was inclusive, was open to them taking on leadership roles, and wanted their ideas and participation, they all got together with the leader and produced

A Project-Based Learning Approach

an outstanding product. Based on observations, African-American students perceive group work as a comfortable environment in which to work. When conflicts occurred with group participation, African-American students were willing to provide explanations for their conflicts and to openly resolve the conflict as soon as possible. When African-American students missed an online discussion session, they were quick to seek follow-up information about what they missed. Resistance to group work appeared to be based on lack of some required skills, rather than lack of cooperation to participate in the group. They were only concerned with not being able to assist with certain needs within the group and were not concerned about having to work in a group.

CONCLUSION

Successfully completing a project assigned to an online group was dependent on a number of factors. How successful the project was depended on the leadership style of the group leader, with the most important factor being the success of the group as the main concern. Setting goals and accepting responsibility for the group's project were also major factors in the success of the finished product. These were not just the team leader's goals and responsibilities but were also the entire group's. Groups also felt that they were more successful with their project when they followed the guidelines and the proposal for the project. Peer support during the development of the group project was a very important part of the success of the project. Students felt that, without the spiritual and emotional support of their peers, the project would not have been as successful. If one were looking for a negative factor in online group collaboration, it would not be found in gender or race group preferences. Students worked together regardless of the race or gender of their group members and expressed a preference for having mixed races and genders in their groups.

They felt that the variety of contributions from different races and genders were very important to the group work.

Chapter 2.43

Task–Oriented Online Discussion: A Practical Model for Student Learning

ABSTRACT

A dynamic task-oriented online discussion model for deep learning in distance education is described and illustrated in this chapter. Information, methods, and cognition, three general learning processes, provide the foundation on which the model is based. Three types of online discussion are prescribed: flexible peer, structured topic, and collaborative task. The discussion types are paired with tasks encouraging students to build on their adoptive learning, promoting adaptive learning and challenging their cognitive abilities, resulting in deep learning. The online discussion model was applied during two semesters of an online multimedia design for instruction graduate-

level course. The strategies for creating dynamic discussion serve to facilitate online interactions among diverse learners and assist in the design of assignments for effective interactions. The model proposed and the strategies for dynamic task-oriented discussion provide an online learning environment in which students learn beyond the course goal.

INTRODUCTION

The purpose of this study was to apply a theoretical model in an actual online discussion context. Deep learning, the holistic acquisition of higher-order skills (such as analyzing, interpreting and

evaluating) exhibited through higher-order problem solving (Entwistle & Ramsden, 1983), serves as the educational goal for this model. Deep learning, according to Weigel (2001), is “learning that promotes the development of conditionalized knowledge and metacognition through communities of inquiry” (p. 5). The theoretical underpinnings of the model may be applied to many diverse educational environments. This chapter offers distance learning educators strategies within the proposed model that will enhance online courses. The model reveals an approach to distance learning that fosters and encourages deep learning for higher-order thinking. Application of this model in distance learning may be applied to a variety of online courses to enhance student learning.

THEORETICAL FRAMEWORK

Several researchers have contributed to the effort of understanding the learning process. Their conclusions can help in the process of developing models for analyzing the distance learning process. Henri (1992) developed an analytical model that can be used by educators for a better understanding of the learning process. This model was developed to emphasize five dimensions of the learning process exteriorized in the message: participation, interaction, social, cognitive and metacognitive dimensions. Henri’s model provides information on participants as learners and on their ways of dealing with a given topic. Oliver and Mcloughlin (1996) suggested some changes to Henri’s analytical model. They recognized five kinds of interactions: social, procedural, expository, explanatory and cognitive. Oliver and Mcloughlin’s model has been used for analyzing the different kinds of communication in distance learning and traditional teaching.

The model of deep learning for distance education (see Figure 1) is established through the categorization of the five kinds of interactions

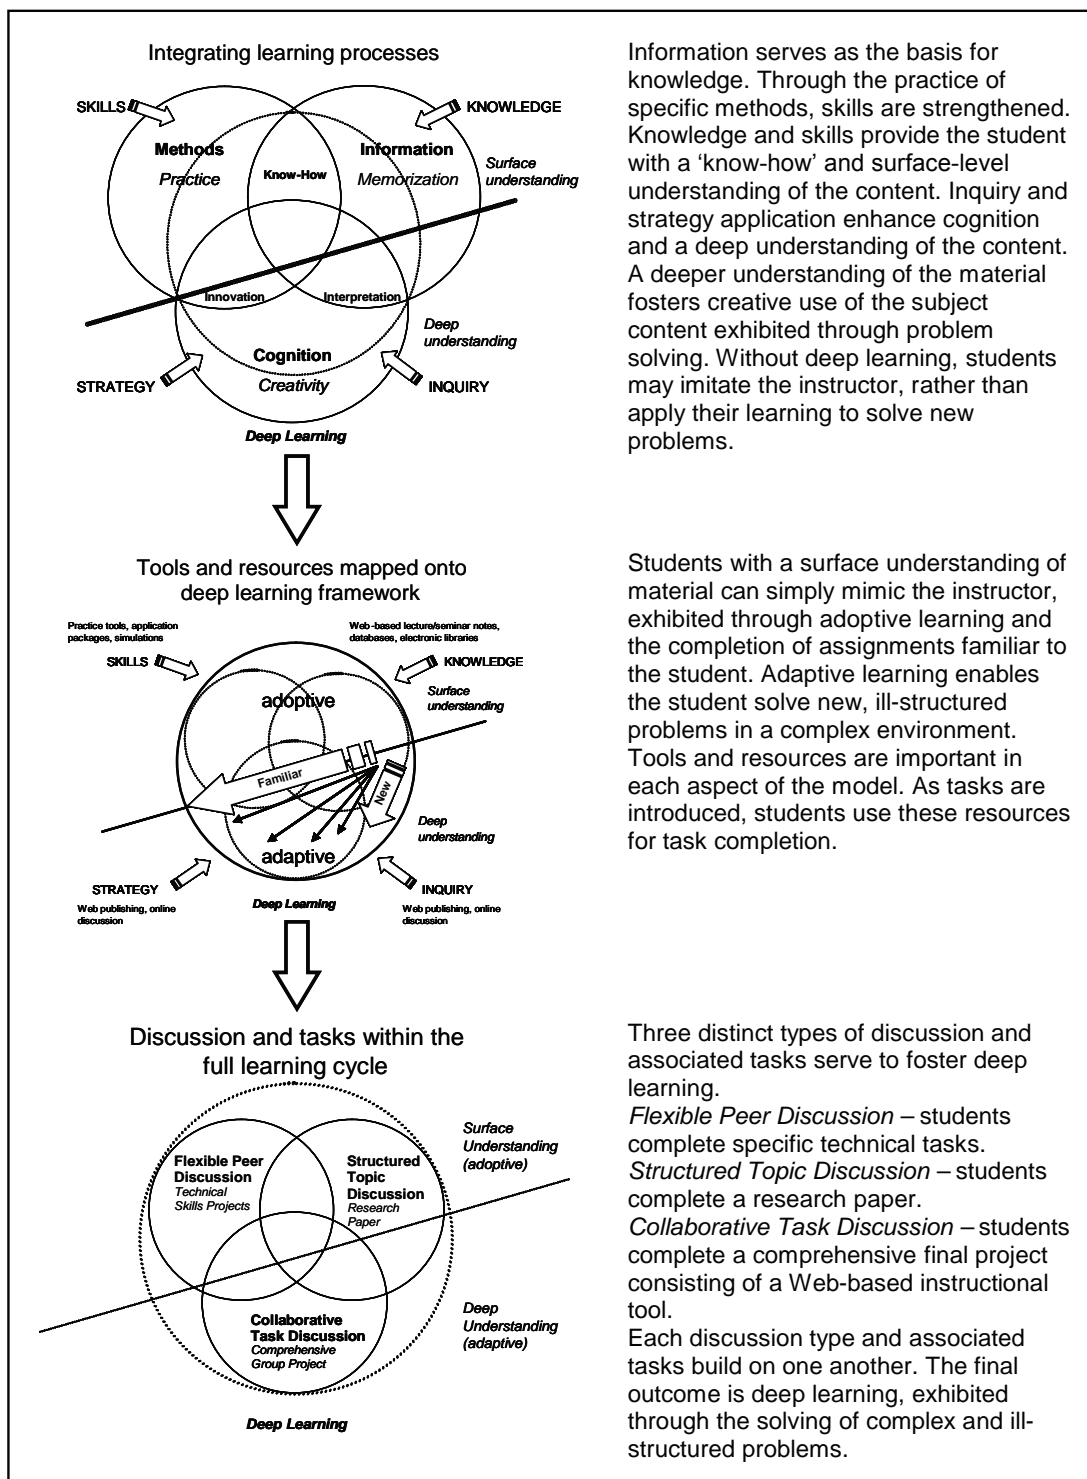

proposed by Oliver and Mcloughlin (1996) into three general processes: information, methods and cognition (Du & Havard, 2003). The first stage of integrating these learning processes is the acquisition of knowledge, representing a surface level of understanding. Skill development, the second stage of the model, is often accomplished through drill and practice. Students operating at these two levels develop a ‘know-how’ of the material, but on a very limited basis. The third stage represents cognition, where inquiry and strategy application assist students in learning to solve problems. A deeper understanding of the material fosters creative use of the subject content. Without deep learning, students will simply imitate the instructor, rather than apply their learning to new problems.

New and complex assignments require students to build on their existing knowledge of a topic, challenging them to systematize this information with newly acquired information in a variety of ways (Laurillard, 1984). Greene (1995) emphasizes that imagination can help people create new orders, bring pieces together, assemble or reassemble patterns. The foundation of deep learning relies on assignments that encourage inquiry and creativity. Thayer-Bacon (2000) stresses that “reason is an invaluable tool to help us construct quilts of knowledge” (p. 148). Reason can aid one to filter useful and useless information, organize them into meaningful entity, retrieve previous knowledge and ultimately gain new or deeper understanding.

Problem-based learning provides the rich context in which higher-order thinking is essential for problem resolution. Students working through a difficult ill-structured problem have more opportunity to develop a much deeper understanding than students who simply memorize information or develop specific skills without context (Tiene, 2002). Through innovative assignments, students can inquire about the process they are using rather than inquire about the product or answer to a specific question (Ruberg, Moore, & Taylor, 1996).

Task-Oriented Online Discussion

Figure 1. The information, methods and cognition model with two layers

Information serves as the basis for knowledge. Through the practice of specific methods, skills are strengthened. Knowledge and skills provide the student with a 'know-how' and surface-level understanding of the content. Inquiry and strategy application enhance cognition and a deep understanding of the content. A deeper understanding of the material fosters creative use of the subject content exhibited through problem solving. Without deep learning, students may imitate the instructor, rather than apply their learning to solve new problems.

Students with a surface understanding of material can simply mimic the instructor, exhibited through adoptive learning and the completion of assignments familiar to the student. Adaptive learning enables the student solve new, ill-structured problems in a complex environment. Tools and resources are important in each aspect of the model. As tasks are introduced, students use these resources for task completion.

Three distinct types of discussion and associated tasks serve to foster deep learning.

- Flexible Peer Discussion* – students complete specific technical tasks.
- Structured Topic Discussion* – students complete a research paper.
- Collaborative Task Discussion* – students complete a comprehensive final project consisting of a Web-based instructional tool.

Each discussion type and associated tasks build on one another. The final outcome is deep learning, exhibited through the solving of complex and ill-structured problems.

Two fundamental concepts inherent in the proposed model are adopt and adapt (see Figure 1). Students with a surface understanding of material can effectively adopt what the instructor does. They may simply mimic the instructor. Students are unable to adapt their learning to unique situations because they have not developed a deeper learning of the material. They lack the strong grasp of the material required to adapt to a complex problem-based environment. Assignments familiar for the student measure surface learning, while new and innovative assignments measure a student's deep learning. Adoption and adaptation become very important when change is introduced in the distance learning environment regarding the material students are learning. It is not enough to adopt what the instructor teaches. Encouraging students to effectively adapt to changes in the distance learning environment requires students to think for themselves rather than rely on learning guidance from the instructor (Brookfield, 1982). In this type of distance learning environment, the instructor acts as a facilitator, requiring students to take more responsibility in the learning process. The role of facilitator is complex, but through the proposed model, techniques and student activities are diagrammed to assist in reducing this complexity.

APPLICATION OF THE MODEL

Distance learning requires special course design techniques, special methods of communication, as well as special organizational and administrative arrangements (Moore, 1989). To further explore the model of deep learning for distance education, we applied the model during two semesters of a graduate-level multimedia design for instruction course. Learning technologies were mapped to learning processes. Students began the full learning cycle with resources supplied by the instructor. These include: (a) Web-based lecture with seminar notes, (b) databases for details related

to specific concepts, (c) electronic libraries for additional reference material, and (d) CD-ROMs as supplemental information, in addition to the formal course content. These resources served to provide the foundation on which knowledge of the course topics were based. This multimedia design for instruction course is required for all students enrolled in the Master of Science in Instructional Technology (MSIT) program. Students enrolled in the MSIT program and in this course represent a wide range of diverse backgrounds. They reside throughout the state of Mississippi, Tennessee and Alabama. Each semester, approximately 30 students are enrolled in this course. The purpose of this course is to provide students with an overview of hypermedia/interactive multimedia technology through working with various hypermedia/multimedia tools. Students are introduced to the design and production process of developing multimedia applications and are provided the opportunity to learn various tools, concentrating on different aspects of the technology: text, graphics, audio, animation and video. Through working with these tools, students are expected to develop an understanding and the skills required for the creation of instructional tools for application in education and industry settings. Students are required to apply design principles necessary for the creation of hypermedia/multimedia when developing multimedia-based applications.

Learning Environment

The course simulates practices in the multimedia industry. Students work in groups and take on different roles in the multimedia development process. The contexts for learning in this course are primarily interactive, collaborative, multidisciplinary and student-centered. Students are required to actively participate in weekly discussions regarding specific multimedia development topics. Assignments on learning different tools are given to assess application skills. Students must write a research and reflective paper on

hypermedia/interactive multimedia instruction. Group projects for the semester both develop and assess students' ability to comprehensively apply the theoretical and technical requirements for multimedia design for instruction. Through these activities, we have observed students developing deep thinking in higher-order problem solving, from the foundation of surface understanding to deeper understanding exhibited by problem resolution.

