According to market research held in June 2005, a total of 30% of the Dutch consumers said that they were interested (19%) or might be interested (11 %) in subscribing for a triple-play package to get digital television, broadband Internet, and telephony for a relatively cheap price (Heliview Nieuws, 2005). However, the competing companies use different standards to gain exclusive access to the living room. Their strategy is based on the expectation that in the long run exclusive access will be the gold mine of the online economy. As the former owner of one of Europe's biggest independent television production companies, John de Mol, revealed in a television interview in August 2005, providers would invest 1,500 euros for any consumer subscribing to digital television. John de Mol had just launched a new television channel called TALPA on the highly competitive—and according to experts saturated—Dutch television market. TALPA is De Mol's second attempt to conquer Dutch television. His first attempt to market a commercial sports channel failed within only a few months, when too few viewers subscribed

(Maarsen, 1999, pp. 108-123). As opposed to this short-term strategy targeting a niche market, John de Mol's new TALPA enterprise is designed as a family channel. As a business plan it only makes sense when seen as a strategy that anticipates the crucial transformation of the television market in the context of a developing online economy.

At the moment, De Mol's TALPA is broadcasted as free-TV and accessible via all television providers within the Dutch market. It is part of the various analogous or digital cable TV packages and can be received digitally via satellite (CanalDigitaal) or terrestrial (KPN Digitenne). But there is one significant exception: UPC's digital television package does not contain John de Mol's TALPA that owns the exclusive rights for live broadcast and other coverage of the national football competitions. As everywhere in Europe, coverage of national football has been the most attractive programming for decades. De Mol, who up until 2005 held a total of 42% of the Versatel stocks, cooperates closely with Versatel, whereas UPC is next to the regional cable distributors, Versatel's fiercest competitor on the market of digital TV and triple-play packages. In the long run, TALPA will only be accessible for subscribers of exclusive digital TV packages or as pay per view, as De Mol honestly announced in a TV interview on the occasion of TALPA's release. According to his strategy, TALPA's exclusive national football coverage would help TALPA and thus Versatel too, to achieve a dominant position in the Dutch television market. De Mol's enormous investment in his new television network is not just the realization of the multi-millionaire's old dream of owning a television channel, but follows a well-calculated economic strategy aimed at the business model of future interactive television. Television functions as a portal that not only provides exclusively access to the living room, but also one that cashes in on and registers any form of (media) consumption.

CORPORATE INDUSTRY'S REDEFINITION OF INTERACTIVITY

Although the Dutch television market has nationally specific characteristics, the business strategies of the Dutch television industry can be seen as an example of international developments. Television is no longer developed and marketed as a distinct medium, but is part of a media center in the living room that gives users access to many different types of media and other forms of consumption. At the same time, it makes the living room accessible to the industry in terms of consumption patterns and consumption behavior. Both an individual's actual consumption and the data registering these acts of consumption as a personal profile are cashable, and thus form the economic sources for media concerns in the online economy. Whereas the promise of interactive TV and the new interactive media was that the user would gain control of media communication, these developments point to a reconfiguration of the relationship between the industry and the audience that can not be correctly described in terms of "participation" or "empowerment" of the user as active citizen. In his fundamental critique of the new online economy Andrejevic (2003) describes this redefinition of the relationship between industry and users in terms of an increasing exploitation of the users' consumption:

Interactive media are rapidly being assimilated into an economic framework in which participation has nothing at all to do with power sharing. [...] Instead of power sharing, the contemporary deployment of interactivity exploits participation as a form of labor. Consumers generate marketable commodities by submitting to comprehensive monitoring. They are not so much participating, in the progressive sense of collective self-determination, as they are working by submitting to interactive monitoring. The advent of digital interactivity does not challenge the social relations associated with capitalist rationalization, it reinforces them

and expands the scale on which they operate (pp. 196-197, emphasis in original).

Here Andrejevic (2003) describes the result of a well-known process in media history. Following a phase of invention and appropriation by amateurs and activists, economically promising new media technologies will subsequently be incorporated by the established concerns on the market. That which in a first utopian phase of the invention is discussed and appropriated as a means of communication, is turned into a medium of distribution tailored to industry interests (Zielinski, 1999). Regarding the Internet, this process has been referred to as the "normalization of cyberspace" (Resnick, 1998, p. 48).

Looking at the recent and current development of the so-called interactive television that uses the return channel to register user profiles and behavior, the advent of the "prosumer" era should no longer be embraced with enthusiasm. In this media order a user who is logged on and connected whenever he or she consumes media or other services, cannot *choose not to* interact. The media center in the living room, be it a Media Center PC or a set top box, interacts behind the user's back all the time thanks to the return channel. Instead of being the "active prosumer" one should think of the future fettered consumer as the "conducer." The conductor has no option but to collaborate, intentionally or unintentionally, at any given time, being seduced by the ever increasing entertaining value of contents, applications, and services of the converged media center in the living room. The interactive revolution is not just about people—as Pearce (1997) has put it—it's about a reconfiguration of power relations between the industry and the consumer.

Chapter 3.42

Beauty and the Nerd: Ethnographical Analyses in the Japanese Digitalization

Gaby Anne Wildenbos

Utrecht University, The Netherlands

Yuichi Washida

Hakuhodo Inc., and The University of Tokyo, Japan

ABSTRACT

This chapter focuses on the Japanese usage of digital products. Both the consumer and production side are addressed, whereby emphasizing the mobile phone industry on the basis of two consumer groups *otakus* and *kogals*. First, key characteristics of each consumer group are described. Second, social and cultural aspects related to consumption behavior of the *otakus* and *kogals* are examined—that is, collectivism, individualism and *kawaii*ness (cuteness or coolness). This is followed by the production side of digital products in Japan, highlighting two major companies involved in mobile telephony: NTT DoCoMo and Label Mobile, which in their turn, are linked to the consumption cultures of *otaku* and *kogals*.

JAPAN IN RELATION TO THE WEST

Japan plays a key role throughout the world, especially regarding technological innovation. Barclay (2004) surveys the state of contemporary Japanese technology in his report *The Technology of Japan*. In this survey it is apparent that Japanese technological capabilities are on the same level as those of the U.S. Moreover, Japan and the U.S. have a long-lasting relationship regarding this matter, which dates from the postwar period. Together with Russia, the U.S. has been in charge of Japan after World War II until the beginning of the 1950s. With regard to technology it wanted to make sure that Japan would lose its military nature. Evidently, it can be said Japan owes its strong economic position to this occupation period: “They chose to forge a new path, a path that led to postwar Japan being a military-political

dwarf but an economic giant.” (Nakayama, 2001, p. 2). Japan cannot afford to withdraw from the technological relationship with the U.S., since its technological dependence on America is essential. Another way of saying it would be that the technological alliance between both countries is a matter of strategic interest for the U.S., whereas it is one of economic and technological necessity for Japan (Barclay, 2004).

Where does this place other Western countries, like Europe? Although some countries in Europe import technologies from Japan, their relationship on this matter is less strong than the Japanese-American alliance. Nevertheless, Europe’s influence on Japan is noticeable in a more general sense, namely Japan’s movement towards Westernization. Westernization was first offered to Japan in the 16th century through southern European countries. Not only did the Europeans transport an interesting cuisine, more importantly, they brought medical and scientific knowledge. However, at that time the European or Western influence was limited, since the practical needs for their science and technology was small. The second period when Japan came into contact with Westernization was at the beginning of the 20th century. Then they did experience an internal need to adapt to some of the Western modernization (Kasulis, 1995). The Japanese saw Westernization as an import item; they could use modern European and American ideas or products for practical needs related to political, military, and economic necessities. Nowadays, it is even said that “seeing the skyscrapers of Tokyo’s downtown districts, hearing Western rock or classical music even in village coffee shops, or tasting the French cuisine of its fine restaurants, it is easy for one to think of Japan as part of the Western-based family of cultures” (Kasulis, 1995, p. 1).

JAPAN VS. THE WEST

Yet, apart from Westernization, Japan seems to present totally different characteristics as well. Ian Condry (personal interview, March 24, 2005), Professor of Japanese Cultural Studies, says that Japanese see their country as: “Japan is that which is not the West.” This can be related to the period that stands in between the first and second introduction of Westernization, in which the foreign influence was kept to a minimum. After this period of isolation the Japanese realized that in order to “relate and compete with the U.S. and Europe, it is they who would have to adapt.” Within the process of modification it seems as if the Japanese value their modes of behavior insignificant compared to the ones of the West, which shows itself in their ability to copy almost any Western attribute. Idealized versions of the West are presented in Tokyo Disneyland, German Happiness Kingdom, Canadian World in Hokkaido, Garasunosato “the Venice of Japan,” Huis ten Bosch “Dutch Village,” and so on.

Paradoxically, every time Japan tries to catch up with the West, their national identity becomes stronger in this process:

They [Japanese] ended up ahead of the power they were catching up to and redefining their own uniqueness. The Japanese view their entire past in terms of foreign influence and native sentiment. They consciously distinguish what came from China and the West and what is natively Japanese. (Eckstein, 1999, p. 9)

In other words, by means of westernization, Japanese people are in search of what is “Japanese-ness”—A pursuit that is accompanied by the West. Other than Japanese technology, Japanese popular culture and lifestyle also appear to be booming

in Western countries, especially in the U.S. Since it is not exactly clear where this interest comes from, recent writings on the influence of Japan on Western countries seems to be focusing on which specific Japanese characteristics attract the West, which can be exemplified by this chapter.

CONSUMPTION: BEAUTY AND THE NERD

What is most striking about Japanese mobile communication or usage of mobile phones? First of all, mobile phones appear everywhere: on the streets, in the elevators, in the trains, during lunch, during meetings, in back pockets or Louis Vuitton bags of girls (and boys), and so on. This would imply that everywhere mobile phones will be ringing; however the usage of the mobile phones is apparently silent. When people use their phones to communicate with each other they mostly speak quietly. Moreover, the ability to send a text message is frequently used; especially in young girls, they send more text messages than they use their phone to actually make a call. More than 70% of Japanese send e-mail through mobile phones at least once a day (Washida, 2005). Another characteristic of the silent usage differs from the original communication means of a (mobile) phone. The phones are often used as wireless devices to obtain information and entertainment. It is possible to use your phone to listen to original music, to get information about your favorite restaurants, and what is more, discount coupons of that restaurant can be stored in the same device. Recently, even systems are developed to use your mobile phone as a mobile wallet; for example, to pay for your train ticket. Besides a communication tool or content provider, mobile phones are used as a means for self-expression. Although the design of the mobile phones is rather similar, the added straps and decorations speak for themselves.

There are two important consumer cultures surrounding digital products, that is, the otaku

and the kogal culture. These terms may sound familiar yet there exists no detailed analysis of these cultures in relation to digital products. Therefore, I attempt to provide an in-depth study of these cultures in order describe their relevance to the Japanese usage of digitalization whereby focusing on both the production side and the consumption side.

OTAKU: TECHNOLOGIES AS LIFE VALUE

Otaku and kogal do not mean male and female, still their association with gender is evident (Washida, 2005). They are of importance to the Japanese high-tech manufacturers since they offer a double-feedback structure; the small group of otakus give detailed technological feedback, whereas the large cluster of kogals provide information that is useful for a wide-ranging market. In general this means that the manufacturers use otakus to do test marketing when they initially release their products. The information obtained during this test marketing is used to improve products successfully. On the other hand, manufacturers get hold of kogals' curious behaviors regarding digital products. Feedback provided by marketing research helps the manufactures to make their products more attractive and competitive for the general market. Manufacturers even imitate kogals' behavior: They transform the new uses invented by the kogals into their own new commercial services (Washida, 2005).

Originally the term otaku can be translated into "fanboy" or "geek." "It refers to a person who is so involved with a particular kind of fan subculture that he or she comes obsessed with it, or even insane" (Newitz, 1997, p. 1). This is probably the most known reference. Nevertheless, the term can be put into a broader perspective. Nowadays otaku is used in the U.S. to describe the affiliation and love of fans towards a specific category differing from anime to motorcycles.

This goes for Japan as well, however here the term is still mostly associated with males.

The first generation of otakus in Japan are generally referred to as “banana generation” and they are now in the end of their 30s and early 40s. They are today’s managers of small companies, which they run according to the traditional business hierarchy in Japan. The second generation of otakus is called *dankai* junior generation. They are in the end of their 20s or in the beginning of their 30s and the main difference with the former otakus is that they do not support the traditional (business) hierarchy in Japan, because they experienced the difficulties in getting jobs or promotions due to the poor economic situation after the Japanese economic bubble.

Key characteristic to otakus is that they find out about new information and products soon. Therefore, they are “usually the impulse buyers of electronic devices in the very early phase of the development of products, and also abandon them easily if they find the product unsatisfactory” (Washida, 2005, p. 27). This specific consumption behavior is rooted in deep and narrow personal desires. In general, otakus experience trouble in their social life; it is difficult for them to establish a good relationship with the elderly or girls. The label otaku did not come out of the blue, since the Japanese nuance of this word includes the meaning of “you isolated in your house” (Washida, 2005, p. 27). As a solution to dissatisfaction with their social life otakus constitute a technological dream. Successful technological stories, like *Star Wars* movies and the rise of Apple Macintosh or NASA, influence the otakus in such a way that they believe that technology can make everything in life pleasant, whereas reality cannot. Consequently, even some of the otakus detract from society.

One could say that otakus think technological innovations can help them to accomplish things in society; things like status, marriage, and moreover, a better future. Probably they can be best compared with *hackers*, since hackers are also influenced by technological innovations by

which they think they can change society for the better (Levy, 1984).

Some of these ideas are confirmed by information from the contemporary otakus that is obtained at interviews that were conducted with two employees of Hakuhodo, Japan’s second largest advertising agency. These young men are employed in the branding and marketing division of Hakuhodo and appear formally dressed with a willing attitude to cooperate; both seem content with working at a large advertising agency and are adjusted to the corporate style. However, they do want to be noticed as an individual. This shows itself for instance in their clothing, which is formal as well as distinctive from most outfits in the company. In other words, although they may not agree with the traditional business hierarchy, still the otakus choose to change society by accomplishing success within an organization. On the contrary, the hackers attack an organization with the same purpose. Nevertheless, both hackers and otakus possess the aspect of fanaticism. The fandom of anime is typical for otakus and consequently it is at the core of our interview.

Both men knew that the interview would be focusing on otakus and therefore they brought two anime DVDs with them: *Gundam* and *Innocence*, which shows loving anime is characteristic for otakus in their opinion as well. As a result they use these movies as an example to explain more about this topic. Most apparent is their passion for anime along with their enthusiasm to talk about it; they categorize it into different types, explain which people are attracted to what type, and why this is the case. Their interest shines through in the detailed knowledge they have. In a fragmented manner they tell about many different anime examples and almost without pausing they anticipate each other’s information. During this explanation the relation between anime and technology is at the center. *Gundam* and *Innocence*, both masterpieces of anime according to the interviewed otakus, deal with technological subjects since it involves humans next to robots and the interac-

tion between them. The otakus state they go beyond Hollywood movies like *I-Robot*, because the main question in the anime movies is how to identify yourself rather than a battle between humans and robots. Moreover, anime seems to be an inspiration for Hollywood—though it can be questioned how the main theme of these specific Hollywood movies differs from anime movies as robots in anime movies seem less threatening to human beings. They often function as a protection shield or weapons that support humans fighting evil creatures.

This observation may be helpful when contemplating the approach of otakus to technology. As one man said during the interview: “These [anime movies] make you think more about life, and that is why those anime movies can be recognized as masterpieces.” In other words, the anime does not make him question the (threatening) difference between technology and humans; instead technology and humans seem to be familiar with each other in the otaku’s perspective. It must be said this line of thought is mere speculation, because the relationship between technology and otakus is a personal matter which makes it impossible to expect a straight answer while questioning them on this topic. Still, there is a noticeable observation which has less to do with the explanation of anime from the otakus themselves. That is to say, since the otakus alternate in talking during the interview, one otaku is drawing anime pictures in his notebook to kill time while being silent. All the more this indicates their unconscious familiarity and passion towards the animation style.

The passion for anime does not only express the fandom associated with otakus, it also concerns their values in life. When asking the otakus what is most important to them in daily life they fall silent. After some thinking they answer that, of course, working and friendships are essential. Nonetheless, of more importance is thinking about life, looking deeper, and being moved; the effects they experienced while watching anime movies. Consequently, they have ideas about how

life and technology or digitalization is involved with each other. This might sound paradoxical regarding the previous statement that the otakus have no answer on the subject of the relationship between technology and themselves—A paradox that can be justified. In Japan it is not custom to share personal information with unfamiliar persons, which makes it difficult to obtain information about the otakus themselves in relation to technology and digitalization. On the other hand, it is less complicated to talk about this matter in general and therefore some interesting insights on this matter are provided during the interview.

When discussing the concept of digitalization with the otakus the technological or digital dream comes to mind. Especially in their childhood they used to have specific thoughts about how technology and digitalization would be at hand in the future. One of the men explained that at school there was a special name for the child who had many of these futuristic ideas: doctor. Children, like a doctor, used to have dreams about a technological world that were very physical, such as flying cars. These dreams turned out to be different in the perspective of the interviewee. He thinks digitalization is humanistic; it can make a package of life. For instance, when using digital systems and products a person can make a “blog” to let someone in on his own thoughts or share files adjusted to personal taste. These insights are interesting since they confirm the presence of a technological dream in the minds of otakus. Yet, the current otaku perspective on technology can be best seen in the final words during the interview. At the question why one of the men understood technology, his colleague took the privilege to answer: “Because he loves it! He just bought a new gadget, just because it is cool!”

KOGAL: COLLECTIVISM VS. INDIVIDUALISM?

Kogal literally means “girlish female.” “They are very active young girls, who love shopping,

chatting, and being fashionable” (Washida, 2005, p. 27). Whereas the kogals used to be associated with the Japanese girls dressed up in school uniforms on purpose, nowadays their fashion is quite different and varied.¹ Another important characteristic is that “they are surprisingly good inventors of new ways of using electronic devices” (Washida, 2005, p. 27). These innovations are an expression of the heavy use of electronic devices. For instance, through the 24-hour use of mobile phones kogals thought of adding music data to phones to change the traditional tone into a music ring tone; a popular feature nowadays.

Kogals can also be divided into different generations. The first generation of kogals is now 30-34 years old. These women, however, used to be kogals in their teenage years and in their early 20s. At that time, they suffered from the economic depression and had to develop a new lifestyle. The second generation consists of today’s teenagers and can generally be said to be in their early 20s. They are used to the shifting economy in Japan, which causes them to think they have to be unique in order to succeed in making a living. They use new media and technologies to experiment with different lifestyles and to promote their uniqueness.

Before discussing the importance of the kogals’ use of mobile phones, it is necessary to explain some aspects of the Japanese culture to understand the kogals’ consumption behavior, that is, collectivism and individualism in Japan. The concepts of collectivism and individualism have been widely researched in the fields of psychology as well as sociology in order to explain cultural differences. Initially, the difference between collectivism and individualism was viewed as a contrast. Psychologists Strunk and Chang (1999) write:

Collectivism promotes a sense of the self as interdependent. Collectivistic people are motivated by the norms and duties of their collectives, give priority to the goals of the collectives and emphasize their connectedness to members of the

collectives. In contrast, individualism promotes a sense of the self as independent. Individualistic people are motivated by their own desires, give priority to their personal goals and use reason to analyze the advantages and disadvantages of associating with others. (p. 2)

Since the beginning of the 1990s, scholars have sought to revise the contrast between the terms. Niles (1998) explains this by describing the writings of Harry Triandis, a well-known professor in psychology. Triandis (1995) states that most cultures include a mixture of collectivism and individualism. Moreover, the dimensions became characterized by rather specific attributes of which the ones most important to the situation of the kogals are described. The difference in defining oneself as part of a group rather than focusing on a concept of the self that is independent of the group stays the same. More significant is the contrast in commitment to a group or relationships. The social behavior of collectivists tends to be driven by duty and obligations, whereas among individualists social behavior relates to attitudes and other internal processes. Furthermore, relationships are of great importance among collectivists, even when it requires personal sacrifice. Individualists tend to let go of relationships when they involve too many personal costs (Niles, 1998).

Perspectives on collectivism and individualism in Japan are changing, due to Western influences such as globalization. In particular the younger generation is less keen on the traditional values including collectivism. This does not mean that they do not hold on to these values, but they are open to other perspectives or lifestyles as well. In other words, nowadays the contradiction between collectivism and individualism is not as straightforward as was once thought. Relating to the statement of Triandis, a mixture of both dimensions can be found in Japan. Indeed so, this is a complicated mixture, since either collectivism or individualism takes lead depending on a particular context.

Beauty and the Nerd

Considering now kogals, it seems difficult for these young girls to cope with what direction in life to choose. Or, how can you decide on a way of life if your options are not clear? As a result, the kogals wish not to choose at all, which can be associated with mobile phone usage. The mobile phones of the girls that are interviewed are mostly used for sending e-mails; this includes keeping in contact with close friends as well as making new friends, which is an important difference as will be shown later. The girls divide their friends in categories, based on which school they attended. In other words, they talk about friends from elementary school, junior high school, and high school. Moreover, they value high school friendships as less close than primary school and junior high school friends; the latter seems to be valued as being closest to the interviewed kogals, which can be related to their use of mobile phones.

When kogals are asked when they got their first mobile phone, they said that it was during the period they attended high school. Then they started to use their mobile phone to communicate with friends rather than talking to them face-to-face which is referred to by the terms *pre-mobile-phone-stage-of-life* and *mobile-phone-stage-of-life*. Although perhaps slightly exaggerated and simplified, owning a mobile phone is important in the process of making new friends. The first thing to do is the exchanging of e-mail addresses, preferably mobile addresses as it makes an instant reply possible. Getting an immediate response implicates you are going to become friends. On the other hand, not receiving a response at once means you most likely are not going to be friends. The use of mobile e-mail gives the young girls the opportunity to have more control over who they include as their friends. Therefore, they can use it as a tool to form groups as well.

Also, it allows them to manage the distance or closeness of communication within these groups, which gives the girls a chance to keep in touch with many friends and to belong to many groups, while simultaneously not becoming a true part as

the communication device allows them to have little intimacy. Put aptly by Leopoldina Fortunati in *Towards a Sociological Theory of the Mobile Phone*:

Cell phones can even better be used to shield oneself from wider surroundings by escaping into the narrower realm of highly familiar, predictable and self-controlled social relationships with close kin or friends. (Geser, 2004, p. 10)

Although the Japanese girls do make new friends through their mobile phones, their families and close friends are those they are most intimate with. The information derived from the interviewees confirm this by stating that they value friendship most with friends with whom they communicate face-to-face more often than friendships with friends from the mobile-phone-stage-of-life.

Another example that may indicate that kogals face a hard time making decisions can be illustrated by the mobile phone devices themselves and their ability to provide entertainment and information. Although the design of mobile phones is rather similar, the decoration of the phones is not. For example, each phone has different straps that can be a means of self-expression or individualism. On the other hand, the decoration often includes many pictures of friends as well, which shows the girls belonging to a group. The phones of the girls interviewed are a good example as well: They are made fancy with straps and key cords, most likely to express the girls' own vision on *kawaii*.

Then, what does *kawaii* mean? Moreover, why is it important within the description of the kogals consumption behavior? It is difficult to translate what this word exactly means. "Cute" is one translation; "adorable" might also be used. Japanese people use the word *kawaii* to describe the value of wishing to own the described object. In other words, where Japanese people use *kawaii*, Western people would probably use the word

“cool.”¹ In the interviews it became apparent that the girls choose their products on kawaii-ness. A mobile phone is kawaii for communication and e-mail. However, it is less kawaii to use it for listening to music. Instead, an iPod is most kawaii for listening to music nowadays.

Choosing products on kawaii-ness is most likely related to the role models of the girls. In general, they do not have a straight answer to who their role model might be; they describe powerful women who are beautiful, successful, and independent. Moreover, they have a strong focus on study and career for their futures and are eager to put effort into achieving this image of the powerful woman. This causes them to appear very strong and well balanced; even the conductors of the interviews are impressed by the seriousness and confidence of the girls. Nevertheless, from in-depth conversations with researchers from Hakuhodo Institute of Life and Learning (HILL) it becomes clear that this seriousness can be easily mistaken. It is rather loneliness that causes the girls to appear that way.

The description of the kogals' usage of mobile phones tells us about the combination of silent communication and the longing for entertainment and information through mobile phones—a combination causing the girls feeling pressured. Contemplating this and the framework of collectivism and individualism, it seems plausible that this pressure can be said to derive from the inability to choose a lifestyle. On the one hand, there is the longing to become part of a group which brings along obligations and personal sacrifices. On the other hand, they see new opportunities to let go of certain relationships, which involves both courage and anxiety since this choice is rather unfamiliar to these Japanese girls. A feeling of loneliness is the result of these pressures.

Consequently, the mobile phone becomes more than just a device; it becomes an indispensable friend. All the girls say that they “freak” if they do not have their phone near or if the network is not working properly. In other words, the mobile

phone becomes an item to fill the lonely gap since it is capable of fulfilling both desires of the kogals: belonging to a group as well as being an individual. Moreover, consumption of other (digital) products based on kawaii-ness can conceal their loneliness as it contributes to the image of being a powerful woman.

PRODUCTION: NTT DOCOMO AND LABEL MOBILE

Today the penetration rate of the mobile phone among Japanese consumers has reached approximately 70%. The usage frequency of mobile phones in daily life has surpassed that of fixed-line phones. The biggest market share is held by NTT DoCoMo, who has approximately 56% of the market share. The key factor for success of NTT DoCoMo is its aggressive strategy to expand data communication usage, for example, text messaging and Web browsing via mobile phone, based on the popular i-mode service that launched in 1998, while competitors focused on voice communication services and pricing strategies. For the ordinary Japanese, the mobile phone has become the primary everyday life communication tool (both voice and data) alike, for example, the situation of a cell phone in the U.S.

Another important aspect of the Japanese mobile phone industry is the emergence of other mobile-phone-related markets such as the ring tone business. In 2004, the total market size of the Japanese ring tone business—including the latest digital music distribution business via mobile phone—had reached approximately \$1 billion per year, while that of traditional music products such as CDs, is approximately \$4 billion indicating that, in Japan, the mobile phone industry has become a “hub” for various other digitalized industries.

The influence of production on the use of (digital) products can be divided into three key elements: organization structure among the pro-

ducers, motivation, and the actual production itself. Information deriving from several interviews with Japanese manufacturers illustrates these three aspects. Two of these interviews are most relevant for this research. The first is a meeting with a marketing manager from NTT DoCoMo. The second is a conversation with a marketing manager at Label Mobile, a company that offers music ring tones, called *chaku-uta*'s. Both will be discussed in relation to the three aspects of the production side.

It has been said that manufacturers imitate kogals' behavior regarding digital products. NTT DoCoMo is an example of such a manufacturer—kogals can be said to be responsible for using mobile devices for written communication. Initially, the girls used pagers to exchange information with each other silently. NTT DoCoMo noticed the kogals' use of pagers and applied it in their development of i-mode; they developed the idea of developing an e-mailing service together with their subscriptions targeted at young people. One of the founders of i-mode says:

At first, a lot of people didn't understand our decision. But I knew (...) young people had strong communication needs. (...) Plus, they were attracted to new things; they liked innovation. I felt that if we could capture this group of people, everyone else would follow their lead. (Moon, 2002, p. 3)

The reason why NTT DoCoMo is able to pick up on this information from kogals, and create services like i-mode, is related to their organizational structure.² During the interview the manager at NTT DoCoMo made clear that they invest a lot of money in research that can help to develop and improve their products along with their services. Sometimes this research is put out to contract to survey companies, for instance when mapping the future market. Nevertheless, most research is done by NTT DoCoMo's significant research and development division.

Label Mobile is another company that learned from kogals as well. They copied the invention of adding music ring tones to mobile phones. Label Mobile was founded by record companies; these included almost all major record companies in Japan. Its mission is to make a structure for distribution for music content. In other words, the record companies use Label Mobile to sell their music to consumers, in which Label Mobile adjusts the systems and the Web sites properly to provide and distribute the content.

During the development of Label Mobile, the record companies have put shared effort into making it a success and they still have numerous meetings to maintain its popularity. Moreover, the relationship of Label Mobile with the handset makers and providers of mobile phones is beneficial, since the latter have influence in the development of *chaku-uta*'s. In other words, the organizational structure of this company is trustworthy and stable as well as unique, motivated by its employees that besides making money, have a love for music, which they want to share with their clients. As a result, the actual production of *chaku-uta*'s is fast, adequately targeted at consumers, and has been profitable for a few years now.

The examples of NTT DoCoMo and Label Mobile can then be linked to the otaku and kogal cultures. This is best explained by the example of NTT DoCoMo. Here, the motivation to produce (digital) devices and services is highly related to a belief in the technological dream. To illustrate this, a recent press release article from NTT DoCoMo states: "Every employee of the NTT DoCoMo Group will create MAGIC by following our DREAM" (1999, <http://www.nttdocomo.co.jp/>). This is result of the influence of the otaku employees working at large companies such as NTT DoCoMo. Otakus are motivated to create technological innovations as they believe these innovations will benefit and enrich their lives. Nevertheless, (digital) technology can not survive without the social and cultural aspects of consumption surrounding it, shown by the influence of ko-

gals' consumption behavior. The examples of NTT DoCoMo and Label Mobile explain how innovative behavior of kogals impact on the development of new products, which—indirectly—relates to the kogals' emotional consumption behavior; kogals invent new usages of digital products by using these products extensively which, in turn, helps them to experiment with different lifestyles.

CONCLUSION

This chapter has investigated Japanese consumption behavior of (digital) technological products by providing an overview of consumer groups: otaku and kogal, followed by the production side of technology in relation to these consumer groups. In so doing, it hoped to provide accurate information on the Japanese consumption and production of (digital) technologies in order to widen the Western perspective on Japanese digitalization. This study also meant to trigger questions about which aspects of what characteristics attract the West. How do consumer groups in the West correspond to Japanese consumers? How are economical issues related to “emotional” consumption behavior on a global scale? Where is the attraction of Japanese technology and popular culture heading for? Will Japan become of growing importance in these matters or is the interest of the West in Japan just a fad? What gives the West the idea that Japan is “awesome”? Having raised more questions than answers, further investigation is needed to build a theoretical and empirical framework on the relations between West and East and digitization issues.

ACKNOWLEDGMENT

ENDNOTES

¹ Some scholars and students at Harvard University named these phenomena *cutism* and explored how influential it has been to current Japanese society at the *Cutism Conference in 2004* (Harvard Project for Asian and International Relations, and the Reischauer Institute of Japanese Studies at Harvard University, Cutism, Harvard Hall 201 in Harvard Yard, 2004). They discussed that kogal generation is significantly important not only when we think about Japanese youth culture such as girl's comics and female celebrities, but also Japanese marketing trends and transnational culture diffusion among East Asian countries. The exact definition of cutism was not given at the conference. However, they shared the certain significance of the kogal phenomena, using this keyword, to identify current characteristics of Japanese society.

² The organization structure is intertwined with the business goals of the company. The Web site of NTT DoCoMo explains it is NTT DoCoMo's intention to stimulate "further growth of the mobile communications market via mobile multimedia, and thus improving the quality of life and revitalizing industry." The opportunity for NTT DoCoMo to achieve this goal is provided by investments in research and development. These major investments are also used to show recent achievements of NTT DoCoMo regarding technological innovations. For instance, the Web site of NTT DoCoMo contains a short movie of a future vision, titled *Vision 2010*. In this movie the company presents their "insight into a world enriched by wireless communications services in

the near future.” Nowadays NTT DoCoMo presents their actual production as a step forward towards that future. Nevertheless, the recently released services which are related to videophones and e-commerce rather appear to be entertainment or convenient, instead of resembling the future as portrayed in *Vision 2010*. For example, according to

NTT DoCoMo the main advantage of video phones is that people can see each other anytime and anywhere, regardless of the distance between them. In contrast, at this time the actual service of video phoning offers the ability to create an avatar in case you do not want to be seen.

Chapter 3.43

Digital Imaging Trek: A Practical Model for Managing the Demand of the Digitally Enabled Traveller

Stephen C. Andrade

Johnson & Wales University, USA

Hilary Mason

Johnson & Wales University, USA

ABSTRACT

This chapter introduces the concept and activities of the digitally enabled tourist and the impact such as tourist has on the travel and tourism industry. It summarizes the existing and emerging technical environments that encourage the use of hand held digital recording devices and personal Internet communications. Additionally, it looks at ways tourists publish and exhibit digital visual and written artifacts of their travel experience. The chapter introduces general types of digital communication infrastructure to be considered by the industry to create an experience to support this type of tourism. The authors hope that further understanding of the digitally enabled tourist will inform travel professionals to better facilitate commerce and practice in the industry.

INTRODUCTION

Technology has had a great influence on the tourism and travel industry. In recent years digital communication platforms and technologies have evolved and become accessible to a wide mainstream audience of tourists and travelers. Organizations engaging in travel and tourism commerce need to understand this wave of innovative behavior among their customers. From cell phones to high speed wireless Internet connection to the variety of creative ways customers have applied digital technologies—the travel and tourism industry is being widely affected by these emerging trends in information and communications technologies (ICT). Is the digitally enabled traveler the wave of the future? How will companies and services shift business models to optimize the experience of people with digital devices? Are there commercial opportunities

embedded in these? What does a traveler need to know to keep current with changing technologies? It is critical that services providers and travelers alike stay informed, because one thing is certain, technological innovation and change will be a constant companion for the travel and tourism industry.

This chapter provides insight into technology trends that will be helpful to the practitioner, student, educator and the tourist-travelers themselves. Being prepared to meet the new demands of customers will provide rewarding experiences for parties on all sides of the tourism equation.

BACKGROUND

Since the wide spread use of the telephone in the 1920s, information and communications technologies (ICT) have had a great influence on the industry of tourism. In the 1990s, the wide spread use of powerful desktop computers, enterprise wide systems, and the World Wide Web (WWW) continued to transform the way business was conducted in all facets of the travel and tourism. While ICTs have had a dramatic impact on the mechanics of tourism business practices, the virtual explosion of new inexpensive digital communication technologies is transforming the experience of tourism from the traveler's point of view.

The new generation of hand held mobile technologies, the expansion of wireless (WiFi) networks and the surge in digitally hosted social interchange services present new opportunities for engaging all sectors of the tourism industry. This new generation of technologies also presents new challenges to the industry to structure services with the digital service users in mind.

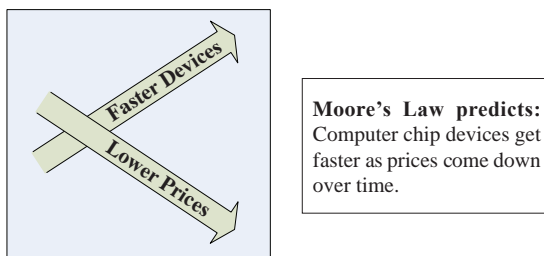

New services that provide online collaborative and social interaction through the World Wide Web now shape and influence vast communities of millions of online customers. Traveler-centered mobile technologies are increasingly used

for many activities embedded in the tourist and traveler experience. This chapter will explore the model of the digital imaging trek and the digitally enabled traveler as a way to structure experiences to satisfy the demand of the technically savvy traveler in a world of advancing mobile technologies and online services. It also will provide basic technical background about the devices and infrastructure that drives these technological innovations.

Understanding the use of advanced hand held devices from the traveler's point of view is becoming more critical to tourism industry providers. Both new and veteran professionals in the tourism industry need to think about how these technologies influence the customers' choices, activities and ultimately their economic decisions about tourism. Customers have eagerly adopted the cheap and easy to use digital technologies. Tourism professionals need to understand the role mobile digital technologies play in the expanding global tourism field. For customers, mobile digital technologies are helping to shape the experience of tourism from initial research of a destination, through the reservation process to the final visual record of the experience.

Mobile digital technologies include a wide array of products that are inexpensive and easy to use. When mobile digital technologies are used to shape a tourist's experience they become powerful digital communication tools reaching out to an infinite audience of like-minded users on the World Wide Web. New products in cellular telephony, visual still imaging, motion and sound recording, wireless digital connections to the World Wide Web and the services on the World Wide Web, all converge to offer a digital environment unlike any before it. The combinations of these technologies are dynamic, unique and ever expanding. These digital technologies are in a constant state of enhancement—services become faster, devices become more powerful and feature-rich, and prices come down. This evolution of technology is known as "Moore's

Figure 1. Moore's Law

Moore's Law predicts:
Computer chip devices get faster as prices come down over time.

Law” (see Figure 1). Just what is Moore's Law and why is it important?

Moore's Law is the observation made in 1965 by Gordon Moore, co-founder of Intel. In it he states that the number of transistors per square inch on integrated circuits had doubled every year since the integrated circuit was invented. Moore predicted that this trend would continue for the foreseeable future. In subsequent years, the pace slowed down a bit, but data density has doubled approximately every 18 months, and this is the current definition of Moore's Law, which Moore himself has blessed. Most experts, including Moore himself, expect Moore's Law to hold for at least another two decades. (<http://www.webopedia.com>)

Consider what it means to double the capacity of digital technologies every 12-18 months. Few if any physical systems or resources in the world of tourism have this capacity and potential. Moore's Law not only means faster and better technology, it also enables dynamic changes in the way people use technology. In fact, it is difficult to predict exactly how consumers will respond to innovative devices and new digital gadgets. Tourism professionals need to understand this dynamic process and prepare for the digitally enabled traveler.

Who is the Digitally Enabled Traveler?

The digitally enabled traveler is a new breed of traveler equipped with devices, connectivity, skill

and motivation to create and access real-time, online, rich media knowledge bases of travel and tourism experience.

The digitally enabled traveler is motivated by the same principles as the conventional tourist. People involved in tourism are visiting locations for leisure, recreation, sight seeing, vacation and other activities. The global travel industry hosts not only tourists, but professional travelers on professional missions as well. People travel for business, cultural, scientific, educational, governmental and other kinds of activities in the world of global tourism. Most forecasts for travel of all types indicate a steady rise of 4% a year over the next decade. Even a causal observation in any busy transportation hub, such as an airport or train station will reveal how critical mobile technologies and wireless connections are to both the recreational and professional traveler alike.

People who travel with digital devices are highly motivated to stay connected to business and social networks. Minimally, most travelers today require basic voice and Internet connectivity service to maintain contact with families and tourism providers. Travelers want to stay in touch with the sources of lodging, travel bookings, reservations and other critical contacts during their trip. Some travelers thrive on constant digital connection to not only monitor progress in plans, but also stay in touch with their virtual communities.

Beyond the basic business function and family contact, travelers are using a wide array of digital devices to capture, record, edit, and exhibit the

experience of tourism and travel. The days of a single film camera used in a casual manner to take pictures of highlights are over. As the tourism industry embraces near-endless global locations for travel destinations, travelers are highly motivated to capture and share their experience with digital recording and connection devices. Why? In spite of all the technical gadgetry, it is still human nature to want to discover and share a new experience. This mode of communication has been going on for generations, only now, it is played out on a global digital stage.

Digital still and video cameras along with powerful laptops and hand held devices have opened new territory for the digitally enabled traveler. These new digital technologies also offer new service-business opportunities for the tourism industry.

Today's digitally enabled traveler is highly motivated to stay in-touch with a virtual community of people through services on the Internet. With millions of people subscribing to World Wide Web sites that host virtual communities the trend of communicating in digital interactive space has been set. Social networking through digital services is widely accepted as common practice. This segment of the technology service industry is rapidly growing as the each successive generation matures into an economic demographic that can afford the expense of travel and tourism. Millions of people are now involved in what is called "social networking." As counter intuitive as it may seem, the way to establish human bonds is through digital technologies. Numerous Web sites have been established as sources for self-published digital image galleries, digital video galleries, audio files, user profiles, and blogs.

Social Networking: The Latest Trend

Social networking systems are an emerging technology that is beginning to have a significant influence on how people communicate. Social networking systems are Web sites that offer a

collaborative or shared virtual experience, generally around a particular theme or human interest. Visitors to the site can connect with each other through shared attributes, such as interests, activities, or geographic location.

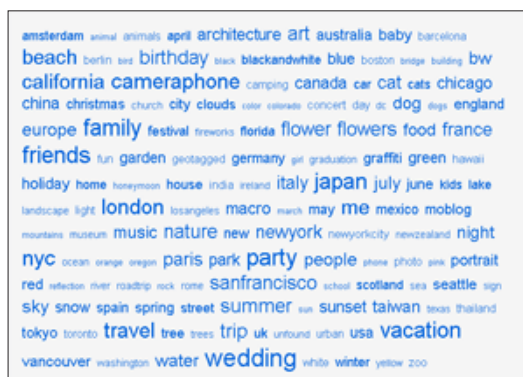

Some social networking sites, such as Facebook (<http://www.facebook.com>), are designed simply to facilitate the process of making social connections. Other sites, such as Delicious (<http://del.icio.us>), offer a core application, such as allowing users to share Web site bookmarks. An essential quality of a social networking site is that it must allow users to share information via a network of nodes (users) and connections (users with similarities). Users also can easily identify other users with similar interests.

Most social network sites utilize the community to develop an ontology via tagging. Tagging is a simple method of allowing users to attach key words to a piece of data. Users searching for those keywords can then locate a wide variety of matching media. This works on the assumption that humans will generally choose similar terms to describe similar items. Most of the time, the assumptions works well, and people network with other people's experiences.

Tags are often represented in a "tag cloud" (see Figure 2). Larger text indicates a more popular tag. Other visualizations include history, topics, and information origin. This visual model of popularity makes these sites friendly to even the most non-technical visitors.

Social networking sites are beginning to have a large impact in business. Consider the common professional activity of attending industry-specific conferences. Attendees meet for seminars, meals, and networking. Several attendees may take photos of this event. They can upload their photos to a photo networking site such as Flickr (<http://www.flickr.com>), and tag them with the name of the conference. Anyone searching for the conference would be able to find a complete photographic record of the event.

Figure 2. Sample tag cloud

Social networking has even made an impact in tourism. “Where Are You Now?” (<http://www.wayn.com>) is a site that connects travelers, for logging trips and comparing destinations, finding travel buddies, and making friends with like-minded people. WAYN even helps with off-line networking by allowing users to send SMS (short text messages) to each other’s cell phones.

Social networking presents an innovative solution to the problem of information overload. By organizing information collaboratively, useful content filters toward the people who would most like it, while useless content is dropped altogether. Finally, it is a core technology with implications that will touch all disciplines in the years to come.

A blog, or “Web log” for short, is a collection of posts around a theme or topic collected on a Web site. At the time of this writing, blog search firm Technorati (<http://www.technorati.com/>) was tracking 25.4 million blogs with 1.9 billion links.

A blog is a collection of time-stamped journal entries on any possible topic. Blogs cover every subject from politics to education to technology to one particular person’s social life. Some blogs are only of interest to a few people while others have thousands of readers daily.

The Pew Internet Survey estimates that about 11%, or 50 million people, read blogs. (http://www.pewInternet.org/PPF/r/113/report_display.asp).

Eighty percent of people contacted by the Business Blog Consulting Web site, a site focused on the growing use of blogs in business, believe that blogs are not a fad. Traditional media outlets (such as the BBC) have begun to add blogs to their media offerings.

The digitally enabled traveler is motivated to share experience in an immediate, visual and highly subjective manner. For a digitally enabled traveler, the personal reaction to a destination like a museum, a historic site, or a travel adventure is typically recorded as a highly personalized written blog. The digitally enabled traveler will supplement the blog with a gallery of digital images. The gallery will then be linked to a short video, compressed for Web hosting, of the activity at the site. With a reasonably fast wireless Internet connection or access to a local Internet café, this material can be posted within minutes of the experience, or in some cases, in near real time. Digitally enabled travelers with the proper digital gear and Internet connection can produce a personalized digital stream of video, images and words. Often defined as “rich” media, the mix of all these files—sound, still, motion, text—are a critical and creative connection to a virtual world for the digitally enabled traveler. For the digitally enabled traveler, contact with the social network on the Web is critical. This technical and

artistic practice is easy to achieve and among the members of the digital generation, a routine and necessary activity.

Table 1 offers a way to understand the devices, practices, skills, and motivations of a digitally enabled traveler.

Professionals in travel and tourism should understand that the focus of these technologies is the individual consumer, not necessarily the business enterprise.

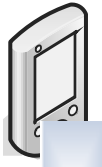

Digital Imaging Trek: A Model for the Tourism Industry

The digitally enabled traveler is equipped with an endless array of digital products designed to cap-

ture and record the tourism experience. Through these devices travelers are highly motivated to stay connected to virtual communities online. Patrons of tourism will use their technology skills to create visual and rich media collateral—high quality digital media artifacts. There are countless Web-based outlets to connect the traveler’s experience and collateral to an eager virtual community and social interaction network. As digitally enabled tourism becomes an expectation among patrons and customers, tourism professionals need to understand and shape usage models.

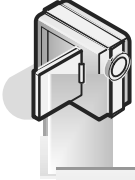

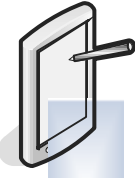

The model of the digital imaging trek proposes information and technical architectures to capture travel experience, create a virtual record of tourism, and meet the demands of the digitally enabled traveler.

Table 1. Understanding the devices, practices, skills, and motivations of the digitally enabled traveler

Device	Connectivity	Skill	Motivation
<p>Cellular phone with low resolution camera function</p> 	<p>Commercial wireless network, satellite connection in remote areas</p> <p>Multifunction chips available for international functionality</p> <p>Limited WWW access if available</p>	<p>Easy to use, entry level skill</p>	<ul style="list-style-type: none"> • Basic voice communications; real time voice conversations with social and business network; voice mail. • Basic e-mail if function available • Basic organizational information: names, addresses, telephone, fax • Basic low resolution images, very limited storage • Limited to real time voice based research and basic business functions such as reservations, bookings, and so on • Limited keyboarding if necessary

Table 1. (cont.)

<p>Battery power laptop with wireless connectivity</p> 	<p>Commercial or free wireless, Internet café, locally provided high speed network connection</p> <p>Satellite connection in remote areas</p> <p>Wireless chip functional in international standards</p> <p>Access to rich sources of information on WWW</p>	<p>Moderate to advanced, able to detect wireless signal; may require some basic problem-solving</p> <p>Powerful image editing software applications</p>	<ul style="list-style-type: none"> • Voice over IP if function available • E-mail, online social networking, post digital images and video • Advanced organization of rich information on device's data sources • Edits and stores high resolution still images and digital video with sound • Likely to use laptop for extensive research and business functions such as reservations, bookings, and so on • Uses laptop as critical extension of travel experience; connectivity to online, social network a priority
<p>Digital still camera</p> 	<p>Direct connect to laptop or other device with Firewire.</p> <p>Interconnect to Web through computer device</p>	<p>Easy to expert level skill</p>	<ul style="list-style-type: none"> • Record images • Record technical file type and related information • Field edit • Organize image files • May be critical to business communications • Critical to social network and social communications
<p>Digital video camera</p> 	<p>Direct connect to laptop or other devices with Firewire</p>	<p>Easy to expert level skill</p>	<ul style="list-style-type: none"> • Record motion and sound • Record technical file type and related information • Field edit: shoot to edit • May be critical to business communications • Critical to social network and social communications
<p>Computing tablet</p> 	<p>Direct connect to laptop or other devices with Firewire</p> <p>Essentially same connectivity as laptop, yet these devices are relatively new to the marketplace and not widely adopted by travelers</p>	<p>Moderate to advanced, able to detect wireless signal; may require some basic problem-solving</p> <p>Application base still developing</p>	<ul style="list-style-type: none"> • Typically less functional than laptop • Consumers are urged to match intended use to tablet functionality

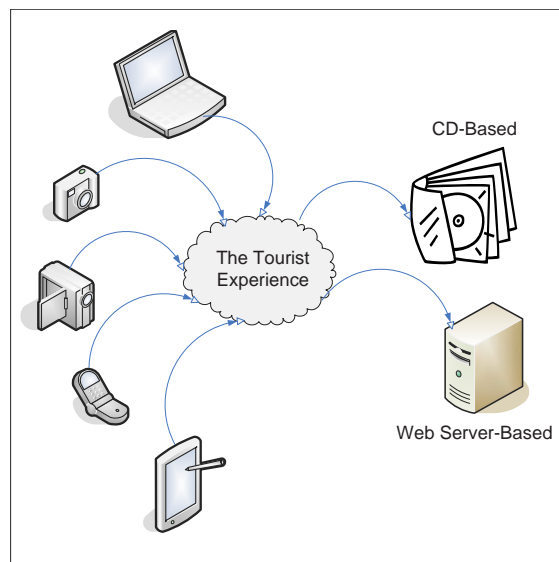

From early times of travel, the notion of a “trek” has long been regarded as a journey of self-exploration for the traveler. Many tourists and travelers today are seeking a heightened experience as part of their tourism through digital communication technologies. Putting practice in to models, especially the practice of the digital imaging trek, is a way to understand the processes and practices of the digitally enabled traveler (See Figure 3). Using all the digital tools available, a digital trekker will produce files from a wide range of sources and self-publish material in two methods; saved as CD-based files (or some other permanent memory such as DVD or portable USB Flash Memory) or published on the World Wide Web.

A typical day on digital imaging trek starts with a destination selection. Digitally enabled travelers will turn to the Internet to locate and decide upon a location. Whether it is a museum, a regional historic location or a cultural performance, the digitally enabled traveler will seek all types of information from Web site based services

to make plans. When made available on a Web based system, transportation schedules, phone numbers, hours of operations, special information about exhibits, costs, and other related information about the region, are always instantly available to the traveler. Web based systems allow the digitally enabled traveler to acquire information regardless of time and in a preferred language.

In digital imaging trek model, the traveler is focused on acquisition of digital still and video images that record the daily experience of the trip. In any environment—built or natural—the visitor will always encounter new scenes that are novel, exciting, and educational and from the perspective of the traveler, representative of the tourism experience. With cheap recording memory in the form of Flash Memory, a digitally enabled traveler has near infinite storage space to capture images. Digitally enabled travelers also can edit on the fly. The advantage of digital imaging over traditional film imaging is in the use of storage and field editing. If an image is not worth keeping, it can be immediately erased. Images worth keeping are filed and stored until needed later.

Figure 3. The general digital imaging trek model embraces technology communication devices and self publishing

Digital Imaging Trek

As the day progresses on the digital imaging trek, travelers will want to spend time reviewing images, editing images, and corresponding to the social network with e-mail, uploads and blogs. Editing and organizing images are tasks that most travelers will conduct when time is available. Typically image editing is done on a portable laptop computer. Many people prefer to travel with laptop computers as they are light weight, highly functional, and a repository of software tools and information necessary to conduct digital imaging while traveling. (For the business traveler, a laptop is practically required gear for the trip.) Editing image files requires some time and concentration and will likely occur during a break in activities. When editing still images with a popular image editing software such as Adobe Photoshop, travelers will crop, color-correct, merge and manipulate images.

Similarly, digital video footage also will be edited. Travelers on a digital imaging trek will likely download and edit video footage with commonly available video editing software such as Adobe Premiere or Apple's iMovie and Final

Cut Pro. Still image editing software and video editing software is widely available. With basic skill and proficiency, digital travelers can achieve remarkably high quality results. For travelers on a digital imaging trek, it is the primary focus of experience and a rewarding achievement to acquire these images.

The ease of use of digital imaging equipment—still cameras, video cameras and laptops, promotes the phenomena of “hyper-imaging”—taking thousands of images to sort through later. Travelers who are serious about digital imaging are continuously shooting images throughout the day and night. The result of hyper-imaging is an overabundance of images and footage that must be sorted and organized. Powerful laptop computers with optimized internal and external storage are perfect for this task. Sorting and organizing images and footage is typically done to suit the desires of the traveler on a digital imaging trek. Images are categorized by group or class and notated with keywords for access at a later time. Various gallery and filing software makes the task of organizing relatively easy.

Figure 4. Students and faculty from Johnson & Wales University on a digital imaging trek to Paris; wireless digital connection to the Internet is abundant in urban environments; checking e-mail and editing images in a street side café is now a common tourist experience

A Short Primer on Digital Photography

Unlike film cameras, which store images on film, digital cameras capture images via electric sensors and store those images on reusable solid-state memory.

The first digital cameras targeted toward consumers were released in the early 1990s. Since then the digital camera revolution has taken off, and there are hundreds of models available. Competition has remained fierce and manufacturers are producing digital cameras with limitless capacity. Just 15 years after the introduction of the first consumer digital cameras, current models are taking pictures that are as high or higher quality than film cameras. Digital cameras take some getting used to, but tourists and travelers who taking digital imaging seriously will find numerous camera choices in the marketplace.

Digital cameras fall into three general categories: consumer, prosumer, and professional. Consumer cameras generally have a single, non-removable lens that mimics a standard 35mm film lens. However, manufacturers now produce consumer level models with nearly every feature of a traditional Single-Lens Reflex or SLR camera.

The term prosumer is a blend of “professional” and “consumer” and refers to consumers who demand more than the standard technology available while being unable to afford professional equipment. In the digital camera market, the prosumer devices are Single-Lens Reflex, or SLR, models, and are falling below the \$1000 price point. Prosumers tend to be technologically savvy and more tolerant of quirks and bugs in new products.

Many professional photographers are moving entirely to digital photography, enticed by the low cost of shots, ease of printing, high resolutions, and ability to edit photos easily with software such as Adobe Photoshop. Professional cameras generally accept the same standard lenses as film cameras and store photos in RAW format, which allows for greater flexibility in editing. The RAW format can be thought of as a digital negative.

The editing and sorting activity is often a precursor activity to the act of e-mail, blogging and posting images on a Web site to interact with digitally connected social network. Travelers with a laptop and access to the Internet will use the online connection to communicate frequently and for sustained periods of time—sometimes hours at a time. If connectivity is available from

Figure 5. Digital cameras are popular among travelers and tourists; they are portable, easy to use, and affordable

a wireless service, the traveler with a laptop will connect, log in to services, and communicate on a frequent basis throughout the day. If the Internet connection is more concentrated, in an Internet café with computers for instance, the traveler will dedicate a portion of the day to connect and communicate online. It is not unusual to see Internet cafés through Europe and Asia, but the model is less attractive in the U.S. Internet connection services should allow the traveler to connect and spend as much time as necessary to conduct the typical activities as blogging, image posting, e-mail, checking itinerary, and so on. As the day winds down on the digital imaging trek, the digitally enabled traveler has acquired a new database of images, published and shared select image-files, and communicated stories of their experience with their social network online through e-mail and blogs.

Taking pictures on a vacation is not new to the world of tourism, but digital equipment has changed the business and behavior equation. Given the proper technical infrastructure, im-

ages can be acquired and posted—essentially published—to a world-wide audience in a matter of minutes.

Digital photos are easy to share. Most photos are already stored on a computer or memory card, and it is a simple matter to upload them to the Internet, either through a private gallery (such as the digitaltrek.org site), or a social photography Web site such as Flickr (www.flickr.com).

Most thriving urban centers and developed destination resort complexes have a mature ICT infrastructure to support instant access to the Internet. Even smaller rural locations now boast access to the greater world of the Internet. The goal of a traveler on a digital imaging trek is to capture and publish images that reflect travel experience in new places and foreign cultures.

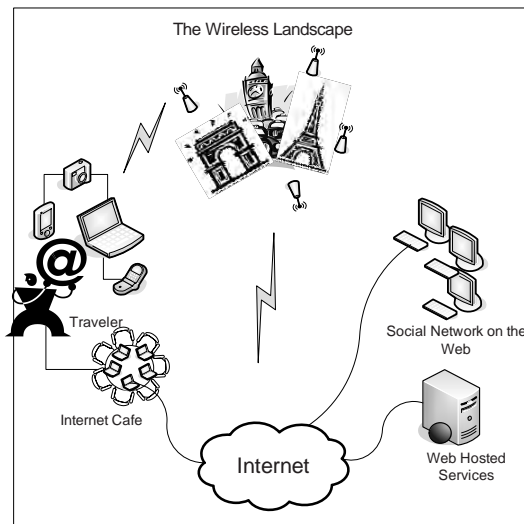

Tourism and Information Architecture

It is critical that both traveler and tourism enterprise alike prepare for the use of digital tech-

Figure 6. Digital imaging trek file types, platforms, and purpose

File Type	Hardware Platform	Software Platform	Purpose
Text file	Laptop, desktop, or handheld device with keyboard. Privately owned, or available through Internet cafe	Word processor-editor software	Written log of experience. Creating and sending attachments on e-mail. Creating and posting blog on Web services
Still image	Digital still camera Cell phone with still camera function Multifunction still and video camera	Embedded software in camera platform. Image editing with additional software on laptop or other device	Create a visual record of still images of travel experience. Sort and publish on Web server to share with social network. Send as attachments in e-mail.
Motion images	Digital video camera Cell phone with motion camera function Multifunction still and video camera	Embedded software in camera platform. Editing with additional software on laptop or other device	Create a visual record of motion images and sound. Edit and publishing on Web site to share with social network. Send attachments.
Hyperlink	Web based hosting services – social networks	Embedded feature on Web site	Allows author to ‘link’ from one type of information to another. Series of links create trails for others to follow.

Figure 7. The architecture for wireless network and infrastructure model for digitally enabled traveler

nologies through “architecture.” Travelers and organizations need to plan and think ahead of how to respond and conduct activities through the travel and tourism experience. While some things are left to chance or serendipity the deployment of digital infrastructure requires some thought. That plan is called “architecture.”

Architecture for information services is similar to that of architecture for buildings—it is the deliberate planning, modeling, and delivery of ICT services. Architecture requires adopting a model of approach and solution, both in systems architecture and information architecture. How does a highly connected, fast speed digital environment that serves the digitally enabled traveler sprout up? It is not a singular act by any tourism organization, but a system wide policy approach of local and national partners in business and governmental bodies. In most cases, experts from companies that provide ICT services will consult on the array of services available in the technology marketplace.

Much of the communications infrastructure that has developed in the past decade is a confluence of commercial profit-driven interest, digital user culture, and regional policy and laws. The

combined effect of the built ICT environment serves residents and visitors alike. Localities with new digital infrastructure enjoy digital connection to a broader world. Travelers to areas that are served with high speed digital services also reach out and use the infrastructure for all their related travel communication activities. This ever growing presence of widely accessible digital communication services represents different challenges to different cultures. While most Western cultural sensibilities accept the openness of access to the World Wide Web, other cultures are more circumspect and reserved, wishing to control the vast onslaught of information pouring out of the Web.

Cost has always been considered the primary barrier for entry in the world of ICT. The receding cost barrier—as Moore’s Law predicts—has lowered the cost barrier, particularly with technology products and services. Tourist properties such as hotels and resorts now can achieve Internet access as easily as telephone access. In many instances, travel infrastructure such as airports, train stations, and the aircraft and trains themselves, provide Internet and advanced telephone access. Countries and regions are now adopting

ICT's and installing a fiber-optic telecommunications system with wide spread wireless digital access points, which has distinct advantages over older, legacy "wire based" telecommunications infrastructures—particularly for the traveler. In some ways, the new fiber and wireless based connectivity infrastructure offers advantages for the digitally enabled traveler.

Of course, this entire ICT infrastructure model represents enormous business opportunity for the properties in which they exist. Hotels, resorts, travel destinations, travel hubs, restaurants, coffee houses, business outlets can differentiate themselves from competitors by providing ICT for a fee to the traveler. Travelers in turn, view access to ICT as a cost associated with travel and plan to spend money to acquire it. It is common for travelers to purchase short term access to ICT services at these sites on terms ranging from a few hours to several days.

When collaboration on planning and development of digital infrastructure occurs, the stage is set to promote services to the digitally enabled traveler. A highly developed infrastructure and usage model promotes rapid creation and publishing of rich media collateral by the digitally enabled traveler. All parts of the technology infrastructure work in unison to support the activities of the traveler.

Digital communication technologies of many platforms have become accessible to even the most inexperienced traveler. Mobile technologies of all types and sizes and wireless network signal have brought the Internet to the most distant of locations. This convergence of technical infrastructure and tourism presents opportunities and challenges to the tourism industry.

Yet even as the cyber-record of digital travel experience explodes, there are many issues the profession must consider. The more available common digital technologies become, the more travelers and tourism enterprises grapple with the complexity (and confusion) of choices including but not limited to privacy, intellectual property,

systems integration, systems management, training, best practice, and so on.

Digitally Enabled Travel: Knowledge Targets for the Novice

As the digitally enabled traveler becomes more of an influence in the world of travel and tourism, young professionals seeking degree based education and career opportunities in the field need to be familiar with basic technology. Whether looking at a college level curriculum or training opportunities for adults wishing to gain new skills, look for some of the topics covered here.

College level curriculum in hospitality, travel, and tourism programs should include an introductory level course in this area of digital technology. The topics taught in such a course do not necessarily have to be technical but young professionals entering the business should know the basics and be prepared to research and understand technology. A sample of college level curriculum might include topics such as the following.

Foundations in Technology

Many professionals and educators mistakenly think that learners know all there is to know about basic computer operations, productivity software and Internet access, Web searching and surfing. While these topics are often part of many school systems, not everyone has mastered basic skill and techniques in all these areas. Interacting with computer interfaces and mastering the sophistication of some productivity tools such as word processing, spreadsheets, databases and browsers requires instruction, time and practice. Many colleges, universities, technical institutions and similar educational organizations offer courses in computer technology. The popular press is filled with instructional books complete with CD based video for those who are adept at self instruction. Many conferences, training seminars, and "Webinars" (seminars of text, sound, and motion hosted

on the Web), offer similar instruction. Regardless of the model one uses to get trained, using digital technologies requires constant “tune ups” to one’s skill set. Find the type of education that works for you and take advantage of it.

Basic Information and Systems Architecture

Information and systems architecture introduces models to help solve problems in the field of technology. As with providing digital services for travels to use to communicate with social networks, technology applications start as a way to provide a solution to a problem.

While it is convenient to say technology will solve a problem or make some situation more efficient or less cumbersome, the idea has to be communicated in a visual model. Professionals in the world of information technology communicate regularly with visual models that reflect the structure or architecture of a system. Devices and the networks that connect them are shown so all can understand and agree on system solutions. Understanding basic architecture in work flow, information flow, and management, networking, service devices, client side devices, and so on will be very valuable for new professionals in the world of hospitality, travel, and tourism.

Basic Web Design and Interface

Many professionals in the field of hospitality, travel, and tourism will likely be asked to participate in design teams to design and build Web sites that will host information for customers or be used internally as sources of information for the business enterprise. Conceptualizing and building a Web site is a skill that requires practice and experience although of software tools such as Microsoft FrontPage and Adobe (formerly Macromedia) Dreamweaver make it easy to try this

activity. With a little training in software features of such applications, college level courses can quickly teach students the essentials in basic Web site design. This is both a technical and creative challenge, but most people quickly see the results of a little effort. For people just wishing to start with a simple Web site to host information about a trip or a destination, these tools are cheap, accessible, and relatively easy to learn.

Basic Digital Imaging and Image Manipulation

There are an abundance of off-the-shelf software tools in the marketplace that will introduce college student (or anyone with the motivation to learn) skills in digital imaging and image manipulation. While many people have digital cameras a course on digital photography will introduce a wide range of topics from composition to technical specifications. Understanding the wide range of options in today’s digital cameras can be helpful for young professionals who need to deal with a customer base that is armed with the latest camera gadgetry. Learning the process involved in capturing an image and uploading an image to a devices that can store the image in important. More knowledge in these areas will help improve customer empathy and ultimately customer satisfaction.

Editing images in software like Adobe Photoshop has a double benefit to a college curriculum. Students with added technical skills such as digital photo editing are in more demand. Many businesses need such skills to help with developing creative collateral to promote the commercial activity of the business. Understanding the creative process from image acquisition to image editing also will help the professional in dealing with agencies that provide that service. For instance, image editing is a time consuming activity, and in negotiating advertising contracts, such knowledge will be helpful.

Desktop Publishing

Desktop publishing is a content area that will provide a young professional with the knowledge of how to put assets such as text and images together in print collateral to serve the business. Even in the digital age, many businesses still have a great need for printed products to advertise, inform and attract potential customers. Tourism properties still have a great need for pamphlets, brochures and signage to keep customers informed about policies, regulations, events, calendars, and so on. A course in desktop publishing will give practitioners an opportunity to learn a skill that will help promote and organize business. In desktop publishing, students can learn how to conceive and construct various types of print pieces using software such as Microsoft Publishing or Adobe Indesign.

Editorial, Content Creation and Content Management

While learning technical tools is vital, helping young professionals identify and manage the message is critical to the success of travel and tourism businesses. Courses that emphasize the basics of how to construct the message in both text and visual design are important for a basic college curriculum.

Systems and Technology Primer for the Digitally Enabled Traveler

As digital communications platforms and technologies have become adopted by a wide mainstream audience two factors have been critical to widespread use—practicality and ubiquity. Along with the explosion of digital gadgets, contemporary travelers now have high expectations of availability of connectivity and complimentary technologies.

If the tourism industry is to appropriately harness and cater to this new and demanding audience,

the industry must build a model of digitally enabled travel that supports both traditional goals of tourism and the new goals of digital media acquisition. Understanding the pieces of the technology puzzle can serve as a starting point.

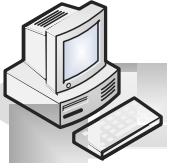

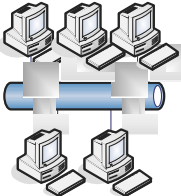

Several recent world events have highlighted the role mobile technology plays on the world stage. The first images of the London tube bombing in 2005 came from the cell phone cameras of survivors. These images were published by the BBC and forwarded around the world within minutes of the attack. Similarly dramatic images, particularly digital video, were quickly spread after the 2005 tsunami disaster in the Indian Ocean. Whether it is a global or local scale, digital imaging devices are ever present and serve as eyes to the world. Building a world class digital environment brings with it many more challenges, not just in the technical realm, but in the human realm as well.

A Word on Privacy and Security in the Digital Age

Privacy, security of information, copyright, information ownership, censored, and uncensored material are all issues that become concerns of the industry when technology is introduced. It is a grey area because decorum and respect relies as much on personal behavior as it does on personal technology. Travelers with powerful digital recording tools must understand the local cultural norms, as well as the global broadcast power of the World Wide Web.

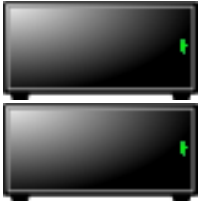

Privacy is an important and sensitive issue. Visitors to a Web site may be reluctant to share information—such as their e-mail address—because they fear that their personal information will be sold and they will be subjected to unsolicited advertisements. Spam, the endless barrage of meaningless e-mail advertising, has become an onerous burden to all citizens using online tools. It is best avoided by constricting the use of e-mail addresses.

Table 2. Core components of an information technology system

Technology	Location	Skill-level	Description
<p>Computer Client</p> 	<p>Computing cluster such as an Internet café, business service office, hotel lobby, etc. One or more for use by customers</p>	<p>Basic to advanced software such as e-mail, word processing, file management; basic computer knowledge</p>	<p>The computer client serves as the starting point for the customer. Recreational and business travelers alike will budget time and funds to access basic computing services such as e-mail, word processing, file uploading.</p>
<p>Laptop Computers</p> 	<p>Anywhere, travelers port and manage</p>	<p>Basic to advanced software such as e-mail, word processing, file management; basic computer knowledge</p>	<p>A laptop computer is a computer client and the traveler's link to the Internet and workstation for writing blogs or editing digital photos.</p>
<p>Card Readers</p> 	<p>Anywhere</p>	<p>Basic computer knowledge required.</p>	<p>Digital cameras accept different memory cards depending on brand. A generic card reader will allow any computer to read any card from any camera, with no additional software.</p>
<p>Portable Storage</p> 	<p>Anywhere</p>	<p>Basic computer knowledge required.</p>	<p>Backups are a major issue for travelers concerned about potential data loss (from theft or equipment failure). A portable hard drive (or a device that can burn CD's) provides a cheap and easy backup solution on the road. Small and easily packed.</p>
<p>Network-wired</p> 	<p>Anywhere</p>	<p>Intermediate to advanced computer knowledge required to build and support. Entry level user knowledge to access and use.</p>	<p>Wired Internet connections are generally located in institutions (such as hotels, business services, universities), and may incur a cost for access.</p>
<p>Network-wireless</p> 	<p>Anywhere</p>	<p>Intermediate to advanced computer knowledge required to build and support. Entry level user knowledge to access and use.</p>	<p>Wireless Internet connections can be found in built environments, particularly popular in urban settings with restaurants, parks, museums, hotels, and cafes.</p>

continued on following page

Table 2. (cont.)

<p>Mass Storage</p> 	<p>Any secure building location, typically attached to host devices such as advanced workstations or mainframes.</p>	<p>Intermediate computer knowledge required to configure, install and support.</p>	<p>A mass storage device, is a very large, commercial grade hard drive. It supports data and functions core to large businesses. While computer users may see the results of such devices in a routine Web search, these devices work in the background of daily user activities.</p>
<p>Servers</p> 	<p>At a hosting company; typically a technology company which provides a secure physical location, as well as technical knowledge to support services. Locations are typically built specifically to house the servers.</p>	<p>Advanced technical skills in Web hosting and server based data services.</p>	<p>The server will host all of the content for a Web site and code for Web applications such as a gallery or blog. Often a class of computers known as workstations; function solely as servers. A hosting service provider will maintain and support all server hardware and software. Computer users access these devices through client computers to update Web sites, post images in galleries and blog.</p>

Information that may be personal or sensitive, such as vacation photos or a travel journal, should be posted with care. In many cultures people do not wish to have their images posted for the world to see. Privacy for individuals is a sensitive matter. Even in public tourism venues, digital photographers are challenged when taking images and asked to refrain. Religious and private properties often post requests to refrain from photography and video recordings.

Institutional Web sites should consider developing a privacy policy, or a legal statement that reflects what the institution may and may not do with information provided by users. The World Wide Web Consortium (the standards body for the Web) has developed the Platform for Privacy Preferences (P3P) (<http://www.w3.org/P3P/>), a standardized language which provides Web site administrators with a simple and automated way to quickly generate a customized policy for their site. Individual digital travelers, eager to capture a unique image, must apply their own standards.

The golden rule though is “do unto others” as you would have done to yourself. Consider the impact of each image that is posted.

Travelers must be aware of their physical safety and security at all times. Broadcasting information on the Web can add to this worry. For example, travelers, especially solo-travelers, are advised against posting a personal and complete itinerary until their trip is complete. No only does it tell the world where you will be, but it also tells the world where you are not. Home safety as well as trip safety is the paramount concern.

With reasonable precautions, a Web site can *increase* safety. It allows a large number of people to check in on the well-being of travelers. While theft and other dangers cannot be eliminated, careful use of a Web site, instant messaging, and e-mail can reassure those back home. The personal technology of a digital enabled traveler is an attractive target for thieves. Common sense should guide the novice and experienced traveler in protecting personal possessions.

Web Hosting: What Travel and Tourism Professionals Need to Know

All Internet applications such as a Web site or a search engine run on a server. The server is a computer workstation in a class of computing machines that is specially constructed to manage the constant demand of service to clients on the network. Servers require special software and in most cases, comparably advanced knowledge and skill to configure and maintain. While it is possible to run a server in-house, it involves purchasing a machine, installing and supporting an operating system and applications, and maintaining an “always-on” Internet connection. Managing a server requires routine management as well as prompt response emergencies, 24 hours a day, 7 days a week. For most travel and tourism providers, becoming a technology company is a distraction from the core business. It is generally advisable that any business requiring a host on a server be outsourced to a Web host business provider.

A Web host is a company that provides space on their Web servers, use of their programs, and a certain amount of bandwidth use for a monthly

cost. Often referred to as a “solutions provider” or a “Web hosting service” the hosting company will handle all computer hardware and software issues such as installations, configurations, back-ups, updates, and any unforeseen maintenance. Of course, solution providers contract these services for a fee, but competition works in this marketplace as it does in any other, and a shopper is wise to research and compare costs and services among a range of businesses.

There are many Web hosting companies and there are many attributes to consider when researching them. Choosing a hosting company is a long-term commitment. Transferring a site from one hosting service to another generally involves several days of unreliability and possible downtime. Carefully consider all of the factors onlined in Table 3 before making a decision.

All of these considerations are important indicators of a successful Web hosting experience. Remember, anyone can run a server, including a college student living in an apartment with a space for a computer on a network. Make sure that you are dealing with a professional company that has a reputation for handling routine business as well

Table 3. Qualities for evaluating a hosting company

Factor	Description
Reputation	Every company must market itself on its reputation for service to customers. Ask for reference of other businesses that have used the services. Search for comments on the Web about the company and its performance. Are there any instances of how the company performed in a crisis, such as a virus attack or power failure? Have you toured the facilities or conducted due diligence on the company?
Reliability	Does the company publish statistics on technical performance? What level of support and customer service contact is there? Will you be able to contact people in off hours? What kind of technology do they support? Is there a specific platform or hardware and software and do you recognize the vendor? Ask about back-up, power supply, physical security, data security, and so forth. Do they publish their reliability data? Conduct an Internet search through popular search engines to find information about them.
Technology	Is the hardware and software platform up to date and current? Can you speak to vendors who supply the company with technology. Do they publish any related information about platforms?
People	Making a business agreement is as much about people as it is price structure. Have you met the principals of the company? Are you generally familiar with their organization and business structure? Do you have confidence in the people you have met? Is there generally superior business communication to your proposals?

as crises. Like the travel and tourism industry, professional protocol in handling technical matters as well as high grades on customer service are key to sound business practice in the technology marketplace.

As with every business, hosting is about people as much as technology. Find a company with knowledgeable employees who are happy to deal with their clients. You should find support personnel who are professional, courteous and eager to answer questions at your knowledge level, no matter how basic or advanced.

Every good host publishes their uptime (the amount of time the service has run without interruptions) and customer testimonials. Don't necessarily trust the quotes on the company's Web site; do an Internet search with any popular search engine (Yahoo, Google, etc.), and find out for yourself.

Once you have identified a few companies that you feel comfortable dealing with, consider the technical requirements of your project. The first decision is about the type of hosting that the project requires. The options are:

- **Dedicated hosting** means that you are leasing an entire computer, which gives you access to the entire hard drive and allows you to make certain configuration requests that are not possible on a shared machine. By leasing a server (rather than purchasing it and placing it in your office), you outsource the need for physical setup, administration and backup services. You also avoid the upfront cost of a powerful machine, and take advantage of your hosting company's ability to quickly purchase and maintain the machine with professional qualified vendors.
- **Shared hosting**, sometimes called managed hosting, means that you are leasing part of a server, which you will share with other customers. This kind of plan generally involves very low monthly fees (as low as

\$10/month) and provides complete technical support. Unless you are hosting multiple blogs or Web sites, a shared hosting plan is probably sufficient.

Travel and tourism organizations could have a range of needs to contract an outside hosting provider. Setting up a Web page to inform customers of features and offerings of a property or package, or architecting more advanced online services for customers may be among the ideas you will have. The next step in this process of selecting a hosting provider is to explore what you want to do with your hosting provider. The type of service you offer will determine the software applications that the hosting provider will need to run on the server. Additionally, your requirements will guide the features that you'll select for the server. Each software package will list the special requirements on their Web site, but some general guidelines are:

- **Static Web page:** Simple Web pages that hyperlink information that is relatively static. Information does not change too often. Static Web pages require little to no special software or technical support.
- **Downloadable images:** No special requirements, similar to static Web page
- **Image gallery with uploading:** Image galleries containing collections of image (often hundreds and thousands) require server-side programs. Server side programs mean that special software has been loaded and manipulated to provide an easy user interface and experience. A database will be required to track and maintain a medium to large size collection of gallery images.
- **Blogs:** Blogs, or written text entries also require special server-side software to accepted entries, organize them and display them, blog software, like image galleries is generally database-driven.

Several hosts offer blog-friendly plans that require minimal configuration and no technical skills. Lists of these can be found at <http://wordpress.org/hosting/> and <http://www.sixapart.com/movabletype/hosting>.

Identify your minimum technical requirements. In general, look for the criteria listed in Table 4.

More Technical Tools of the Digitally Enabled Traveler

Digitally enabled travelers will quickly embrace new and experimental technologies. For them, it is a challenge to figure out ways to adopt a technology and make it work in the daily flow of travel.

For instance, instant messaging, or “IM,” is a technology for rapid-fire asynchronous mes-

saging across a network. Instant messages can be thought of “instant e-mail,” and are generally used to communicate to a select social network, but often composed on the computer screen while doing something else. Digitally enabled travelers multitask on the computer—that is, they conduct more than one activity at the same time—with ease.

IM was first popularized in the mid-1990s by ICQ, a product introduced by Mirabilis Ltd in 1996. Mirabilis Ltd was later acquired by America Online, which ran a competing product called “AOL Instant Messenger,” or AIM. By acquiring ICQ, AOL became the largest operator of instant messaging networks in the world.

Other competitors include Microsoft, which offers an instant messaging feature as part of the Microsoft Network (MSN), and Yahoo!, which offers the feature as part of their community-build-

Table 4. Criteria for evaluating Web hosting services

Feature	What to Look For
Technical Support	At the very least, 24-hour e-mail technical support. Also consider telephone support (generally, the company promises to address your problem and call you back within 24 hours).
Domain	Most hosting plans include one domain registration (for example, www.yournamehere.com) for free. Make sure that the price for a second is reasonable (not more than \$20/year).
Disk space allocation	Disk space, the space on the hard drive that is allocated to you, should be adequate for your application. Storing Web pages or blogs requires a small amount of space, while storing photographs requires multiple gigabytes. Look for at least 10GB of space. Also, research in advance what it will cost to expand your allocated space. Understand the incremental hikes in cost for more disk space.
Server-side program access	The applications that you wish to run will guide your need for server-side program access. In general, look for PHP, which is a coding language that manages how customers see and interact with your services.
E-mail addresses	Your plan should offer the ability to create your own me@mydomain.com e-mail addresses. Web-based e-mail access is a nice feature for frequent travelers, and is offered at no additional cost by many hosts.
Bandwidth	Bandwidth refers to the total amount of data transfer between your server and visitors to your Web site. More bandwidth is good. Understand that bandwidth to the end user is limited by their personal connection and rate of speed.
Statistics	It’s always helpful to know exactly how many visitors your site has. Hosting companies typically provide this information with some graphics and analysis.
Databases	If you wish to run a dynamic application such as a blog, you’ll need access to a database.
Operating System	Your operating system choice should be guided by your application requirements. Most hosting plans are based on either Linux (which tends to be cheaper), or Windows.

ing options. All of these services are free to use, though some may display advertisements.

Unfortunately, all of these services are based on proprietary protocols and do not interoperate. Therefore, a digital traveler must choose the service that most of the people that they wish to communicate with use. If this is not practical, digital travelers can invest in a product such as Trillian, from Cerulean Studios (<http://www.ceruleanstudios.com/>), which is an IM program that supports all major networks.

Instant messaging is favored by digital travelers, because it allows instant communication with anyone on the network, no matter where their physically located. If a device (such as a computer or cellular telephone) has Internet access, it can connect to an IM network. This is an extremely low-cost method for travelers to communicate with their social network of friends, family, and colleagues around the world.

More recently, voice over Internet protocol (VoIP) has become an important buzzword in the latest digital tools becoming available to digital travelers. VoIP is a technology for transmitting traditional “telephone calls” over the Internet. Imagine using a laptop as a phone and conducting routine two-way audible conversations. Such calls are indistinguishable from normal Internet data and promise to make international conversational calls extremely cheap. Imagine no more phone calling cards and the end to frustrated travelers trying to decipher local and international calling codes.

While still in the early stages, VoIP is available to any digital traveler with a laptop, speakers, and a microphone. Services such as Google Talk or Skype (<http://www.skype.com/>) are up and running and can be used to converse with telephone quality audio for free. Skype also offers “Skype Out,” which permits computers to connect with telephone numbers anywhere in the world for extremely reasonable rates.

Needless to say, it is important for travel and tourism organizations to be familiar with trends such as VoIP for two reasons. The early adopters of such technology—the digitally enabled traveler—are the bell weather for change in the industry. It won’t take long for entrepreneurial technology providers to create a competitive business model for VoIP and shift the commerce to a new marketplace.

CONVERGENCE AND FUTURE TRENDS

Given the rapid evolution of digital communication tools, both hardware and software based, it is not hard to imagine that many of these products will continue to transform.

The technology industry is creating faster, lighter, devices that better integrate with each other. This trend of “convergence” is one to watch for. It wasn’t long ago that a cell phone was simply a way to have voice conversations with other parties. Today, other features have converged on the platform of a cell phone. Is a cell phone a camera, a video recorder, a video viewer, organizer and personal digital library? The answer is “yes”—it is all those things and more.

A digital camera is no longer a camera; it is an image processing workstation. Images can be acquired, edited, filed, and stored. Images are dynamic files that merge and morph into other applications and devices through infrared proximity connections.

The ubiquitous iPod from Apple computer started off not too long ago as a just another platform for listening to music. Today an entire lucrative industry revolves around providing rich media content for viewing on a tiny screen. Need an exercise multimedia instruction package for keeping fit during travel, it can be purchased and downloaded to your iPod.

CONCLUSION

Digital gear to enhance the travel and tourism industry is a constantly evolving marketplace. The future is part evolution and part revolution, from wildly popular devices to culturally challenging information flow. Regardless of the intricacy, allure or popularity of digital devices, the seasoned digitally enabled traveler will always find ways of incorporating new devices and new services to enhance experience and communicate to a social network in digital space. Travel and tourism providers must influence the role of the digital imaging trek by understanding the role they themselves play in this ever changing landscape. Who is the provider, the host, the arbitrator of this new world of digital travel? By seeing and

understanding the big digital picture, tourism and travel providers will retain perspective and offer quality services to patrons worldwide.

Chapter 3.44

Adaptive Use of ICT in Response to Disintermediation

INTRODUCTION: EVOLUTION OF THE WEBMAIL SYSTEM

Traditionally, the Australian travel agency sector has operated as the premium intermediary in a relatively simple distribution chain that can be depicted in Box 1.

In such a system, it is estimated that travel agents have traditionally handled over 85% of consumer transactions (Wilde & Rosen, 2000). The advance of online technologies and ICT-based distribution systems has changed the dominant role of travel agents in the distribution and sup-

ply of travel products. This has impacted on their relevance, returns, and individual financial viability.

There is a vast amount of literature on new forms of product distribution made possible by developments in ICT. This literature has raised many issues (see, for example, Clemons & Hann, 1999; Klein, 2002; Anckar, 2003), but our comments are restricted to the concept of disintermediation and, in particular, to its application to the travel agency sector in the tourism industry (Anckar & Walden, 2002; Buhalis & Licata, 2002).

Box 1.

The key literature on disintermediation has been summarised by Anckar (2003) as follows: the threatened intermediaries (or disintermediation) hypothesis essentially describes the reduction or elimination of the role of the middleman in transactions between the producer and the customer, as in the new electronic marketplace, where consumers interact directly with producers. With the resulting bypass of intermediaries, which adds significant costs to the value chain, there could be shifts in power from one channel layer to another. Due to the presumed suitability of the tourist product for e-commerce and the fact that the travel distribution chain traditionally has been heavily dependent on middlemen, the travel industry has been hypothesized to be among the first sectors to experience disintermediation on a large scale as a result of ICT developments.

While there is voluminous theoretical literature, the empirical evidence of disintermediation in the international tourism industry is still patchy (Alamdari, 2002; Klein, 2002). In the United States, for example, while online transactions have grown dramatically, the overall industry impact in terms of market share has been significantly less than predicted—the evidence certainly does not support “travel agents are extinct” predictions (St. Clair, 2000). In Asia, a region with rapidly growing air travel, over 80% of all ticket sales are still made through travel agents (Alamdari, 2002). One can speculate that the drivers for disintermediation have not been as strong as expected, or that travel agents have been successful in their adaptive response, or as one writer (Klein, 2002) observed, “...the incumbents tend to fight back and leverage their financial power, their brands, established relationships, and click and mortar strategies” (p. 227). Consumer reluctance to use new technologies used for product distribution may also be a factor (Anckar & Walden, 2000; Alamdari, 2002), although more recent evidence indicates that substantial “conversion” might be underway (Anckar, 2003; Buhalis & Licata, 2002; Mowat, 2003).

We have noted that although travel agents still appear to have a substantial role in the industry, forces at work (including ICT impacts, e-ticketing, changes to commission arrangements, consolidation in the industry, etc.) have been working toward a significant diminution of that role. In this context, it is not important as to whether the debate is on disintermediation, reintermediation, or cybermediation, the impact on travel agents is generally negative. It is difficult to promote a scenario in which travel agents will become *more* important (Vasudavan & Standing, 2000; Klein, 2002).

This article discusses the development and implementation of the WebMAIL initiative as a response to the disintermediation of travel agents in Australia.

BACKGROUND

The Australian Federation of Travel Agents (AFTA) is the main industry body representing Australian travel agents. Its WebMAIL initiative is an Internet-based, business-to-business (B2B) system for the distribution and management of sales-related information covering “regular” travel and offerings products as well as “special” options. It is the only multisupplier, consolidated, product promotion database of its type in the country. WebMAIL provides suppliers with an Internet-based communication link to the Australian travel agency sector. It presents AFTA members with opportunities to embrace new technologies and to counter the threat of disintermediation. AFTA hopes that WebMAIL will reinforce the position of travel agencies in the distribution channels.