WebCT served as the online learning environment for this course. WebCT is a database-driven, Web-based course management system designed to support online learning environments (Hutchins, 2001). The database elements available in WebCT enable the instructor to record, manage and support the activities and interactions of a large number of students. There are several important aspects about this environment regarding skill development, theoretical and technical issues, and the application skills and knowledge towards the successful development of a comprehensive multimedia instructional tool (Popolov, Callaghan, & Luker, 2002). Through online group communication using the asynchronous discussion feature and synchronous chat available through WebCT, students' skills and knowledge regarding multimedia development are enhanced. The social aspect of the learning environment is critical (Vygotsky, 1978). This requires focused attention by the instructor, as knowledge is socially constructed and enhanced through peer-to-peer and instructor-to-peer communication (Boud, Cohen, & Sampson, 1999; Kitchner, 1983; Kitchner & King, 1981).

Application of the model within the context of a distance learning environment will be described. The strategies used through model application may assist others in implementing the model within their own distance learning environments. The information, methods and cognition model serves to foster and encourage learning and, specifically, deep learning in an online environment. Through implementation of the three-stage model, we have

established a learning environment that supports problem-based learning with synchronous and asynchronous tools for students to collaborate on set problems, share resources, post solutions, and compare and review answers from other groups (Graham & Scarborough, 1999; Popolov, Callaghan, & Luker, 2002).

Online Discussion and Tasks

A structured and moderated online discussion may be defined as a Web-based bulletin board for peer learners to communicate and collaborate, where the instructor takes active responsibility to structure, scaffold and moderate the collaboration. The proposed model of information, methods and cognition involves a number of activities and assignment tasks that provide powerful contexts for learning course content. The structure of the bulletin board is divided into the three processes related to the model. Through this structure, a number of key skills are demonstrated by students in the higher-order problem-solving process; from surface understanding to deeper understanding.

Students complete assignments requiring them to apply their surface learning and develop their deeper learning. The difficulty of the assignments progresses, challenging students to hone their abilities and problem-solving skills. Scaffolding is important throughout the process, and is most pronounced during the first two assignments. As students' deep learning develop and their competence to accomplish the assignments increase, the necessity to scaffold is reduced (Gredler, 1997). The assignments in this course consist of two technical projects, a theoretical research paper and a comprehensive technical and theoretical final group project. The purpose of these assignments and their structure is to scaffold students' learning from surface to deep. Online discussion is used extensively in this course as a means to develop deeper learning. The WebCT bulletin board is composed of three categories; technical, theoretical and comprehensive, corresponding to

the three general process of the model; information, methods and cognition.

Flexible Peer Discussion. Students use Dreamweaver and Fireworks as the multimedia development tools for this course. Within the technical category of the bulletin board, discussion points are further categorized into topic technical issues, practice issues and peer discussion. Students are presented two questions per week within the topic technical issues related to the technical aspects and use of Dreamweaver and Fireworks. Students must respond to the question presented and must also critique one other peer's response. Students are also presented with weekly practice assignments, progressing in difficulty. As they work through the assignments they must post one question regarding an issue they encountered while working on the assignment. They must also answer at least one peer's question that was posted. The peer discussion category of the bulletin board is available for open discussion about Dreamweaver and Fireworks, and students are required to post at least one new item they learned while using either of these multimedia development applications.

Structured Topic Discussion. The theoretical category of the bulletin board consists of three questions posed to the students over a 3-week period prior to the middle of the semester. Through focused and concise answers, students are able to develop the foundation for their theoretical research paper. Students are encouraged to discuss the question and offer opinions on how the question may be addressed. Responses do not occur immediately; instead, students spend time clarifying the questions among themselves. Discussion occurs during the week. Towards the end of the week, students begin to formulate and post their responses. Discussion continues as students submit their responses. Students must also critique two other peers' responses each week. In the critique, students must provide constructive criticism and assist in further developing each peer's topic. The questions are meant to be a

guide to assist students in topic development. The first question guides students towards describing how the specific multimedia development tools in the course may be used. They must cite their reading assignments within their response to support their claims. The second question focuses on instructional design principles. There are two required textbooks for this course and journal articles provided by the instructor, posted online, which serve as additional reading. Students must describe how the instructional design principles are applied in an actual multimedia development project, including details related to learner and context. Students must work together in groups to complete the final comprehensive project. The third question requires students to propose a group project they will collaborate on and submit as their final comprehensive project. Their responses must include details regarding the learner, instructional context, subject content and the needs for the proposed multimedia instruction. They must provide a rationale for the development tools they wish to use. They must also describe the instructional strategy they will use and describe why they chose that particular strategy. After submitting responses to all three questions, students must then complete a theoretical research paper.

Collaborative Task Discussion. The outcome of the comprehensive final project is a Web-based instructional tool. The project combines the technical aspects and theoretical issues discussed online during the semester. The groups must apply the instructional design principles towards the development of a "real" Web-based educational product. Three progress points during final project development are meant to focus students towards the desired outcome in a professional manner. These points consist of a proposal presentation, progress report and a final project and presentation with documentation. The groups are composed of five students, with one serving as the coordinator. Asynchronous and synchronous discussion occurs among the groups. The bulletin board is used by the group for introductions. The group must decide

which member will accomplish what task based on the proposed project. The topic is decided on through discussion and deliberation among the group members. Each member proposes a topic and must negotiate online to determine which topic the group will agree on for the final product. As group members begin gathering information on their chosen topic, they post this for other group members. Discussion and clarification is often necessary as the information is refined (Flynn & La Faso, 1972). Synchronous chat offers the group opportunities to discuss issues in real time. Specific chat dates and times are decided on through the bulletin board. Students meet in their group's chat room to discuss issues with the instructor and to present their proposal and progress report. Each group conducts their final presentation through chat with the instructor present. Students receive immediate feedback from the instructor and must respond to questions posed by the instructor regarding the final product.

The proposed model and the design of the discussion activities applied within the model provide students both adoptive and adaptive learning opportunities. The technical and theoretical discussion aspects occur as students complete the first two assignments. This provides a strong surface level of understanding regarding the multimedia development tools used in this course. The theoretical portion of the discussion, as students respond and critique one another's responses to the three questions posed by the instructor, provides students with a strong surface understanding of the instructional design principles for multimedia development. Students begin moving towards adaptive learning as they begin focusing their efforts on the final comprehensive project. Through asynchronous and synchronous discussions regarding the development of the instructional product, students move from surface to deep learning. The learning is adaptive, as they are creating a product to fulfill an instructional need where no right or true answer exists.

FINDINGS

The information, methods and cognition model provides very powerful contexts for learning the course content. The assignments encourage students to interact with the course content, to read and explore beyond the immediate setting and to reflect on what is being read (Warschauer, 1997). At the same time, the assignments encourage and support many other useful skills, including negotiation, written communication, diversity, constructive criticism, strategy development and execution, and reflection.

When the assignments undertaken by the students exposed to this form of learning environment are examined in the light of a model proposed by Bennett, Dunne, and Carre (1999), its capacity to support students achieving deep understanding immediately becomes evident. Based on the model we have proposed, the distance learning setting helped and encouraged students to practice and develop higher-order thinking across the full range of information, methods and cognition. The following major points emphasize the importance of the activities when applying the model in a distance learning course.

The assignments required learners to plan their steps, explore the domain and work towards a goal. Similar to Fenwick (2002), students perceived their most valuable learning was related to two main areas: group process and self-knowledge. In the process, they needed to confront unexpected outcomes and hurdles, reflect and judge their progress, and use a variety of learning strategies to develop their solution. In the group setting, students were required to work with others and maintain a good working relationship throughout the semester. On a day-to-day basis, they needed to be cooperative and attentive to the group's needs, defend their own stance, negotiate, and give and accept criticism.

The assignments required students to apply various technologies available to them in the learning environment. These include e-mail,

chat and bulletin board. Through the strategies for dynamic discussion, students consolidate the large amounts of information obtained and discuss how to delineate the importance and value of the information towards assignment completion. They needed to interpret the information and balance the multiple perspectives presented. Succinct summaries of the information required reflection and critical thinking.

Students' reflections on the course based on e-mail, collaborative discussion and chat demonstrate their positive attitudes regarding the course. Their satisfaction with the structure of the online environment was expressed in the individual student evaluations gathered at the end of the semester. Through their final documentation submitted with their final product, students described their appreciation for their diligent work.

Finally, in terms of managing assignments, these activities compelled students to identify sub-tasks and conceptualize the problem they were required to solve and how it could best be managed. The activities required the students to formulate a plan and execute the course of action, and reflect on the directions and outcomes. Each member of the group takes on specific responsibilities, executes tasks to benefit the group, and works together with team members towards achieving a common goal; a finding similar to other research (Hinds & Weisband, 2003; Dehler & Parras-Hernandez, 1998). Amid differing opinions and perspectives, groups were highly capable of resolving the problems assigned throughout the course.

CONCLUSION

Online discussion strategy is imperative for student learning. Many distance learning courses experience high attrition rates that result from factors such as students feeling isolated, unmotivated, overwhelmed or unchallenged in online courses. Based on the model proposed in this chapter,

dynamic task-oriented discussions (e.g., flexible peer, structured topic and collaborative task) in these two classes encourage participation in all aspects of the requirements for course completion. Students are made to feel as if they are part of a community, where their input is valued by their peers and where their suggestions are encouraged (Blumenfeld, Marx, Soloway, & Krajcik, 1996). The supportive environment created in this type of discussion serves to assist students that may feel overwhelmed by the course requirements. Motivation to learn and share ideas is encouraged and evolves naturally as the course progresses. Continuous peer review of posted responses to items challenges each student to provide their best input for the learning community created through dynamic task-oriented discussion.

Discussion is an integral part of an online course. As students work through the assignments, the importance of discussion and the sharing of ideas and opinions cannot be ignored. The assignments in this course require extensive peer-to-peer discussion throughout the semester to achieve the desired outcomes for the course. Through the structure of the dynamic task-oriented discussion presented in the model, students engage in discussion as part of assignment completion. In a sense, the discussion and the assignment cannot be separated; both act as a means for attainment of the course goal. The nature of online interactions and communications must be understood by both instructors and instructional designers (Pincas, 1998). The strategies we have proposed for creating dynamic task-oriented discussion serve to facilitate online learning among diverse individuals and assist in the design of assignments for effective interactions.

Providing students with a learning environment that will assist them in achieving the course goal is important, but we must look beyond the boundaries of a single course. The model proposed and the strategies for dynamic task-oriented discussion provide an environment in which students learn beyond the course goal, paving the way

from surface to deep learning. Students build on the adoptive learning taking place through assignments designed to promote adaptive learning and challenge their cognitive abilities, resulting in deep learning. Students' cognitive process is challenged through learning to use collaborative tools, learning to work collaboratively on complex learning assignments, and learning how to collaborate at a distance both asynchronously and synchronously.

Chapter 2.44

An Analysis of Student Persistence in Online Education

Steven F. Tello

University of Massachusetts Lowell, USA

ABSTRACT

This study examines the relationship between instructional interaction and student persistence among adult students in online courses. A survey research methodology was used to examine the frequency and the method of instructional interaction in online courses, student attitudes regarding instructional interaction, and the reasons online students provide for persisting in, or withdrawing from, online courses. The results indicate that student perceptions regarding the contribution of asynchronous, discussion forum use combined with frequent use of asynchronous discussion account for 26% of the variance in course persistence rates. Consistent with the literature on adult student dropout, the findings identify additional situational and institutional barriers to persistence among students in online courses. The findings suggest that strategies to facilitate student persistence in online courses

should address online instructional techniques, faculty development, technology development, and program development.

INTRODUCTION

The growth and popularity of the Internet and the World Wide Web among students and faculty at institutions of higher education across the country has coincided with the expansion of online distance education programs. As institutions of higher education expand online course offerings, it is important to identify strategies that promote student participation and success in online courses and programs. One obstacle to student success in online courses is student withdrawal or dropout, a failure of students to complete a course and/or program of study. Research suggests that online courses have significantly higher dropout rates

than face-to-face courses (Carr, 2000; Levy, 2005; Simpson, 2004; Terry, 2001).

While a number of factors have been identified as contributors to student dropout, few research studies have examined the classroom factors contributing to a student's decision to withdraw from, or persist in, a course or program of study (Barefoot, 2004; Simpson, 2004; Tinto, 2002). One factor that is consistently identified as contributing to student achievement, satisfaction, and persistence in face-to-face college classrooms is interaction. A significant body of research documents the role of student and faculty interaction in supporting positive learner outcomes on the traditional college campus (Kuh & Hu, 2001; Pascarella & Terenzini, 1991; Tinto, 2002). More recently, researchers have identified a clear relationship between faculty interaction and student perceptions of learning and student satisfaction in online courses (Jiang & Ting, 2000; Roblyer & Wiencke, 2004; Shea, Frederickson, Pickett, Pelz, & Swan, 2001; Swan et al., 2000). This study examined the impact of instructional interaction on student persistence among adult students in online courses while also examining the reasons online students provide for persisting in, or withdrawing from, online courses. Specifically, this study examined the relationship of persistence to (a) the frequency of instructional interaction, (b) the method of instructional interaction, and (c) student attitudes regarding interaction and their online course experience.

LITERATURE REVIEW

Relationship Between Interaction and Persistence

The importance of interaction between students and teacher in supporting positive learner outcomes among campus-based undergraduate students is well-documented (Pascarella & Terenzini, 1991; Tinto, 2002). Pascarella's work

distinguishes between formal (academic) interaction that occurs within the classroom and informal (social) interaction that occurs outside the classroom. Studies have found that the frequency and content of formal and informal interaction between instructors and undergraduate students in on-campus courses are correlated to gains in student achievement (Kuh & Hu, 2001; Pascarella & Terenzini, 1991), student persistence (Terenzini & Pascarella, 1980; Tinto, 1987), and degree completion (Tinto, 1987). Kuh and Hu found that as students progress from freshman to senior year, their frequency of interaction with faculty increases and shifts from social to academic or career-related interactions.

More recently, a number of researchers have examined the role of interaction in supporting positive learner outcomes among online students. Arbaugh (2005) found a strong, positive relationship between interaction in online courses and both perceived student learning and student satisfaction. Shea and his colleagues found that prompt instructor feedback and quality feedback (as reported by student respondents) are each positively related to levels of perceived student learning and satisfaction (2001). Hay, Hodgkinson, Peltier, and Drago (2004) found that instructor-to-student interaction and student-to-student interaction are each positively associated with student ratings of online course effectiveness.

Student persistence addresses a student's commitment to complete a course and program of study. Persistence is considered a positive outcome measure as compared to dropout, which is the negative equivalent outcome (Cookson, 1988; Simpson, 2003). Much of the literature on persistence and dropout draws its theoretical framework from the research conducted by Vincent Tinto. Tinto's model of college student dropout suggests that persistence is an outcome of the student's academic and social integration into that institution's community (Tinto, 1987). While Tinto's research was conducted primarily on undergraduate students in residential four-year

colleges and universities, later researchers applied a similar theoretical framework to different student groups including undergraduate commuter students, (Pascarella & Chapman, 1983), undergraduate students enrolled in correspondence courses (Sweet, 1986), distant learners enrolled in video-based college (Towles, Ellis, & Spencer, 1993), and online college students (Willging & Johnson, 2004). These studies suggest that Tinto's model of college student dropout provides a framework for understanding the relationship between student-faculty interaction and student persistence in environments beyond those examined by Tinto himself.

Interaction in Online Education

The terms interaction and interactivity are sometimes used interchangeably in the distance education literature (Anderson & Garrison, 1998; Smith & Dillon, 1999); however, a close review of the literature suggests that interactivity defines aspects of a delivery system, while interaction defines a two-way communications process (Moore, 1989; Moore & Kearsley, 1995; Wagner, 1994). This distinction is important and supports the focus of this study on the communication process between student and teacher and among students. Computer mediated communication (CMC), a central characteristic of online education, uses e-mail, chat, and computer conferencing systems to facilitate communication between students and teachers and among students (Kearsley, 2000; Turoff & Hiltz, 1995).

For the purposes of this study, instructional interaction is defined as directed communication regarding course content and topics between the instructor and students or among students in the online course. This definition is consistent with previous researchers' efforts to refine the definition of interaction to reflect the communication process that occurs in distance education courses (Moore, 1989; Wagner, 1994).

In addition to focusing the definition of instructional interaction on the exchange of course-related information between instructor and students, the emergence of different methods of communication in online courses (e.g., text chat, e-mail, discussion forums) suggests the need to specify methods of interaction. Kearsley (1995) suggests that a distinction must be made between immediate (synchronous) interaction and delayed (asynchronous) interaction. Synchronous interactions are supported through text-chat, audio-chat, desktop video conferencing, and emerging groupware applications, while asynchronous interactions are supported by tools such as e-mail and electronic discussion forums (Collison, Elbaum, Havind, & Tinker, 2000; Kearsley, 2000; Salmon, 2000). This distinction regarding the method of interaction is important since it affects the provision of feedback to the learner, a concept that Freedman, Tello, and Lewis (2003), Holmberg (1995), Smith and Dillon (1999), and others identify as critical to the learning process. Synchronous methods of interaction can provide immediate feedback to learners while, asynchronous methods of interaction can provide the learner with more control over where and when the instructional interaction occurs (Moore & Kearsley, 1995).

Characteristics of Adult Students

The student population participating in this study was composed primarily of adults enrolled in online courses offered by a continuing education division at a major public university. The majority of students enrolled in this program are age 25 or older (85% of students were age 25 or greater during the study period). This age range is consistent with the literature that finds that adults, aged 25 or older, compose the majority of students enrolled in continuing education programs. As part-time students with multiple responsibilities, the student role held by adults tends to be secondary to other roles as family members, workers, and community members (McGivney, 2004; Morgan

& Tam, 1999; Simpson, 2003). This distinction has particular implications when examining adult student dropout and persistence since these other primary roles place demands on adults that may interfere with their ability to complete a course or program of study.

Researchers have categorized the reasons adult students drop out of college into situational barriers, institutional barriers, and dispositional barriers (Cross, 1981; Morgan & Tam, 1999; Simpson, 2003). Situational barriers arise from a student's life situation and can include cost, lack of time, family responsibilities, and job responsibilities. Dispositional barriers are related to a student's attitudes and self-perceptions as a learner. Institutional barriers include institutional policies and practices that impede adult participation (e.g., inconvenient course times, extensive prerequisites or program requirements, inconvenient location).

METHOD

Purpose and Overview

A non-experimental, correlation study was conducted that examined the relationship between instructional interaction and student persistence in online education. This study utilized a survey research methodology and records review to investigate the relationship between instructional interaction and student persistence. Specifically, this study asked:

1. Is there a relationship between the frequency of instructional interaction and levels of student persistence in online courses?
2. Is there a relationship between the method of instructional interaction and student persistence in online courses?
3. Do other variables emerge as correlates of persistence among students in online courses?

An important aspect of research on persistence and dropout is contact with those students who withdraw from a course or program of study (Simpson, 2003; Turoff & Hiltz, 2000). For this reason the study also asked:

4. What reasons do online students provide for persisting in, or withdrawing from, their online courses?

Participants

The online learning program that participated in this study is operated by a public university located in New England. This university offers online programs in education, engineering, management, information technology, liberal arts, and the health professions at the undergraduate and graduate level. The online program enrolled 5450 students in 264 course sections during the year this study was conducted.

The online program uses a course management system (CMS) for the development and teaching of online courses. The CMS allows faculty to develop course materials that are then accessed by students online via a Web browser. All faculty teaching in the online program participate in a training program that introduces online pedagogy and instructs faculty in how to use the CMS to develop and teach an online course. The CMS used by the program supports both asynchronous and synchronous communication methods. These methods include synchronous text-based chat, asynchronous text-based discussion forums, and asynchronous e-mail lists.

Sample

The population for this study included 1569 undergraduate and 51 graduate students enrolled in 76 online courses offered in the fall semester by the continuing education division of a public university. The unit of analysis for persistence data (i.e., data from students who maintained enroll-

ment throughout the semester) was each online course. Criteria for selection included:

1. The instructor agreed to allow presentation of a survey tool to all students in the course.
2. The instructor agreed to allow researchers to review course communications.
3. The course met enrollment-based survey response rates.

Participating courses included all of the disciplines offered online by the program at the time of the study.

Following approval by the University's Institutional Review Board, an e-mail was sent to all online instructors requesting permission to survey their students at the end of the semester. If permission was granted, the option to complete an online survey was presented to students when they logged into their online courses during the last three weeks of the study semester. Once a student completed an online survey for a course, they were no longer presented with the option to submit a survey for that course. Upon submission of a survey, student identification data were separated from student response data, protecting the anonymity of individual students.

Response Rates

Persister survey data were collected from students enrolled in each course during the last three weeks of the semester. Student responses were grouped by course, and per course response rates were calculated. A total of 714 online surveys were returned for the 52 courses that met the participation criteria, representing an overall 64% response rate. Courses that met the response rate criteria closely reflected the distribution of disciplines in the overall online program and included four graduate and 48 undergraduate courses.

Non-persisters (i.e., students who filed paperwork with the Registrar's Office declaring

withdrawal from a course prior to the final grading period) were identified through a review of course enrollment records. The non-persister group included 138 students who administratively withdrew from a course in the online program prior to the end of the 14-week semester. Students who withdrew from multiple online courses were asked to complete a non-persister survey for only one course. The sample was reduced to 102 non-persisters after removing students who withdrew from multiple courses, as well as five students with out of country or undeliverable mailing addresses.

A paper copy of the non-persister survey was mailed to each non-persister along with a \$2.00 cash incentive. Two follow up contacts were made with non-respondents, one by mail and one by telephone, asking if they would prefer to complete the survey over the telephone with a trained research assistant. The response rate among non-persisters was 45%, representing 25 of the 52 courses participating. While this low response rate prevented comparison of responses at the course level, it did assist in identifying reasons why individual, non-persisters withdrew from online courses as well as situational differences between students who were persisters and non-persisters.

Instrumentation

This study utilized a survey research methodology to collect data regarding instructional interaction in online courses and student attitudes to their online course experience. An online survey was developed to collect data regarding the online course experience of students who maintained enrollment in their online course throughout the 14-week semester. This 37-item survey collected data regarding student demographics and characteristics; the frequency and method of interaction in each online course; and student attitudes toward interaction, their online course experience, and the contribution of interaction methods (available online at <http://frontpage.uml.edu/faculty/stello/>

survey.htm). Students could only submit one survey per registered online course.

A non-persister survey was developed that included items similar to the demographic, interaction, and attitude items contained in the online student survey, but also solicited the students' reasons for dropping out of their online courses (available online at <http://frontpage.uml.edu/faculty/stello/survey.htm>).

Independent Variable

The independent variable in this study is instructional interaction. For the purposes of this study, instructional interaction is defined as directed communication regarding course content and topics between the instructor and students or among students in an online course (Kearsley, 1995; Wagner, 1994). This study examined two aspects of instructional interaction, the frequency and the method of instructional interaction. Frequency of instructional interaction refers to how often students and instructors, and students and students, interact regarding course related materials. Frequency of interaction data were collected through persister surveys. Students responded to two items on the survey on a 5-point Likert scale asking them to indicate how frequently they used course communications tools to communicate with their instructor regarding course matters and how frequently they used course communications tools to communicate with their classmates regarding course matters. Per course Frequency of Instructor Interaction scores ranged from 2.12 to 4.00, with a mean score of 3.10 ($SD = .41$). Per course Frequency of Student Interaction scores ranged from 1.25 to 3.86, with a mean score of 2.59 ($SD = .54$). A strong, positive correlation between frequency of instructor-to-student and student-to-student interaction ($r_{50} = .68, p < .001$) suggested the creation of an Interaction Index as an overall measure of instructional interaction within each course. The sample mean Interaction Index score was 2.83 ($SD = .44$). Per course

Interaction Index scores ranged from a low of 1.97 to a high of 3.93.

Method of instructional interaction refers to whether the interaction within a course occurred asynchronously, using the discussion forum or e-mail lists, or synchronously, using the online chat tool. Correlational analysis between the method of instructional interaction and course persistence rates required the creation of three method of interaction indexes. These three indexes reflected the overall interaction on the part of instructors and students within each method of interaction per course. A reliability analysis of the three items composing each index revealed coefficient alphas of .92 for the Chat Method Index, .93 for the Discussion Method Index, and .77 for the E-mail Method Index. Once the three Method of Interaction Indexes were calculated, the distribution of course scores and descriptive statistics were reviewed for each index (Table 1).

Intervening Variables

Two attitude indexes were developed to examine student satisfaction with each online course along with student attitudes to dimensions of interaction. Previous research suggests that student satisfaction with individual online courses is a key indicator in a student's decision to persist or dropout of a course (Chyung, Winiecki, & Fenner, 1998; Jun, 2005; Levy, 2005). Additional research has also established a clear relationship between faculty interaction and student perceptions of learning and student satisfaction in online courses (Arbaugh, 2005; Hay et al., 2004; Jiang

Table 1. Means and standard deviations for three method of interaction indexes

Index	M	SD
Chat Method Index	8.08	1.66
Discussion Method Index	9.00	2.00
Email Method Index	6.97	1.02

& Ting, 2000; Roblyer & Wiencke, 2004; Shea et al., 2001; Swan et al., 2000). Each index provides a composite, ordinal measure of the variables under examination (Babbie, 2001).

Students were asked to indicate their level of agreement on a 4-point Likert scale with three statements examining their satisfaction with their online course. A reliability analysis conducted with these three items resulted in a coefficient alpha of .89, with item to total correlations between .56 to .92, suggesting a high degree of reliability and the creation of an attitude to course index. Student responses to these three items were summed at the course level and a mean Attitude to Course value was calculated for each course.

Students were asked to indicate their level of agreement on a 4-point Likert scale with four statements examining dimensions of instructional interaction: (a) timeliness of instructor feedback, (b) utility of instructor feedback, (c) amount of instructor communication, and (d) amount of student communication. A reliability analysis conducted with these four items resulted in a coefficient alpha of .91, with item to total correlations ranging from .55 to .86, suggesting a high degree of reliability. Student responses to these items were summed at the course level and a mean Attitude to Interaction value was calculated for each course.

Three items on the persister survey examined student attitudes toward the use of each method of interaction. These course contribution by method items examined the strength of student agreement with the following statement: "Overall, would you say (method) contributed to your online learning experience?" Student responses for the three Contribution by Method items were grouped at the course level, and descriptive statistics were calculated. An initial review of the distribution of per course responses for each item approximated a normal distribution, supporting the use of these items for correlational analysis.

Dependent Variable

Student persistence, the dependent variable in this study, is considered a positive outcome measure but is often quantified through the measurement of its negative equivalent outcome, dropout. Student persistence was measured by examining enrollment rosters for participating courses at the end of the two-week Add/Drop period (Total Course Enrollment) and again after final course grades were submitted. The examination of course enrollment rosters assisted in identifying the number of students who administratively withdrew (i.e., students who filed paperwork to withdraw) from their online course after the two-week Add/Drop period (Voluntary Dropout) and the number of students who failed or took an incomplete for a course (Involuntary Dropout). A final course enrollment was calculated by subtracting Voluntary Dropout and Involuntary Dropout from the Total Course Enrollment, then dividing this number by the Total Course Enrollment.

The per course persistence rate provided a measure of the percentage of students completing each online course. The 52 courses that met the persister survey response rate criterion for this study had a mean persistence rate of .80 (SD = .11), meaning 80% of the students enrolled in online courses selected to participate in this study completed the course with a passing grade. Persistence rates among courses ranged from a low of 42% to a high of 100%.

Characteristics of Persisters and Non-Persisters

Demographic data (Table 2) were collected via the online student survey from students who maintained enrollment in their online course through the end of the semester (persisters). Comparable demographic data were also collected for non-persisters who participated in the telephone survey or who completed and returned a mail survey.