The WebMAIL tool is, in effect, a reintermediation of service provision. The initiative is a response by the sector’s industry representative body rather than by the individual enterprises that comprise the sector. Also, while the technology underlying WebMAIL is relatively simple, its

business model is self-funding in that the suppliers (the source of disintermediation and associated threats) fund the entire system. Initial success with this business model suggests that in Australia, at least, the travel agent sector can still add sufficient value to retain a viable role in the supply chain of travel and product services.

WEBMAIL FUNCTIONALITY

Prior to the development of WebMAIL, individual suppliers of travel services contacted individual travel agencies by fax or by e-mail. In recent times, most travel service suppliers have also developed Web sites. Typically, a travel supplier would send information on various offerings to the travel agents in its distribution chain. Until the advent of WebMAIL, this information was generally stored in physical personal folders or in individually designed electronic folders. Effective use of such systems is heavily dependent upon individual skill and memory and has in-built difficulties with regard to currency, uniformity, and rapid ease of access. Clearly, with the continual emergence of more efficient electronic systems becoming widely available in workplaces and home environments in Australia, there was a need for a system that would better manage the information flow and for creation of a database that not only manages filing but contains an effective search and retrieval facility.

WebMAIL (Figure 1) collects and collates travel product and service offers from participating travel industry suppliers around Australia and compiles these with the individual user profile of each travel agent registered in the system. The system provides travel agents with one e-mail per day (usually at the start of the business day). WebMAIL supports this targeted communication with an automated filing and archiving system, along with simple-to-use search and retrieval functions.

Travel product and service suppliers can load information regarding their products and marketing initiatives directly into a central, searchable database. Suppliers also control when and to whom this information will be available. They stipulate the validity period for their information, and it is automatically removed from the “current” area upon expiry date. This reduces the chances of agents offering out-of-date information.

In addition to the notification by the “daily alert,” travel agents can search for information in the WebMAIL database by supplier name, product type, information type, region, country, or date of issue. Hence, using WebMAIL, suppliers are no longer reliant on agents trying to maintain their own filing systems for this information.

ICT-RELATED BENEFITS OF THE WEBMAIL SYSTEM

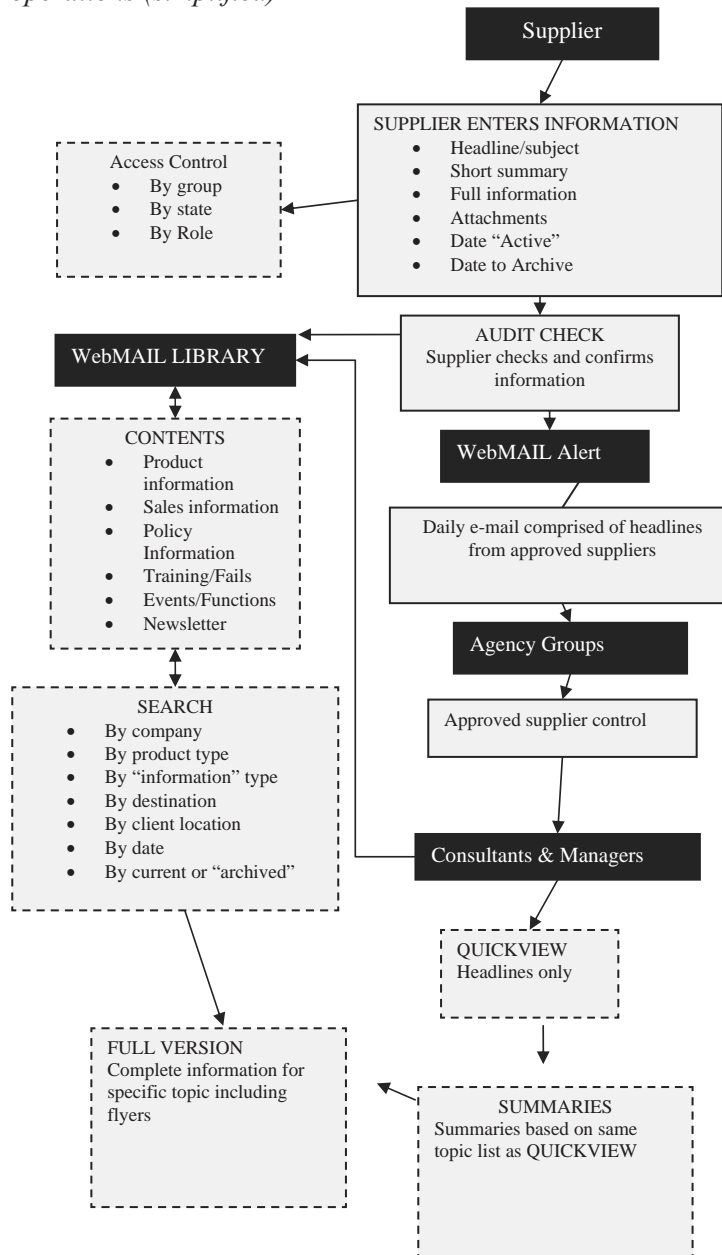

Table 1 summarises some of the benefits that the WebMAIL technology has brought to the travel-agent sector.

POTENTIAL REGIONAL BENEFITS

The WebMAIL system may offer several benefits for regional travel agencies. Perhaps the main one is to effectively level out the availability of product information for all agencies, regardless of location. Importantly, it achieves this without requiring any extra financial outlay from individual agencies. WebMAIL opens up suites of product information and details previously inaccessible to regional clients through their local agencies. The result is that, should it choose to, a small, low-turnover regional travel agency can access and obtain the same product information as its large, city-based counterparts.

The method of access to information through WebMAIL may also result in real savings for

Figure 1. WebMAIL operations (simplified)

regional agencies. Prior to its inception, for example, regional agencies bore the costs of staff time and telecommunications access in obtaining up-to-date information about tourism products. Keeping in mind that regional travel agencies are generally small operations that are sometimes co-located with other retail outlets (for example,

a news agent/travel agency business), these savings may prove to be significant.

In summary, WebMAIL can be described as friendly to small regional business, because it offers a low-cost and low-risk solution to obtaining up-to-date product information. It enhances the timeliness, quantity, and quality of information

Adaptive Use of ICT in Response to Disintermediation

Table 1. The benefits of WebMAIL to suppliers and travel agents

WebMAIL Features	Benefits to Suppliers	Benefits to Travel Agents
Productivity and cost savings	<ul style="list-style-type: none"> Suppliers can load product and marketing information directly into a central, searchable database. This greatly reduces costs of continuous and scattered fax and e-mail broadcasts. 	<ul style="list-style-type: none"> Travel agents no longer waste time searching for missing information they have misfiled. All supplier updates are on the database and can be easily searched and retrieved. Business model whereby suppliers pay to have their information distributed, rather than the travel agents paying to receive that information.
Information management	<ul style="list-style-type: none"> Provides automated filing and archiving, so supplier information is always available to agents. Links to supplier Web sites and booking portals can also be included. Promotional documents like flyers can be attached for agents to download and supply direct to the customers. 	<ul style="list-style-type: none"> Receive one concise e-mail notification of all the latest updates from all suppliers each day. This greatly reduces the administrative burden in fax notifications, e-mail broadcasts, and all other forms of marketing directed by suppliers to agents. Set their own profile for information to be tailored to their needs. This allows for the provision of superior service to potential clients. Provides easy access to all past updates. Agents can quickly check the product information and advise both the customer and the supplier.
Product management and target marketing	<ul style="list-style-type: none"> Suppliers can choose to send updates to all agents, or to specified groups only; to all consultants, or to managers only; and to all states or to specified states only. They can also choose when the information will be shown as “current” and when the information will be transferred to the “noncurrent” archive. 	<ul style="list-style-type: none"> Searches of all previous “alerts”/updates can be made in the AFTA WebMAIL database (see Figure 1).

that is available to the enterprise so that a level information playing field is established for all travel agencies.

RESULTS: WEBMAIL IMPACTS

Since the introduction of WebMAIL in Australia in September 2002, more than 5800 travel agents now access the WebMAIL system, with 120 unique travel product and service suppliers subscribed as of September 2003. In this introductory 12-month period, over 4,000 product offer notices (many referring to multiple products) were lodged with WebMAIL; the site receives approximately 1000 unique visits from travel agents per day. In the January to March 2003 quarter, the Web

site monitoring company Hitwise ranked *www.afta.com.au* number 7 in Australia in the Travel Agency category and number 5 in the Business & Finance—Professional Associations category. Responses to an online survey in September 2003 indicated a high level of satisfaction with WebMAIL.

CONCLUSION

The introduction of online technologies into travel and tourism distribution channels has had a substantial impact on the relationship between product suppliers and intermediaries. AFTA has responded to the threats created by the process of disintermediation with the WebMAIL ICT system.

The WebMAIL initiative has enabled suppliers to realise substantial benefits in maintaining intermediary channels, including the capacity to enlist distribution mechanisms that are seen as largely independent and objective. Travel agents have benefited from reduced “information overload,” while both groups have improved information management practices. Importantly, this ICT initiative may realise real benefits for travel agencies in regional areas.

One indicator of the success of WebMAIL has been the subscription of suppliers to the business model, whereby it is the suppliers who pay to have their information distributed, rather than the travel agents who pay to receive that information. This model has proven successful in the first year of WebMAIL’s operation; however, the future of WebMAIL is undoubtedly in the hands of the suppliers. The challenge is for travel agents to continue to provide value for money for subscribing suppliers, and in this sense, WebMAIL represents one component of adaptive responses to potential disintermediation in Australia. Further research is required to identify what other components are required and how online technology may be employed more effectively.

KEY TERMS

AFTA: The Australian Federation of Travel Agents. AFTA is the peak representative body for Australia's Travel Agents, representing the majority of travel agencies in Australia. Its aim

is to "...stimulate, encourage and promote travel, and to uphold the interests of travel agents" (AFTA Web site: www.afta.com.au, 2004).

Disintermediation: Describes the reduction or elimination of the role the middlemen in transactions between the producer and the customer as, in new electronic marketplaces, consumers interact directly with producers.

WebMAIL: An online system developed by AFTA providing travel agencies in Australia with access to tourism product and service offerings from participating industry suppliers.

Chapter 3.45

Virtual Reality

Mapping Revisited: IT Tools for the Divide Between Knowledge and Action in Tourism

Malcolm Cooper

Ritsumeikan Asian Pacific University, Japan

Neil MacNeil

Ritsumeikan Asian Pacific University, Japan

ABSTRACT

This chapter provides a brief overview of the available technologies and opportunities for the use of virtual reality in tourism marketing. It acknowledges that in almost all formulations of the tourism marketing model to date however, much has been made of the notion that tourism is unique because production and consumption occur not only at the same time but in the same place, and therefore that location or proximity is often a critical determinant of the take-up of tourism opportunities. The chapter then goes on to posit the question: what if the place variable could be removed from this equation through the further development of virtual reality techniques? The impacts of this might include: less requirement for travel per se (perhaps); better and more real information about the physical actuality of

a destination for the potential consumer (likely); price and service quality information very much simplified and improved (definitely), and changed tourism promotion strategies would change (undoubtedly). At the barest minimum, the uncertainties involved in relying on unverified initial information for tourism travel decision-making could be considerably reduced.

INTRODUCTION

As consumers become more committed “Web surfers,” their processes of decision making based on the information found there will become more sophisticated, particularly when purchasing products and services (Buhalis, 1998; Sheldon, 1997). In the early days of mass use of the Internet to contact potential clients, anyone with anything

to sell or provide information on could develop a Web site to advertise their intention to trade; a process that was really nothing more than transferring print or television/cinema-based static visual information to the new medium (Buhalis, 1998). With respect to tourism and hospitality such users ranged from the major airlines and hotel/resort chains to the family with a holiday villa for rent in Europe, or to a bed and breakfast operator in Australia, or to an *Onsen* proprietor in Japan. By assisting the promotion of tourism services in this way the early e-commerce boom certainly dramatically extended the marketing reach of tourist operators (Buhalis, 1998). With maturity however, markets generally become more sophisticated and demanding, and require higher standards of interaction, particularly at the more expensive end of product cost (Weiermair & Mathies, 2004). As a result, the variety and scale of information the purchaser of tourism product now has in terms of making informed buying decisions, and the increasing sophistication of both consumers and tourism marketing organizations is leading to more creative applications of the Web as a channel to reach consumers in this industry (Sitepal, 2005).

Nevertheless, much of the information currently provided to tourism consumers remains 2-dimensional; if it is visual then it is at best generally only composed of good photographs with associated text, unless video capture is used. However, very high processor and memory demands on the destination computer make the latter less attractive to the average Internet user. So, in practice, consumer processing power constraints mean that operations on current tourism Web sites remain heavily dependent on text for their message delivery, with software robots used “behind the scenes” to retrieve text-based information for consumers (Ishida, 2002). Obviously this search and retrieve metaphor works well, even on a global basis, but if the Internet is to be used for real personal interaction with the tourism environment an immersive image-based

geographical interface is ultimately going to be needed. One way to provide this is to construct a 3-D virtual image of a destination or travel route for the potential consumer; however there has to date only been limited adoption of virtual reality (VR) technology in the sales pitch of tourism organizations and businesses large and small, so despite the widespread availability of appropriate receiving media this form of message representation has not really entered the mainstream as yet (however, see Google Earth, <http://earth.google.com/tour/>).

THE ADVENT OF NEW TECHNOLOGIES

This situation is likely to change in the near future as products like more sophisticated digital cameras become accessible to the wider consumer market, allowing tourists themselves to depict destinations in virtual reality terms to their friends and contacts. The technical sophistication of the Canon IXY is one example of what the next generation of digital cameras will be capable of. With a photo-stitch assistant built in, the photographer using one of these cameras (and others like them) is able to make seamless panoramic images over 360 degrees. The wider spread of technology of this nature will force producers of commercial promotional material in tourism to undertake more sophisticated use of VR to ensure that their products are visible in these ways to the more sophisticated user. In this context it is no surprise to see that immersive video and the ability to stream high quality video content to the Web consumer are now becoming increasingly acknowledged as an acceptable technology in promotional terms (Buhalis, 2002), and for this reason we argue in this chapter that such advances in technology will add to the VR impact of tourism marketing on the Web in the very near future.

Set against the development and general societal take-up of new technology is the extent and

speed of its adoption by individual consumers, subjects of much interest to the marketing and tourism industries for many years (Bierman, 2002; Buhalis, 2002; Cetron, 2001; Hall, 2000; Inkpen 1998; Leiper, 1995; Prideaux, 2000, 2002; Weaver & Lawton, 2002; Witt & Moutinho, 1995). Most studies have found that there is a lag between the introduction of technological innovations and their widespread acceptance (Witt & Moutinho, 1995, pp. 273-284). Here, individual differences in learning and, indeed the whole human learning process come into play (Bednar, Cunningham, Duffy, & Perry, 1995). Effective learning derives from an individual developing a mixture of behavioural (new behavioural patterns being repeated until they become automatic), cognitive (the effects of changes in behaviour are observed and used as indicators to future useful behaviour), and constructive solutions to a given problem. This concept is based on the premise that we personally construct our own perspective of the world, especially with respect to problem solving in ambiguous situations, rather than have it done for us by an external agency (Schwier, 1995). As a result of this mechanism, because a human learner is able to interpret multiple realities depending on need, they are better able to deal with real life situations if they can actively problem-solve within them or before they occur. The actual circumstances surrounding the particular situation help us decide which approach to learning is most appropriate, but the process is intermediated by personal experience, cognitive and physical ability and other specific and non-specific situational variables. The end result is that some problems require highly prescriptive solutions outside the learner's control, whereas others are more suited to the control of his or her environment by that learner (Schwier, 1995).

From these, and earlier observations, a number of conclusions can be drawn about the likely learning behaviors and responses of the tourist to the type of almost total immersion environments (3-D) exemplified by virtual reality techniques (Bitgood,

1990; Psotka, 1995). The most general one is that users will still use specific environmental features as clues to behavior on entering a virtual space, just as they do in real space. Authentic environmental reproduction is therefore required to convey that sense of place. In fact, the inclusion of accurate renditions of artifacts and real environmental elements from the actual places being recreated is essential to effective immersion environments, even if initially the learners involved have very little directly transferable prior knowledge about the content area. What this means is that properly constructed virtual environments could quite easily and satisfactorily replace actual travel for some potential tourists, given the way in which human beings learn experientially, in theory at least.

Prideaux (2002) tested this theoretical conclusion in a small study carried out in 2001 of the reactions of tourism students to the likely impact of the virtual reality concept on the tourist experience, but instead found that while the benefits of virtual reality as an information and marketing tool were well recognized by such technologically-savvy groups, as a substitute for a real-life experience it had not gained any form of mass acceptance and was not in fact much welcomed as a replacement for this. In the light of this result, this chapter investigates the *potential* of virtual reality tools to describe tourist experiences and attractions (especially over the Internet) as a form of tourism marketing, and the current constraints on the full realization of this potential. Through an examination of the advantages of the Internet as a marketing tool and of the characteristics of the 21st century tourism industry and of the social, political, and natural environments in many countries, it is suggested that the use of virtual reality via this medium is likely to become very important for marketing and experiencing tourism for the general public in the near future, notwithstanding the conclusions of the earlier study.

The chapter also looks at some of the reasons why although it might be apparent that imaging

technology can and will be able to help market tourism product at least to the experienced internet user and/or the user interested in specific sites, it currently remains underutilized in most other tourism applications. To provide a partial answer to this question, an online survey of VR imaging professionals was undertaken in early 2005. The results are outlined later in this chapter, but in essence suggest that marketing using fully VR enabled tools is as yet only partly accepted due to cost and perceived difficulty of use. Thus, VR is not yet an essential part of the marketing mix for any significant number of destinations, although its potential is well recognized, at least by the IT industry professionals that would be required by the tourism industry to make its use feasible.

TOURIST DESTINATION DECISION MAKING AND THE INTERNET

The critical components that determine the demand for a destination or product may be collectively characterized according to the 6P model (Weaver & Lawton, 2002, p. 222), and includes such items as place, product, price, packaging, promotion, and people, when applied to the service industries. In regard to marketing most emphasis is usually placed on the dimensions of product and place attributes, price, packaging and promotion. The additional people dimension within the overall model in this case includes tourists, service workers and residents and refers to consumer behavior, service quality and resident support for, or opposition to tourism and has been extensively studied in the tourism literature (Witt & Moutinho, 1995). Topics of interest to tourism market researchers have been how to better evaluate the predictors of destination and travel mode choice, or how to determine the best promotional campaign for a particular destination.

In almost all formulations of the demand-side model to date place has been included not only for its intrinsic value as the location in space of

the desired tourism product, but also because it is generally asserted that tourists must *travel* to a destination in order to consume the tourism product (Weaver & Lawton, 2002, p. 223). Much has in fact been made in tourism marketing theory of the notion that tourism is unique because production and consumption occur not only at the same time but in the same place (Morrison, 2002; Ritchie, 1996), and that relative location (proximity) is often a critical determinant of the take-up of tourism opportunities. While place is of course as much influenced by accessibility (price and physical accessibility) as relative physical location in determining how effective any given connection between market demand and a particular destination actually is, insisting on the importance of relative physical location nevertheless reinforces the notion of the centrality of place and by implication a requirement for travel before tourism opportunities can be realized. But what if the physical nature of the place variable could be removed from this equation through the further development of virtual reality (VR)? There might indeed be less requirement for actual travel, but even if this did not happen at the very least the traveler could be better informed about the physical actuality of a potential destination before travel, assuming that the realities are fully described and adverse aspects not covered up by the VR equivalent of air-brushing. In this way the uncertainties involved in tourism destination decision making could be considerably reduced.

THE INTERNET AS A MARKETING TOOL AND RESOURCE

Before examining the question of whether or not VR will contribute a great deal to future destination decision making, or indeed remove the need for actual travel entirely, it is useful to look at the current use of the Internet in the marketing and experiencing of tourism. Tourism has been amongst the top three commercial users of

the Internet for some time and information and communications technologies (ICT) continue to rapidly change “spatial relationships” in society as a whole and in tourism in particular (Buhalis, 2002). For example, e-mail is pervasive, the Internet is everywhere despite some attempts at its control in some countries, there has been a massive uptake of broadband capability, and there has been a very high penetration of mobile devices as both information sources and as communication facilitators; indeed the use of ICT is pervasive in the workplace and the home. With respect to tourism, using the Internet to research, request and feedback information and to purchase is now “taken for granted” by tourists (Prideaux, 2002). It is probably therefore possible, even at this relatively early stage in our use of the Internet as a marketing tool to say, as do Buhalis, Jafari and Werthner (1997) that there is really no choice for many tourism operators but to include this new technology as a central part of their marketing repertoire in order to satisfy tourist demand and to survive in the marketplace in the long run. Organizations that fail to participate in the electronic marketplace in the future face severe competitive disadvantage and may lose market share (Buhalis, 1998).

The Internet also is very important on the supply-side of the market. It offers a means to sell to final consumers at a reasonable price without many overheads, allowing individual tourist operators to compete with wholesalers (agents), and to improve their distribution channels in many cases. It is a particularly important information source for international and domestic travelers, with the travel sector rated amongst the top three product/service categories purchased via the internet (Heung, 2003; Weber & Roehl, 1999). As Buhalis has noted, this could be very important for small and medium enterprises in a market traditionally dominated by larger firms (and their allies in government tourism organizations—Buhalis, 1998, 2002). By using the Internet their costs of marketing can be contained, the

influence of often peripheral spatial locations reduced (Vich-I-Martorell, 2002), and/or the small firm’s almost universal inability to effectively utilize local/regional business assistance and tourism promotional organisations offset (Cooper & Abubakar, 2004).

On the demand side how does the Internet currently impact on buyer behaviour? Models of consumer purchase decision making range from the very simple *need—information search—evaluation—decision—post purchase evaluation* type to more complex formulations for services that are based on a range of psychological and socio-economic factors (Palmer, 1994, pp. 116-120). These models incorporate the following elements:

- **Inputs:** Information about the range of competing services and products that may satisfy the immediate felt need
- **Behavioral determinants:** The individual factors in decision making, influenced by socialization, personality, culture, level of information, and so on
- **Perceptual reactions:** Interpretation of information inputs through personality and experience
- **Processing determinants:** The way in which a decision is made, incorporating motivation to satisfy felt needs, critical product requirements and attributes, past experiences of suppliers, ability to use and recognize available information, and so on
- **Inhibitors:** Ease of access, price, terms and conditions for delivery
- **Outputs:** The outcome of the decision process (proceed, defer, do not proceed)

Palmer (1994, p. 118) notes that most buyers of services do not act with total rationality—to be able to do so would require that all possible sources of information would be known to them and that their contents could be fully and logically evaluated. Of all the service industries, tourism

is a confidence or experience good (Werthner & Klein, 1999), where product characteristics such as quality or price value are difficult to observe and can only be fully ascertained upon actual consumption (or from a reasonable facsimile of this provided by the much discussed 'word of mouth' phenomenon). Experience goods pose difficulties for consumers in accurately making consumption choices because at the moment of decision making only information about the product, but not the product itself, is available. Moreover, the role of experience in consumption decisions is only now being realized in effective marketing strategies for tourism (Gretzel & Fesenmaier, 2002). This is based on the fact that experiential learning, often assisted by friends and relations is not only entertaining and stimulating but also central to the travel decision making process because it lets consumers understand and evaluate the travel product in ways not bound by the need to describe such products in functional terms or in monetary values (Vogt & Fesenmaier, 1998). This is precisely why those VR technologies that allow experiential learning of an environment independently of travel to the actual destination should have a great future in the tourism industry.

But, beyond the use of evocative photographs there has been little virtual reality product in the tourism industry's commercial uses of the Internet to date. While consumers are becoming mature Internet users, in that they are more "cyber-savvy," more demanding, more willing to search, and more willing to provide community feedback to business, these "consumers with attitude" are not apparently demanding VR products in addition to text and 2-D image based information (see Chapter VII of this book). So, while the process of attracting, drawing-in, and retaining potential consumers of tourism product is becoming more challenging for operators and their agents, and consumers are talking to each other like never before on the Internet through blogs, review sites, opinion sites, user groups, chat, or other online communities, business is not yet taking the next

step and providing virtual reality experiences for their potential customers, other than the 2-dimensional photograph or the video clip.

VIRTUAL REALITY TOOLS TO ENHANCE THE TOURIST EXPERIENCE

As a marketing channel, the Internet is thus now a mature medium for the tourism industry. The travel and tourism sector blazed the trail of e-commerce in the 1990s (Buhalis, 1998). Even as long ago as 1999 "Travel" was the No.1 online product; considerably exceeding the combined online sales of books, software, computers, music, flowers, and toys, so why are the new VR technologies of the 21st century not being taken up in a similar fashion to develop the individual consumer's experience of tourism products? By being able to "walk through" or otherwise experience a more complete model of a destination for example before purchasing accommodation and/or tours surely the potential consumer would be able to gather more information than is available through 2-D photographs and the like. On this question Prideaux (2002) notes that, in an increasingly affluent world the pressure of numbers of tourists on particular environments may in fact encourage tourists to begin to demand this alternation between real and cyberspace experiences in a much more systematic way than at present. In other words, the use of virtual reality in tourism may be in fact more likely as a replacement for *travel* than as a more sophisticated tool for marketing destinations, under pressure from external factors like conservation of the environment. Thus while for some "tourists" the increasing possibility of becoming a voyeur in a personalized and private cyber-world may be strong (Williams & Hobson, 1995), for a greater number the chance to visit an otherwise *unattainable* location may be paramount in their decision to make use of such technologies in the future.

Nevertheless, VR has been a buzzword for over ten years now, and despite widely available VR imaging technologies such as QuickTime, Java, and other authoring tools, widespread use of the medium remains elusive in the tourism industry. In the next section we define virtual reality as it is currently used with respect to human experience of environments, and describe some of the tools for constructing such virtual realities that presently exist or may be developed in the near future to enhance the tourism experience.

The Nature of Virtual Reality

Virtual reality is exactly that, a computer generated environment that seems real to the user (HarperCollins, 1996). Extensively used in computer gaming software, with increasing levels of “reality” as computing power has evolved, in the business world educational/instruction virtual reality-based tools are moving from highly specialized uses such as flight simulations to building business skills for sales and call centre reps and enhancing coaching and leadership skills for managers and executives. The use of simulations through immersion in virtual realities increases the efficacy of online teaching as much as 75% by involving employees for example in virtual job situations in which they gain experience without the risk of making mistakes (Psotka, 1995). Equally, IMAX and other large-format immersive experiences, from a realistic 360° panorama of objects and landscapes to a flythrough of an interactive virtual world on the Internet, aim to stimulate the senses of the user to get them as close to the real world as possible, virtually.

Alternatively known as Immersive Media (Bitgood, 1990; Psotka, 1995), virtual reality also can be used as a component of e-brochures, e-catalogues, Web sites, and other interactive presentations to provide a realistic look and feel of consumer products, hotels, cars, real estate, or other facilities. In addition, technologies such as *Immersive Television* that can engender in view-

ers a “sense of being there” in depicted scenes and 3D broadcast experiences may be widely available to the consumer in less than 10 years time. Immersive imaging is a technology that lets users experience 3D photographic scenes as if they were really there.

There are two types of immersive images that may be used for tourism experience and marketing purposes: panoramas and objects. *Panorama* (panospheric—panographic) type images are 360 degree views that allow users to look up and down, turn around, and zoom in to see the detail, or zoom out for a broader view. These are photographic images, presented in a software “player” that permits navigation on each of the x, y, & z axes. Multiple, overlapping images are stitched together with software tools and photos are taken using special tripod attachments or the multiple image features of digital camera software. As users change the view of a scene the correct perspective is maintained, giving the ability to look around just as in real life. Panorama images are currently used to provide realistic views and walk-throughs of real estate, outdoor scenes, and hotel resorts. Figure 1 is a 2-D static representation of a 360 degree panorama by Spinning-Eye, a specialist VR imaging company that can be experienced as 3-D on the Internet. Many other tourism and hospitality examples may be found on the Internet sites.

Object imagery on the other hand allows users to “pick up” and view an item from all sides using software tools. Its uses include being able to look more closely at consumer products, fashion, automobiles, and heritage items as if the consumer was really handling or otherwise experiencing them physically, and this applies as much to the tourism facility (from airplane seats through attractions) as it does to any other item. Virtual manipulation of, to the observer, an apparently physical object has immediately obvious uses in heritage and cultural tourism for example, while its combination with panoramas would allow

Figure 1. Panoramic view of a hotel room (Courtesy of Jens Look, Spinning Eye)

much richer sampling of potential environments before purchase of the “trip.”

Digital Preservation, Digital Visitation

For those lacking the desire or money to travel, or where there are restrictions on travel for environmental or political reasons, a virtual destination could provide an acceptable substitute for actual visitation (Sung, Lee, Kim, Kwon, & Jang, 2000). This may be especially so where the tourist’s desire is actually for re-creation of history or heritage rather than in visiting the current physical remains of a past culture. Virtual reality special effects are already being used to great effect in the television documentary format and in “epic” film making such as the Lord of the Rings film trilogy, and these will ultimately allow the virtual tourist to visit a site during different (re-created) stages in its history. Along with this opportunity virtual guides or “avatars” also are available to provide expert commentary and feedback in a number of languages, a service that can be quite costly to provide in the real world (Weaver & Lawton, 2002). An important example of the use of this technology is the World Heritage Preservation Project, initiated by UNESCO in 2001, and designed to ultimately provide panoramic VR tours through the creation of a documentary image bank of panoramic pictures and virtual reality films

for all sites registered as World Heritage by the United Nations Educational, Scientific and Cultural Organization (<http://www.world-heritage-tour.org/list.html>, 2005). At the time of writing, a *virtual* tourist can visit World Heritage Sites in Afghanistan, Bangladesh, Eastern Canada, China, Cambodia, Egypt, India, Indonesia, Iran, Korea, Laos, Malaysia, Nepal, Pakistan, Sri Lanka, Thailand, The Philippines, and Vietnam. This represents 15% of all 812 such sites, and covers 125 sites in 700+ panoramographies, a number of which are of sites that are in areas of political tension (for example in Sri Lanka, Afghanistan).

Is the Potential of VR for Tourism Going to be Realized in the Near Future?

From this brief discussion it is readily apparent that imaging technology (the creation of virtual realities) could be of assistance in the marketing of tourism products to the internet consumer and/or the consumer interested in historical/heritage sites, but has not been taken up in any significant way as yet. The prevailing view amongst developers and users of existing VR technology is that it is ideally suited for these tasks because it is immersive, compelling, and the consumer is in control, even though it remains underutilized by the industry and consumers. To examine possible industry-based reasons for this situation an

online survey of VR imaging professionals was undertaken in late 2005. The respondents were sourced from professional mailing lists and user groups available to the authors, and the data was collected using an open source survey tool. The respondents represent a small but fairly representative sample of the major players in this field; however care should be taken in generalizing from the results as no corresponding survey of either tourism marketers or of the use of VR technology by tourists themselves has been undertaken at this stage.

Results of the Industry Survey

The aim of the survey was to determine how easy it is to produce VR images of tourist destination and heritage items, to determine if the technology, expertise, and knowledge required was a real barrier to its wider use and adoption in tourism marketing, or is the real reason for underutilization something else entirely? Our respondents (n

= 80) were ICT professionals, with 57% having been in this industry for four or more years, and 86% for more than two years (Figure 2). Respondents self proclaimed status in the industry with respect to their expertise in VR simulations was expert (25%), advanced but not yet expert (45%), intermediate (19%) and novice (11%—Figure 3). Of the respondents, 86% produce VR images professionally, and 65% have produced VR images for tourism marketing purposes. Overwhelmingly however, 80% of respondents said that it was still difficult to produce such images and required specialist knowledge, equipment and expertise, but 92% believed that they were more effective than normal photographic images, and 80% believed that VR is more popular now than before in the industry. We also asked if they thought that consumers “enjoy” using VR imaging and if VR images more effectively promote tourism products than regular images. Again, over 90% of respondents thought this was true in both cases given their intimate contact with the tour-

Figure 2. ICT Industry experience of respondents

Figure 3. Expertise status of respondents

Virtual Reality Mapping Revisited

ism industry. The key issues for the respondents with respect to the further development of VR technologies for tourism came down to the following (Figure 4):

- Tourism operators are not aware of the technology.
- If they are aware, they believe it is very expensive at this time.
- Many Web designers also are not aware of the technology.
- If they are, they are reluctant to engage a specialist to translate their needs into suitable presentations.
- File size and download time remain a real concern (despite increasing broadband use).
- There is a prevailing fear that readily available browser software will not be capable of displaying the image.
- There is no “easy to use” software for potential consumers.

Until these concerns can be overcome, either through overwhelming user demand or through the advent of even newer technologies, the VR professionals surveyed concluded that there will be a continuing resistance to the use of 3D virtual reality techniques in tourism marketing. Instead,

the current 2D enhanced methods will remain the standard at least for the short term future (to 5 years). The reason for this is the prevailing opinion amongst the professionals that while VR imaging and tourism appear to be a great fit, this is only really true in the context of skilled Web or multimedia advertising and promotion. Their view is that at the present stage of development a quality photograph is more usable, can be produced by far more people, can be used in both printed and Web-based media with little or no specialized training, and can be accurately judged for quality by tourism marketing professionals and the public in real time. Video and VR is presently restricted to knowledgeable producers and developers and used in Web, CD, or trade-show kiosk delivery. In these contexts VR is easier and cheaper to produce than a promotional video, but still more difficult than traditional photography. It will only be when the cost and quality of VR imagery is close to that found in computer-based gaming that the tourism marketer and the tourist will consider the technique as having more than just novelty value, except perhaps for its uses in the heritage preservation field as outlined above.

In summary, the VR production industry appears to believe that tourism marketers are either not aware of the possibilities of this new technique for promotion, or that these are seen

Figure 4. Issues in the further development of VR technologies for tourism

by the tourism industry as being just a different format of photography that costs more and doesn't dramatically improve public perception or use of the end product. Alternatively, it may be that the key problem is in fact that VR producers themselves do not know how to market their services to the tourism marketing and promotional people, and this problem itself ultimately reflects on the current low acceptance of VR for tourism promotion.

CONCLUSION

This chapter undertook a brief overview of the available technologies and opportunities for the use of virtual reality in tourism marketing. It acknowledged that in almost all formulations of the tourism marketing model to date much has been made of the notion that tourism is unique because production and consumption occur not only at the same time but in the same place, and therefore that location or proximity is often *the* critical determinant of the take-up of tourism opportunities (e.g., Weaver & Lawson, 2002, pp. 222-223). But it then posited the question: what if the place variable could be removed from this equation through the further development of virtual reality techniques? The impacts of this possibility have been seen to include: less requirement for travel per se (perhaps); better and more real information about the physical actuality of a destination for the potential consumer (likely); price and service quality information very much simplified and improved (definitely), and changed tourism promotion strategies (undoubtedly). At the barest minimum, the uncertainties involved in relying on unverified 2D or text-based information for tourism travel decision-making could be considerably reduced using VR techniques.

Many educationalists and psychologists have noted that effective learning in human beings is closely associated with experiencing and therefore comprehending in a more structured way

something that they have never seen before, or is dependent on being exposed to new and usable information that adds to and/or refines their existing knowledge base (summarized by Schwier, 1995, and many others). From these discussions certain general conclusions can be drawn about the likely responses of the tourist to virtual reality immersion environments. The most general one is that such users will notice and use the same way specific environmental features as clues to understanding and perhaps action on entering a new virtual space, just as they do in real space. For virtual reality tourism marketing to succeed then, authentic reproduction of a given environment (or as close as it is possible to get to it given available technology and funds) is required to convey the all-important sense of place. Secondly, the inclusion of accurate renditions of artifacts and action elements from the actual places being recreated (i.e., walk through and similar renditions) is essential to the creation of effective immersion environments. Despite the technical difficulties in doing this, and the expense of current versions of software and hardware, these criteria can now be fulfilled according to the VR professionals we surveyed for this discussion, so the use of virtual reality simulations of real places in order to provide either extra pre-travel information, or ultimately perhaps to replace travel entirely is now possible.

For the future, the VR industry is apparently much more excited about the possibilities inherent in these emerging technologies than the tourism and hospitality industry. Therefore it will require consumers (tourists) and their agents to reach the same level of understanding before their use will become ubiquitous throughout the tourism industry. At the very least however these technologies now support the creation of a documentary and educational image bank of panoraphies (online virtual tours) for all sites registered as World Heritage by United Nations Educational, Scientific and Cultural Organization (UNESCO) and for hotel marketing, etc, thus enabling tour-

ists and other users to visit and learn about such facilities and sites before actual travel or indeed to replace travel entirely. The availability in the future of more and more powerful and cheaper recording and display facilities for virtual tourism, ultimately in the form of personalized ubiquitous devices (Hoshino, 2005) that also provide GIS, travel information, and interpretation of language and artifacts (heritage archives and tourist attractions) in real time will allow the tourist the freedom to choose between a virtual reality experience and/or actual physical presence in that environment at will.

Chapter 3.46

USE IT to Create Patient–Relation Management for Multiple Sclerosis Patients

Margreet B. Michel-Verkerke

Ton A. M. Spil

University of Twente, The Netherlands

ABSTRACT

Patients with multiple sclerosis (MS) visit various healthcare providers during the course of their disease. It was suggested that information and communication technology might help to orchestrate their care provision. We have applied the USE IT tool to get insight in the relevant problems, solutions, and constraints of MS care both in the organizational and the information-technological area. There is hardly a chain of healthcare, but rather, a network in which informal communication plays an important role. This informal network worked reasonably effective, but it was inefficient and slow. The MS patient count is small for most care providers. Patients thought that a

lack of experience caused their major problems: insufficient and inadequate care. To improve care, we proposed a solution that combines an MS protocol, the introduction of a central coordinator of care and a patient-relation management (PRM) system. This is a simple Web-based application based on an agreement by the caregivers that supports routing, tracking, and tracing for an MS patient and supplies the caregivers with professional guidelines. It is likely that we would have suggested a far more complicated ICT solution if we had only analyzed the MS care process as such without specific consideration of the dimensions in the USE IT tool.

INTRODUCTION

Research in human-computer interaction (HCI) has been spectacularly successful, and has fundamentally changed computing (Myers, 1998). The adoption of information technology has changed less dramatically and is a major problem in healthcare today (Berg, 2001). The HCI community has tended to portray the average user as someone who knows how to deal with IT and who willingly participates in this interaction (Marsden & Hollnagel, 1996). The average user does not exist in healthcare, they range from laggards to innovators (Rogers, 1995), and most times HCI is designed to address the innovators (Spil, Schuring, & Michel-Verkerke, 2004). This means that highly complex systems are designed that have to be used by people that have limited capacity to deal with computers. Interaction design, a newly coined discipline (Coiera, 2003), believes that information-systems design should include the people who will use them. We developed an interview model, called USE IT, that includes the end user in the IS design process by determining his or her user characteristics before the actual system design process starts.

In this article, the USE IT model (Spil et al., 2004) is applied to define what use of information and communication technology would support healthcare professionals in providing care to patients suffering from multiple sclerosis (MS). Two aspects of the relation between technology and humans will be discussed in this research: first, technology partly replacing human interaction, and second, factors that influence the success of human interaction with technology in respect to actual use.

The next section describes what problems in the MS healthcare chain motivated us to conduct the research. Then, it is discussed why the USE IT model is the appropriate methodology for this research. The complete research design is given next. After that, the results of the case study are

presented. The discussion of the findings will then lead to the presentation of patient-relation management (PRM) as a solution for the problem. In the last section, overall conclusions will be drawn.

BACKGROUND AND MOTIVATION

A rehabilitation hospital asked us to study the healthcare chain of MS in a Dutch region that serves about 500 MS patients and includes three large hospitals (with a total of about 1,800 beds) in order to know what ICT solution could improve MS care. In this research, a healthcare chain is defined as follows: The healthcare chain is constituted of all care providers involved in the care for a particular group of patients (Michel-Verkerke, Schuring, Spil, & Hummel, 2003). In the ideal situation, a healthcare chain is designed and implemented and is not a randomly originated collection of care providers. To make a healthcare chain a chain, the care providers should be linked by binding engagements concerning the care to provide to the particular patient group. These engagements comprise agreement on (1) what care should be provided by whom in what way for how long in what place, (2) how and when patients are transferred from one care provider to another, and (3) how patient information is communicated. Since healthcare is organized in a functional way (i.e., wards and practices are grouped by the profession or specialty of the care provider) and not in a process-oriented or product-oriented way, it is hard to organize and implement healthcare chains cross-organizationally (i.e., across the healthcare institutions). For the same reason, and because the level of ICT resources in healthcare is low, none of the participants used an electronic patient record (EPR). Many healthcare professionals consider implementing a cross-organizational EPR to support the care processes in a healthcare chain to be utopian at this moment. Still, a strong desire

to improve MS care and the awareness of the potential benefits of the use of ICT in healthcare were the motivation to start this research.

The challenge of this research project was to find a solution that on the one hand is locally, practically applicable, and that on the other hand can serve as a base for a more general, broader solution like an EPR. Since it was not clear to what kind of ICT solution the research would lead, the second challenge was to find an appropriate methodology to perform the research. As will be explained in the next section, we considered a methodology for requirements analysis not adequate to comply with the explorative aspects of our research. Based on the results of a previous research, we decided to use this research to investigate whether the USE IT methodology, developed from an evaluation study on IS success, is also suitable for reveal-

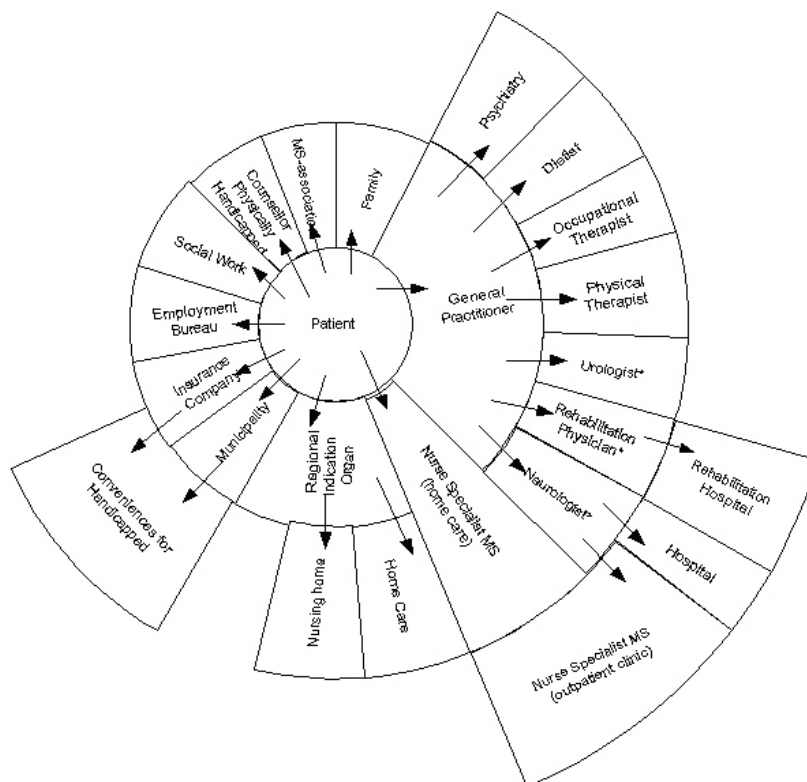

ing the factors that determine IS success in this particular case (Spil et al., 2004).

MULTIPLE SCLEROSIS

MS is a disease that affects the central nervous system. Due to causes that are not entirely understood, the sheaths of the nerves change, which reduces the ability to transmit signals. Patients may suffer from tiredness, have difficulty moving, and may have reduced sight and a range of other problems. There is no cure available for MS; treatment may be able to relieve the patients' symptoms, and by that extend the period that the patient is able to function independently.

Patients with multiple sclerosis visit various healthcare providers during the course of their disease. A general practitioner (GP) might be

Figure 1. The formal referral model of the MS health-care chain

their first contact, but, as the disease progresses, a neurologist, urologist, rehabilitation hospital, home care, home adaptation, and many other types of support are normally needed. In a perfect world, all these types of care are delivered in an orchestrated way. However, reality is different. Each care provider uses his or her own patient records and working method. The patient needs to be self-managing. Based on the formal documents we studied, we were able to model the formal referral model through the MS chain (see Figure 1; Michel-Verkerke, Schuring, Spil et al., 2003).

Referral takes place from the inside to the outside. The patient does not need any official referral to go to the GP, regional indication office (RIO), municipality, insurance company, employment bureau, social worker, counselor, or the MS association. The RIO is an organ independent of healthcare organizations subsidized by the local municipality. Its task is to indicate and allocate home care, or admission to a nursing home or old-people's home. Adapted conveniences are available through the healthcare insurance company or the municipality, that is, the Dutch Wet Voorzieningen Gehandicaptten (WVG) authority, which can be translated as law facilities for the handicapped.

The RIO decides on admission to a nursing home or whether the patient is eligible for home care. The latter may concern nursing or general care. Advice, information, or instruction by home care is available without intervention of the primary physician or the RIO. This is the type of home care that is given by a nurse specialist who is specialized in MS patients. Referral by the GP is needed to get access to treatment by other

physicians or paramedics. The asterisks in the boxes for the physicians indicate that physicians may generate referrals to the same paramedical healthcare workers as the GP. The rehabilitation physician serves as the gate to other healthcare providers in the rehabilitation hospital. The neurologist decides on admission to the hospital and is also the person who refers to a nursing specialist in the outpatient clinic. In one part of the area that was studied, these two specialized nurses are in fact the same person.

METHODOLOGY

As was stated in the introduction, the attitude of healthcare professionals toward the use of computers varies as viewpoints from innovators to laggards (Rogers, 1995). Because of this, the actual use of available computers cannot be taken for granted, and we consider an information system only successful when it is actually used in practice as part of the care process. In order to discover what factors make care providers use an information system, we reviewed papers on tools to reveal the user's requirements or tools to stimulate user participation in the development of information systems in healthcare that have been published in the previous years (e.g., Beuscart-Zépher, Anceaux, Crinquette, & Renard, 2001; Brender & McNair, 2001; Meijden, Tange, Troost, & Hasman, 2001; Staccini, Joubert, Quaranta, Fieschi, & Fieschi, 2001). These tools usually focus on a fit between the developed system and the user on one aspect of innovation diffusion. The USE IT tool is built on a large number of such publications

Table 1. The USE IT model (Michel-Verkerke, Schuring, & Spil, 2003)

USE IT-model	<i>User Domain</i>	<i>Information Technology Domain</i>
<i>Product</i>	Relevance	Requirements
<i>Process</i>	Resistance	Resources

and helps to get insight in the nature and relevance of problems and of possible solutions, and thus considers all of the above-mentioned aspects of the problem. It considers constraints and prerequisites, which are particularly relevant when resources are limited and choices have to be made as to which problems will be solved and which will not. The USE IT tool also demonstrates that the requirements determinant is not the only determinant of user adoption. Proposed solutions that come to mind after the analysis can be organizational changes, IT-related changes, or both.

USE IT Methodology: Overview

First, we present the dimensions of the USE IT model — the innovation dimension and the domain dimension — to predict and evaluate the innovation and diffusion of information systems. They

make four determinants for success: relevance, requirements, resistance, and resources (Rogers, 1995; Spil et al., 2004).

With the process, the innovation process is meant, similar to the process defined by Saarinen and Sääksjärvi (1992) and the innovation process structure of Larsen (1998). The product is the result of this innovation process. This corresponds with the definition of the product by Saarinen and Sääksjärvi, and the artifact structure in the framework of Larsen. Also, the IT domain is part of the artifact structure; the user domain represents the organizational structure in Larsen’s framework. The time horizon structure can be part of the requirements, and the knowledge structure can be considered as an element of the resources.

Table 2 shows the determinants with their subdeterminants. Every determinant comprises two levels: the macrolevel and the microlevel. The

Table 2. The USE IT determinants based on Michel-Verkerke, Schuring, and Spil (2003)

Determinant	Sub-determinants
Relevance	Macro-relevance: Economic improvements Social improvements Functional improvements Saving time and effort Micro-relevance: Solve here-and-now problems Compatibility with working process
Resistance	Macro-resistance: Lack of opportunity to change Micro-resistance: Inability to change Bad attitude
Requirements	Macro-requirements: Strategic general requirements Tactical approach Micro-requirements: Functional Performance requirements
Resources	Material: Hardware & Software Time Money Immaterial: Adaptability Capabilities Reliability

macrolevel represents a general perspective, for example, the organizational level. The microlevel refers to the individual user.

The relevance determinant is defined by Schuring and Spil (2003) as “the degree to which the user expects that the IT-system will solve his [or her] problems or help to realize his [or her] actually relevant goals.” The word *expects* expresses that relevance is a factor that is important in the course of the adoption process, not only in evaluation. The word *actually* is crucial in view of relevance. Relevance is not to be confused with the degree to which the user considers outcomes as being positive. The set of outcome dimensions that someone considers positive is larger than the set of outcome dimensions that are relevant. Imagine a physician who basically considers IT outcomes of a computer decision-support system, such as for assistance in diagnosis, disease prevention, or for the more appropriate dosing of drugs, as positive. This does not automatically imply that the IT adoption is relevant to him; it is only relevant if these dimensions are high on his goal agenda.

Relevance defined in this way comprises relative advantage (Rogers, 1995), net benefits (DeLone & McLean, 2002), perceived usefulness (Davis, 1989), and job relevance (Chismar & Wiley-Patton, 2003). It results in task support satisfaction, which is a criterion for user satisfaction (Garrity & Sanders, 1998).

In their study on the implementation of an electronic prescription system, Spil et al. (2004) found that a lack of relevance was the major determinant that explained the failure of the implementation.

Resistance is the personal attitude of all stakeholder groups toward the introduction of an information system (Spil, 2003). The main IS quality aspect of resistance is the attitude and the willingness to change. Pare and Elam (1999) also focus on the attitude of the professional when they assess clinical information systems. The end users have an important role because their

norms and values determine the effectiveness of the information system. Resistance was found to be the cumulative effect of the other three determinants (Spil et al., 2004).

The expectance of reduced quality in work-life satisfaction, high complexity, and the lack of trialability can result in resistance (Garrity & Sanders, 1998; Rogers, 1995). Observability reduces resistance (Rogers). Offenbeek and Koopman (1996) connect people with resistance potential because they can feel that the quality of their working life will be decreased. Mumford (1995) observed that user participation contributes to effective organizational change. Wissemma (1987) defines resistance as willingness to change and the difference between results and expectations.

Resources are defined as the degree to which material and immaterial goods are available to design, operate, and maintain the information system (Spil & Schuring, 2003). The main focus of the determinant resources will be on the people and on the costs these people cause. Next to that, the reliability of the information technology and the information systems are considered. Resources defined in this way refer to service and system quality (DeLone & McLean, 2002), management support, and mature IS functions (Saarinen & Sääksjärvi, 1992). Resources (human, physical, and monetary components; Ansoff, 1965) are needed to implement the new information system into the organization. The human resources can be insufficient both in time and in experience (risk of technology). Insufficient material resources (Offenbeek & Koopman, 1996) will have a limiting influence on the other three risk domains.

The requirements determinant evaluates the meaning of the information system. Requirements are defined as the degree to which the user is satisfied with the product quality of the innovation (Spil & Schuring, 2003). This includes such aspects as the functional capability, ease of start-up, and ease of use. Meeting the end user’s requirements results in high information quality, high system quality (DeLone & McLean, 2002), high interface

satisfaction (Garrity & Sanders, 1998), and high compatibility (Rogers, 1995).

USE IT Methodology: Strategy

To measure the determinants, the USE IT tool consists of structured interviews. In this way, more precise insight can be obtained in the nature and relevance of problems and solutions before implementation, and this insight can be tested with the same tool during the evaluation of the implementation. For the interviews with patients, we used a much shorter questionnaire, which is listed in Table 3.

RESEARCH DESIGN

From the literature review, it can be learned that the successful implementation of an information system depends on the degree to which the characteristics of the intended end users — being relevance, requirements, resistance, and resources — are taken into consideration. This knowledge, together with the purpose of the research as described earlier, leads to the formulation of the following research questions:

1. In what way does an improvement of the information services in the healthcare chain contribute to the improvement of the

quality of care for patients with multiple sclerosis?

2. What should a solution look like that solves the local problem, but that also aligns with knowledge and standards on EPR and serves as a first step or building block of an EPR?
3. What user characteristics of care providers will influence the successful implementation of a proposed solution?
4. Is the USE IT tool an adequate tool to reveal these user characteristics?

So, could ICT help to coordinate the work flow for MS patients, and does the USE IT tool help to find out?

At the start of the research project, a workshop was organized to generate commitment for the research. Of each institution or profession involved with MS care in the region, those care providers with a special interest in treating MS and who were actually involved in providing care to MS patients were invited to be interviewed. This resulted in 17 USE IT interviews. Each interview took about one and one-half hours. Table 4 gives an overview of the categories of interview questions. Table 5 shows the professions and institutions of the interviewees.

Also, 6 of the approximately 500 patients were interviewed to get an impression of how they experienced the provided care (see Table 3).

Table 3. The USE IT interview protocol for patients

MS-patient (Pat.)	
Pat.1	Would you be so kind to describe the course of your illness to me, and especially your route through healthcare?
Pat.2	What care do you receive at the moment?
Pat.3	Do you experience bottlenecks in the care delivered?
Pat.4	What role does MS play in your life?
Pat.5	How do you experience the cooperation between care providers or institutions?
Pat.6	How do you experience the supply of information on MS?
Pat.7	How do you experience the way care providers deal with the information about you?

Nursing-home	Medical doctor	1
Social Pedagogic Service	Counselor Physically Handicapped	1

These interviews took about one hour. A report was made of each interview and all reports were analyzed. The results are presented in the next section.

RESULTS

Studying the communication patterns, as reported by the care providers in the interviews, showed the lack of orchestration of patient flow or work flow in MS care. Actual communication between

care providers does not at all match the formal referral pattern. Depicting the actual communication on Figure 1 would give a tangle of dozens of arrows. Table 6 is a cross-table of information flows between the parties involved. From this, it can be learned that there is hardly a chain of healthcare; rather, a complex network with many cross-relations exists.

The two coordination mechanisms that could be found were the official referral system and informal communication (mutual adjustment; Mintzberg, 1979). Formal communication did

not suffice for two reasons: Not all information needs were covered and the GP cannot fulfill his or her formal role as central coordinator of care because he or she is too busy with other tasks. The informal network between care providers seemed reasonably effective, but also inefficient and often slow. Within this network, we found

handovers between caregivers that were executed by the patient. Six care providers indicated that the patient is the major source of information. A survey of the care provided and the progress of the care process was missed by both patient and care provider. Electronic records, when in use, only contain administrative information. Care-

related information was only recorded in local paper patient records.

It is not a great surprise that patients and caregivers sometimes get lost or stuck in the jumble of MS care, although patients felt these problems to a lesser extent than caregivers. All in all, patients seemed satisfied about the provided care, although they consider it very fatiguing to arrange new facilities or access new caregivers since a very proactive role of the patient is necessary; the patient needs to be his or her own case manager. This is especially bothersome because MS patients get less energetic when the disease develops. The patients had little complaints about the low level of contacts that have been noticed to exist between caregivers. The relation with each caregiver may continue for years, so, they saw little need for intensive contact between these caregivers. Table 7 gives an overview of the bottlenecks and disturbances as reported by care providers.

The USE IT interviews also made clear that MS care is not very relevant for most care providers. That is to say, caregivers have high compassion toward MS patients, but most caregivers only occasionally saw MS patients. The only notable

exceptions to this were the specialized MS nurse and some of the caregivers in the rehabilitation hospital. But even in this group, the maximum percentage of patient time spent on MS patients does not exceed 40%. The neurologist in the largest hospital in the area is specialized in MS. However, also for him, MS patients create just above 10% of his work.

Because of this infrequent contact with MS patients, the knowledge of caregivers about MS care seemed to be lacking at times. All interviewed patients said this lack of knowledge was the cause of one of the major problems they reported: incidents of insufficient and inadequate care. It should be noted that none of the care providers mentioned this theme. Not all healthcare providers were aware of the service that other caregivers could provide in general and do provide for a specific patient. Another consequence of the rather low prevalence of multiple sclerosis is a lack of knowledge present at the municipality, RIO, and insurance companies about the urge and specifications of needed conveniences.

The low relevance of MS care for care providers also caused resistance toward a specific solution for MS care. Care providers feared the

Table 7. Bottlenecks and disturbances (care providers)

Bottlenecks and disturbances	Total
Waiting-lists for conveniences, nursing home and psychologist	9
Coordination, communication, working according to plan	9
Double work, fragmentation and lack of survey, due to lack of coordination	5
Care providers do not know each others possibilities in care	5
Care providers do not know about each others progress according to the patient	5
Limited time for providing care	4
Insurance companies, municipality and GP are unfamiliar with MS	3
Care provider only listens to the patient and ignores advise of other care providers	3
The patient does not have survey of who is treating him	2
The MS-association behaves as being a professional care provider	2
Patients wait too long before requesting a convenience	2
General Practitioner should be coordinator, not just referrer	2

situation where each patient group has its own computer-based record. They feared to be loaded with separate solutions for every separate chronic disease. Little or no resistance toward the use of ICT as such is reported. The reported lack of time to provide proper care and long waiting lists for nursing homes are general healthcare problems and not specific to MS care.

DISCUSSION

The interview results clearly show that formal referral is not the backbone of the healthcare chain, and the GP and neurologist do not play a central role in MS care. Since referrals not only comprise the transfer of the patient to another care provider but also the transfer of the patient data, the failure of the formal referral tree has major consequences for the transfer of patient information. The many communications between care providers proved to be a very inefficient and slow compensation for the lack of information flow through the healthcare chain. The hampering information flow caused a reduced quality of provided care: The patients do not receive all the care they need at the moment they need it. This leads to the answer of the first research question: To improve the quality of care for MS patients, the information services should be improved in such a way that all care providers have all relevant patient data available at the time they see the patient, know what care is provided already, and know what care they themselves should provide to the patient. They also need to know to whom they should or could refer the patient when he or she has finished treatment. This means that the information services should support the transfer of relevant patient data, provide relevant up-to-date medical knowledge about MS to each care provider, and expose knowledge about the structure of the MS healthcare chain.

The interview data did not result in a straightforward answer to the second research question;

that is, they did not give a clear design of the best solution, but they gave the constraints and prerequisites that have to be taken into account when designing a solution. These constraints and prerequisites follow from the user characteristics as described in the results: the low relevance of MS care and low resistance to ICT, but high resistance to a specific solution, little resources, and a desire for good coordinated care and good communication. This means that a solution to the problems in MS care has to meet the following constraints: (1) There is no isolated solution for MS care as a specific solution must be expandable for other diseases, (2) implementation and maintenance must take very little effort and costs, and (3) the solution must adhere to the present conditions. Since the future users of the solution can be characterized as care providers with little to no resistance to the use of ICT as such and in favor of innovations as long as it is clear what benefits these will bring to the patient, the implementation of a solution that meets the constraints and prerequisites can be expected to be successful. What this solution could look like is further described in the next section.

The USE IT tool proved to be very helpful in revealing the user characteristics. The interviewed care providers appreciated the chance to express themselves, but at the same time, the interview questions did not provoke the interviewees to exaggerate or to trivialize. Information on all determinants was gained, but before designing an information system, a requirements analysis on a detailed level should be performed.

PATIENT-RELATION MANAGEMENT

The discussion of the results revealed the objectives a solution has to achieve. First of all, care for MS patients must be orchestrated in order to improve the flow of patients and related information through the healthcare chain. The second purpose of the solution is to raise the level of

knowledge about MS, its treatment, and the way MS care is organized. To accomplish these results, it is crucial that care providers actually use the solution and comply to the agreed way to provide care to patients with multiple sclerosis.

Several interviewed caregivers considered a regional cross-functional and cross-organizational EPR as the solution to the problems in MS care; however, many did not consider this a realistic solution since no regional electronic patient record or likewise ICT facility that could serve as a basis for a solution existed in the area studied. The main benefits of an EPR would be to know who is involved with what patient and to have access to the necessary information without being dependent of other caregivers such as the GP as “a pass-on desk” of information. An EPR could help to make clear amongst care providers what each of them does for an individual patient. However, both the realization and the use of a regional EPR for all patients (not just people suffering of MS) and all care providers (not just involved in MS care) demand much more effort, time, and expenses than is available for improving MS care. Also, the fact that MS patients make up a small percentage of the total patient population for most healthcare professionals is unaffected. As a consequence, patients will retain the problem that healthcare providers do not give adequate care, and they are unsure that referral patterns will improve.

That is why we suggest a solution that combines three elements. First, we suggest the orchestration of MS care by an MS protocol that lists the options of care that each of the care providers offers, and in which an agreement is accomplished about the routing of a patient through the healthcare chain when the patient is diagnosed as having MS.

Second, we suggest that the nurse specialist should play a central role as coordinator of care. But to fulfill this coordinating role, support is needed. So, the third element is to build a patient-relation management system. Since almost all care providers had (or would have in short notice) access

to e-mail or the Internet, this PRM will consist of a Web-based patient-routing system based on an agreement of the caregivers in the region on patient flow (cf the MS protocol). When a patient is reported to the system, a message will be sent automatically to those caregivers that should be informed. The information in the system comprises the names of the reported patients, the names and functions of the caregivers that are or have been involved with the treatment of the patient, and the likely next steps (of caregivers) in the treatment. PRM does not substitute the patient records from the various caregivers. PRM also does not contain any medical data of the patient in its simplest version, but it could be considered to expand PRM with two options: (1) composing structured notes about the patient contacts, and (2) composing referral or transfer letters or messages. Both options are meant to support the information flow through the healthcare chain. The composed notes and messages should be structured and standardized, for example, by using HL7, in such a way that they can be received and processed by linked healthcare information systems, like a hospital information system (HIS) and EPR. The system is accessible via a Web site that contains general information on MS and medical guidelines for caregivers.

PRM is based on both work-flow management and customer-relationship management (CRM). The MS protocol is incorporated in PRM and serves as the work-flow definition (Reijers, 2003). In this way, PRM steers the care processes; care providers are alerted when a patient is referred to them, and are advised to whom they should refer the patient. In this way, PRM acts as a work-flow management system (WfMS): PRM “delivers the right piece of work to the right resource at the right time” (Reijers, 2003). Since care providers have their professional responsibilities, they are free to ignore the given advice. PRM users can also track and trace the patient’s contacts with healthcare professionals. Although PRM lightens the task of the coordinator of care, a human coordinator

is still required to evaluate and to update the MS protocol and the system.

Improving communication and cooperation in healthcare by linking care providers of different professions can cause communication problems of a different nature. Each profession uses its own terminology, and the same terms can have different meanings and trigger different actions. Although the care providers only mentioned the lack of communication and information and did not complain about misinterpretation of information, the risk of semantic problems is real when human communication is partly replaced by information systems, especially when information systems are linked to create a WfMS (Cardoso & Sheth, 2003). When creating PRM, it is important to manage the risk of semantic heterogeneity from the start, that is, at the compilation of the MS protocol. All professional terms and actions should be clearly defined and agreed upon by the participating care providers. Using a standard like HL7 when designing and implementing PRM can be very helpful to prevent semantic problems.

The CRM aspect of PRM helps to create an overview of the nature and progress of patient contacts (Peppers & Rogers, 1999; Scheers, 2001). In contrast to the application of CRM in commerce, PRM is not intended to raise the number of client (i.e., patient) contacts, but to raise the satisfaction of the client and the efficiency and effectiveness of the patient contacts. PRM supplies the patient and care provider with a survey of patient contacts that occurred, and the option of making notes can serve as a record of agreed arrangements and actions. The information in PRM can also be used to evaluate the MS protocol and PRM.

PRM supports the organizational solution of the main problem of the caregivers by making the agreed guidelines and patient flow available and easy to maintain, and enriching it with knowledge caregivers need. They know to whom they should refer the patient and which caregivers can be asked for more information about the patient. From the USE IT model, we can learn

that an information system is only actually used when it is relevant to the end users. The interview results showed us that relevance for a specific MS solution is low and any solution will only be used when use takes little effort. The motivation to use PRM originates from the high compassion care providers have with patients suffering from MS and their desire to provide good care. We expect that the effort to report a patient to the system is rewarded by the more efficient communication that results and the information the caregiver can retrieve about the treatment of the patient. Many caregivers who seldom see an MS patient lack this knowledge.

Eventually, PRM could serve as a first step to accomplish a cross-functional, cross-organizational regional EPR. During the interviews, it became clear that other chronic diseases have similar problems (Michel-Verkerke, Schuring, & Harten, 2003). So, PRM could be expanded to healthcare chains for other chronic diseases.

To be a building block of an EPR, PRM must be designed and built according to international standards. Its architecture has to be open and transparent to make linking possible to different information systems, such as an EPR or an HIS in a different institution. Since PRM contains information of patients and caregivers, security is important and should conform to the security code for healthcare.

A major advantage of PRM is that it is a simple, inexpensive solution to actual problems experienced by local caregivers that does not create a new island of automation. Neither does PRM prohibit the development and implementation of an EPR. On the contrary, we think that PRM can pave the way. The success of an EPR is determined by several conditions. When looking at physicians, an EPR has to meet three requirements to be successful: (1) The EPR must expose all relevant data and functions anywhere and anytime, (2) using the EPR must be compatible with the medical process of each individual physician, and (3) the EPR must allow different levels

of authorization to protect professional autonomy (Michel-Verkerke, 2003). According to several authors, an EPR should also contain active elements (Dick, Steen, & Detmer, 1997; Ginneken & Moorman, 1997). To meet these four criteria of success, an EPR must cross the borders of its orientation (Michel-Verkerke & Spil, 2002). The importance of a well-designed architecture and the use of standards are stressed by Ginneken (2002) and Stegwee (1999).

PRM does not offer all of this. PRM stems from the care process orientation, but could also be applied in the medical technology or administration orientation (Michel-Verkerke, Schuring, & Spil, 2003). PRM fails on the first EPR criterion, and its activity is limited to notifying caregivers that a patient who should be seen is reported. Further analysis would be needed after the introduction of PRM to clarify which design of a regional EPR could have added value.

CONCLUSION

Existing tools to identify processes and interviews with future users are common ways to map the conditions where IT solutions can be applied in healthcare. We learned from this research that the USE IT analysis of the characteristics of the end user helps to provide a more appropriate picture of the problem, and the constraints and prerequisites for solving it. It is likely that we would have suggested a far more complicated ICT solution if we had only analyzed the MS care process as such without specific consideration of the USE IT dimensions. The USE IT analysis helped us to balance the breadth of the proposed solution with the nature of the situation the future users of the system will be in. The use of IT does not automatically mean that an EPR is needed (Berg, 2002).

This article gave an example of a thorough analysis of problems of work-flow management in a healthcare setting. The solution we suggest

is specifically geared for this type of care (i.e., for a network rather than chain, and one that has chronic low relevance for most care providers). It is a complex solution in the sense that it combines the creation of a protocol with the introduction of a new organization form (the coordinator) and with the introduction of the PRM. It is a simple solution in the sense that none of these three elements is in itself complex or difficult to realize. Each of these three elements is equally important as only the introduction of all three elements will lead to improved work-flow management. When we particularly focus on the role of IT for work-flow management in the healthcare network, it is once again an essential enabler for new organizational forms. We have tried to find solutions that were entirely organizational or IT related, but we have not managed to design one that could work. So, in line with what many thought when we started the project, IT was essential to create a solution, although it could not bring a solution on its own.

Chapter 3.47

Participatory 3D Modelling

Giacomo Rambaldi

Technical Centre for Agriculture and Rural Co-Operation (CTA), The Netherlands

INTRODUCTION

Mapping is a fundamental way for displaying spatial human cognition. “It is a representational medium that both has a history and is part of the practice of history” (Herrington, 2003). For centuries and increasingly with the advent of Geographic Information Technologies (GIT), graphic representations of part or the whole of Earth in cartographic, electronic, two or three dimensional formats have been playing significant roles as media (Sui & Goodchild, 2001) used to store, display and convey information and as basis of analysis for decision support.

BACKGROUND

In the past maps have been made primarily to serve precise tasks like describing discoveries, navigating space, defining boundaries, registering ownership and locating resources. In the early '90s, Monmonier (1996, p. 2) wrote that,

a single map is one of an indefinitely large number of graphical models of the spatial aspects of real-

ity that might be produced for the same situation or from the same data.

Changes have occurred since GIT have become accessible to civil society and graphic representations of space have been used as channels for two-way communication purposes to support social learning, dialogue and negotiation processes.

The participatory use of maps started in the late '80s. At that time, development practitioners were inclined to adopt PRA¹ *sketch mapping* tools (Mascarenhas et al., 1991) rather than venturing into more complex, demanding and time consuming *scale mapping*, particularly because preference was given to eliciting village dynamics and facilitating communication between insiders and outsiders (researchers), rather than to courses of action enabling communities to interact efficiently with policymakers (Rambaldi et al., 2002a). In addition, in many developing countries aerial photography, satellite imagery and official large-scale topographic maps were under governmental control and their access restricted because of national security concerns.

The situation changed in the '90s, with the diffusion of modern GIT including geographic information systems (GIS), low-cost global positioning

systems (GPS), remote sensing image analysis software, open access to data via the Internet and steadily decreasing cost of hardware. Spatial data, previously controlled by government institutions became available to and mastered by non-governmental and community-based organisations, minority groups and sectors of society traditionally disenfranchised by maps and marginalized from decision-making processes (Fox et al., 2003). This new environment facilitated the integration of GIT into community-centred initiatives particularly to deal with spatial information and communication management (ICM). Practitioners and researchers around the world have been working on different approaches making use of a variety of GIT, but all sharing the goals of placing ordinary people in the position to generate, analyse, manage and exchange geo-referenced data, integrate multiple realities and diverse forms of information to foster social learning and broaden public participation across socio-economic contexts, locations and sectors. This has spurred a rapid development in the management of spatial multimedia information through what is generally termed as Public Participation GIS (PPGIS), where maps are conceived as interactive vehicles for discussion and information exchange, are physical or virtual, in 2-or 3-Dimensional formats and are enriched by an array of data types including sound and images (Aberley et al., 2002).

Large scale maps (> 1:20,000 scale) and physical or digital terrain elevation models have been used for conducting collaborative research (Hampson et al., 2003; Tran Trong Hieu et al., 2002; Martin et al., 2001; Tan-Kim-Yong, 1994 and 1992), community-based planning, monitoring change, asserting territorial claims (McCall, 2004; Bersalona et al., 2004; Rambaldi et al., 2002a; Zingapan et al., 1999; Poole, 1995), managing territorial disputes and supporting related negotiations (Chacon, 2003; Carton, 2002a; Rambaldi et al., 2002b; Wood, 2000; Johnson, 1999) and consultative policy making (Carton, 2002b). While most authors point to the effectiveness of GIT &

GIS used in a participative mode, McCall (2004), Fox (2003), Rambaldi (2002a), Abbot (1998) and Rundstrom (1995) call for caution as these may lead to increased conflict, resource privatization, and loss of common property.

PARTICIPATORY 3D MODELS

Participatory 3D Modelling (P3DM) is a relatively new communicative facilitation method conceived to support collaborative processes related mainly to resource use and tenure and aimed at facilitating grassroots participation in problem analysis and decision-making.

P3DM integrates people's knowledge and spatial information (contour lines) to produce stand-alone scale relief models that have proved to be user-friendly and relatively accurate data storage and analysis devices and at the same time excellent communication media. Relief models works best when used jointly with GPS and GIS facilities.

Participatory 3D models are manufactured at the village level based on the merger of tra-

Figure 1. Discovery learning, the first step for informed decision-making

ditional spatial information (elevation contours) and peoples' spatial knowledge (cognitive maps). Elevation contours are used as templates for cutting out sheets of carton board of a given thickness (i.e., expressing the vertical scale). Cut-out sheets are progressively superimposed to build the relief. Based on their spatial cognition, informants depict land use and cover and other features on the model by the use of pushpins (points), yarns (lines) and paint (polygons). Once the model is completed, a scaled grid is applied to transpose spatial and geo-referenced data into GIS. The grid offers on one hand the opportunity of adding geo-coded data generated by GPS readings or obtained from secondary sources to the model, and on the other hand to take approximate coordinates on the model and verify these on the ground by means of GPS. This is extremely useful when models are used to support boundary negotiations.

P3DM brings GIS potentials closer to rural communities and bridges the gap existing between externally supported GIS and capacities found among marginalised, isolated, and frequently natural resource-dependent communities.

The manufacture of a 3D model leads participants through a collective learning process (Figure 1) to the visualization of their economic and cultural domains in the form of scaled and geo-referenced relief models which can be used subsequently for different purposes.

One major constraint of physical elevation models is their limited mobility. Their use is therefore confined to those in the position to convene around them.

To upscale its utilization, P3DM is best integrated with GPS and GIS. Such integration allows adding precisely geo-referenced data, conducting additional analysis and producing impressive cartographic outputs. Resulting synergies make community knowledge portable and sharable at all levels of society and more importantly add veracity and authority to it. This paves the way for peer-to-peer dialogue and more balanced power-sharing when territorial issues are at stake.

Practitioners using relief models at the community level in the Philippines (Rambaldi et al., 2002a and 2002b; PAFID, 2001; Zingapan et al., 1999), Vietnam (Rambaldi et al., 2003; Hardcastle et al., 2004), Thailand (Tan-Kim-Yong, 1992; Hoare et al., 2002) and India (Chakraborty, 2003), have experienced that when informants are provided with a blank relief model instead of a blank contour map or a blank sheet of paper, they can easily depict their spatial knowledge in a scaled, geo-referenced manner and add a lot of precise details.

The fact that 3D models augment the power of mind and facilitate scaling, allows for filling in information more fully and accurately on a given area. Generally this is not the case with sketch mapping, which has been widely used to represent spatial knowledge in the context of participatory action research. The difference between a blank contour map and the corresponding relief model is the physical vertical dimension that provides essential cues for stimulating memory, establishing spatial associations and depicting cognitive maps (Rambaldi et al., 2002).

LESSONS LEARNED

By carefully documenting and analysing over 20 cases where P3DM has been applied in developing countries (Tan-Kim-Yong, 1992; SM-HDP, 1998; Srimongkontip, 2000; Rambaldi et al., 2000, 2002a, 2002b, 2003; Martin et al., 2001; Tran Trong Hieu et al., 2002; Hoare et al., 2002; Hampson et al., 2003; Hardcastle et al., 2004) practitioners and users noted the following advantages of P3DM.

Enhancing Learning Capacity and the Power of the Mind

3D models offer a more efficient spatial interpretation base by displaying the vertical dimension which provides additional cues to memory and

facilitates mental spatial knowledge processing. By providing a bird's eye view, and by accommodating different layers of information², relief models contribute to widening the users' evaluative frame of reference on spatially defined issues, and thus stimulate active learning and analysis. In other words, scaled relief models help participants in understanding bio-physical and socio-economic dynamics going beyond their individual cognitive boundaries.

Fostering Self-Esteem and Social Cohesion among Marginalised Communities

Both process and output fuel self-esteem, raise local awareness of linked ecosystems and delineate intellectual ownership of the territory. Experience documented in the Philippines has shown that P3DM exercises conducted at the community level and as a response to local needs versus external threats have yielded positive effects in terms of community-cohesion and identity building, through the revival of local knowledge. "Old people share history with young people, passing on legends and religious beliefs, sacred rites and places so essential to conserving tradition" (Alcorn, 2000, pp. 1-2).

Bridging Communication Barriers by Offering a Shared Perspective and Visual Language

Different opinions are frequently based on different perspectives and the quality of the media used to communicate. When a process is geared towards addressing conflicts bound to the territory, appropriate communication channels are essential to grant all parties equal access to information in order to develop a common understanding of the issues at stake. Case in point is the so-called *bird's eye view* offered by a scaled relief model through which a viewer acquires a holistic view

of the landscape wherein landmarks and salient features are equally visible to everyone. In addition, when language barriers represent a constraint, information exchange best occurs via visual communication means based on colour, shape and texture, like in a 3D model.

Filling the Data Gap According to Users Perspectives

In developing countries baseline data available from official sources are frequently limited, inconsistent, outdated, scarce and/or inaccurate. Local geo-referenced knowledge is very valuable in such environments. If P3DM is applied in a genuinely participatory manner, it generates relatively accurate qualitative and quantitative geo-referenced data that are intellectually owned and understood by those who have compiled them (Chambers, 2002).

Scaling the Territory to Bridge Isolation

By miniaturising (1:5,000 – 1:20,000) real world features as known and perceived by participants, the method has proved to be particularly effective in dealing with relatively large and remote areas, and overcoming logistical and practical constraints to public participation in land/resource use planning and management.

Dealing with Boundary Conflicts

Resource use, control and access are increasingly the issues at stake in latent or explicit conflicts. P3DM has been successfully used in the Philippines (Rambaldi et al., 2002b) and Thailand (Srimongkontip, 2000) to deal with such controversies. By creating shared vantage points and offering a common visual vocabulary, 3D models and derived maps are instrumental in bridging

communication barriers, facilitating dialogue and limiting subjective interpretations, thus setting the basis for fruitful negotiations.

Surfacing “Submerged” Knowledge

The possibility of using 3D modelling for mapping out water bodies deserves special mention, due to the partially hidden nature of these environments and the value of human cognition in its description and depiction.

Mapping out wetlands and coastal areas characterised by shallow waters is difficult, because of their instability and frequent change (e.g., river deltas). Nonetheless, in cases where the topography has been stable for a long period and reliable contour and bathymetric lines are available, the production of a participatory 3D model leads to generating an extremely rich information base on existing ecosystems and their interaction with wetland-dependent communities.

The reproduction of the seabed also depends on the availability of bathymetric lines. Exercises carried out in the Philippines (Figure 2) have demonstrated how well fishermen could map out the details of their fishing grounds including the detailed description of coastal and marine ecosystems (Rambaldi et al., 2002).

Figure 2. El Nido-Taytay managed resource protected area, Palawan, Philippines (1999)

Inherent Risks and Mitigating Measures

Because of their accuracy, relief models may have also negative implications. Alone or combined with GIS, “they turn local knowledge into public knowledge and conceivably out of local control. This can be used by outsiders to locate resources and meet development needs, or merely, to extract more resources, or increase outside control” (Abbot et al., 1999). Researchers, planners and practitioners should be aware of these possible drawbacks and be careful applying the method.

Being on a map, on one hand, means to exist vis-à-vis the external world, thus to be in the position to get or claim services and assistance. On the other hand, for communities wanting to maintain their cultural identity and traditions, it may carry undesired development pressures. From a biodiversity conservation perspective, depicting habitats of endangered species, or rare resources in demand on the black market, may lead to their further depletion (Rambaldi et al., 2002).

Therefore, exercises dealing with sensitive issues should be carried out with caution and behind closed doors in the course of focus group discussions.

Data at risk of abuse or culturally sensitive, should be removed from the model and eventually stored as confidential GIS layers with limited or protected access (Harmsworth, 1998).

CONCLUSION

The most important lesson learned with respect to the analysis done, is that the use to which the P3DM outputs can be put definitely depends on their integration with appropriate geographic information technologies and systems, and on the existence of an enabling regulatory environment.

As part of a widespread capacity-building effort involving institutional and customary custodi-

ans of natural resources, P3DM has been gaining increasing recognition as an efficient method to facilitate learning, analysis and proactive community involvement in dealing with spatial issues related to the territory. If properly administered, P3DM can support collaborative natural resource management initiatives and transcend the local contexts by establishing a peer-to-peer dialogue among communities and central institutions, agencies and projects.

KEY TERMS

Cognitive Maps: Internal representations of the world and its spatial properties stored in memory (also called mental maps).

Geo-Reference: The relationship between page-coordinates on a planar map and known, real-world co-ordinates.

Geographic Information Systems (GIS): An organized collection of computer hardware, software, data, and personnel designed to capture, store and update, manipulate, analyze and display geographically referenced information.

Participatory 3D Modelling (P3DM): A participatory mapping method based on the merger of traditional spatial information (elevation contours) and peoples' spatial knowledge (cognitive maps), the output of which are solid terrain models and derived maps. The models are used in development and natural resource management contexts and have proved to be user-friendly and relatively accurate data storage and analysis devices and at the same time excellent communication media.

Participatory Learning and Action (PLA): Umbrella term for a wide range of similar ap-

proaches and methodologies to involve communities in self-help and development projects. The common theme to all of these approaches is the full participation of people in the processes of learning about their needs and opportunities and the action required to address them.

Public Participation GIS (PPGIS): A spontaneous merger of participatory development methods with geo-spatial technologies (P-mapping, P3DM, GIS, GPS and remote sensing). PPGIS is usually geared towards community empowerment through measured, demand-driven and user-friendly applications of geographic information technologies and systems. PPGIS is an integrated practice which has multiple dimensions, builds on diverse tools, and highlights the integration of outsider with socially differentiated local knowledge, and builds essentially on high levels of participation at all stages of project implementation.

ENDNOTES

- ¹ Participatory Rural Appraisal, currently known as Participatory Learning and Action (PLA).
- ² Thanks to the variety of coding means (paint, yarns and pins), a 3D model can accommodate overlapping layers of information like, for example, "land use" and "land tenure" depicted by colour-coded paints and yarns respectively.

This work was previously published in the Encyclopedia of Developing Regional Communities with Information and Communication Technology, edited by Marshall, S., Taylor, W., and Yu, X., pp. 538-543, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Section 4

Utilization and Application of Information Communication Technologies

This section introduces and discusses a variety of the existing applications of ICT that have influenced government, culture, and education and also proposes new ways in which ICT can be implemented in society. Within these selections, particular issues related to ICT utilization, such as the existence of a cross-cultural digital divide and the existence of a gender barrier, are explored and debated. Contributions included in this section provide excellent coverage of today's IT community and insight into how ICT impacts the social fabric of our present-day global village.

Chapter 4.1

A Dissemination Strategy for the Management of Knowledge in Rural Communities

Ken Stevens

Memorial University of Newfoundland, Canada

ABSTRACT

Schools in rural communities of the Canadian province of Newfoundland and Labrador have been reorganized in the last decade. Because of rural to urban migration and the consequent challenge to the continued existence of many small schools, new academically and administratively open structures have been established within an Internet-based environment. Accordingly, traditional closed, autonomous schools in this province have increasingly become open sites within Internet-linked teaching and learning environments. What began as a research project linking eight schools in a single Digital Intranet has been extended to include schools across the province managed by a recently established branch of the Department of Education of Newfoundland and Labrador—the Centre for Distance Learning and Innovation. This chapter provides an outline of how information and communication technologies have been used to reshape education in a

predominantly rural Canadian province, thereby preparing people for participation in the emerging knowledge-based economy.

INTRODUCTION

A decade ago tele-learning (e-learning) was described as the future of distance learning (Collis, 1996). In spite of this, e-learning remains, for many people, an unfamiliar term in the educational lexicon, the implications of which for teaching, learning, the management of schools, and educational policy are unclear. At the present time, many schools are in transition between traditional and virtual ways of organizing teaching and learning as they seek to integrate information and communication technologies in classrooms. This chapter outlines the transition from traditional (face to face) to virtual teaching and learning environments in a small network of rural Canadian high schools. It is argued, on the

basis of research in science classes in this network in Newfoundland and Labrador, that the introduction of e-learning in schools involves a shift from a closed to an open model of teaching and learning. The shift from closed to open teaching and learning has implications beyond the school for regional development.

In most states of the United States and provinces of Canada there are communities that live beyond major centers of population. Although most North Americans live in urban centers, many Americans and Canadians live in small communities in rural and sometimes remote parts of the continent, in Alaska, Wyoming, and Montana, for example in the United States, and the in the Canadian prairie provinces of Saskatchewan and Manitoba as well as in Atlantic Canada. The development of natural resources such as lumber and fishing and the extraction of oil and gas that are important to the economies of both countries, often takes place in locations far from major centers of population. In the resource-based Canadian economy rural schools are, therefore, integral to the economic infrastructure. A decline in the viability of rural education has implications for provincial, and, indirectly, national economic infrastructures. However, it is sometimes difficult for professional people to justify enrolling their sons and daughters in small schools in rural communities if they provide fewer curriculum options than urban institutions.

Information and communication technologies (ICTs) are central to the development of the knowledge economy whose significance for rural schools was recognized in the mid-1990s (Barker, 1994; Stevens, 1994). Almost a decade ago the Canadian government set out two documents (1995, 1997) to prepare the country for the digital world. Small schools in rural communities have been particularly active in Canada (Cey, 2001; Healey and Stevens, 2002; Stevens, 2000, 2001) in using new technologies to promote educational opportunities for students and more efficient ways of

organizing and managing knowledge in connected (Ertl & Plante, 2004), collaborative, electronic structures. The rapid growth and educational application of the Internet has led to a challenge to traditional ways of teaching and learning at a distance (Ben-Jacob, Levin & Ben-Jacob, 2000) that were based on paper and the postal system. The introduction of e-learning in schools in Atlantic Canada has been particularly noticeable in rural communities and has been influenced by declining enrollments because of rural to urban migration (Brown, Sheppard & Stevens, 2000). While the population of rural Atlantic Canadian communities has declined, the management of schools has been changed so that actual and virtual classes have, to some extent, been integrated. One of the Atlantic Canadian provinces—Newfoundland and Labrador—provides an example of rural population decline, a challenge to the continued existence of many small schools and a loss of local educational and economic opportunities. These changes have been countered by the development of a dissemination strategy for the management of knowledge in small communities in this province that provides a possible model for other parts of North America.

RURAL EDUCATION IN ATLANTIC CANADA: NEWFOUNDLAND AND LABRADOR

Atlantic Canada consists of four provinces: New Brunswick, Prince Edward Island, Nova Scotia, and Newfoundland and Labrador. Newfoundland and Labrador covers by far the largest area of Atlantic Canada and, particularly in Labrador, there is very sparse population settlement. Newfoundland and Labrador's small population of approximately 550,000 residents in a large geographic area (156,185 square miles) presents challenges for the delivery of education, particularly at the senior high school level. Newfoundland and Labrador

has many small coastal communities a predominantly rural lifestyle in most of the province and a distinctive history and culture.