An Analysis of Student Persistence in Online Education

Table 2. Contingency table analysis between persisters and non-persisters in regard to demographic and situational characteristics of respondents

	Persister	Non-persister	χ^2	<i>p</i> value
Total Sample	<u>n</u> = 714	<u>n</u> = 46		
	%	%		
Characteristics				
Age at time of survey (years)			2.97	.23
18-24	14.9	20.5		
25-44	67.2	54.5		
45 or older	17.9	25.0		
df=2				
Gender			0.88	.35
Male	52.8	45.7		
Female	47.2	54.3

Years of Internet usage			2.95	.09
1-3 Years	9.9	2.2		
More than 3 Years	90.0	97.8		
df=1				

Note: Values represent % within persister and non-persister groups.

A two-way contingency table analysis was conducted to evaluate differences between persisters and non-persisters in regard to these characteristics. This review suggests that in many respects, these two groups are quite similar. Both groups are distributed similarly, with no significant differences noted, in respect to age, gender, primary adult roles, presence of children in the home, and Internet use experience. A larger percentage of non-persisters report working more than 40 hours per week; however, this difference was not statistically significant.

A larger percentage of persisters report being enrolled in a certificate or degree program (15.5% difference), and a larger percentage of persisters indicate that they intend to take another online course in the next semester (28.7% difference). A two-way contingency table analysis was conducted to evaluate the difference between persisters and non-persisters in regard to both their enrollment in a program and their intent to take another online course (Table 3). Persisters were significantly more likely to be enrolled in a degree or certificate program than non-persisters were and were also significantly more likely to indicate that they intended to take another online course in the subsequent semester.

Frequency of Interaction

This research asked if there is “a relationship between the frequency of instructional interaction and levels of student persistence in online courses.” An examination of the scatterplot comparing Course Persistence Rate and the Interaction Index scores did not identify a linear relationship between these variables (Figure 1).

A strong positive correlation was observed between the frequency of instructor-to-student interaction and the frequency of student-to-student interaction within the online courses participating in this study. A Pearson Product Moment Correlation conducted between the course scores for Frequency of Instructor Interaction and Frequency of Student Interaction confirmed a positive correlation between frequency of instructor-to-student and student-to-student interaction, significant at $r_{50} = .68, p < .001$. The strength of this correlation suggests that as the frequency of instructor-to-student interaction increases in a course, the frequency of student-to-student interaction also increases.

Table 3. Contingency table analysis between persisters and non-persisters in regard to certificate/degree status and intent to return

	Persister	Non-persister	χ^2	p value
Enrolled in Degree Program			5.03*	.03
Yes	72.0	56.5		
No	28.0	43.5		
	N=714	N=46		
Intent to Return			15.74***	.000
Yes	86.4	57.7		
No	13.6	42.3		
	N=469	N=26		

Note: Values represent % within persister and non-persister groups.
 $df=1$, * $p < .05$, ** $p < .01$, *** $p < .001$

Figure 1. Course persistence rates by frequency of interaction index scatterplot

Method of Interaction

The second research question asked if “there is a relationship between the method of instructional interaction and student persistence in online courses.” A series of scatterplots was constructed pairing each of the Method of Interaction Indexes to Course Persistence Rates (Figure 2).

An examination of scatterplots comparing course persistence rates with each method of interaction index did not suggest a linear relationship between these variables; however, our earlier review of the mean Method of Interaction scores (Table 1) suggests that some differences exist in how each course used each method of interaction.

Student Attitudes to Interaction

A third research question asked if “other variables emerge as correlates of persistence among students in online courses.” The persister student survey asked respondents to consider how other aspects

of interaction contributed to their online course experience. These data were used to examine the relationship between persistence and student attitudes to interaction, student attitudes to the online course experience, and student attitudes regarding the contribution of a specific interaction method.

Strong, positive correlations, as indicated in Table 4, were observed at the course level between Student Attitudes to Interaction and: (a) the frequency of instructor-to-student interaction, (b) the Discussion Method Index, and (c) the E-mail Method Index. Similar positive correlations were observed at the course level between Student Attitudes to Online Course and the same three variables. These findings suggest a strong, positive relationship between the use of asynchronous methods of interaction by the instructor within a course (i.e., discussion forum, e-mail lists), and positive student attitudes toward that course. A modest, positive correlation was observed between Student Attitudes to Interaction and Course Persistence Rates, $r_{52} = .30$, $p < .05$.

Three course level measures, Course Contribution by Method, examined students' perceptions regarding the contribution each method of interaction made to their online learning experience. A strong positive correlation was observed between Course Persistence Rates and the Course Discussion Contribution scores, $r_{52} = .42$, $p < .01$ (Table 5).

A multiple regression analysis was conducted to evaluate how well the contribution by method variables and method of interaction indexes predicted persistence. The predictors included the three contribution of method variables and the three method of interaction indexes. The Course Persistence Rate was the criterion variable. A stepwise multiple linear regression analyses was conducted. The Contribution by Discussion Method variable and the Discussion Method Index were significantly related to the Course Persistence Rate, $F(2, 48) = 8.87$, $p = .001$. The sample multiple correlation coefficient was .51, indicating that approximately 26% of the variance in the course

persistence rate in the sample can be accounted for by the linear combination of these two measures. The remaining Contribution by Method and Method of Interaction variables did not add to the predictive value of the equation.

Reasons for Withdrawal

As discussed earlier in the Literature Review, student dropout is a complex phenomenon caused by multiple factors. This study has established that 26% of the variance in the study's course persistence rates can be attributed to the use of asynchronous discussion forum for activities that students perceive as contributing to the course learning experience. In order to better understand the range of factors contributing to a student's decision to persist or dropout, both the persister survey and non-persister survey asked respondents to provide reasons for persisting in, or withdrawing their online courses. Student responses were grouped into situational and institutional barriers

Figure 2. Course persistence rates by three method indexes

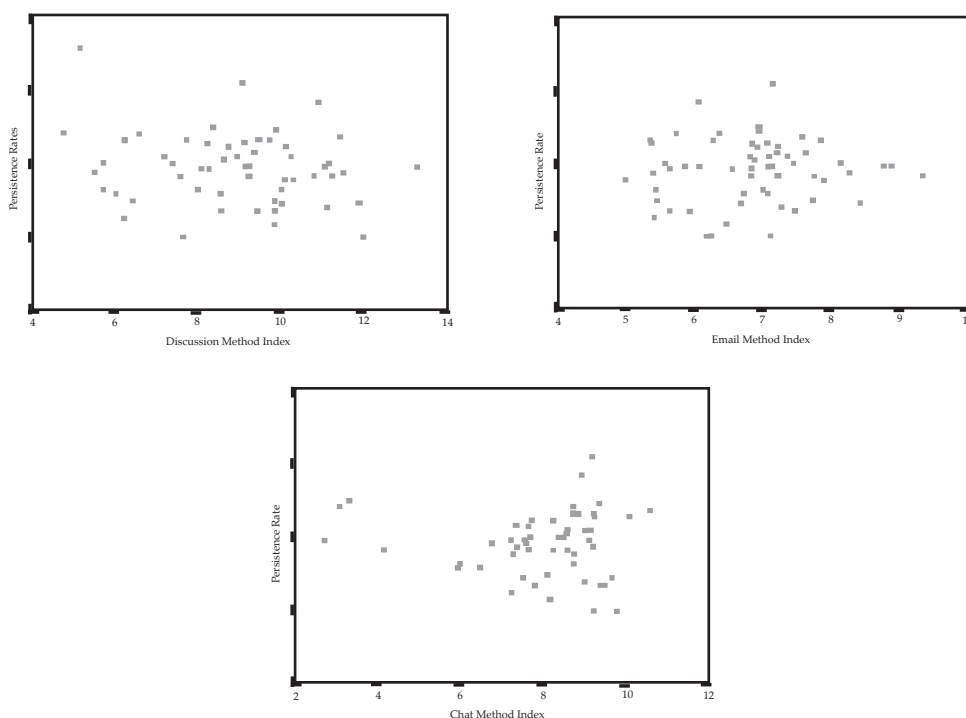

Table 4. Intercorrelations of per course attitude scales by per course frequency and method of interaction scores

	Attitude to Interaction	Attitude to Course
N = 52		
Frequency of Instructor (to Student) Interaction	.62***	.41**
Frequency of Student (to Student) Interaction	.22	.07

	Persistence Rate	n
Chat Contribution	.008	51
Discussion Contribution	.416**	52
E-mail Contribution	.226	52
2-tailed significance, * p < .05, ** p < .01, *** p < .001		

as discussed earlier (Figure 3). Situational barriers accounted for 62% of the reasons non-persisters provided for withdrawing from their online course. The primary reason identified by non-persisters for withdrawing from their online course was work commitments (30%).

In contrast, persisters identified institutional barriers (46%) slightly ahead of situational barriers (40%) as the reason they did not intend to take a future online course (Figure 4). The primary institutional barrier persisters identified was that the course they required was not offered online (29%). Only one persister identified work commitments as a reason for not taking a future online course.

The analysis conducted to examine this research question suggests there may be differences between non-persisters and persisters in regard

to their commitment to complete a program of study as well as the impact the number of hours worked per week has on a student's ability to persist in their online studies. This analysis also suggests that instructor interaction accounts for a modest percentage of the reasons students provide for dropping (11%, non-persister, Figure 3) or not enrolling in a future online course (11%, persister, Figure 4).

DISCUSSION

The results of this study suggest that the relationship between student persistence in online education and the use of asynchronous discussion forums is mediated by student attitudes toward their respective online courses and the perceived

An Analysis of Student Persistence in Online Education

Figure 3. Percentage distribution of non-persister reasons for withdrawal

Figure 4. Persister reasons for not taking another online course

educational contribution of discussion forum use. The data indicate that student attitudes to interaction and student perceptions regarding the usefulness of particular methods of interaction are positively related to course persistence rates. Factors such as the timeliness of instructor feedback, appropriateness of instructor feedback, and amount of course-related communications can positively or negatively impact student attitudes toward the course and their decision to persist or drop out of an online course.

In addition to the correlational analysis discussed previously, this study examined situational and demographic characteristics of students enrolled in online courses.

While persisters and non-persisters were similar in many ways, several differences emerged between the groups that may influence their decision to persist or withdraw. A larger percentage of non-persisters reported working more than 40 hours per week for pay. A significantly larger percentage of persisters were enrolled in a certificate or degree program, and a significantly larger percentage of persisters indicated that they intended to take another online course in a subsequent semester. Situational barriers—comprised primarily of student work commitments, student family commitments, and student time commitments—accounted for the majority of reasons non-persisters provided for withdrawing from their online course.

Taken together, the results of this study suggest that adult learners, facing demands on their time from family, work, and school commitments, respond favorably to properly structured asynchronous course activities such as the discussion forum. These findings have implications for online faculty development programs, the design and development of new online programs, as well as for the technology we use to “conduct” online courses. Online program administrators should thoughtfully consider these results as they pilot new blended programs, which require on-campus meetings, and introduce synchronous video

technologies, which require students to meet online at the same time as the instructor. While a number of factors influence a student’s decision to persist or dropout, it will become increasingly important for online program administrators to control institutional factors that support student participation and success.

Chapter 2.45
Transitioning from
Face-to-Face to
Online Instruction:
How to Increase Presence and
Cognitive/Social Interaction in an
Online Information Security
Risk Assessment Class

ABSTRACT

This article briefly reviews two important goals in online education: interaction and presence. These are important goals in online education because they are linked to learning and motivation to learn. The article provides guidelines and an extended example of how to design an online course in information security in a manner

that will enhance interaction and presence. This article's contribution is to provide guidelines with a corresponding extended and concrete example for those who are tasked with designing and delivering online courses. Although the guidelines and example were targeted to the field of information security, they can be readily adopted by other disciplines.

INTRODUCTION

Although online education can offer convenience and flexibility for learners, it is not without challenges. Frequently, online education is no more than instructor notes and lecture materials posted on a Web site, perhaps with some required discussion. Much online instruction is designed, developed, and delivered without careful consideration of foundational instructional design principles. Research has shown that online courses that lack substantive and meaningful interaction, coupled with a sense of presence (feeling as though belonging in a virtual environment), contribute to a sense of isolation, unsatisfying learning experiences, and high dropout rates (Aragon, 2003; Bennett, Priest, & Macpherson, 1999; Glickman, 2003; Moore & Kearsley, 1996). The goal of this article is to provide a set of online course design guidelines based on research findings and best practices to enhance interaction and sense of presence, which are two critical factors that impact learning and motivation to learn in online courses (Moore, 1992; 1993; Muirhead, 1999; Richardson & Swan, 2003). Finally, an example is provided for applying the guidelines to transition a face-to-face class to an online class, using an information security risk assessment class. In order for these guidelines to make sense, we start with a brief discussion of interaction and presence.

Interaction

Moore (1989) identified three major types of interaction: a) learner-content, b) learner-instructor, and c) learner-learner. Learner-content interaction refers to the amount of substantive interaction occurring between the learner(s) and the content. Content could be in the form of text, radio, television, and/or audiotape. Participant interaction (learner-learner and learner-instructor) refers to the engagement of the learners and instructor in the learning and teaching process. It also refers to dialogue between and/or among different

participants in online learning environments. Thus, interaction is more than a communication exchange; interaction occurs when objects, actions, and events mutually influence one another (Wagner, 1994). Instructional interaction is meaningful communication that challenges learners' thinking, shapes the acquisition of knowledge in meaningful ways, and changes learners, moving them toward achieving their goals. Effective interaction is not necessarily more interaction, rather it is interaction resulting in learners thinking in new and more profound ways. While the literature and research confirmed the importance of interaction in the learning process (Muirhead, 2001), online learners frequently do not interact at sufficient levels and/or in substantive ways with the instructor or other learners in online courses. The lack of appropriate and deep interactions is a common inadequacy of current online courses (Bennett et al., 1999).

Presence

Closely related to interaction is the concept of presence. From the learner's perspective, presence is the "sense of being in and belonging in a course and the ability to interact with other students and an instructor although physical contact is not available" (Shin, 2002, p. 22). Presence also refers to the "involvement, warmth, and immediacy" (Danchak, Walther, & Swan, 2001, p. 1) learners experience during communication and interaction with others in the online learning environment. According to Picard (1997), an online course that conveys affective or emotional information to learners will lead to a higher sense of social presence and interaction. Leh (2001) found lack of interaction, originally due to lack of physical and face-to-face contact, in online learning environments leads to a sense of isolation (or lack of social presence). On the other side, an appropriate level of interaction promotes a better sense of social presence (Rovai, 2001). Research also has shown social presence is positively re-

lated to learner satisfaction, perceived learning (Richardson & Swan, 2003), and learning success (Rifkind, 1992; Tu, 2000). In other words, a good sense of social presence influences interaction and interaction influences students' sense of social presence. Together, appropriate interaction and presence lead to increased cognitive activity and also cognitive activity at higher levels, resulting in more meaningful learning in online learning environments. While these relationships are known, many designers, developers, and instructors of online courses do not consciously implement instructional methods and techniques that will effectively increase interaction and social presence. We asked ourselves why. The answer, we believe, is that they have not had access to pedagogically content-based guidelines grounded in research. With this information, we turn to the guidelines.