31% of educational institutions in the Canadian province of Newfoundland and Labrador are designated “small rural schools” (N = 122) and 75 of these have fewer than 100 students. 70 of the small rural schools in this province are classified as “all-grade” (K–12) which means that they must offer a senior high school program. The search for appropriate new educational structures for the delivery of education to students in rural Newfoundland and Labrador led to the development of School District Digital Intranets, within which virtual classes, based on e-learning, have been organized. The large proportion of small schools located in rural communities, required special consideration in the development of these new, electronic educational structures.

In the last decade there has been considerable reorganization of the school system in Newfoundland and Labrador, largely because of rural to urban migration together with a net outflow of people from the province. Small schools are not only getting smaller; many of them have been closed permanently. In 1996, 10 Anglophone school district boards were created in the province together with one province-wide Francophone board, a reduction from 26 school boards. In this reorganization of school boards, the Vista School District was created. With continued reduction in school size in most rural Newfoundland and Labrador communities, the provincial administration of schools was further reorganized in 2003 to create four Anglophone and one Francophone school board. This study was conducted before the most recent reorganization, when there were ten school boards, one of them serving the Vista district.

The Vista School District contained 18 schools ranging in student enrollment from 650 down to 40, including Eastern High School (not its real name). The region in which the Vista School District is located extends from Bonavista in

the north, (the place where John Cabot landed in North America in 1497) to the Burin Peninsula in the South. It is a large geographic area covering about 7,000 square kilometers. The region had a population of about 35,000 people and an economy supported by a diverse infrastructure including fishing, forestry, farming, mining, aquaculture, and tourism. There were 5,165 students enrolled in 18 schools in the district, taught by 366 teachers. The Vista School District was approximately two hours by road from the capital city, St Johns. Eastern High School, (not its real name) with a student enrollment of 480, was initially chosen for intensive study.

The path from a closed model of the school in rural Newfoundland and Labrador to the beginnings of an open model began in selected science classes of Eastern High School. At the time of the study, computers and the Internet were fairly new in schools and many teachers were not aware of the nature and potential extent of their applications for teaching and learning. Five phases can be identified in the ways these technologies were organized in what became a move from closed to open teaching and learning in the Vista School District.

Five Phases in the Move from Closed to Open Classes

The introduction of computers and the Internet to schools in Newfoundland and Labrador took place gradually, in closed teaching and learning environments which gradually became more open. At the beginning of the study, Eastern High School was at phase four.

Phase One: The Introduction of Computers in Schools

In the late 1980s and early 1990s computer technology was introduced to classes with little or no formal training of the teachers who used it. Teachers frequently learnt how computers worked

though their own study of them with little help from outside sources. In this phase of e-learning, computers were a subject of study. Some teachers studied computers to find out how they worked and how they could be programmed while, to most of the profession, this technology was not considered to be directly relevant to classroom life. There was little thought given to the integration of computers to teaching and learning.

Phase Two: Computers and Course Redevelopment

In the early 1990s increasing numbers of teachers began to realize the potential of computers for both teaching and student learning. Local Area Networks (LANs) were introduced in Newfoundland and Labrador. While there was awareness of the Internet, it was not used in Newfoundland and Labrador schools at this time. However, computers were used to capture data for science experiments using Vernier hardware and software. Students were shown how to use word processing, spreadsheets, and graphing software in completing their assignments and some entire courses were re-developed around such uses of computer technology.

Phase Three: Internet Access

In 1993 the introduction of Internet access to selected teachers in Newfoundland and Labrador led to the formation of STEM~Net, the provincial arm of the federal program SchoolNet which was established to encourage computer and Internet use in Canadian classrooms. STEM~Net was based at Memorial University of Newfoundland, the only university in the province. Within a two-year period more than 5,000 teachers were provided with access to the Internet through STEM~Net. Training sessions were provided in the use of e-mail and the development of Web pages using HTML.

Phase Four: Integrating Technologies

By 1996-97 Newfoundland and Labrador schools had a high level of connectivity, per capita. The development of Web pages by students in schools was accompanied by the introduction of other areas of school life to the Web such as homework exercises, answers to questions, school policies, and schedules of events. Early attempts to bring information technologies into teaching and learning were in the form of text on line and links to other sites (mostly universities). Internet resources and CD-ROMs became increasingly available to both teachers and learners, facilitating interaction between dispersed sites.

Phase Five: The Vista School District Digital Intranet

The Vista School District Digital Intranet project that began in 1998 was an attempt to determine how to deliver real-time instruction across dispersed sites, all of which were located in rural Newfoundland. Lead teachers in biology, chemistry, mathematics, and physics piloted the delivery of Advanced Placement (AP) courses in these subjects. Advanced Placement courses are available to students in both Canada and the United States. As the name suggests, these courses are designed for students who wish to prepare for university by undertaking studies over and above their final-year high school program. Universities throughout North America determine the level of credit towards first-year courses they will award students who pass AP subjects. Students who pass AP courses, therefore, often enter North American universities with a small part of their degrees already completed. Success in AP examinations (all of which are moderated in Baltimore, Maryland) gives students confidence that they can succeed in university-level courses and provide a useful bridge between high school and university-level studies. AP credits are of considerable value to

high school leavers in gaining entry to the college or university of their choice.

THE CLOSED MODEL OF TEACHING SCIENCE USING INFORMATION TECHNOLOGIES: BIOLOGY AT EASTERN HIGH SCHOOL

Biology was chosen for study at Eastern High School because of the breadth it provided for research. Physics and chemistry were not considered to be as appropriate because of the much narrower and more academic stream of students who enrolled in these courses. Biology attracted a wider range of students within the school than either chemistry or physics. All the biology courses in this school were taught by one teacher who had advanced computer skills.

Students taking the course Biology 2201 were involved in a study to evaluate the use of Internet resources to enhance their education in this subject. Three Biology 2201 classes were selected to take part in the study. The study involved three topics taken from Unit IV—Homeostasis. Each of the three classes was taught using three different methods of instruction defined as:

1. **Traditional** (lectures and assignments). In the traditional group, students were taught face to face by the teacher from the textbook. This was the way in which students were used to being taught so this created no change for either teacher or students. The students in this group did not experience any changes in their mode of instruction.
2. **Cooperative** (students being much more responsible for their own learning and sharing what they learn with their peers). In the cooperative group, students were able to work together on learning biology, using text sources as well as a Web site that enabled them to visit appropriate areas of the
3. **Internet** (students gathering information from Internet resources to complete the intended learning outcomes). In this group, students were to work individually and to use Internet sources to complete their biology units of study. Internet students were able to work with more freedom than those being taught face to face and were, therefore, dependent to some extent on personal discipline as well as facility in using information technologies.

Each topic of study involved 9 periods (57 minutes) of instructional time and one period for evaluation (pre-test and post-test) over a 14 day school cycle. Upon completing each cycle of instruction in a given methodology, each study group began the next topic using a different instructional practice. By the end of the study each class group would be exposed to all three instructional methodologies. The topics chosen were considered by the instructor to be of equal difficulty. Pre-test and post-test data was collected so that a quantitative comparison could be made. Upon completion of the study, students completed a qualitative evaluation which asked them to provide information about their preferences for each instructional method. All students had the same prescribed text, *Biology: The Study of Life* (Schraer & Stoltze, 1995). The tables below indicate the pre-test and post-test class averages and standard deviations. Each pre-test and post-test (Tables 2, 3, and 4) contained 25 multiple choice questions, and each question had 4 possible answers. Data in the tables are raw scores and are not corrected for guessing.

Table 1 compares the three Biology 2201 classes that took part in the study. The letters “B,” “C,” and “D” only refer to the slot within the school timetable and have no other significance. The Eastern High School timetable ran over a

Table 1. General information for comparison

Class	Number of Students	Class Average Prior to Study	Class Average Unit examination	Standard Deviation Unit Examination
B	21	61.7	46.8	12.7
C	33	68.5	60.6	17.5
D	29	68.4	58.2	14.4

Table 2. Chapter 14

Class	Method of Instruction	Pretest Average Mark	Pretest Standard Deviation	Posttest Average Mark	Posttest Standard Deviation
B	Traditional	25.0	8.2	54.9	14.6
C	Cooperative	30.6	9.5	59.9	23.3
D	Computer	25.9	10.0	59.4	21.8

period of 14 school days. Each 14 day cycle had 10 periods (57 min. each) of biology instruction. “Number” refers to the number of students in each of the Biology 2201 classes. “Class Average Prior to Study” refers to the class average mark based on all work prior to the start of the study. This mark represents the average of 27 pieces of evaluation in each of the three classes. Each quiz, lab report, and assignment was the same for all students and all three classes and was collected throughout the year of instruction prior to the study period. “Class Average Unit Examination” refers to the class average on the unit examination completed at the end of the study. “Standard Deviation Unit Exam” is the standard deviation for each class on the unit examination. The unit examination covered five (5) sections (Chapters 12-16) of work. Only three sections (Chapters 14-6) were part of the study.

Table 2 shows the results of the first round in the study. This was a study of the nervous system (Chapter 14). Each class was taught using a different teaching strategy as indicated in the

table. Students received 9 periods of instruction during a 14 day cycle. Period 10 of the cycle was used for evaluation.

Table 3 indicates the results of the second round (Chapter 15). The classes remained the same in terms of the students but the teaching strategy was changed as indicated under “Method of Instruction.” Again, students received 9 periods of exposure to the teaching strategy in the 14 day cycle. The 10th period was used for evaluation.

Table 4 indicates the results of the third round in the study (Chapter 16). Again the students remained the same but the teaching strategy was shifted. Students of Class B and D received 9 hours of instruction and 1 hour for evaluation. Class C (33 students) received six periods using computer, three periods using traditional instruction, and one period for evaluation. With 33 students in the Class C, it became necessary to abandon the study after six periods (rather than the intended nine periods). This was due to several factors including: students complaining about overcrowded conditions, the room being

Table 3. Chapter 15

Class	Method of Instruction	Pretest Average Mark	Pretest Standard Deviation	Posttest Average Mark	Posttest Standard Deviation
B	Computer	N/A	N/A	41.6	21.3
C	Traditional	N/A	N/A	63.6	22.8
D	Cooperative	N/A	N/A	64.9	18.6

Table 4. Chapter 16

Class	Method of Instruction	Pretest Average Mark	Pretest Standard Deviation	Posttest Average Mark	Posttest Standard Deviation
B	Cooperative	27.5	11.0	67.4	8.2
C	Computer	31.8	7.7	66.4	19.9
D	Traditional	29.0	13.2	71.7	11.1

too hot and uncomfortable, no printer, and only 11 computers were in service.

On completion of the study students completed a qualitative evaluation survey intended to gather data regarding their experience with each teaching method. Each student was asked to explain in their own words, what “traditional,” “cooperative,” and “computer” teaching strategies meant to them. The student also wrote a brief description of what they believed represented the best teaching method—how they would like to be taught in future.

Traditional:

“The teacher told us what we needed to know and gave us notes.”

“The teacher stands in front of the class writing out notes ... it’s basically boring.”

“I feel this type of learning was good, but it is the most boring.”

Cooperative:

“I think this is a very effective way of learning”

“Students look for information themselves and help each other. The teacher is just there for guidance.”

“The teacher gives us a concept or question—we form into groups and do the research.”

Internet:

“Very hard to use but if used right it can help a great deal.”

“This was the greatest method but people got off the topic.”

“Most students spend their time on topics completely unrelated to the subject and the teacher doesn’t know.”

The feedback indicated that students preferred to be taught using a combination of strategies. All three groups indicated that reliance on a single instructional strategy was not to their benefit. It was suggested that students first receive training in the use of the technology (to become familiar with the software and hardware) before they could make efficient use of Internet resources. Most students reported some degree of frustration, mostly associated with their lack of computer skills and their inability to focus on the task assigned.

It was found, from this experiment, to be necessary to provide time for students to learn how to make efficient use of the technology before engaging in the study of science. It appeared, however, that use of Internet resources had some potential to enhance student learning in biology. The possibility of using computers in other subjects was raised in an end of year meeting during which the above work in biology was outlined. Other schools in the district were interested in the possibilities that computers offered for teaching and learning.

The closed model of the teaching of science in a single high school, using computers, was the basis for the creation of the open model that followed. In the closed model, the school teachers and students engage with one another within a single, autonomous institution to which teachers are exclusively appointed and students enrolled. From this traditional model of schooling a new possibility emerged based on earlier work in New Zealand (Stevens, 1995a, b) and Iceland (Stefansdottir, 1993) in which selected classes in some schools within a district were linked so that teachers and learners could collaborate. This became known as the open model within which schools began to open to one another both academically and administratively. Teachers appointed to a particular institution also taught selected classes in other schools by linking them electronically from the school to which they were appointed. In Newfoundland and Labrador the open model

had its beginnings in the Vista school district digital Intranet.

THE OPEN MODEL OF TEACHING SCIENCE: THE DEVELOPMENT OF A SCHOOL DISTRICT DIGITAL INTRANET

The electronic linking of nine rural schools across dispersed sites within the Vista School district to collaborate in the teaching of Advanced Placement biology, chemistry, mathematics, and physics created a series of virtual classes in Newfoundland. Classes began in September 1998 and several reports were completed (Stevens, 1998, 1999; Stevens, Piper & Power, 1998; Stevens, Power & Barry, 1999). The introduction of the Vista School District Digital Intranet represented two dimensions of change: in the relationship between curriculum and technology and the reorganization of classes within an Intranet.

THE INTEGRATION OF INFORMATION TECHNOLOGIES INTO THE SCIENCE CURRICULUM

The development of Advanced Placement Web-based courses in biology, chemistry, mathematics, and physics took place within a development team in each subject area. A lead science teacher in each discipline was paired with a recent graduate in Biology, Chemistry, Mathematics and Physics respectively who possessed advanced computer skills including Web page design, Java and HTML. The lead teacher and the graduate student were, ideally, to have been assisted by a Faculty of Education specialist in each curriculum area together with a scientist from the Faculty of Science at Memorial University of Newfoundland. The extent to which each Web-based course was developed by a team of four people varied. Most of

the development was through interaction between the lead teacher and the recent graduate with reference, as appropriate, to two professors (of science education and science). This model provided a measure of interaction between schools, graduate students, and the Faculties of Education and Science of Memorial University of Newfoundland. To provide a connection between the high school and Memorial University, faculty members were asked to take part in providing resources, quality control evaluation, and suggestions for improvement. Although at times professors had different opinions as to the most appropriate way to design the courses, this approach enabled each of the four subjects to be developed over the summer vacation in time for the new school year. Many software packages were evaluated and finally WebCT was selected. This package enabled the instructor to track student progress, it contained online testing and evaluation, private e-mail, a calendar feature, public bulletin board for use by both instructor and student, a link to lessons and chat rooms for communication between teacher and student. For real time instruction, Meeting Point and Microsoft NetMeeting were selected. This combination of software enabled a teacher to present real-time interactive instruction to multiple sites. An orientation session was provided for students in June of the year prior to implementation. Visits by instructors were made to participating schools from time to time and students learnt how to communicate with each other and with their instructor using these new technologies.

THE REORGANIZATION OF CLASSES IN A SCHOOL DISTRICT DIGITAL INTRANET

The question how students would work in a largely independent learning environment was prominent in the minds of researchers from the outset of each AP course. There was no AP teacher present on

site for these courses. Students were not used to being alone and largely unsupervised for much of the time even though most of the initial AP students were considered by their schools to be "independent learners."

It was recognized that a common schedule had to be adopted throughout the Vista school district to allow students to interact in real time with their instructors at selected times during the week. The initial plan was to allow for five online sessions and five offline sessions. This schedule was not followed in all schools. Online sessions were scheduled in the mornings when network traffic was at its lowest point. Offline sessions were scheduled for afternoons. Some schools chose not to be coordinated with the AP schedule for various valid reasons. As a result the instructor might be teaching another subject when the AP student would be in a traditional face to face class. Students in different schools throughout the Vista district, therefore, had differing access to their AP Instructors.

FIVE PHASES IN THE DEVELOPMENT OF A DISSEMINATION STRATEGY FOR THE MANAGEMENT OF KNOWLEDGE

The move from closed to open classes in Newfoundland and Labrador, based on the introduction of computers and the Internet and the creation of school district digital Intranets, provided a basis for the dissemination of knowledge among the participant schools. There were five phases in this process.

Phase One: The Introduction of a Digital Intranet

The creation of the School District Digital Intranet within which AP biology, chemistry, mathematics, and physics were taught, was an attempt to

use information and communication technologies to provide geographically-isolated students with extended educational and, indirectly, vocational opportunities, that would otherwise not be locally available. This was part of a broader pan-Canadian initiative since 1997 to prepare people in Canada for the Information Age (Information Highway Advisory Council, 1997). The significance of the first digital Intranet within a single school district was in moving the management of knowledge from closed, autonomous schools to an open teaching and learning structure for selected students. Adjustments had to be made administratively and academically in each participating site so that AP classes could be taught within the fledgling open learning structure.

This development was a milestone in the organization of education in Newfoundland and Labrador for two reasons. First, while AP courses are a well-established feature of senior secondary education in the United States and Canada, it was unusual for students to be able to enroll for instruction at this level in small schools in remote communities. The organizers of the project could find no other rural sites in North America in which AP subjects were available. Second, the provision of AP subjects within the Vista school district digital Intranet was, as far as could be established, the first time this curriculum had been offered online, anywhere.

Phase Two: The Development of Online Courses

In the process of developing e-teaching and e-learning within digital Intranets in rural Newfoundland and Labrador, teachers, learners and administrators had to adapt to a new, electronic educational structure. In the open teaching and learning environment of a school district digital Intranet, participating institutions academically and administratively interface for that part of the school day during which classes are being

taught. This is a different educational structure from the traditional and, by comparison, closed educational environment of the autonomous school with its own teachers and its own students. There is a potential conflict between a school as an autonomous educational institution serving a designated district and schools which become, in effect, sites within electronic teaching and learning networks. Principals and teachers appointed to the closed, autonomous learning environments of traditional schools frequently discovered that the administration of knowledge required the development of open structures within which they were increasingly expected to collaborate with their peers located on a range of distant sites. Some principals found that the positions to which they were appointed in traditional (closed) schools had become, in effect, collaborative roles within the new open electronic environment.

Students in the initial digital Intranet were frequently subject to scrutiny by their peers as they responded through chat rooms, audio, video, and with their AP online teacher. The digital Intranet provided students with access to multiple sites simultaneously, as well as the opportunity to work independently of a teacher for part of the day. The need to prepare for classes before going online became increasingly apparent to both teachers and students if the open, synchronous, science classes were to succeed. The advent of the Vista School District Digital Intranet had implications for students who began to interact with teachers and their peers in a variety of new ways. Many students experienced difficulty in expressing themselves and, in particular, asking questions in open electronic classes when they did not know their peers from other small communities. The organization of social occasions for students learning science in open classes in the first Intranet in the province helped overcome these problems. As students became more comfortable with one another after meeting in person, inhibitions such as asking questions online were overcome.

Phase Three: Increased Access to Online Courses

The Vista School District Digital Intranet provided new pathways for senior students to higher education through the initial AP subjects. By linking traditional schools to create open teaching and learning environments expertise was shared and new learning spaces for students were created. Since this pioneering venture in rural Newfoundland, other AP subjects have been added, as well as subjects from the regular school curriculum. The Internet-enhanced learning environments that have succeeded the initial Intranet have been extended province wide, including schools in Labrador, by a branch of the provincial Department of Education. The Centre for Distance Learning and Innovation (CDLI) has extended learning opportunities for students in the province's schools to all school districts and across the curriculum (<http://www.cdli.ca/>). Henceforth, online education is no longer the preserve of AP students in the senior school.

Although the Vista School District Digital Intranet opened new possibilities for teaching and for learning, particularly for senior students, many adults in rural Newfoundland and Labrador remain unemployed or underemployed in their rural communities. This is an outcome of the demise of the traditional source of employment in this province—the cod fishery. While an increasing number of schools in Newfoundland and Labrador have become high-technology beacons that connect with one another to add a virtual dimension to traditional face to face instruction, many adult learners have not been able to take advantage of the new, open learning environment. Therefore, exploration of the adult-learning potential of the high-technology hubs that many small schools throughout rural Newfoundland and Labrador have become remains an untapped aspect of regional economic development.

Phase Four: The Integration of On-Site and Online Teaching and Learning

The advent of digital Intranets across all school districts of Newfoundland and Labrador has led to a prominent role for the Centre for Distance Learning and Innovation in the organization of the province's schools. Distance learning, in the form of e-learning, is increasingly integrated with traditional face to face instruction. Students in many of the province's rural schools now receive part of their education on-site in traditional classrooms through face to face instruction. E-teaching has developed from the initial four teachers in the Vista School District Digital Intranet to become an established part of the profession today. New professional positions have been established to support e-teaching: m-teachers and a range of technical support staff. M-teachers (mediating teachers) support e-teachers within schools that receive e-learning for students on-site (Barbour & Mulcahy, 2005). Usually, m-teachers have traditional classroom roles but also have responsibilities to support e-learners by mediating between problems they present on site, with e-teachers who provide instruction from other places. Recently the concept of m-teams, outlined below, has been considered to replace m-teachers that include technical and administrative support as well as the on-site mentoring of e-students.

Phase Five: A Dissemination Strategy for the Management of Knowledge

The introduction of inter-school electronic networks added a new dimension to education in Newfoundland and Labrador and continues to bring new challenges for teachers and learners (Stevens & Stewart, 2005; Van Manen, 2002), and administrators. The linking of schools within an interactive electronic structure was a direct use of ICT for rural development that had three

immediate outcomes for regional development. First, rural to urban student migration was considerably reduced as senior students could access an extended range of subjects within the School District Digital Intranet. Second, new Internet-based pathways from schools to homes became possible with implications for adult learners, although there is much work still to be undertaken in this sector of Newfoundland and Labrador society, and thirdly, access to information became transparent, facilitating engagement between schools and local as well as non-local expertise.

THE COFFIN MODEL OF M-TEACHING TO INTEGRATE ON-SITE AND ONLINE EDUCATION

In the development of small schools in rural Canadian communities as centres of information and communications technologies for teaching and learning, a more central role for all staff, particularly those at the senior high school level, is needed. In a concept paper that compared m-teachers and m-teams, Coffin (2002) pointed out that:

The benefits of a technology-enabled school will not be realized unless the human resources in those schools also possess the knowledge and skills needed to function effectively in those technologies. Technologically advanced schools need to prepare and organize their human resources so as to support an alternative delivery method which operates not as a competitor to traditional face to face (teaching and learning), but as a complement to it. Assigning one individual as a school's only resource to mediate between e-teachers and e-learners is far from sufficient to realize that vision. (p. 2)

Coffin (2002) argued against the practice of appointing m-teachers to support e-teachers and

e-learners by creating a team approach. He suggested that m-teams be established, with specific responsibilities to replace m-teachers in rural schools in Newfoundland and Labrador:

The report Supporting Learning (Government of Newfoundland and Labrador, 2000) envisioned a teaching role to provide school-based support for students who were instructed by an off-site e-teacher. Initially conceived of as a singular role, that is, one performed by a single teacher, evolving research ... suggests that a team concept is perhaps better suited to fulfilling CDLI's vision of small schools as "beacons of technological innovation" with respect to distance learning. Conceptually, then, e-learning needs the support of a team of people providing four sets of skills: technical, coaching, administrative and resource advisor. We can attach an order of priority to those tasks as well, based on research. We have noted that students in e-learning courses have a high dependence on the technology used to deliver the courses. The higher the dependency, the greater the requirement that the technology be reliable. This feature is so important that it deserves the highest ranking among tasks performed by m-teams. Using students' assessments of the role of m-teachers, the coaching function is the next most helpful role, followed by administrative and, then, that of the resource teacher. Teams may be real or virtual or a combination of both.

By that we mean the expertise can reside on-site in the form of a teacher or staff person or it can exist apart from the school, for example, a content-area Web-site maintained by a teacher in another school or province. So the idea of a team doesn't have to imply people getting together periodically to plan strategy or solve problems. The team represents more of a bank of resources easily accessible to on-line students which can be used to facilitate their learning. (p. 1)

An m-teaching scenario, outlined by Coffin (2002) in a moderate-size rural high school with 100-250 students may have:

- At least six teachers teaching high school courses.
- A resource center with at least a part-time resource teacher.
- Some secretarial time assigned to the school.
- Technical expertise located in the school (or community) and additional expertise available within two hours drive of the school.
- A toll-free help-line for technical advice.
- There is no on-site subject area expertise that can be made available to online students.
- The technology teacher and coach would have some time in their schedules for discharging their responsibilities to online students.

The m-team could consist of a technology teacher, a technician, help line desk, advanced computer studies student(s), a coach (another teacher with an interest in distance learning), the school secretary, the resource teacher, and an administrator. Each person on the team would be responsible for specific support services. The technology teacher, the technician and the help-line desk and students will handle technical problems according to an agreed set of protocols. The coach will provide the nurturing, encouragement and advice that students need to persist in their studies. The technology teacher could also be the coach. The coach will also be the school-based contact for the e-teacher when that is necessary. These two professionals together will handle most of the pedagogical functions associated with online learning. Coaches should be assigned to students, rather than courses because the services they need to provide are client-oriented rather than content-oriented. The school secretary will take responsibility for conveying hard-copy correspondence between the e-teacher and students and other clerical functions.

The resource teacher will provide services similar to those provided for classroom instructed students. This person could also catalog, store and

control the distribution of the learning resources for the online courses. The administrator would provide the administrative support services that ensure the smooth and efficient operation of online learning (including supervision of instruction).

In the Coffin model, the m-team may be the whole staff, consisting of teachers, support staff, and administration. The configuration of small schools varies considerably, so it is not appropriate to consider a single model for m-teams in all schools. This approach to supporting e-learning in rural schools has recently been adopted in Newfoundland and Labrador by the Centre for Distance Learning and Innovation and m-teams are replacing m-teachers.

FUTURE RESEARCH

There have been major changes in the management and dissemination of knowledge in rural communities in the last decade and this has been particularly noticeable in the Canadian province of Newfoundland and Labrador. With the introduction of new organizational structures such as digital Intranets and the Centre for Distance Learning and Innovation together with internet-based instruction, there are several possibilities for research in the immediate future. The term “digital divide” is often heard in relation to those who are technologically literate and those who are not. Nowhere is this more evident than in rural communities. With the introduction of an increasing range of online courses, young people who live in rural communities in Newfoundland and Labrador have been provided with electronic educational pathways to other institutions while their parents are often left behind both figuratively and actually. They are left behind because the new technologies that have transformed small rural schools into regional high-technology hubs for accessing educational facilities and, thereby, job opportunities, have not yet been able to influence the lives of unemployed local people who have

little formal education. Future research could very useful in finding ways of strengthening regional economic development by linking adult learners in local (and non-local) homes with the technologically enhanced rural schools that have emerged in the last decade in Atlantic Canada.

A second area of future research is the implications of mobile technologies for rural schools and regional economic development. Computers have become increasingly mobile in the ubiquity of laptops (Lowther, Ross & Morrison, 2003; Rockman, 2003; Russell, Bebell & Higgins, 2004), an expanding range of hand-held devices (Norris & Solloway, 2004), and wireless technology. The possibilities of using mobile technologies for linking homes and, if appropriate, workplaces, in rural communities with technologically enhanced local schools has not been considered.

Finally, there is the possibility of making much stronger teaching and learning connections between small schools in rural communities and large urban schools, particularly in specialized areas of the senior curriculum. The developments outlined above in Newfoundland and Labrador provide a possible template for sharing educational resources, particularly teachers, and enabling students to engage in enlarged peer groups. There is now a need for policy research into the significance of geography and school size (as determined by students who physically attend on a daily basis), into the equitable distribution of educational resources.

CONCLUSION

The claim a decade ago that e-learning was the future of distance learning (Collis, 1996) has proved to be the case in the Canadian province of Newfoundland and Labrador and in other places with many rural schools (Griffin & Sherrod, 2005; Hawkes & Halverson, 2002). New electronic structures in the form of school district digital Intranets to support e-learning have de-

veloped that have changed the nature of schools, encouraging them to become increasingly open to one another. Within the electronic structures that have become part of the education system in this province new processes have also emerged. As electronic structures have been developed to complement traditional schools, particularly in rural communities, the possibility of new pedagogy has emerged (Cavanaugh, 2001) and with it, new expectations for teaching (Mathiasen, 2004). The term “cybercell” (Stevens & Stewart, 2005) has recently been coined to describe the integration of actual and virtual classes. A cybercell is a face to face group whose members extend their discussions to include virtual visitors. As students and teachers across Newfoundland and Labrador further integrate actual and virtual teaching and learning, cybercells are likely to develop.

Schools in rural Newfoundland and Labrador have been reorganized in the last decade. Traditional (closed, autonomous) schools have increasingly become open sites within Internet-linked teaching and learning environments. What began as a research project linking eight schools in the Vista School District Digital Intranet has been extended to include schools across the province managed by a recently established branch of the Department of Education of Newfoundland and Labrador—the Centre for Distance Learning and Innovation. Perhaps the most significant development that has taken place is one that is not readily seen—the challenge to the notion of the school as an autonomous institution with its own teachers and its own students. Because of rural to urban migration and the consequent challenge to the continued existence of many small schools, new administratively and academically open structures were created. The next challenge is to develop pedagogy that will take advantage of the extended learning environments across Newfoundland and Labrador. Cybercells—within which actual and virtual teaching and learning take place simultaneously—may become the next step in the management of knowledge in rural communities.

The establishment of electronic educational structures and processes linking small, dispersed communities in Newfoundland and Labrador has provided a model for economic development in the knowledge society that Canada has become. Through the dissemination of these methodologies and the effective utilization of ICT in other parts of the world, competitive knowledge based communities can be created. Knowledge based communities are likely to yield knowledge products that could act as catalytic agents for regional development.

Chapter 4.2

ICTs for Intercultural Dialogue (ICT4ID)

Victor Giner Minana

UNESCO ICT4ID Programme, Spain

This case study will focus on UNESCO's cross-disciplinary programme spanning the sectors of communication and culture, "Information and Communication Technologies for Intercultural Dialogue: Developing Communication Capacities of Indigenous Peoples (ICT4ID)." It will show a general overview of the five ongoing pilot projects. This programme aims at preserving indigenous peoples' cultural resources by fostering access to ICT. These are the expected results:

- Indigenous community representatives trained in media content production and ICT use.
- Indigenous cultural content produced for television, radio and news media.
- Awareness raised at an international level of indigenous creativity.
- Advocacy made for the importance of cultural diversity and its expression through ICTs.
- Reinforcement of intercultural dialogue through the inclusion of indigenous peoples'

cultural expressions in mainstream knowledge societies.

In order to achieve these objectives, the programme has begun to implement five pilot projects worldwide. These five projects can be divided into two groups: the first group of projects focusing on the audiovisual and the second group consisting of two projects related to multimedia.

AUDIOVISUAL PROJECTS

The projects of the first group (audiovisual) are being implemented in Peru, Bolivia and Gabon. These projects have three phases: training, production and broadcasting. During the first phase, indigenous representatives are trained in audiovisual techniques. The training also includes classes in indigenous culture, focusing on topics such as history, artistic expression and narrative skill. In the second phase the participants film documentaries which allow them to express their

view of the world through the audiovisual tool. Afterwards, during the third phase, this work is broadcasted nationally and internationally. This phase is very important because its objective is to show other social groups the tasks carried out by the indigenous populations and therefore, by doing so, achieving an intercultural dialogue.

These three projects have all concluded the first phase. A first survey has been carried out among the trainees who participated in the project in Peru. This project takes place in Villa El Salvador, a district in Lima inhabited by the Quechua population which began to migrate in the forties from the Sierra to the capital. The target group of the project is the second generation of Quechuas living in Villa El Salvador — children of the migrants who have grown up in an environment consisting of two cultures and two worlds.

The training has been highly appreciated by the 14 students who took part. They have emphasized the importance of the classes of Quechua culture (they had never studied it before) and the fact that the work that they will film in the second phase of the project will be seen abroad. Even if most of them had no prior experience in audiovisual techniques, they have easily learnt the basic audiovisual language. Nevertheless they are aware of the high price of the audiovisual equipment, which hinders them from feeling comfortable using it.

MULTIMEDIA PROJECTS

In the second group (related to multimedia) there are two projects. The first one takes place in Namibia and its target population is the Himba people. The second one takes place in South Africa and its beneficiaries are the San people. There is a close collaboration between both project managers.

The “Kaoko Local Knowledge Living Archive project” (Namibia) aims to revive the oral history of the Himbas through several activities. They are:

- The production of the documentary “Katjira’s Dream: Memory, Land and Ancestors in the Land of Kaoko” by Doxa Productions.
- Setting up of an ICT centre in Kaoko, which will also be a base station for the mapping and recording of the oral history of the Kaoko people. Along with this, the centre and its ICT facilities will provide information in areas such as education, political representation, HIV, cattle diseases and tourism. Cornelius Tijuma, a Himba who has worked with Doxa Productions in the last few years, has been trained in order to be able to train other Himbas in ICT and to manage the ICT centre.
- The production of an interactive DVD-ROM by a multidisciplinary team consisting of anthropologists, filmmakers and DVD designers who will work together to create a living archive of the Himba oral culture which will be made accessible to them.

The “San Interactive Archive, Training and Heritage Management” project aims to train and enable the San people to manage their cultural heritage and express their own cultural contents through audiovisual media and multimedia. As a first step, the San representatives were trained in cultural management. As a second step, the community will produce a DVD on the San people dealing with the loss of their land in 1935. In the long run, by making use of all the audiovisual archives that the project coordinators have gathered during the last years of fieldwork, it will be possible to organise and conceptualise all these audiovisual and multimedia materials into inter-linked interactive archival packages which could be used to create local-content productions, such as documentaries, short narratives, animations and DVDs in collaboration with the representatives of the San communities.

In this paper the five ongoing pilot projects of ICT4ID have been presented. The programme is currently at the midpoint, so it is too early to as-

ICTs for Intercultural Dialogue (ICT4ID)

sess its results, even if the first outcome has been successfully achieved. It is likely that UNESCO will decide to extend this programme which would allow the implementation of more projects taking advantage of the lessons learnt during the implementation of these five projects.

Chapter 4.3

Information and Communication Technologies Provision to Rural Communities: The Case of Gutu World Links Telecenter in Zimbabwe

Shirley Chikowore-Kabwato

International Association of Physicians in AIDS Care, South Africa

Isola Ajiferuke

University of Western Ontario, Canada

ABSTRACT

This chapter introduces information and communication technologies as having the potential of aiding the sustainable development of rural communities through distance education, telemedicine, and the provision of timely information on agriculture and the environment. It argues that telecenters offer practical and community-oriented ways to bring information and communication technologies services to the rural people. Furthermore, based on the outcome of an evaluation of a telecenter in Zimbabwe, it is suggested that in order for a telecenter to offer effective, efficient and sustainable services, local needs assessment would need to be conducted, the telecenter located

at a central place, and an awareness-building campaign targeted at potential users.

INTRODUCTION

Advances in information and communication technologies (ICTs) have aided the social and economic transformations of many industrialized nations (Mansell & Wehn, 1998). However, these technologies also have enormous potential for developing countries in their quest for sustainable development (Jensen, 1998). Though the applications of ICTs have potential impacts in both urban and rural areas of developing countries, rural communities stand to benefit more as they

face extreme pressure due to poverty, illiteracy, environmental degradation and remoteness.

Agricultural production can be improved through the gathering of useful information from the Internet by community information centers and farmers' organizations, and subsequent dissemination to farmers via local radio stations and other local information-sharing networks (e.g., cooperatives, local stores, transportation hubs, agricultural supply outlets and social gathering points) and tools (Richardson, 1998). Health care problems can also be improved through the practice of telemedicine, which permits the transfer of patients' records from the rural areas to urban areas for better diagnosis as well as the provision of medical advice/training to the health care staff in remote areas. For example, HealthNet provides free medical advice and information to community health workers, doctors and hospitals in 15 African countries through the use of low orbit satellites. Distance learning through the Internet can broaden the educational opportunities available to the people in the rural areas. These opportunities range from elementary education to the university (e.g., African Virtual University) and these can aid in the reduction of illiteracy, which is a major obstacle to the development of rural areas. Also, telecommunications can be used for effective communication between the various levels of government and the rural populace to ensure safety, security and good governance (Barr, 1998).

One of the major constraints to the realization of the potential of ICTs in rural areas is lack of access (Adam & Wood, 1999) and the most popular solution to this problem is the establishment of telecenters (Graham, 1997; Whyte, 1998; Gomez & Hunt, 1999). Telecenters offer practical and community-oriented ways to bring new information and communication technologies to the rural people without incurring large set-up costs. The normal telecenters (often referred to as "phone shops" or "public call offices") offer basic telecommunications services, while the advanced

telecenters (often referred to as multipurpose community telecenters) may include facilities such as libraries and seminar rooms, and provide Internet services, videoconferencing, distance education, and training in ICTs, telemedicine and e-commerce (Oestmann & Dymond, 2001).

Telecenter projects have been initiated in many developing countries, including the African countries of Benin Republic, Egypt, Ghana, Mali, Mozambique, Senegal, South Africa, Tanzania, and Uganda. For example, Nakaseke Multipurpose Community Telecenter has proved useful in providing telemedicine services for the Mulago and Nakaseke hospitals, enabling health workers to consult with each other by phone, fax and e-mail (Mayanja, 2001). It has also been shown that a Web site set up by the Timbuktu Multipurpose Community Telecenter for artisans' handcrafts has proved very useful to tour agents organizing visits to Timbuktu, and as a result boosted the sales of the handcrafts (Benjamin, 2000).

In Zimbabwe, the first rural community telecenter was established in Gutu by the World Links for Development Program, an international donor agency, in 1999. Since then, 11 other pilot telecenters have been established in other rural communities by the international donor agency. However, just as is the case in most developing countries, while a lot of efforts and resources have been devoted to setting up these pilot telecenters, little or no effort has been made to evaluate their services. An evaluation of the services would assist in understanding the uses of these centers as well as in the determination of their impact on the communities they serve (Gomez, Hunt, & Lamoureux, 1999). Also, the outcome of such an exercise would assist in improving the services being provided at these telecenters as well as serve as a guide in the establishment of similar projects in the future.

Hence, the goal of this chapter is to evaluate the services of the first rural telecenter in Zimbabwe with the hope that the exercise would illustrate: (i) the problems being encountered in the establish-

ment of telecenters in rural communities; (ii) how well telecenters are meeting the needs of rural communities; and (iii) ways in which ICTs can be better utilized to improve the quality of lives of people in the rural areas.

BACKGROUND

Zimbabwe, which attained its independence in 1980, has an estimated population of 12 million people, with about 1.6 million people living in Harare, the capital city, while the majority (70%) are living in the rural areas. Agriculture is the mainstay of Zimbabwe's economy, and the principal crops are tobacco, cotton, and sugarcane.

Gutu rural village is located about 280km from Harare, and about 40km from Masvingo town, one of Zimbabwe's several small towns. It has a population of about 245,000 people and covers an area of 700,000 hectares. It lies in a highland area which receives adequate rainfall and has fairly fertile agricultural land. Gutu has been installed with electricity and telecommunications infrastructures such as telephone lines.

Gutu World Links Telecenter (GWLT) is located at a growth point, a central location that the government has targeted for its rural development program. Gutu growth point comprises small business enterprises, community banks, postal agencies, clinic, hospital, local council, and primary and secondary schools. A few government offices, such as the ministries of health, education, veterinary services and agriculture, are also located in the area. GWLT was built closer to the community library in order to ensure that both facilities complement each other.

Questionnaires, interviews and observation were the main methods used in the evaluation of the services of GWLT. First of all, questionnaires containing both closed and open-ended questions were used to gather data from users and non-users of GWLT. The questionnaire for the users asked questions related to their experience in using

the telecenter while the one for the non-users solicited reasons for non-usage of the telecenter services. From the preliminary discussions with the GWLT coordinator, it was established that the telecenter normally gets about 30 to 40 users a week. Hence, every user that visited the center during a four-week period was given a questionnaire to complete. Some users completed the questionnaire immediately, while others took the questionnaire away and returned it later. In all, 120 users completed the questionnaire within the four-week period. Non-users of the telecenter were approached at the local library, schools, local district council, local clinic, local government council, business/community center and the village, and after a period of about three weeks, 105 non-users had completed the questionnaire.

The personal interview method was used to gather data from the telecenter coordinator, national coordinator of World Links for Development Program, and a few users and non-users. Interviews were necessary in order to supplement the responses from the questionnaires. Also, in order to obtain a clear picture of the activities of the telecenter, some time was spent in observing some people making use of the telecenter's facilities.

AN EVALUATION OF THE GUTU WORLD LINKS TELECENTER

Objectives and Functions of the GWLT

GWLT was established by the World Bank as part of its World Links for Development Program. Based on the interview with the national coordinator of World Links for Development Program-Zimbabwe, we gathered that the program's main objective was to provide ICT services to those members of society who do not have access to them.

GWLT was set up in collaboration with the Ministry of Education, Sport and Culture, Computer Society of Zimbabwe, I*Earn, Alliance for Global Learning, US Peace Corps and Voluntary Service Overseas, among others. The telecenter receives funding from the World Link for Development Program but it has also embarked on a program where users pay for the services provided. In this way, the telecenter hopes to become self-sustainable in the near future. In fact, the responsibilities for the telecenter's recurrent expenditure (e.g., phone and electricity charges) are soon to be assumed by the telecenter.

GWLT has 10 networked computers, server (running Windows NT software), printer, modem and Internet dial-up connection for its operations. The center is managed by only one staff member who has a Diploma in Education (Computers) and is known as the coordinator. According to him, GWLT provides Internet services, computer literacy programs (these include introduction to computers, word processing, Internet and e-mail basics and WWW search), telephone services, e-mail, and basic computing services. The telecenter receives between 30 to 40 people per week and the number of users is increasing almost on a monthly basis, especially from students, professionals and the unemployed. GWLT has already trained many people who knew nothing about computer technology but with some of them later

securing employment requiring computer literacy. The telecenter has, however, faced a number of problems that were beyond the coordinator's control. For instance, since its establishment, the center has been experiencing problems of inadequate electricity supply (especially because of continuous disruptions) and lack of proper telecommunications infrastructure. These problems are similar to the ones being experienced by some other telecenters in developing countries (Gaster, 2001; Mayanju, 2001). Also, the telecenter lacks facilities such as fax and photocopying machines, and it is also under-staffed, as one person has to manage all the activities of the telecenter single-handedly despite the continuous increase in the number of users.

Demographic Characteristics of GWLT Users

Seventy-seven (64%) of the users were male while 43 (36%) were female. This is not surprising, as it corroborates Richardson's (1997) assertion that overall there are more male ICT users than female. GWLT users come from various age groups but the majority are teenagers or young adults (see Figure 1). In fact, only about 6% are older than 40 years. The popularity of GWLT with young people supports Rolinson et al.'s (1995) "computer mythology", which states that "younger people

Figure 1. Age distribution of GWLT users

are happier using computers than older people.” This also corroborates the results of a study carried out by Teo et al. (1997), which revealed that Internet users in Singapore generally comprised teenagers and young adults.

Figure 2 shows that the majority of GWLT users (62.5%) have had secondary school education. Secondary education includes Zimbabwe Junior Certificate (ZJC), ‘O’ level, or ‘A’ level education. Thirty-one (25.8%) of respondents indicated post-secondary as their highest qualification, while 13 (10.8%) respondents indicated primary education as their highest qualification. The large number of literates among the respondents might mean that GWLT’s services do not cater to the needs of the illiterates, as only one (0.8%) respondent indicated having no formal education.

The major patrons of GWLT are students, administrators, unemployed, and teachers (see

Table 1). The administrators included clerks and managers in both the government and private sectors, while the unemployed comprised mainly school leavers, that is, those who had just completed their secondary education. GWLT also has a few users who are businessmen, communal farmers or health workers.

Sources of Awareness of GWLT

The coordinator of the GWLT indicated that the telecenter publicized its services through brochures, posters, meetings/workshops and newspapers. In order to determine the effectiveness of these publicity media, the users were asked how they came to know of GWLT’s existence and its services. Fifty-four (45%) of the respondents knew of GWLT through brochures, 43 (35.8%) through friends, 11 (9.2%) through meetings/workshops,

Figure 2. Highest educational level for users

Table 1. Occupation of users

Occupation	Number of respondents N=120
Unemployed	21 (17.5%)
Teacher	15 (12.5%)
Health worker	3 (2.5%)
Communal farmer	4 (3.3%)
Student	36 (30.0%)
Businessman	6 (5.0%)
Administrator	31 (25.8%)
Other	4 (3.3%)

10 (8.3%) through newspapers, and two (1.7%) through the Internet (see Figure 3).

The above scenario indicates that many of the respondents got to know of GWLT and its services through the distribution of brochures. This probably means that brochures are effective tools for publicizing GWLT and should be the main medium of publicizing the telecenter's services. Many of the respondents also got to know about GWLT through friends. Word of mouth is a powerful tool and if GWLT continues to provide good services, it should be able to count on satisfied users publicizing its services. Few respondents became aware of GWLT through meetings/workshops and newspapers, partly because of the frequency of meetings and cost of newspapers. However, the two media can be used occasionally to supplement the use of brochures to publicize the telecenter's services.

ICT Use at GWLT

Forty-five (37.5%) and 38 (31.7%) of the respondents had to travel about one and two km respectively to use the facilities at the telecenter (see Figure 4). Also, 25 (20.8%) lived three to four km away from the telecenter while only 12 (10%) of the respondents who lived five to 10 km away visited the telecenter during the period of this research. The fact that significantly fewer respondents who had to travel distances covering three km or more visited the telecenter as compared to those who lived within the one to two km vicinity indicate that distance might be limiting the number of people who patronize the telecenter.

Eighty-three (69.2%) of the respondents claimed to have used basic computer systems at the telecenter, 60 (50%) had used the telephone, 36 (30%) had used the Internet, and 30 (25%) had

Figure 3. Source of awareness of GWLT

Figure 4. Distance traveled by users to telecenter

been to the telecenter to use the e-mail facility (see Figure 5). The basic computer systems were used mainly for word-processing and computer literacy programs, which shows that the rural people are becoming aware of the benefits of being computer literate.

The majority of the Internet users claimed to use it to search for educational information, while a few used it to search for agricultural, health or business information. Telephone and e-mail services were used mainly for personal and business communications. A few of the respondents also claimed to have used e-mail to exchange ideas for both personal development and career advancement.

In terms of frequency of ICT use, about 38% of the respondents claimed to use ICT at the telecenter about one to three times a month while about 27% use it less than once a month (see Figure 6). The remaining 45% use ICT at the telecenter at

least once a week. It would appear that a majority of the users do not visit the telecenter frequently, probably due to the distance from the telecenter, work or school commitments, or dissatisfaction with the services at the telecenter.

Evaluation of ICT Services at GWLT

Most of the respondents found the ICT services at GWLT very useful and some expressed their satisfaction at being able to access information easily and quickly. Some other respondents expressed appreciation at being able to share large amount of information as well as exchange ideas locally and abroad. Some of the respondents also claimed to have benefited a lot from the computer literacy programs and word processing services offered by the telecenter. However, the majority of respondents (65.8%) said the ICT services were inadequate. Some of the reasons stated for

Figure 5. ICT use at GWLT

Figure 6. Frequency of use of ICT at GWLT

their dissatisfaction with the services include the continuous breakdown of the computer systems, slow access to the Internet and e-mail facilities, and insufficient number of computer systems. Respondents also expressed disappointment at the fact that there was only one staff member (the coordinator) at the telecenter. Respondents felt that the coordinator had too many responsibilities and this left him with little time to attend to their individual needs.

In order to improve its ICT services, the respondents would like the telecenter to increase the speed of its e-mail and Internet services as well as increase the number of computer systems. They would also like the telecenter to introduce fax, telex and photocopying services.

Reasons for Non-Use of GWLT Services

The 105 non-users that were included in the survey varied in gender, age, educational qualification, and occupation. The group included: males and females; teenagers, young adults, adults, and seniors; from those with no educational qualification to those with post-secondary qualification; and unemployed, teachers, housewives, health workers, communal farmers, students, businessmen, and administrators.

The major reason for non-use of the GWLT services was the lack of awareness, as 72 (68.6%) claimed not to be aware of GWLT and its services (see Figure 7). This indicates that there seems to be a lack of effective publicity and promotional programs. This result corroborates the coordinator's views, who acknowledged that despite an increase in the use of ICT services at the telecenter, the level of general public awareness of ICT and its services was low. The coordinator felt that there is still need for more publicity and promotion programs to be done by the telecenter to let the expected beneficiaries or users be aware of GMTC and the benefits they would get by utilizing the services offered.

Thirteen (39.4%) of the respondents indicated that the cost of the services prohibited them from using the telecenter, as they did not have enough money, while 10 (30.3%) of the respondents said they did not use GWLT services due to the fact that they were not readily available to them. Distance could have been a contributing factor to the non-availability of GWLT services to this group of non-users. Eight (24.2%) of the respondents stated that they did not have enough computer skills to use ICT. This group of people seemed not to know that GWLT offered computer literacy programs. Two (6.1%) of the respondents said they did not use GWLT because they did not see the need for use.

Figure 7. Reasons for non-use of GWLT

CONCLUSIONS

The study has revealed that the users of GWLT have been making use of telephone, e-mail, Internet, and basic computing services at the telecenter. The basic computer systems were used for word processing and computer literacy programs. Acquiring basic computer skills will definitely enhance the job prospects of the unemployed youth in Gutu. E-mail and telephone services were used for business and personal communications while the Internet was used for searching for information. Some of the users searched the Internet for health, business, agricultural and community development information (though on a small scale) which, according to Richardson (1998) may lead to economic development for farmers, expansion of community development programs, and promotion of small business enterprises.

Users rated the GWLT services as useful but requested additional services. These include fax, telex and photocopying services. In order to identify other ICT and related needs, it may be necessary for World Links for Development Program to conduct a needs assessment survey of the people of Gutu. Also, to ensure that rural people have access to adequate information, GWLT should consider working hand in hand with institutions and extension officers. Intermediary organizations such as extension field offices, rural NGOs, health clinics, government offices, and church organizations, together with small businesses can offer benefits to their rural client groups in numerous ways. These groups can use ICT services, especially the Internet, at the telecenter to access information and pass it on to the rural people, especially the illiterate, who are likely to benefit more from oral provision of information (Leach, 1999).

GWLT publicized its services through brochures, newspapers, meetings/workshops, and posters. However, it seems as if the publicity is not enough, as the majority of non-users were not aware of its services. Community sensitization and

awareness-building is required, with the technologies and their capabilities being explained to all. Local media resources such as popular theatre, town meetings, radio, television, video and films should be used in educating the rural people on the objectives of GWLT and ICT services and the benefits it would provide to the community.

Distance was also found to be an access barrier to GWLT and its services. This problem could probably be solved by introducing ICT mobile vans. Rural Libraries and Resource Development Program (RLRDP) in Bulawayo is also planning on introducing ICT on its mobile donkey cart and making it accessible to the rural masses (SADC, 1997). RLRDP has already started developing the use of solar powered televisions and video plays in its donkey cart. The government and district councils should also upgrade roads in Gutu to ensure easy accessibility to some rural villages in Gutu.

The telecenter coordinator expressed concern at the lack of manpower at GWLT. It was observed that the telecenter has only one staff despite the fact that the number of users is increasing. For example, the coordinator indicated that in most cases he had very little time for publicity activities and also had little time to attend to individual problems of users. GWLT should lobby for funds from the private sector, NGOs, government and individuals so as to be able to hire additional staff as well as make its services affordable to most people in the community. Also, GWLT should establish close working relationships with local community groups who may then be asked to provide volunteers to assist at the telecenter.

Constraints such as poor telecommunications infrastructure (e.g., low Internet bandwidth) and unreliable power supply have seriously affected the effectiveness of ICT services at GWLT. The telecommunications problems have limited access to the Internet and e-mail facilities at GWLT. GWLT should lobby the Post and Telecommunications Corporation (PTC) to provide high quality, reliable telephone lines. Otherwise,

serious consideration should be given to the use of alternative means of connecting to the Internet such as radio links and satellite technology (Smith, 2000). GWLT should also lobby the Zimbabwe Electricity Supply Authority to stabilize power supply or install stand-alone generators. More importantly, the government of Zimbabwe should aim at improving the general telecommunications infrastructures in the country.

Finally, despite the teething problems being encountered in the establishment and operations of telecenters in rural communities in Africa, such telecenters have the potentials to transform the rural communities. Hence, it would be desirable if developmental and non-governmental agencies continue to establish more telecenters in rural communities in Africa while efforts are being made to improve the effectiveness of such centers.

FUTURE TRENDS

The evaluation of Gutu World Links Telecenter suggests that in order to ensure effective, efficient and sustainable services, any agency setting up such a center should: (i) conduct needs assessment in order to tailor the technological services to the needs of the rural populace; (ii) locate the telecenter at a central place where it would easily be accessible by the rural populace; and (iii) target awareness-building campaigns at potential users of the telecenter, as information and communication technologies are new to many people in the rural areas (Anderson, Van Crowder, Dion & Truelove, 1998).

The kind of evaluation done in this study and similar ones done by Benjamin (2001), Gaster (2001) and Mayanja (2001) is referred to as 'formative evaluation' by Hudson (2001). However, only very few studies have attempted to go beyond the formative evaluation to determine the socio-economic impact assessment of the telecenters (Oestmann & Dymond, 2001). One such study

was conducted by the International Development Center (IDRC) on Acacia telecenter projects (IDRC, 2000). The study compared community data from 59 communities with telecenters (40 in South Africa, 14 in Senegal, two in Mozambique and three in Uganda) with those from approximately 50 communities without telecenters (almost all in South Africa). The study revealed that the telecenters are successful in ensuring access to ICTs, leading to community development, and also that communities with telecenters are more empowered with knowledge than those without. It is hoped that there will be more of such studies in the future that will seek to determine the contributions of the telecenters to the socio-economic development of the rural communities in which they are located.

Chapter 4.4

Indigenous Peoples and the Cultural Construction of Information and Communication Technology (ICT) in Latin America

Juan Francisco Salazar

University of Western Sydney, Australia

ABSTRACT

Indigenous media have become an intensely debated subject in discussions of cultural diversity and access to information and communication technologies (ICTs). In many circles, the question of the equitable and affordable access to communication and information has begun to be conceptualized as integral to human rights and as an essential element in the foundation of a knowledge and/or information society. The purpose of the chapter is to analyse current approaches to indigenous ICT practices in Latin America by examining several case studies that explore, enliven and criticize the often ethnocentric discussions of the digital divide. The analysis

is placed in the context of the rise of coordinated indigenous movements in Latin America, the wave of media privatisation in the region and the impact of IT policy and reform. It argues that, beyond consideration of the social impact of ICT on indigenous cultures, it is also relevant to consider the cultural construction of new technologies of information and communication in order to better understand the ways in which indigenous peoples adopt and make use of new digital technologies according to traditional knowledge and systems of law. The chapter concludes by supporting the need for self-identification of local practices and knowledge within the communities in order to design adequate strategies to gain benefit from the use of ICTs.

INTRODUCTION

Today, halfway through the first decade of the twenty first century, it is outstanding to see that a large number of indigenous organizations, collectives, groups, tribes and nations worldwide have been able to set up their presence on the World Wide Web. Moreover, several indigenous organizations actively use various information technologies for different purposes on an everyday basis, ranging from political advocacy to electronic commerce, film and television marketing or biodiversity research. Nevertheless, despite increasing access to information and communication technologies, indigenous peoples worldwide have made it clear that the promotion of the Internet by governments and non-governmental organizations alike may constitute yet another exercise in control and coercion. If digital division is cultural exclusion, digital inclusion has not necessarily meant cultural inclusion. In this regard, the dynamics of visibility/invisibility of indigenous peoples in the information society remain as complex an issue as ever before.

An important example of this is the inclusion of indigenous peoples in discussions on the information society, like the ones that took place as part of the World Summit on the Information Society (WSIS) in Geneva in 2003 where a Declaration of Indigenous Peoples and the Information Society and a Programme of Action were articulated. On that occasion it was made clear that indigenous peoples do not seek inclusion in the information society at the expense of their civil rights, cultural identities, ancestral territories or bio-resources. Moreover, it must be indigenous peoples themselves who decide on how and when they access and use new technologies.

Keeping these broad issues in mind, this chapter examines current literature and proposals on the topic, particularly those calling for new frames for action regarding the technological, cultural and policy use of ICTs by indigenous peoples

in Latin America and the Caribbean. While we may celebrate the possibilities for developing new social literacy, political alliances and independent cultural production, at the same time we must understand that indigenous peoples are still faced and confronted with a paradox of media power and control, particularized by the fact that technology may be disruptive of traditional knowledge if exerted as an imposed gadget.

In the following pages it is argued that the indigenising of digital information and communication technologies is a clear example of what might be called the cultural construction of information technology. Culture is not only shaped by technology, but also determines its use and value. The increasing appropriation of ICTs by indigenous organizations and individuals in Latin America in the past decade can only be grounded in new processes of ethnic resurgence sweeping the region, and has to do with finding efficient ways for intra-communal communication and ways to communicate and inform the broader societies within which indigenous nations live. More importantly for the Latin American case, ICTs have been constructed as useful technologies for the formation of a new “pan-indigenous discourse” (Bengoa, 2000, p.138) and also an incipient pan-American indigenous public sphere. What is striking in the international indigenous movement in recent years is that the indigenous demands of today have moved from mere complaint to compound proposals. In other words, they have stepped forward from complaint and objection to the proposal for a world of decentralised but coordinated autonomies (Lara, 1999). For this reason, to consider the impact of ICT on indigenous peoples is certainly a critical issue, yet we should not overlook the impact of culture on technology and the implications of the indigenising of IT. Therefore, I propose to consider indigenous media as a socio-technical system of relations where technology becomes a cultural construction appropriated according to relevant cultural codes and social relations.

In the following pages I have summarized some of the critical issues in Latin America today in relation to indigenous peoples and the information society. In examining a range of literature on the topic, I refer to broader questions of, first, how indigenous peoples feel incorporated into the information society, and second, up to what point ICTs offer fresh possibilities for empowerment to indigenous peoples. Both have direct relation to more complex concerns of ethnic citizenship and political autonomy.

INDIGENOUS PEOPLES, ICT, AND RESEARCH

Much of the emphasis of the existing literature that explores indigenous peoples and information technology has dealt with the negative or positive impacts of ICTs on indigenous peoples. Little work has been done to understand the cultural constructions of technology or what the “cultural impact” of indigenous knowledge on IT may be in the near future. Recent literature examining indigenous peoples and ICTs in Latin America and the Caribbean has been important in defining those aspects of the “information paradigm” that have helped promote indigenous marginalisation in regard to what some called the “digital revolution” (Hernandez & Calcagno, 2003; Monasterios, 2003; Forte, 2002; Delgado, 2003; Becker & Delgado, 1998; Pilco, 2000; Salazar, 2002). The expansion of digital capitalism has often resulted in the commodification of indigenous identities, which are pushed to overcome issues such as lack of electricity in remote areas, geographical isolation, lack of technical know-how, absence of regulatory legal frameworks or low degree of connectivity in some areas.

The question of digitalisation of knowledge is particularly critical as new digital information and communication technologies offer alternative possibilities — from cultural recuperation, revival

and political mobilisation, to questions of cultural autonomy and indigenous rights to artistic and intellectual property. In many cases, information technology has proven to be a useful tool beyond a symbolic field of struggle to become, in certain cases, an option for the construction of alternative spheres of public debate, or what Fraser (1993) has called “counter public spheres” in reference to the limitations of the original concept of public sphere put forward by Jurgen Habermas. The latter may not be appropriate to understand the way “ethnic citizenship” has been absent in most constructions of the public sphere in modern states.

The first academic references to indigenous peoples and the Internet in Latin America began coming out in the late 1990s, mostly analysing the impact of the Zapatistas use of the medium after the uprising of 1994 as part of their political and cultural program against the expansionism of the Mexican State (Froehling, 1997; Knudson, 1998; Cleaver, 1998; Becker & Delgado, 1998; Barnhardt-Park, 2000; Villarreal & Gil, 2001). These were primarily academic examinations of a new phenomenon, written in English and targeting mainly a small section of politically aware English-speaking academics.

Since then, several other documents have been published in several languages including indigenous languages. One of the first was written by Sami Pilco, an indigenous woman from Ecuador as part of a postgraduate degree at the University of Bergen, Norway. This document written in 2000 may be regarded as one of the first critical analyses from an indigenous perspective of the challenges of IT to indigenous peoples in Latin America. What is interesting in Pilco’s early analysis is her critical problematization of the “democratic” nature of the Internet, the logic of IT towards consumerism and profit and the challenges that ICTs pose to indigenous peoples. This work is definitely the first attempt to systematize different experiences of indigenous appropriation of the Internet in Latin America and

critically analyses the politics of representation (and self-representation) of indigenous peoples in cyberspace. The study concluded that with notable exceptions, most Internet sites with indigenous content were produced by international NGOs as a way of promoting indigenous development and as part of technology transfer programs of European cooperation agencies, but only a few were produced by indigenous peoples themselves. This has changed in recent years as several indigenous organizations have become autonomous in their use of the Internet.

More recently, in what is perhaps the most comprehensive analysis of indigenous peoples' access to IT in Latin America, Hernandez and Calcagno (2003) have written a significant case outlining the opportunities, challenges and possible paths for indigenous peoples' involvement in the information society. The document, elaborated by the United Nations Economic Commission for Latin America and the Caribbean (ECLAC) and the Institute for Connectivity in the Americas (ICA), is a serious and respectful attempt to develop a typology of indigenous Internet sites in Latin America, and a summary of the modes that indigenous communications may take within a Latin American "information society."

In their study, Hernandez and Calcagno (2003) distinguish Web sites by the ethnic origin of their creators, by the level of representation of the institutions, by the geographical location of the creators, by the origin of the funding agent, by the language used on the Web site and by the main interests or subject matter of the Web site. In the first instance, the authors include two variants. First, those Web sites developed by non-indigenous peoples, generally intellectuals, foundations, academic institutions, governmental organizations, social science professional associations and NGOs. These have an emphasis on disseminating historical, social, political, linguistic, ecological, ethnic and technical information; legislation; and denouncements against actions

that threaten territories, organizations and people, as well as human and cultural rights. Second, there are Web sites produced by indigenous peoples, as in the case of those developed by local grassroots organizations, NGOs and associations that coordinate the activities of various regional, national and international ethnic organizations. The primary objective of these sites is "to use the Web to display the presence and points of view of the indigenous organizations about topics of interest for the communities: globalization, the economy, indigenous politics, relations with the national society and transnational businesses, cosmology, history, art, native language courses, dictionaries, grammars, etc." (Hernandez & Calcagno, 2003, p. 11).

More importantly, the document promotes a practical framework for action by way of a regional strategy for the reduction of the *information marginalization* of indigenous communities. This regional strategy is put into practice through specific programs for indigenous access to the new information and communication technologies, which in turn are based in the demands of the communities themselves. The study clearly acknowledges that the digital divide has become a new form of indigenous cultural exclusion. However, it moves beyond the critical study of the impacts of ICT to an attempt to incorporate the specific cultural variables of indigenous peoples' appropriation and use of IT.

First, in this regard, the study emphasizes the need for respecting community organizations, social and communal solidarities and indigenous law in the design of consensual policies and actions that correspond to concrete means of reduction of the social phenomenon of information exclusion.

Second, there is the assumption that the principle of self-determination — where a community or nation plays an active role in its own development and is capable of making its own decisions in matters of "national" interest — is

intimately tied to the principle of self-management. Self-management of ICTs refers to the ability “to learn the concrete tasks that require the gradual incorporation of the population and the indigenous communities into the digitalization process” (Hernandez & Calcagno, 2003).

THE POETICS OF INFORMATION AND COMMUNICATION TECHNOLOGIES

In this section of the chapter I put forward some theoretical considerations before going on to look at several case studies of indigenous peoples’ use of IT. I propose an examination of the “poetics” of information technology or, in other words, the process of media *making*. A poetics of ICT is therefore concerned with the way media comes into being and functions in a given community, group or culture through its practice, or poiesis. It is concerned with the way social practices of technology are grounded in cultural politics and social action, generally rooted in local social solidarities. This poiesis, or making of communication technologies, is both a process and product of cultural representation. Therefore, the term ICT should be understood more in a practical way, as a form of action, and not exclusively in a technical way, as the incorporation of material gadgets or tools into indigenous peoples’ lives. By acknowledging that indigenous engagements with digital technologies of information and communication have their own logic, then the structuralization of indigenous information technology in Latin America can be contextualized in broader processes of cultural activism, including the new processes of ethnic resurgence originating primarily since 1992 onwards.

In attempting to decolonize research on indigenous peoples and information technology from the often ethnocentric assumptions of development and technology transfer, it must be assumed

that the appropriation of a new technology is ultimately a process of negotiation between different constituencies and the creation of content is ultimately a social process. Thus, indigenous media production in general and the appropriation of new technology in particular shouldn’t be seen as isolated phenomena, but as inserted in historical conditions and placed in intertextual and intercultural frames of reference, like the struggle of the Mapuche against the logging companies in Chile, the Zapatistas against the Mexican State or the Ashaninka in Peru as a way to defend their biodiversity rights against the onslaught of American transnational companies.

INDIGENOUS PEOPLES AND THE USES OF ICT IN LATIN AMERICA

In 1998, only 0.8% of the population in Latin America had access to the Internet. In 2004, more than 55 million users — or 10% of the total population — had access, marking the single most important increase worldwide. Among these users, 50% are located in urban centres of Brazil, while the previous year Uruguay and Chile had the highest levels of internet penetration in the region, with 34% and 29% respectively. However, despite exponential growth, the average cost of Internet access in most Latin American and Caribbean countries is still much higher than the average connection in the U.S., Canada, Australia, Japan or western European countries. This growth may be partly explained by the strong wave of privatisation of the Latin American telecommunication markets during the early 1990s, leading to an explosion of new technologies, new services and an influx of new market players, including also the move by several states to become part of the “information revolution.”

The wave of privatisations, deregulation and liberalization of the information and telecommunication sectors during the last two decades, to-

gether with a reorientation of foreign cooperation development funding towards programs dealing with new information and communication technologies and a more active role of public policy and state involvement, have paved the way for more innovative implementations of ICT initiatives in indigenous communities, ranging from literacy to political activism and e-commerce. Many initiatives have sprung from indigenous organizations themselves, who have been able to access IT through their own means. Let us look, then, at some important examples of the favourable use of ICTs by indigenous organizations in Latin America.

ICT Access and Literacy

Information technology literacy has become a critical aspect of the incorporation of indigenous cultures into the information society, as shown by a variety of pilot programs in different countries in the region. One of the most notable cases in recent years has been the Telematic Network for Indigenous Populations begun in 2000 simultaneously in Bolivia, Peru, Ecuador and Colombia. The pilot project is funded by the United Nations and coordinated by INKARRI, a non-governmental organization and indigenous documentation centre with headquarters in the Basque country. Since its inception, the project has sought the systematization of mechanisms for the appropriation of telematic technology and computer science by indigenous organizations. The five-year plan (under review in 2005) has aimed at strengthening local capacities through promotion of a more democratic participation, the latter stimulated by shared access to ICTs through public or collective telecenters in rural and peripheral-urban areas. What seems really critical in this initiative is the emphasis on the self-identification of local practices that benefit through the use of the ICTs, which in turn has encouraged the appropriation and use of new

digital, computer-based technologies within the communities.

Another similar initiative began around the same time (1999), the Internet Radio for Ashaninka Aboriginal Communities in Peru, which promotes computer literacy and community access through telecentres for over 60 Ashaninka communities in the Peruvian Sierra. The Ashaninka project — funded by IDRC, the Canadian International Development and Research Centre, through one of its PAN Americas initiatives — has been strongly motivated by new forms of self-management offered by the new technologies and the opportunities for the production of content; this in turn has fostered processes of appropriation and training of indigenous ICT users. Through the use of high frequency Internet radio, over 60 Ashaninka communities, located in a relatively extensive area of the Peruvian Andes, have been able to establish a network of intra-communal information that ranges from cultural revival to protection of native rights to natural resources and traditional medicine. In addition, e-commerce is promoted, whereby the communities are able to sell products — such as coffee — in big urban centres such like Lima. The project has also become an important way for the Ashaninka to fight for traditional knowledge of medicinal plants and the access to their ancestral environment resources, which have been seriously threatened by the activities of large foreign transnational companies.

ICT and E-Commerce

The issue of e-commerce is not unique to the Ashaninka communities of Peru. Otavalo communities in northern Ecuador have established important businesses in Europe, where they market weavings and other crafts. Another example is the pilot project Virtual Bolivian Market, financed by the International Telecommunication Union in 1999. This is an innovative project of indigenous e-commerce that aims to supply indigenous and

peasant communities with e-commerce tools, such as an online purchasing portal that allows visitors to buy various products, including music, handicrafts and food.

The commercial use of IT in indigenous communities is still marginal and, despite these cases, the Internet is yet to become a technology for profit. Up until now, IT has been primarily an instrument of political advocacy and cultural activism, as it has allowed for wide ranging and fast circulation of information.

ICT and Political Advocacy

When looking at the shaping of ICT for political activism and advocacy, it is important to remark the ways in which ICTs have been constructed as fields of symbolic struggle all over the region (Bonilla, 2000). Some of the best known cases of indigenous organizations that have made effective use of ICT for political purposes are the Zapatistas in Chiapas, Mexico and the Confederation of Indigenous Nations of Ecuador (CONAIE). The CONAIE was formed in 1988 and is today one of the strongest indigenous organizations in the world. Computer networking played a pivotal role when the CONAIE was able to coordinate and organize mass mobilizations of indigenous peoples and peasants during the massive protests of 1997 and 2000, both of which led to the ousting of Ecuadorian presidents. Similar events have occurred in Bolivia with the rise of Aymara ethno-nationalism in recent years. In Panama, some Kuna communities have forged institutional partnerships with international environmental NGOs to work towards the preservation of their traditional resources and environment, and, in similar circumstances, indigenous groups in Colombia have made useful exercise of information technology to arrest the offensive of transnational oil companies and the onslaught of both the guerrilla and paramilitary forces. In Bolivia a new project by CIDOB, the Confederation of

Indigenous Peoples of Eastern Bolivia, is creating an information system (database and Web site) to work on claims by Bolivian indigenous groups regarding their land rights. The information is collected through CIDOB's regional offices, and is used to inform the indigenous groups as to the state of their claims and to obtain information in relation to conflicts and negotiations regarding indigenous land.

In this regard, Bolivia is at the forefront of indigenous peoples' use of new technologies. The country has been one of the regional centres for indigenous media production in recent years, for example, hosting the regional office of CLACPI, the Latin American Indigenous Council of Film, Video and Communications. The Bolivian Plan of Indigenous Audiovisual Communications, designed in 1996 after a regional meeting of CLACPI in La Paz, constitutes a concrete outcome of a long process by which several indigenous and peasant organizations in Bolivia established a long-term scheme of audiovisual communication in conjunction with CEFREC, an independent Film Education Centre. Mainly working with video, but recently with new technologies as well, it is interesting to note how indigenous peoples in Bolivia have been able to begin inserting their cultural narratives into broader spheres, based on their ancestral forms of communication and representation. Through this scheme, a varied and thriving indigenous media practice has emerged, establishing the foundation for a series of exchange practices at the national level that allow for the continuation of traditional forms of oral and collective memory. As such, video has come to be conceptualised as a tool for empowerment and as a tactic to elaborate an ambitious strategy for cultural survival, promoting a more democratic and multicultural participation in the mass media.

In Chile, the Mapuche movement has also been active in the use of ICT for creating alternative public spheres of debate. Mapuche organiza-

tions and individuals, both in Chile and abroad, have constructed a remarkable digital network of Web sites and online communication. These organizations have vehemently embraced the Internet as a viable tactic for building a counter-hegemonic discourse that has started to impact the national public sphere. These instances stand out as notable cases of radical indigenous media practices which I argue can be seen as a strong yet incipient indigenous (Mapuche) public sphere. Today there are at least twenty-five distinctive Mapuche Web sites, some hosted in Chile, many others in countries like Sweden, the Netherlands, the United Kingdom, France, Germany, Belgium and Spain. Most of these sites have been used as vehicles of expression for processes of “rebellious communication” (Downing, 2001) as well as mobilisation originating at the community level (see also Salazar, 2003). To support the argument that one of the primordial uses of the Internet for the Mapuche has been to develop an oppositional public sphere, I will focus here only on those cases that I believe have played a key role. In general terms, the Mapuche Web sites have continued to bare witness to the legacies of the military dictatorship, even after fifteen years of democratic administration. Examples of this are the neo-liberal policies impacting negatively on indigenous peoples and the environment, or the infliction of the anti-terrorist law of 1979 — designed under the military dictatorship of General Augusto Pinochet to counter Marxist guerrillas — on Mapuche peasants and activists. The Mapuche Web sites have been crucial in showing images of police abuse, the action of paramilitary groups and the militarisation of rural communities in the south. They have raised fresh claims over the control, production and circulation of images and the ownership of media and communications outlets. In general, the Mapuche online network is a locus without a centre and without vertical control with the potential to host a “free and influential public space, a sphere of social action

not separate but fully linked to and a protagonist in conflicts and antagonisms” (Carlini, 1996, in Bentivegna, 2002, p. 59).

THE FUTURE AHEAD: INDIGENOUS COMMUNICATION RIGHTS

The social impact of ICTs on indigenous populations has been a critical issue in recent years. The chapter has summarized some of the current issues, literature and contexts of use regarding indigenous peoples and ICTs in Latin America. It has been argued that to move beyond the “impact of technology on society” approach, we need to attend to the cultural constructions of technology and the way indigenous groups may use, appropriate, conceive and image technology differently than other populations. Questions of self-determination that have been so important within indigenous movements worldwide need also to apply to communication. Further research on the topic should focus more on examining ways of developing autonomous indigenous communications and self-management. As indigenous communities gain increasing access to ICT in coming years, researchers, advocates and policy makers will also need to put more attention to the design of appropriate regulatory frameworks to ensure indigenous communication rights and to open truly intercultural information spaces. This begins with the design and implementation of programs aimed at reducing computer illiteracy and at promoting favourable attitudes for the incorporation of the ICTs within communities and organizations based on principles of indigenous knowledge and law. The incorporation of indigenous languages within these new frameworks will be of critical importance in deploying a new configuration of indigenous communications.

Moreover, indigenous peoples around the world have a broad range of knowledge with

high potential commercial value for national and transnational corporations. This has been demonstrated through a series of international studies and reports by non-governmental groups and indigenous organizations that have shown the critical importance of implementing intellectual property rights to such knowledge so that local and indigenous communities can have an instrument to fight against “piracy” by foreign companies and researchers. As has been shown in the case studies mentioned in this chapter, ICTs will have critical importance in promoting a more equitable distribution of profits from the commercialization of indigenous knowledge, whether it be of plants with medicinal properties, television programs or alternative farming practices.

Chapter 4.5

Assessing Universal Access to ICT in Ghana

Godfred Frempong

Science and Technology Policy Research Institute, Ghana

Imoro Braimah

Kwame Nkrumah University of Science and Technology, Ghana

INTRODUCTION

Information and Communication Technologies (ICT)¹ have become part of the key factors driving social and economic advancement. They have not only altered the way people live, work, communicate and entertain themselves but also created a new infrastructure for business, scientific advancement and social interaction.

Given the importance of ICT, many countries (developed and developing) have evolved policies that would enable every citizen to participate in the digital revolution. However, access to the ICT is concentrated in few regions, countries and population groups. The result is that there is a deepening gap between the developed and developing countries in the availability and accessibility to ICT services. This is referred to as the digital divide. The digital divide is following and supplementing the prevailing income and economic divides existing between developed and developing countries (Navas-Sabater, Dymond & Juntunen, 2002).

According to Navas-Sabater, Dymond and Juntunen (2002), there are two aspects of the digital divide—poverty and isolation. They defined the two aspects, as disparity between the rich and the poor on one hand, and disparities between urban and rural areas on the other. They argue that although both components are important, isolation poses a greater challenge to the utilisation of the service. Therefore, addressing the internal disparities becomes central to universal access discussions.

The policy objective of developed countries is to ensure equal access to ICT services by all the populace—universal service. The concept of universal service is based on the need for uniform geographical coverage of the service, quality, price, and the service offered on a non-discriminatory basis so that the expected benefits of ICTs would be available to the whole population (Tarjanne, 2000). The concept of universal service has increasingly been narrowed down to the connection of households to the public-switched telephone network. Here, the objective

is to achieve a minimum level of ICT services that must be available to all users regardless of where they are living and at a price which should be affordable to all (Wellenius, 2000).

Developing countries on their part have adopted a policy that emphasises community's access to ICT services—universal access. Efforts to promote universal access to ICT in Africa have been on the agenda of meetings of high-level policymakers since the early 1990s (Etta & Parvyn-Wamahiu, 2003). As a result different criteria such as distance, population size, time, etc., have been used by these countries to define what they mean by universal access. For example, in Ghana, the criterion is a telephone in every locality of 500 people, whilst in Burkina Faso it is a telephone within every 20 km (ITU, 1998).

The objective of this paper is to assess the deployment of ICT to achieve universal access in Ghana. Given the broad definition of ICT, the assessment will cover telecommunication (specifically telephone), the Internet, computer hardware and broadcasting (radio and television). Until 2003, achievement of universal access in Ghana was more related to increased penetration of telephones—fixed line and mobile, therefore, prominence is given to the deployment of telephones.

UNIVERSAL ACCESS POLICIES IN GHANA

For a long time, Ghana had no definite policy on universal access to ICT services. However, references can be made to programmes that gave some indications of government's intentions. The first of such programmes was the Accelerated Development Plan (1994 – 2000) for the telecom sector. The general objective of the Accelerated Development Plan (ADP) was to revamp the telecom sector through the participation of the private sector to meet the increasing social and

economic needs of Ghanaians. This was to enable Ghana to be integrated into the global economy as well as achieving the broad national objective of becoming the “gateway” to West Africa (Atubra & Frempong, 1999).

The government under the ADP adopted the use of pay phones as a way of achieving universal access. The target was to provide every rural community of 500 people with one pay phone. The ADP also had the objective of raising the national teledensity to a level between 1.5 and 2.5 by the year 2000.

The second evidence of government's policy on universal access can be found in the National Communications Regulations of 2003 (Legislative Instrument). Section 2 of the Legislative Instrument emphasised that the services of communication operators should reach the entire geographical areas specified in their licenses, which include rural, remote parts and sparsely populated areas. Therefore, in the issuance of licenses, the National Communications Authority (NCA) had an intrinsic objective of ensuring universal access to ICT services.

The first succinct ICT policy for Ghana was launched in the latter part of 2003. For universal access, the general objective was to promote equal and universal access to ICT services and resources to all communities. The universal access objective is to be achieved through:

- Implementation of community-based national ICT programmes and initiatives including telemedicine, multi-purpose community telecentres, tele-education and schoolnet initiatives.
- Community-based village information and communications infrastructure initiatives.
- Special ICT initiatives targeted at the disadvantaged communities and sections of the Ghanaian society, including the underserved communities and the physically and mentally challenged (Ghana Government, 2003)².

ICT INFRASTRUCTURE

In the early part of the 1990s, Ghana liberalised both telecom services and the airwaves. This liberalisation policy had had profound impact on the development of ICT infrastructure³ in the country. In this section, we provide an overview of the deployment of ICT infrastructure in the country. The overview shall include telecommunication, the Internet, radio and television.

TELECOMMUNICATION SERVICES

Fixed Line Telephones

There has been considerable improvement in the penetration of fixed-line telephones in the country. In 1990, there were a little over 44,000 telephone lines in the country and this increased to 288,500 in 2003.

Ghana has three companies providing fixed line telephone services—Ghana Telecom (GT), Westel and Capital Telecom. In 2003, there were 291,978 telephones in the country of which the incumbent GT had about 98.8% share. The teledensity of the country was 1.42.

Work by Frempong (2004) revealed that the Greater Accra Region, which hosts the national capital has about 67% of the telephone lines in the country. In this sense, availability of the service in the other regions was limited and therefore, has negative implications for achieving universal access to the service (see Figure 1).

The concentration of telephone lines in the Greater Accra does not necessarily mean that there is increased access by residential users. Most of the service is subscribed to by government departments and agencies, and corporate organisations operating in the Accra-Tema Metropolitan Assemblies.

Pay Phones

There has been a considerable improvement in the deployment of the service in the country. There were only 25 pay phones in the country in 1993, but as at 2003, the number had risen to 6,921. The penetration of pay phones per 1,000 people in 2003 was 0.33, while the ratio of pay phones to private main telephones was 1:42. But the penetration level is less than a pay phone for a community of 500 and in this sense the goal set by government with respect to the development in rural areas was not achieved.

Table 1. Basic telecommunications data (ITU [2003] Telecom Indicators and Ghana Telecom [2004])

Indicators	Number
Fixed-Line Telephone Networks	3
Fixed Telephone lines	291,978
Teledensity (Fixed telephone lines)	1.42
Waiting list for Fixed Telephones	183,755
Pay phones	6,921
Pay phones (per 1000 inhabitants)	0.33
Ratio of Pay phones to Fixed Telephone Lines	1:43
Cellular Mobile Telephone Networks	4
Mobile subscribers	775,000
Mobile subscribers per 100 inhabitants.	3.8
Ratio of Fixed Telephone subscribers to Mobile subscriber	1:2.7
Total No. of Tel. Subscribes (main line + mobile)	1,066,978

Figure 1. Regional distribution of Ghana Telecom fixed line telephones (Source: Ghana Telecom)

Communication Centres

Another source of telephone service is through what is locally called Communication Centres. Communication Centres in Ghana are basically private commercial ventures which re-sell telephone services from a few number of lines obtained largely from Ghana Telecom. They do not include Internet cafés. However, some of the operators have arrangements with some of the Internet Service Providers (ISPs), notably Africa Online to provide points where people can send and receive e-mails. At these Centres, people make and receive calls and this provides an important access to telephone service for the rural population.

In general, there has been appreciable improvement in the access to telephone service including pay phones after the liberalisation of the sector in 1996. This is contrasted with the situation in some African countries where mobile telephone deployment has negatively affected fixed line telephone.⁴

Mobile Telephones

Mobile telephony was introduced into the country in 1992 by Millicom SA. Presently, there are four

mobile telephone companies—Millicom Ghana Limited, Kasapa Telecom, Scancom Ghana Limited and One Touch (a subsidiary of GT)—making Ghana one of the most liberalised mobile telephone markets in Africa as the African average is two mobile operators. The total mobile telephone (i.e., cellular) subscription in 2003 was 775,000 with mobile teledensity of 3.8. The deployment of mobile telephones outpaced the fixed-line telephones in 2002. The ratio of fixed line to cellular mobile telephone was 1:2.7.

Mobile telephony in Ghana started early within the African context. However, subsequent development was not as fast as in many other countries. For example, countries like Senegal, Cote d'Ivoire, Cameroon, Kenya, Tanzania and Uganda have outperformed Ghana (Frempong and Henten, 2004). In 2001, mobile penetration in Ghana was 0.64, while that of Uganda, which introduced the service six years later, was 1.16. Absence of rigorous competition among the operators, especially between 1993-2000 largely contributed to the poor performance of the sector.⁵ Problems of interconnection has also negatively affected the operations of the mobile telephone companies.

INTERNET

Internet penetration in Ghana is very low compared to some African countries, especially the Republic of South Africa and the Maghreb region. In 2003, South Africa had more than 3.1 million Internet users, Egypt had 1.9 million users, while that of Ghana was 170,000 (ITU, 2003). Most users in Ghana have access through shared Internet connections—offices, cyber cafes, friends and to a less extent homes (Ahiabenu II, 2003). The country had 313 Internet hosts in 2003 and users per 10,000 inhabitants were 78.4 (see Table 2) which were below the African average of 123.21.

The Internet cafes are the most important sources of Internet access. In early 2003, there were over 750 Internet cafes in Ghana mostly using dial-ups. About 90% of these cafes are located in Accra, with the rest in the other cities such as Kumasi and Takoradi (Ahiabenu II. 2003).

BROADCASTING

Television

As of September 2003, the NCA had licensed 21 companies to broadcast and/or re-broadcast foreign TV signals in the country. Out of this number, only 10 are operational. Four companies were to provide free on air services of which three were to cover the whole country. However, it is only Ghana Broadcasting Corporation which has nation-wide coverage. The rest provide the service on a “pay as you view” basis largely in Accra-Tema, Kumasi and Takoradi—the major cities in the country.

In 2000, the penetration rate of television sets was 118 per 1,000 persons. In absolute figures, there were about 1.1 million TV sets in the country. However, the number might have improved considerably due to the influx of used TV sets into the country largely from Europe.

Radio

The National Communications Authority in September 2003 had allocated frequencies to 127 companies to operate FM radio stations in the country. However, not all of these companies had utilised their licenses. But a greater number (about 62%) of the companies had commenced business (Brammah and Frempong, 2003). From Figure 1, FM radio stations are available in all the 10 regions of the country. However, the majority (69%) of the stations are located in four regions - namely Greater Accra, Ashanti, Western and Brong Ahafo. The rural-based regions, especially the three in the northern part of the country had less FM stations. Therefore, access to radio services is more pronounced in the urbanised regions of the country.

From Table 2, though the number of TV and radio sets is not significantly high, the communal way of life, especially in the rural areas, increase

Table 2. Other ICT indicators (ITU, Information Technology Data [2003]) and NCA, 2003 Please note: not all service providers have commenced business)

Category	No.
Paging Service Providers	10
Internet Service Providers	112
VSAT Data Operators	96
Public/Corporate Data Operators	57
FM Stations	127
TV Stations	21
TV Sets	1.1 million
Total of Personal Computers	82,000
Personal Computers (per 100 persons)	0.38
Radio per 1000 persons (in 2000)	710
TV per 1000 persons (in 2000)	118
Internet Host	313
Internet users	170,000
Internet users per 10,000 inhabitants	78.43

Figure 2. Regional distribution of FM stations as of September 2003 (NCA, 2003)

the accessibility to the two services. People in such areas can watch TV and listen to radio programmes from the homes of friends and relations, and in this case, provide accessibility to the service.

REGIONAL DISTRIBUTION OF ICT COMPANIES IN GHANA

From the survey conducted as part of the Scan-ICT study⁶ in 2002, close to 45% of the ICT companies surveyed were in the Greater Accra region (mostly in Accra, the national capital). Ashanti Region, (mostly in Kumasi, the second largest city in Ghana) had 31% and 10% in the Central Region (see Table 3). Predominantly rural-based regions were not attractive to the ICT companies, due to the smallness of the market in those regions. In this case the vast majority of the people are denied access to the services those companies provide.

The ICT companies surveyed were business houses involved in the sale of ICT equipment, peripherals and services that conform to the International Standard Classification (ISIC) Rev. 3 and Rev. 3.1 of 2002. They include wholesale and retail of electronic and telecom equipment, computers, peripherals, software, television and radio receivers. Others were involved in ancillary

activities such as training, repair, installation of ICT related equipment and peripherals, and wiring of customers' premises.

These companies are important to the achievement of universal access as they enable people to acquire ancillary services, ICT equipment and peripherals, and invariably help increase access to ICT services. Profit being the ulterior motive of every business, these companies concentrate in areas where there are markets for their products and services. Invariably, their concentration in a particular locality (in this case Accra and Kumasi) will help increase the access to ICT services.

Table 3. Regional distributions of ICT companies (INIIT, The Ghana Scan-ICT Study, 2002)

Region	Percentage
Gt. Accra Region	45
Ashanti Region	31
Central Region	10
Western Region	4
Eastern Region	3
Brong Ahafo	2
Volta Region	2
Upper West Region	1
Upper East Region	1
Northern Region	1

To conclude, there has been considerable improvement in ICT infrastructure in the country. The liberalisation of the telecom and the airwaves provided a springboard for the introduction of many ICT services in the country. However, the objective of achieving universal access is still a mirage. Deployment of ICT infrastructure is skewed to the urban areas. In that case, the majority of the populace who reside in the rural areas have limited access.

CHALLENGES TO ATTAINING UNIVERSAL ACCESS

The discussion has revealed that in spite of the significant improvements in the deployment of fixed line and cellular mobile telephones, universal access is still far from realisation. A number of factors have constrained the attainment of universal access in the country. In this section, we shall look at some of these constraints.

Interconnection

One of the major problems that has mitigated against the achievement of universal access is interconnection between telecom operators. Telephone is the foundation for many of the ICT services. The interdependent nature of the telecom networks make it necessary for all operators to interconnect to provide a seamless network to enable users from different networks to communicate (Melody, 2001). The reform and the subsequent introduction of competition in telecom services have made interconnection a prominent feature of the telecom market.

Interconnection difficulties have adversely affected the deployment of telecom services and also constricted access to the service. Restrictive interconnection agreements had affected the performance of the other operators. For example, interconnection controversies between Westel and

GT delayed the former in launching its services in 1998. Problems of obtaining more EIs⁷ from GT had also constrained the ability of the mobile telephone operators to expand their services as quickly and widely as possible.

The problem of interconnection had also negatively affected the flow of foreign investments into the sector to help in the expansion of the network to improve the accessibility. For example, Westel attributed its inability to attract more investment to expand its service to the initial interconnection problems it encountered with GT. According to Westel, the problem sent a wrong signal to prospective investors and they became apprehensive about investing in the country.

Affordability

Access to the service is not only the physical availability but also the issue of affordability. Affordability depends on the financial strength of customers to pay for the service. In Ghana, accessibility and affordability are critical problems confronting the achievement of universal access.

The increase in the interconnection charge between cellular mobile and fixed line networks from US\$0.06 to US\$0.2 per minute in October of 2003 had serious financial implication on accessibility to telephone service, especially for rural dwellers. The increase in the interconnection call rate meant that callers to the cellular mobile network from fixed-line telephones had to pay more for the service. For example, previously callers to cellular mobile networks from fixed-line networks paid US\$0.1 per minute, however with the new tariffs, they pay US\$0.3 per minute at the communication centres.

The communication centre and Internet café concept provides a better way of ensuring universal access to ICT services in the country. At these cafes and centres, users can make and receive calls, send and receive faxes, check e-

mails and browse the Internet for a fee. Presently, the average cost of browsing the Internet for one hour is US\$0.65. This is increasing accessibility to the service, especially for the young people in the urban areas.

One of the problems affecting Internet penetration is limited access to telephone service and high connection charges. Access to Internet service is mainly through the dial-up system. Therefore one pays the normal telephone charge of US\$0.02 per minute for a dial-up access, in addition to the monthly subscription. The Network Computer System in 2003, charged a one-time connection fee of US\$50.00 and a monthly subscription of US\$35.00 for unlimited Internet service. The charges are considerably high for many potential private subscribers.

Low E-Literacy Level

The idea of e-literacy is based on the premise that people have the skills, awareness and understanding to participate in the e-services such as e-governance and e-mail service. People should be e-literate (individual e-readiness) to make use of these opportunities given by ICT technologies. The ability to become e-literate is strongly linked to being literate (ability to read and write) as ICT services are knowledge-intensive.

However, the low level of literacy in the country is a handicap to many people becoming e-literate to utilise these services. The estimated illiteracy level in Ghana is about 38.1% (Ghana Statistical Service, 2000) and in this case, a sizeable number of Ghanaians cannot use these knowledge-intensive services even if they are available in their communities.

CONCLUSION

It can be concluded that generally there has been improvement in the deployment of ICT infrastructure in the country since the liberalisa-

tion of telecom and the airwaves. However, the achievement of universal access is still far away from reality because much of the improvements in the ICT infrastructures are concentrated in the urban areas. The accessibility to telephone service (presently fixed line) is the first step towards the participation in the digital revolution but the teledensity is greatly skewed towards Accra, the national capital.

It is argued that the use of pay phones as a strategy to achieve universal access has limitations. Pay phones can only support voice communication and if universal access is extended to cover data transfer then pay phones will not be suitable. Therefore, there is the need to adopt a system that can support access to broad range of ICT services.

In terms of the electronic media, its uniqueness presents a better accessibility than telephones. One can easily receive the signal of radio and TV broadcast if one lives within the coverage area. The limiting factors, especially access to TV, are the initial cost of the set and availability of electricity. Notwithstanding, the communal way of life of most Ghanaians, especially those in the rural areas will enable many rural people without TV and radio sets to benefit from others.

KEY TERMS

Communications Centres: Commercial ventures which are reselling telephone services from a few number of telephone lines.

Digital Divide: The disparity in access to ICT services between people of different countries and those of the same country.

EIs: The links used for the physical interconnection between different networks.

ICT Infrastructure: The deployment of telecom (both fixed and mobile), TVs, radio, computers and Internet connections to enable the populace access ICT services.

Internet Cafes: Business units that resell Internet access to people.

Internet Service Providers: Companies that provide Internet access to individuals, groups or corporate organisations through normal telephones, satellites or fibre optics.

Universal Access: Communal access to telephone and other ICT services usually measured by indicators such as distance, population and time.

Universal Service: Widespread access to telephone and other ICT services normally related to household access.

ENDNOTES

- ¹ For the purpose of this study Information and Communication Technology (ICT) includes the production and utilisation of hardware, software and services for the processing, communication and maintenance of information.
- ² Programmes for the implementation of these universal access strategies and programmes are yet to be drawn as the national ICT policy was launched in the latter part of 2003.
- ³ ICT infrastructure as used here refers to the deployment of telecom (both fixed and mobile), TVs, radio, computers and Internet connections to enable the populace to access ICT services.
- ⁴ This was the general observation of the papers presented by the members of Research ICT Africa network meeting held in Cairo on 2nd May, 2004 as part of the Expert Forum on Telecom Regulation organised by World Dialogue on Regulation.
- ⁵ The launch of One Touch mobile service by the incumbent in October 2000, brought some dynamism into the market.
- ⁶ The SCAN-ICT project—an initiative of the International Development Research Centre (IDRC) and the Economic Commission for Africa (ECA) is designed to: build support for the phased development of a comprehensive African capability to collect and manage information on key ICT-related indicators to support the growing investment in ICTs as well as the transition of Africa to an information society.
- ⁷ The EIs are links used for physical interconnection between different networks.

Chapter 4.6

Caribbean Companies and the Information Superhighway

Simon Fraser

The University of the West Indies, Trinidad and Tabago

INTRODUCTION

With the explosion of public awareness of the Internet in the early 1990s, much attention has been focused on ways in which these new technologies can be used in developing nations. Some of the primary proponents of these initiatives include the World Bank, The United Nations Conference on Trade and Development (UNCTAD) and the Inter American Development Bank. The major themes include ways in which the Internet and electronic commerce can be harnessed for development, impediments to rapid diffusion of Internet technologies and success stories in small and medium companies.

Perhaps the most comprehensive review of these themes can be found in the United Nations Conference on Trade and Development's E-Commerce and Development Reports 2001, 2002 and

2003 (UNCTAD, 2001; UNCTAD, 2002; UNCTAD, 2003). Another rich source of information is Development Gateway's very comprehensive Web site, (<http://developmentgateway.org>), with links to hundreds of reports, publications and articles on the use of information and communications technologies in the development process.

Caribbean governments have also recognized the potential of the new technologies in fostering economic development. A search of the Web sites of regional newspapers turns up many stories written over the last decade promoting the Internet and electronic commerce. Once again, the major themes include the promise of electronic commerce for small and medium enterprises and factors precluding the effective utilization of the associated technologies and strategies in the region. (E-normous role in Ja for Net, 2000; Welcome to the Land of Pan, 2000).

Over last decade many Caribbean countries have witnessed massive investments in information and communications technology. Together, telephone companies, public and private corporations, cable television operators and Internet service providers have invested billions of dollars (United States currency) in new plant and equipment. These investments led to the introduction of an impressive array of new information and entertainment services. Simultaneously, many domestic banks introduced local and international credit cards.

These developments have given Caribbean businesses and residents unprecedented access to new information sources via the Internet and cable or satellite television. Their credit card accounts also give them the ability to act on advertisements shown on American television and Web sites. As such, there is a possibility that local companies could find themselves in direct competition with larger, better-financed corporations in more developed economies.

This paper will briefly highlight some salient characteristics of the English speaking Caribbean. The second section will review developments in the information and communications technology arena throughout the Caribbean during the period 1990 to 2002. This will be followed by a brief discussion of the impact that the Internet and its associated technologies can have on buyer search costs and information asymmetry. The fourth section will attempt to show how declines in information asymmetry in the region may translate into lower market shares, prices and in some cases business failure at the regional level. Evidence from U.S. industries will be considered. The section before last will also briefly examine how local retailers may benefit from the Internet and electronic commerce. Finally, the paper closes with a review of avenues for future research that will help close the knowledge gaps at a regional level.

OVERVIEW OF THE ENGLISH SPEAKING CARIBBEAN

The English speaking Caribbean is made up of former and remaining colonies of the United Kingdom. Geographically the region stretches from the Bahamas in the northwest to Guyana, located on the South American mainland. While many Caribbean nations are categorized as developing states, per capita incomes, access to health care, education and technology are significantly greater than the developing regions of Africa, Asia and Latin America. Some of these characteristics are summarized in Table 1.

Another critical characteristic of the English speaking Caribbean is the close proximity of most of the territories to the United States—the leading adopter of electronic commerce technologies and processes. Miami is a major international trade hub for the region. The flying time from Miami to any of the islands ranges between 30 minutes to the Bahamas and 4.5 hours to Guyana. Each country is served by daily flights to the United States. Several shipping lines offer scheduled service between the United States' eastern seaboard and each country.

Selected ICT Developments in the Caribbean (1990-2002)

Telephone Companies

The largest ICT investor in the region is almost certainly Cable & Wireless (C&W) and its regional subsidiaries. C&W subsidiaries have invested billions of US dollars in fiber optic backbones, digital switching technology and cellular networks (C&W Deal Signals New Investments, 1999). Most have joined international consortiums such as the Americas I and II undersea cable projects (TSTT to spend \$540 million on upgrade, 1998).

Caribbean Companies and the Information Superhighway

Table 1. Selected developmental statistics for the Caribbean, Africa, Latin America and South East Asia

Caribbean	Population (2003) ¹	GDP Per Capita US\$ ²	Infant Mortality (per 1000) ³	Gross Enrollment Ratio (Secondary Level) 2001	Motor Vehicles (per 1000 inhabitants) ⁴	Telephone Lines ⁵	Internet Users as % of total population ⁶
Barbados	270,000	9,486	11	103.3	268	48.1	5.56%
Bahamas	314,000	10476	18	91.5	342	40	6.75%
Guyana	765,000	936	51	90.5	100.8	9.2	12.42%
Jamaica	2,651,000	2,990	20	83.6	74	20.5	3.77%
St. Lucia	149,000	4,994	15	86	172	31.7	8.72%
St. Vincent and The Grenadines	120,000	2,940	16	72.5	117.8	22.7	4.58%

Mauritania	2,893,000	353	97	21.7	11.2	1	0.35%
Kenya	31,987,000	367	69	32	16.7	1	1.56%
Somalia	9,890,000	110	118	5.9	No Data	.3	0.10%

Latin America							
Brazil	178,470,000	\$2,925	38	107	111.9	21.8	8.01%
Argentina	38,428,000	\$5,267	20	99.6	197.7	22.4	10.67%
Chile	15,805,000	\$4,310	12	85.5	135	23.3	19.63%
Peru	27,167,000	\$2,053	33	81.7	50.1	7.8	7.36%
Ecuador	13,003	\$1,666	41	59.2	47.1	10.4	3.87%
Venezuela	25,000,000	\$3,134	19	68.6	100.2	10.9	5.08%

Asian Counties							
China	1,300,000,000	\$918	37	68.2	10.2	13.7	1.19%
Philippines	80,000,000	\$925	29	81.9	34.3	4.2	2.50%
Indonesia	219,883	\$678	42	57.9	27.6	3.5	1.82%
Malaysia	24,425,000	\$3,748	10	69.6	18.8	19.8	26.61%
Thailand	62,833,000	\$1,865	20	82.8	126.1	9.9	7.64%
Vietnam	81,377,000	\$416	34	69.7	.7	3.8	1.84%

Cable television companies have also invested heavily in new plants and equipment. Several are positioning themselves to enter the voice market when the telecommunications environment is liberalized. Caribbean consumers also have access to US television programming via DirecTV Latin America.

The Internet

Internet access is now firmly established in the English speaking Caribbean. Consumers can now access the Internet through dial-up connections, cyber cafes, schools, offices and kiosks (Net Kiosks Online, 2000). Most Islands now have at least one local Internet Service Provider, and the bigger territories have up to ten. Competition between the ISPs is fierce and prices have declined rapidly (Net War Heats Up, 2000) in the late-1990s before stabilizing.

Credit Cards

Consumers in the English speaking Caribbean were also able to open local credit card accounts for the first time during the 1990s. Visa International's Web site indicates that, as of March 31, 2004, the company had over 125 million credit card accounts in Latin America and the Caribbean (<http://corporate.visa.com/mc/stats/statistics-cardsissued.shtml>).

LITERATURE REVIEW

Information Asymmetry and Buyer Search Costs

One of the most powerful effects of the Internet is in its ability to reduce information asymmetry by lowering buyer search costs. Information asymmetry is thought to occur when one party to a transaction has more relevant information about

that transaction than the other party (Akerlof, 1970). While Akerlof's initial original article focused on asymmetric knowledge as it relates to quality, we can almost certainly apply his analysis to asymmetric knowledge as it relates to prices in different markets.

Buyer search costs refer to the cost incurred by the buyer to locate potential sellers, product information and pricing. These search costs include expenditure on driving to retail outlets, telephone calls, magazine subscriptions and the opportunity cost of the time spent searching (Bakos, 1997). The premise is that information and communications technology decreases search costs, allowing customers to easily compare prices from various potential suppliers (Bakos, 1991). Thus the reduction in buyer search costs leads to reduced information asymmetry which in turn should lead to more intense price negotiations, and correspondingly lower prices.

Several possible scenarios can be anticipated. First, the Caribbean consumer discovers that a product (called A) sold in a retail outlet in the Caribbean for X can now be purchased online for .3X (inclusive of shipping and handling). Second, the consumer discovers a superior grade of the product (B in this case) not available for sale in Caribbean retail outlets but available online for the same price as A retails for in the nearest shopping center. The consumer is then faced with four possible alternatives. First, she can choose to purchase at the local retailer knowing that she is probably not getting a good price. Second, she can forgo purchasing the item altogether. Third, she can bypass the Caribbean retailer and purchase from an American retailer. Finally, she can negotiate with her local retailer for a better (lower) price or better quality. Options two and three leave the retailer with no sale. Option 4 results in a sale but at a reduced price and perhaps reduced profit margin. Option 1 preserves the status quo, but may leave the consumer dissatisfied.

Recent work in the insurance industry suggests that the Internet has reduced prices (premiums) for term life insurance policies, a fairly homogenous product by 8% to 15% “*and increased consumer surplus by \$115-215 million per year*” (Brown & Goolsbee, 2000).

These studies concentrate on developments in the United States. There is a dearth of literature of similar studies carried out in the developing world in general or the Caribbean in particular. However, it seems reasonable to assume that Caribbean businesses and consumers are using the Internet to search for information relating to planned purchases. Prior to the Internet, the primary source of information on a wide variety of products and services would have come from the local distributors/agents and producers. Finding “off island” sellers and comparing prices would have required expensive long distance phone calls, faxes, and sometimes even site visits.

Some of the primary questions relating to downward pricing pressure include the following:

1. To what extent have prices paid by Caribbean consumers and businesses for various goods and services declined as a result of Internet access?
2. If there have been price declines, are they fairly uniform over industry, or do they vary from industry to industry?
3. Do Caribbean buyers perceive that they now have more power to negotiate lower prices vis-à-vis traditional suppliers, given increased access to information?
4. Are regional firms aware of any downward pricing pressure and, if so, have they attributed this development to reduced information asymmetry in favour of the buyer?

Channel Disintermediation

The threat of disintermediation is another issue facing Caribbean companies. Option 3 above

specifically refers to this threat. Recent business and academic literature has focused on the ability of producers and consumers to conduct transactions directly with each other, thus doing away with intermediaries in the supply chain. The rationale was that as the Internet dramatically lowered transaction and search costs, consumers and producers would now find it economical to do without intermediaries (Gellman, 1996).

Subsequent studies suggest that Gellman’s hypothesis is only partially correct (Brown & Goolsbee, 2002). What seems to be happening is that while some traditional intermediaries become less relevant (Traditional Travel Agents), new intermediaries are springing up in many industries—for example, Expedia.com and Travelocity. Reintermediation is the term applied to the emergence of new intermediaries based on the Internet. What seems to be occurring is that existing business processes and business models are being challenged by more efficient variants. Firms that are able to use the Internet to improve business processes and value systems will prosper. Firms that cannot will disappear over time.

The question then is will Caribbean companies, with limited financial, human and technological resources, be able to evolve quickly enough to adapt to a more competitive environment?

Studies on disintermediation have focused on the United States and other developing countries. A search of the EBSCO Host Business Source Premier and Academic Search Premier databases yielded 219 references to the term “disintermediation” but not one of them referred to developing nations.

However, Coulthard (2000) reported that studies in Australia indicate that while electronic commerce yielded “unequivocal” benefits for 30 out of 57 regions, 24 out of 57 experienced an increase in economic activity, but a decrease in employment. The remaining three experienced declines in economic activity and employment. In trying to explain the differences, Coulthard

cites the study conducted by Australia's National Office of the Information Economy which states that, "*What matters is the composition of the region's underlying economy...regions more dependant on just a few key activities are vulnerable to an overall contraction as a result of greater use of eCommerce*" (Coulthard, 2000, p. 2, italics added).

Coulthard seems to attribute this decline to the disintermediation of companies located in small regional towns in rural Australia. While Australia on the whole is significantly more developed than many Caribbean nations, rural Australia probably shares several traits with the islands of the Caribbean. The most important of these is a reliance on a few industries for employment and earnings—primarily farming, mining and tourism.

Some of the preliminary questions relating to disintermediation include the following:

1. Is disintermediation taking place in the Caribbean?
2. If so, what industries are most vulnerable?
3. What industry attributes raise the risk of disintermediation and what attributes lower the risk?
4. Do local companies perceive that they are losing market share to their suppliers or to larger "hypermediaries"?

Not All Bad

Despite the gloomy scenarios described above, some Caribbean companies will benefit from the diffusion of the Internet throughout the region. There are many success stories on www.developmentgateway.org pointing to individuals and companies throughout the world that have been able to develop export markets through contacts made over the Internet. Like UNCTAD (2001), The United Nations Development Programme in its Human Development Report 2001 highlights the many ways in which the Internet can ben-

efit companies in developing countries (UNDP, 2001).

The United Nations, the World Bank, and many other development agencies focus primarily on export development. However, Caribbean companies who choose to focus on their own domestic markets can also benefit from the Internet. These companies, like consumers, benefit from a reduction in information asymmetry brought about by lower search costs. Consequently, they can source higher quality goods at lower costs and at lower expense. To the extent that selling prices in the domestic market remain stable, these lower costs translate to higher profitability. If regional companies pass these savings onto consumers, as they are likely to do in a competitive environment, then consumer welfare improves.

A key question that arises, however, is that even with these benefits, can Caribbean companies reduce costs, improve assortment and convenience quickly enough to compete with the giants corporations in North America, Europe and Asia?

CONCLUSION

Regional investments in ICT and the diffusion of the Internet in the English speaking Caribbean when considered alongside the literature on the effects of reduced search cost and information asymmetry suggest that there is the potential for negative impacts in the profitability of Caribbean business organizations. However, while the potential for negative side effects are prevalent, the author is not aware of any attempts to study these phenomena in any detail.

Promising areas for future research include:

1. Longitudinal studies on consumer and business attitudes about, and use of the Internet for, pre-purchase research on an island-by-island basis. These studies will show changes over time and regional variations between countries.

2. Comparisons of prices paid by Internet users versus those paid by non-users in selected product and service categories.
3. Longitudinal market share studies in selected product and service categories. These studies will assist in determining if regional businesses are being squeezed out of the value chain.

Without the data provided by these types of studies, economic policy makers and business executives will have an incomplete understanding of the full impact of electronic commerce in the Caribbean.

KEY TERMS

Buyer Search Costs: The financial, time and psychic costs incurred by a buyer as he or she searches for any type of information on a prospective purchase. These could include trips to the mall, telephone calls, purchase of reviews, etc.

The Caribbean: Also known as the West Indies, refers to a group of islands that border or are near the Caribbean Sea. This archipelago stretches southeastward from Florida to the north eastern coast of Venezuela. The Bahamas, Turks and Caicos and Guyana, though not geographically adjacent to the Caribbean Sea, are normally considered part of the Caribbean due to shared history, culture, language, etc.

Disintermediation: Disintermediation refers to the removal of intermediaries from the Supply Chain. The possibility of disintermediation is said to occur when there is market transparency and the final buyers become aware of manufacturers' prices intermediaries.

Electronic Commerce: Electronic Commerce refers to the buying, selling and servicing of goods over computer networks. These networks can be either public, such as the Internet, or private, such as the private Electronic Data Interchange (EDI) systems used by large companies.

Information and Communications Technologies: ICT refers to the computing and telecommunications hardware and software used to capture, process, transfer and store data.

Information Asymmetry: A situation where one party to a transaction has more information than another party. In many cases it is the seller who has more and better information about the quality and underlying costs of a product than the buyer.

Internet: A global public network that utilized the TCP/IP protocols to transfer data from one computer to another. The Internet is often referred to as a 'network of networks' as it is made up of thousands of smaller privately owned networks.

Reintermediation: The process of using ICT technologies to identify and exploit new intermediary roles in the supply chain. Reintermediation strategies are often based on providing superior service or convenience to buyers. New intermediaries that have taken advantage of the Internet to build large organizations include Amazon.com, eBay and iTunes.com. Reintermediation is often seen as the opposite of disintermediation.

Chapter 4.7

Technology Leapfrogging in Thailand

Louis Sanzogni

Griffith University, Australia

Heather Arthur-Gray

Griffith University, Australia

TECHNOLOGY LEAPFROGGING

The phrase “leapfrogging development” reflects the belief, especially in the 1980’s, among policymakers and theoreticians that information technologies, especially telecommunications, can help developing countries accelerate their pace of development or telescope the stages of growth (Singh, 1999).¹

The telecommunications literature uses the word “leapfrogging” in three ways:

- First, it is meant to imply that telecommunications can help developing countries skip over the stages of development and become members of a post-industrial society.
- Second, leapfrogging is used in “an engine of growth” sense to mean that telecom-

munications can help developing countries accelerate their pace of development².

- Finally, leapfrogging is used in a technical sense to signify skipping over the technological frontier or product cycle³.

Often the word leapfrogging is used interchangeably referring to both technical and economic “leaps”⁴ (Singh, 1999), usually though the two are interdependent. The term “Technology Leapfrogging” is also being used to describe the phenomenon that is being seriously and widely considered in the developing world with countries such as Egypt, Malaysia, Thailand, Canada and Bangladesh having gone or going through the experience at the moment (Davison, Vogel, Harris & Jones, 2000).

PROMISE OF ICT-DRIVEN GROWTH

The possibility of developing countries leapfrogging has come about through the progressively lower cost of technologies and the user friendliness that is allowing the development and implementation of systems that would otherwise be unavailable to them (Weiss, 1994). Further, “economic and social progress has forged in South East Asia (SEA) a perception of growth previously unparalleled in human history” (Lander, 2000). There is an inevitability in SEA that ICT-driven economic expansion will simply occur because of the size of the population, “which is young, well-educated and with rising incomes” (Lander, 2000). It can be further suggested that the expanding market and the use of high-tech devices are interpreted as cultural systems that are used in the construction of modernity and that the economic and social focus of the South East Asian nations is on market corporatism, market socialism and high tech developmentalism” (Boyd, 2002). Asian Tiger countries have been pursuing a number of projects that use Technology Leapfrogging to surge forward in this development and economic race, to rescind the ever-growing gap between the developed and developing countries (Gray & Sanzogni, 2004).

Availability of funds in the South Asian region has attracted \$4.196 billion (2.5% of total FDI) (Saidi & Yared, 2002). However, it is unclear how many countries fully appreciate the need for a coordinated effort across all sectors in terms of the implementation of an ICT-based commerce strategy. Such an implementation represents a considerable challenge requiring integration of technology, law, policy, business processes and skilled people (Keretho & Limstit, 2002). But that’s not all. A major problem facing developing nations is the lack of a sound telecommunication infrastructure which forms part of the basic building block for a modern ICT-based socio-economic infrastructure (Davison et al., 2000).

The close relationship of communication networks and development is one of the reasons that investment in communications has become a priority for so many governments. Only 5% of the population in developing countries has access to the Internet. With the measure of telecommunication access expressed as teledensity, we note that 50/100 people have telephones in the developed world against 1.4/100 in developing world (Tipton, 2002). In Asia the lag in provision of a basic telephone service was starkly illustrated by a report estimating only 10% of the 500 million telephones in the world were in Asia in 1991 (Asia Money, 1991; Larson, 1995). ICT has good potential to create (via communication) social and economic networks leading to advances in development. However, lack of ICT implementation not only runs the risk of an economic divide, but also a political divide with people being potentially cut off from participation in future economic activities beyond regional boundaries.

Further clouding the issue, there is no clear evidence, according to economists, to support the belief that ICT can create growth. There is also indication (Tipton, 2002) that difficulties in measuring success in ICT solutions increase when moving from the private to the public sector as there is lack of a framework of analysis (ultimately the P&L). Other difficulties cited are of a cultural nature, such as the resistance to systems leading to greater transparency and accountability, as in developing countries there are cultures of subterfuge, gifts in exchange of favours, etc.

NATIONAL FRAMEWORKS FOR “TECHNOLOGY LEAPFROGGING” DRIVEN DEVELOPMENT

Ultimately however, governments recognise the need to enhance physical and knowledge infrastructures to improve competitiveness. ICT solutions are seen as a strong central to enabler of these initiatives and successes in some countries in

Technology Leapfrogging in Thailand

the region give an optimistic outlook to leapfrogging implementations. Chalmers Johnson's study of Japan and later Weiss', Evans', and Wade's studies of South Korea, Taiwan and Singapore, all identified models of governments intervention for the fast-paced introduction of ICT (Tipton, 2002). These studies contributed to the identification of "pilot agencies" whose successful drive of ICT implementation stood out as good examples to follow. The respective agencies are Japan's Ministry of International Trade and Industry (MITI), South Korea's Economic Planning Board (EPB), Taiwan's Council for Economic Planning and Development (CEPAD), and Singapore's Economic Planning Board (EPB). Tipton (2002) attributes the ICT implementation successes of these nations to:

institutionalised position and organisational structure. They are elite institutions, attracting high-quality staff, possessing a high degree of cohesiveness and strong sense of commitment to national goals. They are not large bodies, but have adequate staff and independent funding that provides sufficient resources to achieve their mission. They possess powerful capabilities for assembling and analysing data, giving them insight into both current conditions and possible future directions of development. They are 'insulated' from direct contact with industry groups, but they are not 'insular' or isolated from the concerns of their constituents. This can be achieved organisationally by a combination of 'horizontal' departments responsible for overall policy and 'vertical' departments concerned with particular industries, but it depends to a large degree on the acknowledged expertise of the officials and their resulting prestige in dealing with industry groups. They are also insulated from short-term political concerns. They do not depend on politicians for their positions, and they must be able to resist pressure from politicians whose interest may clash with long-term approaches to economic policy.

Pilot agencies traditionally have performed two tasks:

- The provision of advice on policy development.
- Administrative responsibilities for the deployment of funds into specific industries for the introduction of new technologies whose benefits are judged to have the greatest probability of a beneficial spill-over effect into the economy as a whole.

It is important to note that while these agencies played and play a significant role in terms of policy development and technology implementation at the national level some, as in the case of Singapore's EPB, also helped in paving the way for foreign investment and the positioning of local offices of foreign firms with special emphasis on high tech.

We now turn our attention to two particular economies, namely South Korea and Thailand and draw comparisons in terms of leapfrogging success. Both these countries have emerging economies and plans to become leaders in the region by investing heavily in ICT. However we note that one economy is still essentially in reactive mode responding to issues and circumstances as they arise, while the other has adopted strategically-based proactive initiatives in order to promote and retain business investment. Mashelkar (2003) in his address to the Royal Society (10th Zuckerman Lecture) clearly elucidates the difficulties and promises that the introduction of a dynamic economic environment (such as in Singapore) can bring to developing nations.

South Korea

South Korea's successful initiatives leading to the transformation of its communications industries and environment are a great example of technology leapfrogging, which included infrastructure

development, technological progress, growth of its electronics industries, regulatory changes and changes in media culture and habits of the Korean people (Larson, 1995). Larson's (1995) study expounds the processes that South Korea utilised to advance to an information society, indicating teledensity increased faster than any comparable country in the world from 1978 to 1990. This rapid telecommunications network development during the 1980's attracted a great deal of attention because it occurred in a developing country. Accordingly many policy makers and industry experts believe that a modern telephone network is a prerequisite for development (Larson, 1995).

Korea's high level of literacy and high participation in education is seen as a prerequisite for the success rate enjoyed by ITC-based technologies. So much so in fact that today its knowledge and information industry plays a significant role in the nation's economy. Other significant factors in Korea's Internet access growth point to:

- The explicit introduction of Korean content on the Internet (a policy also adopted by Thailand).
- The release of broadband Internet access to facilitate streaming, gaming and e-commerce.
- Fibre-optic backbones across the country.
- Sound international connectivity that stood at 5.2 Gbps as of December 2001.
- The lowest broadband access prices in the world.
- Mobile/Internet numbering integration to facilitate mobile Internet.

Korea is now ready to move from e-readiness to e-nation since implementing a number of e-government projects. In 200 all government agencies and ministerial offices were connected to the Internet via high-speed backbone. About 80% of official documents are in digital form

with a 60% rate of document handling over the Internet. Property titles and owner registration is now handled online, as are births, deaths, marriages and divorces with citizens able to access and alter records online.

Korea's ICT success factors are:

- A National Project Evaluation to allow the government to put achievements into an international perspective, and also the comparison of different government strategies.
- An evaluation system for national IT projects composed of government officials as well as academics and experts from research organisations and industry.
- Research and development in the field of electronics and telecommunication, policy and vision for a knowledge-based society.
- Universal access as a direct challenge to the digital divide with goals to furnish every region in the country with broadband access.
- The distribution and supply of PCs with Internet access to children of low-income families and the availability of Internet access in public places.
- Right environment for ICT implementation and operation with the support of just legislation in the form of cyber laws and a secure operating environment.
- Learning from and sharing with others through a liberal dissemination of reciprocal experiences through conferences, workshops, forums, etc.

From the evidence, Korea's approach to ICT's successful implementation as a technology leapfrog should be seen in terms of a national enabler across all significant sectors and thus (in Korea's case at least) the ICT leapfrog appears to have achieved the status of a leapfrogging technology.

Thailand

In the case of Thailand Information Communication Technology (ICT) developments are divided into two diverse yet related areas (Technology and Telecommunications, respectively), which are fundamental for progressing Thailand into a post-industrial nation. Those technologies more specifically relate to the development of telecommunication and Internet infrastructures within the nation (Gray & Sanzogni, 2004). The National Information Technology Committee (NITC) oversees Thailand's ICT initiatives at the national level through a number of sub-committees.

Historically, in the early-1980s there were two state enterprises managing Thailand's telecommunications, the Telephone Organization of Thailand (TOT) and the Communications Authority of Thailand (CAT), providing a limited service of two telephones per 100 people (Corey, 1995; Weiss, 1994). The Asian Technology Information Program (ATIP) on IT&T in South East Asia conference 1995, reported that "Thailand has critical telecommunications infrastructure needs," indicating Thailand's national plan to add 8 million telecommunications lines by 2001 with a further goal to increase the lines per 100 people from two to 20 early in the new century. They estimated the growth demand at 600,000 lines per year (Corey, 1995). TOT estimated in 1996 that demand would rise to 800,000 (Palasri, Huter & Wenzel, 1999). Projected estimates for telecommunications installations were high in 1999, although this positive progression would have been significantly effected by the economic crash in 1997. These targets have not been met, according to the National Statistical Office of Thailand, which reports in the Thailand Development Indicators Report of 2003 (Ministry of Information and Communication Technology, 2003) that only 9.6 people per 100 people in the population had telephones, with a ratio of only 3.89 per 100 people having mobile phones. These figures are

no longer being distorted, as they are now being reported as separate telecommunications devices. Additionally another high-profile project, the SchoolNet project, seems to have stalled from an initial indication of 5,000 schools having Internet access by the year 2001 to only 4,794 reported as being online as of October 2004, after which there has been no further reporting (Ministry of Transport and Communications, 2001).

In 2000 Thailand's cabinet directed the National IT Committee to study e-ASEAN, a framework established in November 2000 by ASEAN (Association of South East Asian Nations) to facilitate the set up for an information-sharing medium, with a view to make recommendations with particular emphasis on e-services, e-government, and e-trade (<http://www.aseansec.org/11499.htm>). Thailand is pushing strongly for an e-Thailand identity as a forerunner to full participation in the global electronic marketplace. The formulation of Thailand's IT draft policy "IT 2010 (2001-2010)" signals Thailand's intention to move toward a knowledge economy. Within the course of the decade Thailand intends to move from a position of "Dynamic adopter" to "Potential Leader" with fully embraced and mature ICT-based technologies (Tipton, 2002).

To date, it appears that although Thailand had established an aggressive commitment to reform in the 1980's under the guidance of the then Prime Minister Prem Tinsulanonda, lack of recent coherent policy leadership since Prem Tinsulanonda left office in 1988 seems to have left a void where a comprehensive national IT policy is required (Corey, 1998) to aggressively utilise technology leapfrogging and make the significant funds available to develop the telecommunications network throughout Thailand in order to avoid a looming expansion of the digital divide. There is evidence that population reach is not good and far from uniform. Telephone lines per capita are still low, e-government initiatives are lagging behind and the education systems is still struggling to get

online or produce graduates to drive the economy. There is an ongoing need to promote e-commerce as a trading tool, which can be taken as a sign that it has not been taken up (seemingly due to lack of adequate supporting technical infrastructure, although negotiations are occurring in terms of further broadband development) (World IT Report, 2003). The harmonisation of cyber laws across trading partners is still in its infancy and, although on the National's IT committee agenda, quick progress is not expected in terms of an implementation across ASEAN trading partners (Bernama, 2003).

CONCLUSION

In concise terms (given the discussion thus far), the measure of success for an ICT leapfrog should be its pervasiveness throughout the nation's population, with clear, uniform support across its ethnic, social, cultural, economic, religious and political groups, men and women, the rich and poor, and the young and the old. ICT should thus be seen as an enabler of a national and eventually global epistemology model that is emergent, liberating, pluralistic and participatory on the world stage. With this mindset a nation can reap the full benefits of an ICT leapfrog, as ultimately it will have created a firm opportunity for the populous to inform and be informed at will.

Although Thailand is pursuing initiatives that have good potential as both technological (ICT) and economic (e-business, e-government, e-education and e-commerce to name some) drivers, the impetus seems to have stalled somewhat. The culprits seem to be inadequate funding, key committees under political jurisdiction, and a shortage of local experts and professionals (outside the political system) to drive the leapfrog (Tipton, 2002; World IT Report, 2003; ITU, 2003).

KEY TERMS

ASEAN: Association of Southeast Asian Countries.

ATIP: Asian Technology Information Program.

CAT: Communications Authority of Thailand.

E-ASEAN: A concept capturing the essence of the intent to establish electronic links at all levels between ASEAN countries.

E-Business: A concept capturing the essence of conducting business by electronic means in addition to or as a substitute for a physical location (bricks and mortar). E-business (electronic business) is, in its simplest form, the conduct of business on the Internet. It is a more generic term than e-commerce because it refers to not only buying and selling but also servicing customers and collaborating with business partners.

E-Commerce: A concept capturing the essence of carrying out commerce by electronic means. E-commerce (electronic commerce) refers to the buying and selling of goods and services on the Internet, especially the World Wide Web. In practice, this term and a newer term, e-business, are often used interchangeably.

E-Education: A concept capturing the essence of carrying out education by electronic means.

E-Government: A concept capturing the essence of carrying out the business of government by electronic means including the delivery of public services, and voting (in some instances).

P&L: Profit and Loss statement.

SEA: South East Asia.

TOT: Telephone Organization of Thailand.

Chapter 4.8

An ICT Enabled “Community” in Rural Nigeria and the UK

Pamela McLean

Cawdnet (CAWD)¹ and Dada McLean Ltd.², UK

INTRODUCTION

Development initiatives in Nigeria tend to be delivered down through layers of administration, from federal government, to state government, to local government, before they get implemented. Often developments are concentrated in urban areas rather than rural communities.

CawdNet¹ aims to link top-down research and development initiatives with people at the rural grassroots, not just through NGOs working with the “grassroots” community, but also by opening up existing communication channels amongst farmers, women, teachers, health workers, and young people, and integrating them into the communication channels of the connected community (McLean & Johnson, 2004). CawdNet³ has worked across the digital divide in its internal organisation, since 2001. Increasingly CawdNet is looking outwards and as a result members of the rural communities and members of various “connected communities” are becoming directly involved in these information flows.

THE CONTEXT OF CAWDNET: THE WORK AND WORKERS

CawdNet is an informal group, a “community,” whose existence has been enabled through Information and Communication Technology (ICT). The core members of CawdNet collaborate on work concerned with farmers, women, micro-credit, livelihoods, youth, health, education and other aspects of community development. The CawdNet core members are from Oke-Ogun Community Development Network (OCDN), Fantsuam Foundation (FF) Rural Searchlight (RUSEL) and CAWD volunteers. Although most of the core members are in local community development organisations in rural Nigeria, there are two CAWD volunteers in the UK, who act as a (proactive) link between the Internet and CawdNet in Nigeria. All CawdNet core members in Nigeria have some kind of e-mail link with CAWD volunteers, even if their access to e-mail can only happen infrequently because of difficult journeys to a cyber cafe.

There are very few paid "CawdNet workers."⁴ Most work with their CawdNet organisations happens "as and when" that work can be fitted in around other responsibilities and "day jobs." All CawdNet workers, except for the CAWD volunteers, are active in rural Nigeria.

"CawdNet friends" are comprised of individuals, groups or organisations that are helping (or have helped) to forward CawdNet's work in some way. Friends may have a formal or informal relationship with CawdNet, or with one or more of the organisations it represents. Many CawdNet friends are engaged in some kind of information exchange, free of charge, which enhances CawdNet's work. Free information exchange can range from someone sending occasional e-mails, with advice or information, to a graduate student working with the project for weeks or months at a time. Some friends help in cash or in kind. Voluntary Service Overseas (VSO) has been a much-valued friend in this way, but information is a more usual form of help. Most, but not all, of the CawdNet friends who give information are involved in some aspect of development in a professional full-time way. Some are exploring ways to collaborate on various planned projects.

Acquaintances of CawdNet are those we know less well, familiar names from discussion lists, or contacts at face-to-face meetings, people we have exchanged ideas with in a public way, who have helped to influence our thinking, but not in the personal, specifically "CawdNet directed" way of friends.

CawdNet, ICT AND COMMUNICATION

CawdNet's initial existence and subsequent development is totally an outcome of ICT. It is not a traditional organisation or group where communication, and the relationship to information, is simply enhanced by ICT. Without e-mail CawdNet could not have come into being. Without the In-

ternet, CawdNet could not have learnt so much about the "development world" of which it is a part. Without mailing lists and discussion groups CawdNet could not have started to make a place for itself within the wider context of the "development world." It could not have established many of the relationships that it values highly. Without those relationships, and the opportunities afforded by e-mail, it would not be exploring the various collaborative projects on community development that are currently under consideration.

CawdNet uses e-mail for internal communication. This is not desk-to-desk office e-mail communication. CawdNet workers typically have to travel to cyber cafes to send e-mails. This is necessary because their community work is based beyond the reach of the telecommunications infrastructure. VSAT links are making e-mail increasingly available. This means that access is gradually improving, regarding distances travelled, but expense is still a great barrier. As e-mails become easier for more people to send, there is a gradual increase in information exchange in the CAWDNET network. Also with increased access, more CawdNet workers, beyond the CawdNet core members, are communicating with CAWD volunteers. This improves the quality and quantity of information exchanged between the rural areas and the connected community.

The CAWD volunteers in the UK began their work through links of friendship with Peter Adetunji Oyawale, not through prior knowledge of the development initiatives. Hence there was a need for extensive effort to learn about the Nigerian development issues using e-mail and the Internet, which is supplemented by "on the ground" understanding in Nigeria. For most CawdNet workers in Nigeria, surfing the Net is excruciatingly slow and prohibitively expensive. Therefore, the CAWD volunteers undertake Internet work for other CawdNet workers and the communities they serve. The resulting information is forwarded by e-mails and on CD-Roms. Using such processes volunteers are often able to

find out about free material that can be supplied to them and which they would not otherwise have known about if they had relied upon traditional government services.

The e-mails to CAWD volunteers from the community are currently both short and few in number, but this traffic is increasing as access, knowledge and trust increase. It is important to understand that to the volunteers every e-mail is significant not just for what it says, but also for what it represents. The two following examples give some context to this:

1. The farmer society of Ago-Are are progressing and we are preparing for harvesting of yam and maize. Mr. Oyawale also said you should help him greet the Oyawale's family over there. Bye.

To the volunteers a personal greeting such as this plus a sentence about the harvest represents the very first report from the Farmers' SIG (Special Interest Group). It is evidence that the representatives of this group are trying to keep in touch. There is communication across the digital divide. Most of the people in the Ago-Are farmers group are illiterate and struggling in poverty, yet representatives of this group are making the effort to send traffic along the information “footpath” (it is far from being an “information highway” yet).

2. Dr E.Akioya:-“pls lorain can i get any free cd rom on HIV/AIDS,and polio. i was directed by pam.I am a medical doctor in nigeria.pls also keep me posted on other available health cds.”

An e-mail from a doctor, requesting specific information, is evidence that the Health SIG is beginning to “pull” information, where previously the information had been “pushed” by the volunteers.

Discussion lists, virtual conferences and other interactive exchanges on the Internet have two important functions for CawdNet. First there is

a lot to be learnt from acquaintances in this way. Secondly, some of these acquaintances develop into friends. Fantsuam Foundation and CAWD volunteers were Internet acquaintances long before they started working closely and the name CawdNet was adopted. Most of CawdNet's friends began as acquaintances on the Internet. This is even true of friends based in Nigeria, including some who are in fact geographically close to CawdNet core members.

In the connected community, CawdNet has friends and acquaintances from many parts of the globe, including Nigeria, and from many sectors: academia, development organisations, the Diaspora, alternative technology groups, ICT professionals, Open Source groups, research and development people, publishers, health professionals, social entrepreneurs, and others, each with their own particular area of interest which relates in some way to rural development. Most of these contacts have come through the work of Fantsuam Foundation and CAWD volunteers, actively reaching out to the connected community. Others have come unexpectedly, through people finding CawdNet through the Internet, via the Web sites of FF, or CAWD, or through the e-newsletter.

There are many virtual communities. What makes the small CawdNet community unusual is the boundaries that it crosses, by working both in the connected communities and in rural Nigerian communities. CawdNet has links, through personal networks, beyond the telecommunications infrastructure. Someone in the connected community who links with CawdNet, links with the formal and informal networks of rural Nigeria. OCDN, FF and RUSEL are grassroots organisations, led by people deeply embedded in their communities. They are networking with the poorest and most un-empowered members of their communities—subsistence farmers (men and women), petty traders, and unemployed youths—as well as knowing the elites, the highly educated, the professionals, business people, traditional rul-

ers, chiefs, politicians, administrators, religious leaders and community committees.

Another unusual feature of CawdNet is that the roots of its work are with the poor. RUSEL and FF both began as micro-credit organisations. CAWD was started by Peter Adetunji Oyawale, who was the son of a poor and illiterate farmer. Peter started the work in Oke-Ogun (now led by Oke-Ogun Community Development Network) because he wanted to help people like his parents and his friends from primary school to have a better future, and he believed that ICTs had a part to play. It was Peter who had the vision, and who made the initial links across the digital divide, from which CawdNet developed.

LOOKING FORWARD

CawdNet is a developing network so its form and its function are evolving. It is influenced by the ideas and examples of social entrepreneurs (Bornstein, 2004). Social entrepreneurs fit somewhere between the conventional models of "a charity" and "a business." CawdNet sees itself becoming increasingly involved in a mixture of new enterprises:

- Some charitable (such as subsidising education and training opportunities).
- Some sustainable businesses (perhaps related to alternative technologies; some perhaps providing an umbrella/franchise arrangement for small businesses, in enterprises that are more ambitious than the present micro-credit enabled opportunities; some others. Various ideas are emerging).
- Some hybrids of charity/business.

The businesses that CawdNet sees itself supporting tend to be small scale, in harmony with "Small is Beautiful" ideas of economic development (Schumacher, 1973).

CawdNet hopes the way forward will be one of increasing collaboration, of a situation where people who have knowledge of development (in whatever way), or a desire to support it financially, will join with people who know the realities of rural Nigeria (because it is the life they lead). This is already happening, but we hope it will greatly increase. CawdNet does not see its rural communities as passive potential recipients of development aid, but as partners and potential "rural consultants." Together with development workers they can try things out. In addition to being involved in the normal grant making and investment programmes, they could work within cross-cultural teams for a practical research and development, "R and D," approach to development (along the lines of what educators might term "project-based learning"). Such collaborations could lead to genuine problem solving on various issues of sustainable development and the Millennium Development Goals.

ENDNOTES

¹ CawdNet is not a formal organisation. The inclusive group term “CawdNet” was adopted because the people involved needed to be able to say “we.” The name came about because one of the benefits of working together is an increased ability to network—hence the “Net.” CawdNet traces its roots back to the vision of the late Peter Adetunji Oyawale and his original “CAWD” the Committee for African Welfare and Development—hence CawdNet. The name CAWD lives on through CAWD (Charity for African Welfare and Development, registration no 1104228) which was set up in June 2004 to fundraise.

² Dada McLean Ltd —Knowledge Brokers (UK registered company active in UK and Nigeria) is a key sponsor of CAWD. Web site www.dadamclean.com

Chapter 4.9

ICT in Medical Education in Trinidad and Tobago

Marilyn Lewis

The University of the West Indies, Trinidad and Tobago

INTRODUCTION AND BACKGROUND

Information and communication technology (ICT) allows users to access information without taking geographic position into account. These users are also unconstrained by time, volume, or format of the information. ICT applications have enormous potential as a tool for aiding development in countries such as Trinidad and Tobago. Telemedicine, which can provide medical services to persons in isolated places, in emergencies, to the homebound, or the physically challenged, is but one example. Mansell and Wehn de Montalvo (1998) noted that “ICT applications facilitate telemedicine” (p. 85), and that “economic development can be fostered by tele-working and tele-services in some developing countries” (p. 83).

The twin-island nation of Trinidad and Tobago lies at the southern end of the Caribbean chain of islands, approximately seven miles off the northeast coast of Venezuela. The area covers 1,864 square miles (5,128 sq. km.), with a population of approximately 1.5 million. The economy of this small nation state is based mainly on petroleum and gas-based industries, but there is a growing service sector. PAHO figures (2002a, b) show a highly literate population with an overall adult literacy rate of 98.5% (males at 99.1% and females at 97.9%).

Transshipment and telecommunications facilities contribute to this country’s position as the most industrialized in the Caribbean. The country’s technical capacity and access to information have grown enormously in recent years. Telecommunication tools extend to the

vast majority of the population. Per capita GDP stands at US\$8,500.

There is a shortage of medical staff in general, with the ratio of doctors to inhabitants at 7.5 per 10,000. Shortages in primary health care are more acute than in other areas and have resulted in the employment of retired nurses and the recruitment of professional staff from other countries, particularly from Nigeria, India, and more recently, from Cuba. Trinidad and Tobago therefore stands poised to benefit from further development by fully embracing ICT, especially in the areas of education and medicine.

MEDICAL EDUCATION IN TRINIDAD AND TOBAGO

Medical education in Trinidad and Tobago engenders self-directed, lifelong learning through the use of the problem-based learning (PBL) method of teaching. The Faculty of Medical Sciences (FMS) of the University of the West Indies opened in St. Augustine, Trinidad and Tobago, in 1989, and has utilized PBL from its inception. Students' relative independence has been noted (Donner & Bickley, 1993) in students following PBL programs. Donner and Bickley noted that "they differ markedly from those following traditional medical programmes... [becoming] more skilled at an eclectic style of learning" (p. 297). These students show particular personal characteristics that encourage them to take a proactive role in their own learning, making them lifelong learners.

Research has also shown that PBL students make maximum use of library resources and that librarians taught the use of technology as a means of accessing, organizing, and managing information (Marshall, 1993). Library instruction is therefore a required part of the curriculum. Librarians become not just providers of books and other materials but also instructors in the

use of modern technology. The library, therefore, prepares medical students for wider use of other applications and technologies to support their future information needs. This has implications for how these students will operate when faced with adverse conditions such as rural health offices and hospitals with limited resources, and for development in the community generally; these students in their homes, in their practices, and in the wider community will generate a multiplier effect.

INSTRUCTIONS IN THE USE OF MODERN TECHNOLOGIES IN THE MSL

From its inception, the Medical Sciences Library (MSL) has embarked on a program of information literacy for undergraduates and other categories of users. From as early as 1993, topics such as "MEDLINE: basic and advanced"; "International Pharmaceutical Abstracts (IPA)"; "MedCarib—health literature for the Caribbean"; "ProCite"; "Introduction to Computers"; and later, "EPI Info"; "Introduction to the Internet" and "PubMed" have been taught. In facilitating this training, the library equips its clientele with survival skills for the 21st century.

The Trinidad and Tobago Ministry of Health also recognized a need for retraining, because new demands were being placed on practitioners by health care transition, health care reforms, increased public and patient expectations, and advances in medical sciences and technology. The Ministry found that medical practitioners required additional skills. This was part of the rationale for the introduction in 2000 of a new postgraduate diploma in Primary Care and Family Medicine being offered by dual mode, face-to-face initially, and thereafter, through distance education.

The library component of this course focused on skills such as "Locating and evaluating health

information”; “Skills base for managing health information resources”; “Innovations in health information practice”; “Effective search and retrieval principles”; “MEDLINE on the Internet”; “Finding biomedical information on the Internet”; “Evaluating information resources”; and “Managing bibliographic references”. Assessment tasks included:

- Joining and leaving an electronic discussion group
- Subscribing and unsubscribing to a mailing list
- Posting to a discussion group
- Locating an electronic serial and printing an article or abstract
- Executing a search on MEDLINE or PubMed and printing the results
- Creating a small database and generating a bibliography

Each session represented distinct skills requirements and supported the utilization of applications to manage the efficient exchange of information among health professionals.

ICT IN EDUCATION: PRIMARY, SECONDARY, AND TERTIARY

Primary and secondary schools in Trinidad and Tobago are also embracing the technology. Many secondary schools have computer science as a subject on the curriculum and typically have computer laboratories. More than 35% of the 78 primary and 120 secondary schools listed in the telephone directory for 2003–2004 have computers with Internet access facilitated by Telecommunication Services of Trinidad and Tobago (TSTT), the only telephone company on the twin islands. Additionally, there are 22 Internet cafes listed in the yellow pages of this directory. Some of these Internet cafes are located in rural areas such as Enterprise, in Central Trinidad, and Penal in the

south of the island. Eighteen Internet Service Providers are listed as well.

Other initiatives to produce a computer literate society in Trinidad and Tobago include the government making computer loans available to all public servants. In 2002, the government also launched an initiative, the National Information and Communications Technology Plan (2004), that aims “to connect people, communities, business, government and educational institutions through an integrated technology network. It will also examine the policy, financial and skills development requirements that will be necessary to ensure sustainability and to ensure that the benefits of connectivity continue to grow, and accelerate, as new technologies, innovation and thinking emerge.”

A survey (NIHERST, 2002) designed to provide empirical data on the penetration of ICT in private households reflects the varying penetration of ICT in private homes of varying socioeconomic status. Data were collected from a representative sample of 2,812 households throughout Trinidad and Tobago. Thirteen percent (13%) of the households in Trinidad and Tobago (approximately 44,600 households based on national statistics for 2000) had a home computer as of June 2001. By comparison, more than 30% of the households in a number of Organisation for Economic Cooperation and Development (OECD) countries were equipped with computers in 1997, and more than half (54%) of the households in Australia had computers in May 2000. Other important findings of the survey were that affordability was the major constraint in 56% of all households without computers; ranging from 43.9% in the City of Port of Spain to 78% in the Borough of Point Fortin. Also, 53% of households purchased computers from private savings; 13% accessed government loans. Households (20%) with gross monthly incomes of \$6,000–\$7,999 had the largest proportion of home computers, followed by 15% of households with incomes of \$4,000–\$5,999. Only

5% of households with monthly incomes of less than \$2,000 had computers. In 2000, 27% of the computers were acquired compared with 6.7% in 1997. Almost three out of four persons (73%) in each household used the computer. The proportion of male (51%) to female (49%) computer users was generally similar. Approximately 16.6% of computer users were between 15 and 19 years of age, 16.3% between 30 and 39 years and 14.5% between 40 and 49 years. Of computer users, 50% had acquired secondary level education, and only 3.8% had a university level education in computer studies. Approximately 50% of computer users were employed and self-employed, and 39% were students. In private enterprises, 59.8% of employees used the computer compared with 29.7% in government. Windows 98 and 95 were the main operating systems in 74.4% of households. Most households (70.8%) used the computer daily between two and five or more hours. Only 11.8% of households were engaged in software development, and 20.2% accessed distance learning/education compared with other activities such as games (78.4%), Microsoft Office (66%), e-mail (62.4%), and Web searches (61.5%).

Apart from the Faculty of Medical Sciences, the university as a whole is also involved in programs to implement ICT applications. The UWI, St. Augustine, in its latest strategic plan (2003–2007) identified student-centeredness as one of its strategic objectives. The campus libraries, of which the MSL is a branch, determined that promoting the use of ICT in delivery of service and products was one way of meeting this objective. Additionally, an increasingly complex print and digital environment was emerging, and people began to expect certain services without coming to the library. Facilitated by the technology, the libraries were able to accomplish one of their main missions by launching a valuable new campus-wide online course, “Foundations of Information Literacy” on March 2, 2004. It is a modular course covering the following seven topics:

1. Basic computer literacy
2. Basic research skills
3. Using the OPAC (online public access catalogue)
4. The Internet as a research tool
5. West Indiana and Special Collections
6. Online databases
7. Managing references

There were tutorials on how to use each of the databases to which the libraries subscribe, as well as a quiz and online feedback, discussion board, and on-campus WebCT server.

In its quest to keep abreast of technology, the St. Augustine campus libraries is looking at further ways to implement applications in ICT in its ongoing program of work. Initiatives such as a digital reference service are also being considered. This project aims to answer students’ reference queries in real time and will enable persons needing live human assistance while using the Web to immediately get the help they need from librarians who can quickly provide the answers. Speed and responsiveness are critical to this initiative, which will radically change the way we serve and support our clientele.

A TOOL FOR COMMUNITY DEVELOPMENT

Based on our epidemiological circumstances, where the Caribbean is second only to Southern Africa in the proliferation of HIV/AIDS and other STDs, ICT can indeed be seen as an effective tool for development. The toll of HIV/AIDS is heaviest on young persons between the ages of 18 and 45, who form the majority of the workforce. CAREC figures indicate that in Trinidad and Tobago, 5,000 persons have died of AIDS since 1985. The nature of the response to these diseases has to do with preventive education, capacity building, and treatment, care, and support.

ICT can play a role in the way people connect with information. Through ICT, people in remote areas can have access to the same information as many of the people in developed countries. With an infusion of ICT learning, people in underdeveloped countries such as Trinidad and Tobago can access and share critical health information that can help in the fight against HIV and AIDS, and its related morbidity and mortality. Ideally, health education should begin in primary schools. When this occurs, the transformative nature of ICT on the epidemiological status of affected countries can become visible.

CONCLUSION

The type of medical education available in Trinidad and Tobago, the campus libraries' program of instruction in the use of ICT, the government's initiatives to make computers available to public servants, the provision of computers in primary and secondary schools, the burgeoning economy, and the developing infrastructure all signal that this country is capable of embracing fully ICT applications that can enhance community development. Additionally, the postgraduate course has been viewed as an investment in the health care of Trinidad and Tobago nationals, in terms of an enhanced quality of health care that will be rendered by the practitioners involved. Healthy individuals contribute to a more productive economy. The course is ongoing, therefore, there will need to be an increment to those receiving training, as well as those receiving enhanced care. Three further cycles of the postgraduate course have been held, resulting in at least 60 primary care physicians who have already been exposed to and benefited from the postgraduate training provided by the MSL.

By teaching the core competencies of information literacy, identifying the information needs, accessing information, and understanding the legal and other issues in the use of information,

the St. Augustine campus libraries aim first to increase the competitiveness of the student. However, not only have the libraries supported the academic enterprise, but they have also made available resources for knowledge creation and capacity building. At the Medical Sciences Library, we assisted in the retraining of primary care physicians to make them comfortable with the new technologies. This has resulted in more effective, efficient high-quality health care for the national community and has contributed to development.

Today's information consumer wants seamless access whenever and wherever they want it. They are comfortable with Web-based information. In this complex and rapidly changing, increasingly interconnected environment, ICT can be an effective tool for community development.

KEY TERMS

Digital Reference Service: A human-mediated, Internet-based service in which users' queries are answered in real time.

Discussion Group: Any system that supports group messaging, e.g., a shared mailbox, Usenet, bulletin board system, or possibly a mailing list, used to publish messages on some particular topic (FOLDOC, 2004).

Information Communications Technology (ICT): The study of the technology used to handle information and aid communication. The phrase was coined by Stevenson in his 1997 report to the UK government and promoted by the new National Curriculum documents for the UK in 2000 (FOLDOC, 2004).

Listserv: An automatic mailing list server, initially written to run under IBM's VM operating system by Eric Thomas. Listserv is a user name on some computers on BITNET/EARN which processes e-mail requests for addition to or deletion from mailing lists. Examples are listserv@ucsd.edu, listserver@nysernet.org. Some listservs provide other facilities such as retrieving files from archives and searching databases. Full details of available services can usually be obtained by sending a message with the word HELP in the subject and body to the listserv address. Eric Thomas has recently formed an international corporation, L-Soft, and has ported Listserv to a number of other platforms including Unix. Listserv has simultaneously been enhanced to use both the Internet and BITNET. Two other major mailing list processors, both of which run under Unix, are Majordomo, a freeware system, and Listproc, currently owned and developed by BITNET (FOLDOC, 2004).

MedCarib: A database of the health literature of the Caribbean.

MEDLINE: A CD-ROM database of medical literature in journals produced by the National Library of Medicine, United States.

Problem-Based Learning (PBL): A concept in which students focus from the beginning of their course on a series of real professional issues, where the knowledge of the various academic disciplines that relate to these issues is integrated.

PubMed: An online database of over 14 million citations of biomedical articles from 1950 to the present time. This database is available free over the Internet.

WebCT: Software that provides electronic learning in a flexible integrated environment.

Yu, pp. 382-386, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 4.10

Clustering Dynamics of the ICT Sector in South Africa

Sagren Moodley

Human Sciences Research Council (HSRC), South Africa

INTRODUCTION

Both the production and use of ICT are unevenly distributed across countries and regions. While this is typical of emerging and fast evolving technologies, there are particularly significant spatial differences in the patterns of ICT production. Traditional explanations for these differences include distinct factor endowments, technologies and policies. Regions with originally similar characteristics may develop in very different directions. Hence, the *locational patterns* of ICT cannot be explained in terms of factor endowments and policy regimes only (Barrow, 2001).

The tendency of knowledge-driven industries in particular (such as the ICT sector) to cluster geographically has been recognised in policy-making (Lall, Shalizi, & Deichmann, 2004). Proximity to university laboratories and other research centres provides ICT-related firms located in innovative clusters with easier access to scientific expertise and research results, thus, facilitating transfer of research into commercial applications (Acs, Audretsch, & Feldman, 1992, 1994; Jaffe, 1989). Furthermore, firms located

in a science park benefit from agglomeration economies, due to the fact that numerous high technology enterprises are clustered in a relatively small area, especially if they operate in the same sector, or in closely connected sectors (Palmai, 2004). The networking opportunities of tenant firms are also widened, basically for the same reason. Finally, the park acts as a bridging institution providing tenant firms with suitable accommodation on flexible terms and technical and business services which are particularly valuable to new high-growth enterprises (Duroo, Sarmiento, Varela, & Maltez, 2004).

This article looks at the clustering dynamics of the ICT sector in South Africa. The article focuses on two regional (i.e. Western Cape and Gauteng Provinces) ICT cluster case studies which illustrate a clear and intensifying concentration tendency of ICT-related production and R&D, viz. the Bandwidth Barn (a flagship project of the Cape IT Initiative [CITI]) and the Innovation Hub (a component of the Blue IQ project). Finally, the author draws a number of generalisable issues from the case studies which have wider applicability for developing countries.

THE INNOVATION HUB

In March 2001, in a bold bid to position Gauteng (which is South Africa's wealthiest province) as South Africa's "Smart Province", the Gauteng Provincial Government launched an initiative called Blue IQ. The Innovation Hub is part of the Gauteng Government's ZAR 1.7 billion Blue IQ project, under the auspices of the Strategic Economic Infrastructure Investment Programme (SEIIP). Blue IQ is Gauteng Province's high-tech industrial promotion agency. The Innovation Hub's vision is to "create a unique space where high-tech entrepreneurs, businesses, education, research and venture capital can meet, network and prosper" (Innovation Hub, 2003, n.p.). The 11 Blue IQ projects focused on three sectors:

- **Smart industries:** i.e., the Innovation Hub and Gautrain Rapid Rail Link;
- **High value-added manufacturing:** i.e., Gauteng Automotive Cluster; Wadeville Alrode Industrial Corridor; Johannesburg International Airport (JIA) Freezone; and City Deep Terminal; and
- **Tourism:** i.e., Cradle of Humankind World Heritage Site; Constitution Hill; Newtown; Dinokeng; and Kliptown.

The Blue IQ initiative aimed to: (1) create an environment in which smart industries in the ICT and bio-medical sectors can thrive; (2) shift Gauteng's manufacturing sector away from traditional heavy industry into more sophisticated, high value-added production; and (3) develop business tourism in order to capitalise on Gauteng's status as South Africa's commercial and financial hub.

The Innovation Hub became a full member of the International Association of Science Parks (IASP); the only full member in Africa. Furthermore, the Business Incubator at the Hub became a member of the National Business Incubators Association (NBIA) in the United States, which

seeks to provide professionals worldwide with information, education, advocacy and networking resources for early-stage companies. The Innovation Hub consists of:

- A high-tech incubator;
- An entrepreneur/innovator development programme, including Coach Lab where postgraduate students are mentored to work on industry projects;
- Initiatives targeting empowerment; and
- Alliances with world-class academic and research institutions.

The Innovation Hub was developed to:

- Establish a high-tech hub in Gauteng;
- Develop infrastructure to implement and stimulate high-tech business in a conducive and mutually beneficial environment; and
- House other essential components such as incubators, venture capital funders and professional service suppliers, to form the basis for a world-class 'innovation corridor' in the province.

The Innovation Hub was South Africa's first science park and a joint initiative between the Gauteng provincial government and the Southern Education and Research Alliance (SERA), an alliance between the University of Pretoria and the Council for Scientific and Industrial Research (CSIR). Construction started in October 2003 (and is expected to be finished in late 2004/early 2005) with the objective of creating South Africa's own 'Silicon Valley'. The ZAR 300 million Hub, located in Pretoria, was being built around the concept of technological convergence. The sectors that were being targeted include biosciences and biotechnology, ICT, electronics, aerospace, advanced materials, and advanced manufacturing sectors such as automotive, defence and defence spin-offs. The Hub was positioned adjacent to

the University of Pretoria and directly to the east of the Hub—just across the N1 highway—lies the CSIR. Hence the Innovation Hub, situated on a “knowledge axis”, was therefore deemed to be at the centre of knowledge and information. Pretoria is only 60km by freeway from South Africa’s commercial capital, Johannesburg. Furthermore, the Gautrain Rapid Rail Link, another Blue IQ project, is set to link Pretoria, Johannesburg and Johannesburg International Airport by 2006.

The provincial government saw the hub as: (1) creating a unique location in Gauteng Province where high-tech industry, academia and entrepreneurs will be able to meet and work together; (2) better positioning the province as a globally-competitive knowledge economy; (3) a catalyst to enhance the innovative and growth capacity of high-tech companies and to improve productivity and technology; 4) an incubator for high-tech start-ups; and (5) promoting black economic empowerment by acting as an incubator for innovative black start-up companies.

Processes and outputs of the Innovation Hub are benchmarked on a continual basis, against international best practice. The objectives of the incubator are:

- To facilitate the accelerated growth and sustainable development of technologically innovative start-up companies;
- To position the Innovation Hub incubator as the prime location for technologically innovative start-up companies; and
- To be a leader in South African best practice incubation.

Facilities and services offered by the incubator include:

- Flexible leases and a variety of office sizes;
- Reception and secretarial support;

- Sophisticated ICT infrastructure for the guaranteed supply of unlimited connectivity and high bandwidth;
- Management advisory and mentoring services, including structured training programmes focused at the developmental needs of the new venture;
- Business support services (financial, legal, administrative);
- Access to business networks and markets;
- Assistance in finding suitable black economic empowerment partners;
- Assistance with obtaining venture capital or financing;
- Assistance in accessing technical expertise;
- Entrepreneurship development and education;
- Participation in a high-tech cluster with access to like-minded people, i.e., being part of an entrepreneurial, innovative community;
- Being part of an established brand, viz: the Innovation Hub;
- Market visibility by means of corporate advertising (marketing support);
- A research interface; and
- Technological support.

The incubation programme is made up of three phases: (1) *pre-incubation phase* which was designed to last for about six months and to make sure that the start-up had a good business plan and tested the market with its product; (2) the *incubation phase* designed to last for between three to four years; and (3) the *associate stage* was designed as the final phase of the programme, as a year-long “after care” stage. The incubation programme produced early success stories such as Expertron, a start-up which invented a new information security solution product. Expertron concluded a 30% shareholding deal with Grintek early in the process, and was granted a lucrative

contract for the product by the ERP.com group. Another start-up Naledi3d Factory, successfully established an interactive virtual reality development facility in Uganda.

THE BANDWIDTH BARN

The Bandwidth Barn was the pioneer project of the Cape Information Technology Initiative (CITI), a not-for-profit promotion agency for the ICT industry in the Western Cape. The Cape IT Initiative (CITI) was established as a non-profit public-private partnership funded by the Western Cape Province and City of Cape Town governments, as well as more than 40 corporate members including UUNET, Microsoft, Telkom and other national, regional and local businesses. CITI aimed to promote the development of the Knowledge Economy in the Western Cape Province of South Africa and to act as the marketing agency for the Western Cape ICT sector. CITI's intention is to grow the Western Cape into an international ICT hub, creating jobs and building the regional economy. The Bandwidth Barn offers entrepreneurs the facilities, bandwidth, mentorship, support and networking required to grow young businesses and foster innovation. The overall aim of the Bandwidth Barn is to facilitate the creation of jobs (social goal) and wealth (economic goal) through ICT, and to make the region more attractive for direct foreign investment (economic goal).

The Barn was financed by a million Rand sponsorship from the Department of Trade and Industry's Sector Partnership Fund (SPF) and it received a multi-million Rand sponsorship from UUNET SA, the largest carrier of Internet traffic in Africa. The Barn is located in Cape Town's central business district, in close proximity to three major universities, i.e., University of Cape Town, Stellenbosch University and the University of the Western Cape—all of which graduate computer engineers. The objectives of the Barn are to:

- Serve as a focus point for ICT entrepreneurship in the Western Cape and to bring the benefits of 'clustering' to the budding ICT sector in Cape Town;
- Provide fast 24/7 Internet connectivity (ADSL) to high-tech start-ups;
- Provide small ICT businesses with affordable office rentals, shared office facilities to reduce overhead costs for services like Internet connectivity, telephone and reception;
- Provide incubation for start-up ICT entrepreneurs in the Western Cape;
- Provide a supportive networked community to create synergies; and
- Create a network of strongly interdependent firms and specialised suppliers, knowledge producing agents (education institutions, research bodies, engineering companies), bridging institutions (brokers, consultants) and customers, and to link together in a value-adding production chain.

The Barn is a unique incubation model where the stability of anchor tenants is coupled with a dynamic and evolving set of small companies. The Barn aims to remove the barriers that impede small start-ups, i.e.:

- The cost of high quality Internet access;
- The difficulty of finding premises and the requirement to sign long-term leases;
- The cost of reception and PBX services; and
- The isolation of operating on one's own.

One Barn success story is the black empowerment company, *Liquid Thought*, which is an e-business consulting service. The company is three years old, employs 10 people and its turnover is likely to exceed ZAR 10 million by the end of the 2003 financial year. Zulfiq Isaacs, the MD of Liquid Thought, had this to say:

The Barn was critical to our success. Clustering enables you to reduce overheads by sharing the cost of Internet access and other infrastructure, it quickly raised our profile in the marketplace and created networking opportunities. Most importantly, we were able to partner other companies with different skills to create joint projects. (CITI, 2003, n.p.)

CITI has formed the “Cape Lab” initiative to help teach entrepreneurs about international markets and to forge links with peer organisations like *Enterprise Island* in the UK and *Enterprise Ireland* in the Republic of Ireland to help address this issue. CITI envisions the Western Cape duplicating India’s success in attracting offshore software development projects and international software support centres. Further, the Bandwidth Barn has been actively involved in local and provincial ICT initiatives (e.g. the Cape Online e-Government Strategy) and in policy-making organisations such as the Internet Service Providers Association (ISPA), the Internet Society of South Africa (ISOC SA), ICANN, etc.

DISCUSSION

The geographical structure of the Bandwidth Barn and the Innovation Hub are concentrated, with a multitude of linkages between core firms, their spin-offs and local subcontractors, world-class universities and research centres, and local/regional authorities. Some key common features characterising this specific production model can be identified, namely:

- The geographical proximity of small and medium sized firms;
- A spatial development where the interface of research with commerce and industry is encouraged for the better exploitation of technology;

- A dense network of inter-firm relationships, in which the firms cooperate and compete at the same time;
- A dense network of social relationships, based mainly on face-to-face contact, which is inter-connected with the system of economic relationships;
- The presence within the area of complementary competencies and skills;
- Facilitating the creation and growth of innovation-based companies through incubation and spin-off processes, and provide other value-added services together with high quality space and facilities;
- Creating a culture of innovation where the physical infrastructure stimulates the cross-fertilisation of ideas and the flow of knowledge and technology to create the “buzz” that comes with shared exploits, innovation and dynamic social interaction; and
- A high degree of specialisation of both the firms and the workforce.

Both the Barn and the Innovation Hub are not-for-profit incubators and the owners do not hold equity in their tenants. They have close links to each other and often network and share resources. CITI and the Innovation Hub have strengthened existing ties through an informal partnership that is aimed at consolidating the activities of both parties for the greater benefit of the ICT sector nationally. This includes sharing knowledge resources, such as ICT guest speakers and information on high-profile international delegations to South Africa.

The two case studies clearly underline the importance of local and regional policies in promoting ICT clustering dynamics. Focusing merely on national policies is insufficient. Further, the close proximity to centres of teaching and research is particularly favourable for the creation and growth of knowledge-based businesses. Both the Bandwidth Barn and the Innovation Hub are innovative ICT clusters which (1) have formal

operational links with centres of knowledge creation, such as universities and research centres; (2) are designed to encourage the formation and growth of innovative businesses; and (3) have a management function which is actively engaged in the transfer of technology and business skills to “on-park” located small high-tech firms. Moreover, the objectives of the two technology incubator programmes are to: (1) provide a mechanism for the commercialisation and transfer of technology; (2) promote the concept of growth through innovation and application of technology; (3) support economic development strategies for small business development; and (4) encourage growth from within local economies.

GENERALIZABLE ISSUES

Entrepreneurship is at the heart of sustainable, organic growth for most developed, as well as transition and developing economies, and high-tech incubators have often served as catalysts and even accelerators of entrepreneurial cluster formation and growth (Harwit, 2002; Link & Link, 2003). This may be more so in less developed economies where incubators can help bridge knowledge, digital, socio-political and even cultural divides and help increase the availability, awareness, accessibility and affordability of financial, human, intellectual, and even social capital, the key ingredients of entrepreneurial success. Incubation has recently experienced increased attention as a model of start-up facilitation in the ICT sector (Molnar, Grimes, & Edelstein, 2001). Venture capitalists see incubators as a means to diversify risky investment portfolios, while would-be entrepreneurs approach incubators for start-up support. Incubators are thus faced with the challenge and the opportunity of managing both investment risks, as well as entrepreneurial risks.

There is value in establishing innovation hubs or clusters as an appropriate vehicle to help

promote and facilitate the development of ICT firms within incubation programmes in developing countries. However, it is evident that science parks and incubators take place in different environmental and institutional contexts, which are also dynamic. This points to the need for a structural contingency perspective that relates the different types of science parks and incubators to different institutional contexts and objectives. Furthermore, the needs of tenant incubators at different stages of development are varied. Hence, if the purpose is to assess whether or not a particular incubator programme is of value to tenant incubators at different stages of business development, the comparative evaluative approach should be modified so that the effects on technology firms throughout the venture development path could be captured. For cluster formation in the ICT sector to be successful, the innovation hub should: (1) be sustainable; (2) have operational links with universities, R&D centres and/or other institutions of higher education; (3) encourage and support the start-up and incubation of innovative, high-growth and technology-based companies; and (4) stimulate the transfer of technology, know-how and innovation.

CONCLUSION

Despite the fact that the cost of transmitting information has declined tremendously and has become largely invariant of distance, the importance of location to innovation and production remains. The primary reasons for this are benefits that the proximity of others generates to the firms in the area, i.e. Marshallian externalities (Marshall, 1920). ICT companies located in the area of a specialised cluster of firms may benefit from knowledge spillovers: information concerning new applications or other innovative practices may spread faster among the firms that are located geographically closer to each other. As the two

case studies have revealed, there are other factors fostering spatial agglomeration such as the availability of skilled labour, good infrastructure, and supporting institutions, e.g. universities and research centres.

Both the Innovation Hub and Bandwidth Barn are examples of innovation being driven in an institutional way. Castells and Hall's (1994) concept of technopoles aptly describe the Blue IQ and CITI initiatives, viz. "deliberate attempts to plan and promote within one concentrated area, technologically innovative, industrial-related production" (Castells & Hall, 1994, p. 8). However, both of these clusters are still at a very early stage of development, therefore it is difficult to critically assess their success. That said, international experience suggests that few incubators succeed, and those that do are driven by experienced, hard-core entrepreneurs (Colombo & Delmastro, 2002, p. 1103). Ultimately, the success of the Innovation Hub and the Bandwidth Barn will be determined by how much venture capital experience and business experience that the people running them have. Finally, ICT-based innovative clusters in the Third World must be strategic, properly managed and implemented, without becoming bogged down in politics and bureaucracy.

KEY TERMS

Agglomeration Economies: Refers to the spatial concentration of economic activities. For example, a firm that is located in close proximity to other firms in the same industry can take advantage of localisation economies. These intra-industry benefits include access to specialised know-how (i.e., knowledge diffusion), the presence of buyer-supplier networks and opportunities for efficient subcontracting. Employees with industry-specific skills will be attracted to such clusters giving firms access to a larger specialised labour pool. Another case of agglomeration economies external to the firm relates to benefits that accrue from being located in close proximity to firms in other industries, i.e., urbanisation economies. These inter-industry benefits include easier access to complementary services (publishing, advertising, banking), availability of a large labour pool with multiple specialisation, inter-industry information transfers and the availability of less costly general infrastructure.

Business Incubators: Business Incubators are property-based organisations with identifiable administrative centres focused on the mission of business acceleration through knowledge agglomeration and resource sharing. The main role of the incubator is to assist entrepreneurs with business start-ups and development.

Clustering: This occurs when high-tech firms of similar characteristics and within the same value chain are attracted to co-locate and gradually emerge as a strong allied group complementary to each other. An innovation-driven cluster aims to encourage and facilitate the formation and growth of ICT-based businesses by providing access to structural elements, e.g. infrastructure and supporting facilities, and generating mutual synergies.

ICT Sector: The ICT Sector can be defined as a combination of manufacturing and services industries that capture, transmit and display data and information electronically.

Information and Communication Technologies (ICT): The term “Information and Communication Technologies (ICT)” reflects the technological convergence between digital computing, telecommunications and broadcasting. Whereas computers were largely focused on the processing of information, ICT undertake both processing and communication of information.

Innovation Hubs: Are designed to encourage the formation and growth of knowledge-based enterprises or high value-added tertiary firms. Innovation hubs generally aim at promoting and catalysing innovation and entrepreneurship within an innovative milieu.

Knowledge Economy: The knowledge economy is a state of economic being and a process of economic becoming that leverages, both intensively and extensively, knowledge assets and competences, as well as economic learning to catalyse and accelerate sustainable and robust economic growth.

Science Park: A Science Park is a business support initiative whose main aim is to encourage and support the start-up and incubation of innovative, high-growth, technology-based businesses through the provision of infrastructure and support services, including: (1) collaborative links with economic development agencies; (2) formal and operational links with centres of excellence such as universities, higher education institutions and research establishments; and (3) management support actively engaged in the transfer of technology and business skills to small- and medium-sized enterprises.

Chapter 4.11

ICT and the Tourism Information Marketplace in Australia

Andrew Taylor

Southern Cross University, Australia

INTRODUCTION

In November 2003, the Australian Government released the Tourism White Paper, a medium- to long-term strategy for the Australian tourism industry. The Paper provides for funding to improve the availability of high-quality information for the development of tourism in regional areas of Australia. More than \$21 million, a historically large amount, has been identified for "... extending the provision of quality research and statistics" (Prime Minister John Howard, Media Release, November 20, 2003).

A growing body of literature about systems of innovation (SOI) supports the notion that secondary information is a vital input to the evolutionary processes of innovation (see, for example, Edquist & McKelvey, 2000, p. 4). The efficient production and distribution of knowledge, of which information is a precursor, is widely discussed as a prerequisite for innovation in economic systems.

There is a long history of relatively poor access to and application of strategic business intelligence in the Australian tourism industry, particularly by those in regional areas. Examples of coordinated

and sustained efforts to engender a research-based ethic among tourism enterprises, organizations, and other institutions have been, at best, sporadic (Hunt & Prosser, 1998).

ICT systems are increasingly seen as primary enablers in the dissemination of information to regional economic systems. Online technologies can reduce dissemination costs for suppliers and consumers of strategic business intelligence. ICT systems assist by encouraging the formation and growth of regional- and sector-based networks and cooperatives, facilitating interactions in the global economy, encouraging wider use and application of information, and bridging the information divide between cities and regional areas.

Several tourism information systems have been developed worldwide to help address technological and capacity issues in the industry. Examples exist in Australia, Spain, Austria, Canada, and New Zealand.

The availability of quality research and data for the tourism industry is one side of the information equation and has been the focus of most discussions on the topic (Scott, 1999). However, supply-side issues are not the sole impediments

to more widespread procurement and application of tourism research in Australia.

This paper introduces the concept of the Tourism Information Marketplace (TICM) to demonstrate that the historically poor dissemination and application of strategic tourism information in RTS is, in part, the result of barriers to its efficient procurement on the demand side. Previous analyses of this issue have identified weaknesses that exist in the current delivery systems for regional tourism information. These relate to administration of data collections, the knowledge management capacity of small firms and local tourism associations, quality and availability of data, and the technologies that are used in its distribution. This research augments these findings by identifying the barriers to the efficient exchange and procurement of tourism information commodities.

THE IMPORTANCE OF STRATEGIC INFORMATION COMMODITIES TO REGIONAL TOURISM SYSTEMS

There is voluminous representation in the literature of the growth in the size and importance of the global information, or knowledge-based, economy (see, for example, Levine & Lippman, 1995; Nelson, 2000; Shipario & Varian, 1999). Most acknowledge the emergent role of knowledge as an enabler of wealth creation and economic growth. Indeed, some argue that the modern economy is tending toward the application of knowledge for the sake of knowledge itself (Johnston, 1999).

The concept of Systems of Innovation (SOI) is being increasingly described in the literature. SOI are networks of firms, organizations, and other parties who apply knowledge and innovations through interactive learning processes to generate favourable economic outcomes (for a review, see Edquist & McKelvey, 2000). An SOI may exist at any geographic level and may be sector-specific, as in the case of tourism.

Regional tourism in Australia is also characterised by networks and interactions between tourism product suppliers, public-sector organisations, community organisations, other intermediaries, and the legislative and political regimes that influence the region. The systemic nature of these interactions points to the existence of RTSs, which are focused largely around regional destinations (Carson et al., 2003).

There has been some past research on the information needs of key agents in Australia's RTS. The Centre for Regional Tourism Research (Prosser, 2000) conducted a national research roadshow in 1999 that included participation from over 500 regional tourism operators and association managers. In 2001, the Australian Regional Tourism Convention in Port Macquarie (Kelly, 2001) included a national forum that identified the broad information needs of regional and local tourism associations. The results of these two initiatives were supplemented by a series of focus groups in 2002 and 2003 to determine the current data or information needs in regional tourism, and the perceived barriers to obtaining and using this information.

All three investigations highlighted the difficulty organisations (particularly small businesses and local tourism associations) have in articulating their data and information needs and in procuring information to address these.