GUIDELINES FOR PROMOTING INTERACTION AND PRESENCE IN AN ONLINE COURSE

There are four main components to consider when transitioning a traditional face-to-face course to an online version: a) introductions, b) organization, c) instruction, and d) feedback. There are techniques to use for all four of these components that will allow students to be more socially and cognitively interactive and present in an online course.

Introductions

Much of the current literature on online courses emphasizes the value of creating a learning community among the online participants. According to Hanna, Glowacki-Dudka, and Conceição-Runlee (2000), "a learning community is a group of people who have come together to form a culture of learning in which everyone is involved in a collective effort of understanding"

(p. 14). This sounds great, but as an instructor you are probably asking what techniques can be used to accomplish this task. "You need to build a climate that will foster professional learning or collaboration by crafting communications that support a sense of safety in the discussion areas" (Collison, Elbaum, Haavind, & Tinker, 2000, p. 30). You want students to share their experiences with each other, but this is difficult unless they feel comfortable with each other. There are a number of strategies that can be used to foster this feeling of community.

In the course content discussion area, start with a social icebreaker for students to introduce themselves. This should be a non threatening type of interaction that "breaks the ice of using technology to communicate," (Conrad & Donaldson, 2004, p. 47) is participant focused versus academic content focused, and requires reading and responding to other postings (Conrad & Donaldson, 2004). Conrad and Donaldson (2004) list and describe a number of different types of ice breakers. For example, BINGO requires everyone to post a short biography on the discussion board. The instructor then e-mails everyone a bingo card with something from everyone's posting in a box. Students must then determine which box belongs to which student and fill in the correct name. Another possible icebreaker is TWO TRUTHS AND A LIE. Students post two truths about themselves and one lie. Other students then try to determine which is the lie. This is most fun when the truths are so outrageous it is hard to distinguish them from a lie.

Another method to help foster the feeling of community is to have a page dedicated to the biographical sketches and pictures of the students. This could also be a social space with a title, such as lounge, hallway, or water cooler, where students can discuss any off-content topics. Students need a space provided just for "*social dialogue* or simple chitchat" (Collison et al., 2000, p. 20). This helps prevent clutter in the content-discussion area and encourages students to contact each other via e-mail, instant messaging, or chat.

As the facilitator of this community, you will want to send an opening message to each student or post one on the content-discussion board. It should be a warm, welcoming message, perhaps with a friendly photo. The opening message should include a question requiring a response from students. This first message will set the tone for the class; it also can serve as a model for online discussions.

Organization

There are a number of organizational strategies to use to help increase interaction and presence in an online class. As the instructor, you will want to hold “online” office hours. This can either be a specified time when you will be answering e-mail or using instant messenger to “chat” with students either synchronously and privately. Another strategy is to provide job aids on how to use the technology employed in the course, which allows the technology to become invisible as students become more familiar with using it.

The course syllabus should consist of more than taking the face-to-face paper copy and making it digital. In an online course, the syllabus needs to include things such as guidelines for discussions, definition of roles, and so forth, and to function as a contract between instructor and students. In addition to content traditionally included in a syllabus, you should include contact information for student technical difficulties. Instead of listing “participation” or “online attendance” and the point value, define what participation entails. For example, we suggest the participation grade be based on the quality of the postings and not just the quantity. Participation could include posting on an asynchronous discussion board, showing up for a synchronous chat, working on a team project, and so forth.

One strategy to help foster quality asynchronous postings is to ask the students to send private e-mails for single comments, such as “I liked your last posting” or “I agree.” According to Moore and

Kearsley (1996), this helps prevent cluttering the discussion board; they encourage only postings that will contribute to the “community’s pool of knowledge (p. 151).” Do not discourage positive comments like this, because they contribute to the social presence of the community.

Another strategy is to group students into teams of three or four and have them write up what they believe are good ground rules for discussions and participation. For example, what to do if someone reads all the postings, but does not post any. These could be posted in a forum that explains discussion board procedures and guidelines. Guidelines that include a posting with “emoticons” for students unfamiliar with how to express text-based emotions are helpful (e.g., ☺ means smiling or happy). In addition, some students might use abbreviations that are now common in Internet-based chat, such as LOL or “laughing out loud.” These small additions can add personality to the text-based “voices” of the participants. In a face-to-face classroom, physical presence is displayed through “voice, body language, intonation, expressions, [and] gestures” and helps communication (Ko & Rossen, 2004, p. 12). In the online environment, participants rely solely on text-based communication and need to avoid words that could be misinterpreted, such as sarcasm, inappropriate jokes, and so forth. Thus everyone in the community must demonstrate a culture of respect, so participants “feel what they say matters and is valued by the other members of the community” (Collison et al., 2000, p. 30).

An additional aspect of the syllabus that needs to be addressed is the schedule. The schedule is the lifeline of the online course. Students will look to this to effectively manage time. Therefore, it is critical to present course content in a consistent manner, either all up front or on a regular schedule. This will reduce confusion and promote consistent checking of the site by students. Keep in mind not everyone is logged on when an assignment is posted. Give approximately a week for assignments, to allow for those who log in

later in the week. This is one of the advantages to online learning: the ability to log on anytime of the day or night. You could require everyone to log in every two to three days to ensure they have the most up-to-date information. Supplying information, such as due dates, in more than one location on the course Web site is also a good idea as some students might look in different locations for information.

Instruction

There are a number of different instructional techniques to use when attempting to increase presence and interaction in an online class. Collaboration can be fostered in small or large groups of students. If you choose to have large class projects, there are grouping considerations. Before grouping the students into teams they will work with for the large class project, consider pairing them up for a smaller assignment, such as an article critique or peer review. This helps foster feelings of comfort when learning how to work with others over distance. When assembling teams for a large class project, groups of four are typically the optimum number. Encourage collaboration to prevent the group from splitting up the work, then putting it together to turn in; you want them to “construct their learning together” (Palloff & Pratt, 2005, p. 39). Also, explain to the students why it is important that they work collaboratively and that it is a requirement.

Palloff and Pratt (2005) discuss the importance of collaboration, saying it promotes critical thinking skills and helps to foster the feeling of community. There are a number of ways to do this online. Students first can do the work individually and bring it to the group for critique and to certify the correctness of the papers. Then the instructor can pick one student randomly to answer the questions studied by the group or choose one paper from the group to grade with everyone in the group receiving that grade. A second technique is to provide different team members with the

charge of finding different information. This is called information interdependence, or the jigsaw strategy, where students have the different pieces needed to complete the puzzle. In order for all the team members to do well on the assignment, they need to rely on the information the rest of the team members have learned. Hence, the students are held accountable for teaching the material to their team members. Another technique is to have the team devise a “charter” or team agreement delineating the different roles individuals will play, how they will interact, and different project deadlines. It is helpful to provide a sample charter, so students know what is expected of them. Some possible roles are secretary, liaison to the instructor, organizer, discussion board poster, and so forth. These roles might change during the project’s phases. Have the team create a team name; this helps with team identification on the discussion board and also with a sense of community. To encourage team buy-in, give the team choices in determining project topic. Monitor the team’s progress and intervene if there are participation problems. Johnson, Johnson, and Holubec (1991) state that there are three reasons an instructor should intervene:

1. To correct misunderstandings or misconceptions about task instructions and the academic assignments they are completing;
2. To correct the absence, incorrect use, or inappropriate use of collaborative skills; [and]
3. To reinforce the appropriate or competent use of collaborative skills. (pp. 6:29)

In addition, tips for online conflict resolution could be included as a job aid (Palloff & Pratt, 2005). When assessing the collaborative assignment, perhaps include peer evaluations in the grading criteria. This can help prevent noncontributing team members. In addition, ask each team member to write a reflection on what they did to contribute to the project, and how they tackled their role and task throughout the process.

As many online courses are taught using mainly asynchronous discussion boards, there are discussion strategies and activities that encourage interaction and a sense of presence online. A main goal is to ensure there is a high level of interaction and dialogue. This can be facilitated by using different types of questions, activities, and presentations.

Questions

When posting discussion questions, the instructor does not always need to be the initiator. After the instructor has modeled question facilitation, allow students, or pairs of students, to take turns facilitating different discussion topics. This allows students to see that each participant in the community is as valuable as the instructor because every participant shares personal experiences to help the community learn. It also allows participants to see multiple perspectives. During online discussion, it is important to provide the discussions with a distinct beginning and end to prevent information overload and frustration among students (Conrad & Donaldson, 2004). Different types of questions can help encourage critical thinking, such as questions asking for more evidence, questions asking for clarification, open-ended questions, hypothetical questions, cause and effect questions, and summary and synthesis questions (Palloff & Pratt, 2005). In addition, you or the discussion topic facilitator should write a wrap-up paragraph summarizing the main points of the discussion, including students' names and the different points they made, which contributes to the feeling of presence.

Activities

Different types of activities can take place on a discussion board. The typical threaded discussion can get boring to students who read numerous posts. Some activities to increase interaction are the following: a) role playing, b) debates, c)

simulations, d) case studies, e) outside experts, f) sharing related personal/professional experiences, and g) electronic virtual field trips. In addition to these asynchronous activities, consider having a few required synchronous discussions. It should be noted, however, synchronous discussions tend to be more social; therefore, they are usually more effective at fostering social interaction than cognitive interaction. Guest lecturers via audio or video conferencing and synchronous large group sessions, where the instructor uses a whiteboard to demonstrate a problem, also can be used. If the instructor must present some sort of lecture to provide information to the class, include meaningful interactive links, discussion threads, and other activities to make the lecture interactive.

Presentations

Online course technologies often allow for different types of presentations. Individuals can post papers, PowerPoint presentations, and other documents in discussion threads. However, how do you have a group do a presentation to the entire class? If the students have access to software, such as Breeze, Camtasia, or Articulate, they can create multimedia presentations the class can watch. If this type of software is not available, students can prepare a discussion thread led by the team to present their project. Teams also can create simple Web sites to showcase their projects.

Feedback

The final component we are going to discuss is the use of feedback, which is essential to fostering interactivity. Online feedback should consist of both instructor-to-student and student-to-student (or peer) feedback. Responding to individual e-mails asking the same questions can get redundant; therefore, encourage students to post questions on the discussion board, so everyone will benefit from the response. In addition, provide a discussion

forum that allows students to provide feedback about the course; perhaps these are recommendations for improvement or lessons learned that can be shared with future classes.

No matter the activity students are involved in, provide opportunities for individual as well as group practice and feedback; this may be the first online class they have taken. In addition, the instructor should respond to all student queries. Make sure responses are prompt if it is a technical question. If there is a delay in responding, explain the reason. Instructor feedback should offer detailed analysis of student work and suggestions for improvement, along with additional hints and information to supplement learning. These can be private, via e-mail, or public to a team via the discussion board. If a student is not accessing the site enough, the instructor can send informal e-mails to see if the student is having problems in terms of the technology. The instructor should send encouraging supportive e-mails to individuals on an ongoing basis. Include questions that require the student to respond, thus drawing them into active participation.

Students should complete peer reviews for student-to-student feedback. This provides the reviewer the opportunity to focus on others' interpretations and the original writer to receive multiple perspectives. Provide guidelines and the rubric to be used for grading. Both the instructor and the students should use "track changes" in Microsoft Word documents to provide feedback, so everyone can see changes made, comments, or notes that include questions. Also try to get feedback from participants about their progress. This can be done through direct questions, assignments, quizzes, polls, and questionnaires.

THE ONLINE INFORMATION SECURITY CLASS EXAMPLE

This section of the article begins with a brief overview of how to introduce and organize the

online information security course. Next, there is an in-depth focus on three weeks of instruction, explaining how the course was transitioned from face-to-face instruction to an online format. While this specific example focuses on an information security course, the purpose of the example is simply to enact the guidelines. The guidelines can be generalized to other topics and fields in technology education.

Introductions for Building a Learning Community

When building a learning community in a face-to-face security assurance class, the instructor tends to have class introductions and perhaps an ice breaker activity. For an *online* security assurance class, the instructor needs to facilitate a learning community in a similar, yet different way. The instructor needs to provide a Web-based orientation to both the online environment and the course materials. An opening message should be sent by instructors, including a question requiring a response from students. In order to allow students to get to know each other early in the course, online ice breaker activities that are via discussion boards as well as having students work in virtual teams to produce a visual presentation about the team are useful. In addition, a space is provided on the class Web site for students to post their digitized images. The instructor also should encourage students to contact each other via e-mail and chat.

Course Organization

When organizing a face-to-face security assurance class, the instructor has a syllabus that includes a schedule, required textbook, and office hours. In the online version of the security assurance class, the instructor needs to go further. In addition to the online syllabus, the instructor needs to post a schedule with hyperlinks to that day's information as well as discussion and par-

icipation guidelines and requirements. Links to online readings, in addition to the listed textbook, are included. Furthermore, the instructor needs to hold online office hours when the students can be sure to reach him or her immediately.

Instruction—Week One

Perform Asset Identification and Classification

In the first week of the face-to-face security assurance class, the instructor provides the students with readings on the risk assessment process and various models. She also presents a lecture to provide them with additional information. A discussion ensues about asset identification. They look at the different authors and different information provided in order to compare and contrast what each author said. They also discuss the purpose in the risk assessment process. In addition, the class brainstorms assets in the k-12 setting. The instructor assembles small groups and has the students apply asset identification to the k-12 setting. The groups then compare their new list to the other groups' lists. As a class, they then group information assets (types of data, part of classification). FIPS 199 is discussed as a classification scheme for sensitivity of assets. For homework, students are asked to apply FIPS 199 to their list and write a critique of the usability of FIPS 199. They can revisit the first readings to discuss their classifications.