THE ROLE OF THE TOURISM INFORMATION MARKETPLACE

Externally sourced, or secondary, knowledge and information is important to innovation at the enterprise level and, consequently, to the RTS. For entities engaged in the Australian tourism industry, the potential for secondary information to contribute to innovation is growing in line with global trends (Scott, 1999, p. 14). Secondary information can help to establish a competitive advantage in a globalised, competitive, and de-

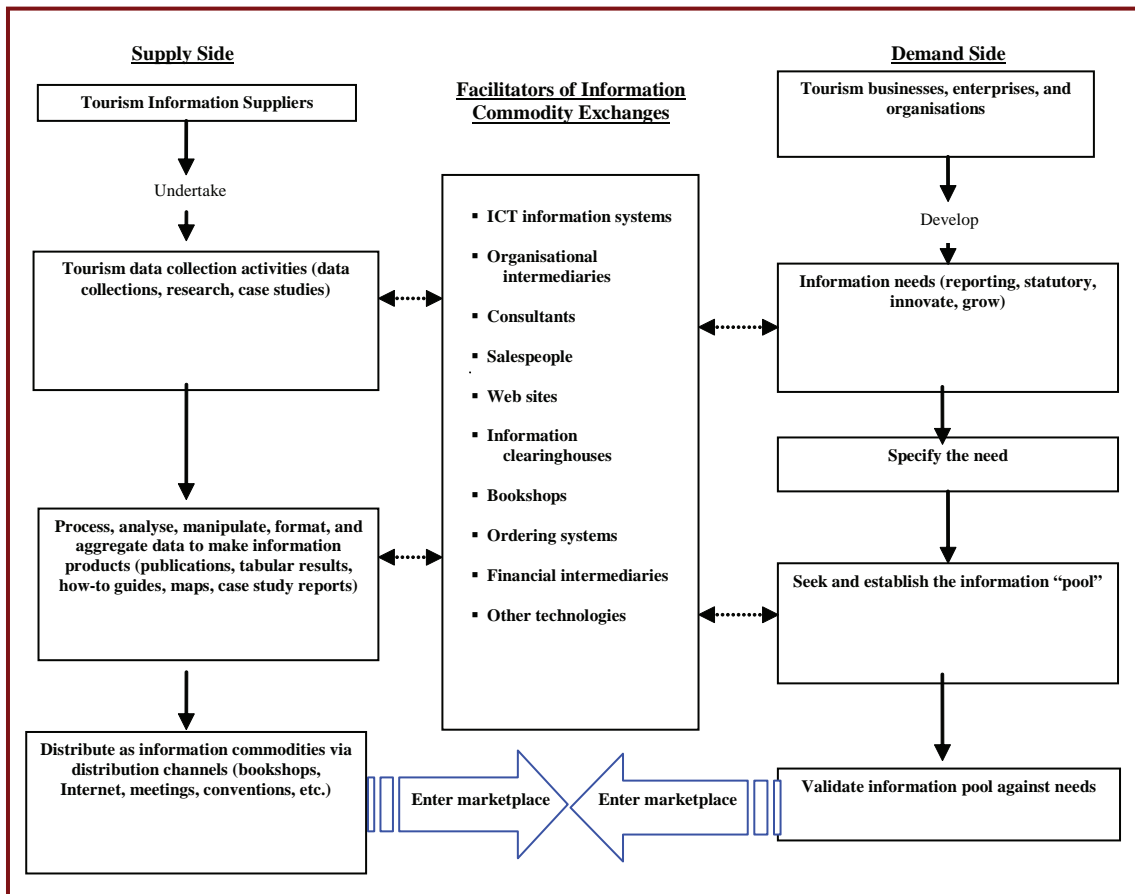

mand-elastic industry; benchmark against other regions or competitors; promote evidenced-based approaches to management and reporting; develop or diversify products or services; and guide future decision pathways. The effective procurement and application of secondary information relies on an efficient marketplace that facilitates its exchange. The TICM is a conceptual model depicting the processes involved in the exchange of tourism information commodities.

At a broad level, the TICM (see Figure 1) is similar in structure to other commodity marketplaces. Suppliers offer information commodities in the forms of publications, tabular data, research products, and case studies. Demand for these is generated by the information needs of tourism

businesses, research bodies, and other organisations. The exchange of information commodities is facilitated by intermediaries such as technology-based systems (for example, online bookshops) and organizationally based facilitators (such as regional tourism organisations).

Neoclassical economic theories on marketplaces focus on how marginal price changes affect the demand and supply for commodities. A marketplace is said to be operating efficiently when all the commodities offered to the market are cleared. The price at which this occurs is the equilibrium price (Mansfield, 1985). These rudimentary economic theories rely on several assumptions, including that suppliers and consumers have perfect information available on

Figure 1. A conceptual model of the TIM

which to base their decisions, and consumers are rational to the extent that they consistently seek to maximise their marginal utility.

Even with such assumptions in place, marketplaces in which the commodity is information are inherently different (Shipario & Varian, 1999). Reasons for this include that information is an “experience good” that must be consumed before you realise its value; the price of information tends to move toward the marginal cost that can be close to zero for some information commodities; and many suppliers of information commodities do not engage in the marketplace with the intention of profit maximisation (Edquist, 1997).

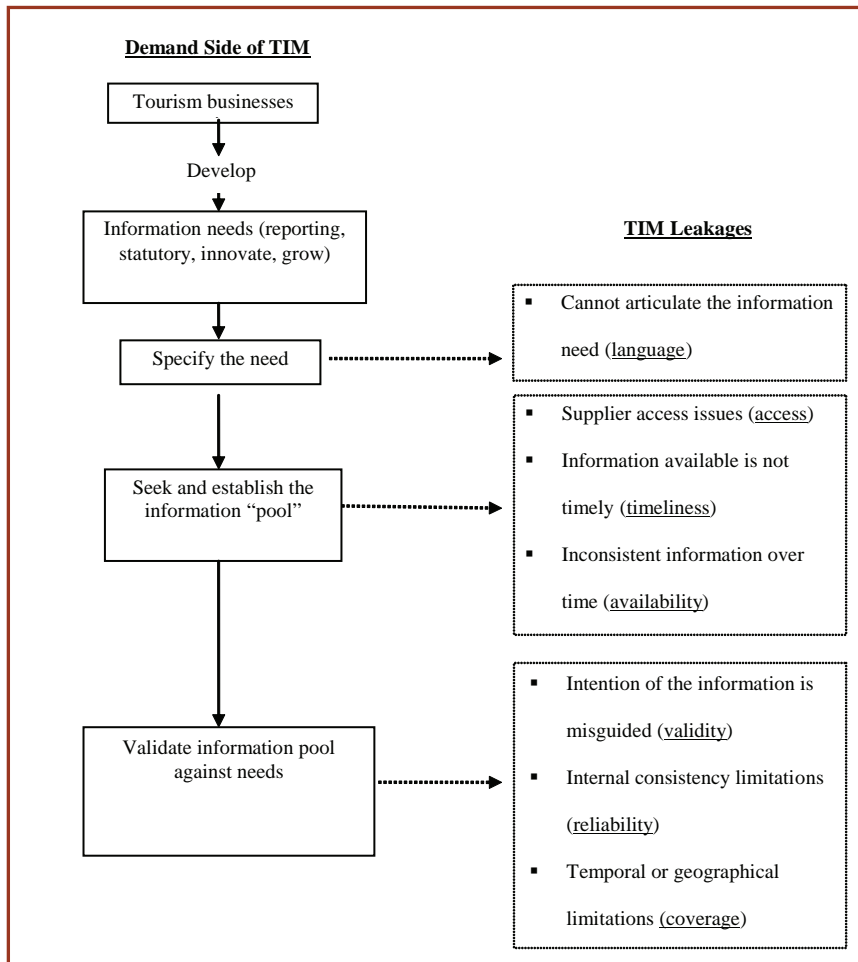

The uniqueness of information as a commodity means that the efficiency of the marketplace in which it is exchanged cannot be ascertained in terms of its ability to reach a state of equilibrium. An alternative approach is to assess whether information can be procured in the marketplace efficiently. If this was the case, tourism enterprises, after identifying their information needs, would be able to specify them to suppliers in a common language; readily assess the pool of information commodities available to address their needs; and apply relevant knowledge and skills to validate each information commodity to determine its appropriateness and relevance. Price impacts on the behaviour of the marketplace (especially consumers) become subservient to procurement activities, which are outlined in the model.

A closer examination of the Australian TICM and supporting literature reveals that the steps toward information commodity procurement are not efficient. Demand-side leakages are evident, masking the true demand for tourism information commodities. Leakages cause demand “drop out” on the demand side of the model. They are evident in each of the “specify,” “seek,” and “validate” phases (see Figure 2).

Causes of TICM leakages are identified in brackets in Figure 2 as follows:

- **Language (specify stages):** Carson and Sharma (2001) note that the supply of tourism information commodities in Australia is not bounded by a standard data model. Several attempts to produce standard classifications of tourism information have, nevertheless, been made. These include the Framework for Australian Tourism Statistics (Australian Bureau of Statistics, 2003), the National Tourism Information Model (Carson & Sharma, 2002), and the work of Scott (2000). The National Tourism Information Model, in particular, has recognised the importance of a “universe of discourse,” or common language, for the efficient distribution of tourism information.
- **Access (seek stages):** Efficient procurement of tourism information requires well-organised and defined access points to supplier commodities. After identifying and specifying their information needs, consumers must seek relevant information commodities from suppliers. Access to key information about the set of appropriate commodities can be obtained from intermediaries or directly elicited from suppliers. Degrees of access vary, ranging from direct access to information experts to no means of access at all. To highlight the magnitude of the access issue, the Decipher project in Australia currently provides a single point of access to information commodities from more than 150 suppliers (www.decipher.biz, April 2004).
- **TICMeliness (seek stages):** Timeliness describes the temporal lag between data collection and the public release of the data in the form of information commodities. The importance of timeliness to the tourism industry is underlined by the impacts of recent geopolitical shocks. These have underscored the high elasticity of demand for international tourism products. To respond effectively, tourism businesses require

Figure 2. Leakages in the tourism information marketplace

information on current and likely future implications. Until recently, lags of 12 to 18 months were not unusual for national-tourism-specific data sets. This situation is improving with advances in technology and increased experience in data management.

- **Availability (seek stages):** Relates to the assurance that information commodities are based on data that will continue to be collected and made consistently available. Recent funding cutbacks to public-sector suppliers have restricted their capacity to continue to deliver some knowledge commodities.

- **Validity (validate stages):** Validity describes the degree to which information consumers can ascertain the value of the information commodities relative to the current information needs. Information not produced specifically for tourism may still be highly valid where it contains generic “lessons.” Prominent suppliers usually provide guidance on the validity of their products through metadata.
- **Reliability (validate stages):** In terms of statistical reliability, technical considerations include sample size, sampling procedure, benchmarking processes (if used), and is-

sues of bias in data collection. A range of technical skills at the user end is required to assess reliability issues. This may be further complicated by the intended application for the information. For example, sample sizes may determine a data set to be reliable at the national level but not at the regional level. Tourism firms and organisations have been found to be lacking in their understanding of the impacts of reliability issues (Scott, 1999, p. 21).

- **Coverage (validate stages):** Relates to both the geographic scope and temporal scope of the information. National and state data sets are usually established for purposes of national- and state-level analysis, and coverage at regional levels suffers as a result. Some knowledge products contain generic, or globally, relevant content. Temporal coverage involves the time frame of reference for the data collection. This can be particularly important in tourism analysis because of seasonality effects.

THE POTENTIAL FOR ICT TO FACILITATE EFFICIENT TOURISM INFORMATION COMMODITY EXCHANGE

Coupled with the global shift to knowledge-based economies, there has been growth in the trade of information. Where previously, in capitalist-based economic systems, knowledge was an input to the development of industrial assets (such as machinery), knowledge in the information economy is the tool of specialist workers. Such workers seek, procure, and apply knowledge to wealth-creation processes, such as developing new production techniques and organisational structures and establishing competitive advantage. Processes that facilitate these outcomes can be described as innovative processes. This approach represents a major paradigm shift insofar as knowledge

and innovation are no longer exogenous to core economic processes.

Technologies such as online ICT systems have led to a proliferation in the availability of information by reducing storage, transfer, and handling costs. The World Wide Web is an obvious functional example. While information may still be relatively expensive to produce, it is cheap to reproduce (Shipario & Varian, 1999, p. 3). At the enterprise and organisational levels, information may be sourced from within the organisation as tacit or “prior related” knowledge (Brockman & Morgan, 2003) or from outside as secondary information.

A small suite of online tourism information systems has been developed around the world. Each system offers the capacity for technology-based solutions to the challenge of placing appropriate business intelligence in the hands of tourism enterprises and organisations. As a group, these systems demonstrate the capacity for ICT to address or minimise leakages in the TICM. Table 1 summarizes these and briefly indicates their main features. Table 2 summarises the potential contributions of the systems identified above to reducing marketplace inefficiencies the TIM.

CONCLUSION: AN ASSESSMENT OF THE IMPLEMENTATION POTENTIAL OF TOURISM ICT SYSTEMS

“Implementation potential” can be described as the likelihood that a particular innovation will be adopted in the system for which it was intended and in a way that is similar to its intended purpose. A closer examination of the Decipher ICT system in Australia substantiates that systemic barriers to implementation potential may reduce the capacity of ICT systems to be diffused in systems. Consequently, the innovative potential of such systems is diminished.

Table 1. Summary of existing online tourism information systems

ICT System	Features and Strengths
Decipher (Australia) (www.decipher.biz)	Information from over 150 suppliers
	Delivered in context through intelligent user pathways
	Dynamic report-building and resource-tracking functionalities
Tourism Studies Austria (http://www.studien.at)	Database containing studies, research reports, and conference reports
	Searchable in multiple languages on title, keywords, summary, date of completion, etc.
Canadian Tourism Exchange (http://www.canadatourism.com/en/ctc/ctx/ctx-ind_watch/tourism_stats/index.cfm)	Business-to-business network for the Canadian tourism industry
	Access to a series of applications offering significant added value to its members
	Access to a series of html reports, statistical tables, publications, online professional development courses, and events calendars
Tourism Research Liaison Group of the United Kingdom—StarUK (http://www.staruk.org.uk/)	Delivers research reports and statistics in pdf and html formats
Tourism Studies Institute Spain (www.iet.tourspain.es)	Users can search for tables and pdf reports
	Sophisticated tools for manipulating tables
Tourism Research Council New Zealand (http://www.trcnz.govt.nz/)	Delivers publications and standard tables in html, pdf, and Citrix database format
	Index of research and publications from other sources
	Resources organized according to topic areas

Table 2. Potential of ICT systems to resolve TIM issues

Tourism Information Dissemination and Application Barriers	Potential ICT System Solutions
Language	Common discourse (e.g., NTIM) used to execute standard functionality (searches, retrieval of resources, etc)
Access	Single location access to resources from multiple suppliers
	Ability to facilitate and broker supplier–consumer interactions
Timeliness	Encourages suppliers to release soft-copy information commodities
	Facilitate “on time” public availability through automated delivery channels
Availability	Ability to deliver related resources where availability is poor
	Access to previous versions and trends (e.g., time-series data)
Validity	Potential to restrict the application of resources with poor validity
	Contextualization of validity issues to tasks
Reliability	Provision of metadata to assist with validation
	Access to related resources where reliability is poor
	Potential for automated warnings about reliability
Coverage	Provision to “push” resources with generic and extra-regional relevance
	Potential to build industry knowledge on seasonal impacts

The Decipher ICT system meets a regional tourism need that has been consistently identified as a high priority (see, for example, Department of Industry Science and Resources, 2003; Prosser, 2000). From the neoclassical viewpoint, this market demand and product superiority would be considered sufficient for the technology to be widely diffused and adopted in the system. However, the tendency has been for developers of online tourism initiatives to encounter difficulties in achieving widespread uptake, despite the market need. To a degree, this is illustrative of the complexity inherent in RTS and the inability of the system to facilitate diffusion of technology for innovation (Daniele, Mistilis, & Ward, 2000; Sharma, DeLacy, & Carson, 2000).

Based on the Decipher experience, Table 3 details some of the impediments to more widespread diffusion and application of online information innovations in a systemic context.

Two main conclusions can be drawn from these discussions. First, the analysis of the TICM construct illustrates that a focus on increasing the production of information commodities without addressing the barriers to efficient exchange, uptake, and application may represent an imprudent investment of resources. This brings into question the policy of growing the stock of tourism information as purported in the White Paper. It also provides a generic lesson for developers of ICT systems insofar as information dissemination technologies can only be considered to be successful if they recognise the uniqueness of information as a commodity and address the barriers to exchange.

Second, as the Decipher case indicates, there is no guarantee that ICT systems will achieve their implementation potential. Developers must consider the capacity of the system to adopt, use, and apply the technology according to the purpose

Table 3. RTS impediments to the implementation potential of ICT systems (derived from Carson et al., 2003)

Regional Tourism System Characteristic	Factors Impacting on Implementation Potential
Commercial imperatives	Most ICT projects require (at least) a part-return on investment; there is a poor history of users (especially small firms and local tourism associations) purchasing research and business intelligence
Information rich vs. knowledge poor	Inability of tourism information consumers to muddle through the leakages in the TIM and to apply skill sets to develop knowledge and learning
Regional dispersion	A key barrier to all ICT uptake in regional tourism (see Sharma & Carson, 2002; Carson, Sharma, & Waller, 2002); affects marketing, training, and the cumulative uptake of technologies
Structure of the tourism industry	Large numbers of small firms with generally poor ICT skills
	Low levels of contact between ICT system proponents and users
Sourcing of innovation champions	Reluctance among user groups to provide a lead-user role in the diffusion of innovative technologies
	Low levels of risk-taking behaviour associated with high elasticity of demand for tourism products
“Technophobia”	Inability to achieve a critical mass of users because of a poor understanding of the potential for technology-driven innovation
Tourism institutional stagnation	While imperatives for innovation are recognised in policy circles (Department of Industry Science and Resources, 1999), institutions focus on ICT development to facilitate product marketing and bookings

for which it was designed. In RTS in Australia, the problems may be particularly acute. Addressing these may require coordinated strategies from policy makers, peak industry groups, and key tourism organisations. While ICT systems can demonstrate the need for such responses, their ability to progress the system toward this is beyond the influence of ICT developers.

KEY TERMS

Information: Contextualised data that can be analysed and applied to decision-making circumstances.

Innovation Implementation Potential: The likelihood that a particular innovation will be adopted in the system it was intended for in a way similar to its intended purpose.

Knowledge: The outcome of the application of skills and resources to transform what were contextualised facts (information) into resources for learning.

Marginal Utility: The relative satisfaction gained from consuming additional units of a commodity. For many commodities, marginal utility diminishes (for example, a cream bun).

Metadata: Data or information that is about data. For example, a table of standard errors, a definition, and a library classification system are all examples of metadata.

Regional Tourism Systems (RTSs): RTSs in the Australian context are sectoral networks of organisations and institutions that interact or are interdependent, where the hub of such interactions is located outside of major cities.

System of Innovation: A conceptual framework in which networks of firms, organizations, and other parties apply tacit and secondary knowledge to interactive learning processes to generate favourable economic outcomes.

Tourism Information Marketplace (TICM): A conceptual model depicting the entities that participate and interact in the processes that facilitate the exchange of tourism information commodities.

This work was previously published in Encyclopedia of Developing Regional Communities with Information and Communication Technology, edited by S. Marshall, W. Taylor, and X. Yu, pp. 360-366, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 4.12

Potential Challenges of ICT Implementations in Sri Lanka

Kennedy D. Gunawardana

University of Sri Jayewardenepura, Sri Lanka

ABSTRACT

This chapter offers a state-of-the-art review of the implementation of ICTs strategies in a developing country with special reference to Sri Lanka as a case study. This chapter is based on primary and secondary sources (books, articles, Web sites, white papers, and grey literature). It also brings in a small number of empirical studies that serve to illustrate the practical use of the ICT to support arguments. Traditionally, access to ICTs and information has not been viewed as basic a need. However, if needs are interpreted as being dynamic and changing over time and culture (Max-Neef, 1986), access to information and knowledge could be treated as a basic need.

Information and knowledge have become increasingly important in the contemporary globalized economy, as advancement in ICTs has enabled larger amounts of information to circulate at a much higher speed and at lower cost. This is partly due to the balance between knowledge and natural resources, but with regard to being the most important factor in determining the standard of living in a country, it is said to have shifted in favor of knowledge. This has led many authors to claim that the people are now living in an information society or a knowledge-based economy (Drucker, 1993). Nowadays, it is a country's ability to assimilate, use, and diffuse knowledge that will essentially determine its chances of uplift in the new economy.

EMERGING ICT ISSUES IN SRI LANKA

Sri Lanka's ICT industry is thriving but faces significant problems, such as lack of transparency in government acquisitions (the largest prospective client); lack of moderately priced international bandwidth; lack of trained ICT professionals and classes knowledgeable about ICT; and a tax structure that does not reward local sales. In recent years, USAID has funded a number of projects aimed at increasing the competitiveness of various industries in Sri Lanka, and ICT is one of their prime foci. Their ICT sector studies have been well-performed, and their recommendations, if followed, will help guide the industry. However there is some danger that they may widen their scope to include the application of ICT in peripheral areas and, as a result, dilute their resources to no longer focus on their original crucial targets.

In general, the use of ICT in the commercial sector is irregular. Often, computers only seem to be found in managers' offices; they are rarely integrated throughout all levels of an organization. Some financial institutions have invested heavily in ICT, and as a result they are country leaders in the use of technology. Other sectors are far behind and their use of ICT is not visible. Even those companies that have invested in ICT often do so in restricted ways that are poorly integrated into their businesses. The same is true in case of the use of the Internet. In part, this is a small percentage (less than 10% of their total revenue) of Sri Lankan's access to the Internet, but the prime reason is, no doubt, the low level of managerial knowledge about the ICT capabilities in their business area.

At all levels of aggregation, statistics about any aspect of ICT in Sri Lanka are highly misleading and can be deceptive when used for policy purposes. Virtually all ICT activity is centered in Colombo, with small pockets in the Galle and Kandy areas (100 kilometers away from Colombo

city). There is clearly a desire to spread ICT development over a wider geographic area than just in Colombo, but it appears that it is not going to be an easy task.

The regions outside the urban areas are particularly poorly served with respect to electricity and telecommunications. Total consumption of the western province is 3,699 Gwh in 2003, compared to the rural sector's consumption with an average of 340 gwh. Moreover, the rural areas do not provide the level of comforts and conveniences often expected by people with the high-end technical and managerial skills needed to drive this sector. Lastly, the supply of lower level technical skills is substantially lower in these regions.

The telecenter movement is in its infancy in Sri Lanka. In many countries, telecenters have become the focal point for introducing technology into rural areas, and in fact to disadvantaged groups in urban settings. The concept shows up in many reports and plans, but despite this, there are a very few active telecenters. Of more concern is that the groups that are developing telecentre plans are doing this in isolation from each other, and from the worldwide community that has a rich knowledge on what works and what does not.

Underlying most issues in Sri Lanka is the 19-year civil unrest and conflict between the Government of Sri Lanka and the Liberation Tigers of Tamil Eelam (LTTE), which has controlled territories in the northern and eastern parts of the island and been the source of disruptions in the south. There are 362,000 (both Tamils and non-Tamils displaced due to Tamil conflict) who have been killed by the war.

When it comes to socioeconomic development and the uses of technology, Sri Lanka is a country of achievements and contrasts. It has achieved high levels of life expectancy, education, and health at par with countries having a Gross Domestic Product (GDP) per capita more than twice than Sri Lanka. Sri Lanka's per capita income was US\$1,000 in 2005.

Albeit all these constraints, the country has achieved a United Nations Development Program Human Development Index that is impressive relative to its GDP per capita. Its healthcare system includes the latest technologies: open-heart surgery, CT, and MRI scans (although access to some of these in public hospitals is limited). The southwest and the Colombo area in particular, have fiberoptic networks running along roads where carts are pulled by bullocks. Universities teach not only advanced computer science programs, but also the entire administration of the university, including students' academic records that was based on paper and manual operations, is being computerized.

BACKGROUND

The speed of global technological and economic transformation demands urgent action to turn the present digital divide into digital opportunities for all. A discussion about the allocation of resources is imminent if looked at the connectivity of the Internet in developing countries. One way to measure the digital divide is to monitor the penetration of telephone subscribers and Internet users, as well as literacy rates in developing countries. Poor access to the Internet in Sri Lanka is widely acknowledged.

A few of the ICT parameters have been discussed here to illustrate the current scenario of ICT in Sri Lanka.

Telecommunications

Over the years, with the advances in the telecommunications field, Sri Lanka Telecom Corporation (SLT) has taken steps to upgrade and strengthen the telecommunications infrastructure in the country. Strategies such as expanding the optical fiber network and applying new digital technologies have contributed to greater reliability and

efficiency. According to 2003 data, there were 822,992 telephones in Sri Lanka. It had 85,500 Internet customers by 2003. The services provided include PSTN dial-up at 56 kbps, ISDN dial-up at 64 kbps and 128 kbps, Internet Leased Line services at 64 kbps, 128 kbps, 256 kbps, 512 kbps, and 2Mbps, client mail server installations and Web hosting.

Other than SLT, there are a number of private telecommunications service providers, cellular mobile telephones, pay phones, trunk telecommunications networks, radio paging service, and trunk radio networks. Mobile cellular phone services, which started in 1989 (a first among South Asian countries), continue to grow very rapidly. The number of cellular connections, which stood at 1,800 in 1991, increased to 2.5 million in 2005. Phone charges per minute are comparatively high. The price \$0.25 per minute for local calls and \$0.40 for International. Domestic phone rates continually increase, and vary from zone to zone, while IDD rates have decreased slightly in recent years. Cellular phone rates are also high, but have declined gradually due to intense competition. Restructuring of telecom services started in 1995, and since then steps have been taken to privatize SLT in stages, opening for foreign investment and with the intention of making the services more efficient.

Internet and Computer Networks

Lanka Internet Services initiated commercial operations in 1995 and SLT started its Internet service facility in 1996. At present there are over 20 Internet Service Providers (ISPs), including SLT and private companies. The services of ISPs cover a wide geographical area, and Internet connectivity and e-mail software are readily available. Despite this fact, the cost is high and it costs around \$0.45 per hour. Currently, most of the Internet usage is in the commercial sector.

Potential Challenges of ICT Implementations in Sri Lanka

In 2003, there were 85,500 Internet users in Sri Lanka. According to the Telecommunications Regulatory Commission of Sri Lanka (TRCSL), the total number of Internet accounts was 121,532 (0.02% of total population of Sri Lanka) in 2005.

Although government initiatives have attempted to provide Internet facilities and access in schools and other educational institutions such as the National Colleges of Education, its use is minimal due to prohibitive cost. The Lanka Educational Academic and Research Network (LEARN) is a facility that interconnects educational and research and development institutions throughout the country. Initiated in 1990 as a project by the Department of Computer Science and Engineering (CSE) at the University of Moratuwa, it provided LEARN mail, the first e-mail service in Sri Lanka. Now administered by the Institute of Computer Technology at the University of Colombo, with technical operations being carried out by the CSE at the University of Moratuwa, it provides e-mail, dial-up, and dedicated Internet connections to its members.

IT in Primary and Secondary Education

Since 1983, the Ministry of Education and Higher Education has taken steps to familiarize and encourage school children in the use of IT. Computers were provided to some schools in 1984. In 1994, Computer Resource Centers (CRCs) were set up in a number of schools with the assistance of the Asian Development Bank. The main objective of setting up CRCs was to provide basic computer literacy to students during their vacations or after they had left school. In 1999 and 2002, a small number of computers were supplied to selected schools in all provinces. This was done with the intention of implementing the “activity room” concept, where students of junior secondary level (Grades 6-9) were to be familiarized with com-

puter use. Despite all these attempts, IT was not integrated into the formal school curriculum. The major emphasis seemed to be on hardware supply for schools rather than on IT education.

Realizing this shortcoming, the IT unit of the Ministry of Education and Higher Education initiated a National Policy on Information Technology in School Education (NAPITSE). It has implemented a number of strategies to improve the situation. This policy includes a six-year strategic plan from 2002 to 2007, which is divided into three stages. Focusing on two main aspects—use of IT in education (learning and teaching) and use of IT in management of the education system—the strategic plan is being implemented under four major themes: curriculum development, human resource development, physical/infrastructure development, and support initiatives development. As a result of NAPITSE, syllabi on General Information Technology (GIT) and Computer Assisted Learning (CAL) courses for GCE A-Level and GCE O-Level classes have been developed, and GIT for GCE A-Level has already been implemented. About 700 A-Level teachers have been trained up to now and 5,000 teachers will be trained next.

IT in Higher Education

The National Policy on IT made several recommendations to enhance IT in university education. These included providing IT awareness to all undergraduates, establishing campus-wide networks in all 14 universities, providing Internet access to all, and introducing computer science courses. Open University of Sri Lanka (OUSL) offers six programs of study including IT courses, ranging from certificate level to master’s degrees. All registered students at OUSL are provided with the opportunity to undergo a basic computer awareness course, and to use the computer facilities available at the elementary computer laboratories at the Colombo Regional Centre

and other regional centers. Internet facility is also provided to students free of charge at these labs and in the main library. The campuswide computer network integrates resources such as the library and IT division.

Initiatives to integrate e-learning with the existing courses are currently being implemented. The staff development center of OUSL conducts multimedia training sessions for its staff, as well as staff from other universities. The IT division also conducts IT training sessions for staff. The Institute of Computer Technology, an independent institution established within the University of Colombo, with modern facilities, is well-recognized by the University grant commission in Sri Lanka.

Providing IT training for students at universities, it is also involved in software development and research in IT (ICT, 2001). The Sri Lanka Institute of Information Technology (SLIIT) was also recently established by the Government of Sri Lanka to train IT professionals. At this institution, courses are offered in IT, development of software, and research and development in IT. The SLIIT conducts a program of study leading to a Bachelor of Science degree in Information Technology (SLIIT, 2004).

The Sri Lankan educational environment is undergoing a phase of rapid transformation with adoption of information technology at various levels. Teacher training on various educational media such as online resources has been identified as one of the key approaches to integrating ICT in the classroom. At the same time, efforts to develop learning materials indigenously are ongoing at various educational institutions.

Before proceeding to the next section, author would like to detail out a comprehensive ICT based educational plan of the Sri Lankan government for national capacity development that will assist to face the challenges of the ICT implementations.

The National Policy on Information Technology in School Education (NAPITSE) affirms the

commitment of the government towards providing the state of the art knowledge in IT to Sri Lanka's younger generation, preparing them to face the challenges in the 21st century. This policy will provide a clear vision and direction in making this a reality, followed by an action plan as a six-year strategic plan from 2002 to 2007. This six year project period is divided into three stages:

- Stage 1: 2002-2003
- Stage 2: 2004-2005
- Stage 3: 2006-2007

The NAPITSE will be implemented via an action plan titled, "National Policy on Information Technology in School Education, Action Plan, and Operational Strategies." It will be in the form of a rolling plan, undergoing periodic changes with necessary academic and professional inputs being incorporated as and when necessary.

The action plan will focus on:

- Use of IT in education (Learning and Teaching)
- Use of IT in management of the education system

Vision:

- A new generation of Sri Lankans empowered with Information and Communication Technology
- To facilitate the planning, implementation, and sustenance of Information Technology education in schools to enhance student's learning and quality of teaching

Goals

The NAPITSE will have the following overarching goals:

Potential Challenges of ICT Implementations in Sri Lanka

- Envisage and foresee the future global challenges in IT education and lay the foundation for appropriate human resource development to meet such challenges
- Create conditions enabling the effective use of IT as a tool in learning and teaching at all levels in the general school education
- Provide “information literacy” for all school leavers
- Create conditions for effective involvement of school system in lifelong education
- Create an information literate population of teachers/educators

Objectives and Strategic Themes

In order to reach the goals, the following objectives would be achieved under four major strategic themes:

- **Curriculum Development**
 - To introduce, sustain, and enhance IT involvement into general education in schools and create opportunities for IT based learning and teaching
 - To introduce IT into pre-service and in-service teacher development and training programs, and create opportunities for system-wide professional development of teachers
- **Human Resource Development**
 - To provide necessary education and training to all teachers in government schools and making them competent in using IT for teaching purposes
 - To upgrade officers in the education system to handle IT related activities competently and with ease
 - To create opportunities for out of school population to utilize resources in school based IT resource centers, thus creating an environment for community learning
- **Physical/Infrastructure Development**
 - To allocate and distribute optimal resources in an equitable manner to meet the learning needs of students and learning/teaching requirements of teachers
 - To set up an Information Technology Education Resource Center (ITERC) at the national level, provincial level and zonal level ITERCs for teacher training/development
 - To establish an IT education laboratory at the National Institute of Education (NIE) to improve curriculum development
 - To establish an ITERC at the Center for Professional Development of Management of Education
 - To dedicate a National College of Education (NCOE) for development of IT teachers under pre-service teacher training
 - To provide innovative means of training through activities, such as mobile training laboratories
 - To set up a Multimedia Education Software and Web Development Center
- **Support Initiatives Development**
 - To establish IT school clubs
 - To encourage preparation of Web sites for schools
 - To encourage teachers to own personal computers
 - To design, develop, and maintain a Web site for the Ministry of Education and Higher Education to assist the school system in e-learning and information management
 - To convene appropriately time-framed IT education research and development conferences/colloquia
 - To facilitate the setting up of a professional body for those who are involved in IT education in schools

- To establish a fund to support innovative approaches and creative initiatives for school IT education development
- To initiate an award scheme to encourage educators for promoting innovative IT in education
- To forge strategic partnerships with other government institutions, Sri Lankan Missions abroad, foreign missions in Sri Lanka and national and international NGOs and the private sector to extend the coverage of IT education, promote, and enhance the quality of IT education in the school system

In the new millennium, nations are judged by the well-being of their citizens; level of education is one of the major determinants. Computer literacy of a nation in the future will be a yardstick to measure the level of education. Sri Lanka's success in achieving high levels of basic literacy and numeracy can be capitalized on by pursuing a well thought-out strategy on achieving high quality IT education in the general school system.

Under various foreign-funded projects, the Ministry of Education is currently taking several measures to enhance IT facilities in schools. For instance, under the World Bank funded General Education Project II, planning is underway to provide 400 schools island-wide with ICT centers, equipped with 10 computers each and other accessories, as well as Internet facilities. The pilot project, in which ICT centers were established in 80 schools, was implemented in 2001 and was evaluated in 2003. The initiative was found to be providing the opportunity for students and teachers to develop basic competencies in the use of IT in education; and, despite various constraints, all schools are attempting to make the best possible use of the centers (Karunanayaka, Kularatne, & Udugama, 2003). The Secondary Education Modernization Project currently being implemented with the support of the Asian Development Bank

intends to develop computer literacy and narrow the digital divide. During 2001-2006, about 2,300 schools will receive 10-20 computers; and the project envisages improving access for an additional 5,000 poor students annually, by upgrading 1,000 existing schools (Reddi & Sinha, 2003).

THE CHALLENGES

A few parameters will be discussed here that may be treated as potential challenges for ICT implementations in Sri Lanka.

Lack of Skilled ICT Professionals

The lack of sufficient, trained ICT professionals has been a recurring focus in ICT studies and reports in Sri Lanka. There seems to be four main drivers for this shortage:

- Sri Lanka produces only a small number of ICT-trained university graduates (albeit high quality) each year. The number of positions in the state-funded universities is severely limited. This is part of a bigger problem. Sri Lanka has a good record for primary and secondary education but admits to university only about 6% of successful secondary school leavers (16,000 out of 200,000).
- Sri Lanka has about 30 state-supported, commercial and quasi-private technical training institutes. However, the quality of training at these institutes is highly variable.
- Sri Lanka loses many ICT graduates soon after graduating. Their ICT skills demand far higher salaries abroad. An IT-qualified graduate earns per month US\$800 to \$1,000 locally.
- Sri Lanka faces a serious shortage of experienced ICT professionals. Senior people with 6-10 years experience are lacking in software design, project management, and network design and management. This short-

Potential Challenges of ICT Implementations in Sri Lanka

age is felt both in industry and education. Sri Lanka has only 10 IT graduates out of 500 graduates.

The problem of insufficient ICT graduates has several dimensions, some of which are addressed below:

- All 14 state-funded universities provide some form of ICT education. However, in the majority of them, it is just computer science or information management courses within a general BS degree.
- Several fee-levying institutes (arms of foreign universities) offer computer science programs, but the prices tend to be above what most of the population can afford. It costs around US\$10,000 for a 3-year program and normally recruits 120 students per batch.
- Though in state-funded universities ICT training is being increased (a recent example being the new Faculty of Information Technology at the University of Moratuwa), this effort is tightly constrained by the lack of senior instructors.
- The University of Colombo has recently begun an innovative 3-year program called the External Degree of Bachelor of Information Technology (BIT). Under this program, the university sets the curriculum and the exams. Student can prepare for examinations through self-study, or they can go to one of about 40 fee-for-service institutes that provide training and/or tutoring. To promote the quality of such sources of training, the university will publish on its Web site student success rates by institution attended. The BIT program is designed to allow students to stop with a Certificate of Information Technology after year one, an Advanced Certificate of Information Technology after year two, or a full Degree Certificate after

completion of year three and other degree requirements. This strategy produces three levels of ICT skills.

For the application of ICT across the non-ICT sectors of Sri Lanka (government, health, primary/secondary education, small and medium enterprise (SME), and the rural sector) more people will need to be computer literate and computer trained. There are many user training programs in place, but as in the case of more technical training, the quality of the training programs remains uneven and erratic. The institution providing the Computer Driver's License may be effective in helping to manage and measure the growth in computer literacy, and offer employers a measure of confidence in hiring staff.

Two skills retention strategies that seem to be underdeveloped in Sri Lanka are the virtual repatriation of the skills of expatriates, and the retention of ICT professionals by linking them online to education, research, and work abroad. Some Latin American countries, for example, resort to the Internet to repatriate the skills of overseas nationals, for use in education, research and development, industry, and for civil society activities. Such efforts are low cost and in many cases the expatriates themselves organize them. Other countries, Ghana for example, have used the Internet to retain local skills, by linking local medical researchers to overseas research networks.

Basic ICT Skill Development

The twin problems of how to increase both the supply and the quality of training, across a number of skill areas and skill levels, should be addressed in collaboration across the relevant stakeholders, including the training institutes. Sri Lanka is not in a position to simply institute various levels of formal certification of ICT training facilities. There can be schemes such as the University of Colombo external BIT plan that certify skills.

Furthermore, publishing students' performance by training institute will allow students, and their families, to identify quality, and influence training quality. Publishing statistics on how many graduates obtain employment utilizing their new skills will also provide a measure of success, but one must be careful that these statistics are honestly presented.

There are discussions going on at a number of levels to institute formal certification of ICT professionals. Certification not only labels the prospective employee, but the type of certification will provide guidance to employers who do not themselves have the skills to identify good employees. The relevant stakeholders, including the training institutes, should consider a mix of *guard dog* and *guide dog* strategies to improve ICT skills and the performance of ICT training institutes. The objective is to expand the supply of quality ICT skills, not to restrict supply just to those that currently produce quality ICT skills.

Weak Strategies for Retaining ICT Professionals

There remains a serious obstacle to a rapid ramp up of ICT activity in the software sector, and the large-scale application of ICT to organizations. While it is possible to quickly expand the supply of entry-level ICT personnel, it is not possible to immediately produce high-level professionals, especially when that includes 6-10 years of proven experience in software design, project/implementation management, and network management. Some of this demand could be met by the virtual repatriation of the senior skills of expatriate Sri Lankans abroad. Again, an end to the civil unrest will also help, both in the potential for full-time repatriation of ICT skills, and for the short term return work stints of expatriates whose ICT skills are being repatriated online the rest of the time. It remains to be seen as to who might organize such efforts.

One interesting and successful way to circumvent this problem is to subcontract high-end tasks to the Computing Services Center (CSC), a group within the Institute of Computer Technology (ICT) of the University of Colombo. ICT is one of the few really concentrated centers of technological expertise in the country, and the CSC has been involved in many successful projects. These have included feasibility studies, project specification and design, tender evaluation, network design and implementation, as well as overall system development. This group has been involved in some of the most strategic projects involving both government and private enterprise. As a side-benefit, this also serves to give staff members an additional source of income, partially alleviating the low academic salaries. The salary of the university senior professor is around US\$600 per month.

OVERCOMING THE CHALLENGES

The author proposes a few strategies to overcome the challenges and uplift the human capacity of Sri Lanka.

Computer Literacy in the General Population

As information and communication technologies (ICTs) become a part of everyday life, it will be increasingly necessary for all citizens to have some basic familiarity with computers. Technology revolutions are complete when such skills are taken for granted and the technology seems to have disappeared into the background. It is necessary to (a) be clear as to what the actual goals are, (b) have an evidence-supported strategy for getting there, and (c) engage in a planning process in which both stakeholders and champions are brought on same side. It is essential to convert strategy into resources, or Sri Lanka will run the risk of reproducing the shortcomings of similar efforts elsewhere.

The main shortcoming is the tendency to substitute the provision of technology with implementation strategy. It is better to deploy one-half, or one-quarter of it, rather than engaging in a technology-intense strategy. One such strategy is helping donor agencies understand the issues, in terms of providing computers in the school and computers in the community.

A method that has been successful elsewhere is to provide technology to a school if there is a local champion and the school management is committed to the success of the project. A champion could be a staff member at the school, or a local company that will provide help and guidance. The essential characteristic of champions is that they passionately care for the computers' better use, and will do whatever is necessary to ensure that outcome. A success in a school with a local champion tends to spread to nearby schools with a ripple effect.

It is also noteworthy that, to date, the technology has not been used in support of other educational goals, specifically those related to English and other language training. It has been found that exposure to the still largely English-dominated computer and Internet world does wonders to increase functional English language skills. And the poor quality of English language education, particularly in rural areas, was highlighted as a major problem by several interviewees. There are 196,597 teachers in 2003 and English teachers who can teach English as a subject in schools are only 10% out of this number.

Improved Internet Access

There are six ISPs in Sri Lanka, with Sri Lanka Telecom (SLT) being the largest. Most of these players are quite small. SLT has 50,000 subscribers out of 19 million of the total population. SLT provides simple dial-up, dedicated to broadband Internet services through its Internet Service Provider (ISP) SLTNet. SLT has points-of-pres-

ence (POPs) across the country and this allows its subscribers to access the Internet for the cost of a local call through a single number (150) using SLT's unmatched superior quality backbone bandwidth of 90 Mbps.

SLT currently offers Internet-leased lines at 64 kbps, 512 kbps, and 2 Mbps, mail server services, Web and Domain Name Server (DNS) hosting are other value added products for business customers. SLT also provides Internet services to most of the other ISPs. All ISPs (or their downstream supplier) interconnect at the Sri Lanka Domestic Interchange, so that, intra-country traffic will never go offshore. SLT provides domestic leased circuits under the name of SLT Data. It offers data circuits of capacities ranging from 64 kbps up to 2 Mbps and in multiples of 2 Mbps. Our services include domestic and International Private Leased Circuits (IPLCs), Frame Relay (FR) circuits, Internet Leased Lines (ILLs), Direct Inward Dialling (DID) and Direct Outward Dialling (DOD) connections.

The cost of Internet ISP access is comparable to similar services elsewhere in the world. Many non-SLT providers only offer 28.8/33.6 kbps dial service, and access from many non-SLT local loops is limited to 28.8 (presumably due to the use of compressed 32kb voice services). A typical cost (from SLT) is US\$11 per month for 150 hours. But, the actual per minute cost of dialup Internet access is normally high because of the additional per-minute cost of voice service. The base cost of a telephone line is low (about US\$3-4 per month). However, the cost per minute, particularly during weekday daylight hours, is abnormally high (for SLT it is US\$1.80 per hour after the first 8 hours).

Incorporate New Technologies

Virtual Private Networks (VPNs) have emerged as a modern solution for meeting the challenge of integrating data, voice and video traffic in an

easily manageable, scalable, and flexible network. VPNs provide economical, efficient, and secure solutions for modern businesses.

SLT has launched its IP-VPN service in 2003 and built a Managed Private Leased Circuit (MPLC) based IP-VPN network covering almost all commercial locations in the Western Province (including Katunayake and Kandy). SLT now offers IP-VPN services to virtually any location within Sri Lanka by providing access through leased lines, frame relay or Digital Subscriber Lines (DSL).

The Managed Private Leased Circuit (MPLC) protocol has emerged as the preferred protocol. It combines the security and performance of Frame Relay Services with the flexibility and cost-effectiveness of IP.

Deregulation of ICT Policies

The telecommunications sector in Sri Lanka was at first a state-owned department. The department was converted to a corporation and regulation was introduced in 1991. The Sri Lanka Telecommunications Authority (SLTA) was created by an Act of Parliament in 1991. It was converted to a commission in 1996. The dominant operator Sri Lanka Telecom (SLT) was privatized in 1997 with the government of Sri Lanka disposing of 35% of the share to the NTT Corporation of Japan. Licenses were issued to two operators for fixed

access telephone services using WLL technology to compete with SLT. At present there are also four cellular operators, six facility based international data transmission providers, twenty-two licensed ISPs and two licensed pay phone operators. To show the current status of ICT, a few parameters are given in Table 1.

The new National Telecom Policy recommends the support for the establishment and promotion of the Sri Lanka information infrastructure and includes focus on new ICTs such as the Internet and e-commerce. In order to develop information technology, the Council for Information Technology (CINTEC) was established under an act of parliament. CINTEC has been involved in the development of e-commerce in Sri Lanka. It has several subcommittees and one of them is on law and computers.

This institution came under the purview of the Ministry of Telecommunications and Information Technology in October 2001. The growth of the telecommunications sector has given the foundation for developing the e-commerce industry in Sri Lanka. Within this improvement, e-commerce has received the attention of consumers, business persons, journalists, private and government organizations during the last few years. It brings a new trend in the policy agenda of Sri Lanka. With the development of technology and Internet applications, the e-commerce operations are becoming very fast, cheap, and simple.

Table 1. A few ICT parameters of Sri Lanka Source: Sri Lanka Telecom LTD 2004 (NA-Not available)

Item	2000	2001	2002	2003	2004
Wireless local loop telephones	11,4267	12,1082	11,4488	11,6021	N/A
Cellular mobile tele-phones	430,202	667,662	931,580	1,393,403	2,211,000
Radio paging	7,009	6,535	5,516	2,851	3,679
Public pay-phones	8,222	7,281	6,681	6,440	N/A

Better Utilization of the Internet

As mentioned above, various industries in Sri Lanka are making use of e-mail and the Web. However, it is notable that virtually none of them have truly integrated them into their business. It was difficult to find examples where the use of either e-mail or the web was a crucial link to business success.

The attitude of communities is changing with the introduction of Internet at all levels. It is now used extensively in schools, universities, private and government organizations, banks, journalists, and business organizations. This is a very important aspect for the development of e-commerce in Sri Lanka. The business community of the country started to gradually experience applications such as online merchandising, stock trading, and banking and information database. These applications promote the e-business culture locally. A limited number of the organizations are using e-commerce for their international business activities.

Sri Lanka is also in the process of establishing an Electronic Data Interchange Network, which would link up all key public organizations. This development will help to the penetration of an e-business environment in Sri Lanka.

The SMEs use the Internet extensively for trade research. As in any other country, Sri Lankans use the maximum potential of the Internet to absorb the technical know-how from the outside world. Almost 100% of the SMEs who used the Internet at the time of our survey reported that they were using the Net for at least one of the following:

- Free downloading of device drivers from the OEMs
- Free evaluation software downloads
- Obtaining technical documentation/research papers
- User manuals and sales catalogues
- Getting competitor information
- Getting trade know-how and new ideas

Sampath Bank (one of the leading IT introduced local banks from inception) and HSBC Bank are the main bankers used by the Sri Lankan SMEs for Internet banking. The reasons for using them were convenience, proven security, fewer conflicts (words from a respondent), economical operation, and so forth. The normal Internet banking operations were balance verification, requesting statements, transferring funds between accounts, paying bills, requesting check books, and so forth. The length of period of use averaged to about one year. Almost all respondents agreed that Internet banking once implemented with proper security precautions would benefit the customer providing state-of-the-art technology at a touch of a button. The major advantage being the rapid response and dynamic operation without having to waste time in the traffic jams.

Wireless Application Protocol (WAP) Implementations

The mobile phone companies have been promoting WAP applications for quite sometime now. The available applications include exchange rates, cricket scores, horoscopes, stock market, flight information, and so forth.

However, the business volumes on WAP implementations are low due to the lack of proper equipment, lack of customer awareness, and attitude, and so forth. At the same time, the phone companies see that high promotional and operational costs are main barriers to enhance this service.

Improved Policy Initiations

The rapid developments of ICTs in Sri Lanka have significantly affected the current legal system. Many privacy experts in Sri Lanka have shown that there is a need for new laws to adequately regulate new technologies.

The absence of a data protection law and a data protection authority in Sri Lanka is a real threat

to the recently introduced e-Sri Lanka program. The e-Sri Lanka program aims at computerizing all governmental departments in the country and facilitating electronic documentary service, as opposed to the traditional government service that still processes everything manually.

In 2003, the Parliament passed the ICT Act No. 27 for the establishment of a national policy on information and communication technology and for the preparation of an action plan. Under this Act, the Information and Communication Technology Agency (ICTA) has given the responsibility to implement the national policy in both the public and the private sectors. The agency functions as the single highest body involved in ICT policy in the nation. It also assumes the role of implementing the e-Sri Lanka initiative.

The Computer Crime Bill of 2003 has also been approved by the Cabinet of Ministers and established by the Parliament. This act aims at combating computer crime in Sri Lanka. The Electronic Transaction bill Act has been established for providing the legal recognition of electronic transaction and other transactions carried out by means of electronic communications commonly referred to as “electronic commerce.” This act is based on the UNCITRAL Model Law on E-Commerce 1996 and the 2001 UNCITRAL Model law on Electronic signatures.

Enhanced Governance

The e-government index of Sri Lanka is 0.92 which is below the global mean e-government index of 1.62 and it indicates that present e-government capacity of Sri Lanka is poor. A research on the Web survey of government institutes revealed that 30% of ministries in the country do not have Web sites or may not be access able since they are inactive. 38 of the ministries are still in the early stage and information available in Web pages in terms of content is not rich. Only about 17% of ministries offer interactive Web content, where users have access to regularly updated informa-

tion and can communicate through e-mail and download government documents through the Internet. 15% of the ministries provide some online services to the citizens. In same study a sample e-mail was sent and the time taken to reply was recorded. It was found that 99% of e-mails were not responded to by the Web masters (E-government survey, 2004).

The State Accounts Department (part of the Ministry of Finance) is leading a government-wide effort to progressively adopt International Public Sector Accounting Standards (IPSAS) for the reporting of government accounts (revenue and expenditure). The financial statements (i.e., accounts) for 2002 were prepared for the first time in accordance with the IPSAS cash accounting formats and have received a clean audit opinion from the Auditor General (except for a historical reconciliation issue). The previous 198-page dense financial report has been drastically reduced to just nine pages of well laid-out information (a one-page consolidated statement of cash receipts and payments with eight pages of supporting notes) designed to be read and understood by non-accountants.

The technical assistance project funded by the Asian Development Bank has provided the international good practice functional expertise to guide the adoption of the IPSAS cash accounting format. This assistance was grant funded at no cost to the Government of Sri Lanka. The cost of developing the overall information systems that underlie this project has been significant—recent costs for consultancy inputs, training, and overall Web site construction alone (excluding hardware costs and earlier construction of information systems) totals around US\$150,000. However, construction cost of the financial statements and directly-related Web outputs has been reduced to a few thousands of U.S. dollars.

The improved quality and accessibility of accounts have a positive knock-on for transparency and accountability. Expected gains in this regard include but are not limited to informed

parliamentary debate, media coverage based on financial facts, and increased reliance on government financial reports by international investors. Such non-quantifiable benefits will take some time to accrue and perhaps the greatest benefit in quantifiable terms might be the willingness of the international financing institutions to commit additional aid funds on the basis of increased transparency and accountability in government financial management.

Support Outsourcing in Software

Sri Lanka has a small emerging software development industry concentrating on exports, which ran at about \$50 million in 2000 with a high percentage on a subcontract basis. Most of the industry consists of small firms founded by computer professionals, some returning from the U.S. to start their own companies. The industry faces constraints from shortage of skilled professionals, lack of venture capital, and narrow telecommunication bandwidth. Sri Lanka has not been able to take advantage of its high literacy rate to promote the IT industry. Local IT entrepreneurs, however, remain guardedly optimistic that Sri Lanka can carve a niche for itself in the high value-added software product development rather than the low value-added IT services which gravitate to India because of its large English-literate population and low wages.

The recent expansion of the software development industry has resulted largely from outsourcing for American, Middle Eastern, and European clients in Internet-based software development and business applications. Only a handful of companies are engaged in internationally recognized product development. In offshore services sector, local programmers produce software for overseas clients based on their designs and specifications. Some companies providing outsourcing services have dedicated support service centers abroad as well. John Keells Computer Services (JKCS), a subsidiary of Sri Lanka's leading conglomerate

John Keells Holdings (JKH) and one of the leaders in software services in Sri Lanka, employs nearly 2,000 programmers in 2003, and after they recruit every year, 50 qualified people go to their companies. Another major player in software outsourcing is eRunway. eRunway, headquartered in Boston, has an Internet software development center in Colombo employing over 300 software engineers.

Millennium Information Technologies (MIT), founded by a local computer professional, is the most successful company in product development. Valued at over \$100 million, MIT hopes to list on NASDAQ. MIT has built an international reputation for capital market and telecommunication industry software. Its state of the art stock exchange suites are used in stock exchanges in Malaysia (MESDAQ), Croatia, Mauritius, and Sri Lanka. The Colombo Stock Exchange (CSE) is one of the world's most technologically advanced stock exchanges. The catalyst for this change was a systems integration contract from the Colombo Stock Exchange, which was reinterpreted as an opportunity to design and install a straight-through processing system which actually worked. The CSE solution became the basis for Millennium IT's suite of capital markets software products.

Various programs are underway to develop the software development industry in Sri Lanka. The government has recently created a separate Ministry for Information Technology and Higher Education. Despite government's precarious fiscal position leaves little room for investment in related infrastructure, the government believes that due to the high literary rate, Sri Lanka can be converted to an information technology savvy nation by 2010. Bureaucratic barriers have prevented setting up of a regional Java Training Center in Sri Lanka by SunMicro systems. The software industry, according to industry leaders, will continue to develop more on individual company efforts. For instance, some software developers have set up their own training institutes to meet the human resources shortage.

Elevated E-Readiness

Sri Lanka is ranked 54th out of 82 developed and developing countries in the Networked Readiness Index published in the Global Information Technology Report (2002/2003). The report, the collaborative effort of leading academics worldwide, seeks to benchmark and monitor the progress of nations in different dimensions in the field of ICT.

The report highlights the networked readiness of the three major stakeholder's viz. individuals, businesses and governments within a country's economic and political context. The variables used to measure the Networked Readiness Index are grouped into three broad categories, particularly environment, networked readiness, and network usage. Each component index is composed of three subindexes with the computation of the final Networked Readiness Index being based on the 64 variables included in 9 subindexes.

The final index captures the critical factors relating to the environment, readiness, and usage of ICT by the three stakeholders. The rankings relating to both the component index and subindex, help in identifying the relative strengths and weaknesses in specific areas of competence. The Index therefore provides a useful measure of benchmarking the progress in networked readiness across a wide spectrum of nations worldwide.

Sri Lanka, with a score of 4.66 in the sub-category government readiness, is ranked 25th a high rank in comparison to its overall position of 54. This is a firm indication of the top priority and the thrust provided by the government to ICT in Sri Lanka.

Workforce Strengths

The key to any successful development initiative is the development of its stakeholders. Sri Lanka's labor is reputed for its precision, quality of its work, and productivity. English is widely spoken and understood throughout the island. The World Bank reports have indicated that Sri Lanka has one of the highest literacy rates (92%) among designated low-income countries; a population of 19.2 million has a workforce of approximately 6.7 million. There is a steady pool of manpower resources for both existing and new industries. The government provides free education from kindergarten to university. Sri Lanka is also ranked high on the Human Development Index and compares well with developed countries. Table 2 shows the Human Development Indices of Sri Lanka in comparison to the global or regional context.

Table 2. Human development indices of Sri Lanka and other regions. Source: UNDP (2003) Human Development Report

Country or Group	HDI Value
Countries with high human development	0.908
Sri Lanka	0.730
World (Average)	0.722
Countries with medium human development	0.691
Developing Countries	0.655
South Asia	0.582

FUTURE ISSUES

Sri Lanka has the highest literacy rate in the South Asian region and has a large pool of educated persons with skills in computer programming. At the higher end of the skill spectrum, qualified software engineers offer levels of supervisory skill that is among the best in the world. The country's IT leaders believe that software development, outsourcing, systems integration, and a vast range of IT related services are the passport to the future.

The Sri Lankan Government has actively encouraged the spread of computer literacy by providing duty concessions on hardware imports. This environment is further enhanced by modern data transmission systems and complementary hardware. Low cost offshore data entry operations have also thrived in Sri Lanka since the early 1980s. Sri Lanka already serves as the headquarters of one of the largest software development houses in South East Asia.

It has to be remembered that in Sri Lanka, data communication facilities are limited within Colombo and its peripheries, the western province and the major provincial towns such as Kandy, Galle, Batticaloa, Ratnapura (about 100KM from Colombo main Capital city), and so forth. Individual usage and, to a great extent, access in the workplace is tied heavily to social class and income. Internet access remains unaffordable for the majority of the people, and cyber cafes, though increasingly spreading, are still limited to urban areas. However, there are a few pilot projects currently being implemented to achieve island-wide coverage through VSAT technology.

In recent years, the growth in ICTs in Sri Lanka has been rapidly increased. At present, the number of websites that cater to the Sri Lankan diasporas as well as to the Sri Lankan public is on the rise with an emphasis on Sri Lankan content either in Sinhalese, Tamil, or English (main languages used by Sri Lankan citizens).

E-mail and Internet reached Sri Lanka at the end of the 1980s making it one of the first countries in Asia to use the Internet, though the potential of the Internet for conflict transformation and resolution remains largely untapped in Sri Lanka, with a few notable exceptions. Sri Lanka still believes that the mere creation of Web sites engenders the use of the Internet, and does not place an onus of educating the masses on how to best use the Internet. However, given these limitations, some NGOs are taking the lead in the creation of interactive Web site that provoke and stimulate online discussion and sharing of viewpoints as an underpinning of classic conflict transformation.

The importance of ICT cannot be ignored by government, civil society, and NGOs in Sri Lanka. ICT by itself is an impotent tool. What animates it is a culture in which stakeholders use ICT to buttress and build confidence between communities, engender discussion, and help in the dissemination of information regarding state-of-the-art conflict resolution techniques and events. Though there are no easy solutions for the peaceful settlement of protracted ethnic, a realization of the power of ICT can help efforts on the ground to bring a negotiated and justified solution to war in Sri Lanka.

CONCLUSION

Sri Lanka's greatest weakness is the poor telecommunication infrastructure. Complete lack of telephone connections to some areas of the country is evidence of this. While Internet connections and e-mail software is now readily available, the pricing puts them beyond the reach of a greater majority of the population. In 2004, the telecommunication sector, in terms of subscriber network, expanded by 36 percent. The external gateway operation, which was the monopoly of Sri Lanka Telecom (SLT), was opened for com-

petition in 2003 with 32 licenses being granted by the end of 2005.

The Government of Sri Lanka has initiated the e Sri Lanka plan which, aims to electronically connect and service the entire country. The labor force is being enhanced with education, skills training and a focus on productivity. Hoping to use trade to spur growth, Sri Lanka is emphasizing its central position in the region and key shipping lanes, Free Trade Agreements with its neighbors and its relatively friendly business climate to grow into a regional hub for manufacturing, commerce, and transport. The private sector also has responded to the peaceful environment with increased business activity and investment. Sri Lanka's economy expanded by 5.6% in 2005, and further progress was made on macroeconomic stabilization.

The government has committed itself to reduce corruption, but problems remain. Tender procedures are opaque, decision making is slow, enforcement of intellectual property rights (IPRs) is uneven, and bureaucracy, caused by a large public sector, hinders efficiency. However, the progress largely depends on the continuation of the peace process, policy adjustments, private sector development and structural reforms. Though still faced with substantial economic, social, and political challenges, Sri Lanka accomplished much in 2005, a fact recognized by the international community.

On 26 December 2004, an undersea earthquake registering 9.3 on the richter scale struck in the Indian Ocean, off the Western coast of Northern Sumatra, Indonesia. Sri Lanka was seriously affected by the tsunamis. They caused extensive damage along more than two thirds of over 1,000 km of the coastline extending from the northern coast, through the eastern and southern coasts to the western coast. The total damage is estimated to be around US\$1 billion (4.9% of the GDP) and the reconstruction, which is likely to spread over a period of about three years, is estimated to cost around US\$1.8 billion (8.9% of the GDP). It is

expected that this will create new coping strategies and a natural disasters plan, in addition to developing new IT culture in the country.

Chapter 4.13

The E–Pabelan National ICT4PR Pilot Project: Experiences and Challenges of Implementation in an Indonesian Context

Alex Robinson

University of Huddersfield, UK

ABSTRACT

The chapter presents a case study of an ICT-based attempt to reduce poverty (ICT4PR) in a rural Indonesian community. Differences between the theoretical approaches adopted by the implementing agencies and the difficulties inherent in achieving these aims in practice are outlined. The chapter is particularly concerned with how issues relating to implementation impact on efforts to move toward greater beneficiary inclusion in socioeconomic networks. Crucially, the chapter stresses the ongoing need in practice to move away from a homogenising digital-divide-style approach to ICT4PR, and to better engage with localised realities and contexts.

INTRODUCTION

We have plenty of information. We visit other farmers, talk...listen to the radio, watch television... read books! ~Farmer and local official, male, nonpoor, December 4, 2004

Maybe the telecentre is only for rich people [orang mampu]....Information [in Pabelan] does not flow evenly [tidak merata]—it is only for certain people. So poor people, like me, often do not in fact receive information. ~Occasional child minder, female, poor, February 29, 2005

In recent years, there have been increasing interest, speculation, and debate regarding the

potential of information communication technologies to facilitate and contribute toward a process of development (ICT for development, ICT4D). This interest has been accompanied by a plethora of activities seeking to harness the potential of ICTs to a correspondingly varied array of development ends. This chapter focuses on an attempt to utilise ICTs for poverty reduction (ICT4PR) in a rural Indonesian community. Research informing this chapter was conducted at the e-Pabelan national ICT4PR pilot project in the village of Pabelan between October 2004 and August 2005.¹ e-Pabelan (<http://e-pabelan.myserver.org/portal>) is the initial pilot of the Partnerships for e-Prosperity for the Poor (PePP) programme (<http://www.ict4pr.org>) of the National Development Planning Agency (Badan Perencanaan Pembangunan Nasional, BAPPENAS) and the United Nations Development Programme (UNDP).

e-Pabelan became operational in May 2004. The project takes the form of a telecentre that was established with five computers providing dial-up access to the Internet, plus ancillary equipment including a scanner, printer, and digital projector.² More established ICTs such as a telephone or facsimile machine were not provided. The equipment was provided by BAPPENAS/UNDP as was payment for the Internet connection for the first year, some educational materials, and limited training for some staff and members of the community. The chosen local partner was the Islamic boarding school Pondok Pesantren Pabelan acting through its community development wing Balai Pengkajian dan Pengembang Masyarakata (BPPM). The pesantren is a coeducational secondary (equivalent) school, which, alongside the emphasis on Islamic teachings and proper conduct, follows the Indonesian national curriculum. Additional emphasis is placed on the teaching of languages, including English, and science classes, as well as a range of extracurricular activities. The pesantren is highly regarded nationally and has attracted students from across

the archipelago and from abroad. In its capacity as a local partner, the pesantren provided the use of the BPPM building and payment for electricity. Staff, acting on a volunteer basis at the telecentre, were appointed from within the BPPM as well as some senior students from the pesantren (all male). Usage of the Internet at the telecentre was free for the first year, although there were some complaints that individuals from outside the pesantren had been asked to pay in the early months. The project was, somewhat optimistically, expected to be financially independent after the first year.

The chapter proceeds through presenting a case study of the e-Pabelan project rather than a more theoretical analysis of ICT4PR, and limits itself to issues arising from the implementation and development of e-Pabelan over the project's first year. Enthusiasm for ICT4PR is first briefly situated against a broader backdrop. e-Pabelan is then placed in its local context. The chapter emphasises that such contextualisation is critical. Experiences from the three different stakeholder levels are then outlined: from the implementing agencies, the local partner, and from the intended beneficiary level. Differences in expectations and conceptualisations from these groups urge the need for reflection and realism within ICT4PR. The chapter stresses the need for acknowledging continuities and for approaching ICT4PR as an ongoing development process. In closing, an alternative approach is presented that emphasises the need to better engage with existing networks within communities prior to, and in conjunction with, the establishing of access to external networks mediated via ICTs.

Before proceeding, it is necessary to clarify a number of points. With regard to ICTs, the chapter accepts that ICTs are "electronic means of capturing, processing, storing and communicating information" (Heeks, 1999, p. 3), and is mindful of the fact that ICTs "handle information in digital format. That's all" (Heeks, 2002, p. 2). Within a poverty-alleviation context, the importance

of more established forms of communicating and receiving information beyond the digital is acknowledged (Hewitt de Alcántara, 2001). The concept of poverty is similarly viewed in multidimensional terms. It is accepted that ICTs may be used to facilitate improvements in the related spheres of empowerment, opportunities, and security (World Bank, 2000).

The stated aim of e-Pabelan, and PePP, is to reduce rural poverty with a particular reference to the agricultural sector. Project documentation states that this aim is to be realised through a pro-poor process and by “empower[ing] and mobilis[ing] poor communities for economic activities and accessing social services through better access to information and communication” (documentation courtesy BAPPENAS/UNDP, September 2004). Reference is also made to accessing market prices and to the exploitative role of middlemen in agricultural market networks along with the need for the provision of basic information. It is also noted by the implementing agencies that the provision of information alone is not enough and that the pilot project will be “tightly focused,” localised,” and include capacity-building activities (ibid). On paper, therefore, e-Pabelan reflects widely accepted approaches to ICT4PR and community-oriented rural development. The implementing agencies, however, do not proffer a precise working definition of poverty, although under PePP, at least 30% of the beneficiary community must fall below national poverty lines. It is thus assumed that ICT4PR at Pabelan is targeted at this segment of the local population. In this context, ICT4PR is viewed as the direct introduction of ICTs within a community to bolster flows of communication and information to and within that community in order to improve opportunities, empowerment, and security for the poor.

SUMMARISING THE POTENTIAL AND LIMITATIONS OF ICT4PR

The related concepts of an information age and information society have spurred increasing interest in the role of both information and technology in development.³ For the proponents of ICTs, the future is conceived as boundless in a vision of unfettered and immediate access to digitally communicated information (Cairncross, 1997). However, as this book explores, such a situation can lead to both opportunities and costs. The information age and its associated technologies present a double-edged sword that could potentially cut a swathe, for better or for worse, through the development sphere. Increasing interest in ICTs in development circles may be summarised, to a degree, by drawing on the words of the foremost commentator on the information age, Manuel Castells (1999), and through what he sees as the emergence of a “fourth world”: “This fourth world of social exclusion, beyond poverty, exists everywhere, albeit in different proportions, from South Bronx to Mantes-la-Jolie, from Kamagasaki to Meseta de Orcasitas, and from the favelas of Rio to the shanties of Jakarta. There is ... a systemic relationship between the rise of informational, global capitalism, under current conditions, and the extraordinary growth of social exclusion and human despair” (Castells, 1999, p. 10).

If we accept that the emergence of new digital technologies is a critical factor behind such increases in exclusion, the significance of ICTs in and for development becomes clearer; it is increasing disparities between the digitally networked and the marginalised other. At the same time, the emergence of more affordable and flexible ICTs presents new opportunities for inclusion and for empowerment. Such concerns are reflected in calls to bridge the so-called digital divide. The need to bridge this divide has been widely used to leverage access to ICTs as a development priority as the link between poverty and a lack of access

to ICTs is “indisputable” (Flor, 2001), one argument follows. Issues of inclusion are undoubtedly central to attempts to alleviate poverty, but there is also the danger that the adoption of such an approach can lead to an overemphasis on technically oriented fixes in practice.

A more cautious view maintains that the notion of a digital divide is misleading. Prioritising a link between ICTs and poverty confuses cause and effect and pays scant attention to the complexities and underlying causes of poverty and social exclusion (Marker, McNamara, & Wallace, 2002; McNamara, 2003). Viewed in such light, the provision of access to ICTs can be construed as little more than a flirtatious diversion from more deep-rooted concerns. There is also the need to ask what the provision of access to ICTs actually means and on whose terms such access is promoted and established (Gurstein, 2003). An overemphasis on technical access, it has also been suggested, reflects, somewhat ironically, a return to the values of modernisation theory in development thinking (Schech, 2002). Modernisation theory was similarly concerned with imparting knowledge and the transferal of technology from “us” to “them.” Modernisation theory may be considered the antithesis of community-based or alternative approaches to development. Although different development paradigms coexist within ICT4D (Houston & Jackson, 2003), at the beneficiary level, alternative understandings and realities need to be better acknowledged (Avgerou, 2000).

With reference to poverty alleviation, we may summarise that enthusiasm for ICTs can obscure complexity and prioritise the dominance of particular values and norms. Such an approach raises issues regarding power, representation, and voice and cannot, therefore, be construed as constituting inclusion in its own right. For the marginalised, there is the risk that without due care, ICT4PR may well mean more of the same. The danger of ICT4PR, as both discipline and practice, is that by prioritising universal approaches and fixes, the

realities and actual needs of the poor can be de-emphasised. This is not just a point of theoretical concern, but one that can have very real implications in practice. As this case study illustrates, there is a need for fuller engagement with local contexts within ICT4PR. One size does not fit all. In stressing the need for contextualisation, the context in which e-Pabelan was established needs to be outlined.

E-PABELAN IN CONTEXT

The village of Pabelan lies roughly 30 km to the north of Yogyakarta near the Buddhist temple complex and world-heritage site of Borobudur. Pabelan borders the market town of Muntilan and straddles central Java’s main transport artery. The village is not, therefore, isolated in a broader communicative sense. Within Pabelan, poor individuals also utilise various ICTs. Within the village and immediate vicinity, there are 12 public telephone kiosks (wartel). The telecentre cannot, therefore, be considered to be filling a void in access to basic communication technologies. Clustered around the main road there are also businesses offering photocopying services, two computer rental businesses offering off-line applications by the hour, and more recently, kiosks selling mobile telephones and accessories have begun to multiply. Poor households within the village also reported owning radios (76%), televisions (64%), and at least one mobile telephone (13%). No poor households reported having a fixed-line telephone.⁴ A lack of ownership of ICTs, however, does not necessarily equate to a lack of access.

Official statistics place the population of Pabelan at 6,955 within 1,839 households (Badan Pusat Statistik, 2005). Broadly speaking, the majority of livelihoods within the village may be said to be centred on agriculture and related activities, including the home-based production

of foodstuffs and small-scale trading. The latter two are particularly important livelihood options for women. There is also a significant handicraft industry producing wood, bamboo, and stone products. However, livelihoods within the village are best viewed in terms of diversity and range from salaried government employees to occasional labourers. Importantly, and contrary to popular opinions, households that own land and make a living solely from farming no longer represent the majority. The inheritance of smaller parcels of land through the generations and a lack of alternative local employment opportunities have resulted in a significant number of villagers seeking work in other areas of Indonesia and as far afield as Saudi Arabia. In some subunits (*dusun*), villagers complain that youth unemployment runs as high as 70%. Poverty estimates vary but suggest that between 30% and 50% of the population are living in poverty.⁵ Pabelan livelihood options and limitations are varied and reflect changing patterns of land ownership and wider structural changes within the Indonesian economy.

THE PROJECT

While it may appear unrealistic for e-Pabelan to have had a notable impact on poverty by the end of its first year, the project could not be said to have made significant progress toward achieving that end. During the year, the number of farmers, being the primary target group, recorded as visiting the telecentre (rather than using the Internet *per se*) amounted to 12. This figure showed little change since early training at the telecentre, and the overall profile of users remained consistent throughout the year. The typical user was male (65%), young (mean 19 years), and educated (73% currently in education). In order to account for poor participation by target groups at e-Pabelan, it is necessary to relate the project's implementation to the local context.

Implementing a Vision

As noted, the implementing agencies stress that e-Pabelan is a pro-poor community-based development project and moves were made to establish local ownership through partnering with the *pesantren*. Nevertheless, ensuring wider community involvement became increasingly difficult to realise as the project progressed. In practice, the social, political, and structural *contexts* into which e-Pabelan was introduced had a considerable bearing on the project.

Initial difficulties arose from differing understandings between the implementing agencies and the local partners. Establishing a partnership with the *pesantren* was based on two principle notions. First, the BPPM had active community-development activities, and second, the *pesantren* was a regular source of information for the community. Both of these assumptions were, to varying degrees, misplaced. While it is true that the BPPM was active in the past, this has not been the case for some time.⁶ The heyday of the BPPM was from 1986 to 1990. It is the case, however, that the *pesantren* is a source of religious information (mostly) for some members of the community. For others, the *pesantren*'s relationship to the wider community is seen as increasingly distant. This is primarily due to changes within the *pesantren*'s leadership since the death of the reportedly charismatic founder in 1993. A change of village heads (*kepala desa*) has also been significant.⁷ The current *kepala desa* (1989 onward) is regarded by many as being less active within the wider community than the former. Both the current and former *kepala desa* occupied positions in the BPPM. While the status of the BPPM was not checked by the implementing agencies, neither was it clarified by the local partners. One member of the BPPM was later to speculate, with no obvious irony, that "perhaps they [the implementing agencies] got that information from the Web?" (male, March 15, 2005)

Regardless, the memorandum of understanding (MoU) was signed, and the broad aims of poverty reduction and community development sealed. Concurrently, the telecentre was implemented through what may be described as established political channels and institutional structures.

Within Indonesia, there is a clearly defined political hierarchy extending from the national level to, and within, the village. Under the New Order regime of President Suharto, these channels proved effective in disseminating information to the level of neighbours (*rumah tangah*) if needed. Equally, this structure facilitated both paternalism and repression up to Suharto's fall in May 1998 (Schwarz, 2004). Although moves toward decentralisation have been established, e-Pabelan was implemented through essentially the same political structure.⁸ However, political and social changes within Indonesia since 1998 have also opened new opportunities for both agency and resistance (Bebbington, Dharmawan, Fahmi, & Guggenheim, 2004). Individuals, therefore, are far more able, and increasingly willing, to question the motives behind, and value of, externally driven interventions.

The implementation of e-Pabelan reflected established top-down approaches to development and stands in contrast to the project's stated participatory and community-based aims. The project was directed from the national level down, opened by the mayor (*bupati*), and initial open public meetings were dominated by invited officials, village leaders, and selected (some villagers claimed) members of the community. All, naturally, showed their support. The result was that the intended beneficiaries were, or perceived themselves as being, excluded from the process. The paradigm (community-based development) adopted in theory did not materialise at the local level. As one villager offered by way of explanation, the political structure both within and beyond the village serves to maintain the status quo: "The political trick is that there is already

an arrangement into levels, from the national level down, in Indonesia...[and] Pabelan is like a mini Indonesia" (handicrafts, male, January 31, 2005). From the beneficiary level, attempts to subsequently market the project to the community appeared as little more than an afterthought. Ten months after the signing of the MoU, it was found that less than 50% of poor households surveyed knew of the existence of the telecentre. Those that did know had, in the main, found out from friends or family or from simply passing the BPPM building. Information regarding the project did not flow to the intended beneficiaries, and what information did reach members of the wider community was partial and superficial. As one farmer tellingly noted, "I've never been told about the project...maybe, that's because it's not for me" (sharecropper, male, February 28, 2005).

The utilisation of related institutional structures was mirrored in the initial trainings (June-July 2004). Early training focused on staff at the *pesantren* and formal community groups (*kelompok*). These trainings sought to disseminate both awareness of the telecentre and information from the Internet to the wider community. However, formal *kelompok* membership by poor households in Pabelan is currently low. The notable exception is the women's group Pendidikan Kesjahteraan Keluarga (PKK) Village level women's welfare and educational group. Addressing the specific target group of farmers, 52% of poor households surveyed had employment in agriculture; however, only seven households reported a family member attending a farmers' *kelompok*. Poorer farmers, in particular, often complained these meetings were merely formalities for the better off and politically connected. One official (female, August 23, 2005) explained that the reason *kelompok* in Pabelan are not as active as they once were is precisely because individuals now have better access to information through alternative channels, television and radio in particular. Higher attendance at the PKK meetings can be accounted for by the incorporation

of a rotary savings scheme (arisan). The arisan is both a social occasion and an important source of independent capital for many women. The critical point about the early trainings, however, is as one of the telecentre staff (male, November 30, 2004) reflected: "They did not come back."

The community trainings were not always completed and quickly came to an end. Any early impetus was rapidly lost. By September 2004, recorded visitors to the telecentre had dropped to 16 from 273 for the previous month. This fall was also attributable to an array of technical problems that the local partners were ill equipped to deal with alongside falling enthusiasm from some local staff. The elite bias (Chambers, 1997) within the implementation was not without its implications.

LOCAL PARTNERS, POLITICS, AND RESPONSES

From a local-partner perspective, it is not difficult to imagine the attraction of a telecentre and the trappings of modernity it implies. Nevertheless, this does not mean that local partners will be equipped to envisage what such a project may entail in practice. Neither does it imply that they will have the necessary will and resources to respond to difficulties that, inevitably, will arise. Within Pabelan, they did not. Although initial trainings for staff at the telecentre were conducted by some external partners, the trainings were limited in both scope and reach. Difficulties at the local level were exacerbated by the lack of coherent systems for monitoring and evaluation, resulting in sluggish responses as problems emerged. Neither were there clear mechanisms for providing essential support to the local partners initially established. Furthermore, confusion persisted at the local level over how exactly the telecentre, and the Internet in particular, was to help in reducing poverty and bring material (primarily)

benefits to the community. As a result, interest quickly waned.

The fall in enthusiasm also reflects a more specific agenda on the part of the local partners. Interest in the project by the local partners was based on the potential of the telecentre to reconnect the activities of the pesantren to the wider community. That the pesantren is perceived as not having the same links to the community as it once had is not something that local officials are blind to. It is also a situation they wish to change. The telecentre was seen as a potential vehicle to do just this and to rejuvenate (*menghidupkan*) the activities of the BPPM. However, lacking the BPPM's previous expertise, community links, and external support, the local partners were not well placed to achieve this aim. Difficulties were further compounded by the lack of a clear mechanism for achieving the broad aim of poverty reduction. For the BPPM, it became clear that the telecentre was of limited use unless it was tied to more concrete development goals. As one member of the telecentre team reflected, "they [BAPPENAS/UNDP] just gave us the equipment; the telecentre was placed in a vacuum" (male, March 15, 2005). Despite the theoretical considerations of the implementing agencies, in practice, e-Pabelan was established as if the project would and could in some way have a direct impact on poverty; it was left up to the local partner to join up the dots. Although, the implementing agencies stress that the project was not just about the Internet, at the local level the project very much was.

The local partner's response to difficulties was to reorganise the management structure of the telecentre (January 2005) in order to better incorporate the telecentre into the BPPM and its future activities. The initial focus of the BPPM was to be on education and not on poverty reduction per se. Considering the expertise of the pesantren, the user base of the telecentre, and the value placed on children's education by many poor households, this seemed a wholly reasonable response. At the

end of the first year, however, any such plans were very much still in the process. Coinciding with the BPPM's response to difficulties, the implementing agencies' hand was forced and a number of interventions were funded. In March 2005, a local technical administrator was appointed for a period of 1 year. The individual was supported, primarily online, by a BAPPENAS technician in Jakarta. Although the telecentre continued to face technical problems, particularly regarding the erratic Telkomnet Instan dial-up service, this was a significant improvement.

In January 2005, the implementing agencies also agreed to fund a dedicated manager for 1 year. By way of compromise with the local partner, a new management team was finally appointed on a job-share basis in May 2005. The management team (two female, one male) were proposed by, and have previous connections to, the pesantren and the BPPM. Continuity, to a degree, with the BPPM's earlier plans was thus assured. Whilst this was an important development, the choice of management team did not, needless to say, directly increase involvement in the running of the project by the intended beneficiaries.⁹ A related development (January 2005) was the starting of a 10-month English-language course and computer-skills course for nonelite youths.¹⁰ The English course significantly helped to boost attendance at the telecentre, reaching a peak of 726 recorded visits in May 2005. However, the English course did not change the overall profile of users. The choice of students for the course was problematic. Members of the community complained that the course was dominated (approximately two thirds) by students from the pesantren and from outside of the community. For older members of the community, the perception reinforced was that the telecentre was not for them. Any sense that the project might be for the poor community within Pabelan was further eroded as the news of free Internet access spread, attracting young people from neighbouring areas. That the English course

should inadvertently cement such perceptions is unfortunate. However, the point of concern is that the situation persisted.

In summary, the choice of local partners presented little more than a facade of local ownership. Local ownership in the sense of ownership by the intended beneficiaries themselves was neither achieved nor moved toward. The officials initially consulted by the implementing agencies seldom visited the telecentre and were yet to use the Internet. For these individuals, the telecentre presented its own opportunity. In contrast to the stated inclusive approach, the development of the project continued to reflect the local political structure and to prioritise the interests of elite institutions within the village. Furthermore, interventions at Pabelan meant that the implementing agencies were forced to extend their financial commitment significantly beyond the project's first year as originally planned. It is highly improbable that the telecentre will be able to employ the additional staff after their contracts end. As the new managers are working toward what they see as a more realistic 3-year time frame, this is somewhat troublesome. Although a business plan was implemented for the telecentre in July 2005, the figures had yet to add up. Considering the current status of e-Pabelan, it is unlikely that the telecentre will be able to cover the costs of the current Internet connection alone.¹¹ In the absence of significant change, e-Pabelan faces a highly uncertain future.

BENEFICIARY CONTEXTS AND EXPERIENCES

Usage of the telecentre was dominated by the young (primarily students from the pesantren), reflecting both the location of the telecentre and the attraction of the Internet for this particular group. The majority of these users were in education, and a large number had previous computer experience.

It should be noted, however, that the majority of young individuals from within the village itself have not visited the telecentre. Older educated individuals also seldom visited the centre. Some individuals with previous computer experience, and local computer owners, had also yet to visit. This casts doubts on suggestions that one of the major obstacles to accessing the Internet at Pabelan by poor households is illiteracy and low educational attainment. Within Pabelan, this is not the case, and such arguments reflect taking the head of the household as the point of reference. Within the household, educational attainment has steadily risen with a few poor household members educated to degree level (S1). The situation at Pabelan is testament to overall increases in educational attainment within Indonesia over recent decades (Moertiningsih Adioetomo, 2005). Attainment by gender is also evenly matched, but this is not to imply that all things are equal. At times, circumstances dictate they are not:

Every year the cost of schooling goes up. If a farmer has other work, it's not a problem, but if you don't have other work like me, it's very difficult. Before we had children the income from farming was enough, but that was before school. After you have children it's not enough....Our son [14 years] goes to school in Magelang; it has computers and the facilities are good, so it's expensive.
(husband)

...Our daughter [11 years] goes to school in Borobudur [lower school fees]. She has registered, but she hasn't started yet because we haven't been able to pay the fees.
(wife)

...Of course, we want both of them to go to a progressive school (sekolah maju)...but it's just too expensive.
(husband)

(farming household, July 22, 2005, shortly after new school year began)

Naturally, things could always be improved, but within Indonesia, relatively high levels of educational attainment should, in theory at least, be conducive to the adoption of ICTs. While the rising cost of education is a major concern for poor households and represents the major household expenditure for many, it is a cost that families, and particularly women, go to lengths to bear.¹²

It is also not the case, as the experience of trainings at Pabelan demonstrates, that after individuals have been introduced to the Internet they will automatically see its worth:

I attended the basic training...No, I didn't go back. I don't see the benefit [manfaat] of the telecentre; also I have a young child and don't have the time. Also, the PKK has new leaders and is not as active as it was before...The PKK did find lots of information about KIA [mother and child health] and recipes, for example...but this was the usual information...that we can already find everywhere...also the health clinic [bidan] is next door to the telecentre...They would have been happier if they had found new information [for example] if it was possible to find information that could raise the income of a family...After the training, the women were still ill at ease [masih canggung] and scared [of the Internet]...they need continuous training.
(housewife, April 29, 2005)

The above illustrates that trainees were taught to access the Internet. This is not the same as accessing previously identified and processed information that is conveyed in a manner appropriate to particular needs.¹³ An emphasis on technical access can blur this crucial distinction. Furthermore, the utility of any information accessed did little to impress and did not sustain interest. Not all information is equal, and individuals within the wider community had more pressing concerns. Furthermore, it is evident that training was not ongoing and that the importance of such activities for building capacity and nurturing de-

The E-Pabelan National ICT4PR Pilot Project

mand within the community was not sufficiently acknowledged in practice. The choice of local partners was also decisive in shaping intended beneficiaries' perceptions:

I want to look for information about [business] capital, training for hairdressing, but I'm scared [to go to the telecentre] because it is owned by the Pondok and is only for the Pondok... We don't know what the aims [of the project] are and people don't know about it... Pabelan [i.e., Pabelan IV] receives lots of help, but it never reaches Batikan or Jagalan.¹⁴ ... The information does not reach here... The village head has projects, such as the orchid growing [World Bank funded training] and telecentre project, and there are socialisation programmes for the community, but the issue is that they have yet to ever reach here... The poor community are afraid to speak out against this. (hairdresser, female, March 1, 2005)

Furthermore, e-Pabelan also had to compete with the established demand for existing technologies, and the Internet does not always have an obvious comparative advantage in terms of either communication or information:

People in the community, especially women staying at home, don't have the motivation to use the Internet... you have to walk to the telecentre, write an e-mail and then wait for a reply. It's more convenient to use a mobile phone [i.e., short messaging service]. (health worker, female, March 17, 2005)

Similarly, existing technologies (television and radio) already provide access to specialised local programming for groups such as farmers. Needless to say, individuals also access information from an array of formal and informal sources. Whether individuals actually do act, or are able to act, on this information is another point entirely, but it is evidently not the case that the poor in

Pabelan need access to basic information. To emphasise that they do is overtly paternalistic and homogenising. The information individuals require is specific to particular needs and situations. Such needs are in turn dependent on gender, age, occupation, social status, and the various combinations of these factors.

At Pabelan, any assumed link between accessing the Internet and increasing the security of livelihoods has yet to be demonstrated. At the risk of oversimplification, the fundamental reasons for low participation boil down to some simple home truths. For the poor and nonpoor alike, the utility and relevance of the telecentre, and particularly the Internet, remained far from clear. The community voted with their feet; the majority walked straight past the telecentre, and the few intended beneficiaries who did enter left and did not return. All the same, at the intended beneficiary level, this does not imply that there is no need for information. Equally, it should not be inferred that the abstract notion of information is viewed as a priority by the poor. The importance of information is regularly acknowledged, but its immediate relevance remains unclear in the face of efforts to secure daily needs. However, it is the case that a working knowledge of computers and the Internet are seen as important for the future of the community's children, particularly in the face of limited employment opportunities for the young. That the selection of participants for the English course was not more beneficiary focused was an opportunity missed. Again, the intended beneficiaries, along with their aspirations, were passed by:

I feel disappointed [that nobody ever told me about the telecentre] because my children want to learn how to use a computer... and I don't clearly know what the procedure is for using [the telecentre]. (laundry service, female, February 28, 2005)

In contrast to its stated aims, e-Pabelan has not been inclusive. The project has merely accentuated differences and reconfirmed preexisting relations of power. While intentions may have been well placed, e-Pabelan is, in effect, something that “we” have done to “them.” The implementation and ensuing development of e-Pabelan over its first year cannot be considered pro-poor. Furthermore, it is unlikely that the Internet will ever entirely replace a visit to the health clinic or a hands-on demonstration by an agricultural extension worker. As elsewhere, sociability is valued highly, information is tested, and trust is accrued through the attainment of tangible results.

From the beneficiary viewpoint, the challenge that ICT4PR faces at Pabelan is how to utilise ICTs to increase employment opportunities (particularly for the young), raise incomes (particularly for women), and improve entitlements (Sen, 1981) to and command over resources. ICT4PR must also engage with widening participation and inclusion in localised networks. In this sense, information clearly has a role to play. However, a blanket approach to poverty that ignores complexity and prioritises the technical will achieve little. The wider lesson from e-Pabelan for ICT4PR is that it is essential that the provision of information does not become subordinated to the mechanisms of information delivery within a project’s design. e-Pabelan provides access to the Internet for a minority; it has yet to provide access to beneficial information for the majority. As such, the project finds itself lumbering awkwardly somewhere between promise and utility. There has been no information revolution in Pabelan.

PRIORITISING AND ENGAGING WITH LOCALISED NETWORKS

The experience of e-Pabelan illustrates the importance of accounting for, and responding to, local contexts. The danger of a digital-divide

approach to ICT4PR is that local contexts can become subordinated to the provision of technical access. The Internet is all too readily perceived as a reified artefact (Hand & Sandywell, 2002) of universal benefit and worth to all. Correspondingly, the poor are glossed as an amorphous mass ready to gratefully receive. Individuals’ agency and realities are ignored. The approach also reflects a view that conceptualises information as a “public good” (Olson, 1971). While such an approach may well be worth aiming for, this is not the reality of the poor. Within Pabelan, existing flows of information exclude. The structural and political realities of the poor, therefore, need to be actively engaged within ICT4PR. Outside enthusiasm for ICTs needs to be situated against insiders’ realities and perspectives.

It is clear that access to ICTs does not automatically result in accessing relevant information. Also, both the economic and social means to enable individuals to act on any information received (Duncombe & Heeks, 2001) needs to be incorporated into the project design. ICT4PR is not an event addressing problems that are merely and conveniently to be bridged *à la* the digital divide; it is a process. Policy makers, therefore, need to be clear in what it is that they wish and are realistically able to achieve. A project aimed toward providing access to either the Internet or information is not synonymous with a project directed toward poverty alleviation. The latter is far more likely to be achieved by establishing clearly defined development programmes and targets. The role for ICTs in this sense is one of facilitation. In practice, ICTs and poverty remain uneasy bedfellows. For ICT4PR to be effective, it is suggested that the emphasis needs to be placed back on information. It is yet to be conclusively shown that the provision of access to ICTs alone will directly raise the incomes of the poor, although, as e-Pabelan illustrates, projects continue to be implemented as if they may. In a poverty-alleviation context, ICT4PR’s potential

lies first and foremost in increasing inclusion and empowerment. Somewhat ironically, this is what efforts to bridge the digital divide imply, but for ICT4PR, to attempt to empower and to include requires the acknowledgement that sociopolitical relations matter. It also requires that the approach adopted in practice is active, ongoing, and context specific. A more fruitful point of departure may be found through focusing on more locally oriented networks.

The Importance of Horizontally Oriented Networks

Within ICT4D as a whole, there is a tendency to prioritise the accessing of external networks. Examples from e-Pabelan include the provision of access to externally produced information and the claim that poor farmers can, irrelevant of capacity and resources, and are willing to, irrespective of established market relations, access distant markets. These external networks are hierarchical in nature. As such, these vertically oriented linkages remain socially, culturally, and economically distant. In short, they are of questionable immediate relevance and utility to the poor. Consequently, ICT4PR needs to become more locally and horizontally focused.

Exclusion from localised networks and institutions is commonplace for the poor. During the initial implementation stage of ICT4PR, an alternative approach would be to prioritise the widening of access to information within the community. The initial focus should not be on the deployment of ICTs per se. It is overtly unrealistic to expect individuals to access external and untested networks from a starting point of exclusion. Empowerment and the building of capacity, therefore, need to be prioritised. In order to achieve empowerment, fuller participation within the design and implementation of the project by the intended beneficiaries is required. The concept of participation is not, of course,

without its problems. If the answer has already been decided, for example, in the form of a telecentre, participation can become little more than coercion. However, as e-Pabelan indicates, participation remains critical. ICT4PR needs to draw on wider development experiences, and increasing participation should be (re)approached as a politically empowering act (Parfitt, 2004; Williams, 2004). Without empowering individuals to better participate and engage with local political processes and socioeconomic networks, the potential of ICT4PR is severely curtailed.

A further step in establishing the prerequisite environment for a later introduction of ICTs is the identification of beneficiaries' needs. However, while information needs are often emphasised in ICT4PR, it is the identification of development needs that remains critical. It is also the latter that poor individuals are more likely to relate to and be better placed to discuss and convey. ICTs offer the flexibility to be adapted to the development needs of a community. The community should not be expected to bend and conform to a predetermined outside agenda. As e-Pabelan illustrates, the community will, in all likelihood, not. It may well prove to be ICT4PR in both outlook and practice that requires some adjustment. An initial emphasis on participation and empowerment within a community also provides a foundation from which a project can work outward.

From a localised point of departure, networks should be extended laterally. Although hierarchical relationships (as networks remain prone to differing relations of power) can not be totally avoided, they should be minimised. Partnerships with individuals and institutions with locally relevant expertise and experience should be sought. While partnerships for e-Pabelan were established, these partnerships were high level and again vertically orientated. In practice, these high-level stakeholders had limited community involvement at best. Through extending local

networks, a sustainable and accessible network of support for the project can be established. Furthermore, such a network can be drawn on to widen access to alternative sources of information, create critical local content, and provide potential sources of community trainings. Such trainings are again a prerequisite to the introduction of ICTs and should be development focused. Examples of trainings relevant to Pabelan would include locally oriented marketing for microenterprises and farmers, and information relating to child psychology for young mothers from poor households—the point being that the information required is specific and is more likely to be better conveyed through personal interaction. Both of these examples require a degree of trust, and individuals need to be able to actively engage with and question the information received. By starting within the target groups and building networks outward, the utility of ICTs is more likely to be apparent on introduction.

Crucially, the introduction of ICTs should be governed by the prevailing communicative environment. In the case of Pabelan, the utilisation of community-based radio may well have proved more effective in disseminating locally relevant information. A staged introduction of differing ICTs should be considered depending on the needs, receptiveness of the beneficiaries, and the intended development goals. Within a more horizontally focused approach to ICT4PR, it may well be that communities of shared experiences have the information that is required; however, they are unlikely to have access to the Internet. The Internet is, of course, subject to network effects, and without relevant information or a trusted source of information at some other node, it is of no use at all.

The challenge that ICT4PR faces in practice is how to shift the emphasis from being an externally driven, supply-led venture to one that begins with the beneficiaries themselves. For the poor to benefit, ICT4PR needs to shed its neutral

apolitical stance and universalising approach, and better engage in establishing a process of empowerment and inclusion for the poor. With regard to the Internet, this is problematic as it is currently hard to envisage a situation where access to the Internet for the poor is not mediated in some shape or form. ICT4PR, therefore, needs to tread with caution, strive for inclusion, and engage with and continually reflect upon local contexts throughout the project process. Despite the simplistic allure of the digital divide, policy makers must be mindful of the fact that ICT4PR offers no quick fixes. To continue to act as though it does shows little understanding of the realities of the poor.

CONCLUSION

e-Pabelan proved to be far harder to implement in practice than anticipated. Despite acknowledgements of social factors, community engagement, and a pro-poor process, in practice, the project reflected an attempt to bridge the digital divide. e-Pabelan was implemented as if it was an event and was subsequently forced, by necessity, to try to become a development process. ICT4PR needs to be viewed as a coherent and targeted process of development from the outset. This requires both a significant commitment and, perhaps, a shift of emphasis. A way forward may be found through moving away from an emphasis on the external to better engaging with networks and relations of power within communities. Contrary to digital-divide-based promises, e-Pabelan has yet to increase inclusion in either external or internal networks for the poor.

Within ICT4PR, there can be a temptation to focus on the tangible rather than the intangible. While the bricks and mortar of a telecentre are a highly visible use of funding, the fact remains that it is information that lies at the heart of ICT4PR. Needless to say, information alone does not have

the same immediate appeal to donors as buildings, hardware, and RAM. It may well not have the same appeal for potential local partners also. However, the experience of e-Pabelan demonstrates that the utility of ICT4PR ultimately rests on the socioeconomic and political environment into which such projects are introduced. ICT4PR is also heavily dependent on the linkages through which such projects are implemented, and the socioeconomic and political networks they seek to influence. Due attention must be paid to these issues if fuller inclusion is to be achieved. An approach that emphasises universally beneficial technical access obscures such critical factors. A start toward increasing the goal of inclusion may be obtained through emphasising horizontal rather than vertical linkages. The danger of ICT4PR is that enthusiasm for the technical can, if left unchecked, lead to ICT4PR riding rough shod over many development fundamentals already accrued. The continuation of such an approach will do few favours for ICT4PR or the individuals and communities that ICT4PR seeks to empower.

ENDNOTES

- ¹ The research project combined both qualitative and quantitative methods including direct and participant observation, open-ended interviews, questionnaire surveys, and rural appraisals. The statistics referred to on participation are based on data from the telecentre logbook from July 2004 to June 2005 and include repeat visits. Other statistics referred to in this chapter are based on a randomly sampled survey of 216 poor households in five village subunits conducted at the 95% confidence level. Included supporting statements are indicative of commonly voiced concerns within Pabelan. However, it should be noted that throughout the research period, awareness of and interest in the telecentre (and the project's aims) remained low within the community. For the vast majority, life carried on as before. This chapter focuses on the intended beneficiaries' conceptualisations and not the minority (predominantly students) who utilised the telecentre. To focus on the latter would require distinguishing what the actual difference is in practice between e-Pabelan, being a poverty-reduction project, and a privately run Internet café (warnet). This remained a troublesome issue, and space does not permit a fuller analysis here.
- ² The term telecentre is used in this chapter as this is the term often used at the implementing-agency level and exclusively at the local level (alongside TC or tele). It is also a more apt descriptor in this context than, for example, multipurpose community centre.
- ³ Whether an information society or age actually exists, and in what form, remains the subject of debate. For an overview, see Webster (2004). The term information society probably first emerged from Japan in the late 1960s (Duff, 2000).
- ⁴ The most used, and most overlooked, communication technology within Pabelan is the motorcycle. Within Pabelan, there were 375 motorcycles in 2004 (Badan Pusat Statistik, 2005) and growing.
- ⁵ Poverty figures courtesy of *PT Risadata Utama* (2004) and local figures from *Kepala Desa* (2004, 2005). Local figures reflect income- or consumption-based approaches to measuring poverty. The external source utilised a somewhat broader composite approach.
- ⁶ Two projects originally established by the BPPM are currently running. They are a telephone kiosk and a health clinic near the pesantren. Both now run independently of the BPPM. The current health worker at the clinic was not aware of any links with the BPPM itself, although she started work there in 2000.
- ⁷ The local political context is further complicated in that the current village head is the spouse of the leader (pimpinan) of the pesantren.
- ⁸ Regional autonomy (Otonomi Daerah) resulting in increased powers at the level of the provinces in Indonesia came into being January 1, 2001.
- ⁹ An "infomobiliser" with no previous links to the pesantren was also appointed. Toward the end of the research period, this individual was in the process of conducting appraisals with a view to introducing newly formed learning groups (kelompok belajar) to information from the telecentre and then to the telecentre itself at a later date. Although, at the time of writing, it was too early to gauge the effectiveness of this initiative, it should be regarded as a potentially significant development.
- ¹⁰ The English course was established in association with a Jakarta-based nongovernmental organisation and funded by the Regional English Language Office (RELO) of the United States embassy, Jakarta.

- ¹¹ In August 2005, the implementing agencies agreed to extend payment for the Internet connection for a further 6 months. Charges for using the telecentre were introduced August 1, 2005.
- ¹² Married women often reported receiving the sum of 10,000Rp (just over \$1) per day (but not every day) from their husbands. This is to pay for expenses, including food, bills, clothing, and education for children. While some women have independent income sources, others are dependent solely on such money and informal sources of credit.
- ¹³ The contrast with utilising radio for development is striking. No one would expect an individual to benefit from accessing a radio station that was devoid of preprepared relevant content.
- ¹⁴ Pabelan is comprised of 10 dusun. The pesantren and telecentre is located in Pabelan IV, which may be considered the political hub of the village. Correspondingly, the telecentre is not located in one of the poorest parts of the village.

Chapter 4.14

Determining Whether ICT Improves Social Interactions

Raj Gururajan

The University of Southern Queensland, Australia

INTRODUCTION

Previous innovations, such as telephones allowed individuals to communicate on a one-to-one basis, or for powerful, central institutions to speak one-way to the masses (Burrows, 2000). New technologies such as the Internet are revolutionizing communications as a positive force, improving the efficiency and accountability of local government, and strengthening communities. This requires a vision in order to be able to actively *use* technology rather than passively reacting to change. Any advancement which is able to significantly empower people, also threatens to entrench the division between haves and have-nots—both as organizations and as individuals (Burrows, 2000). In the current climate, local government agencies are beginning to use these new technologies to open up the process of communication between governments and the citizens.

Essential to the technological challenges is the balance between three major elements—social capital, Quality of Life (QoL) and the technology itself. For instance, social capital is realized

when the public perception that technological changes implemented in societies would enable advancements in daily routines of the public. These advancements, then, would contribute to better QoL. The link between the daily routines and the advancements is provided by technology. For example, using the Internet technology, public can order their groceries and this is seen as advancement as there may be considerable time savings, resulting in quality time spent with family. Therefore, local government agencies introduce technologies in their communities with the anticipation that the social fabric can be strengthened via these technologies.

Over the last five years social capital has become a main topic on the public agenda. Social capital is realized *between people who establish networks, norms, social trust and facilitate co-ordination and co-operation for mutual benefit and there is* increasing evidence to suggest that social capital is an essential ingredient in civil society, economic development, the health of people in communities and community development (Stone, 2001; UNCTD, 2002). Thus in communities

where social capital is strongly rooted, people will feel that they are part of the community, useful and be able to make a real contribution to the community, will participate in local community networks and organizations, work together for the common good in times of distress, and valued for who they are (Chamber, 2002). This is shown in Figure 1, where the “ME” component is centered upon the family, work, friends and relatives, and the immediate neighborhood.

Quality of Life (QoL) is defined in various forms in the literature. For example, QoL is defined as subjective well-being by the Global Development Research Centre. QoL reflects the difference, the gap between the hopes and expectations of a person and their present experience. Earle and Fopp (1999) asserted that technology is a major social and occupational determinant in QoL and indicated that technology has reduced the need for direct interaction. As a consequence, communities are culturally experiencing a change. Others found that technology itself (e.g., Internet access) ultimately plays little role in determining individuals’ quality of life as maturity and life experience replace the need for any dependence on an artificial support system (e.g., Granzin & Haggard, 2000). Therefore, while technology plays a crucial role in the social determination, how it

is implemented is essential in order to ascertain the reach of this technology on the public. If the technology is properly implemented, then it may be possible to realize a better social capital.

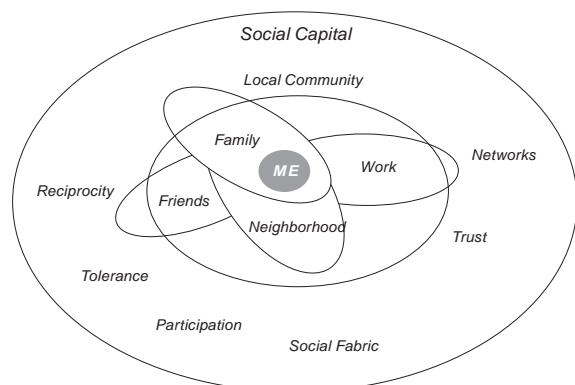

NETWORK NEIGHBORHOOD

Network Neighborhood (NN) is about using online technologies in order for people to communicate with each other when they want to, and develop strong communities of interest to keep them involved and interested in their neighborhood, so they have a sense of belonging (Gill, 2003). NN is a program designed to enhance the economic, cultural, social and environmental development and deliver better quality of life. Its main aim is to deliver a social dividend while increasing the reach and relevance of government and significantly cut the cost of government service delivery (Gill, 2003). Picton Waters Network Neighborhood project is one such NN project developed by an Internet-based software application in Western Australia to see if the Internet can help make stronger communities and better neighborhoods.

A growing body of literature has confirmed that social capital is correlated with positive individual and collective outcomes in areas such as better health, lower crime, better educational outcomes, economic development and good government (Carroll, 2002, p. 647). According to Bullen and Onyx (1999), it is possible to measure social capital in network neighborhood as there is a general social capital factor available in many forms such as participation in local community. In a neighborhood context, indicators help to evaluate whether local actions are having the effects desired.

Therefore, the main aim of this study is to test the claim that the NN would improve the QoL of the neighborhood community.

Figure 1. Social capital (Adopted from Bullen & Onyx, 1999)

METHODOLOGY

This study used a mixed methodology. Initially, an interview method was employed in this study to identify indicators for measurement. This was then followed by a survey method. A QoL survey relies on the respondent's subjective rating of perception about QoL. Typically the spheres measured are primarily based around finances, health, family, friends and work (Ventegodt, 1996). Zehner (1996) measured QoL in terms of economic security, physical environment, family life, contentment, well-being, personal relationships and values, job-satisfaction, social relationships (non-family), leisure activities, health, religious values, parenting and housing and found housing, community, physical environment, social environment, and work, transportation and living costs to be significant factors. Shookner (2000) suggested that indicators such as social, health, economic and environmental should also be included in the QoL Index. This study used those social indicators identified by Zehner (1996) with consideration to the concerns raised by Earle and Fopp (1999) who found that technology has reduced the need for direct interaction, and, as a consequence, communities are experiencing a change in the way their members interact with each other using online technologies.

The vital component of this project is to evaluate the effectiveness of NN in terms of whether the use of the online technologies improves the QoL of the community. It is hard to determine the most optimal or most suitable indicators to measure QoL in the context of ICT as the proposition that "the use of ICT in a community would improve (or worsen) the QoL" is quite new. It appears that there is limited research conducted to measure that impact of ICT on QoL (Keyes & Bancroft, 2002, p. iii).

Selection of Indicators

The QoL indicators have been selected following interviews with key personnel in the Department of Premier and the Cabinet in Western Australia.

The interviews yielded specific characteristics appropriate to the indicators. They are timeliness of the indicators, reliability and stability, understandability, relevancy, usefulness, simplicity and honesty. Based on this, an initial theme for the indicators was developed from Kingsley (1999) and elaborated during informal, open interviews. The theme includes depression, stress, social isolation, safety, trust, opportunities, and equality. The themes were further studied resulting in a set of hypotheses.

Discussion of Hypotheses

Social support helps give people the emotional and practical resources they need. Belonging to a social network of communication and mutual obligation makes people feel cared for, loved, esteemed and valued. According to the World Health Organization Regional Office for Europe, this has a powerful protective effect on health. Through the use of NN, the members of the community can interact with each other through mail or being part of the various communities that are available through the network site. The NN helps in bringing the physical proximity of family and friends together, and one needs to measure the degree to which a person is socially integrated, or if there is any availability of social support networks being developed through the use of NN for the overall social well-being of the community member. Social well-being here is defined as including interactions among the members of the Picton Waters neighborhood community.

The hypotheses developed for this study covers areas such as depression, social isolation, safety, trust, opportunities and equality. These factors appear to have an impact on social isolation, and it is believed that by using ICT, it may be possible to alleviate the adverse impact of these factors. For instance, depression is a major medical disorder, just like high blood pressure or heart disease, and influences people day after day, affecting thoughts, feelings, physical health

and behavior (Cleveland Clinic, 2001). These concepts are tested in the following hypotheses: s tested in the following hypotheses:

Hypothesis 1a: The use of the NN technology helps in the decrease of depression through the increased use of making friends and allies through chatting and e-mail.

Hypothesis 1b: The use of the NN technology helps in the decrease of stress levels through the increased use of making friends and allies through chatting and e-mail.

Hypothesis 1c: The use of the NN technology helps in the decrease of social isolation of a community member through the increased use of making friends and allies through chatting and e-mail.

Hypothesis 2: The use of the technology of NN helps in the feeling of mental and physical security when in crisis and hence creates a sense of safety.

Hypothesis 3: The prolonged use the NN helps in developing and building trust between members of the neighborhood community.

Hypothesis 4: The use of NN helps local small businesses with increased opportunities to exchange skills, goods and services.

Hypothesis 5: The use of NN site promotes a sense of equality among members.

Data Collection

The data collection involved the use of the survey as a vehicle for measuring social capital in family and community life. Questions in the survey are measured on the basis of the Likert scale, with respondents ranking their responses to a set of items on a range of numbers, from 1-5. The Likert scale has been used basically to ascertain the correlation between the positive and negative halves of the answer to the question. The Likert has been selected because it is easy to construct, tends to high reliability, is flexible and is the best in scaling people on attitudes, perceptions,

personality characteristic and for the assessment of multidimensional constructs.

The questions compiled for this study were checked by the staff of the Department of Premier and Cabinet at Western Australia to ascertain the suitability and appropriateness. The questionnaire was then pilot tested by students and staff of a university in Western Australia. The pilot testing revealed that some questions were ambiguous and these questions were considered for refinement. Further, some other questions were re-worded for appropriateness. The Western Australian Government administered the questionnaire to the residents of Picton Water Community. The questionnaire was sent to a total of 39 households and the total valid responses received were from the 39 households. The responses were entered into a spreadsheet by two data entry operators and tested for any typographical errors. Any mismatch identified was corrected by using a file comparator method. Once the data entry was complete, the data was transformed into an SPSS software file.

Data Analysis

Participant demographics indicated that the majority of the respondents have been living in the neighborhood for a period of 3-10 years (33.3%). The majority of the respondents were in the age group 30-36 years (15.4%). The majority of the respondents had a tertiary qualification (51.3%) and was currently employed (74.4%). The entire respondents used the Internet (100%). And the average number of people in the household was four people. The data on location of Internet usage and intention for use had missing values and could not be thus quantified.

The data was initially analyzed for standard statistics such as mean and standard deviation. A normal curve was plotted on the descriptive to identify any "outliers" as responses sometimes may end up in extreme boundary values of the scale used. Any such outliers were eliminated from the

Determining Whether ICT Improves Social Interactions

data as these may cause bias. In this study, of the 39 questionnaires distributed, all responses have been considered valid and were considered for analysis. The data was then checked for “normality” and ensured that this feature was obtained. Further reliability tests were performed on the data and the reliability factor was ensured (over 0.73). Once this basic quality checking was accomplished, the data were tested for correlation.

The data were tested using the Pearson’s correlation method. It was found that the correlation varied between 0.327 and 0.667 in many cases, with significance level under 0.05. This indicated that the questionnaire was an appropriate instrument, and the questions were measuring what was intended to be measured. Most of the questions were correlating positively with other questions either at 99% or 95% level of confidence. Exceptions to this were questions 16 and 12 and questions 14 and 3. Questions 12 and 16 measured community participation and making new friends and found to be negatively correlated. Questions 3 and 14 measured attendance in community events and the resulting social interaction and found to be negatively correlated.

DISCUSSION

The survey clearly indicated that people in the Picton Water community lead their lives mainly within their own household. They do not know the name of their immediate neighbours and rarely socialize with friends who live within a close distance of their home. They rarely talked to the people in the neighborhood. However, a surprising factor that emerged was that if there is a community or service group activity in the neighborhood, the majority of the respondents participated in the event. The respondents also indicated that they attended events in the nearby areas. The results of these interactions indicate that they are capable of making friends. While this study was not able to conclude whether the

network technology facilitates the same level of interactions, it is believed that community members can increase their interactions using this technology. The “decrease in stress” level factor resulting from these interactions is not conclusive.

In terms of the second hypothesis, where “safety” factor was measured, the respondents indicated that a majority of them felt that if they socialize more and involved in more community work together they may get to know each other. Further, a majority of them are confident of making new friends/acquaintances if through various social events. The results also demonstrated that the majority of respondents do not meet outside these local events. The survey also indicated that the majority of the respondents felt a general feeling of safety in the neighborhood. The survey indicated that the “safety” factor was better at night time as well. This feeling of safety has been strong because a majority of respondents felt people in the community have a respect for their community and each other. Further, they participated in local events even if they are not personally asked or invited to do so and are not afraid to participate even if they do not know anyone or won’t be accepted. Therefore, it is concluded that using the network technology, it is possible to build “safety” in communities.

Hypothesis 3 dealt with “prolonged” use of technology and its effect on trust. As it was not possible to collect longitudinal data in time for this publication, it is not possible to provide comments on this hypothesis.

There is clear evidence to indicate that socialization and interactions in community events is limited only to these events. The results also show that the majority of respondents do not have sense of belonging to their neighborhood and this can be attributed to the fact of they do not know their neighbors personally and do not socialize with people close to their home. Further, due to lack of data on their use of technology for online transactions, it is not possible to ascertain whether

there are opportunities for exchange of goods and services using this technology. While the indications are that there are possibilities, due to lack of strong numerical evidence, hypothesis 4 is rejected.

The fifth hypothesis, equality among members, is accepted as the data clearly indicates that members in the community felt that they have equal opportunities in event participation. Further, when this aspect is combined with the safety data, it is evident that the perception of equality is valid. Therefore, this hypothesis is accepted.

CONCLUSION

This research has made a number of findings about the social behavior of people of Picton Waters and has documented a number of issues in the use of NNs. In terms of project completion at the preliminary stage, the objective of accessing the social behavior (through the measurement of the social indicators identified) of the people in Picton Waters through the introduction survey was successfully completed.

The second objective, a longitudinal survey based on continual use of technology was not completed on time due to some unanticipated problems in administering the survey to the same set of respondents. Therefore, the results of the same were not available in time to prepare this report. Hence, the hypothesis with the use of NN technology could not be measured as planned initially.

In conclusion, it can be said that there are indications that the NN technology could help in improving the QoL of the people in the Picton Waters community as it could be an excellent way of improving the social interactions between the community members.

KEY TERMS

Identity: Identity results from interplay of three related factors: “whether one considers oneself part of the group, whether other group members treat one as a member, and whether people outside the group do” (Resnick, 2002, p. 654).

Quality of Life (QoL): QoL may be defined as subjective well-being. Recognising the subjectivity of QoL is a key to understanding this construct. QoL reflects the difference, the gap, between the hopes and expectations of a person and their present experience. Human adaptation is such that life expectations are usually adjusted so as to lie within the realm of what the individual perceives to be possible. This enables people who have difficult life circumstances to maintain a reasonable QoL (The Global Development Research Centre, 2003).

Social Interaction: Social Interaction/Belonging includes links with social environments and includes the sense of acceptance by intimate others, family, friends, co-workers, and neighborhood and community (University of Toronto, 2003).

Sustainable Communities: A sustainable community (like NN) offers its members a greater sense of security which leads to less reliance on the health and welfare systems as replacements for social activity, and crime decreases as individuals feel a greater sense of inclusion and are not disenfranchised (Gill, 2003, p. 7). In addition to that, a greater sense of security would also mean “greater sense of personal safety in the community” (Canadian Policy Research Network, 2001). Therefore, greater sense of security would lead to higher QoL, with less worry and more freedom (greater feeling of being safe).

Chapter 4.15

Formation of a Knowledge-Based Society through Utilization of Information Networking

Hakikur Rahman

SDNP Bangladesh, Bangladesh

THE CONTEXT OF THE INFORMATION SOCIETY FOR BANGLADESH

“Information society,” “knowledge network” and “digital divide” are terms becoming increasingly common in many parts of the world over recent years. The key element in these concepts is that of “information,” and its fluidity in the modern world. Information can be viewed as the foundation stone of this new phenomenon and is the collation of raw and un-processed data into meaningful dialogue. Many societies and communities in developed and developing situation have settled on the term “information,” to describe the new economy and be the basis of development in the new millennium.

The Information Society is created by information, in a similar way that the industrial society area was created by manufacturing. This new Informa-

tion Society is therefore a society being produced by a reliance on information as the most significant factor in the means of production. Hence, it relies on the information economy to produce products, services, employment, wealth and life style on which the community depends. It is believed that ultimately the whole community of a country can benefit from the optimum utilization of information in each and every corner of society.

Knowledge, on the other hand, is dynamic and capable of creating dynamism in a similar way to capital and labor. Money, work and information are catalysts, while knowledge, capital and labor are concepts containing stored endurance and cultural interpretation. Given the right incubation, they are capable of creating fruitful outcomes. Building a knowledge network molded by information can accelerate the pace of development.

In Bangladesh, efforts have been allocated to accommodate propositions on developing a nation wide information network using the existing

information backbones. As a result, a centrally driven content repository may eventually be established.

INTRODUCTION

The Information Age is challenging the role of the expert in society and, therefore, the relationship between expert and amateur (Handy, 1997). The WWW (World Wide Web) has created new opportunities for self-learning in a wide range of expertise previously dominated by specialists. Specialists and professionals in all aspects of human life are benefiting through this expert support. Thus, knowledge is evolving as the result of information acquisition melded with experience where many amateurs can develop to act as effectively as experts.

Knowledge management incorporates huge data storage facilities, contents in distributed databases and an effective retrieval system. It means planning for research, linking ideas to generate information and conceptualizing the notion of a knowledge society. The knowledge society can bring more ability and options to the stakeholders through methodologies like self-paced learning, forming common communities through mass networking and by maintaining maximum flexibility in learning sequences.

Mass networking is one of the prerequisites to form a homogenous, multidimensional, dynamically developed and research-potent knowledge-based society. Academics, institutes, research organizations, civil society, government and non-governmental agencies, and other partners/stakeholders of the community should be able to interact with each other through a common horizontal platform.

In response to the challenges of globalization and the information society, each country needs to set out its own strategic objective for the coming decade, and to become the most competitive and dynamic knowledge-based economy in the global

market, capable of sustainable economic growth with better jobs and greater social cohesion.

Bangladesh is a country of 133.4 million people. With a minimal GDP of 357USD, 33% of the population lives under the national poverty line. More than 80% of the population resides in difficult accessible rural regions, where information infrastructure is very thin and formation of a common information backbone still remains an open challenge to the society.

In order to address the issues faced by much of Bangladesh, detailed programmes and action plans on the future of education and training systems need to be prepared. The policies need to be implemented using “open coordination concept” among all the partner organizations.

STRATEGIES

In addressing the obvious needs of Bangladesh in the Information Age, strategic plans need to be initiated at the national level and incorporate flexibility in each stage of the development and action, to deliver optimum resource utilization and to maximize benefits. The new strategy requires an indigenous method, an open coordination concept, a realistic measure:

- identifying and defining common objectives; and
- stimulating the quality and relevance of locally based capacity enhancement programmes.

In discussing information and knowledge, it is useful to start by observing that both are human creations (or social constructs). They are designed to explain and meet some of the challenges that individuals or groups face at a particular time and place. No one fully understands the meaning of knowledge and information without recognizing that they can both be “double-edged swords.” They can be used to empower individuals and

groups. They can also be used to continue and reinforce relations of power and control. When a ruling group uses information and knowledge to control (dominate) people, those people are led to despair, powerlessness, and unsustainable life styles (Mchombu, 2002).

Several aspects of the emerging framework for the Information Age in Bangladesh that are essential for bringing communities to a common platform by raising their capacity through the utilization of ICT techniques are now discussed.

Policy Initiation

To increase socio-economic development, government must undertake broad-based action plans. The inclusion of the following section in the ICT Policy of Bangladesh, is a positive step in this respect:

Socio-economic development can be accelerated if more people can have access to information. Teledensity is important in this respect and it will be increased to broaden the coverage, which will improve the socio-economic condition of the people through ICT-related activities in line with experience of developed countries. (ICT Policy, 2002)

Secondly, ICT Policy accommodates steps towards capacity development of the general population:

Widespread introduction of ICT education in public and private educational institutions is a prerequisite for producing skilled ICT manpower. (ICT Policy, 2002)

Finally, the ICT Policy needs to recognize that the information infrastructure needs to be upgraded to allow the formulation of a national data bank to assist the development of millennium initiatives:

A central depository for collection and dissemination of ICT information and research findings will be developed. This will be done under a network, connecting all university libraries and research organizations to this central depository, which in turn will be connected to the Internet. (ICT Policy, 2002)

Education

Education is by necessity a primary concern in all countries. Although the structures of education systems differ considerably, both within and amongst different countries, a mass literacy campaign should be given the first preference in a country's education system. Bangladesh, with 38% of the population being illiterate, needs to upgrade its education programmes to raise literacy. The government is keenly interested to make the country 100% literate by 2006.

Predictions about the economic and social impact of Information and Communication Technologies (ICT) abound in the literature and the economic and social behavior of society. The technological trends are extrapolated to illustrate potential benefits and by adopting a visionary perspective, resulting in predictions of "revolutionary changes" in the global knowledge society. Advances in ICT have been particularly striking in the areas of digital computing and communication networks (Carlos et al., 2003). Superimposed on these factors, education systems no longer remain removed from the basic societal aggregations. Scholars, researchers, and educators are striving hard in Bangladesh to produce quality education systems using the benefits of ICT. Educational networks have become a prime urgency in Bangladesh. In this context the interaction between technological development and new approaches to education become increasingly important in previously unserved situations.

The Semantic Web is expected by many to open new opportunities to manage information

while allowing for new Web functionalities with significant storage potential. Artificial intelligence and expert systems are expected by many to gain a novel power and utility as standards for distributed computing and grid systems spread around the world. New technology-based infrastructure developments open new possibilities for regions with low-bandwidth connectivity to leapfrog stages of development by entering the “broadband” phase via wireless solutions. The Wi-Fi phenomenon is a good example of the “law of unintended consequences” in action as a technology originally designed to support wireless local area networks is beginning to pave the way to establish of low-cost broadband telecommunication systems at the outset (Rahman, 2003a).

Lifelong Learning

Another core element of the Bangladesh ICT strategy is the concept of lifelong learning, which is central not only to competitiveness and employability but also to social inclusion, active citizenship and personal development (EU, 2002).

Lifelong learning has become the guideline principle for the development of education and training policy. Following this path the learning of new technologies has become a priority in an ever-changing society.

Although the area of corporate distance education is new, a study by the International Data Corporation (IDC) reported an annual growth rate of 63.5% for distance learning from 1992 to 1997 (EXEN Partners, 1998).

Learning is dependent on the use and application of information and in how information is contextualized to become knowledge. That such a process is socially mediated and is dependent on social interaction is evident (Freund, 2003). Developing a learning organization is a huge challenge. Developing a learning partnership is an even greater challenge. It hinges very much on a willingness to learn from each other (Chetley, 1998).

Networking

Increased networking among education institutes, research organizations, and eventually government and non-governmental agencies to establish interactive information exchange platform, by sharing knowledge and expertise in formulating effective governance, knowledge networking and mass information dissemination at the grassroots level would enhance the development processes.

Proficient utilization of network resources in disseminating knowledge-based information in online and off-line environments formulates a concrete platform of a collaborative research base and collaborative learning sequences (Rahman, 2003b).

Transborder data flow (TDF), or the transfer of information across borders, is becoming commonplace due to developments in electronic communications. Amongst developed countries in the Western world, TDF has been happening for years with the facsimile machine being the first major tool for easy information transfer. But developing and transitional countries are lacking the basic infrastructure to allow them to carry out TDF, leading to gaps in their knowledge base and creating information impoverished societies (Allen, 1999).

Today, developed countries show that access to the Internet can, and has, dramatically transformed every aspect of the society and economic activity that rely on access to information. For developing countries, large-scale access to the Internet still remains to be fully addressed, leading to an ever-increasing digital divide with developed countries. Recent studies by the World Bank show that Internet access, based on telecommunication infrastructure (fixed networks, mobile or satellites), constitutes the fastest growing technology within the ICT sector. There is, therefore, a need to accelerate the on-going Internet penetration efforts (especially in developing countries), by deploying technology that is both scalable and

affordable to end-users. High prices charged by few service providers, and poor (or at times a lack of) terrestrial connectivity to majority of the population in rural areas may inhibit large-scale Internet access in developing countries (Koyabe, 1999).

Virtual Networking

Networking can be divided into two forms: Physical networking and Virtual networking. Physical networking is infrastructure independent, while Virtual networking is being superimposed over the available infrastructure. Virtual networking should adopt low cost or open-source software utilities to form a common platform of communication among geographically distributed locations. Based on this concept, educators are availing the facilities to form groups and dissemination hubs through e-mail, e-groups, BBS (Bulletin Board Service), virtual seminars and moderated discussions.

Available technologies can be integrated to form low cost information provider. Utilizing interactive distance education techniques, educators and learners can be brought together in a common collaborative platform to make the system cheaper and easily available to remote users.

Virtual learning involves the use of some form of electronic media to enhance the learning processes. Sometimes confused with distance learning (a broader delivery medium that would include text-based learning and courses conducted via written correspondence), courses are delivered via “e-learning” when technology is used to bridge both an instructional and a geographical gap. Accommodating a range of activities, from effective use of digital resources and learning technologies in the classroom, to a personal learning experience enabled through individual access at home or elsewhere, virtual learning is essentially the facilitation of teaching and learning via the use of some electronic medium.

Knowledge Management

As the term “knowledge management” slips easily into the vocabulary of libraries, we are in danger of understanding the power and extent of the paradigm we invoke. It is not just that industries based on knowledge are developing. It is not just that information, like machinery, becomes essential to any business or enterprise. If we consider what infrastructure—networks, organization, bodies of research, commentary, jobs, regulation, legislation—is in place to support the constructs of labor and capital in our society, we begin to glimpse what might be in store for the “knowledge” concept in an information society (Dellit, 1998).

Knowledge management is not a precise enclosure of means that professionals can easily learn and just apply in specific situations. Knowledge management is a complex web of ideology, values, dependencies, power relationships, learning, maneuvering, social and economic analysis, the essence of knowledge, behavior and techniques.

The European Union (EU) is a forum for the exchange of ideas and good practice. It does not have a common education policy, however. On the contrary, its role is to create a system of genuine cooperation between the Member States by preserving the rights of each Member State in terms of the content and organization of its education and training systems (EU, 2002).

Information Networking

Information networking is not a new concept in this globalized society. Utilizing the information backbone and Internet, educators, society leaders, researchers, policy initiators and other development partners are acting around the globe for promoting sustainable development and alleviating poverty. Awareness raising, promotion of literacy, agricultural extension, disaster management, and many other important aspects

of the current society are taking benefits of the communication networking.

There exist several networks in Bangladesh, in discrete and isolated forms. Bangladesh Open University with 12 Regional Resource Centres spread over the country through a dial-up network (<http://www.sdnbd.org/sdnbd/maps/pic6.htm>) is used mainly for administrative purposes. Similarly, another secluded network, the Bangladesh Education and Research Network (BERNET), is maintained by the University Grants Commission (UGC) (<http://www.ugc.org>).

BERNET included 128Kbps radio link connectivity with a private ISP and this link has been distributed to the Bangladesh University of Engineering and Technology (BUET) (64Kbps) and the Dhaka University (64Kbps). Some of the other state-run universities are connected to UGC server by dial-in connection. Among them, the Shahjalal University of Engineering and Technology in Sylhet has its own VSAT linked network connected to the Internet.

Recently, a few other universities are establishing their own network using VSAT connectivity. Government organizations, like, the Ministry of Health, Ministry of Education and Ministry of Agriculture are extending their networks down to their district town outlets, using mainly dial-up. The state-owned telco, the Bangladesh Telegraph and Telephone Board (BTTB), is also trying to connect each district town through several types of connectivity (Fiber, Digital Data Network and Dial-up).

Sustainable Development Networking Programme (SDNP) of Bangladesh (<http://www.sdnbd.org/sdnbd/maps/pic4.htm>), a UNDP-funded project, under the Ministry of Environment and Forest (MoEF) and implemented by the premier socio-economic research institute, Bangladesh Institute of Development Studies (BIDS), is maintaining a network comprised of radio links, ADSL and dial-up. One of its regional setups has been running successfully for about a year in the Bangladesh Agricultural University

(BAU) in Mymensingh at a distance of 120Km away from the Dhaka city (<http://www.sdnbd.org/sdnbd/maps/pic3.htm>, http://www.sdnbd.org/sdnbd/tech_support/4.gif). Recently, SDNP has extended its network along the coastal belt of the country using VSAT connectivity (http://www.sdnbd.org/sdnbd/maps/radio_station.htm, <http://www.sdnbd.org/sdnbd/maps/mcpc.htm>). This project aims to capitalize on this information network to create an appropriate IT-based mechanism for facilitating the exchange of information/knowledge among policy makers, the civil society, academia and development partners, locally, nationally and internationally, to support initiatives and processes of sustainable development in Bangladesh.

Among others, schoolnet (http://www.sdnbd.org/sdnbd/maps/school_pro.htm), online blood bank (<http://www.sdnbd.org/sandhani>), virtual library information system (<http://www.sdnbd.org/cgi-bin/books.cgi>), sustainable development information data bank (<http://203.76.110.35/sdi/home.jsp>) are other initiatives towards formation of a knowledge-based society in the country for sustainable development. However, the project should accommodate the deprived southwestern part of the country, where an infrastructure backbone is almost missing. SDNP has been proposing (<http://www.sdnbd.org/sdnbd/maps/pic2.htm>) for alternate funding to accomplish this task.

Coordinating the majority of the above-mentioned networks, a nation-wide information backbone has been established to act as an advanced research network (Bangladesh Advanced Education, Research and Information Network, BAERIN) (<http://www.baerin.net>) in the country. With little initiative and effort, this network may emerge as the national repository of information and provide enormous opportunities in information networking and knowledge management.

CONCLUSION

With open discussions and public input, also including education researchers, the integration of a scientifically based research network for education and research may be developed on the back of existing individual efforts. This will necessitate regular interaction and a highly developed spirit of cooperation through a core work group under a National Steering Committee. It is encouraging to note that already the government has initiated some changes in the ICT policy as a result of input and scrutiny from the education and research community.

To become critical users of information and knowledge, community members will want to analyze critically both the knowledge that comes from outside the community, and their own inherited knowledge. The community will want to study, for example, how cultural and elitist definitions of gender, race, tribe, class, poverty, are developed as both historical and social constructs. In most cases, these definitions should be questioned and critiqued so that value is added to achieve more transformative knowledge and information for the community (Mchombu, 2002).

The nation-wide distributed network should give emphasis to the accumulation of local content directly beneficial to the community and localized global content fitted to suit the capacity of the participant. Integrating modular learning patterns in different platforms of the society, overall capacity can be raised at a functional level.

KEY TERMS

Digital Divide: “Digital divide” is a term used to describe the gap between the technology “haves” and “have-nots.” It is a gap in opportunities experienced by those with limited accessibility to technology.

Information Society: A society in which economic and cultural life is integrated by complex communication networks, and critically dependent on information and communications technologies.

Knowledge Management: “Knowledge management” is a concept in which an enter-

prise gathers, organizes, shares, and analyzes its knowledge in terms of resources, documents, and people skills. It involves capturing, warehousing, transforming, and disseminating data/information within an organization to leverage knowledge for competitiveness enhancement.

Knowledge Network: Knowledge is information with guidance for action based upon insight and experience. A network is the connection of two or more entities so that they can share resources. A knowledge network is an interconnected resource entity to improve the results of perception and learning, and reasoning.

Lifelong Learning: A process of acquiring knowledge or skills throughout one’s lifetime via education, training, work and general experiences. It is a concept of continuous personal development through personal learning with an emphasis on independent study determined by contextual personal needs.

Virtual Network: A form of network that refers to the appearance of a single, seamless network system. This type of network provides virtual circuits established through a real network.

Chapter 4.16

Transforming the K–12 Classroom with ICT: Recognizing and Engaging New Configurations of Student Learning

Colin Baskin

James Cook University, Australia

ABSTRACT

This chapter begins with four very public examples of how K-12 education providers across Australia are attempting to assimilate new teaching and learning technologies into existing teaching and learning structures. The transition as predicted is not altogether smooth, and questions are raised as to where and how the discourses of literacy, education, and technology converge in the information and communication technology classroom. The discussion presents a layered case study that brings together the practical discourse of the teacher, the new discourses of literacy, teaching and learning confronting our students, and the challenge these provide to the management discourse of school administrators. In doing so, it points conclusively to the fact that new configurations of learning are at work in our online classrooms.

INTRODUCTION

Using a convenience sample of middle school SOSE students, the discussion draws on quantitative as well as qualitative methods to explore and document the educational, social and information literacy outcomes of students (and their teacher) in their first experience of online learning. The emerging community of practice is the crucial node at which technology-in and technology-and education is aligned, and its members organised and merged. This situated account describes how this merging is taking place, and how allegiance to the practice of learning both reengineers and re-orientes the very roles, relationships, and distributed knowledge of the school community. In particular, the chapter offers a *gendered* account of how students mediate online learning, how new literacies are appropriated in learning exchange, and how ICT-enhanced teaching challenged one teacher's classroom practice. The chapter urges

that before we discount the transformative values of ICTs in teaching and learning, we need to consider the case for a new definition of student learning that focuses on “the demands of the new world environment” (Blasi & Heinecke, 2000, p. 5).

NEW LEARNING TECHNOLOGIES AND EDUCATIONAL REFORM: TRANSFORMING LEARNING

This discussion is framed by the unique and very public circumstances facing schools and school communities across Australia as they endeavour to get up to speed with new learning technologies. In a recent edition of the *Sydney Morning Herald*, an article ambitiously entitled “Experience the Power of E-Learning” (Wilson, 2002) described how the “horse and buggy days of education” were numbered. It went on to announce the transformation of an entire educational system as part of a “learning revolution” capable of “turning education on its head.” Educational reform born of new configurations of learning is walking steadily towards our schools along the information superhighway. Such bold expectations reflect a deeper belief that technology will improve learning, but as yet there remains some gap between the pervasiveness of this discourse and the actual progress of information and communication technologies (ICTs) in adding value to teaching and learning efforts. The following scenarios capture something of this impasse.

Scenario One

Under Australian political structures, the constitutional responsibility for public as distinct to private education provision falls to each of the six state and two territory governments. In 2001, the New South Wales (NSW) State Treasurer announced a State Government plan to commit \$21 million over four years to provide an e-mail account for

every teacher and student in NSW. In doing so, he proclaimed that, “In years to come, I believe people will look back on this as the year we began a revolution in NSW schools.” The Treasurer continued to state that creation of such e-mail accounts “would transform how children learn” (*Sydney Morning Herald*, 2001). Later, when asked to elaborate on how such lofty outcomes could be realised through e-mail provision, he passed the question to the Minister for Education for a more judicious response. A follow-up article reported somewhat tongue-in-cheek:

It turned out [the Treasurer] had little idea how e-learning accounts would work or how they differ from the Internet and extensive education intranets and free e-mail accounts that exist. Instead, he kept insisting the media should ask the... Minister for Education. ‘I’m one of those people who still writes his Budget speech with a pen in hand and a piece of paper so I think I will leave the details to John Aquilina’s people’ Mr. Egan said modestly. And, er, no he doesn’t have an e-mail account at home himself. (Hewett, 2001)

Scenario Two

In one of our Southern states, Victoria, the Federal Member for Murray, Dr. Sharman Stone, has publicly criticised the State Labour Government for its lack of action in addressing rising Internet costs to state educational providers in the rural regions of Victoria. This criticism was delivered against a backdrop where the state government had just awarded 50 state secondary schools across Victoria a \$5,000 share of state grants to foster the further development of information and communication technology skills.

Scenario Three

The New South Wales State Government has been publicly applauded by parent groups for providing free e-mail services to students across the state

(see Scenario One above). The same political administration is simultaneously lauded by local school administrators for providing a quota of only one ISDN line per school, making widespread use of the e-mail system both impossible and impractical (Parker, 2002).

Scenario Four

In Queensland, State Education Minister Anna Bligh has reacted strongly to the recently discovered knowledge that the targeted ‘critical mass’ of teachers with information technology skills has not emerged with the political velocity she would have liked. Teachers in our Northern most state have been slow to embrace technology in the classroom. As a result the minister is examining the value of withholding funding for technology-based projects within “recalcitrant” schools (Johnstone & Fynes-Clinton, 2002).

RECOGNISING NEW CONFIGURATIONS OF LEARNING BEFORE YOU KILL IT!

This discussion raises the possibility that ICTs in teaching and learning can be both rewarding and confronting for all parties involved—school administrators, policymakers, educators, school communities, and their students. The scenarios presented above suggest a widespread belief (at least in political circles) that ICTs will enhance student learning in the K-12 schooling sector. Yet in each scenario (above), as we race to meet this learning revolution, our school administrators create a new casualty on the information superhighway. These same scenarios are indicative of the gap between the pervasiveness of the school reform mantra and the inchoateness with which people address the very real question of how learning will be improved by incorporating ICTs into school curriculum.

What do we mean when we talk about how ICTs might improve learning and teaching? Does, for example, improved learning in terms of ICTs act as a proxy for a known outcome statement? Should this be expressed in terms of higher test scores, or pedagogically as models of *deeper* compared to *shallower* learning? Or, as with the field of Information Literacy, should we document ‘learning’ against the standardised observations common in ICT effectiveness studies that code, measure, and compare observations against sets of industry standards?

A recent U.S. report demonstrates the failure of ICTs to achieve these kinds of results. The National Assessment of Educational Progress test scores for 1999 showed no significant change between 1994 and 1999 in reading, mathematics, or science for any of three age groups: 9-year-olds, 13-year-olds, and 17-year-olds (Campbell, Hombo, & Mazzeo, 2000). Technology has transformed many social practices, but the millions of new computers in schools have delivered no real improvement in aggregated literacy, numeracy, and science benchmark scores in this U.S. study.

An alternate approach might suggest there is something to be gained in pursuing the new literacies, new knowledges path, where “improved learning” is interrogated as a process wherein new learning dynamics, processes, and outcome states are currently in the act of production. If what-counts-as-learning is taken as already existing and known, then “improved learning” can only mean higher steps on the existing ladder of learning outcomes; learning that is more of the same, but incrementally better than the same. If on the other hand new forms of learning are emerging, then “improved learning” describes a form of learning that is different to what has gone before. This discussion posits that recognition of this different learning in an ICT setting poses problems for classroom practitioners in the K-12 setting and beyond.

For example, it is unlikely in Scenario One that even the then NSW Education Minister

could give an adequate response to the question of how and where ICTs are transforming ‘horse and buggy’ schools, because there is very little documented evidence to date to suggest that educational technologies are being used to transform aggregated learning in any meaningful way. Certainly a few resourced schools are able to publicise stories about their use of laptops across the curriculum, document expensive hardware provision, and project this to host communities as self-promotion. Yet, this is not the same as broad scale curriculum innovation that draws on rich constructivist learning sites with embedded rich media. Nor does it deliver, as Scenario Four suggests, the critical mass of ICT skilled teachers required to sustain the ‘learning revolution’ within our schools. Stiles (2000) in his UK-based study of the implementation of ICTs for learning, concluded that failure in the use of technology in learning was based on several factors:

- the failure of ICT-enhanced curricula to engage the learner in authentic learning tasks;
- the propensity of ICT instructors to mistake “interactivity” for engagement;
- the bias in ICT-enhanced teaching and learning towards focusing on content rather than outcomes;
- the futile attempts of teachers in ICT-enhanced settings to mirror traditional pedagogical approaches onto new learning technologies; and
- an across-the-board failure to recognise the social nature of learning.

Stiles’ (2000) fourth point is particularly relevant here. In general, ICT uptake in schools has to date focused primarily on trying to overlay new technologies on traditional forms of teaching, without making substantive changes to the character of teaching (Campbell et al., 2000). As each of Scenarios One, Two, Three, and Four suggest, there exists an attitude that computers

remain separate from, rather than integral to established educational process. School communities are ambitious about technology-and education, but are less adept when it comes to technology-in education.

It is conceivable therefore that many teachers will not take full advantage of computer technology in their classrooms (evident in Scenario Four) as many teachers know and understand that the greatest benefits of ICT-mediated learning cannot wallpaper traditional modes of schooling. For here, the teacher rather than the learner remains in control of learning and predetermines many aspects of computer (class) interactions, how the machines will fit into the overall learning agenda, what the surrogate computer will teach and what the teacher will teach, and how much class time will be allocated to computer activities. This is not a unique view. A parallel U.S. study concludes that despite considerable rhetoric to the contrary, new technologies were hardly being used at all in schools (Cuban, 2001) with Fiske (1998, p. 11) arguing that “the only significant technological innovations of the 20th century to find a secure place in schools are the loudspeaker, the overhead projector, and the copy machine.” To suggest that local Scenarios One, Two, Three, and Four (presented above) are out of context with general trends in the schooling sector would be incorrect. Clearly, the trends repeat in Australia; it is only the setting that varies.

When we consider the more qualitative questions of how and why actual ICT uptake in schools fails to match the uptake of the ICT hype of politicians, perhaps this ‘trend’ is symptomatic of the dwindling capacity of state educational providers and administrators to meet and greet the information age head on. At the heart of Scenarios One, Two, Three, and Four lays a central and important question—how do we as an educational community transform classroom practice using new technologies? In doing so, how do we develop pedagogy and curriculum that engages the interests and (prior) experiences

of the student, whilst opening access to future learning options to them? As early as 1993, Seymour Papert urged the academic community to re-examine how the relationship between children and computers affects the traditional learning culture of schools. In some ways, the attempts of Australian policymakers nationwide reflect this engagement, with technology now a designated 'key learning area' in all state curricula. Computer competence amongst teachers is also articulated in policy; in our Northern most state Queensland, the Education minister has developed teacher competency measures and a performance continua to include benchmarks that feature changing a printer cartridge, word processing operations, and knowledge of e-mail and the World Wide Web (Johnstone & Fynes-Clinton, 2002). Policy rhetoric, though at times inconsistent with current examples of practice, clearly underlies a reformist move towards integrated information literacy, technology, and education. New learning technologies (ICTs) aim to facilitate "rich curriculum tasks," but as yet stop short of umbrella status as pedagogy in their own right (Lankshear & Knobel, 1995), and remain on the periphery of classroom practice. From the limits-to-technology-growth argument's annotated list of critics, Perelman's (1992, p. 23) key point is that schools are "no longer the primary modellers of information processing and knowledge transmission." This position is elaborated somewhat by the Queensland Minister of Education, Anna Bligh, in her affirmation that schools will now have to "prove their teachers can use IT equipment" before they receive it (Johnstone & Fynes-Clinton, 2002).

DIVERGENT DISCOURSES: CONVERGING PRACTICES

Clearly, there is a widespread climate of expectation about the new technological era. Schools and school systems are grappling with these expectations and competing as to what they try

to put in place. It is a period when many people (from parents to bureaucrats) really want to know what is meant by improved schooling and therefore what constitutes good educational practice. Some indication of what this may be is provided in the Queensland School Reform Longitudinal Study (QSRLS), located within the literature on effective schools, and which has wide appeal for policymakers, administrators, and parents alike. It attempts to identify pedagogies, school contexts, and external conditions that are linked to improved student outcomes (Lingard, Hayes, & Mills, 2002; Newmann & Associates, 1996). Potentially, 'improved learning' under such a model sees schools, teachers, and students using ICTs in ways that are intellectually demanding, in learning environments that are socially supportive, that value difference, and that have connections beyond the immediate confines of the classroom.

At a very instrumental level, Scenarios One, Two, Three, and Four offer a rough consensus to the technology/education problem. If school reform is stalling as each of these scenarios imply, and if ICTs are not the umbrella answer to improved learning as the lack of teacher uptake (Scenario Four) reflects, then the question becomes one of convergence. At what point (if any) do the discourses of information literacy, education, and technology converge and reconcile? How does this intersection better align the practical discourse of the teacher and the management discourse of school administrators such that it opens space for navigating new educational, social, and technological outcomes? The community of practice that comes to occupy this emerging space is the crucial node at which technology-in and technology-and education is aligned and its peoples (students, teachers, parents, administrators, and policymakers) implicated and merged.

"Rich description" is the tool of analysis commonly used to examine these types of connections. Recent research debates have made clear that "we do not so much *describe* as *inscribe in*

discourse” (Lather, 1991, p. 90). What we see and how we name things is shaped by the conceptions and agendas we bring to it. There is a difference providing rich descriptions from familiar guiding agendas (disadvantage, words and what they construct, explicit and inexplicit pedagogical devices), and ones where, to some extent, it is not clear what aspects of the ICT-enhanced classroom we should even be considering. The next part of this discussion brings to life a situated account of how the merging of ‘technology-in and technology-and’ education is taking place within a local North Queensland school, and of how allegiance to the practice of learning has reengineered and re-oriented the very roles, relationships, and distributed knowledge of the classroom. It begins with a quantitative analysis of student learning behaviours in their maiden online experience, and uses their teacher’s qualitative account of the online classroom as a tool to help guide reflections on changing classroom practices. In this case, the crucial node at which technology and learning align is in an early high school Studies of Society and Environment (SOSE) classroom; it is also the site at which emerging learning identities are formed.

IF YOU GO DOWN TO THE WOODS: A MIDDLE SCHOOL STUDY OF RAINFORESTS ONLINE

The essential impact of learner engagement with online learning environments is an emerging sense of learner control over the learning experience (Baskin, 2001). To the teacher in a K-12 setting, this represents substantive curriculum change, but not merely in terms of teaching and delivery. Resource-based learning and the shift from teacher-centred to learner-centred environments require that teachers rethink the fundamentals of their teaching role. To effectively weave usage of new information literacies, resources, and ICTs into the curriculum and culture of an early

secondary school classroom requires improved understandings of learning theory. This may involve a questioning of:

- What are the essential characteristics of the classroom environment in terms of stimulating learning? Can these be replicated online?
- Furthermore, what is meant (for example) by a ‘learner-centred approach’ to an early high school SOSE program?

The Blackboard® Learning Management System (LMS) was the e-learning platform featured in this classroom. The sample presented here is a Year 8 early high school class, engaged in a semester-length integrated SOSE classroom. The unit of study featured in this analysis was intended to occupy a timetabled block of five weeks; its focus was on local, national, and global rainforest issues. This unit was chosen to be developed and taught online as it contained pre-existing:

- peer-to-peer learning activities (paired and group collaborations);
- cross-disciplinary collaborative interactions (science, technology, health sciences, commerce, sociology, and administration);
- situated problem solving (task and interpersonal components); and
- stimulus for learners to engage with a variety of new literacies (learning objects, databases, e-paedias, virtual tours, and resource repositories).

The aim of offering the subject online was to extend the borders of the classroom to enable learners to have increased access to information resources for simulations, group work, and problem solving. A second focus of the online delivery of the Rainforests Unit was to enable interactions that promote a sense of belonging to a wider and *richer* learning environment than the traditional classroom. To achieve these dual aims, a heavy

reliance was placed on the communication and collaboration suites embedded in the host learning management system (Blackboard®) to extend student learning into new spaces and places.

CHALLENGING EXISTING TEXTUALITIES

One feature of current educational practice in the SOSE field is the codifying of knowledge into existing subject matter, for example the diversity of topics woven into a representative Year 8 SOSE textbook and course of study. The resultant package is an anthropological and theory-laden textual construct, what Callon (1986) calls “obligatory” passage points of discourse around what “counts as social education.” Its treatment of the Rainforests Unit warrants mention. Its textual device attempts to enrol students in “established” understandings of rainforest problems, while at the same time convincing them of the indispensability of existing (and at times ideological) solutions to rainforest issues. This kind of textual engagement at some level obviates the need for the student to participate in the search for active solutions, perhaps to the extent that “knowledge is lifted out of practice” (Wenger, 1998, p. 265). In this light, the teaching of Rainforests Unit does not necessarily cause learning about rainforest issues.

To the extent that teaching and learning are linked in practice, the linkage is not one of cause and effect, but more of resources and negotiation. Unlike a traditional K-12 classroom where everyone is learning the same thing, participants in an online setting contribute in a variety of interdependent ways to the learning of the class and to engaging with others around that purpose. The online setting becomes a way of organising learning, while providing the technology context in which learning can be demonstrated through active participation. The role of information literacy in the online setting lies in its capacity to enable teaching and learning about rainforests to interact so that each becomes

a structuring resource for the other. Perhaps the sharing of some observations may illuminate this point in more detail.

Something Different Happened: Time Zones in a Rainforest

Data presented here is a summary of the learning experiences of 33 Year 8 students ($n=17$ female, $n=16$ males) and their teacher. These participants were drawn together as a convenience sample, surveyed and interviewed after completing a five-week online unit on “*Rainforests*” as part of their Year 8 SOSE program. The first sign that something different had happened in the ICT classroom was that the planned five-week unit was much shorter than anticipated. In fact the teacher completed it in two weeks, most of the student groups in three, and one group of boys failed to complete it in the five allocated weeks. The class was both divided and together in its online experience of learning about rainforests. Not only did the online setting separate student/teacher and student/student in learning *time and space*, but the online medium also showed that learning time does not align with teaching time, and that learner perceptions of both are a powerful influencer on learning experience and outcomes. When the traditional stop signs of the classroom—the bells and timetabled periods—gave way to 24/7 orientations to learning in an “already there” online setting, students began to adopt individual and self-paced approaches to learning by freely accessing learning materials. This increasingly happened outside timetabled classroom activities; the teacher’s original reaction was one of dismay: “What about my lesson plans?”

LEARNING DESIGN AND LEARNING ARCHITECTURE

The Rainforests host subject site is heavily constructivist, and the aim of its design is to

stimulate candidate membership by recruiting learners *vis-a-vis* Wenger's (1998, p. 270) three-component design infrastructure of "engagement, imagination, and alignment." For many students, the option to work online was not just a curriculum delivery experience, but also an opportunity to connect, relate, and have serious fun through an established learning resource. The learning architecture (LMS) supports the pervasiveness of Wenger's (1998) mantra of engagement, imagination, and alignment by providing opportunities for access to:

- **Communication suites/tools/places to promote and expand asynchronous engagement:** This involved group architecture that featured small learning groups each comprising six students, as well as class-level discussion boards, file exchange, and e-mail facilities.
- **Web-mounted materials and experiences (i.e., Virtual Amazon tour):** These enable students to negotiate and construct an image of themselves in their world that is not timetable nor teacher-centric, and which is not reliant on *right-answerism* for its confirmation.
- **Simulations and interactions to practice and form practices about how to critically interact with the rainforest:** These include, but are not limited to, embedded learning resources, featured Web sites, and online threaded discussions. Peer review and collaboration was also a feature of the rainforests learnscape, in so far as student's were asked to act as both reviewers and producers of texts.

For the learner, the lure of technology is both obvious and profound; the short-run rewards in supporting the teaching and learning process and its management are significant. Information and communication technologies open pathways to the creation of learning environments that are

able to support the diverse needs of learners whilst widening traditional access to learning opportunities. Despite the novelty of the subject site and method, the degree to which students appropriated online learning behaviours varied incredibly. Some students identified strongly with new learning approaches; others did not at first. Some reacted to the online environment with suspicion, some with resistance. Some saw it an opportunity to participate, whilst others saw it as an invitation for peripheral lurking.

Teacher appropriation was similarly varied. The LMS offers a variety of features and new literacy tools to enhance the delivery of subject content materials and activities. These include a conferencing system, online chat, student progress tracking, group work organisers, student self-evaluation, grade maintenance, access control, navigation tools, auto-marked quizzes, e-mail, course calendar, student homepages, digital drop boxes, and embedded search engines. The choice for uptake by the classroom teacher is comprehensive and the technologies broad. Initially the magnitude of the pedagogical divide confronted the host teacher.

...we used to spend a week on this or a week on that and now they (students) are all over the place...I worry that they don't spend enough time on the important bits, and I'm buggered if I know how to test them? (Teacher)

The teacher, like his students, reported that the traditional teaching pyramid had "been inverted" and felt at times at the "bottom of the technological totem pole." Despite initial feelings of inadequacy, by the end of the Rainforests Unit, learning relations had significantly reformed, as teacher and students began to engage in new ways of learning through the online learning resources. A new set of learning relations slowly began to evolve.

We learned a lot...even about Rainforests, but mostly about how to learn. I would like to say we

Figure 1. Rainforests online

met on a level playing field, but the kids were way ahead of me. But (we) swapped ideas and traded skills and before long I was in about 12 discussion groups, and was able to start pointing and linking these together. The silence in the classroom was deafening...the noise in the discussion boards was huge. It was like unleashing a monster...I wondered how these things stop but then remembered we still have the bell, thank God! (Teacher)

A METHODOLOGY FOR CAPTURING STUDENT FEEDBACK

When a classroom teacher states that we “learned a lot...but mostly about how to learn,” I am intrigued to know more about the nature of this learning, how it is (re)distributed within this particular classroom, and what kind of learning improvements or costs accrue. In keeping with the online setting, an authenticated Web survey featuring 20 items (a CGI form) was generated and posted to the host subject Web site. Raw data from the survey was treated by placing the data (ranked 1-5 in nominal format) into a frequency distribution to view comparative differences of median scores across and between participating students. There were 33 out of 58 valid

learner responses, valid in so far as they contained completed student data sets.

Additionally, factor and multiple regression analyses were conducted to locate and measure the learning behaviours students identified as the most ‘relevant’ to their learning in an online environment. The data collection process ensured anonymity for all participants. The aggregated data confirmed that the online setting facilitated an authentic learning context for the study of rainforests by opening access to relevant forms of learner participation. The subject design and architecture emphasised active, learner-centred learning paradigms based on constructivist principles (Beaty, Hodgson, Mann, & McConnell, 2002), including the need for peer interaction and collaboration (Ramsey, 2002). The data set shows that the online environment was able to enrich student learning, and led to a more informed teacher perspective about what-counts-as-learning in a Year 8 SOSE classroom.

Learning-In and Learning-Through Technology

As previously stated, a feature of the Rainforests Unit was the host course management (LMS)

software, which provided opportunities for embedding and networking collaborative learning groups. Learning group activities conducted over (a planned) five weeks featured student collaborations in solving situated problems related to understanding rainforests and rainforest management. Online student meetings consisted of sharing information, dissecting course materials, environmental site analyses, collecting project data, collating project data, interpreting data, as well as publishing results from virtual field trips and projects (e.g., virtual Amazon). The summative assessment for the unit involved students

designing, developing, and testing their own board game simulation entitled “*Rainforests.*” Formative assessment involved a range of progressive online quizzes (using the LMS quiz generator) that often directed students to the archived and published work of other students as a point of reference and debate. The tabled results of the CGI form survey (Table 1) indicate that students endorse the online environment as an appropriate and fun (91%) forum for learning.

The survey questions attempt to capture the what (quantitative) as well as the why (qualitative) factors underlying student feedback about

Table 1. Summary statistics—student perspectives online learning

Individual perspective	Agree		Disagree		Unsure/DK	
	No.	(%)	No.	(%)	No.	(%)
Learnt a lot about Rainforests	28	[85]	2	[6]	3	[9]
Made new friends & connections	24	[73]	2	[6]	7	[21]
Improved my computer skills	28	[85]	0	[0]	5	[15]
Felt at risk at first	15	[45]	7	[21]	11	[34]
Found it easier to speak on-line in a group	26	[79]	5	[15]	2	[6]
Learned a lot through the experiential exercises	28	[85]	0	[0]	5	[15]
Learnt to have confidence in other students	24	[73]	4	[12]	5	[15]
Learnt to use on-line communications	29	[88]	1	[3]	3	[9]
I took control of my own learning	27	[82]	3	[9]	3	[9]
I was able to relate materials to real world issues	25	[77]	5	[15]	3	[9]
I felt comfortable giving/receiving feedback	18	[54]	9	[28]	6	[18]
Group perspective						
Showed up immature students	16	[49]	10	[30]	7	[21]
Saw how my behaviour affects others	24	[73]	3	[9]	6	[18]
Fun	30	[91]	1	[3]	2	[6]
Learnt to include quiet people	24	[73]	3	[9]	6	[18]

Unorthodox/unusual way of learning	17	[52]	12	[36]	4	[12]
Learnt to manage learning	27	[82]	4	[12]	2	[6]
Learnt to manage myself	27	[82]	1	[3]	5	[15]
Learnt to manage others in group work			22	[67]	8	[24]
Forced me to manage my time	25	[76]	4	[12]	4	[12]

online learning at the individual, collaborative, as well as curriculum levels. Reported learning transfer is high (85%), as is the reported increase in computer (85%) and communication tool skills (88%) and software applications. Completion of the online learning activities clearly required learners to apply new literacy and communication tools as a means of actively negotiating learning resources. Learner responses also reflect a high level of acceptance of (and a corresponding shift to) self-directed learning (82%), and increased self- (82%) as well as time-management (76%) opportunities. Some 90% of the survey cohort accessed the learning resources outside of scheduled class time, indicating a readiness to extend (and in some ways challenge) the limitations of the timetabled classroom. This is strong evidence of engagement with and acceptance of a new learning context, one that supports learners to take learning beyond the pedagogical intentions of the traditional classroom setting.

A climate of active learning exchange (73%) was evident as students moved between formative assessments using subject discussion boards. Learners were able to apply information literacy to form connections between ideas (association), create meaningful patterns of ideas (integration), test consistency between new patterns and old ones (validation), and own new information in a way that allows it to inform their practice (appropriation) as resource managers. Students valued the opportunity for learning to learn through both global and local materials and activities (77%), for the inbuilt modelling of learning behaviours (85%) and self-reflection and feedback (54%).

Students also reported a sense of engagement in realistic challenges that mediated their study of the environment, their interactions with peer group members, and the available ICT learning resources. Learning was not just confined to learning about technology, but encompassed learning-in and learning-through technology. Feedback on aspects of member participation

indicate an increased awareness of how “my behaviour affected others” (73%), of the need to manage group processes (67%), and how to include and accommodate others (73%) in collaborative learning tasks. The online environment was clearly able to stimulate authentic experiential and interpersonal challenges for students in a Year 8 SOSE course of study. In the words of one female student: “The boys aren’t nearly as loathsome online” (Georgie).

The ‘identities of participation’ that emerge through these classroom interactions point to a learning community that is closely connected by knowledge resources, whose membership is locally differentiated (by skill, computer orientations, exposure, preferences, proximity), yet one that remains locally connected through learning. This is more significant given the steady drift (over five weeks) away from ‘timetabled’ classes as a critical factor in determining when learning about rainforests would take place. In terms of induction to literacy in technology, some students saw the concept of online learning as somewhat unorthodox (52%) at first, with nearly half the students reporting that they initially felt at risk (45%) in what was an unfamiliar environment. Beyond the initial difference in perceptions, a virtual learning environment does pose a unique set of challenges for the novice user. It immediately enlists the learner in a process of having to decide where to go within the site, what counts-as-learning, and which territories of knowledge need to be claimed and labelled. The traditional classroom setting demands less immediacy from the learner; the initial contrast is the shrinkage of response time, wherein new relations and forms of learner membership are negotiated, owned, and enacted. The feedback from students about their maiden experience of online learning is indeed glowing, and assigns a significant potential to ICT and resource-based learning in SOSE classrooms of the future.

What or Who Helped Me to Learn?

If, as the survey data suggests, ICT delivery can improve learning effort, questions of “when, where, and how” this value adding takes place become important. In order to identify “what-or-who-helped-me-to-learn,” a principal components factor analysis with *varimax* rotation was conducted to examine which (if any) structure of variables (see Table 1) students attribute to “better learning experiences.” Six principle factors with *eigenvalues* greater than one were extracted using SPSS. In other words, a good online learning experience boils down to patterns of learner participation (at a range of levels) within the learning community (Wenger, 1998). In particular, the emerging factors included

1. how learners manage themselves,
2. how learners manage their learning,
3. how they use communication tools and processes,
4. how they organise online collaborations,
5. the degree to which learners seek and incorporate teacher feedback and evaluation, and
6. the gender of the learner.

From these results, a multiple regression analysis was used to examine associations between these six factors (e.g., which, if any, factors above can be used to explain or account for student learning outcomes). The regression analysis showed a strong association ($r^2=.802$) between *learner attitude and approach, learner self-management, learner’s use of Blackboard communication tools, gender, and collaborative learning relationships, with teacher feedback and evaluation* held constant as the dependent variable. In all, 80% of all variance (that is what-or-who-helped-me-to-learn) has been accounted for by these five independent variables.

For the teaching practitioner, this is very good news indeed. What-counts-as-improved-teaching

in the traditional classroom still counts as much (if not more) in the online setting. Teaching with ICTs still requires an ability to generate enough excitement, energy, relevance, and value to attract and engage learners, and to communicate this through feedback and evaluation. What is needed to make the transition to online teaching successful is a translational pedagogy that is able to situate the teacher and their students within more contemporary (read ICT-enhanced) learning systems. As stated previously:

- *The first goal of the “Rainforests subject site is to articulate the internal direction, character, and energy of the classroom. This already is in the classroom; hence the online classroom is built on pre-existing personal networks and clear curriculum statements.*
- *A second goal of the subject site is to open a dialogue between insider and outsider perspectives, whilst making space for different levels of learner participation. Learning is not always direct and declarative.*

These goals advocate greater learner control over the learning experience. The learner control afforded to users of the subject site is best evidenced in its space labelling properties.

- GroupWare enabled easy transition between private and public spaces (subject-wide and small group spaces), shifting the learning focus from the macro (class) level to the micro (small learning group) level through the simple selection of a navigation icon.
- E-mail provided a conduit for one-on-one networking for the sharing of information with limited clusters of people, and back channel group discussion pages (small group pages) helped orchestrate the public space before students go public with publishing their work and/or ideas.

- ICTs were therefore able to add value to learning by raising individual awareness, and in the longer term developing a systematic body (memory or archive) of knowledge that can be easily accessed by each learner within the classroom. This is a powerful characteristic of new literacies.

As the Rainforests Unit progressed, students settled into a pattern of Web site use built around the functionalities of the site. The mix of idea-sharing forums and tool-building projects fostered both casual classroom connections as well as facilitated learner outcomes. The combination of whole class, as well as small learner group gatherings created a balance between the familiarity of teacher-centred interactions, and the buzz students describe from working and playing in a distributed learning environment.

My cyber-identity was Baby Spice, but all the kids christened me Mrs. Doubtfire. I thought I could trick them and just merge into the group but it was not that easy...they were on to me as much online as they were in the classroom. What was different was that they started a discussion thread called ask Mrs. Doubtfire and I suddenly realised how ridiculous Baby Spice seemed. (Teacher)

The Relevance of Gender

The very fact that we have a middle-aged male teacher using ICTs to adopt the *cyberidentity* of Baby Spice is evidence that something different in learning is at work here. Here is evidence that subjectivities and relationships are mediated by literacy in technology, and are associated with shifts in power relationships. There is a long literature on inequalities and schooling, with some longstanding stabilities (class or SES) and some changing forms (gender), and each has been an ongoing issue of interest in relation to the organisation of schools and school systems. The introduction of expensive technology and possibly new forms of literacy, competence, skill, and knowledge display potentially change some existing relationships with which education is instrumentally familiar.

Harding (1997) points to the fact that technology is “gendered space” within the school curriculum. Although it is “dominated” by males, this dominance is not based on competency or learning outcomes (Kirkpatrick & Cuban, 1998; Durnell, Glissov, & Siann, 1995; Cockburn & Arnold, 1985). Girls and women are very pragmatic and confident users of computers. To some degree, this is represented in the higher relative weighting females assign to communication tools as a component of the rainforests learning environment (see Figure 2).

Figure 2. Use of communication tools

The uptake of communication and learning technologies by female students is evidence that learning is changing and that what counts as knowledge is changing. What is more important however is the issue of what the fundamental knowledge, both content *and* competencies, is that learners now need for vocational success (read access), to new worker identities and opportunities. Gee, for example, argues that the new economy calls up a “shape shifting portfolio person,” and that skills in design and collaboration therefore warrant and acquire new significance (Gee, 1999).

Given the outcomes in Figure 2, it is no surprise that female respondents report a higher level of enjoyment of the online learning experience than their male counterparts (see Figure 3). In fact, all female students reported enjoying the online learning experience more than they did their recent unit of study in the traditional chalk-and-talk SOSE classroom. The pragmatic adoption of online communication processes by female students also signalled a change in the nature of learning relationships within the online classroom. Short, Williams, and Christie (1976) hypothesised that users of communication media are in some sense aware of the degree of social presence of each medium and tend to avoid using particular interactions in particular media.

Specifically, users avoid interactions requiring a higher sense of social presence in media which lack such capacity. Social presence, they contend, varies among different media; it affects the nature of the interaction and it interacts with the purpose of the interaction to influence the medium chosen by the individual who wishes to communicate. In this context, a gendered pattern of ICT uptake is emerging through the data; subjectivities and relationships are mediated by technology in so far as female students are transforming their online learning experience by transforming the role of technology to enhance what Stiles (2000) termed the “social” aspect of learning.

In any learning context, knowledge construction hinges mainly on an *understanding* of the *relationships* between different components of knowledge; understanding is demonstrated in the ability to interpret, integrate, and create new knowledge (Resnick, 1987) actively, purposefully, effectively, and strategically. When mediating learning, from a constructivist viewpoint the learner has to do the thinking, relating, constructing, integrating, and interpretation. Knowledge is, after all, personally constructed (Toohey, 1999, p. 56). However, in any teaching context, the teacher needs to make the learning platform available; they must explicate its dimensions and processes, and provide the scaffolding for writing, thinking,

Figure 3. Enjoyed online learning

and constructing to take place purposefully and effectively. Teaching and learning thus have a context of practice.

To this end, Anderson (1995) describes different types of knowledge, each of which can be linked to rainforests. Declarative (also known as representational or propositional) knowledge (Anderson, 1995) is knowledge about facts, beliefs, things, and events usually expressed as theories, principles, rules, and frameworks (knowing what). When this theoretical knowledge is converted into action, it becomes procedural knowledge (Anderson, 1995), realised as the skills and techniques related to knowing how to perform cognitive tasks. When both the theoretical (propositional) and practical (procedural) knowledge are enacted, it becomes conditional knowledge—that is *knowing* when, where, and how cognitive tasks are to be performed and applied. When the theoretical (propositional), practical (procedural), and applied (conditional) knowledge are used as deliberate learning strategies, strategic knowledge comes into being, meaning the learner is negotiating the when, where, how, and why of learning. There is clear (directional) taxonomy between these four categories of knowledge and evidence within this case study that new improved forms of social learning are emerging among female students.

Most student responses identified that traditional teaching and learning relationships and

roles had changed in an ICT-enhanced classroom (see Figure 4).

Female students seemed more aware and indicated a stronger desire for supported online learning than did male students—all female respondents deemed additional peer and teacher support as helpful, important, or necessary (see Figure 5) as a strategy for consolidating learning by balancing information literacy competence with the rhythm of the ICT classroom.

Female students reported enjoying the opportunities for self-directed learning, and in turn using these opportunities to orchestrate and structure whole community and small community communications to support their learning. For all participants, the mix of idea-sharing forums and tool-building projects enabled informal (as well as formal) learning channels to develop in a way that supported interpersonal development. Its culture promoted an increased sense of responsibility for learning, for self- and time-management as a learner, and was able to create dialogue between the learning materials and the context of the learner. The data presented here also suggests that the online classroom is less extreme in its representations of ‘real-world’ classroom identities and dysfunction, and also points to evidence that learning misbehaviour is more transparent when embedded in ICTs. The ICT framework also laid the groundwork for a more explicit examination of

Figure 4. Changed teacher role

Figure 5. Need for learner support

what the traditional classroom enacts as (hidden) largely tacit forms of classroom organisation. Data presented here suggests that ICTs help teachers and learners explicitly declare:

- *who is the authority, and who is expected to listen and is enabled to speak;*
- *how activities, groupings, and transitions are determined;*
- *who judges performance, and how this is done;*
- *what counts as knowledge; what constitutes performance;*
- *what links are made across the curriculum; which have currency beyond it;*
- *where control is located;*
- *where knowledge is produced;*
- *when communication is enabled and for what purpose; and ultimately*
- *why computers are used.*

THE TEACHER'S PERSPECTIVE

As educators we are traditionally encouraged to focus on creating structures, systems, and roles within our classrooms that achieve relatively fixed (sometimes banded, sometimes hierarchi-

cal) goals that enable our students to fit well into other school-based or systemic structures and processes. To most teachers this challenge presents itself in the form of strategies and techniques for classroom management. The interview data presented here brings to a focus the challenges facing teachers and students when interfacing between two textually mediated delivery or classroom management contexts. The teacher in this study reports a range of challenges in a variety of areas: technology, literacy, logistics, organisation, and delivery (Dabbagh, 2001). What emerged from his observations was a sense of dissonance, a fragmentation of teaching practice across two conflicting platforms.

Two roles...on the one hand me, the constructivist, the facilitator moving in and around the knowledge construction processes of the student. They expect me to be their peer, their mentor...I am supposed to contribute equally to the subjective and unstructured as well as the structured discussion within the class. On the other hand a different me...the assignment marker...bringing the lower end of the class closer to the top end...the expert who will ultimately be expected to pass judgement on the rigor of student work in the most objective way possible. This conflict means the roles have to be

performed independently—this results in a huge increase in my workload. (Teacher)

After analysing the activity within the subject-wide discussion forum, over half the discussion threads were generated by the teacher, and more than 50% of the total responses were directly attributable to the teacher. Most of the teacher's discussion threads were attempts to "set (discipline) the collaborative agenda" for the class, including setting up activities, assigning groups, and indicating useful resources. As the Rainforests Unit progressed, more and more of the teacher's online time was spent on 'weaving' the student discussions towards an outcome. In the words of the contributing teacher, this was "heavy reflective work," the "very stuff" of good teaching.

One task had students using e-mail to prepare and submit a summary report of their board game...(you know) the final assessment piece for the unit. This created huge response pressures. Even the suggestion of "e-mail contact" raises the expectation that I am permanently on tap for feedback, and that feedback will be needed yesterday rather than today. Great!...so one Monday I lose my spare period when I would normally send out e-mails and for the rest of the week I am apologising to kids for my tardiness. They got very clever... "Hey Mr: _____, I can't do this assignment until you have approved my concept." The system had turned on me...it was (like) trial by media...make that multi-media (hah). And then...yes there is a then...you (interviewer) told me to use the technology to work for me, you remember...to copy and paste responses in e-mail rather than type it all. So the kids start to compare my feedback comments...and what do you know...they accuse me of sending out the same rotten e-mail. I have never felt more under the microscope. (Teacher)

The conflict between face-to-face and online literacy and learning processes was marked. In

the teacher's words, "It is normal bread and butter practice to close (a lesson) by pulling together the key themes of a lesson." However, the demands of new literacies and their synchronous and asynchronous properties shift the responsibility for mediating discussions (read closure) to the facilitator. As the same teacher concludes, "Closing an online discussion helped me to demonstrate effective modelling and synthesising strategies, but it took me far too long (time) to achieve this."

At the administrative level, the organisational and logistical aspects of online learning seemed also to challenge the response capacity as well as the mindset of school administrators. It was difficult to "get a working computer lab," and even more difficult to "mediate the tribal practices of the IT and multimedia teachers" to secure server access and "some form of ongoing help." Assessment also appeared problematic in an online environment. The teacher felt compelled to be able to 'feedback' to students and parents about the quality of each student's participation, but felt he lacked the 'repertoire' (read time and means) to determine:

...which student contributions actually enhanced the debates; who was original and who was responsive in discussions; how to deal with "lurkers" and non-participation, and how to educate about attribution of ideas and resources. In short...I felt the collective was engaged seriously in learning but I found it hard to say the same for each individual.

As to the degree to which technology added value to the classroom practices of this particular teacher, we must borrow from "Tina's" experiences.

Tina _____ just talks a lot. She is incessant. In class I would speak to her all day everyday if she had her way. I added up all the words I had typed to her over the last four weeks...about 1,800 words. Stay with me...I have a point. Now,

if I speak at...say 160 to 170 words a minute this means that in four weeks I have spoken to Tina for the equivalent of about 10-12 minutes. You tell me...is that enough?