In the online security assurance class, the instructor provides the students with links to readings and Web sites about the risk assessment process and various models. She also posts a short lecture (approximately 10 minutes) with a PowerPoint presentation via Breeze to provide them with additional information. A discussion forum is started in which the instructor poses an initial question about asset identification. The students have two to three days to respond. The instructor assigns different students to read different

authors to gain different information about risk assessment models. Concurrently, the instructor creates a new discussion forum for students to a) post a summary of their article, b) then compare their article to other postings, and c) discuss the purpose of models in the risk assessment process. The students again have two to three days to respond. The instructor creates a new discussion thread to brainstorm information assets in the k-12 setting and posts an initial questions. She has students individually apply asset identification to the k-12 setting then post their responses. She organizes students into groups of three or four and provides them group discussion forums. She has each group create one new list and has groups compare/contrast lists with each other. She also has groups apply a classification scheme to their list as well as write a group critique of FIPS 199. Groups also discuss their classification, according to the first readings they did. The students have four to five days to respond.

Instruction—Week Two

Perform Threat Identification

In the second week of the face-to-face security assurance class, the instructor provides the students with readings on information security threat analysis and classifications of threat types. As a class, they discuss how different threats might correlate to different assets. This is done first in small groups, then together in one large group discussion. The instructor also presents them with information on methods for identifying types of threats. She provides them with existing reports (FBI CIC Survey to Crime Data) and tells them where they can get this type of information for typical threats in other organizations. She asks the students if they can try to generalize to their organization, and how they would monitor their own employees/network/system. She poses the question, "How are you going to get clients to

think about modeling their threats before we go out to the client? Where we do actual threat identification?”

In the online security assurance class, the instructor provides the students with links to readings on information security threat analysis as well as Web sites about classifications of threat types. The students have two to three days to read this information. The instructor creates a new discussion forum about how different threats might correlate to different assets. Students are first assigned to small group discussion areas to answer a posted question. Then students discuss their findings in a large group discussion area. Students have two to three days to respond. Another discussion thread is created about methods for identifying types of threats. The instructor posts open-ended questions about the following: existing reports (FBI CIC Survey to Crime Data); where to get information; typical threats in other organizations; how the students could generalize to their organization; and how to monitor their own employees/network/system. In addition the instructor posts a fourth question: “How are you going to get clients to think about modeling their threats before we go out the the client, where we do actual threat identification?” Students have the same two to three days to respond.

Instruction—Week Three

Perform Vulnerability Identification

In the third week of the face-to-face security assurance class, the instructor provides a lecture and PowerPoint presentation on the three types of vulnerabilities— people, policy, and technology—and about establishing criteria for assessing vulnerability. She asks the students to individually develop an evaluation checklist (for policy) to take into a company. The instructor presents information about technical vulnerability. For example, she discusses the reporting tools companies and schools are likely to have as well as passive scan-

ning tools. The class goes to a computer lab as a group and experiments with a variety of these tools. The students are provided criteria to evaluate different types of scanning tools: purpose, when to use, cost, and advantages/disadvantages; this is done in small groups. For homework, students are put into small groups and asked to select a tool. They are then provided with a flawed system with known vulnerabilities to run their tool against. They must then take, analyze, and report their findings.

In the online security assurance class, the instructor provides the students with links to readings and Web sites on the three types of vulnerabilities—people, policy, and technology—and about establishing criteria for assessing vulnerability. She also posts a short lecture (approximately 10 minutes) with PowerPoint presentation via Breeze to provide them with additional information. She asks the students to individually develop an evaluation checklist (for policy) to take into a company and submit this to the online assignment drop box. Students have two to three days for this. Students are then put into small groups, where each student presents his/her checklist to the other group members. The small group is then tasked with coming up with a “Best of Breed” checklist, using their individual checklists. The instructor presents information about technical vulnerability via an audio presentation. For example, she discusses the reporting tools and passive scanning tools that companies and schools are likely to have. The instructor provides links to demonstration software for students to experiment with different types of these tools. She posts a list of criteria along with an example for students to evaluate different types of scanning tools: purpose, when to use, cost, and advantages/disadvantages; she assigns this to be done in small groups and posted within three days. The students also are requested to select one tool per small group. They are then provided a flawed system with known vulnerabilities to run their tool against. This system is

accessed via a virtual private network (VPN). The groups of students must then take, analyze, and report their findings on the discussion board within three days.

SUMMARY

The goal of this article was to provide guidance to faculty who are tasked with transitioning face-to-face instruction into distance learning. More specifically, these guidelines for an online course and the example of one are meant to provide readers with action steps that can be taken to improve the level and nature of interaction as well as students' sense of presence. The ultimate goal, of course, is to produce equally, if not more effective, results from online learning. Our hope is that faculty who attempt to use these guidelines will see increased learning and motivation to learn among their distance learning students.

ABSTRACT

This chapter illustrates a framework for online group collaborative learning based on Piaget's concepts of assimilation and accommodation and Vygotsky's theory of social interaction. This chapter examined how an online project-based learning approach affected students' cognitive skills development and their motivation, and

explored factors leading to successful collaborative projects. The findings indicated that in a project-based online group environment unique characteristics exist for leadership style and individual role, goal setting and project management, accountability and commitment, peer supportive relationships, individual accomplishment and group accomplishments, and mixed gender and race group preference.

INTRODUCTION

The value of collaborative learning is widely recognized because of its positive effects on social, cognitive and metacognitive development. One advantage of collaborative learning is that it provides students opportunities for self-reflection and joint construction of knowledge, and this environment frequently leads to higher levels of task-related interaction and behavior (e.g., Johnson, Johnson, & Stanne, 1986). When students are able to participate in active learning activities, they find learning more pleasurable and satisfying than non-participative events.

Small-group dynamics have been studied in educational contexts since the 1970s. Research indicates that small groups facilitate learning as compared to individual learning (e.g., Johnson, Johnson, & Stanne, 1986; Hamm & Adams, 1992; Bruffee, 1999), and that peer group work has significant impacts on varied learning outcomes in both face-to-face and online learning environments (e.g., Harasim, 1990; Scardamalia & Bereiter, 1996; Bruffee, 1999; Uribe, Klein, & Sullivan, 2003). Although much of cooperative learning research initially focused on face-to-face cooperation at the elementary school level, it is now gradually extending into higher education, which is the focus of this study.

Positive interdependence promotes 'group cohesion' and a heightened sense of 'belonging' to a group; and can be achieved through the task, resources, goals, rewards, roles or the environment (Brush, 1998). Individual accountability refers to the extent to which students are individually accountable for jobs, tasks or duties, and was introduced to counter the 'free-rider effect': some students would deliberately not invest any (or little) effort. Both principles, however, relate to group dynamics phenomena 'group cohesion' and 'social loafing' (Du & Havard, 2003), and thus apply to any form of small-group learning. Bosworth and Hamilton (1994) proposed a process-oriented design method for online group-based learning

that focused on fostering the envisioned group interaction thought to enhance learning instead of focusing on the formal product of such interaction. This method tends to be the dominant view in most institutions providing higher education and centers on five elements that directly shape group interaction: learning objectives, task type, level of pre-structuring, group size and technological tool used.

The need for systematic design of online learning is amplified by some observations that exhibit conflict regarding coordination during group interaction. These observations suggest conflicts are more likely to occur in asynchronous online settings compared to face-to-face settings (Du & Havard, 2005), since group members are not present at the same time and/or place. Also, the lack of presence concerning immediate feedback and face-to-face setting make asynchronous communication 'unnatural.' Clearly, some support should be designed to help students overcome difficulties in group coordination during asynchronous collaboration.

Group performance effectiveness depends on the groups' use of their alternate opinions and on the handling of increased coordination (Shaw, 1981). Roles, stated functions/duties or responsibilities that guide individual behavior and regulate intra-group interaction (Hare, 1994) can promote group cohesion and responsibility (Boud, Cohen & Sampson, 1999) and, thus, can be used to foster 'positive interdependence' and 'individual accountability' (Hedberg, 2003). In addition, roles can stimulate a group member's awareness of the overall group performance and each member's contribution. Lastly, roles appear to be most relevant when a group pursues a shared goal requiring a certain level of task division, coordination and integration of individual activities.

Despite the potential benefits of collaborative learning, several studies reveal that collaborative learning does not always lead to the desired outcome. For example, free collaboration does not

systematically produce learning (Dillenbourg, 2002), and researchers report large variations in the quality of interaction and learning outcomes (Lehtinen, Hakkarainen, Lipponene, Rahikainen, & Muukkonen, 2000). Other variations may include, but are not limited to, the length of studies, technology used, differences in research methodology and the quality of the group processes (Shaw, 1981; Strijbos, Martens, Jochems, & Broers, 2004). Students who have experienced negative online experiences perceived those experiences as weaknesses of online learning. These problems were most often caused by delayed feedback from instructors (Laszlo & Kupritz, 2003), lack of self-regulation and self-motivation, sense of isolation, monotonous instructional methods (Wang, Sierra, & Folger, 2003), and poorly designed assignments (Hedberg, 2003; Thomas, 2000). Problems in collaborative group projects include social loafing and free riding, disorder due to poor leadership and member role identification, low motivation through no common goal and poor management of tasks.

In this chapter, we argue that collaborative learning has moved beyond the question whether it is effective in accelerating knowledge construction, but should focus on the conditions under which these types of learning environments were optimally effective. The aim of this chapter is to describe students' perceptions of online group collaborative learning and examine how an online project-based learning approach affected students' cognitive skills development and motivation. This study will identify specific group dynamics and factors leading to successful collaborative projects.

A Theoretical Framework for Analysis of the Collaborative Learning Process

From a constructivist perspective, knowledge is constructed via interactions between and among the learner and the social world (Crotty, 1998).

Accordingly, learning will be enhanced when students are supported by and engage in 'meaning-making' experiences (Jonassen, 1999). Cognitive tools provide the means through which many constructivist learning activities are enacted, enabling a wide array of affordances with which individuals access, manipulate and otherwise construct knowledge (Jonassen & Reeves, 1996; Lajoie, 2000). Tools play especially important roles in student-centered learning environments (Land & Hannafin, 1996, 1997), where problems are framed in authentic and meaningful contexts, learners engage problems using multiple resources and tools, and knowledge construction is facilitated using technological as well as human scaffolds (Hannafin et al., 1999).

Constructivism is a term used to describe a number of theories. Two dimensions were focused on in this study: the knowledge construction process of individual learners and knowledge construction as a socially situated process (Driscoll, 1994).

The individual learner constructs knowledge by adapting previously constructed schemes. This view is based on Piaget's theory and the concepts of assimilation and accommodation. This process of schema construction and reconstruction implies the selection of stimuli from the project-based environment, continuous storage and retrieval of schemas between long-term memory and working memory in order to organize, elaborate, refine and/or integrate these schemas. This overall process is monitored by metacognitive processes. These processes help the learner to be selective in stimulus selection, storage, retrieval and response organization (Popolov, Callaghan, & Luker, 2002). The online setting influences this complex of cognitive activities in interaction with the nature of the project-based environment.

The knowledge construction process may also be seen as socially situated. This view is based on Vygotsky's theory of social interaction, where the interaction between people plays an important role. This is where the 'social' part of 'social construc-

tivism' becomes evident. The interaction between learners in the online environment is expected (a) to incite the learner to make explicit the actual level of schema development by writing his or her ideas down, and (b) to demand from the learner an explicit comparison of his or her schema and that/those of others as to defend or criticize them. As such, the interaction demands further elaboration and organization of the schemas at the point collaboration enters. This theoretical description implies that learning in the online environment depends on the amount of schema exploitation activities and the amount of explicit comparison and contrast. The more these activities are invoked, the higher the level of knowledge construction to be expected.

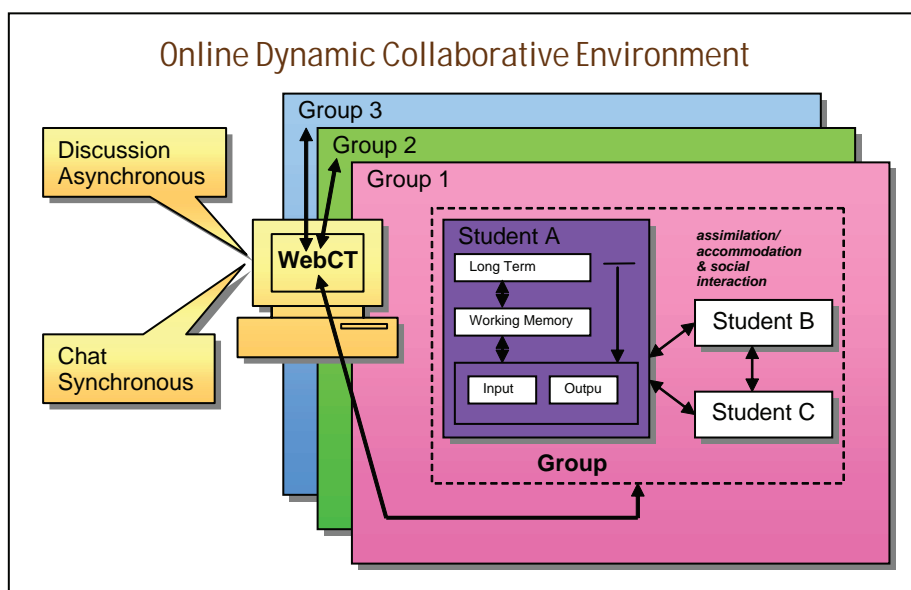

Figure 1 provides a graphical representation of the theoretical base for the present study. This scheme is an extension of the framework used in previous research (Hare, 1994; Kitchner, 1983). It integrates social constructivist principles and concepts derived from the information processing approach to learning (Dillenbourg, 2002).

We consider three elements or levels regarding learning: individual processes, group member processes and group environment processes (see Figure 1). Individual learning is depicted through an information processing perspective, with sensory receptors providing input, refined through short- and long-term memory, and exhibited through output. Individual input and output is affected and refined through social interaction, where familiar information is assimilated and new information is accommodated. Learning continues at the group environment level, where group input and output is refined through review and critique by other groups.