The risk in over-focusing on the ICT experiences of one teacher is that we may tend to over-identify with a very singular and idiosyncratic episode of teaching, vis-a-vis a sample of one. If we ask, looking through the wide-angle lens, “What does literacy in technology do?” a surprisingly focused answer comes back. It recaptures the expressivity of youth cultures which school texts and teacher-generated learning materials exclude. This creates a different sense of self and society: literacy allows us to access human society in the formal terms denied to an oral culture that just narrates its ongoing drama. New literacies enable both sets of rules to speak with equal voice and equal authority. ICTs in this way are transformative tools; the fact remains that this online classroom had an intrinsic quality that led to questioning (both productive and less than productive) about the dual modes of teaching delivery. Despite the glowing response from students to the new forms of literacy and learning, two enduring principles of the ‘trial by multimedia’ exist for our more circumspect teacher.

- online teaching leads to an increase in teacher workload, and
- it can also lead to dissatisfaction (at least ambiguity) with the quality of the teaching experience.

ENGAGING NEW CONFIGURATIONS OF LEARNING

Education has always had at its core the desire and the requirement to prepare students for the world in which they live. Much has been written before this chapter about the challenge of shifting educational practice to reflect the demands of

contemporary society, resulting in suggestions of new skills and new understandings of how such education can be achieved. A growing number of researchers and educationalists (individuals and groups) describe variations on a common range of desirable attributes. Students need to be able to motivate and direct their own learning, engage in creative, productive activities that are relevant beyond the classroom. They need to be well equipped to think critically, make decisions, and be sensitive to multiple cultural and world views. Invariably the ability to creatively and responsibly use information and communication technologies appears as a requirement.

The findings of this project suggest that a learner’s digital literacy skills will emerge in ways that reflect his/her local circumstances; in a Year 8 classroom, this means how they manage themselves, their learning, how they use online communication tools, how they form networks of collaboration, how they appropriate teacher feedback, and how they challenge aspects of gendered practice. The findings also highlight issues impacting social, school, and assessment policy and practice. Revitalised schools are something many of us strive for: staff, students, and communities alike. One problem facing the ICTs in schools movement at the enterprise level is that staff, students, and administrators in our schools experience technology differently. This is reflected in all four opening scenarios, and captured within the student and staff data presented in the body of this chapter.

Because experiences of new learning technologies are different, so too will be the range of outcomes. Technology transforms by inclusion as this project shows: the transition to a better social and learning opportunity for the individual (and for groups) depends largely on where and how you are positioned in relation to information literacy access. If you are a mid-career teacher, a disenfranchised male high school student in a Year 8 SOSE class, or a teacher in a school that for social, cultural, or economic reasons does

not meet the IT state benchmarks, then the social pact of ICT-enhanced education offers at best diminishing marginal returns.

The failure of ICTs in K-12 schooling is that we ask existing teachers to scaffold new learning processes in a new generational context, using old generation theories, approaches, and concepts. This impasse provides the case for a new definition of student learning that focuses on “the demands of the new world environment” (Blasi & Heinecke, 2000, p. 5). The challenge presented here is to find better ways to respond to a clear identification of the need for more relevant and meaningful standards or new definitions of student achievement.

Parallel to this are significant methodological issues for how we might channel ICTs into a study of current K-12 learning practices, and how this could build upon existing research models. Current ICT effectiveness studies are designed to code, measure, and compare observations against sets of standards to draw common classroom observations about improvements in student learning. A more productive outcome might be to place the pedagogical practices of teachers under scrutiny as this project has done, to question what technology is used for, how learning is assessed, and what performances are valued. A new research emphasis on learning recognises that not all learning may be observed by changes in behaviour, and that some learning may well be unplanned and therefore unanticipated (Wenger, 1998). It is the latter, that which Wenger (1998) terms “emergent learning,” that holds much promise for ICTs in education, for here new configurations of learning are at work within our classrooms. That this happens despite our accidental attempts to ‘kill’ them off is a profound statement of their pedagogical potential and productivity.

Chapter 4.17

Strategies for the Cooperation of Higher Education Institutions in ICT

Juha Kettunen

Turku Polytechnic, Finland

ABSTRACT

This study analyzes the strategic planning of the ICT center, which is a joint venture of three higher education institutions. The strategies of focus and operations excellence are natural choices to define the strategic outlines for the center, which aims to increase the economic growth of the region. The selected strategies are described in this study using the balanced scorecard approach. It allows the network of organizations to articulate and communicate their strategy to their employees and stakeholders. The concept of the strategy map is used to describe the strategy. The decentralized efforts of separate organizational units would most likely fail without the network strategy and cooperation.

INTRODUCTION

Higher education institutions (HEIs) try to focus their activities to specific fields of education and

the needs of their geographical area. Each HEI has its historical background and strengths. The educational institutions try to reinforce their strengths and improve their quality by focusing their resources on specific activities. Strategic choices are typically made to focus on the specific segments of knowledge creation and delivery.

Another strategy of HEIs emphasizes the operations excellence theme. Institutions try to reduce their costs and improve quality by doing operations more efficiently. The HEIs can achieve their desired objectives in ways other than traditional pure operational excellence. This study shows how the interests of various HEIs can converge in research and education in information and communication technology (ICT). The close cooperation of institutions has led to a partnership to build a joint ICT center, which produces better labor force and enhances the competitive advantage of the ICT companies in the region.

The various strategic approaches aim to move educational institutions from their present position to a desirable future position (Davies & Ellison,

2003; Fidler, 2002; West-Burnham, 1994; Wheale, 1991). The strategy of focus aims to direct activities to specific customer segments. This also leads to operations excellence and overall cost efficiency. These two strategies are essentially the competitive strategies by Porter (1990, 1996) applied to educational institutions.

The purpose of this study is to show that the balanced scorecard approach and the concept of the strategy map developed by Kaplan and Norton (2001, 2004) can successfully be used to describe and communicate the network strategy of the ICT center, which is a joint venture of HEIs. The communication of strategic objectives is important especially in a network project. The stakeholders have diverse backgrounds which increase the need for enhanced communication. The decentralized efforts of separate organizational units would most likely fail without the network strategy and cooperation. The approach helps to create a shared understanding about the planning and operation of the center. The balanced scorecard translates the center's strategy into tangible objectives and balances them into four different perspectives: customer, finance, internal processes, and learning.

The strategies typically reflect the structure of the organization for which the strategy has been planned. In such cases the implementation of the strategy is straightforward, because the strategies of different administrative units can be aligned with one another to obtain an effective plan for the whole organization. This study presents strategies which are not congruent with the structure of an existing organization but with the network of independent institutions. The strategies favor the cooperation of the institutions in an ICT center in order to increase their external impact.

In many regions there are typically several HEIs, which have their own unique strengths but much in common. In these regions no single HEI is solely responsible for the regional development nor is in complete control of it. Their

strategies can, however, be aligned and linked in order to strengthen their external impact on the local community. This study uses the balanced scorecard approach to plan strategies for virtual organizations to achieve commitment to a common strategy. Thus, the strategy for a virtual organization involves multiple autonomous operators with their own activities.

The ICT center is a joint venture of the University of Turku, Åbo Akademi University, Turku Polytechnic and the Turku Science Park Ltd. As the owner of Turku Polytechnic and Turku Science Park Ltd, the City of Turku has had an active role in establishing the center. The ICT center was planned according to the educational policy outlined by the Ministry of Education in order to increase the external impact of HEIs in Finland.

This is a qualitative study based on the concepts of strategic planning and the balanced scorecard approach. The focus of the study is on the interpretation of how the participants make sense of the planning concepts. The focus is not in the numerical exactness, which is typically the strength of the quantitative research. When a qualitative study is conducted, qualitative data are used to clarify and illustrate the meaning of findings. Typically one case or a small number of cases are studied preserving the individuality of the analyzes.

This study is organized as follows: The next section presents the operational environment of the ICT center. The third section presents the strategic planning and the cooperation of educational institutions. The fourth section presents the balanced scorecard approach and the strategy maps, which are used to describe and communicate the strategy. It also presents the strategic initiative to build the ICT center. The results of the study are summarized and discussed in the concluding section.

THE OPERATIONAL ENVIRONMENT OF THE ICT CENTER

Economic Development of the Region

The strategic location of the ICT center is at the Turku Region situated in the county of Southwest Finland. The Turku Region is one of the largest growth areas of Finland and is the second largest growth area on the southern coast of Finland after the Helsinki metropolitan area. Turku has an excellent location right at the heart of an area comprising the Scandinavian countries, the Baltic countries and St. Petersburg. Turku has only 175,000 inhabitants, but about 30 million people live within an easy reach of Turku. This offers the business in Turku a clear potential for continuous economic growth.

The main clusters in Southwest Finland include ICT, biotechnology, and metal and maritime technology. These clusters are based on high technology, but they mix with low technology, manufacturing, and services. Porter (1998) defines clusters as geographic concentrations of interconnected companies, specialized suppliers, service providers, firms in related industries and associated institutions in particular fields that compete but also cooperate. Recent growth has particularly boosted the ICT and biotechnology. The traditional metal and maritime cluster provide the basis for new products in pharmaceuticals, functional foods and life sciences, transport as well as printing technology and media.

The growth of industrial production in Southwest Finland has been particularly fast compared to the average development of the whole country. The value of production of electro-technical industry in Southwest Finland has increased more than tenfold during the last decade, while the growth rate of other industries has been 15%. Also many other industrial and service industries began to grow faster during the late 1990s. Particularly rapid growth is expected to continue

in transport and storage services, data communication, construction, and services provided for business life.

The fast growth of the electro-technical industry can also be seen in the production structure of the industry. The share of electro-technical industry has reached an all-time high in Southwest Finland. It accounted for 25% of all industrial production in Finland after being only less than 7% in 1990. The share of electro-technical production is the highest among the industries of Finland. The structural change has particularly affected the production in Southwest Finland.

The advantages of clusters involve location-specific factors and public goods. The clusters are supported by the public sector including educational institutions. The advantages of clusters include physical proximity, close cooperation, and access to information. Public investment in knowledge and specialized infrastructure benefit these clusters and increase their competitive advantage. HEIs located within clusters are able to more clearly and rapidly perceive new educational needs (Pfeffer, 1997).

The traditional universities and Turku Polytechnic are closely situated in the same district of Turku Science Park. The City of Turku established a holding and development company Turku Science Park Ltd. to develop the area. Turku Science Park comprises a five square kilometer area in Turku including properties for cluster-specific innovation activities. There are also three cluster-specific development companies ICT Turku Ltd., Bio Valley Ltd. and Turku Technology Center Ltd., which also operate in cooperation with education institutions, companies and other stakeholders.

Turku Science Park links together public and private investments, major construction companies and the companies of the Turku Region. It combines four HEIs, 13,500 employees, 25,000 students, 400 professors and 300 companies in a single location. It combines research, development, education and production involving public and private operators. Turku Science Park breeds

the future products of digital mobile communication, biotechnology and bioinformatics, process engineering and transport technology.

The ICT center will increase the cooperation of HEIs and increase competitive advantage of ICT companies through the research and development and the quality of learning. The center is common ground for research, development and education of multinational telecommunication companies such as Nokia, Siemens, Eriksson, and TeliaSonera. The improved competitive advantage of the companies increases the economic growth of the region and provides employment opportunities for graduates.

Turku Polytechnic

Turku Polytechnic is located in Southwest Finland, which is the second largest economic area after the capital of Finland. Education, culture, and technology are engaged in Southwest Finland in mutually beneficial cooperation with commerce and industry. Regional development is one of the main objectives of Turku Polytechnic. The interaction is close with its operational environment. The purpose of the institution is to react to the changes in its environment in a flexible way. Turku Polytechnic was the first HEI which committed to build the ICT center.

Higher education is fragmented in Turku. There are three traditional universities, the main premises and activities of Turku Polytechnic, and three branch offices of three other smaller polytechnics. The universities include the University of Turku, Åbo Akademi University, and the Turku School of Economics and Business Administration. Åbo Akademi University provides education for the Swedish speaking population. Turku Polytechnic is the largest polytechnic in Finland. The smaller polytechnics Diaconia Polytechnic, Humanities Polytechnic, and the Sydväst Polytechnic have only a relatively small amount of students in Turku. There are plenty of

good examples of cooperation between the higher education institutions in Turku.

Turku Polytechnic is a multidisciplinary higher education institution founded in 1992. The City of Turku owns the Polytechnic, which has 750 full time employees. Turku Polytechnic has seven fields of education and a Continuing Education Center. Technology, communication and transport, healthcare and social services, and business and administration are the largest fields of education. The Continuing Education Center has 6,000 participants in a year. The Polytechnic operates in six municipalities in Southwest Finland.

Turku Polytechnic has 8,300 students in 36 Bachelor's and Master's degree programs, and among them five programmes are taught in English. Internationalization is one of the focus areas of the institution. The objective is to improve the students' ability to work in global environment. Turku Polytechnic has a plenty of cooperating higher education institutions in Europe, Asia, and Americas.

STRATEGIC PLANNING

Strategic Outlines for the Cooperation

The purpose of strategic management is to achieve the desired objectives in the future. The strategic management also involves the development of the organization and its present activities to achieve the objectives set in the strategic plan (Davies & Ellison, 2003; Fidler, 2002). According to Peters (1988), the strategy is used to create organizational capabilities to react to the changing environment. Educational institutions typically develop their internal processes and structures to meet the needs of the changing educational policy, society, and local community.

The competitive strategies were selected for the ICT center on the basis of the strategic outlines. These strategies presented by Porter (1990, 1996)

were originally planned for business companies, but they are also applicable to educational institutions (Kettunen, 2002; Treacy & Wiersma, 1995). The strategy of focus was combined with the strategy of cost-efficiency and applied to the center.

The strategy of focus means that an organization selects a market segment and creates bonds with its customers. It knows the customer organizations and can plan the products and services to meet the needs of customers. The focus may also be on a geographical region, occupational group, and organizational level. The functional policy is to serve the selected market segments particularly well. The focus strategy enables the HEIs to enhance their knowledge in their respective areas.

The strategy of cost efficiency means that the institutions deliver a combination of costs and quality that creates competitive advantage. Typically HEIs have unit-priced funding. They emphasize efficient internal processes and try to achieve high quality in their activities. The strategy of cost efficiency also makes it possible to eliminate overlapping activities and achieve cost reductions. The ICT center use shared premises and support activities to reduce costs.

Even though the focus strategy does not primarily aim to achieve low costs, it does also achieve cost efficiency. The HEIs can eliminate the overlapping activities, focus them, and direct the resources to improve their quality. Cost efficiency is a natural choice for the strategy of educational institutions, which typically have set annual budgets.

Strategic Themes Create Success

The balanced scorecard developed by Kaplan and Norton (1992, 1993) is a general framework for describing and implementing strategy. It can be used to describe a holistic model of the strategy linked to the vision of the future. The balanced scorecard translates the strategy into

linked cause-and-effect objectives and measures, which can be used to communicate the strategy to organizational subunits and workers (Kettunen & Kantola, 2005). It helps to create a shared understanding about the efforts and needed steps for the change.

Balanced scorecards have been developed for business companies, but they are also applicable in public organizations. The balanced scorecards of HEIs look remarkably similar to those developed for profit-seeking corporations. They do not pay as much attention to the financial perspective, but emphasize more on the role of students and employees. Given that the financial result is not the primary objective for most of the non-profit organizations in the public sector, it is reasonable to place the recipient at the top of the hierarchy.

Measurement managed companies tend to have better teamwork at the top, better communication throughout the organization and better self-management at the bottom level (Lingle & Shieman, 1996). The results of the study by Frigio and Krumwiede (1999) show that the performance management systems which used balanced scorecard were significantly more effective compared to other systems.

The general strategic statement is that “the ICT center will strengthen the expertise of HEIs and increases the competitive advantage of the companies in the global markets.” The improved competitive advantage of local companies increases economic growth, expands the employment opportunities of graduates and generates prosperity in the region. The success of the local company Nokia Mobile Phones Ltd. creates expectations for a wider range of flourishing companies.

Strategic themes describe what management believes must be done to succeed and achieve the desired outcomes (Kaplan & Norton, 2001). They describe the strategy of an organization in a concise way. Each organization has a unique set of strategic themes for creating value for customers. The strategy typically emerges from local initiatives and also within the organiza-

tions (Kettunen, 2003, 2004; Minzberg, 1987). Usually, the strategic themes are tailored to a specific case and cannot necessarily be replicated in other regions.

The first strategic theme of the ICT center emphasizes that the HEIs have to focus their activities on their strengths in order to improve the quality of their activities. Each institution has its specific interest areas and strengths. The first theme describes the customer-oriented strategy to create distinct value for the ICT companies, students, and region.

The second strategic theme is to increase the cooperation of HEIs in order to improve cost-efficiency. The center aims to take advantage of the cooperation of HEIs in order to achieve cost-effective and high-quality operation. These themes reflect the generic competitive strategies which are applicable in many types of organizations. The strategy of focus is combined in this case with the strategy of overall cost efficiency.

The strategy of the ICT center can be written as follows:

- The ICT center will strengthen the expertise of HEIs and increase the competitive advantage of the companies in the global markets.
- Each HEI will focus on its strengths to serve its customers better.
- The increased cooperation of HEIs will enable cost-effective and high-quality activities.

The strategy for the joint ICT center describes the activities required in the center. Each HEI is then able to define its own strategic plan, where the overall network strategy is taken into account.

The first theme is a vertical strategic theme that accommodates the underlying drivers in the learning perspective that will lead to the desired strategic outcome in the customer perspective placed at the top of the hierarchy. It emphasizes the development of the existing strengths of each

HEI. The focus on the strengths helps the HEIs to use their resources efficiently and improve the quality of their services. The efficient and high-quality services help the HEIs to serve their customers better.

The other theme is a horizontal strategic theme, which describes the activities in the internal processes perspective. It describes the cooperation of HEIs enabling cost-effective and high-quality activities. Reinforcing strengths and avoiding overlapping operations makes it possible to direct the resources to improved quality in research, development and education and provide regional development and customers with better service. For students this strategy means wider opportunities and higher quality of learning.

Porter (1996) emphasizes that the essence of the strategy is in the activities. The strategy is about selecting the set of activities in which an organization will excel to create a sustainable difference in the marketplace (Kaplan & Norton, 2004). The strategy requires an organizational theory of value creation. The first strategic theme is clearly linked to the activities and describes the value proposition for the customers. The second strategic theme describes the cooperation of different organizational units. The internal processes perspective actually describes the innovation chain, where each institution develops its strengths and cooperates with the others.

Cooperation of Educational Institutions

The University of Turku has a strong and internationally distinguished position as a multi-disciplinary scientific university having 17,000 students. Åbo Akademi University offers the Swedish speaking population in Finland higher education in their mother tongue. It has 7,600 students. The Turku School of Economics and Business Administration provides research and higher education in the field of business science. It has 4,200 students. Turku Polytechnic is the

largest polytechnic in Finland, having 8,300 students. All these HEIs are participating in the ICT center.

Table 1 presents the number of cooperation projects between HEIs in Turku. According to the results of the survey by Puustelli (2002) most cooperation is in teaching, where 72 examples are found. There are 37 projects of cooperation in research and development. In addition, there are 25 projects in other activities, which include mainly cooperation among support units. However, there are only a few examples of cooperation between the polytechnics. This can be largely explained by the fact that the units of The Sydväst Polytechnic, The Diaconia Polytechnic, and The Humanities Polytechnic are small.

The three universities have a joint network, the Turku Center for Computer Science (TUCS), which was started in 1994 to coordinate research and education in the field of information technology. Education is coordinated entirely by the departments up to the bachelor's level. The educational workgroups of the TUCS coordinate the master's level and postgraduate education.

Table 2 describes the education and research at the ICT center. The cooperation between the HEIs was strengthened starting in the 1990s when TUCS started the joint master's and postgraduate programmes. That also enabled the expansion of the cooperation in research and development. The ICT provides a joint and up-to-date learning environment for the institutions to expand their cooperation.

Table 1. The number of cooperation projects between higher education institutions

	Teaching	Research and development	Other activities
Between universities	39	31	16
Between polytechnics	4	1	4
Between universities and polytechnics	29	5	5
Total	72	37	25

Table 2. Activities at the ICT center

Partners of the ICT center:			
Focus:	University of Turku	Åbo Akademi University	Turku Polytechnic
Research and development	Basic and applied research at research laboratories	Basic and applied research at research laboratories	Applied research and development Entrepreneurship
Educational programmes	Master's programme in information technology Graduate programme at TUCS Graduate School	Master's programme in software engineering Master's programme in electronic and mobile commerce Graduate programme at TUCS Graduate School	Degree programme in information technology (bachelor's degree) Degree programme in electronics (bachelor's degree)

The traditional functions of the HEIs are to create new knowledge and deliver it. Research and development serves education, providing new contents and improving the quality of education. It also provides development projects, which can be combined with education. The University of Turku and Åbo Akademi University have basic and applied research laboratories within TUCS. Turku Polytechnic has applied research and development facilities. The development includes, for example, projects that develop entrepreneurship.

It has been observed that the cooperation between the HEIs is more active in information and communication technology than in other fields of study. An important reason that facilitates this cooperation is that the same subject is represented in all three universities and Turku Polytechnic. Another reason is that the HEIs are operating in the same district of Turku. The cooperation includes, for example, the consortium of digital media, exchange of students and teachers, international education, Master's program in software engineering in Salo, Center of Software Engineering, TUCS and data networks.

All the HEIs have different profiles in their degree programs. The universities have graduate programs at the TUCS Graduate School. The University of Turku has focused on information technology. Åbo Akademi University provides education for the Swedish-speaking population. It has focused on software development, electronic, and mobile commerce. Turku Polytechnic has two degree programmes in information technology and electronics.

THE BALANCED SCORECARD DESCRIBES THE STRATEGY

Perspectives of the Balanced Scorecard

Strategies are typically planned for the whole organization and also for its subunits. The plans

reflect the structure of the organization for which they have been tailored. This study shows that the balanced scorecard provides an approach where strategies have not been planned for a single organization or administrative unit, but the strategies can be shared to achieve the synergy of autonomous HEIs.

The planning of strategies for virtual organizations or networks of independent operators is notably different from that of other strategies, because there is no single organization which owns and implements the strategy or is evaluated against it. On their own the decentralized and overlapping efforts of HEIs would likely have a smaller effect on the economic growth of the region.

If the strategy cannot be described and communicated, it cannot be implemented. Here, the balanced scorecard can be used to translate the vision and strategy into tangible objectives and measures that can be communicated to the personnel and external stakeholders. Hence, a good measurement system should have a balanced mix of objectives and measures in the different perspectives to indicate the strategy.

The objectives and measures have to be defined for each of the four perspectives:

1. **Customer:** The customer perspective describes the value created for customers by the internal processes. The customer perspective also includes regional development.
2. **Finance:** The financial perspective describes the funding from central government and external funding, which are aligned with the cost-efficient internal processes.
3. **Internal processes:** The internal processes perspective describes the strategic priorities for internal processes and how value is created for customers.
4. **Learning:** The learning perspective describes the drivers for future performance and the learning which is required for the internal processes.

These perspectives have been found to be necessary and sufficient across a wide variety of organizations (Kaplan & Norton, 1996, 2001).

The customer-oriented process begins in a top-down fashion, defining the objectives of the customer perspective. It starts by asking, "Who are the target customers and how do we measure our success with them?" Then the process continues, "What funding is required?" and "What has to be done in the internal processes?" Finally the process asks, "What skill and knowledge is needed in the internal processes?"

The customers of HEIs include students, employers, and the local community. The Ministry of Education in June 2002 imposed a requirement that the Finnish HEIs should intensify their cooperation in order to increase their external impact. The first regional strategies were planned by the end of 2002 and updated in 2005. The Ministry of Education hopes that the HEIs will offer better integrated activities for the students and employers in the region. The Ministry hopes also that the increased cooperation enhances the cost efficiency of the institutions.

The ICT center can create synergies across the diverse HEIs by providing students with a broad set of courses and services. It is often reasonable to share the lecturers on basic courses and take advantage of scale effectiveness. This enables the concentrations of expertise in a broader set of specific high-quality courses, which offer students wider perspectives. The cooperation of the HEIs depends largely on the activeness of the professors and other members of the personnel. The purpose is also to improve the competitiveness of the ICT companies. The needs of the companies are collected from the employers' advisory boards.

Education is financed by central government. The Ministry of Education also finances the joint development projects of HEIs that have a positive impact on regional development. The additional project-based funding for the ICT center expands the degree of cooperation, removes overlapping activities and increases the external impact of the

HEIs. This study supports the findings by Tolbert (1985) and Gumpert and Sporn (1999) that the activities and organizational structures follow the funding sources.

The additional financial support from the City of Turku maintained sufficient coherence and ensured that the needed decisions for the investment were taken. The meetings organized by the Mayor of Turku stimulated an intense management dialogue, which helped the partners to define their strategic outlines for the ICT center. The extra funding enabled them to share common premises and facilities. The value of the total investment is more than 50 million euros.

The internal processes of the ICT center include many different administrative units. Chandler (1990) describes how synergies across organizations and the economies of scale can be used to achieve cost-efficiency in the operations of smaller and focused organizations. The strategies of different organizational units should be aligned and linked to achieve cost-efficiency. The strategy provides the insight and direction to guide them to increase their strengths, eliminate the overlapping activities and improve the quality of activities.

The ICT center creates synergies across the separate HEIs that aim to increase economic growth and welfare in the local community. The departments of autonomous institutions have intensive interactions with each other. The degree programs of the HEIs benefit from synergies through the sharing of students and staff. They also share libraries, data networks and other facilities which reduce costs and enables higher quality.

The learning of knowledge and skills is the driver of an organization's success (Collis & Montgomery, 1995). Rucci, Kirn, and Quinn (1998) studied the drivers of the future performance of business companies. Their analysis reveals how improvements in training and employees' understanding of the business led to better outcomes. It has also been found that awareness of strategic objectives is one of the key driving forces.

The knowledge-based synergies among the different units enable the whole ICT center to be more valuable than the sum of its parts (Collis & Montgomery, 1995; Goold, Campbell & Alexander, 1994). Typically the strategies of various educational departments are rather similar so that they can be aggregated into larger entities. In this case the different ICT departments have their historical backgrounds and strengths. Their strategies can be combined into the cooperative network strategy of the ICT center.

The importance of cooperation was evaluated in a survey from the different perspectives of the balanced scorecard on the scale 1-5, where 1 is low and 5 is high (Kettunen, 2004; Puustelli, 2002). According to the perceptions of the respondents from the HEIs the cooperation is most important from the perspective of regional development (mean 4.4), customer (mean 3.9) and learning (mean 4.1). Joint ventures, data networks, problem-based activities, and science parks are the most important forms of cooperation from the perspective of regional development. The perspective of customer underlines the subject-related activities. Also the joint ventures and joint support units are evaluated to notably increase the customer value. A pleasing result is that learning is an important motivating factor for cooperation. The finance and internal processes perspective have the lowest importance for cooperation according to the respondents (means 3.9). There are clear financial benefits only in data networks and research schools. These results are obvious, because the HEIs are able to benefit from economies of scale.

Strategy Maps Describe the Way to the Future

The strategy map is a visual representation of the cause and effect relationships among the components of an organization's strategy and a great insight to executives and stakeholders in understanding the strategy (Kaplan & Norton,

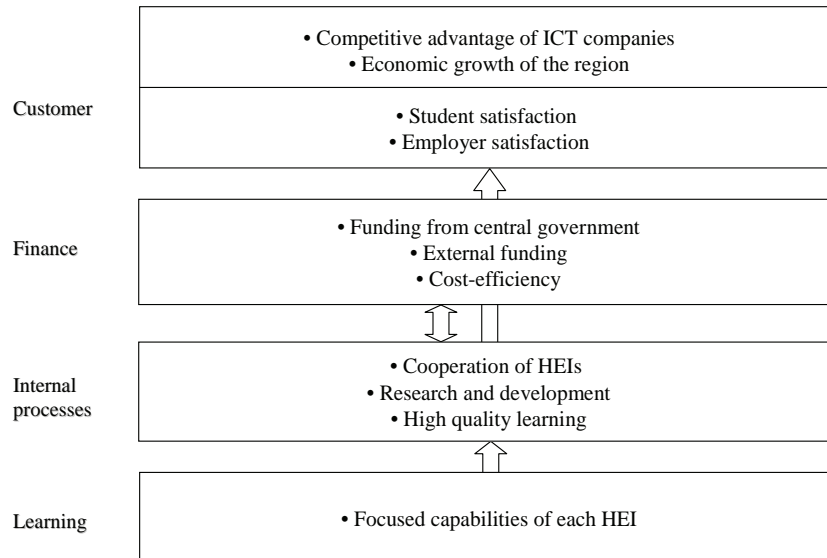

2001, 2004). It has been used in thousands of companies and other organizations. Strategy is a way to a better future described by the organization's vision. The strategy map is simply a graphical representation of the strategy. Strategy maps describe the essential characteristics of the strategy like a road map, but omit all the minor details. They help the employees and stakeholders of the organization to understand why the objectives of the organization have been set and how they can be achieved.

Strategy maps provide tools to describe the strategic themes and help the management of the organization to define the objectives in the different perspectives. Strategy maps describe the causal linkages between the objectives. They provide a comprehensive description of the functioning of an organization and provide an organizational theory, which communicates the organization's desired outcomes and how these outcomes can be achieved. The balanced scorecard approach was selected for the City of Turku and HEIs to provide them a common and understandable framework of indicators. The approach is used in many other cities and educational institutions in Finland.

Figure 1 presents the strategy map of the ICT center, which includes customer, finance, internal processes, and learning perspectives. The perspectives include objectives that have to be achieved in order that the final outcomes in the customer perspectives can be achieved. The objectives in the perspectives and the linkages between the objectives help to understand the strategy, which is necessary for the efficient implementation of the strategic plan. Cost efficiency and improved learning are obvious reasons for the cooperation, but it is difficult to quantify them.

The customer perspective contains two blocks describing the regional development and customer satisfaction. The objectives of the regional development are the competitive advantage of ICT companies and the economic growth of the region. The objectives of customer satisfaction include

Figure 1. The strategy map of the ICT center

student satisfaction and employer satisfaction. High quality learning and employment opportunities are sources of student satisfaction. Employers are satisfied with skilled labor. Customer satisfaction provides feedback on how the ICT center is doing. The objectives in the financial, internal processes, and learning perspectives have to be achieved to achieve the desired outcome in the customer perspective.

The financial perspective includes the objectives of funding from central government, external funding and cost-efficiency. An important objective of the ICT center is to increase the cost efficient activities so that the HEIs can improve the quality and provide better service for companies. The external funding is primarily used to finance research and development. The funding from central government is used to finance education. The funding is a prerequisite for the internal processes but, on the other hand, the cost effective processes ensure sufficient funding.

The internal processes perspective includes the objective cooperation of HEIs. It also includes the

sequential process of research and development and high quality learning. Each HEI identifies and develops its strengths. Overlapping activities are avoided and cooperation between the HEIs is carried out. The cost efficient organization of education makes it possible to increase the resources used in research and development.

The learning perspective includes the objective focused capabilities of each HEI. Each HEI has its own historical background. The ICT center provides shared premises, which afford better possibilities to develop and intensify the cooperation between the HEIs. The strengthening of the capabilities of the personnel is the driver for the objectives in the internal processes perspective.

The strategy map was used in a press conference by the representative of Turku Polytechnic. It helped the journalists to understand the objectives of the ICT center. The analytical presentation got plenty of publicity in the media (e.g., Karvonen, 2004; KunnallisSuomi, 2005). The strategy map was also used in many meetings arranged during the construction of the new ICT building.

It helped the persons involved in the project to create a shared knowledge and joint understanding of the efforts and steps needed to reach the strategic objectives.

STRATEGIC INITIATIVES TO IMPLEMENT THE STRATEGY

Managers typically specify short-term milestones along the strategic path. Once targets for measures have been set, it is possible to assess whether the short or medium-term targets can be achieved by challenging resources in annual budgets to achieve them. If the managers conclude that by solving local problems for continuous improvement of the internal processes, the targets cannot be achieved, then there is a need for long-term development.

In order to satisfy customer needs and improve the competitive advantage of customers, the goal for the strategic initiative should focus on substantial cost reductions and quality improvements. In the longer run, managers should develop or reengineer processes that could be critical to the organization's strategic success, rather than merely applying process redesign where minor gains might be obtained. The managers should link the investment decisions to their strategic plans and long-term priorities. They should be committed to achieving the objectives and at the same time accountable for achieving the organizational vision by directing significant resources.

Strategic initiatives can be planned in a balanced way to effectively implement the strategy. All the necessary objects of the different perspectives must be taken into account. The essence of the strategic initiative is to develop the internal processes to achieve the desired strategic objectives and value for customers. However, sufficient funding is needed to develop internal processes. In addition, sufficient coherence and learning are needed to maintain strategic awareness and capabilities for the change.

The first plans to establish the center were made at the end of the 1990s in order to increase the competitive advantage of the ICT companies and economic growth in the region. The measures were planned in numerous meetings, where specific targets were described and agreed. Precise steps were gradually taken, and a timetable was planned and responsibilities were assigned to named groups and individuals.

Turku Polytechnic was the first institution to commit to the investment in 2002. Shortly after that the University of Turku and Åbo Akademi University made their decisions gradually so that the construction of the new building of more than 30,000 square meters of floor space could be started in 2004. A property developer, Kiinteistö Oy ICT, was established in 2004 to own the building and rent the premises to the HEIs. The construction work will be completed soon and the cooperation can be started from 2006.

CONCLUSION

For several years the various organizational units had a long planning process, which led to mutual understanding about the need to invest in the ICT center. The City of Turku played an active role in the planning of the ICT center to the area of the Turku Science Park, where the educational institutions are located. Each educational institution, however, made their own plans separately and took their own investment decisions following the mutual understanding and commitment to build the ICT center.

The strategy of cost-effectiveness combined with the strategy of focus is the basis for the overall strategy of the ICT center. According to the general strategic statement the center strengthens the expertise of HEIs and increases the competitive advantage of companies in the global markets, so that each HEI develops its strengths to better serve its customers and the increased cooperation

of HEIs enables cost-effective and high-quality operations.

In this case, the balanced scorecard approach is a useful tool to describe and communicate the strategy. It can also be used to accomplish its strategic themes, objectives and measures for the partnership projects. It turns out that the balanced scorecard can also help the institutions to plan a common strategy for the several departments operating in the same center. It assists the senior executive teams of the educational institutions in specifying objectives and allocating resources to achieve the objectives.

The strategy map is a useful tool to translate the strategic statement and strategic themes into a graphic representation which clearly describes the objectives in the different perspectives of the balanced scorecard. Furthermore, the strategy map describes the linkages between the objectives and helps the personnel and external stakeholders to understand why the ICT center has been established and specific objectives have been set and how these can be achieved.

This study shows that the planning period of an investment may last for several years, but in this case it took only 4-5 years. However, sufficient time is needed to describe and quantify the different needs of educational institutions. It is paradoxical that the construction takes much less time than the planning. Unfortunately the balanced scorecard approach was found only at the very end of the planning period. The experiences of this study show that rigorous planning methodology is needed to shorten the planning period and fulfill the various needs of the cooperative partners.

Chapter 4.18

Integrating ICT in Universities: Some Actual Problems and Solutions

Vassilios Dagdilelis

University of Macedonia in Thessaloniki, Greece

ABSTRACT

Universities adopt the most progressive, technologically speaking, methods of research and education. Nevertheless, the adoption of ICTs (Information and Communication Technologies) appears to be necessarily accompanied by a deep shift in the organization of work, and this adoption must to be included in a wider teaching and learning strategy. We present some of the problems arising when ICT systems are integrated in universities and some suggestions to deal with these problems.

INTRODUCTION

Computers and more generally speaking, ICTs (Information and Communication Technologies), have penetrated substantially into every area of human activity: from research to entertainment and from medicine to business management, ICTs have revolutionized the methods used by humans up to now. The field of education is no exception

where ICTs have had a strong impact, perhaps the greatest since the invention of printing. Thus, ICTs seem to be advancing at great speed, and generally are being accepted and adopted by educational institutions, especially universities.

Universities and other similar organizations of higher education constitute socially recognized institutions assigned mainly to research, education, and services. By their very own nature, universities adopt the most progressive, technologically speaking, methods of research and education. Under these conditions, it is expected that they will thus adopt the most contemporary instructional technologies, especially ICTs. In addition, universities are obliged to adopt ICTs, not only because of their nature, but also due to the strong economic, political, and social pressures from external sources — and in actual fact, pressures which often appear for the first time. ICTs offer the possibility of expanding the student body, making available a more flexible schedule, as well as the improvement of teaching methods through the creation of teaching environments with multiple possibilities. Nevertheless, the adoption of ICTs

appears to be necessarily accompanied by a deep shift in the organization of work, and this adoption must be included in a wider teaching and learning strategy (Bates, 2000). Further, ICTs are also the means through which institutions of higher education will be able to respond to the new economic and social demands.

Instructional Systems Design methodologies, such as ADDIE, constitute a generally accepted tool for the design of instructional applications. It has been applied successfully in many cases in the design and the development of modern educational applications. Unfortunately, however, ADDIE cannot be applied to the university instructional systems without some additional work and consideration. Furthermore, it must be added that the design of a new instructional system for the university must take into account the fact that the designed system will function within a larger system, the university itself.

Universities have their own structure and by consequence, new systems like an instructional system destined to function within them must be integrated. Moreover, universities and other similar institutions are also part of a system of larger institutions, with society itself as the largest one. Each one of these institutions, as a kind of homocentric cycle, includes the institutions of the “lower” level and is included in the “higher” one. Universities, for example, are part of institutions of higher education, which is part of the educational system and so on. An analogy is that of live organisms living in a specific environment. Their environment (e.g., a lake) is a part of the regional environment, which is part of a larger ecosystem. Thus, in order to study the function of one organism, we must take into consideration its own internal structure, its parts and their interrelatedness, and also the ecological conditions that govern its interaction with the environment.

Returning to the issue of universities, it is argued that the understanding of their function must be based on the study of their internal structure

and of their “ecology,” i.e., their interaction with the other institutions. Institutions of higher education are influenced both by local as well as general trends which prevail in the economic, political, and social fields. However, it must be kept in mind that the institutions, in turn, also influence these trends (Marginson & Rhoades, 2002).

All the factors, which are included in this interaction, have not been adequately analyzed nor validated — even though many attempts have been made at an international level to create a theoretical framework that would allow for their analysis (Marginson & Rhoades, 2002).

The strong interaction between institutions and the integration of universities into larger institutions creates some complex problems not easily dealt with when tools like ADDIE are used. Traditional ADDIE methodologies are meaningful when applied to a stable environment with known variables. New technologies, besides introducing novel ideas, also change the environment. For this reason, ADDIE does not seem to be a sufficient tool, able to integrate these elements in the construction of a new educational system. In some way, using ADDIE leads to a paradox, because the more a tool like ADDIE is needed, the more insufficient it becomes, as it cannot take into account the consequences of a radical change.

Below, are some of the problems arising and some of the affecting conditions when ICT systems are integrated in universities, and some suggestions to deal with these problems.

SOME IMPLICATIONS FOR ICT IN UNIVERSITIES

As already referred to in the introduction, it is the actual nature of universities that leads them to adopt the most advanced technological systems. However, in the case of ICTs, external factors are applying pressure to the universities more than at any other period in time. Universities are knowledge-driven organizations and thus it is only to be

expected that they will be influenced by progress in ICTs, especially since universities themselves were one of the pioneers in this progress.

First of all, ICTs have had an influence on a fundamental activity carried out by universities, namely that of research (Duderstadt, 1998). The influence has been so deep that nowadays it is absolutely inconceivable to conduct research without the use of ICT: from the actual research procedure which may be based on simulations or huge calculations to the communication among the researchers, all stages of the research appear to need ICTs.

Apart from research, ICTs are used to a large extent by university administration and recently they are also being used in teaching. A basic benefit of ICTs in teaching is their ability to create rich learning environments, which at least theoretically, contribute to the development of more successful teaching methods. In other words, their basic benefit, that which most affects the running of teaching institutions, is that they offer new ways of communication. The new technological possibilities that — thanks to ICT — have been opened up today, allow educational services to be delivered to anyone at any place and at any time, without the limitations of space and/or time (Bates, 2000; Duderstadt, 1998; Langlois, 1997). It is estimated that the effect of ICTs will become even greater — given that no other technological invention in the past, neither the radio nor television, influenced educational institutions so intensely and in such a short period of time (Bates, 2000; Duderstadt, 1998; Langlois, 1997).

The network of relationships in institutions of higher education with the other social institutions, of course, includes the interaction of the institutions among themselves. The institutions are not only interacting when they belong to the same administrative area — State or Nation — but also when they are in the same categories: for example the institutions involved with molecular biology obviously are in constant contact with each other and influence one another. This interaction, as a

rule, has a number of general characteristics: institutions all over the world, more and more, look alike. Institutions of higher education, for instance, tend to be almost homogeneous. Although this procedure is rather complex, it can be explained, due to two types of mechanisms.

The first type is classical: the same reasons cause analogous results, thus, while globalization tends to equate the economic and cultural environments in which universities function, it also causes similar reactions on their part. The second type of mechanism, connected to the first, is that which can be described as the “snakelike procession of academic drift” (Morphew, 2000). This is the idea that as the snake’s tail “follows” the same route as the head, in the same way the least successful academic institutions will follow the most prestigious ones. However, the image of the “snakelike procession” is not fully accurate because the less well-known institutions do not actually follow the same route as the successful ones but just *mimic* them. For example, if a prestigious university adopts a successful strategy after a trial period, then the other institutions will also adopt this same strategy, but without necessarily passing through all the intermediary trial stages. For this reason the process of homogeneity develops faster. If this hypothesis of homogeneity is correct, then strategies adopted by one category of institutions, in this example the most technologically advanced, will in the long run also be adopted by the other institutions all over the world.

An obvious example is the Greek Open University (www.eap.gr), which was established in 1993 and which adopted the successful strategies of other Open Universities around the world. This tendency to be homogeneous comprises a powerful factor that influences the formation of modern universities. Thus, when the large and prestigious universities adopt ICTs, this becomes an indirect factor for the small universities to also adopt them.

SOCIAL AND ECONOMIC FACTORS

However, the most important factors affecting the integration of ICTs in universities are those of an economic and social nature. There is a series of interacting factors which more than anything else not only define the strategy of universities toward ICTs but also, more generally, determine indirectly many of the changes universities make. The study of such complex factors is based on a series of ascertainments or developments. The first development is that the number of students has been increasing much faster over the last 30 years. This increase includes not only the number of “typical” students, i.e., those who go to institutions of higher education straight out of secondary education (18- to 20-year-old high school graduates), but also the number of the mature-aged students who come from a variety of socioeconomic backgrounds. The latter have particular characteristics: they are, as a rule, already employed and have specific training needs that are required in order for them to remain competitive in the employment market. Therefore, neither the regular university schedule nor their presence on campus, nor the typical curriculum of institutions of higher education, meets the needs of these mature students. Their social importance, nevertheless, as well as their economic power makes them as important or even more so than the typical students. Universities are thus called on to readjust in order to cope with the new demands. Mature-aged students have very specific needs, which are directly linked to their type of work. For example, nowadays, production requires the use of a workforce that is computer literate and prepared to undergo independent lifelong learning. Universities are to a degree obligated to readjust under these social pressures.

As is natural, the increased demand for education creates a similar increase in the running costs of universities. The university expenses, however, for research, education, and the rendering of services, have increased at even greater

speed: universities function because of the highly trained staff and the facilities and special equipment, which are all very expensive. Universities are driven by an ever-expanding knowledge base; access and exploitation of this knowledge, likewise, have a very high cost.

At the same time as the cost of the running of universities is constantly increasing, government and other funding sources are drastically being reduced (Katz & Associates, 1999; Bates, 2000; Duderstadt, 1998; Langlois, 1997): “Not only in the USA and in the EU, but internationally has public support for higher education flattened and then declined over the past two decades.” In the USA, this downward trend is obvious at all levels — for example, the aid toward students in the form of grants has been replaced with help in the form of loans. This reaction, on the part of universities, is analogous to the local conditions.

In the USA, there appears to have been an increase in tuition fees that is much higher than the Consumer Price Index. This fact has provoked public interest as to the profitability of investment (public and private), which is made in institutions of higher education. In the EU, the programs are geared all the more toward the direct needs of the economy. Therefore, universities are obliged to readjust to the new social and economic situation.

INFORMATION AS A COMMODITY AND A BUSINESS

Additionally, the great demand in teaching services has an indirect result: information and knowledge, more than at any other time, have become an economic good — and their use appears to be regulated more by the market forces and less by the current governing policy. This means that universities now face external competition. It appears that they are losing, to an extent, their formerly exclusive production of new knowledge, and the power and authority to educate and certify knowledge and skills. Today, large organizations

and businesses are establishing their own educational departments, which offer “just-in-time” and “just-in-case” extra training to their employees. Also, new businesses are appearing, whose only activity is to offer educational and training services. Virtual Universities and “learning-ware” providers are entering the marketplace to compete with traditional institutions (Duderstadt, 1998). It is thus clear that the universities are experiencing multiple external pressures and need to readjust. Clearly, this readjustment is directly connected to ICTs. The use of ICTs in no way decreases the overall functioning costs of a university since its costs are initially high and the equipment used is very quickly outdated. Nevertheless, under the right circumstances, ICTs can lead to improved cost-effectiveness by enabling new target groups to be reached and new, higher quality learning outcomes to be gained at a lower marginal cost per student than through conventional classroom methods (Bates, 2000).

Universities are also undergoing internal pressure, from their own nature and function. The necessity of adopting new technologies because universities have as a basic aim the adoption of modern methods has already been mentioned. To this must be added the fact that university students, who are not simply computer literate, but are actually the so-called “Plug’n’Play generation,” expect the institutions at which they are studying to make extensive use of ICTs — and especially now, since ICTs have been integrated into all levels of human activity such as work and entertainment. Very often, universities are in a position of competition among themselves and their technological infrastructure is an important factor in attracting more and better students.

Finally, the actual members of the academic community who are involved with ICTs also apply a type of pressure either toward the direction of the market for new equipment or toward the direction of employing even more staff for research and teaching that will use ICTs for the institution.

THE UNIVERSITY ECOSYSTEM TODAY

Studying institutions of post-secondary education, within the nexus of their relationships with other institutions, allows for a more complete understanding and interpretation of the problems which arise. In fact, we support the position that the internal and external pressures force universities and in general all higher educational institutions to adopt ICTs and at the same time to alter their own status. This change is so deep-rooted that many believe that universities and institutions of higher education generally will cease to exist in the way that they have been known until now. There are two very important changes: (1) changes in the economic funding of these institutions, especially of universities; and (2) changes in the actual functioning, not only at an internal level of organization, but also the types of services they will provide.

Diversity is a good example. In many countries, diversity has become an important issue in higher education policies. Diversity can be seen as an answer to the continual expansion of universities. It is comparable to the differentiation of studies and services offered by the academic institutions (form, duration, direction) but also in the differentiation between the actual institutions themselves (size, location, type of institution). However, even though diversity has as a general aim the satisfaction of social needs, a number of researchers observe that diversity can and should be analyzed within the framework of a purely economic analysis (Dill & Teixeira, 2000), and believe that diversity and the related concept of innovation are economic concepts and as such they should be analyzed. Considering these concepts from an economic point of view raises a specific *problématique*: “From this point of view, an academic innovation would be considered as a way to better satisfy universities’ customers or to create a clear benefit for the innovating Higher Education institution” (Dill & Teixeira, 2000).

Apart from diversity, a second example is the economies of scope, i.e., the fact that complementary products, which are available simultaneously, function successfully. Thus, some researchers include both doctoral and contract research in this category of complementary products (Dill & Teixeira, 2000).

THE UNIVERSITY AS A BUSINESS

The overall activities, therefore, of a higher educational institution can be put to an economic analysis. Universities and other institutions of higher education in general seem to be progressively losing their academic characteristics and acquiring those of a *business*. For many economic researchers, the only plausible response to the pressures that universities are under is based on a conceptual change: universities, from non-profit organizations functioning on the basis of government subsidies, will be considered as “for-profit firms” (Jongbloed, 2002). In this situation, the influence of the general environment on the functioning of universities will be even stronger, since, for example, the most significant factor for the adoption of innovations will be the wider structure of the market (Dill & Teixeira, 2000). These phenomena, i.e., the obligatory restructuring of universities, can be explained by the fact that the economy itself is being transformed in its entirety from a manufacturing economy into a network economy (Jongbloed, 2002).

It is common to refer to the principal aims of the university in terms of teaching, research, and service. But these roles can be regarded as simply the 20th century manifestations of the more fundamental roles of creating, preserving, integrating, transmitting, and applying knowledge (Jongbloed, 2002). Universities perform a basic function in “creating, preserving, integrating, transmitting, and applying knowledge” (Duderstadt, 1998). In the 20th century, this function was realized in a particular way and thus, universities organized

themselves accordingly so as to produce new knowledge, to transmit this knowledge, and to offer services in accordance with social, as well as other needs of the century. In the 21st century, universities will therefore function more as a type of knowledge server rather than in the way they are operating today. If the more contemporary language of computer networks were to be used, the university might be regarded as a “knowledge server,” providing knowledge services (i.e., creating, preserving, transmitting, and applying knowledge) in whatever form needed by contemporary society.

From this more abstract viewpoint, it is clear that while these fundamental roles of the university do not change over time, the particular realization of these roles *does* change — and in fact, quite fast.

PROBLEMS IN ADOPTING ICTS AT UNIVERSITIES

This whole trend of adopting ICTs and the gradual restructuring of the universities is not without obstacles nor is it unconditional. The main obstacle in the adoption of ICTs comes from the actual nature of the universities, which is basically conservative. For certain academic circles, the use of ICTs could be rather dangerous: “many readers...may think of higher education’s relationship with information technology as a dance with the devil...many of us in higher education now wish that we could push the information technology genie back into the bottle” (Katz & Associates, 1999). Universities have long produced and disseminated knowledge in an old-fashioned way. Traditionally, universities have functioned in a specific location and cater to mainly a specific age group (late teens — early twenties). In addition, the produced and transmitted knowledge is directed toward a relatively limited local group of students. Nevertheless, the new trend reverses this situation and there is a type of inertia at universi-

ties, which is being called on to change a number of their rather strong functioning stereotypes.

What we consider as a major problem in the design and use of ICTs for educational purposes is directly related with the importance of ICTs. As has been stated, integrating ICTs implies a major change for any organization. By their own nature, universities are well-structured institutions, and unavoidably the integration of ICTs leads to a radical change in their function and the balance of “forces” within the system. These changes arise at many different levels: changes in allowing resources for the technological infrastructure and the restructuring of the courses, in order to exploit the new possibilities offered by ICT, constitute typical examples of profound changes which finally influence the whole structure as well as the function of universities.

Experience shows that the adoption of ICTs, even by the most dynamic institutions of higher education, takes place gradually and at a very slow pace. The internal rivalries of researchers, who have dissenting views, are a common phenomenon. A significant factor in this situation is the fact that the university staff is not always acquainted with ICTs. It is not, in other words, computer literate. Naturally, the use of ICTs and the reorientation of a university’s activities require not simply computer literacy but rather a much deeper knowledge of ICTs. This deeper knowledge is many times lacking in the staff members, especially those in fields which are not based on technology, like the Humanities.

At the other end of the spectrum, many obstacles can be found for courses delivered via the Internet. In order to deliver courses via networks, the existence of a fast, robust, reliable, and cheap network (in some places mostly telephone lines) is necessary. Often, for many countries or regions, not even telephone lines are reliable or cheap. It is also necessary that the potential students have the fundamental skills needed in order to be able to follow these courses. The increase in the power and functionality of ICTs, as well as the falling

prices, have contributed to ICT adoption and use in developed and newly industrialized countries — but this remains untrue for large sections of the population within these countries that include a large number of other nations.

In some cases another problem arises, that of *institutional recognition* of the courses delivered from a distance. The low cost of these courses, coupled with the increased demand for new ones, has led to a general tendency for the creation of even more new courses. Their institutional status, however, can remain undefined and a large sector of the educational system refuses to accept the total equivalence of these courses to traditional ones delivered only by recognized institutions.

The consideration of institutions of higher education institutions on economic terms is naturally a choice. Viewing universities as a business is contrary to their academic character, not only generally and ideologically, but also in terms of specific strategic choices. A characteristic feature is the example of appropriability. Appropriability is an important factor in the adoption of innovations. If the diffusion of an innovation is too simple, then not only the business that devised the innovation and which was burdened with the costs of this invention will benefit, but also will its competitors. For this reason, there are fewer incentives for the adoption of innovations (Dill & Teixeira, 2000). However, this principle is in total contrast to academic ideology, which believes in the dissemination of new knowledge without rules and restrictions. Thus, universities will most likely ignore this principle. For example, MIT’s recent decision to make its courses available on the Internet is an expression of MIT’s choice for openness. Cited in Vest (2001): “We have built a system of higher education that is the envy of all the world, and we have developed the Internet as a universal medium for rapidly distributing and accessing information. These forces must now combine to raise educational opportunity throughout the world.”

A second example is the strategic response from universities to the increasing pressure of internationalization, i.e., “the integration of an international dimension into the teaching, research, and service function of higher education” (Van der Wende, 2001). The Anglo-Saxon countries have chosen a categorically stated and at times aggressive — competitive policy, whereas the European countries seem to prefer a more cooperative policy (Van der Wende, 2001).

Universities, therefore, as social institutions must adapt or they will disappear. “Thirty years from now the big university campuses will be relics. Universities will not survive. It is as large a change as when we first got the printed book” (Lenzner & Johnson, 1997). Their readjustment does not mean merely the adoption of ICTs and a few new programs. Universities and institutions of higher education in general must reorganize from their foundations and most importantly redefine their business concept (Jongbloed, 2002).

The views expressed above are most likely exaggerated. However, even if the situation is not as stated, the problem remains open, even on a different scale.

THE STATE OF INSTRUCTIONAL DESIGN TODAY

Up to this point an attempt has been made to explain that the constant pressures, both internal and external, on the universities to integrate ICTs are accompanied by strong pressure for restructuring, which allow them to keep their initial role, but which make them, most probably, operate on a different basis.

Within this framework, it would seem that the traditional methodologies for instructional design are non-existent because they do not seem to take into account all the new parameters, which must now be included.

Many models have been proposed as a more general consideration of the new factors, such as

ACTIONS (Bates, 2000). Khan (1999) proposes a model for the analysis of Web-based courses, which includes many more options than traditional tools. Linguistic themes, cultural considerations and motivations, institutional influences, cost analysis, and so on need to be considered during design. Despite all the proposed analytical tools, none of them seems to be generally accepted. It is, however, very clear that the traditional methods of lesson planning are seriously insufficient at the level of instructional analysis.

The new methods of teaching educational content present many new elements which are not integrated in ADDIE — which presupposes the existence of a class of students with known characteristics, face-to-face teaching, and so on. These basic suppositions, however, do not apply to the new educational frameworks in which distance learning takes place. In fact, the new educational environments are based on a rapidly expanding technology, little researched and little understood (Philson, 1998). Furthermore, up to now, research into the quality of Open and Distance Learning (ODL) has been technology-driven rather than pedagogy-driven (Langlois, 1997).

One important problem arising in Web-based and other technology-based courses is related to their (instructional) efficiency — or inefficiency, as the case may be. Even though potentially ICTs can play a very positive role in teaching, this still remains a strong hypothesis and many researchers have emphasized the absence of a specific pedagogy. To be more precise, the exact conditions necessary to construct a pedagogically efficient course are not known. This seems to be especially true in cases where teaching consists of practical exercises. If one agrees with the constructivist hypothesis, which nowadays is widely accepted, knowledge, either in a procedural or a declarative form, is constructed through a process of interaction between the learner and their environment. In most cases, however, the interaction between them in distance learning courses is very poor, and thus the efficiency of

delivered courses is rather questionable in some cases. For example, one of the most promising computing products is that of the so-called open microworlds such as the language LOGO, the physics environments such as Interactive Physics, the Dynamic Geometry environments such as Cabri-Geometer or Geometer Sketchpad. The most contemporary software of this type consists of simple, open environments, but which also integrates possibilities of dynamic variation and direct use of objects. However, to a large extent, nowadays we are not aware of what might be the most successful use of these environments (see, for example, Jonassen, 2000). ICTs are supposed to be able to improve the quality of teaching, but generally we do not know the methodology to achieve this. The ADDIE methodologies, as a rule, are functional in the analysis and creation of lessons in succession and at specific levels of teaching — whereas the possibilities being opened up by the new educational environments allows that lessons be organized on different bases.

In addition, the new educational environments include not only “local” microworlds in which students can conduct experiments, trials, measurements, and generally develop a variety of activities, but they also offer a variety of communication possibilities inside and outside the classroom. Thus, thanks to ICTs, a new type of organization of the classroom is created and often the teacher within this framework is called on to play a new role. Nevertheless, ADDIE methodologies do not have, as a rule, the possibility to integrate and analyze these new didactic situations and remain at that level.

ICTs’ strongest influence, however, in institutions of higher education appears to be related to the provision of distance learning lessons and mainly to asynchronous teaching. This is because in essence, these types of lessons will allow the institutions to have a significant cost reduction resulting in a reduced cost of teaching per student.

A difficulty in the design of online lessons is the extreme diversity of the public to whom they are geared. Subjects intended for an international public are especially difficult, requiring a more complex procedure since factors of language, and culture and teaching problems that may arise, all have to be taken into account, as these lessons are available to “anyone.”

A second level of difficulty is related to the teaching theory usually implemented with online lessons. Online lessons, in their current form, are most times rather simplistic from the point of view of teaching, and it cannot be sure that they can replace live lessons. As is well known, in a traditional classroom situation, there is a very strong interaction between teacher and students. This interaction is not merely typical; it is not only based on words but on the entire context of the situation. The teacher, for instance, is able to either emphasize or dismiss a student’s answer with gestures of the hands, the expression on the face, and in many other ways. This process is neither marginal nor insignificant, but rather it is very important since it consists of a very significant aspect of the teaching process. The lack of this type of communication in distance education is obviously a disadvantage, and it is not known how it can be overcome. It is the same for the very strong interaction between students, which in distance learning is either totally missing or is replaced by communication through the Net. The lack of direct interaction between those taking part, as is the case with those of a traditional classroom, is thus a disadvantage for distance learning, at least in the way that it exists today. This disadvantage naturally increases in the cases when practical application and the learning of practical skills are required on the part of students.

Up to now, online lessons have been designed with low teaching specifications: they are in fact e-books with very little interaction with the student and have closed-type exercises. Especially in the situations where new concepts are intro-

duced — and particularly where these concepts do not conform to the intuition and experience of students — the understanding of these concepts requires, as a rule, rich teaching environments, and the online environment, as has been shown, is relatively insufficient.

From their experience, teachers gain a whole range of knowledge, which enables them to recognize not only the mistakes but also why those mistakes were made, i.e., students' misconceptions. In this way, a mistake made on reasoning, a question apparently without meaning, and generally students' actions are gauges for the teachers who do not intervene in the mistake itself, but rather in the reason for the mistake. If, for example, students insist that a lighter weight body falls slower than a heavy one, the teacher is able to understand that the students have not simply made a mistake, but obviously have not understood the concept of gravity, and thus the teaching involved will not simply be to correct the mistake, but rather to correct the misconception.

Nevertheless, the methods for expressing in a typical manner the teacher's informal and empirical knowledge are still not known (except for commonplace situations such as the above) and thus we are not yet able to "implement" this knowledge within a system of teaching. The teaching systems, which exist at present, do not have the diagnostic abilities an experienced teacher has.

These problems are usually dealt with empirically, according to each case. And in this case, the methodologies of ADDIE are not sufficiently analytical, in order to allow for the creation of successful educational online lessons.

SOME SUGGESTIONS

The problems mentioned above have a common point. They are all related, directly or indirectly, with the profound, radical transformation in the educational process occurring when ICTs

are used. In most cases, tools for the design of new educational systems or courses do not take into account the implications of these systems in the organization where the systems must be integrated.

In addition, these tools cannot integrate the new and to a large extent unknown possibilities which are opened up — as well as their limits and any possible weaknesses. ADDIE enables the design of different educational applications, but within an educational system that remains stable and in teaching environments with typical parameters. It is possible that in the current situation, we are not in a position to expand systems like ADDIE in order to include new elements such as the ones mentioned above, because data collected from experience and research are not sufficient to deal with these complex phenomena. However, the elaboration of this expansion is considered a necessity, and research in this area must be encouraged.

Is there, at present, a technology, which enables a very successful design to be created? Possibly not. As Vest (2001, p. 4) states, "There is not one grand solution. Indeed, I believe that it is too early to declare comprehensive positions and strategies. Rather, it is a time for substantial experimentation and calculated risks that will help us to sort out opportunities and find effective paths." Thus, research seems to be the only channel for the accumulated experience to be expressed within the framework of a new methodology.

Along with experimentation, which is an acceptable, although time-consuming scientific procedure, there is a pressing need for the adoption of strategies for ICTs on the part of universities.

The experience up till now allows certain practical rules to be formulated on the use of ICTs (see for example Langlois, 1997):

- Recognition of the systemic variables and conditions affecting the design, development, and implementation of online courses needs to be incorporated into the instructional systems design process.

- A cooperative policy is a basic choice that universities have. It should systematically cultivate the elaboration of subjects at all levels. At an internal level, cooperation among students, faculty, and technical staff should be cultivated, and at an external level, cooperation with related institutions who also adopt ICTs is advisable both to better understand ICTs and their functioning, as well as to facilitate shared decision-making at all relevant levels.
- Promote and support the development of course material using ICTs. That means not only to promote and financially support the research on methods of teaching with ICTs, but also an open collaboration policy with other agents involved, such as computer firms, software developers, and enterprises designing educational delivery systems. Nevertheless, this progress must not be made at the expense of lessons, which must follow the accepted quality standards.
- Develop a systematic training for faculty members in order for them to be able to use more effectively ICTs in teaching. This training must be based not only on formal courses, but also in collaboration with the technical staff.
- Develop an infrastructure that will support new technologies not only within the confines of the university, but also between universities and generally as widely as possible. Within the framework of this infrastructure, a system should also be developed which makes accessing the lessons easy for all students, either on or off campus.
- Simultaneously support the development of library technology, hand-in-hand with instructional technology.

All these rules are obviously not sufficient to determine in an analytical way the strategy of universities toward ICTs. They do, however, consist of a summary of tried directions, and in

combination with systematic experimental and related research could be used to formulate a more general policy.

Chapter 4.19

Diffusion of Educational Technology and Education Reform: Examining Perceptual Barriers to Technology Integration

LeAnne K. Robinson
Western Washington University, USA

ABSTRACT

This study examines educators' perceived barriers to technology integration and the relationship to education reform. Educators and administrators from four elementary schools in Washington state were interviewed in their classrooms during a 3-month period. The schools differed in size, location and social economic status, and reported variances in their Washington Assessment of Student Learning (WASL) scores. While all of the schools reported similar barriers to the use of educational technology, distinct differences appeared between those schools that had done long-range planning during the reform process and those that had not. Specifically, staff in the two schools that coordinated curricula, performance standards and a variety of assessment tools while simultaneously allowing teachers the flexibility

to alter the curricula were more likely to state personal responsibility for student learning, and they were also more likely to have overcome barriers to the use of technology.

BACKGROUND

In a recent campaign commercial, a candidate spoke of the need to improve education and to create quality schools. Lined up along a white wall behind him were rows of computers with elementary students quietly absorbed in the computer screens. The message to the public was clear: Computers and computing technology are not only necessary for quality schools, but are indicative of good teaching and student learning. If the state was to have youth who would eventually be competitive in a global economy, technology

would need to be at the forefront of funding and government support.

Computing technology has been marketed as the current solution to education's problems (Rockman, 2000), and the quest for technologically equipped schools has grown dramatically. In 2000, the number of computers in schools numbered more than 10 million (Becker, 2000). By 2003, nearly 100% of all public schools had Internet access, and more than 93% of all instructional classrooms were wired for access. The mean average of computers per school was nearly 136 (NCES, 2004). The estimated cost of technology per pupil in the United States (US) was \$103 per pupil in 2005 alone (Education Week, 2005).

PURPOSE

Research in the integration and institutionalization of educational technology was limited in scope in 1994 (Seels & Richey, 1994), and although educational technology is now available, it is not integrated into classrooms today (Becker, 2000; NCES, 2000). Only 43% of elementary classrooms surveyed used computers on more than 20 occasions during the school year (Becker, 2000). Nationwide, school districts are grappling with education reform and accountability while simultaneously attempting to financially support computing technology and encourage integration by classroom teachers. Currently, there is no clear rationale that explains the apparent difficulty with incorporating the use of educational technology and whether or not there is a relationship between the level of technology integration and the pressure teachers experience as a result of education reform efforts. The purpose of this study was to examine how educators in several schools in a Northwestern state were responding to the pressure to integrate technology while simultaneously being accountable for student achievement.

REVIEW OF THE LITERATURE

In January 2002, President Bush reauthorized the Elementary and Secondary Education Act. This bill contained an even larger allotment of money and support for technology from the federal government than previous education bills (Fletcher, 2002). Currently, 48 states have adopted or are developing assessments that align with standards-based reform efforts (Stecher & Chun, 2001). Reform and standards have impacted classroom practice, and schools and teachers have responded in multiple ways (Adcock & Patton, 2001). Often, technology reform and education reform have paralleled each other as opposed to being incorporated (Peters, 2000), meaning that in many instances the purchasing of computing tools and related technology, as well as a plan for staff development, were not coordinated with a building's reorganization and examination of the curriculum and instructional processes. When both education reform and technology integration have been fully combined with curriculum reform, which includes examining pedagogy, positive results have been found for students (Bain & Smith, 2000).

Barriers to Technology Use

In spite of significant pressure to integrate the use of technology into the curriculum, the presence and accessibility of computers in the schools has not shown that the technology is being used by educators or that students actually can or do use it (Cuban, Kirkpatrick, & Peck, 2002; Kalkowski, 2001). Although they are accessible, computers have not transformed the practices of a majority of teachers (Becker, 2000; Labbo & Reinking, 1999) and Willis, Thompson, and Sadera (1999) have pointed out that integration of computers into the classroom actually has been a slow process.

Defining Barriers

In initial efforts to understand why teachers have failed to integrate technology, barriers have been defined as being 'primary' and 'secondary' (Judson & Sawada, 2000; Prater, 2001; Ertmer, Addison, Lane, Ross, & Woods, 1999). Both primary and secondary barriers are explained as being intrinsic and extrinsic (Ertmer, Addison, Lane, Ross, & Woods, 1999). Primary barriers include: lack of access to computers and software, insufficient time to plan instruction, and inadequate technical and administrative support. Secondary barriers include: beliefs about teaching, beliefs about computers, established classroom practices and unwillingness to change.

Diffusion of Innovations and Educational Technology

In addition to defining barriers, researchers have sought to understand why some specific technologies are adopted. The diffusion of innovations is the study of the process by which the use of a perceived new idea, practice or object is adopted within a given social system (Rogers, 1995). The study of the diffusion of innovations is present in many research traditions, including anthropology, marketing, geography, communication and education. Within the overall research arena, fewer than 10% of the studies of innovations have been conducted in education (Rogers, 1995). While Rogers (1995) provides a generic model of the process of the adoption of an innovation, case studies are showing that alternative models may be more applicable to school systems. These models specifically identify educational technology as the innovation being studied, thus the phrase 'diffusion of educational technology' is often used in place of 'diffusion of innovations.'

The diffusion of educational technology models that have been recently presented are non-

linear, implying that many factors are involved in the adoption (or lack of adoption) of educational technology (Dooley, 1999; James, Lamb, Bailey, & Householder, 2000; Rogers, 2000; Sherry, Billig, Tavalin, & Gibson, 2000). These models vary from the commonly cited model posed by Everett Rogers (1995), as they focus solely on educational technology and attempt to identify more specifically those factors that will lead to the adoption of an innovation in a school setting. All of the models have been developed using a limited number of schools, and none of the models clearly indicate why technology integration has been a slow process.

PILOT STUDY ON MEDIA SELECTION

In spring 2001, the researcher conducted a pilot study at a K-6 elementary school to determine how teachers in this particular setting made decisions regarding media selection. While the majority of staff verbally supported the use of computing tools, few used educational technology and instead tended to blame others or cite circumstances they felt were out of their control for a lack of use. The common theme that emerged from the interviews was that regardless of the reason for failing to integrate technology, the teachers in the building were making the majority of decisions based on a highly structured reading program that had been adopted during a school reform process. All related the lack of technology use to some aspect of the school's focus on educational reform and to their concerns related to teacher accountability and a state-required assessment. The results of the pilot study provided an additional foundation for further examination of the relationship between education reform, educational technology and educators' perceived barriers to technology integration.

METHODOLOGY

Theoretical Underpinnings

Authentic technologies (Clark & Estes, 1999) are “educational solutions resulting from systematic analysis that identifies the problem being solved, selects and translates appropriate, well-designed research and applies it to design culturally appropriate educational solutions” (p. 243). A four-stage model proposed by Clark and Estes (1999) for conducting research in the development of authentic technologies provided the theoretical underpinnings for this study. Authentic technologies can include teaching strategies and processes, not merely computing tools. This research is based in the first, or Descriptive Scientific Research Stage, where the defining of constructs and hypotheses generation are the key goals.

Two research questions guided the study:

1. What are teachers’ perceptions of barriers to the use of educational technology/technology integration, and how do the barriers connect to education reform?

2. What are the connections between perceived barriers to the responsibility for computing technology?

Site Selection

Four separate sites from the same Educational Service District in a Northwestern state were purposely selected. A stratified sample was used (Patton, 1990), meaning that the four sites represented four different subgroups for comparison. Two of the schools were located in rural settings and reported variances between their WASL scores (demographics are reported in Table 1 and Table 2). Access was granted through a key individual at each site, and snowball sampling (Patton, 1990) was used. Semi-structured questions were asked and observations were made of the classroom setup and equipment available.

Data Collection

Twenty individuals were interviewed between March and May, 2002. Interviewees included: three administrators, one administrative intern, three reading specialists, 13 classroom teachers,

Table 1. Demographics of selected sites, 2001

School	Location	Enrollment	% of Free and Reduced Lunch
Wrangle	Urban	370 K-6	56.8
Sandal Creek	Suburb	444 K-4	10.3
East Lake	Rural	263 K-6	34.4
Woodland	Rural	304 K-6	44.4

Table 2. WASL scores for selected sites, 2001

School	% Passing Reading WASL (66.1 state)	% Passing Math WASL (43.9 state)	% Passing Writing WASL (43.5 state)	% Passing Listening WASL (72.4 state)
Wrangle	48.8	23.3	27.9	58.1
Sandal Creek	52.7	28	43	71
East Lake	55.8	30.2	23.3	72.1
Woodland	73.2	39	43.9	80.5

a counselor and a physical education (PE) teacher. Each interview lasted between 45 and 90 minutes. All of the interviews occurred within the individual teacher's classroom or the administrator's office. Following the transcriptions of the interviews and during the analysis, the initial contact person at each school remained available to answer specific questions via phone and e-mail.

The International Society for Technology in Education (ISTE) has developed frameworks that provide progressive descriptions, ranging from teachers who do not integrate technology to teachers that fully integrate technology (ISTE Homepage, 1999). These frameworks were converted into a survey and each teacher was asked to identify his or her current level of technology integration. Notes were taken during the interviews, and observations and comparisons were made between the information gathered during the interview and the teacher's reported level of integration.

Data Analysis

Each interview was read multiple times and the researcher looked for themes within each broad category. A list of themes was generated and selective sections of the interviews that corresponded to the potential themes were labeled. For the teachers, the following themes were identified: primary barriers, secondary barriers, school climate, favorite parts of teaching, frustration/needs, teaching practices, accountability and technology-specific responses.

Interviews were coded and sorted in several ways. The responses of those who had high integration scores on the technology integration survey and those that scored lower were separated for comparison. In addition, responses to both primary and secondary barriers were separated into two groups: those who saw an identified bar-

rier as an obstacle that they could not or would not overcome; and those that were attempting to, or had overcome, the identified barrier. Patterns within and between schools were identified, including those who rated themselves high on the integration survey and those who rated themselves lower. Individual profiles for each school were developed and used to confirm the researcher's initial findings from the organizational charts.

INTERPRETATION

After reviewing the analysis, several distinct differences and similarities appeared between the schools. Remarkably similar were the hindrances to technology integration. All barriers cited in the literature were mentioned at every school. These included: inappropriate training or in-service (Kay, 1996; Maor, 1999); collegial jealousy or pre-defined roles (Sherry & Billig, 2002; Reinking & Watkins, 2000; Wood, 2000); lack of appropriate or relevant software instruction (Becker, 2000; Rockman, 2000; Rogers, 2000; Ruberg, 1993; Sia, 1992); teachers failing to find the relevance of technology use or applications to classroom practices (Maor, 1999; Sherry, Billig, Tavalin, & Gibson, 2000; Rogers, 2000); as well as teachers having a lack of space and time within the curriculum (Cuban, Kirkpatrick, & Peck, 2001; James, Lamb, Bailey, & Householder, 2000).

What differed were the role of curricula within the school reform process, the types and uses of assessments and teachers' statements of personal responsibility for both the use of technology and for student learning. Although all of the schools had participated in school reform efforts, the connection between curricula, assessment and instruction varied. These connections and teacher statements of responsibility at the four elementary schools will be highlighted in the following section.

**Curriculum, Assessment,
Instruction and Teacher
Responsibility for Student
Learning: Looking at a
Disconnect:
Sandal Creek and Wrangle**

A disconnect between curriculum, assessment and instruction existed in two of the four schools: Sandal Creek and Wrangle. At Wrangle, teachers were using the structured curriculum as the primary means of addressing problems with student achievement in reading. Teachers were not the decision makers when it came to reading instruction. Instead, representatives from the adopted reading program and a reading coordinator reviewed scores on a regular basis and directed adjustments. The adjustments were not generally instructional, but related to group placement. Teachers felt that they had little say in what and how to teach and were frustrated. In addition, this highly structured curriculum impacted all other school decisions.

I wish I had more time in the day to teach what we are being expected to teach, for one thing. I wish I could veer from the hard and fast philosophy we are living with now. ... I would like to branch out and be a little more creative. It is the way I used to teach. Now we have to stay with the party line. It is boring for me and it is boring for the kids. (Sixth grade teacher, Wrangle, March 28, 2002)

At the other end of the spectrum was Sandal Creek, where very little structured curricula existed. Like Wrangle, teachers at Sandal Creek were also frustrated, but because of a lack of structure.

Actually, I am sitting on a committee right now that is trying to purchase a curriculum. We are

all frustrated with the hodgepodge. (Third grade teacher, Sandal Creek, May 8, 2002)

For new teachers [the reading program] is really hard. The program itself is really hard to follow, because the way it is set up, and there are two different books. It is just hard logistically because the materials that come with it, well, there aren't any ... philosophically [the teachers] like it, but it is not helpful as far as providing resources. (Reading teacher and administrative intern, Sandal Creek, May 8, 2002)

Sandal Creek had virtually no structure or connection between curriculum, assessment and classroom instruction. No curriculum existed, just frameworks. Wrangle teachers were not the decision makers, but were directed by adopted curriculum. Neither of these two schools had teachers who commented on being responsible for the actual learning of the students.

"I know there needs to be some sort of accountability ... but I wish they were less centered on the teachers ... and that the politicians who actually came up with this stuff would point their finger where the real issue is, which is in the home. (Sixth grade teacher, Wrangle, March 28, 2002)

**Making a Connection:
East Lake and Woodland**

At the two other elementary schools, East Lake and Woodland, teachers discussed multiple types of assessments and multiple purposes for assessment. WASL scores were reviewed, but the results from this assessment were not the only measure of student success. District and classroom assessments were used to adjust instruction and determine individual student needs. Both formal and informal assessments were combined to assist in curricular decisions and teachers were expected to make decisions based on their own professional judgment.

Table 3. The role of curricula between Wrangle, Woodland, East Lake and Sandal Creek; comparison of assessments, curricula, instruction and responsibility

	Schools			
	Wrangle	East Lake	Sandal Creek	Woodland
Primary Assessments				
Classroom		X	X	X
School	X		X	X
District			X	X
State	X	X	X	X
Role of Curricula				
Highly Structured	X		X	X
Adopted Curricula and District Frameworks with Flexibility to Adjust			X	X
No Adopted Curricula and District Frameworks		X		
Teachers State Responsibility for Student Learning			X	X
Teachers State Responsibility for Technology Integration	X*		X	X
Teachers State Plans for Overcoming Barriers	X*		X	X

* Indicates a single teacher

Like I said, in major areas [the District does] have priorities where you can teach. Now the way you get there, obviously, is up to the teacher and up to your classroom. There are other teachers in our district, in our school, that don't stick closely to the adopted reading curriculum, but they do hit the major component parts of it. (Sixth grade teacher, East Lake, May 6, 2002)

... and if all [the curriculum process] has been done, the curriculum is critical; how it's adjusted and adapted and delivered to the students is totally a professional obligation and responsibility of that classroom teacher, but they need to be able to know the curriculum well enough to [know] how to adapt it. I would encourage all teachers the first year to use the curriculum closely ... They are going to have to do some adapting and they'll probably have to work with the special education teachers. We check every day on how they are doing. (Principal, Woodland, May 10, 2002)

I don't feel really badly if we don't make the [state test] because it is a different cohort. There are other conditions that apply. Certainly it is a goal for us to look at, and it certainly is one measurement, but I am more interested in looking at individual students over time. If I see that kids aren't making adequate progress in our classroom assessment, then we have to do something different, and that's going to adjust our school plan, which ultimately should result in the [state test] improvement. (Principal, East Lake, March 28, 2002)

Assertion 1. Comparing the four schools, it appeared that when education reform efforts included the integration of curriculum, assessment and classroom instruction, such as at Woodland and East Lake, teachers were more likely to take personal responsibility for student learning. At East Lake and Woodland, curriculum, assessment and classroom instruction seemed closely connected. There was a clear understanding of

both formal and informal assessments. It was only at these two schools that teachers commented on being responsible for student learning, being accountable to themselves. As one teacher stated, “It’s the teacher’s responsibility.”

Integrating Technology with Reform and Teacher Responsibility

At Sandal Creek and Wrangle, technology remained separate from the rest of the school happenings. For example, a technology plan was being developed for Sandal Creek at the district level, as opposed to the school staff formulating the plan. Staff at both schools rarely cited efforts to overcome barriers. They blamed others for the existing barriers and individuals, and made no problem solving references to how to personally overcome an obstacle or influence policy and practice related to technology integration.

... because people aren't telling us what the research base is, so I'm just finding whatever's there and that's what I will use, but I'm not using it to teach kids with. I'm using it as like a reward for having completed whatever things they've done in the classroom, so I'm not thinking of it in terms of curriculum. It is more like ... it is not part of our curriculum, it is something extra for kids who are finished and need an extension of whatever. (Second grade teacher, Wrangle, May 7, 2002)

At both Woodland and East Lake, teachers were more likely to have mentioned having overcome obstacles to technology use. Technology use was seen as part of the total overall piece of instruction, not as something that was separate from or in addition to the existing curriculum. There had been both long-range planning and the integration of assessment with instruction. Technology had been used as a part of the process; both districts had adopted software that committees felt had supported the curriculum and classroom instruction.

I think [technology] is supportive of the curriculum, it just depends on what you're going to use it for. (Fifth grade teacher, Woodland, May 10, 2002)

Technology is a tool. It is not to be, I mean it is not the goal, the technology is not the goal, it is the means to the end and the is ... we model this for kids ... we don't have time in the day to do those free-standing things that aren't tied directly to goals we have for student learning. (Principal, Woodland, May 10, 2002)

Assertion 2. Teachers took more responsibility for technology use when technology integration was not separate from curricula and/or reform efforts. Even if a teacher had not fully integrated technology, teachers at East Lake and Woodland made statements of personal responsibility for technology use:

It is definitely not what we have now; you know, last year I could have said we don't have great computers. But I think it is just a comfort level for me and I think I need to get in and experiment to how to use it myself and then be able to expect my kids do that, so I think it is something that will happen, maybe next year. (Third grade teacher, Woodland, May 10, 2002)

Access to Technology

The concept of homophily (Rogers, 1995) suggests that the adoption of a new technology is more likely to occur if someone similar, such as an equal colleague, introduces it or is successful at using the new technology. It was interesting to note that Wrangle was one of the schools with a disconnect between curriculum, assessment and instruction, yet had more computers per student than any of the other schools. Three of the teachers had received a total of four large grants and every teacher had at least one computer in his or her classroom. Of all of those interviewed, Wrangle also had a teacher that scored higher than any other

on the integration survey. However, Wrangle had less technology use as measured by the Technology Integration Scale. The large grants received by one specific teacher seemed to have isolated her. The technology provided by the grant stayed within the individual classrooms, although the grant recipients did collaborate with each other. On the other hand, Woodland had received a large grant where the technology moved with the students. Following the initial grant year, the student took the technology, in this case portable word processors, with them to the next grade. The new teachers then began utilizing the technology because the students were accustomed to it and it was still available to them.

Wood (2000) found that teachers who were next to one grant recipient often were jealous and those with the technology were often discouraged from sharing, isolating them from their peers. This was seen at Wrangle. Teachers were often angered by the technology grant recipients who, every year, collaborated in the creation of a play. Two classrooms were involved in the development of the play and the integration of technology throughout was apparent; brochures, advertising, film editing, lights and music were all developed. One of the teachers who was interviewed and had observed the play asked the researcher to figure out, "How, exactly, does that fit with curriculum?"

Assertion 3. For technology to be used in a school, access to technology needs to be made for all. It should be noted that the literature suggests that access to technology does not guarantee that teachers will utilize it (Cuban, Kirkpatrick & Peck, 2001). At Woodland, where the lab provided ample access, some teachers still hadn't used the lab. However, even though the teachers were hesitant, they were not unwilling to try or had future plans to increase use. Once access is provided, addressing individual perceptual barriers and actual needs may be the next step. In schools where there is no access or access is restricted to

specific classrooms, it seems unlikely that other teachers will seek to integrate technology.

DISCUSSION

Schools cannot be centered solely on technology, or just assessment or curricula. Schools that become too focused on one area can neglect the others. To better understand how technology use can be supported, the school processes need to be viewed from the perspective of student learning first. What are the factors that directly influence and impact student learning? Such things as the relationship of curricula, assessment, accountability, leadership style, resources and the individual needs of the teacher need to be examined in a global context. Technology integration fits into many of the categories, but technology alone will not guarantee student learning. It is simply one factor that may contribute towards meeting student learning goals.

Two models of the diffusion of educational technology have identified that the point of rejection of a new technology occurred when teachers failed to see relevance for the learner (Sherry, Bilig, Tavalin & Gibson, 2000; Rogers, 2000). On completion of this study, it seems necessary to further define the diffusion of educational technology models so that they encompass more than one technology and provide direction related to the overall process of technology integration. Technology integration within schools must exceed the adoption or use of a single technological device or application. Most of the models of adoption take a technology-centered view. Even a holistic model presented by Dooley (2000), where internal and external factors of integration are viewed in the context of the school along with types of change facilitators, presents technology as the central focus.

CONCLUSION

Re-Conceptualizing the Role of Technology

The integration of technology into today's classroom needs to be viewed as an integral component of a more comprehensive package of education reform. Although the literature often uses the phrase "integrate technology" to imply that technology is to be part of multiple areas of education, including curriculum, assessment and instruction, it is often presented as the focal point or treated as a separate component. Student learning is truly at the center of education. Perhaps a more appropriate phrase would be to, "Enhance teaching and learning through the effective use of technology." Performance standards or frameworks are in place in almost every state. Curriculum and assessment should be used to inform instruction. Technology and best practices need to be examined within the context of each area of the educational system, and technology integration needs to be re-conceptualized and presented within the context of an entire school system (Figure 1).

For teachers to overcome barriers to technology integration, teachers need to feel in control both of the classroom and the available technology,

be able to take responsibility and have a sense of accomplishment. These three areas can be applied to the use of a single technological innovation, but can and should be applied to the broader context of a school system. Too many schools are taking away the ability for teachers to be responsible. Teachers are being given scripted curricula and are told what to teach and which assessments must be given, as opposed to being given the freedom to make appropriate choices about instruction and appropriate assessment.

Recommendations for School Improvement

Several recommendations can be made for school improvement and restructuring.

First, combine technology with other reform efforts. Make the connection between the uses of certain technologies or best practice with continued student achievement. This can take many forms; projects for increasing student learning, specific software applications for student use, appropriate assessment and continued classroom management. Isolating technology, or any other component of reform, such as curricula, creates frustrations and limits vision.

Second, schools need to have the ability to overcome multiple primary barriers. Focusing on

Figure 1. Conceptualization of the role of technology

one barrier, such as access, neglects the others. Teachers are unique, have differing skills, and need different opportunities for growth. Meeting one need does not guarantee integration; other barriers will arise and the ability to address them needs to be available for all. This includes not limiting materials and resources provided by a grant to a single classroom. This can isolate a teacher from his or her peers and create potential school climate issues. If a teacher does receive a grant, plans for future growth for other teachers within the building need to be thought through. This is the same for the students. What about those students who spend a year in a technology-rich classroom, followed by several years in a technology-poor classroom, or those students at the same grade, because of placement in a certain classroom are then denied access to computing tools? Solutions to the one technology classroom may include team teaching, or cross-age projects.

Third, long-range planning needs to be done for all school restructuring. School goals need to be created within a holistic context that include the close scrutiny of curriculum, assessment practices, how teachers are matching classroom practices with established frameworks and how teachers are implementing best practices in instruction. Building goals should be developed followed with the examination of individual teacher needs. It simply is not enough to set goals without taking into consideration different barriers that individual teachers may face. Teachers need to be active participants in the decision-making process. Student needs are more likely to be met when teachers are able to make active decisions regarding curriculum, assessment, instruction and the use of technology.