Framework Application in Online Group Collaboration

The social constructivist notion of interactivity described above was used as a theoretical framework for building an online collaborative learning. The online learning environment for this course was created in WebCT. WebCT is a database

Figure 1. Graphical representation of social constructivist principles and concepts derived from the information processing approach to learning

driven Web-based course management system designed to support online learning environments (Hutchins, 2001). The database elements available in WebCT enable the instructor to record, manage and support the activities and interactions of a large number of students. This multimedia design for instruction course is required of all students enrolled in the Master of Science in Instructional Technology (MSIT) program. Students enrolled in the MSIT program and in this course represent a wide range of diverse backgrounds. They reside throughout the state of Mississippi, Tennessee and Alabama. Each semester, approximately 30 students are enrolled in this course.

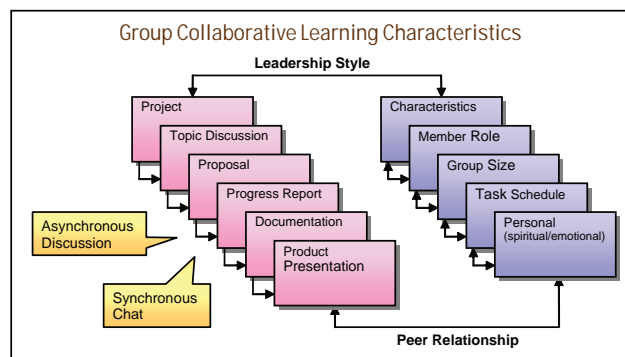

In Figure 2, leadership style and peer relationships have a dramatic effect on the nature and outcome of the final product in a project-based learning environment. Both project and group characteristics are impacted by their related characteristics, leadership style and peer relationships (see Figure 2). This project is sequential in nature, with each phase channeling into the next. Peer relationships and leadership style within a group are interrelated, impacting each phase of the project.

Framework Application

We applied the framework during two semesters of a graduate-level multimedia design for instruction

course. The purpose of this course was to provide students with an overview of hypermedia/interactive multimedia technology by working with various hypermedia/multimedia tools. Students were introduced to the design and production process of developing multimedia applications and provided the opportunity to learn various tools concentrating on different aspects of the technology: text, graphics, audio, animation and video. By working with these tools, students were expected to develop the skills and understanding required for the creation of instructional tools for application in education and industrial settings. Students were required to apply design principles necessary for the creation of hypermedia/multimedia in developing multimedia-based applications. Several important aspects about this environment regarding skill development, theoretical and technical issues, and the application skills and knowledge towards the successful development of a comprehensive multimedia instructional product (Popolov, Callaghan, & Luker, 2002; Slavin, 1995) were examined. Through online group communication using the asynchronous discussion feature and synchronous chat available through WebCT, students’ skills and knowledge regarding multimedia development were enhanced. The social aspect of the learning environment is critical (Vygotsky, 1978). This required focused attention

Figure 2. Leadership style and peer relationships effect on the nature and outcome of the final product in a project-based learning environment

by the instructor, as knowledge is socially constructed and enhanced through peer-to-peer and instructor-to-peer communication (Boud, Cohen, & Sampson, 1999; Kitchner, 1983; Kitchner & King, 1981).

In the multimedia process, students worked in groups and took on different roles. The contexts for learning in this course were primarily interactive, collaborative, multi-disciplinary and student-centered. Students were required to actively participate in weekly discussions regarding specific multimedia development topics. Assignments on learning different tools were given to assess application skills, and students were required to write a research and reflective paper on hypermedia/interactive multimedia instruction. Group projects for the semester both developed and assessed students' ability to comprehensively apply the theoretical and technical requirements for multimedia design for instruction. Students worked together in teams of four or five in developing an instructional Web site as the final course project. The tools used for project development included Macromedia Dreamweaver, Fireworks, Flash, and Hyperstudio. The general target audience for the site included prospective students and teachers. Deliverables beyond the completed Web site included a project proposal, project progress report, project documentation and final presentation of the final product. The project proposal was intended to describe the instructional problem, specific target audience, instructional or training context and objectives to be achieved. The formal project progress report required groups to provide status on their project, including work completed and tasks planned for completion. Project documentation, similar to a detailed design document, revealed details about the product that was developed, justification and use of an instructional design model for product development, audience analysis, formal instructional content, learning objectives, media selection, instructional strategy employed and assessment. Finally, project documentation concluded

with a description of the formative evaluation process and findings. Each group presented their final product to the class. Every member of each group was expected to take an active role in the final presentation.

FINDINGS

Accountability and Commitment

By online, we mean that most learners are likely to be geographically isolated, studying perhaps from home but with full access to all of the necessary resources via Internet connection. Materials (such as lecture notes) and processes (such as assignment submission) will be electronic, and interaction will be either synchronous (e.g., via chat-rooms or videoconferencing facilities) or asynchronous (e.g., via e-mail or discussion lists). By collaborative, we mean that despite their differing locations, most learners will conduct most of their learning in groups. Such groups are likely to be wholly virtual in the sense that their component members may never meet face to face. They are, however, in all other respects very real, and group members will be highly reliant on each other for the quality of their learning.

Almost all students reported accountability, responsibility, unselfishness, commitment and dedication as major attributes that ensured the success of online collaboration. Students felt that their online collaboration on the project was more successful because students in their group exhibited these characteristics. If a student had to be absent from meetings, legitimate reasons such as a death in the family or in a friend's family, work or having to take care of other family obligations were the norm. Being absent did not prevent the student from being accountable. These students returned to the group concerned about what went on during online discussions in which they were absent and what their assignments were without having to be told by other students in the group.

Exhibiting these attributes of accountability and commitment seemed to be contagious within the groups. The more one group member exhibited these traits, the more these traits seemed to become a norm for the behavior of the rest of the group members. There was an “unspoken” appreciation shown by the rest of the group when members participated with this level of commitment, because the rest of the group members seemed to exhibit the same level of behavior when they had to be absent. Complete commitment to the success of the project was exhibited not just by one, but by most of the group members, where leadership with accountability and commitment were practiced.

Leadership Style and Individual Roles

Group dynamics were affected by the leadership style of the online group coordinator. Three groups had female coordinators, two groups had male coordinators. The leadership style exhibited in the group that produced the best results came from a leader who coached his or her team by stepping back and letting team members “shine.” The leader quietly led them to meeting deadlines and goals and following the outline of the project, while allowing them to make decisions for the successful completion of the project. The leader allowed the team members to lead, to shine, to be successful, and to feel complete ownership of the finished product, which was not any one individual team member’s project, but the project of the committed, concerted efforts of the group. Because group members had ownership in the project and were made to feel the importance of their input, the final project was much more advanced than would have been achieved otherwise. A leadership style that promoted inclusiveness, pride, self-confidence, participation and understanding created a much more productive and self-reliant team that was able to produce beyond the norm. A leader that was more interested in the performance of

the team and the quality of the finished product rather than self-recognition produced the more successful product.

One group leader stepped down at mid-semester due to overwhelming outside responsibilities. No one assumed the leadership position and that group was ineffective for 4 weeks, and without instructor directives the group would have failed the project assignment. Two groups had young leaders whom were expected to be at risk, but gained momentum as the semester progressed. Both of the young group leaders initially had difficulty organizing and influencing corporation from the team members, but gradually, with the help of their more experienced team members, the team became focused. One leader, who was a manager by profession, seemed to be the most effective and influenced the team to produce the best project in the class. Another team had high inexperience in Web skills and a leader with a lack of course subject knowledge who was hesitant to lead with firm direction in the beginning. Eventually, this leader pulled the group together to produce a good project.

Individual Accomplishments and Group Accomplishments

By learning, we mean that in group learning environments less emphasis is likely to be placed on memorization, rote learning and cramming for examinations, and more on real-world abilities, such as communication, problem-solving and articulation of solutions. Some groups and some leaders experienced individuals who were more interested in their individual accomplishments than the accomplishments of the team. A few individuals with high Web skills quickly developed the “vehicle” for the final project, but the results were not necessarily compatible with the project goals. Because of existing skills in Web development that some individuals possessed in the group, they may have wanted to take on the design and development of the project without

taking into consideration the input of the other team members. Realizing they could produce a product because of their skills did not necessarily mean that their product would excel as well as a product that included the input and talents of all members of the group. The time limitations and the complexity of this project naturally required that it be a group project, thus requiring the talents and input of everyone on the team. Group members questioned and worked through “compatibility of design with team project goals” until the design fit the project idea and theme. Although team members were appreciative of the individual’s Web design skills, they wanted their input heard and a finished product that met the guidelines of the project. Team members did not want an individual’s accomplishments to overshadow or overrule the accomplishments of the team. Leadership styles definitely affected the group dynamics of each team. These leadership styles included: (1) one that produced the best finished product, (2) lack of leadership when one leader had to step down, (3) inexperienced ones who just needed some practice, and (4) one that required refocusing members who were interested in their accomplishments instead of the team’s.

Setting Goals and Managing Team Project

Setting goals and managing the team project assisted the teams in successfully bonding and completing their project (Pate, Du, & Havard, 2004). Students reported that setting a “common goal” and “establishing a bonding” within the group by “dedicated students” was critical in the process of team development and achieving success. Due to the complexity of the project and the amount of time required to complete it, students explained that this kind of dedication and bonding were vital to the success of the team and the assignment. In addition, it was important for a team to plan, manage and meet the timeline, and equally important for the team leader to delegate

teamwork to accomplish tasks on time. Missing deadlines and not remaining on schedule also caused a much less polished product at the end of the semester.

Accepting responsibility for group assignments and following through in a timely manner with those assignments affected group productivity. Not only were missed or late assignments an indicator of an individual’s dedication to the team, but also indicated the dedication the team member had to the project. A team member without dedication who misses or is late with assignments caused other team members to be late and sometimes miss their assignments, also. Teams that had definite deadlines and frequent communication were able to build more powerful projects than those who had frequent absences and did not honor deadlines. Teams that worked together to demand participation from each member were also more successful. If a team member was not meeting assignment deadlines and goals, improvement would be gained from pressure by the team leader and other members of the group. It appeared that no one in any group wanted to be singled out as the unproductive member. Although there were exceptions, the united strength of the team was much more powerful than just a single individual’s leadership role.

Most of the groups referred to their project proposal plans and final project guidelines to evaluate their own development stages and notes. Groups who did not practice referring to their project proposal or the project guidelines, consequently, had project omissions and components that did not relate or fit their design. Often, there were discussions on adding or eliminating parts concerning the project design, and the limitations were not always skill-based. There was a concern that the element did not comply with the project goals or would have to be restructured to fit the project goals. When met with these types of obstacles, the successful groups looked outside the team for advice or help. They either consulted with the instructor, professionals whom

they viewed as knowledgeable, online sources or with friends who had experience in a particular area. The successful groups viewed limitations as obstacles to overcome, not as roadblocks for which there was no way around.

Positive Peer Support Spiritually and Emotionally

Peer support served as a positive element in groups and helped to spiritually and emotionally support students through the difficult parts of the project development phases. Several students mentioned “friendship” and “trust” as enjoyable online collaborative learning experiences. This meant “close friends getting along well” and “giving a helping hand to a struggling member.” Students seemed to draw an inner strength and purpose when they felt appreciated and were complimented by their fellow group members. This caused the student to be more likely to seek help when needed and to give help where needed. Developing this type of relationship was a gradual process as the group members worked through the obstacles of producing the final project. Gradually, when one member produced a good idea, another member complimented that member and so on. This process of positive team feedback helped make the individual team members more self-confident, thus producing a more self-confident team. This positive peer relationship also enabled the students to “openly discuss problem areas . . . and to avoid any potential disagreements.” Group members were less likely to engage in disagreements when they had this positive relationship. They could maturely work out any disagreements by openly discussing and agreeing on possible solutions. This positive peer relationship produced group members who were more productive and engaging in timely completion of the final project.

Preference for Mixed Gender and Race Groups

Students preferred mixed gender and race groups for their online discussion groups. In one group, the instructor chose a white male as group leader of a predominately African American female group. Initially, the group leader was apprehensive about his ability to lead this group, as was the group about having him as their leader. When the group of African American women saw that the group leader was not domineering, was inclusive, was open to them taking on leadership roles, and wanted their ideas and participation, they all got together with the leader and produced an outstanding product. Based on observations, African American students perceive group work as a comfortable environment in which to work. When conflicts occurred with group participation, African American students were willing to provide explanations for their conflict and to openly resolve the conflict as soon as possible. When African American students missed an online discussion session, they were quick to seek follow-up information about what they missed. Resistance to group work appeared to be based on lack of some required skills, rather than lack of cooperation to participate in-group. They were only concerned about not being able to assist with certain needs within the group and were not concerned about having to work in a group at all.

CONCLUSION

Using a socio-cultural view contained in this study as a valuable theoretical framework, individual students in small groups can utilize their own information stored in their working memory and long-term memory interactively with others

in their group to organize output that becomes relevant for the other learners, thus providing a meaningful collaborative online learning situation. This active engagement in the learning process when jointly working on a learning task with others becomes meaningful when students are allowed to mutually explain the learning contents, give feedback to the contributions of other group members, and asking and answering questions (Du & Havard, 2005).

Successfully completing a project assigned to an online group was dependent on a number of factors. How successful the project was depended on the leadership style of the group leader, with the most important factor being the success of the group as the main concern. Setting goals and accepting responsibility for the group's project were also major factors in the success of the finished product. These goals and responsibilities were not just the team leaders', but also the entire groups'. Groups also felt that they were more successful with their project when they followed the guidelines and their proposal for the project. Peer support during the development of the group project was a very important part of the success of the project. Students felt that without the spiritual and emotional support of their peers, the project would not have been as successful. If one were looking for a negative factor in online group collaboration, it would not be found in gender or race group preferences. Students worked together regardless of the race or gender of their group members and expressed a preference for having mixed races and genders in their groups. They felt that the variety of contributions from different races and genders was very important to the group work.

The findings of this study can also be used to help identify patterns in which online discussion is conducted effectively in conjunction with course context and individual characteristics for enhancing learning growth. Knowledge of such patterns can facilitate new designs and improvement of online collaborative learning.

Chapter 2.47

Using “Blended Learning” to Develop Tertiary Students’ Skills of Critique

Paul Lajbcyier

Monash University, Australia

Christine Spratt

Monash University, Australia

ABSTRACT

Devising pedagogical strategies that will engage students in ways that will assure the development of their skills of critique and analysis presents a challenge to tertiary teachers. This chapter draws on data from a recent case-based evaluation study to argue that innovative assessment and the development of social presence in online learning environments can contribute to developing skills of critique and analysis in tertiary students. The chapter is underpinned by the belief that creative thinking about curriculum issues must continue to lead debates about tertiary pedagogy, the use of educational technologies and online learning. It concludes by posing implications for further research in pedagogical practices in tertiary settings; in particular, it presents a discussion of the potential of “blended learning” and “variation theory” for leading such research.

INTRODUCTION

Pedagogical approaches embedded in constructivism mean that tertiary teachers ought to offer students opportunities to be active learners. Such approaches should see students engaged in learning tasks that are relevant and directed towards mutually conceived learning outcomes and that such engagements ought to be reflective communities of learning (Marton & Trigwell, 2000). We believe this is imperative in undergraduate and postgraduate classrooms, particularly where such classrooms are becoming more diverse. Here we acknowledge the growth in full-fee paying international students; the imperatives of information and communication technologies to develop pedagogical models of flexibility; “creeping credentialism” – that is, the imperative for life-long learning and qualifications as one crucial step in assuring career

progression; as well as the demands of increasingly sophisticated learners.

Therefore, tertiary education ought to exploit students’ existing knowledge and experience. It ought to engage learners in meaningful, relevant and authentic learning experiences, including assessment tasks. Such a curriculum approach aims to promote opportunities for active learning and collaboration where students are engaged in deep learning experiences that develop their capacities to be self-reflective and critical. Deep learning is considered to be critical and transformative, where students develop the capability to:

relate ideas to previous knowledge and experience; check evidence and relate it to conclusions; examine the logic of argument cautiously and critically; become actively interested in the course content; and look for patterns and underlying principles. (Marton, Hounsell, & Entwistle, 1998, p. 19)

This chapter uses a case-based evaluation study of a curriculum unit¹ to raise broader issues related to the design of online learning environments, the potential of social presence in such environments and innovative assessment to influence successful learning outcomes. As a case study, it provides “an evidentiary boundary around which to discuss educational problems” (Walker, 2001, p. 10). In this case, the educational problem concerned engaging students in forms of discourse in an online environment to develop their skills of critique, analysis and decision making.

THE STUDY FOCUS

In previous years, students in this particular unit (a postgraduate unit concerned with financial computation and investment decision-making²) claimed that they enjoyed the unit and assessment tasks very much because they were aligned with their practical, applied interest in investments. While students appreciated the link between the

assignments, the unit coordinator (the first author) was often dissatisfied and disheartened with what he considered was limited critical debate and discussion amongst the student cohort around substantive curriculum content.

To be a literate investor, it is essential that investment decisions be based on a prudent process, including: sound reasoning (considering all available resources), ongoing monitoring of investment performance and the incorporation of new information to modify risk exposure. A discourse among student peers, where they are given opportunities to reflect, debate and compare investment performance, is an ideal way to encourage this process. While the students in the unit are forced, weekly, to present their developing investment portfolios to their peers (and hence to monitor their investment performance), the unit coordinator believed that a potentially more valuable ongoing discourse of critique and analysis was not occurring both inter and intra group as much as he had hoped. In other words, a new strategy was needed, as it became apparent that students were not engaged in an ongoing discourse about their investment decisions as hoped in their large groups (of 10). Instead, only those students responsible for investment decisions on any one week were considering the issues involved in changing their portfolios.

Curriculum renewal is iterative and requires academic teachers to reflect critically on their practice and engage students and other stakeholders in the processes of pedagogical research and evaluation. While the evaluation in this case-based study broadly investigated the student experience in the unit, it focused on investigating the way in which the integrated assessment strategy especially achieved the desired outcomes and the way in which students engaged online to complete the assessment tasks and meet the unit’s goals of developing skills of critique and analysis through debate and discourse. The study aimed to illuminate the following key questions:

- In what ways do electronic discussion fora promote the development of skills of critique and analysis through online debate and discourse?
- How does assessment as a learning strategy in online environments assist in developing the skills of critique and analysis?

Online Course Strategy

The unit is conducted in a flexible delivery mode and used WebCT to support this approach. Flexible delivery means an approach where the development of an online learning environment supports the on-campus experience in an integrated manner. In this case, the online environment was used to enhance learning and provide a degree of flexibility for students in where and how they studied. This is essentially one form of ‘blended learning’, and is discussed in more detail later.

The unit supported a well-designed and innovative assessment strategy that relied heavily on peer learning and group work. The unit coordinator wanted to create an assessment strategy that would create learning opportunities as well as measure learning outcomes. In doing so, the assessment strategy also created opportunities for students to be engaged in activities that were relevant and authentic to their employment settings.

The unit’s pedagogical approach attempted to create a bridge between the pre-existing group assignment and an e-moderated online discussion group to encourage a discourse of critique and analysis that the unit coordinator suspected would ultimately contribute to the development of critical investment decision-making skills. He anticipated the potential challenges of e-moderation and chose to base his approach on the work of Salmon (2000, 2002), which he believed would provide a pragmatic structure and useful guiding principles.

STUDY METHODOLOGY

The study incorporated three principle data collection strategies. First, students’ views of teaching in the unit were surveyed using the university-supported standard evaluation of teaching questionnaire (Monquest survey), which is part of its institutional quality improvement strategy. The Monquest survey was analyzed through the university’s quality teaching unit.

Second, students’ views of the online environment were surveyed. Students were asked to complete a questionnaire developed by the co-authors to gather more specific data about the unit assessment strategy. The unit coordinator devised the WebCT survey on the basis of the desired learning outcomes and his particular interest in ascertaining whether the student cohort believed they had met his intended pedagogical goals. Therefore, the WebCT survey was constructed to gather data about students’ perceptions of the benefits of the online environment in promoting critical debate and discussion in the substantive content areas of the unit. The authors were particularly interested in investigating whether the students believed the unit developed their capacity to make investment decisions. Furthermore, the WebCT survey aimed to gather data about the perceived benefits of the online environment in promoting inter- and intra-group collaboration. The WebCT survey included 25 statements that students were asked to rate (the range was completely agree-completely disagree) on a 5-point Likert scale.

Third, students who had responsibility over the course of the unit as team leaders of designated peer learning groups agreed to participate in a focus group interview. Team leaders were interviewed, as it was believed they would bring a particular perspective to the study and would be able to comment particularly on the way the groups interacted in relation to the learning goals that were anticipated. Seven team leaders (three male, four female) agreed to participate in the

focus group discussion. Team leaders appeared to be chosen by each group as a result of their own actions, such as organizing meetings (i.e., taking the initial step and showing some kind of leadership role, such as e-mailing others). As one student explained, “whoever spoke the most got to be leader!” The second author and a research assistant conducted the focus group interview using a semi-structured interview schedule. The qualitative data were transcribed, and the two interviewers analyzed the qualitative responses, isolated key themes and collaboratively annotated a summary of findings.

STUDY RESULTS

Of the student cohort (n=94), 49 completed the Monquest survey and 49 completed the WebCT survey (a return rate of 52% for each survey). The students were first-time users of WebCT. Some experienced technical issues and were unable to use the synchronous online facility, chat, until mid semester. There were no major technical issues encountered. All students accessed the online environment from home as their primary access point.

The Monquest Survey

The Monquest survey data revealed that the students were highly satisfied with the unit, with 80% of students scoring very good or good responses for six of seven responses for the “Teaching Feedback” and four of five for “Subject Feedback” questionnaires.

The WebCT Survey

The WebCT survey data indicated that, with respect to the unit assessment strategy, the group work assignments were preferred over the individual assignment. Table 1 illustrates the WebCT survey responses. Students recognized that the unit coordinator aimed to develop an integrated assessment approach as a means of giving more coherence to the unit assessment as a learning strategy.

Further, with respect to the use of the online discussion forum to foster critical debate and discussion:

- Students felt that the online chat forum did not make the group assignment any easier.

Table 1. Responses to WebCT survey

Panel 1

Survey Question#	1	2	3	4	5	6	7	8	9	10	11	12
Average	2.5	2.5	2.7	2.6	1.8	2.4	2.8	2.9	1.7	1.8	1.8	2.4
%	63%	66%	81%	75%	8%	56%	92%	100%	0%	3%	2%	59%

Panel 2

Survey Question#	13	14	15	16	17	18	19	20	21	22	23	24	25
Average	2.5	2.6	2.6	2.5	1.9	2.6	2.1	1.8	1.9	2.4	2.4	2.5	1.9
%	61%	69%	73%	61%	15%	71%	31%	7%	17%	56%	54%	61%	10%

Note: Average is the average response (between 1-5) and % is the normalized average response (normalized so that the highest response obtains 100% and the lowest 0%).

- Students were neutral on value of the discussion forum (i.e., bulletin board).
- Students felt that the same amount of debate would have occurred without the online chat forum.
- Students liked to compare the performance of their group with the others using tools provided in the online site.

Focus Group Interview of Team Leaders

The focus group interview data suggested that students saw the online environment as a useful adjunct to the pedagogical structure of the unit. The focus group interview data identified that the online environment was highly valued as a single point of access to reference material, bringing resources together in one place; “the immediacy of it was great” and they liked the fact that “there was one point of reference for unit material.” The following discussion expresses our analysis and interpretation of the focus group interview with the WebCT survey data.

DISCUSSION

Creating an Online Learning Environment

Structured asynchronous online groups were established by the unit coordinator specifically to progress his aim to foster more discourse and debate as a precursor to skill development in investment decision-making. Interestingly, as noted earlier, the WebCT survey indicated that students were “neutral” on value of these discussion fora and felt that the same amount of debate would have occurred without the online chat forum.

However, this was neither reflected in the focus group interview nor in a very visible indicator; that is, the documentary evidence of the use of the

online spaces. These spaces were used frequently and we believe relatively effectively by students. We acknowledge that the focus group interview was comprised of team leaders only; however, we argue that their insight into the groups’ online engagement, coupled with the nature of the text evidence in the online discussion spaces (approximately 698 separate postings over the semester), demonstrates how the student cohort became adept at using the online discussion to meet their perceived needs.

Moreover, the synchronous chat facility was used by students in the absence of any intention in the pedagogical design from the unit coordinator. The synchronous chat facility came to be used by these strategic learners as a means of solving an immediate educational challenge: in this case, to assist them to prepare for the group presentations.

While the survey evidence of neutrality with regard to the discussion fora offers little of itself, the perceived value of the discussion fora and chat is highlighted beyond neutral in light of the focus group interview data. A substantial quantity of material in the form of discussion postings over the course of the semester was generated. This provided some evidence that students were engaging in discussion and debate in the way that the unit coordinator aimed to foster. However, the data generated from the discussion fora and the chat facility were not systematically analyzed as part of this study, and this is addressed subsequently.

In the focus group interview, students recognized that the success of any online discussion (synchronous or asynchronous) lies in their sense of its responsiveness. However, they were quick to point out that they felt, “it was not as good as face-to-face” and, importantly, that “its usefulness depends on the individual and their motivation.” As one student explained, in chat, “you can’t see how people are reacting, if they are arguing with you,” and this can be a disadvantage in gauging the success of the discussion.

Social Presence in Online Learning Environments

Rourke, Anderson, Garrison and Archer (1999, p. 2) see social presence “as the ability of learners to project themselves socially and affectively into a community of inquiry.” These authors draw on the work of Tinto (1987, cited in Rourke et al., 1999, p. 4) when they argue that social presence “supports cognitive objectives through its ability to instigate, sustain and support critical thinking in a community of learners.” There is now an extensive literature that explores the way in which the discourses of text-based computer conferencing environments can develop critical thinking and other desirable cognitive skills in learners. Indeed, as Garrison, Anderson and Archer (2001, p. 1) argue, the acceptance of such environments and the way in which the higher education community has written about them, “has far outpaced our understanding of how this medium should best be used to promote higher-order learning.”

Ostensibly, our intention for this case was the latter. In the context of this case study, the synchronous and asynchronous online groups served various purposes for students, and the signifiers of social presence that were evident (interaction, dialog, responsiveness of the teacher and student peers) may account for the way the students came to value the asynchronous online discussion and the synchronous chat. Furthermore, in this study, social aspects conducive to learning came into the use of chat, but the social elements were developed or formed *outside the online chat and discussion groups*, in the face-to-face environment that the unit already required of them (weekly lectures and tutorials).

However, the online chat and discussion groups were enhanced by those social bonds, which students claimed made it easier to work in online groups because of the pre-existing knowledge of personalities. One student also commented that working online “allowed us to talk more person-

ally within the context of the large lecture class.” Overall, online chat was seen to be useful as a collaborative tool to reach an educational goal (for example, preparing the presentation) and did contribute to maintaining the social relationships required for learning groups to function effectively.

Those who are researching in this field generally take one of two approaches, according to Garrison et al. (2001, pp. 5-7): those who look to investigate “absolute characteristics” of critical inquiry, such as logic, depth and completeness in discussion; and those who are interested in what they call a more “heuristic measure” of critique, where the effectiveness of the process of critical thinking is judged by participants. This supports the more recent and growing appreciation that measures of quality in online discussion are often difficult to gauge and time consuming to analyze (Gerbic & Stacey, 2003). Gerbic and Stacey (2003) review the changing emphasis from quantitative to qualitative research and evaluation approaches in the online learning environments of text-based computer mediated communication spaces. There is increasing evidence for this in the related literature (Agostinho, 2005). For example, in a recent study that explored the dynamics of networked e-learning groups, McConnell (2005) drew on both ethnography and grounded theory to explore the way in which e-learning groups reached their desired learning outcomes. He analyzed the transcripts of three e-learning groups as they collaborated to develop a defined product. The groups were undertaking a postgraduate professional qualification and the program was conducted entirely online.

We accept that the study reported here may well have benefited from a deeper, some might argue more rigorous discourse analysis of the text posted in the asynchronous discussion fora. However, we were more interested in the personal beliefs and perceptions that students had about the value of the fora in developing critical thinking skills and enhancing their experience of learning

in the unit. In other words, we were interested in what students’ perceptions of the unit were and the way it evolved for them as a learning experience, and this is more attuned to Garrison et al.’s (2001) ‘heuristics’ mentioned above.