Chapter 4.20

Evaluating the Learning Effectiveness of Using Web-Based Instruction: An Individual Differences Approach

Sherry Y. Chen
Brunel University, UK

ABSTRACT

The use of Web-based instruction is becoming widespread in higher education; however, much remains to be learned about how different learners react to such instructional programs. The study presented in this article evaluates students' learning performance and their perceptions in a Web-based instructional program, which was applied to teach students how to use HTML in Brunel University's Department of Information Systems and Computing. Sixty-one master's students participated in this study. A number of interesting interactions were found. Students' task achievements were affected by the levels of their previous system experience. On the other hand, the post-test and gain scores were positively influenced by their perceptions and attitudes toward the Web-based instructional program. The implications of these findings are discussed.

INTRODUCTION

Due to the popularity of the World Wide Web (Web), there has been a considerable growth in the use of Web-based instruction. Bonk et al. (2001) stated that no technology has so rapidly become prominent in educational settings as the Web-based instruction. From educational insights, Web-based instruction seems to provide answers to problems confronted by traditional teaching in higher education, such as large class (Freeman, 1997), and students from disperse locations (Dede, 1996). However, the drawback is that Web-based instruction employs hypermedia techniques to present information in a non-linear format. On the one hand, non-linear interaction provides learners some control over the instruction. On the other hand, the responsibility for designing learning paths becomes that of the students. Learners have to decide in what order the topics will be accessed (Sweany et al., 1996).

If learners lack such a skill, their performance may be hindered; in turn, they may have more negative attitudes toward using Web-based instruction programs (Dringus, 2000). It suggests that the use of the Web-based instruction may not improve learning effectiveness (Cummings, Bonk & Jacobs, 2002), and individual differences are critical factors for the successful use of Web-based instruction programs (Chen, 2002). However, there is little empirical evidence of the learning effectiveness of Web-based instruction (Bork, 2001). Therefore, many more empirical studies are needed, because such evaluation can provide concrete prescriptions for improving the design of Web-based instruction. In this vein, the study reported in this article aims to investigate how individual differences influence students' learning effectiveness within a Web-based instruction program.

The article begins by building a theoretical framework to present the relationships between Web-based instructional programs and individual differences. It then progresses to describe an empirical study of students' learning experiences in a Web-based instructional program. Subsequently, the design implications are discussed based on the findings of this empirical study.

THEORETICAL FRAMEWORK

Web-Based Instruction

Web-based instruction provides a revolutionary educational environment (Brooks, 1997), and it is increasingly being used to deliver course content in higher education (Nachmias & Segev, 2003). Perhaps the most obvious advantages perceived by the students are dynamic interaction and flexible schedule. In terms of dynamic interaction, the Web-based instruction presents an enormous amount of information through various interconnections that offer students a rich exploration environment. The development of Web-based

instruction provides learners with many opportunities to explore, discover, and learn in theory according to their own individual needs. Students can create individualized learning paths to reach the desired goals, move at their own speed and retrieve additional information as needed (Hui & Cheung, 1999). There is a shift away from didactic instruction to discovery of information (Smaldino, 1999). This approach is in line with the constructivist philosophy of learning where the learner is encouraged to interact with the environment to construct individual knowledge structure (MacDonald et al., 2001).

With regard to flexible schedule, Web-based instruction allows learners to read course content through a computer network at any time and at different places (Chang et al., 1998). Burton and Goldsmith (2002) found that such flexible schedule makes Web-based instruction appealing to the students, including the convenience of not having to be on campus during the week, ease of arranging personal commitments, and ability to take courses around work schedules. This type of learning may be particularly beneficial to individuals who live in remote places (Daugherty, 1998). The individuals living in remote areas can have access to the same course content as those living in big cities. This is the reason why many educators have tried to develop a distance-learning program on the Web. As pointed by Clark and Lyon (1999), the Web-based instruction has been predicted to be the future of all types of distance learning programs.

However, these advantages may come with a price. Power and Roth (1999) reported that the Web-based instruction is more dynamic and flexible than other learning material, but it creates new challenges related to the effect on learners' comprehension. Ng and Gunstrone (2002) indicated that although students had positive perceptions to self-based learning provided by Web-based instruction, the unstructured nature of the Web made some of the students need more time to search information. Quintana (1996) stated that

while students gained the advantage of flexibility in time, pace, and distance with Web-based instruction, many students, on the other hand, felt isolated, experienced lack of motivation, or lack of support and feedback, and consequently to dropped out of the course. Hedberg, Harper, and Corrent-Agostinho (1998) indicated that some students are still working to come to grips with a new and difficult way of learning. They exemplify the concern by asking for more incentive, more time, more structure, and more guidance.

These studies provide evidence that not all types of students appreciate being given freedom in their learning processes. In particular, students who need more guidance through the learning process may meet an increased number of problems in using the Web-based instructional programs. To address this limitation, the Web-based instruction should be developed to support the unique needs of each individual learner (Carter, 2002). Only when their needs are identified can developers of programs effectively enhance functionality and increase learners' satisfaction (Ke, Kwakkelaar, Taic & Chen, 2002). Therefore, understanding of learners' individual differences arguably becomes an important consideration in the development of Web-based instruction programs.

Individual Differences

Individual differences play an important role in learning. Individuals differ in traits such as skills, aptitudes and preferences for processing information, constructing meaning from information and applying it to real-world situations (Jonassen & Grabowski, 1993). The effects of users' individual differences on task performance in a computer-based learning environment have been one of the growing research areas (Wang & Jonassen, 1993). According to Egan, there are at least two reasons why system designers should pay attention to the differences among the users:

“First, individual differences usually play a major role in determining whether humans can use a computer to perform a task effectively. Second, our understanding and technology have reached the point where it is possible to accommodate more user differences.” (Egan, 1988, p. 544)

Individual differences variables that have been found to be influential factors accounting for learning performance include gender differences (Ford & Chen, 2000; Ford & Miller, 1996), domain knowledge (Lawless & Kulikowich, 1998), and system experience (Chen & Ford, 1998; Reed & Oughton, 1997). In terms of gender differences, previous research indicates that gender differences influence users' navigation strategies in Web-based instruction. Schwarz (2001) found that females and males request different kinds of support when locating particular information. Male users need a larger frame of reference while female users ask procedural directions.

With respect to domain knowledge, research suggests that less knowledgeable users experienced more disorientation problems in Web-based instruction (Last et al., 2001). This may be due to the fact that they are unfamiliar with the subject matter of the text, so they cannot rely on prior knowledge to help them structure the text. On the other hand, more knowledgeable users may experience fewer navigation problems because their greater grasp of the conceptual structure of the subject matter can enable them to impose structure on the Web (McDonald & Stevenson, 1998). In regard to system experience, novices and experts demonstrate different attitudes toward the use of Web-based instruction. Liaw (2002) found students' experience using the Internet to be a good predictor of their computer and Web attitudes. Furthermore, Torkzadeh and Van Dyke (2002) found the transition from low experience to high experience could improve Internet self-efficacy.

Results from these studies suggest that individual differences play an important role in the

use of Web-based instruction programs. These studies also indicate that further empirical works are needed to identify the learners' different preferences, and their results may help to guide the development and evaluation of Web-based instructional programs. This article presents such a study, which aims to examine how individual differences influence students' learning effectiveness within a Web-based instructional program.

RESEARCH DESIGN

Web-Based Instruction Program

The Web-based instructional program that was used to host the HTML tutorial began by introducing the learning objectives and explaining the available navigation approaches provided in the instructional program. The contents were divided into three sections: (1) What is HTML? (2) Working with HTML, and (3) Relations with SGML and WWW. Section 2 is the key element of the Web-based instructional program that covers 12 sub-topics of HTML authoring. Each sub-topic was further split into five parts comprising (a) overview, (b) detailed techniques, (c) examples, (d) related skills, and (e) references. Information

was presented in texts, tables, index, and maps.

The tutorial screen was divided using frames. In the top frame, there was a title bar showing the section name being viewed and the other available section buttons. In the left frame were the Main Menu, Index, Map, and Quit buttons. The right frame displayed the main content for each section, including topic buttons and text-based hypertext links.

In terms of navigation control, the Web-based instruction program took advantage of the features of non-linear learning and provided students with freedom of navigation. Topics and sub-topics could be studied in any order. In other words, students were allowed to decide their own navigational routes through the subject matter. Three types of navigation control were available in this tutorial as shown in Table 1.

Pre-Test & Post-Test

Examining student learning outcome in theoretical knowledge was conducted by using a pre-test and a post-test methodology. The students were evaluated with the pre-test to examine their levels of prior HTML knowledge and with the post-test to assess learning achievement. Both tests were presented in paper-based formats and included

Table 1: Illustration of the Three Types of Navigation Control

Control	Purposes	Tools
<i>Sequence Control</i>	To allow students to decide the sequence of subjects to be learn	<ul style="list-style-type: none"> • <i>Subject Maps</i>: to show all topics and sub-topics in a hierarchical way; • <i>Keyword Index</i>: to list keywords in an alphabetical way; • <i>Back/Forward</i>: to see the page previously visited;
<i>Content Control</i>	To allow students to control the selection of the contents they wish to learn	<ul style="list-style-type: none"> • <i>Section Buttons</i>: to choose three sections of the main content; • <i>Main Menu</i>: to present main topics; • <i>Hypertext Links</i>: to connect relevant concepts;
<i>Display Control</i>	To allow students to choose one of several display options that cover the same concept	<ul style="list-style-type: none"> • <i>Display Options</i>: to include overview, examples, detailed techniques, and so forth.

20 multiple-choice questions with only one right answer. The formats of the questions were similar, with only the specific subject of the question modified. The questions covered all three sections of the Web-based instruction program from basic concepts to advanced topics.

Students were allotted 20 minutes to answer each test and were not allowed to examine the content presented in the program at the same time. Student learning outcome was assessed by:

- *Post-Test Score*: each student's score on the post-test, ranging from 0 to 20, in order to identify general learning performance;
- *Gain Score*: score difference between the pre-test and post-test in order to measure improved learning performance by taking the HTML tutorial.

Task Sheet

Students were assigned to do a practical task that involved constructing a Web page using Notepad in order to measure skill-based learning outcomes. The practical task entailed 10 key areas (e.g., creating hypertext links, changing background colors, formatting text, etc.). A printed task sheet describing the detailed features of the Web page to be completed was given to the students, who were allowed to decide the order in which they attempted to complete the task activities on the sheet. They were also allowed to look at the content of the HTML tutorial simultaneously. One and a half hours were allocated to complete the task. The starting time and the end time for each student were recorded. Student task achievement was evaluated by:

- *Task Score*: a score consisting of summing items successfully completed, on a 0-10 scale;
- *Task Time*: the total time spent for completing the tasks.

Exit Questionnaire

The questionnaire was divided into two parts. The first sought information regarding biographical data relating to the student and her/his experience of using computers, the Internet, and HTML. The second, which was the main focus, consisted of three open-ended questions and 47 closed statements to collect student responses to the Web-based instructional program. It took students approximately 20 minutes to respond to all of the questions.

The open-ended questions were related to student opinions about the strengths and weaknesses of the HTML tutorial and the barriers that they met. Students were requested to express their opinions in their own words. Enough space was provided for them to write their opinions. The closed statements were designed to collect information about student comprehension, preferences, and satisfaction or dissatisfaction with the Web-based instructional program. It included five sections: (A) level of understanding; (B) content presentation; (C) interaction styles; (D) functionality and usability; and (E) difficulties and problems.

Each closed statement could be classified as either in favor or not in favor of the program. The number of "favored" statements was almost equal to the "not-favored" statements (20 favored statements and 27 not-favored statements), in an attempt to reduce bias in the questionnaire. All statements used a five-point Likert scale consisting of: "strongly agree," "agree," "neutral," "disagree," and "strongly disagree". Students were required to indicate agreement or disagreement with each statement by placing a check mark at the response alternative that most closely reflected their opinion. Their perceptions and attitudes were measured by:

- *Positive Perceptions*: the total score for all favored statements of the exit questionnaire with the same Likert scale;

- *Negative Attitudes*: the total score for all not-favored statements of the exit questionnaire with the same Likert scale.

Procedure

All participants took part in the study in the same room at the same time and interacted with the Web-based instructional program using Microsoft's Internet Explorer. The participants were asked to do the following activities:

1. Complete the pre-test to ascertain levels of prior knowledge of HTML
2. Interact with the Web-based instructional program (i.e., HTML Tutorial)
3. Complete a practical task, which involved constructing a Web page using HTML
4. Complete the post-test to identify their learning performance
5. Complete a paper-based exit questionnaire to describe their personal details and to reflect on their opinions of the Web-based instructional program.

Data Analyses

To investigate how individual differences influence student learning in the Web-based instructional program, the data obtained from pre- and post tests, practical tasks, and exit questionnaire were used to conduct statistical analyses to identify student learning experiences. Pearson's r was applied to find the correlations between individual student differences (i.e., gender differences and prior knowledge) and their learning experience (i.e., learning performance and perceptions). The Pearson correlation test reveals the nature and extent of association between two variables and is appropriate for the analyses of binary data and interval data (Stephen & Hornby, 1997). A significance level of $p < .05$ was adopted for the study. In addition, the mean scores are employed to describe the learning outcome for each individual group.

FINDINGS

Overall Results

The participants ($N=61$) consisted of Master's students at Brunel University's Department of Information Systems and Computing. Despite the fact that the participants volunteered to take part in the experiment, the sample was evenly distributed in terms of gender and system experience. They were 32 males and 29 females. The computer experience and Internet experience reported by the participants ranged from average to excellent on a five-point scale. Their familiarity with the subject content, *HTML authoring*, ranged from none to good. There was similar proportion of computer and Internet experience and HTML authoring in both male and female groups. In terms of the perceptions and attitudes, a majority of the students (78%) felt that the Web-based instruction program was useful and they liked the Web treatment of the content.

Tasks vs. Tests

As indicated earlier, students needed to be assessed by both practical task and paper-based tests. It is important to note that both task and tests were markedly different; distinctions similar to those between open-book examination and closed-book examination were noted. The practical task was completed in open-book examination style, with students building Web pages guided by the task sheet. The practical task could be completed successfully without recourse to memory by applying knowledge read from the screen at the particular time it was needed. On the other hand, the post-test, which was a multiple choice factual test, entailed recalling knowledge from memory, and completed after learning using the Web-based instructional program, looked like a closed-book examination. These differences can also be associated with those between *procedural knowledge* and *declarative knowledge*.

Derry (1990) distinguishes between these two. Procedural refers to knowledge of how to do things, while declarative refers to knowledge about the world and its properties (McGilly, 1994). Practical tasks refer to procedure knowledge of how to use HTML, while paper-based tests refer to declarative knowledge about the properties of HTML.

Pearson's correlations found that student task scores were affected by the levels of their previous Internet experience ($r=.44$) and HTML authoring ($r=.35$). On the other hand, the post-test and gain scores were positively influenced by student perceptions and attitudes toward the Web-based instructional program. In other words, the students who had more positive perceptions toward the Web-based instructional program ($r=.40$) could obtain better post-test and gain scores than those who had more negative attitudes ($r=.46$) toward the program.

The findings of the study implied that performance on the practical task of applying procedural knowledge could be promoted by prior system experience in using the Internet and HTML authoring, but it would not be affected by the matching or mismatching of instruction with the student preferences. Conversely, the ability to recall declarative knowledge appears to have been mainly facilitated by matching instructional presentation with learners' preferences, but it is not influenced by prior system experience of using the Internet and HTML authoring.

Gender Differences

There were interesting correlations between student learning performance and gender differences. Female students performed better than male students in the post-test. Conversely, the male students outperformed the female students in the practical task ($r=.39$). The differences between the post-test and practical task can be related with those between declarative knowledge and procedural knowledge. It implies that female students

are better at acquiring declarative knowledge rather than procedural knowledge. Conversely, male students are skilled at gaining procedural knowledge instead of declarative knowledge.

For learning attitudes, male students were patient in completing the task. On the other hand, female students felt nervous doing the tasks, and some of them ($N = 10$) gave up doing the tasks within 15 minutes. In addition, female students needed more guidance than male students did. Female students tended to ask for instruction from the tutor instead of trying to correct errors by themselves. These findings are in line with some previous studies that found males showed more interest in using and learning about computers while females reported fear of using computers and feeling helpless around them (Koch, 1994; Shashaani, 1994). For this phenomenon, educators should help female students build their confidence in facing the challenge of using computers instead of giving too detailed instructions. In addition, educational settings should ensure that instructional programs developed should not place any students at a disadvantage due to their gender differences (Owen & Liles, 1998).

Prior Knowledge

Through analyzing student prior knowledge, one thing seems evident. For doing practical tasks, students who had greater experience using the Internet ($r=.27$) or HTML authoring ($r=.28$) seemed able to look for relevant information in an efficient way. Conversely, students who were lacking prior knowledge of the subject content needed more time to decide the learning paths for completing the task. It seemed that students' existing knowledge did influence their interaction with the Web-based instructional program. These findings arguably supported results from previous studies (Gay, 1986; Shih & Gamon, 1999) that found a positive relationship between learner control and prior knowledge.

Expert learners who had an adequate amount of prior knowledge of the subject felt familiar with the interface and the contents of the Web-based instructional program. They were confident about being more active when navigating the Web-based instructional system. On the other hand, novice learners might not be aware of the best order to read the material or recognize the most important information. Therefore, it is important to provide novice learners with an initial phase of orientation relating to both interface and domain contents (Linard & Zeillger, 1995). One of the ways is to provide visual paths that can be displayed by means of cues to indicate how far students are along a path or by giving some conceptual description for the possible sequences. The alternative way is to provide good labels for the pages. Labels that clearly indicate the role of a particular page may help novices successfully decide on the appropriate coherent path (Lewis & Polson, 1990).

Learning by Doing

In this Web-based instruction program, students were asked to do a practical task (i.e., design a Web page with HTML). A significant number of students (44%) reported that doing the task was a useful way of helping them to set a focus in the Web-based instructional program. From these 44% of students, 52% of them could obtain the post-test scores above the average (= 10.4) and 63% of them demonstrated more positive perceptions of the Web-based instructional program. These results implied that “learning by doing” could assist some students to set their effective learning strategies. As indicated by Smith and Parks (1997), tasks serve to simulate “goal directed” browsing in such a way that learning performance can be enhanced.

On the other hand, a few students (30%) reported that doing the task hindered their learning. They found that they lost other important information that they needed to learn because

they were concentrating on doing the task. From these 30% of students, 58% of them obtained the post-test scores below the average and 54% of them showed more negative attitudes toward the Web-based instructional program. This raises some interesting questions for further studies to consider (a) whether task activities can facilitate promoting student learning performance in a Web-based instructional program; and (b) what the relationships are between student attitudes and their learning patterns as reflected in a Web-based instructional program with/without setting tasks.

CONCLUSIONS

The aforementioned findings provide evidence that Web-based instructional programs may not be suitable for all learners as an instructional methodology. Instructors must be aware of individual differences such as gender and levels of prior knowledge possessed. Some learners, for example novice learners, may need greater support and guidance from the instructors, while others may be able to follow Web-based instructional programs relatively independently. Thus, instructors should not assume that every student would benefit equally from Web-based instructional programs in educational settings. There remains the need for guidance to ensure that all learners attain their learning potential.

Implementing Web-based instructional programs is a complex process composed of interactions among students, instructional content, and the features of Web-based instructional programs. It is important for educational settings to have a good plan in advance. Instructors should remain cautious about making a sweeping decision to convert entire curricula into Web-based instructional programs. The goals of such a process should be weighed against the potential problems (e.g., alienating certain learners). To avoid alienating a certain group, instructors should continue to

incorporate a number of different teaching strategies into their lectures. In addition, this transition requires time for the student and time in the classroom to acquaint the students with Web-based instructional programs. This is especially the case for students who have difficulties in independent learning; there is a need to let them have more time for this shift. With this issue in mind, such innovation in teaching and learning will be more meaningful and valuable.

This study has shown the importance of understanding individual differences in the development of Web-based instructional programs, but it was only a small-scale study. Further studies need to be undertaken with a larger sample to provide additional evidence. The other limitation is that this study adopted a self-developed pre-test and post-test, so the reliability and validity of these tests are questionable. Therefore, testing and modification of the tests are needed in the future. There is a need to conduct future research that would examine the impact of other individual differences such as cognitive styles, cultural background, or domain knowledge. Such research should also be conducted within a more sophisticated multimedia Web-based instructional program, including the presentation of animation and video. It would be interesting to see how individual differences influence student learning in multimedia Web-based instructional programs. The findings of such studies could be integrated to build robust user models for the development of personalized Web-based instructional programs that can accommodate individual differences.

ACKNOWLEDGMENT

This study has been performed as part of the project "Human Factors in the Design of Adaptive Hypermedia Systems: A Cognitive Style Approach" funded by the UK Engineering and Physical Sciences Research Council (EPSRC Grant References: GR/R57737/01).

EDITOR'S NOTE

The author has generously offered an expanded discussion of the research design as well as the survey instruments and assessment tools explored in this article. For copies of this supplementary information, please contact the author via e-mail.

Chapter 4.21

Quality of Online Learning Applications: Impact on Student Enjoyment, Motivation, and Anxiety

Leping Liu

University of Nevada, USA

ABSTRACT

The purpose of this study was to explore the influence of the design-quality of current online K-12 learning applications on student learning via three learning-related variables (student enjoyment, motivation and anxiety level when using those online applications). Nine hundred online K-12 applications (WebQuests, online drills, games, tests and other applications) were evaluated in terms of four design factors (quality of information, design of information, quality of technology use and design of technology use) in relation to the three learning-related variables. Three prediction models were generated and tested in this study. An intermediate effect was found between the design of online application and student learning, which may provide some insights for teachers when they integrate online applications into teaching and learning. The target audience of this chapter may be school teachers, designers or professionals who use online applications for educational purposes.

INTRODUCTION

The Internet has been used in many ways to promote teaching and learning (Aviv & Golan, 1998; Barnard, 1997; Berge, 1997; Coombs & Rodd, 2001; Lengel & Lengel, 2006; Thorsen, 2006), from the use of Web-based resource to the employment of Web-based instruction (Berge, Collins, & Dougherty, 2000; Bonk, Cummings, Hara, Fischler, & Lee, 2000; Cunningham & Billingsley, 2006; Fishman, 1997; Miller & Miller, 2000; Riel, 1992; Trentin, 2001). In the literature, one common use of the Web in K-12 teaching and learning appeared to be the utilization of existing online learning applications, such as tutorials, drills, games or video products developed and posted onto the Web by other educators or designers (Clark & Jorde, 2004; Glazer, 2004; Hillman & Moore, 2004; Liu, 2001; Lombard, 2004; Murphy, 2004; Perkins & McKnight, 2005; Shelly, Cashman, Gunter, & Gunter, 2003; Stvan, 2005). It is hard to imagine and estimate the num-

ber of learning applications available on the Web today: A Google search on “math game” resulted in 691,735 items; and a random exploration on 10 links found that on average, 25 to 35 online math games were under each link.

Unfortunately, the effectiveness of using those online learning applications on student learning achievement was ambiguous (Maddux, Ewing-Taylor, & Johnson, 2002). In a study that consisted of 102 technology integration cases, Johnson and Liu (2000) found that the use of existing Web activity did not significantly contribute to either the success of the technology integration or student learning outcome. The issue is that if the use of those online applications could not effectively improve learning, such tremendous amount of resources would be a huge waste, and sometimes may cause confusion.

Many studies have explored the possible causes of such unsatisfied use of the Web, and suggested that a lack of design was one common weakness in educational applications, such as online communication, online course and online instructional content or activity (Liu & Maddux, 2003; Liu, 2003; Schweizer, Whipp, & Hayslett, 2002; Boer & Collis, 2001). The purpose of this study is to explore the influence of the design quality of current K-12 online learning applications on student learning.

In this chapter, first, the definitions and major types of K-12 online learning applications are introduced. Next, variables examined in this study are identified, including four design-related variables that are derived from a technology integration model (Liu & Velasques-Bryant, 2003; Liu & Johnson, 2003a, 2003b), and three learning-related variables that have been found to have direct impact on learning achievement (Liu & Johnson, 1998; Liu, Maddux, & Johnson, 2004). The four design-related variables are then used to evaluate the quality of 900 online K-12 learning applications in relation to the three learning-related variables. At the end, a set of quality-

related models that illustrate the relationships are generated and tested.

LITERATURE REVIEW

Online Learning Applications

In the context of current study, the term *online learning application* can be defined as *any entity of instructional contents or activities delivered through the Web* that has the following features:

1. It intends to teach a focused concept
2. It meets specific learning objectives
3. It provides a learner-centered context
4. It is an individual piece that can be used and reused.

The concept of *learning application* in this chapter is very much similar to that of a widely discussed term—*learning object*, besides that a learning object is an object-oriented application (Barker, Winterstein & Wright, 2004; Murphy, 2004; Doderio, Aedo, & Diaz, 2002). The author carefully chose not to use the term *learning object*, because some learning applications examined in this study were not object-oriented, and could not concisely fit the definition of a learning object.

Types of Online Learning Applications

A learning application can present learning content, provide learning activity, contain simulation or allow for student assessment. Generally, types of online learning applications can be sorted by format and function.

Two major formats of online learning application are: (a) hypertext-format, and (b) hypermedia-format. Hypertext-format learning applications are developed with HyperText Markup Language (HTML) or other hypertext editors. Examples

include WebQuests, online lecture notes, reading materials or other text-based instructional materials. There are two types of hypermedia-format learning applications: One type includes applications developed directly with scripting language, such as HTML, DHTML, XHTML or JAVA; incorporating with multimedia products, such as graphics, animations, video or audio clips. The other type includes those initially developed with multimedia authoring software, such as Flash, Director, Authorware, ToolBook or HyperStudio. They are converted to a Web run-version, and then published onto the Internet. Examples can be online games, drills, tests or video products.

Two major functions of current online learning applications are: (1) providing information, and (2) providing interactions. Some applications are developed to provide content information or guidelines to learning activities, most of which are hypertext format. Some dynamic Web activities or those pre-designed multimedia instructional programs are developed to carry out interactions, which enable users to interact with the learning application directly from the Web. Currently, more and more online learning applications tend to have both functions.

To select an appropriate online learning application for students, teachers may want to consider whether its format and function fit the learning objectives, content structures, the nature of activities or the grade level of the students. The selection is usually based on the design-related quality of the application.

DESIGN OF THE STUDY

Design-Related Variables

According to a design model Liu and Velasques-Bryant (2003) summarized from a review of 20 years' research and practice in the field of technology integration, successful design of a technology-based instructional application

should reflect the *merging* of three components: information, technology and instructional design. Based on this model, four variables are identified to measure the design-related quality of an online learning application:

1. **Quality of information:** Evaluates the quality of content information (e.g., the accuracy, clarity, currency or verifiability of the contents).
2. **Design of information:** Measures the extent to which instructional design components are integrated into the content (e.g., audience analysis, content analysis, assignment design and delivery, assessment implementation, or the match between the required thinking skill and the developmental stage of the targeted audience).
3. **Quality of technology-use:** Measures the quality of technology applied in the learning application (e.g., screen design, orientation, navigation or interactions).
4. **Design of technology-use:** Examines the extent to which instructional design principles are integrated into the use of technology (e.g., the match between content information and the media use or delivery methods, or the match between required technology skill and the grade level of targeted audience).

All online learning applications in this study were evaluated with these four design-related variables in relation to three learning-related variables.

Learning-Related Variables

Research findings suggest that student learning achievement is influenced by three variables: enjoyment, motivation and anxiety (Liu, Maddux & Johnson, 2004; Liu, 1999; Liu & Johnson, 1998). Students tend to have better performances and higher achievement scores when they enjoy learning (Temple & Lips, 1989; King & Bond,

1996), are motivated to learn (Kellenberfer, 1996; Clariana, 1993; Keller, 1983) or feel less anxious to learn (Liu, 1997; Ayersman, 1996). This study examined these three learning-related variables in terms of how students feel about using an online learning application:

1. **Enjoyment:** Measures the degree to which a student enjoys learning with an online application
2. **Motivation:** Measures the extent to which a student is motivated to learn with an online application
3. **Freedom from anxiety:** Measures the anxiety level of a student when he or she learns with an online application.

According to the purpose of this study, the three learning-related variables were examined to determine an *intermediate effect*, as described in the following logic procedures.

Underlying Logic of the Study

This study was designed to explore the relationships among: A) the design-quality of an online learning application, B) learning-related variables, and C) student learning achievement. The underlying logic of current study follows the three steps:

1. We have known that B influences on C (from literature)
2. If we can determine that A influences B (to be determined), then
3. We can conclude that A can influence C via B (conclusion).

Based on this conclusion, we say that B is the intermediate *variable* between A and C; and the influence “transferred” via B between A and C is the *intermediate effect*. In other words, knowing that learning-related variables influence learning achievement, if the quality of learning applications

influences the learning-related variables, we can conclude that the quality of the learning applications influence learning achievement indirectly, and therefore, an *intermediate effect* exists. This is a method known as *detecting intermediate variable or effect* in educational research (Liu, Maddux & Johnson, 2004). In this study, only the second step was examined.

RESEARCH QUESTIONS

The research questions for this study were:

1. Can *enjoyment* (the degree to which a student enjoys learning with an online application) be predicted by any of the four design variables?
2. Can *motivation* (the extent to which a student is motivated to learn with an online application) be predicted by any of the four design variables?
3. Can *freedom from anxiety* (the anxiety level of a student when he or she learns with an online application) be predicted by any of the four design variables?

METHODOLOGY

Samples

The sample of this study was 900 online K-12 learning applications on the subject areas of arithmetic, algebra, geometry, reading, writing, science, Spanish, history, geography and social science. They were WebQuests, instructional materials, drills, games, tests and instructional video clips. More than 92% of the WebQuests and instructional materials were hypertext information; and more than 86% of the drills, games and tests were hypermedia applications with online interactions.

Of the 900 online learning applications, 375 (see Table 1) were selected by 75 graduate teacher education students, from six classes of an introductory technology course in a western state university from 2002 to 2004. The other 525 applications (see Table 2) were selected by 105 graduate teacher education students, from four classes of an introductory technology course and four classes of a design course in an eastern state university from 1999 to 2002. The distribution of the subject areas and the types of applications are shown in Tables 1 and 2.

Procedures

The author was the instructor of all three courses in the two universities. In the introductory information technology course, students learned basic computing skills and the strategies of technology integration. In the design course, students learned theory and design of computer-based instruction, and created multimedia instructional segments using authoring tools such as Director or ToolBook.

Data were obtained from a technology integration project required for all three courses. In completing this project, each student (referred to as a *mentor*) first located a K-12 student at any

grade level (referred to as a *protégé*). Together, they then determined five learning objectives in one to two subject areas.

After the objectives were determined, the mentor needed to select five online learning applications. He or she was required to do a thorough search on the Web, evaluate seven or more K-12 online learning applications using the design-quality instrument (Appendix A), and determine five applications consistent with the learning objectives.

The mentor then developed five lesson plans. He or she was required to create five learner-centered activities with the use of the five online applications. The instructor provided an instructional worksheet for the mentor to design those learning procedures and activities, which ensured that the major components and procedures of instructional design were included.

The protégé followed the lesson plans, interacted with the five online applications, performed the five activities and completed the assigned learning tasks. Simultaneously, the mentor observed the learning process, and scored the performances in terms of the protégé's enjoyment, motivation and anxiety level toward each online application (using the instrument in Appendix B).

By the time the technology integration project was completed, each mentor had evaluated five online applications and observed the protégé's performances on five learning activities. Therefore, he or she had collected 10 sets of data: five sets of quality evaluation scores on the online learning applications, and five sets of observation scores on the three learning-related variables.

The same procedures were repeated in all classes involved in this study from the two universities. All data were coded and saved for data analysis.

Instruments, Measurements and Scoring

As described above, two instruments were used in this study: The four design-related variables (*quality of information, design of information, quality of technology-use* and *design of technology-use*) were measured by a Likert-Style instrument (Appendix A) consisting of 32 positive statements sorted into four categories, with eight statements in each category. The eight statements in each category measured one design-related variable. Each statement was scored from 1 (strongly disagree) to 5 (strongly agree). The score for each variable was the sum of eight statements, and the highest possible score was 40. Higher scores represented better qualities of a learning application. The reliability coefficient alpha for this instrument was 0.826 from current study.

The three learning-related variables (*enjoyment, motivation and freedom from anxiety*) were measured by another Likert-Style instrument (Appendix B) consisting of 18 statements sorted into three categories, with three positive statements and three negative statements in each category. The six statements in each category measured one variable. The answer for each statement must be chosen from: strongly disagree (SD), disagree (D), undecided (U), agree (A) or strongly agree (SA). For the positive statements, the score for answer SA was the highest (5 points) and for SD was the lowest (1 point); for negative statements, reversely, the score for answer SD was the highest (5 points) and for SA was the lowest (1 point). The score for each variable was the sum of the six statements, and the highest possible score was 30. Higher scores indicate a more positive approach toward the use of an online learning application. The reliability coefficient alpha for this instrument was 0.832 from current study.

The seven variables were qualitative variables. In this study, they were measured quantitatively with the scoring method described above. The Likert scaling implied that each of the items had

the same “level of difficulty.” That is, respondents found them equally easy or difficult to endorse. The reliability coefficient alpha values (0.825 and 0.832) indicated that each instrument did reliably measure each variable, and the scores were “reasonably reliable for respondents like those in this study” (Green & Salkind, 2003, p. 315).

DATA ANALYSIS AND RESULTS

Data analysis was performed in two phases. In the first phase, the *western-data* (data from the western state university, $N = 375$) were used to perform multiple regression analyses in developing the prediction models. In the second phase, the *eastern-data* (data from the eastern state university, $N = 525$) were used to test the prediction models with paired t tests.

Data exploration plots showed that the assumptions of normality and equal variance were not violated, and no extreme outliers were found in the two sets of data.

Phase One: Model Development and Results

The *western-data* ($N = 375$) was used in three multiple regression analyses to develop the prediction models in correspondence with the three research questions. The four design-related variables were treated as predictor variables, and regressed to each of the three learning-related variables.

Results from the First Regression Analysis. In the first regression analysis, the predictor variables were the four design variables: *quality of information* (QI), *design of information* (DI), *quality of technology use* (QT) and *design of technology use* (DT); and the response variable was *Enjoyment* (E).

In the first run that included the four predictor variables, linear model was found significant ($F_{(4, 374)} = 96.373, p < 0.0001$), but one predictor variable—QI—was found not significant to the

model ($t = 0.664, p < 0.507$). Therefore, the next run only included the other three variables: DI, QT and DT. The results showed as the following

The linear regression trend was significant ($F_{(3, 374)} = 128.546, p < 0.0001$). The F ratio indicated that the linear model was the desired model that represented the data better than other regression models. The t statistic for each predictor variable was significant: *DI* ($t = 2.296, p < 0.022$), *QT* ($t = 5.491, p < 0.001$) and *DT* ($t = 5.339, p < 0.0001$), indicating that all three variables significantly contributed to the variation of the response variable *E*. R-Square of the model ($R^2 = 0.510$) indicated that around 51% of the variation of the response variable *E* could be explained by this model, or by the variation in the three design-related variables.

The regression analysis generated a set of coefficients that were used to formulate the *Regression Equation 1*:

$$E = -3.088 + 0.335(DI) + 0.105 (QT) + 0.342(DT)$$

According to this equation, a one-unit increase in DI, for example, would increase 0.335 units on the *E* score.

Results from the Second Regression Analysis. In the second regression analysis, the predictor variables were the same three design variables: DI, QT and DT, because QI was, again, found not significant to the model ($t = 0.222, p < 0.825$). The response variable was *Motivation* (*M*). The results showed as the following:

The linear model was significant ($F_{(3, 374)} = 128.546, p < 0.0001$), and the three predictor variables significantly influenced the response variable *M*, because the t statistics for all three variables were significant: *DI* ($t = 6.241, p < 0.010$), *QT* ($t = 2.259, p < 0.010$) and *DT* ($t = 5.179, p < 0.0001$). R-Square of the model ($R^2 = 0.539$) indicated that around 54% of the variation of the response variable *M* could be explained by this model, or by the variation in the three design-re-

lated variables. The regression analysis generated a set of coefficients that were used to formulate the *Regression Equation 2*:

$$M = -4.098 + 0.398(DI) + 0.123 (QT) + 0.324(DT)$$

According to this equation, a one-unit increase in QT, for example, would increase 0.123 units on the *M* score.

Results from the Third Regression Analysis.

In the third regression analysis, only two predictor variables were included: DI and DT, because *QI* ($t = 1.413, p < 0.153$) and *QT* ($t = 0.071, p < 0.944$) were found not significant to the model. The response variable was *Freedom from Anxiety (FA)*. The results showed as the following.

The linear model was significant ($F_{(2, 374)} = 174.435, p < 0.0001$), and the two predictor variables significantly influenced the response variable *FA*, because the *t* statistics for both variables were significant: *DI* ($t = 3.689, p < 0.010$) and *DT* ($t = 8.056, p < 0.0001$). Around 48% ($R^2 = 0.483$) of the variation of the response variable *FA* could be explained by this model, or by the variation in the three design-related variables. The regression analysis generated a set of coefficients that were used to formulate the *Regression Equation 3*:

$$FA = -3.299 + 0.259(DI) + 0.531(DT)$$

According to this equation, a one-unit increase in DT, for example, would increase 0.531 units on the score of *FA*.

The data analyses generated three prediction models, illustrated by equations 1, 2 and 3. The three models were then tested in the next phase.

Phase Two: Model Testing and Results

The *eastern-data* (N = 525) were used to test the three prediction models; that is, to examine whether the three models and the relationships

developed from *western-data* (N=375) could be used to predict the relationships in the *eastern-data*.

To test the first model (Enjoyment), for example, first we calculated the predicted values of *E* using *Regression Equation 1* (generated from the *western-data*) with the raw data in the *eastern-data*, through four steps:

1. Opening the *eastern-data* file from Excel
2. Creating a new column named “predicted enjoyment scores” next to the column that coded the original raw scores of *E*
3. Adding a calculation function on to this new column according to *Regression Equation 1*: $E = -3.088 + 0.335(DI) + 0.105 (QT) + 0.342(DT)$. In the calculation function, exact column names for the three predictor variables (DI, QT and DT) were used correspondingly. For example, in the datasheet, if the three variables were in columns C, D and E, then the function added into the first cell of the new column should be “=-3.088 + 0.335*C1 + 0.105*D1 + 0.342*E1”
4. Copying this function onto all the cells in the new column. All the calculated values then appeared in this new column, which were the predicted *E* scores.

Second, we tested the enjoyment model (expressed in *Regression Equation 1*) by examining whether there was any difference between the *predicted* values and the original *observed* values of the variable *Et*. If there was no difference, this model developed from the *western-data* had successfully predicted the relationships in the *eastern-data*.

Using this model testing method, we calculated the predicted values of the three response variables: *E*, *M* and *FA*. In addition, three paired *t* tests were conducted to compare the predicted values and observed values of each variable. Results showed that there was no difference between the predicted values and the observed values for each

of the three variables: E ($t_{(524)} = 0.108, p < 0.914$), M ($t_{(524)} = 0.403, p < 0.687$) and FA ($t_{(524)} = 0.011, p < 0.991$). The results indicated that these models could reliably predict the relationships between the quality of online application design and how students feel about using the applications.

The three prediction models have been tested and confirmed, and they can be summarized into the three model functions:

$$E = f [\text{DI}, \text{QT}, \text{DT}] \quad (1)$$

$$M = f [\text{DI}, \text{QT}, \text{DT}] \quad (2)$$

$$FA = f [\text{DI}, \text{DI}] \quad (3)$$

$f []$ indicates a significant linear relationship (“a linear function of ...”)

Function 1 reads “The extent to which students enjoy using the online learning applications is a linear function of the three design-related variables-- *design of information*, *quality of technology-use* and *design of technology-use*.” Functions 2 and 3 can have the similar interpretation.

CONCLUSION AND DISCUSSIONS

In summary, the three research questions have been answered, and three prediction models have been generated, tested and summarized into three model functions. Following the underlying logic of the research design, we may conclude that an *intermediate effect* has been found: the design-quality of online learning applications may have impact on student learning via its influence on students’ enjoyment, motivation and anxiety.

Specifically, when the content materials of the applications were accurate, easy to understand, consistent with the grade level, designed in a learner-centered approach to engage critical thinking and closely related to the learning tasks; and when the application provided a clear layout, interesting interface, easy navigation, convenient assistance information, active interaction and

bug-free running time, the learners would feel more delighted, inspired and less nervous to learn with the online applications. Therefore, they could have better performance and higher learning achievement.

According to the three prediction models, a learner’s *enjoyment* and *motivation* were influenced by the *design of information*, *quality of technology-use* and *design of technology-use*; and his or her *anxiety* level was influenced by the *design of information* and *design of technology-use*. The variable *quality of information* was not significant to any of the three learning-related variables. This does not mean that the variable *quality of information* is not important. One possible cause to the insignificance of this variable may be that all the mentors may have chosen applications with high quality of information presentation and, hence, the variation within this variable was not large enough to make any difference among the scores of the response variable.

The author believed that the sampling of the online applications and the methods of model development had strengthened the study. The 900 learning applications were on the Web over the past 5 years and covered a variety of subject areas, formats and functions. They were evaluated and selected by mentors from two geographical areas in the United States. They should reflect the current trends of online applications. The model development involved two sets of data. The models were generated from one set of data and then tested in the other, which demonstrated the reliability of the models.

LIMITATIONS OF THE STUDY

The author also realized some limitations of the study. First, this study aimed at the overall quality of online learning application design. The author did not conduct in-depth analyses to compare the quality of specific types of learning applications, analyze the quality of specific items under each

design-related variable or examine the quality of the applications by different designers. All the information had been collected, and further analyses will be conducted to explore those details.

Second, the first step in detecting the intermediate effect was based on the literature. In this study, the author did not analyze learning outcomes of the protégés in relation to the three learning-related variables (enjoyment, motivation and anxiety level). To provide a complete picture of the intermediate effect, the impact of the learning-related variables on student learning achievement will be examined with first-hand data in further studies.

Third, the mentors were students from the classes that the author taught over the past 5 years, and the protégés were chosen by the mentors. Although a total of 180 mentors and 180 protégés were not a small sample, they were not randomly selected from the two states. This may influence the generalization of the findings. Therefore, a careful statement may be made that the results and findings best explained the situation within the context of this study, and they may be used as references by other educators and researchers.

Fourth, the measurements for motivation, enjoyment and anxiety were based on the mentor's observations and interactions with the protégé, not responses directly from the protégé him or herself, which may raise a potential issue whether these scores accurately reflected the protégé's feelings. The study was designed to have the mentor score the three variables because, most of the time, teachers were the ones who selected learning applications for their students. They should see how their students interacted with the applications and what kind of applications was appropriate for the students. Analyses based on the teachers' observation would be a meaningful reference for other educators' teaching practice.

This chapter has taken an initial step in developing those models. The author hopes that other educators and researchers could apply or test these models in their practice, and conduct

further studies to revise the models with their new findings.

APPENDIX A: EVALUATION CRITERIA FOR ONLINE LEARNING APPLICATIONS DESIGN

Information:

1. Language is accurate.
2. Language is easy to understand.
3. Language is error free.
4. Language and materials are at the identified grade level.
5. Resources are sufficient.
6. Resources are updated.
7. Materials and resources are verifiable.
8. Designer's information is included.

Design of Information:

9. Activity goals/objectives are clearly presented.
10. Task and processes are designed to achieve the goals/objectives.
11. Task and processes are designed for learners at the identified grade level.
12. Higher-level thinking is engaged.
13. Processes are designed in a learner-oriented approach.
14. Resources are closely related to the task/activities.
15. Assignments/exercise requirements reflect the knowledge/skills that match objectives.
16. Evaluation criteria match the activity processes and objectives.

Technology:

17. Screen layout is balanced, and graphics are positioned appropriately.
18. It is easy to find where you are in the program.
19. It is easy to find where you want to go within program.
20. Users can stop and find a way to exit when they need.
21. All resource links work well.
22. Help or assistance instructions are provided and easy to access.
23. Instruction materials can be downloaded or printed out in a clear layout.
24. Interactions between user and the program are user-friendly.

Design of Technology-Use:

25. Web is appropriate for performing this activity.
26. Technology skills needed for the activity match learners' developmental level.
27. Interface design is appropriate to the grade level and the topic/subject area.
28. Organization of resource links matches the activity processes.
29. Use of (multi-)media matches the objectives of the activity.
30. Design approach (linear or non-linear) matches task processes and objectives.

Quality of Online Learning Applications

31. The interactions are designed to meet the learning objectives.
32. Mapping of the contents and activities is available.

APPENDIX B: MEASUREMENTS OF ENJOYMENT, MOTIVATION, AND ANXIETY

Enjoyment:

1. This program is not very interesting to my students.
2. My students enjoy learning about this concept with this program.
3. My students do not like learning about this concept with this program.
4. Learning about and working with this program is enjoyable and stimulating to my students.
5. This program is dull and boring.
6. My students like trying to solve new problems with this program.

Motivation:

7. My students want to develop their knowledge and skills and study more with this program.
8. My students do not want to work any more on this program than they have to.
9. My students are interested in acquiring further knowledge with this kind of program and activities.
10. My students are not willing to work more on this kind of activities.
11. My students like to work on as many activities like this as they can during their studies.
12. My students are motivated to work very hard on this kind of program or activities.

Freedom from Anxiety:

13. Working on this kind of program or activities make my students feel nervous and uncomfortable.
14. My students are very calm when learning with these activities.
15. This kind of activities and content make my students feel uneasy and confused.
16. Trying to understand this concept with this program does not make my students anxious.
17. Working on online activities is one of the most dreaded subjects for my students.
18. My students did not get upset when studying with this program.

Chapter 4.22

Virtual Reality & Immersive Technology in Education

Patrick E. Connolly
Purdue University, USA

ABSTRACT

Virtual reality, also known as VR, is an exciting but ill-defined field of discovery. The question of how technological advances in this field will impact education is difficult to answer at present with any degree of certainty, but is one that must be considered by educational researchers, teachers, and administrators. This position paper presents the foundational definitions and positions of several investigators in this realm, along with thoughts on difficulties and complex issues that currently hinder the application of virtual reality in educational settings. It is recommended that the excitement that VR generates be leveraged into applications research in order to validate both the effectiveness of VR in education and encourage further development of the technology.

INTRODUCTION

Virtual reality (VR) is a phrase that is frequently used in discussions of technological advance-

ments in the science, computer, and entertainment fields, among others. However, VR is a very broad and multifaceted term that means different things depending on its source and application. Furthermore, is it a technology that has value for the fields of education and training? In this article, the author will attempt to define one aspect of virtual reality and gauge its potential for the instructional environment.

CONCEPTUAL FRAMEWORK

As might be expected, the definition of what virtual reality is differs from field to field depending on focus and usage. Generally VR can be defined as the use of computers and related technology to produce an artificial environment that simulates a targeted one. Senovsky and Kodym (1999) state that VR depends on the design and manipulation of 3D models, and may or may not require the use of other peripheral devices to simulate sensory input. They further claim that there are four key components to a VR program: (1) all events must

happen in real time, (2) the artificial environment must be three dimensional, (3) the user is able to enter into the environment and move in it freely, and (4) the environment is not static but can be manipulated by the user. Several authors (Javidi, 1999; Macedonia & Rosenbloom, 2000; Taxén & Naeve, 2001) emphasize that VR must place the user inside the artificial environment to be truly considered as virtual reality. This capability, known as immersive virtual reality, provides the opportunity for full sensory simulation. Billinghamurst (2002) uses a continuum of reality to differentiate “augmented” reality (partial immersion) from total immersion based on the amount of the user’s world that is produced by computer. These differences in definition have generated some confusion regarding the actual nature of VR and its application in education. This article will focus on immersive VR and its potential in future educational settings.

There is little question that this technology will be critical in future learning environments. Jacobs and Dempsey (2002) claim that the high level goals of education in the future will only be able to be accomplished through the use of artificial intelligence in virtual settings. Taxén and Naeve (2001) point out the significant advantages that VR offers by placing students in discovery and experiential environments that would be impossible in real life. They note that applications have been developed for teaching in the areas of science, math, art, and history, although not always in the fully immersive environment. Interestingly, they predict that too much reality in immersive settings may actually be distracting to students and prevent focus on the desired learning objective. De Moraes, Machado, Gnecco, and Cabral (2002) show an effective use of “Cave” immersive environments in the teaching of statistical interpretation and data analysis. Javidi (1999) suggests that immersive learning is very constructivist and that the level of discovery and experiential learning that the technology provides

will drive education more in that philosophical direction in the future.

The important role that immersive VR will play in the future of education in many technical areas cannot be understated. Beier (2004) points out that any three-dimensional environment can be simulated in VR, including such a variety as “buildings, landscapes, underwater shipwrecks, spacecrafts, archaeological excavation sites, human anatomy, sculptures, crime scene reconstructions, solar systems, and so on.” Pantelidis (2000) describes situations when using VR technologies would be beneficial to educators. She explains that any teaching or training experience in an actual environment that is too dangerous, difficult, inconvenient, expensive, or impossible is a prime candidate for virtual reality scenarios. Kalawsky (1998) states that VR capabilities will aid the educator in simulating complex systems, magnification or reduction of environments, and accelerating or decelerating time passage. Current examples of such educational applications in VR include: architectural design (Donath & Regenbrecht, 1999), ergonomic design (Cerney, Duncan & Vance, 2002), molecular nanotechnology (Stevens & Judson, 2004), and oceanographic and meteorological studies (Moore, 2002). Finally, Kalawsky (1998) lists many potential educational areas for VR application, such as: civil engineering, aerospace engineering, architecture, automotive engineering, chemistry, design, finance, geographical information systems (GIS), historical scenarios, manufacturing, medical, and sports science. Clearly the future use of immersive VR in educational and training settings will only be limited by the imagination (and resources) of the instructor.

In an article by Diana Walczak (2002), several problem areas are described that explain why immersive VR can be useful in education. She states that current teaching practices are directed at the average student, often ignoring the needs of faster and slower learners. One advantage of VR technology would be customizing the learning process

to fit the individual learner's needs. Secondly, she points out the ability of immersive environments to utilize more of the senses, allowing for more experiential learning. Finally, she feels that the use of VR will provide students the opportunity to become curious about their learning, and result in more individual ownership of the learning experience. Realistically, she mentions that there are significant challenges in developing "a more customized and far less simplistic education system" (p. 3). Roussou (2000) also concentrates on issues that must be met for interactive immersive technologies to assist in the educational process. She notes that the technology should not be expected to be stand-alone, but that it must be partnered with the environment, the students, and the learning context and issues. Secondly, the technology must seamlessly fit within the instruction, being non-obtrusive and non-distracting. She also states that VR must provide immediate feedback and long-term engagement for the instruction to be effective. Lastly, Roussou strongly supports proper instructional design methods to ensure valid content, ensuring that the novelty of the technology will not displace the instruction. Barnes (2000) also highlights the need for good instructional design practices to make immersive technology viable in education. He also shows that for VR to be fully effective, the learner must have control of the environment and that the environment must be authentic, simulating the real-world experience as much as possible. Barnes also states that the development and application of such VR scenarios is difficult, and "places much higher demands on the ingenuity, time and patience of course developers" (p. 3). All of the authors mentioned see the compelling need for immersive instruction as a way to truly simulate the real-world nature of issues and problems.

There is little doubt that immersive VR technology will become more prevalent in future educational environments. Although presently expensive, somewhat unstructured, and difficult to implement, the potential advantages will cause

more empirical studies, continuous technological development, and lessening costs that will promote this capability into many instructional and training situations. Neumann and Kyriakakis (2002) optimistically predict:

These new remote immersion systems will bring interactive and stimulating classroom experiences to all student populations—regardless of location. Classroom boundaries will fade as students and teachers are brought together by high-resolution video and immersive 3D shared environments that allow natural discussion, collaboration, and interaction among physically distant participants. With remote immersion, students and teachers will investigate, play, explore, and learn together in an environment that dynamically adapts to the content—from a biology laboratory to a visit to the aquarium. (p. 2)

Both Hinrichs (2003) and Javidi (1999) mention that the effective use of immersive VR in education will impact the role of the instructor. Hinrichs states that the teacher's role will become that of mentor and not be as involved in the direct instruction of the learner. Javidi points out the difficulty the teacher will experience in monitoring a significant number of students if they are immersed in separate virtual learning experiences. He also notes that assessment of learning might prove difficult in virtual environments.

POTENTIAL IMPACT OF THE POSITION

Immersive virtual reality is an educational tool that is still in its infancy. No doubt there will be many technological and pedagogical developments over the next decade that will promote the growth and application of VR in many training and instructional settings. However, for this technology to truly become an integral part of the normal educational environment, many changes

and adaptations will need to occur. Obviously, the technology must continue to mature, become supported by more scientific studies, and become much more affordable to educational institutions. Careful attention will need to be given to instructional design methods and environments to successfully utilize the immersive and experiential nature of the technology. Significantly, the role of teachers would change drastically in a fully immersive, totally virtual environment. While some predict such massive changes in our future, it is more likely that immersive VR technology will be implemented as a complementary strategy to other teaching/learning methods. This more realistic view of the future of VR in education would still require a major shift of the role of the teacher, but would probably be more palatable to educators than many of the more dramatic scenarios envisioned by some authors in this field.

Chapter 4.23

E-Learning: An Investigation into Students' Reactions to Investment into IT at Tertiary Institutions

Solitaire Maherry-Lubbe

Dolphin Coast Enterprises, South Africa

ABSTRACT

Constructivist theories and modern pedagogical concepts emphasize that an activation of students is one of the most influential factors for learning effectiveness. The implementation of those educational concepts in e-learning, especially in distance learning contexts, is a rather difficult challenge. Systems that assist lectures in this intention are required. In this study, a student's reaction towards e-learning is observed. The focus is on student's demographics in order to analyze their reaction towards e-learning. Solving tasks and observing and critiquing this solution process, instead of merely assessing the end product of e-learning processes. A sample of 105 students from the University was drawn and the findings suggest that e-learning investment can help address a need for this type of support.

INTRODUCTION

Technology is developing at a high speed and it has an impact on people's lives, especially the way one shops or does banking online. Gone are those days when one had to stand in long lines to cash money or pay transactions. Students need to study and work at the same time and the answer for that is e-learning. e-learning involves the use of a computer or electronic device (e.g., a mobile phone) in some way to provide training, educational, or learning material. e-learning can involve a greater variety of equipment than online training or education, for as the name implies, "online" involves using the Internet or an Intranet. CD-ROM and DVD can be used to provide learning materials.

The value of this research lies in the fact that it emphasises the importance of technology in teaching. It was therefore with this in mind that the

researcher investigated why people need to invest into IT for teaching purposes. The researcher used Google and EBSCO host to look for articles, using the keywords e-learning, investment into IT and digital teaching as basis for searches for relevant literature. This chapter introduces the reader to the study focusing on the establishment of e-learning at a University in South Africa.

LITERATURE REVIEW

Much of the focus in e-learning today—from analysts, industry observers, consultants, and technologists—is on e-learning in the corporate world. But the biggest impact and opportunity for e-learning may be in education. Governments want to raise the skills and education level of its population, but to date e-learning has had little impact in this area.

e-learning can potentially transform education at every level. It can make high-quality educational experiences available to those whose location, economic, and personal constraints have prevented them from pursuing their educational goals. These learners also represent a wider student market for universities and other education establishments (Mkhize et al., 2005).

Much of the focus in e-learning today from analysts, industry observers, consultants, and technologists is on e-learning in the corporate world. But the biggest impact and opportunity for e-learning may ultimately be in education. Governments want to raise the skills and education level of its population, but to date e-learning has had little impact in this area. e-learning can potentially transform education at every level. It can make high-quality educational experiences available to those whose location, economic, and personal constraints have prevented them from pursuing their educational goals. These learners also represent a wider student market for universities and other education establishments.

Callaghan (2001) notes that much of the literature on the subject of e-learning extols the potential of the technologies for enhancing the

learning experience. As has been mentioned, however, there is little evidence regarding learners' attitude to online learning, their responses to online as opposed to traditional classroom learning, their future use of online learning in their lives and the particular elements in online learning which learners find useful. Much of the literature also notes that traditional educators for their slow take-up of online learning elements in their teaching. Most commentators attribute this to teachers' lack of ability and enthusiasm for incorporating e-learning into the traditional classroom experience. Many of the dot.com e-learning ventures stress the importance of incorporating a wide range of communicative elements within the e-learning environment without producing the empirical evidence for their usefulness for learners (Callaghan, 2001).

Problems, Plagiarism, and Access

University Resistance

One issue is that universities don't see themselves merely as educational "content providers." Universities have a proud tradition of combining learning, research, teaching, and professional development. If one looks at higher education as a whole, it's not obvious how to implement e-learning. A second reason higher education resists e-learning is the absence of many of the technical skills needed as well as the experience in marketing and customer service necessary to support and develop this new market. Many universities are attempting e-learning initiatives, but on a limited scale. To have a chance of expanding the programs, they recognize the need for the right base of skills. Funding for such initiatives at the university level is another challenge.

A number of private ventures, especially in the United States, are attempting to tap into this potentially lucrative market. To date, these ventures have focused on the specific skills and technical capabilities needed. Where they fall short is in the area of access and sponsorship

E-Learning

from universities, which resist giving up control, perceived or real. The result, again, is limited success. The organization needed a great deal of time and resources to become sustainable.

The government has to play a role in e-learning education. It has only recently entered this dialog, and initial results are promising. Governments show an interest in leveraging e-learning to create more widespread and cost-effective delivery of education from most levels, such as literacy training, all the way up to postgraduate degrees. The benefit of governmental support is that it can provide sponsorship and commitment. Universities need a development model that provides a common capability backed by government, allowing universities and other educational bodies to exploit e-learning and focus on content and teaching.

A model has emerged in the United Kingdom where the department for education and skills launched an initiative in 2001 called UK Universities. It was organized as a separate commercial enterprise that was expected to become self-funding and profitable over the next few years. With this organization, universities benefit because they can continue to focus on and own the content on the educational side, while UK Universities provides the capabilities and skills in marketing, sales, learning design, content development, and platform operation and support. All parties shared benefits and costs.

Salopek (2001) notes that accessibility is a buzzword that's been on the lips of people involved with e-learning for many months now. Optavia Corporation defines it as "the ability to use the Internet even when functioning under constraints." Those constraints can be of two types: functional limitations, also known as disabilities, and situational limitations, constraints caused by the devices a user is attempting to use. Salopek notes that one can expand Optavia's definition to embrace not only the Internet but all electronic and IT, as indeed the U.S. government has done.

Smart Force e-learning complied with new government standards for accessibility. Adkins

cited by Salopek (2001) states that Smart Force's goal is to provide user experience to all users and they are making investments to integrate accessibility across [its] entire product line (Salopek, 2001). Smulders (2003) states that people can increase the learning potential of Web courses by following simple principles. Instructors and course developers are well versed in the art of instructional design. Despite this expertise and experience, many Web-based courses suffer from weak Web design and poor usability. Often, learners can't take advantage of good instructional design because the Web environment is too problematic: content is difficult to find, course tools don't work, and navigation is inconsistent.

Plagiarism

Major (2002) argues that universities have vowed to clamp down on businesses offering forged degree certificates. It came to light that a Liverpool based businessman is flouting the law and continuing to sell fake degrees over the Internet. Fakedegrees.co.uk claims to be the largest degree template library available in the world and sells degree certificates for £135. The site offers degree certificates that appear to come from universities based in the UK, USA, Australia, and New Zealand. The site is produced by Peter Leon Quinn, who calls himself a designer of impressive authentic looking certificates. Universities obtained a court injunction stopping.

New measures to help detect cheating students are being demonstrated at a conference in Newcastle. A survey of around 350 undergraduates found nearly 25% had copied text from another source at least once. A service that can scan 4.5 billion Web pages is now online so that lecturers can check the originality of the work submitted by students. The software was demonstrated at a meeting of the Plagiarism Advisory Service at North Umbria University (Major, 2002).

Hi-Tech Answer to Student Cheats

The Plagiarism Advisory Service notes that cheating is not a new phenomenon but the Internet has led to concerns within the academic community that the problem is set to increase dramatically. Service manager Fiona Duggan said:

The software has four databases that it checks students' work against and produces an originality report, which highlights where it has found matches. It demonstrates where the student has lifted text from, and it also takes you to the source where the match was found.

The software has been developed in the USA and the Plagiarism Advisory Service hopes it will go some way to stamping out the practice. Ms. Duggan noted that there are other things that can be done, like the way you set assignments so each student has something individual to put into the assignment so it is not so easy to copy (BBC News, 2002).

Accessing IT Education

Wood (2003) notes that people from ethnic minorities use their computers for education more than their richer neighbours, according to a DfES-commissioned survey into deprived areas of the UK. The study—which surveyed more than 1,500 people in deprived areas showed more than three-quarters of whom were from an ethnic minority—showed that, while 8 in 10 people in such areas recognised that IT skills were essential for their children, nearly two-thirds had beginner-level skills or none at all. Respondents were significantly less likely to own a PC or use the Internet than others in their communities, they found. Just 31% of blacks owned a PC, compared to 37% of whites, 42% of south Asians, and 44% from Chinese and other backgrounds. Some 40% of black people had used the Internet, compared to 38% of South Asians, 45% of whites, and 54% of Chinese and other respondents.

Literacy in English was a problem for South Asian people, with one quarter who did not use a computer citing language problems as the main factor preventing them from using a PC. There were also indications in interviews that gender may also act as a barrier for some Muslim women. South Asian people were less likely than other groups to use public facilities than other groups. Six in ten white non-users cited a lack of interest or need for computers, compared to only a third from black, South Asian, and mixed groups. The DfES welcomed the report. They note that they have a good understanding of the barriers that different groups face. Access to ICT, and the skills for using it, is critical to individuals' learning and employability (Wood, 2002). The Commission for Racial Equality said:

Public authorities need to be alert to the differences between ethnic groups in methods of learning and access to IT and the Internet in terms of messages and information they want to disseminate.

A total of 1,182 black and ethnic minority and 391 white households were surveyed in inner and outer London, Birmingham, Leeds and Bradford, Cardiff and Glasgow.

Wood (2003) argues that the following need to be looked at when preparing ecosystems:

1. **Environment:** Students need a certain environment (PC, connection, software) and some preparation needs to be done to make sure that the student has that.
2. **Technical skills:** Students need to know something about how to use whatever learning system exists. There has to be a way to impart this knowledge.
3. **Subject matter skills:** Students need to have some pre-requisite knowledge in the discipline to take the course.
4. **Study skills:** Students need to have the discipline and learning skills to benefit from the course.

E-Learning

5. **Support:** When students run into problems with any of these there has to be a mechanism to (a) find out and (b) help them through it.
 6. **Content:** Designed for interaction—to keep students engaged—page clicking won't necessarily motivate students.
 7. **Learner:** Disciplined, motivated to learn, has a need for learning, self-directed.
 8. **Instructor:** Aware of students needs/concerns and involvement levels, attempts to draw students in to discussions early, organized schedule, provides resources for learners in need of additional learning (remedial).
 9. **Technology:** Should play a servant role. Tools should be selected that involve learners and help them to connect with each other/content/instructor (e.g., chat, discussion questions, voice over IP are useful for connecting students and can be seen as student-cantered technologies).
 10. **Organization:** Focused on learning, time, and resources made available, learners supported (through help desks etc.).
- Service quality sufficient for voice, fax, and data
 - Rates based on community of interest (i.e., flat rate plans such as extended area service)
 - Universal enhanced 911 (emergency services)
 - Access to optional information services (local or toll-free calls for gateways to e-mail and databases in rural and remote areas)
 - Mobile services

Many of these areas are outside of the instructors influence, but still need to be considered or if an area is weak (i.e., limited organizational support), other areas may have to play a more prominent role to ensure learners are prepared and succeed.

Rural and Urban Access

Conventionally, providing access has been defined as ensuring that rural communities can be wired up. For instance, Hudson (1994) advocates that the following be made available in rural and remote regions, to ensure equitable access:

- Universal single-party touchtone service (digital switching)

Just as salient, however, is ensuring that urban environments, where a majority of the new, visible, and minority immigrants tend to congregate, are able to get connected. A 1995 report by the U.S. Office of Technology Assessment (OTA) concerned the complex problems faced by urban cores with the increasing digitization of our knowledge sector. Given that much of the technological growth is taking place in the outer suburbs, edge cities, and high-tech parks, where there are often tax incentives, and a congruence of higher amenities, central and inner city urban areas are facing population losses and a lack of serviceable amenities (OTA, 1995).

Hvorecky (2004) argues that one of big expectations tied to e-learning speaks about its ability to introduce equal education to everyone. He claims that the possibility of e-courses to reach any corner of our planet will lead to the opportunity of delivering same high-quality education everywhere. The biggest optimists have a vision of top-ranking universities acting over the Internet using ready-made courses for huge amounts of students in third world countries. In accordance to well-known practices of e-learning, the students would study on their own pace by self-learning.

1. **Language barrier:** The World's population speaks several thousand different languages. Teaching and learning at the K-12 level can hardly be performed in any other language but in the children's native one. They must reflect social and cultural specifics so it can

hardly cover more than the particular region. Consequently, most of materials have to be produced locally. Such geographical limitations minimize chances for applications of e-learning.

2. **Absence of prerequisites:** At all education levels in countries behind the digital divide, the total absence of qualified teachers is much bigger problem than the distance from them. There are not enough human resources for preparing appropriate courses in any form, regardless whether on-ground or online.
3. **Technology hurdles:** Some teaching materials can be exploited as they do not require any knowledge of the foreign language or can be understood using limited language abilities. Broadband connection, high-resolution screens, and other course producers' expectations are often difficult to achieve in many countries. Slovakia for example belongs to OECD--the commonwealth of 30 of the worlds's most developed nations.
4. **Difficulties with translation:** Evidently, performing the entire K-12 educational process in a foreign language is almost impossible. Very few courses do not intensive textual support. The last choice is translation of the courses.

Thus, one can only expect wider applications of e-learning at the higher educational levels when the taught material is general enough and student's foreign language skills are adequate. At the same time, high schools and universities in all countries are better equipped by powerful technology. Seemingly, there is a much higher chance to overcome the above obstacles. In this paper we demonstrate another reason why delivering successful and well-designed courses is unlikely even in this cases. Crossing the digital divide is equal to crossing an economic barrier.

Security Problems

Korba (2003) states that security examines ways and means for implementing data integrity and protection policies for organizations involved with e-learning. He recommends that security in e-learning need to be taken serious, security have to-date been largely ignored. At best, they have been accommodated in an ad-hoc, patch-work fashion.

Gender, Race, and Age

Tanner (1981) notes that sexual selection in the hominid divergence also could have increased the capacity of males for relaxed social interaction. What may have been selected for among the transitional hominid males was the capacity to be extremely social but yet sufficiently aggressive when required and an ability to make fine discriminations as to situational necessity. Thus, the males of the transitional population would come to more closely resemble the females than had the males of the ancestral population. Much of the selection pressure engendered by female choice of sexual partners was directed toward male social and communicatory behaviour, reinforcing the potential and capacity for sociability, social learning, and intelligence.

Morris (2004) states that research from the National Statistics Omnibus Survey 2003 estimates that 54% of adults in Britain had used e-learning in the past three months. This represents a 5% point increase in April 2002. Over the period January to March 2003, an estimated 11.7 million households in the UK (47%) can now access the Internet from home.

The statistics claim:

- 85% of adults had used the Internet to e-mail.
- 80% to find information on goods and services.

E-Learning

Table 1. Spread of age of respondents

16 to 24	78%
24 to 44	72%
45 to 54	59%
55 to 64	41%
65+	16%

- 69% to search for information about travel and accommodation.

Research for adults using the Internet, for personal and private use, shows the most popular purchases were travel, accommodation or holidays (54%), tickets for events (41%), books, magazines, e-learning, or training material (40%) and music or CDs (38%). However, younger adults use the Internet far more. Seventy eight percent of people aged 16-24 to only 16% for adults aged 65 and over.

There were nearly 60% of men in the sample. This was not by intention but because the sample was by assembled by chance.

Advantage and Disadvantages of E-Learning

There are many advantages to online and computer-based learning when compared to traditional face-to-face courses and lectures.

- Class work can be scheduled around work and family.
- Reduces travel time and travel costs for off-campus students.
- Students can study anywhere they have access to a computer and Internet connection.
- Self-paced learning modules allow students to work at their own pace.

- Instructors and students both report e-learning fosters more interaction among students and instructors than in large lecture courses.
- Develops knowledge of the Internet and computers skills that will help learners throughout their lives and careers.
- Successfully completing online or computer-based courses builds self-knowledge and self-confidence and encourages students to take responsibility for their learning.

Advantages of Web-Based Learning

Kruse (2001) notes that the general benefits of Web-based training when compared to traditional *instructor-led training* include all those shared by other types of technology-based training. When compared to *CD-ROM training*, the benefits of Web-based training stem from the fact that access to the content is easy and requires no distribution of physical materials. This means that Web-based training yields additional benefits, among them:

- Access is available anytime, anywhere, around the globe.
- Per-student equipment costs are affordable.
- Student tracking is made easy.
- Possible “learning object” architecture supports on demand, personalized learning.
- Content is easily updated (Kruse, 2001).

Disadvantages of Online or Computer-Based Learning

Kruse (2001) lists some of the disadvantages of e-learning as follows:

- Learners with low motivation or bad study habits may fall behind.
- Without the routine structures of a traditional class, students may get lost or confused about course activities and deadlines.
- Instructor may not always be available when students are studying or need help.
- Slow Internet connections or older computers may make accessing course materials frustrating.

CONCLUSION

E-learning is gaining a foothold in school districts across South Africa. Most universities are responding to new technologies, e-learning. Universities have a proud tradition of combining learning, research, teaching, and professional development. Although e-learning is growing fast it still has many problems in South Africa one of them being the fact that in South Africa most of the population are poor they can't even afford basic education. The next section will discuss the research methodology.

WHY THIS RESEARCH STUDY IS IMPORTANT

Most institutions are looking at investing into ICT as a tool for e-learning as a method of providing learning and research. Although some South African universities may have resisted some e-learning, they are all turning to e-learning. Interest in the area has grown over the last couple of years. It is clear from previous research, El-

Khatib (2003), who stated that the major benefits of online distance education are an improved quality of learning, an improved productivity of learning, an improved access to learning, and an improved student attitude to learning. Another advantage of the new online distance education model is the opportunity available for students to interact with others internationally and gain a more sophisticated and global understanding of complex international political issues, while gaining information technology literacy in the process.

Online delivery, if designed correctly, will improve distance education in the way that it will allow an increased level of interaction between students and teachers. The Internet has therefore provided many ways in which students can communicate in real time, which had previously missing from distance education courses. Students of online distance education need to be more motivated in order to keep on track and this will lead to a better level of education for all involved.

The survey was drafted after the first phase of literature review and interviews, which formed the scope and direction of the survey, as well as supporting questions. The population were Information Systems and technology students from the University of KwaZulu Natal (Westville campus) and the sample were 105 students.

The instrument is compiled in such a way it will help answer the research questions:

- Q1-Q5 race, age, gender, and year of study
- Q7-Q14 online services and computer literacy
- Q15-Q 19 e-learning and securities

Students will be given questions with option of choosing the answer from supplied answers. One of the main disadvantages of surveys, according to Dunn (2003), is finding a representative sample of respondents. Items that were covered include:

E-Learning

- What is e-learning?
- Race, age, and gender of students?
- Can e-learning be supportive?
- When should you use e-learning and when should you not use it?
- What competition or risk will the institution put itself in if they get involved in e-learning?
- How do you select the right tool? How do these tools work?
- How do student feel about e-learning?
- Is e-learning real?
- Securities in e-learning?
- How do you prove that the right candidate is doing the assignment?
- What are the best-practices for rapid development processes and rapid instructional design?
- How do you organize your team for e-learning?
- How can you avoid “rapid development” of poor content?
- How do you build instructional templates for reuse and efficiency?

The data was collated on a spreadsheet, and imported into SPSS for processing.

PRESENTATION AND DISCUSSION OF RESULT

Gender

From a sample of 105 students, 52% were females and 48% were male. One of the reasons of having more females than males is because females were more willing to answer questionnaires than males, who complained about lack of time. The aim of this question was to see whether there is a difference in student reaction to e-learning based on gender. Tanner (1981) argues that female cooperation is essential for the maintenance of special

relationships and they thus present an opportunity for females to exercise choice. If female choice is involved, it is of interest to note that the selection criteria appear to be social and care should be taken to obtain the abilities of the males and not their dominance status into account.

Racial Composition

The question on race was aimed at determining whether there is a difference in the way students view e-learning based on race. The questionnaires stated that the purpose of stating race was for research purposes. This was to ease the sensitivity in students when asked to specify their race. The race listed in questionnaires covered all races found in South Africa and the rest of the world with an option of other if you did not belong to any of the race listed in the questionnaires. The racial composition of the research is 58% were African, Indian (35%), coloured (6%), and other (1%). Also, racism requires real or imagined differences and might affect e-learning applications.

Age

Age is important in research as different age groups react different to situations. The aim of this questionnaire was to see if different age groups have differing views about e-learning as it can be seen as follows.

Age does have influence on e-learning if one compare the age group of 24 and above, which are older people ready to start their own families and they are matured enough to know what they want, they turn to like e-learning. This can be a result of many influences they can be under pressure to

Table 1. Respondents' gender

Male	50
Female	55

Table 2. Age of students

Age	No. of Students
16-19	44
20-23	44
24+	7

Table 3. Composition of age and reaction to e-learning

Age	How they feel about e-learning	No. of Students
16-19	excited	22
	will not mind	21
	uncomfortable	1
20-23	excited	15
	will not mind	15
	uncomfortable	14
24+	excited	17

support their families. It can be that they want to work and study at the same time so e-learning will enable them to do both at the same time.

If one takes the age group of 16 to 19 years, you will see that out of 44 students, only one student is not comfortable with e-learning. This can be because many young people like to experience new things without knowing the outcome of it. Another factor can be that if the students grow up playing computer games, they can be influenced by this and turn to technology-based learning.

From the 20 to 23 age group, 15 students will like to see UKZN engaging in e-learning, while 15 will not mind whether they are involved in e-learning or not. The other 14 don't support the idea of e-learning. Some of their reasons for not supporting e-learning was that they enjoy being around campus and they believe in traditional ways of learning

Morris (2004) states that research from the National Statistics Omnibus Survey 2003 estimates that 54% of adults had used e-learning in the past three months. This represents a 5% point increase on April 2002. However, younger adults use the Internet far more.

Composition of Student View About E-Learning

The aim of the questionnaire was to see if student from different geographical areas have different views on e-learning. Table 4 compares students and their views about e-learning.

From the table, it can be seen that students from the suburbs would like to use e-learning, as 17 of them will like to use e-learning and the other five would not mind e-learning. This can be a result of those students from suburbs or developed places using technology so they are unlikely to reject technology-based form of education.

There were 34 respondents from urban areas, 20 of them will like to use e-learning, while six would not mind e-learning, and the other six will feel uncomfortable if they were to use e-learning for their study purposes. More than 30 (36) respondents from township answered questionnaires, where 17 will love to study through e-learning, 18 will not mind, and one will feel uncomfortable. Fifteen respondents from rural areas were given the questionnaires (seven of them will not mind to study through e-learning and eight will feel

E-Learning

Table 4. How students feel about e-learning

townships	17
urban	20
suburb	17
townships	18
urban	6
rural area	7
suburb	5
townships	1
urban	6
rural area	8

uncomfortable if UKZN were to offer courses through e-learning). The reason may be because many students from rural areas are technological disadvantaged when they come to the university. A lot of them have never used a computer before, so it can be difficult for them to support e-learning as they have to adjust to this technology base form of education while they are used to traditional based education. For one to be involved or study through e-learning, one needs to learn the programs and software being used.

It can be concluded that students from rural area are less computer literate compared to students from other places. Though all the students who answered the questionnaire were from the information systems and technology department, some of them can not print while others can't use Microsoft Excel, so they ended up failing the computer literacy test. Many of the students from rural areas who are not computer literate have deregistered IS&T course. They said it gave them problems as they did not know how to use a computer before or during the time they attended the IS&T course, they were not given time to adjust, and they were taken as if they know how to operate a computer. They have decided to reregister the course next year.

Hudson (1994) advocates that the following be made available in rural and remote regions to ensure equitable access:

- Universal single-party touchtone service (digital switching)
- Service quality sufficient for voice, fax, and data
- Rates based on community of interest (i.e., flat rate plans such as extended area service)
- Universal enhanced 911 (emergency services)
- Access to optional information services (local or toll-free calls for gateways to e-mail and databases in rural and remote areas)
- Mobile services

Just as salient, however, is ensuring that urban environments where a majority of the new, visible, and minority immigrants tend to congregate, are able to get connected. A 1995 report by the U.S. Office of Technology Assessment (OTA) discussed the complex problems faced by urban cores with the increasing digitization of our knowledge sector. Given that much of the technological growth is taking place in the outer suburbs, edge cities, and high-tech parks, where there are often tax incentives and a congruence of higher amenities, central and inner city urban areas are facing population losses and a lack of serviceable amenities.

Online Information

The 105 respondents noted as follows: (1) 55 students use online information more often, (2) 43 sometimes depending on the need, and (3) seven students don't use online information. It can be concluded that IS&T students have the capability of adjusting to e-learning as they are used in using online information, accounts, and libraries. From a sample of 105 students, 28 students would not mind if the course was to be offered online only, while 35 students would love to see their course being 100% online, and 42 in total disagree with the course being 100% online. There are many advantages to online and computer-based learn-

ing when compared to traditional face-to-face courses and lectures. There are a few disadvantages as well.

Advantages and Disadvantages of E-Learning

As noted in a previous section, some advantages of online or computer-based learning are:

- Class work can be scheduled around work and family.
- Travel time and travel costs are reduced for off-campus students.
- Students may have the option to select learning materials that meets their level of knowledge and interest.
- Students can study anywhere they have access to a computer and Internet connection.
- Self-paced learning modules allow students to work at their own pace.
- There is flexibility to join discussions in the bulletin board threaded discussion areas at any hour, or visit with classmates and instructors remotely in chat rooms.
- Instructors and students both report e-learning fosters more interaction among students and instructors than in large lecture courses.
- E-learning can accommodate different learning styles and facilitate learning through a variety of activities.
- Knowledge of the Internet and computers skills are developed that will help learners throughout their lives and careers.
- Learners can test out of or skim over materials already mastered and concentrate efforts in mastering areas containing new information and/or skills.

The disadvantages of e-learning are:

- Learners with low motivation or bad study habits may fall behind.
- Students may feel isolated from the instructor and classmates.
- Instructors may not always be available when students are studying or need help.
- Slow Internet connections or older computers may make accessing course materials frustrating.
- Hands-on or lab work is difficult to simulate in a virtual classroom (Iowa State University).

STUDENTS IMPRESSION OF E-LEARNING

Fifty-six students think UKZN has the right resources to offer e-learning, students believe that the institution does not have what it take to offer e-learning, while 35 students were not sure. Some students think that e-learning degrees are not such good value as classroom learning or traditional learning. Seventy-seven respondents believe that e-learning can be supportive and 28 students believe e-learning can not be supportive

Hvorecky (2004) argues that one of the big expectations tied to e-learning speaks about its ability to introduce equal education to everyone. Authors of this claim assert that the possibility of e-courses to reach any corner of our planet will lead to the opportunity of delivering the same high-quality education everywhere. The biggest optimists have a vision of top-ranking universities acting over the Internet using ready-made courses for huge amounts of students in third world countries. In accordance to well-known practices of e-learning, the students would study on their own pace by self-learning. Despite the author's conviction that that e-learning has this potential, it is not difficult to express several counterarguments against such overoptimistic conclusions (Hvorecky, 2004):

1. **Language barrier:** The world’s population speaks several thousand different languages. Teaching and learning must reflect social and cultural specifics so it can hardly cover more than the particular region. Consequently, most of materials have to be produced locally. Such geographical limitations minimize chances for applications of e-learning.
2. **Absence of prerequisites:** At all education levels in countries behind the digital divide, the total absence of qualified teachers is a much bigger problem than the distance from them. There are not enough human resources for preparing appropriate courses in any form—regardless whether on-ground or online. For that reasons, student’s lack “standard volume of knowledge” requested for university enrolment and might struggle with problems during their study.
3. **Technology hurdles:** Some teaching materials can be exploited as they do not require any knowledge of the foreign language or can be understood using limited language abilities. Another question arises: Is if there is technology capable of presenting them in a relevant form and quality? Broadband connection, high-resolution screens, and other course producers’ expectations are

often difficult to achieve in many countries. Slovakia for example belongs to OECD—the commonwealth of 30 of the world’s most developed nations. Yet, a few days ago, who have watched a physician working with a 386 machine in one of the biggest Bratislava hospitals. What can one expect in remote cities of less developed countries?

Thus, one can only expect wider applications of e-learning at the higher educational levels when the taught material is general enough and student’s foreign language skills are adequate. At the same time, high schools and universities in all countries are better equipped by powerful technology. Seemingly, there is a much higher chance to overcome the above obstacles. In this paper we demonstrate another reason why delivering successful and well-designed courses is unlikely even in this cases. Crossing the digital divide is equal to crossing an economic barrier (Hvorecky, 2004)

PLAGIARISM AND E-LEARNING

In Figure 1, respondents were asked whether you can prove in e-learning that the right student is

Figure 1. Plagiarism

doing the work and does plagiarism occur in e-learning. From Figure 1, 28 respondents believe that you can prove who is doing the work, 35 think you cannot prove, and 42 are not sure.

HI-TECH ANSWER TO STUDENT CHEATS

Measures to help detect cheating students are being demonstrated at a conference in Newcastle. A survey of around 350 undergraduates found nearly 25% had copied text from another source at least once. A service that can scan 4.5 billion Web pages is now online so that lecturers can check the originality of the work submitted by students. The software is being demonstrated at a Plagiarism Advisory Service conference at St James's Park (BBC News, 2002). Student Tom Lenham said of the statistics: That's a pretty modest interpretation of the situation at the moment. "From my own experience and that of fellow students, it's a lot higher than that because it is not drummed into the heads from the start. Only more recently one has been told how to use the Internet for referencing. The Plagiarism Advisory Service note that cheating is not a new phenomenon but the Internet has led to concerns within the academic community that the problem

is set to increase dramatically. Service manager Fiona Duggan said:

The software has four databases that it checks students' work against and produces an originality report, which highlights where it has found matches. It demonstrates where the student has lifted text from, and it also takes you to the source where the match was found.

The software has been developed in the USA and the Plagiarism Advisory Service hopes it will go some way to stamping out the practice. Ms. Duggan said:

There are other things that can be done, like the way you set assignments so each student has something individual to put into the assignment so it is not so easy to copy. (BBC News, 2002)

OWNERSHIP OF PERSONAL COMPUTER

Table 5 shows that 59 respondents own a computer or can have access to a computer at any time they want to use it, 46 respondents do not own one and have limited access to a computer. From Table 5, it can be concluded that the geographic place where a student comes from does not have any influence for a student to own a computer. Thirty-nine respondents have full access to the Internet

Table 5. Students that have access to a PC

townships		urban		rural area		suburb

E-Learning

at any time, 62 can access the Internet at any time when there is a need, and only four students have difficulty to access the net.

From Table 6 it can be concluded that all UKZN IS&T students have equal access to the Internet.

COMPUTER LITERACY AND PLACE WHERE STUDENTS COME FROM

The researcher correlated computer literacy and the place where students are from. The purpose was to find out how strong the relationship is between computer literacy and the geographic place where a student comes from. In Table 8, the researcher observed that there is a weak correlation between the place a student comes from and computer literacy. In Table 7, it appears that students from townships, urban and suburbs, are more computer literate than students that come from rural areas. The study also shows that there are more than 50% of the respondents from rural areas are computer

literacy. The correlation is weak which suggest that there might not be causality.

CORRELATION BETWEEN RACE AND ACCESSING THE INTERNET

Table 9 shows that race does not have affect on ones accessing the Internet as all 105 respondents have access to the Internet. Some of them can access the Internet at any time they want and others have limited access to the Internet. There is no student that does not have access to the Internet. Table 10 shows that there is a weak negative correlation between the two variables of -.143.

Accessing the Internet and Places Where Students Live

Table 11 shows that a negative relationship between accessing the Internet and the place where student live.

There is a strong positive relationship between age and the way students will feel if their course was 100% online. From Table 13, one can see that most of the young people (age 16 to 19) want to do their course online. This can be a result of the fact that most young people want to experience new things and that during their days, most of the things are done technological. From turning a TV on to playing computer games and one of the reason that might cause old people to reject e-learning is that old people are not flexible in terms of adjusting for new things they tend to prefer traditional class room compared to e-learning.

Year of Study and E-Learning

There is a weak positive relationship between year of study students are in and the reaction towards e-learning meaning there is no causality.

RECOMMENDATIONS AND CONCLUSION

In this section, the researcher will draw recommendations and conclusion based on the findings. The research questions, which were designed previously, will be answered and recommendations for future studies will be made. It can be argued that e-learning can potentially transform education at every level. It can make high-quality educational experiences available to those whose location, economic, and personal constraints have prevented them from pursuing their educational

goals. These learners also represent a wider student market for universities and other education establishments.

Recommendations

Privacy

The researcher recommended that keeping information privacy in e-learning is very important. If your information is not private, someone else may steal your work and submit it before you do and when you submit it later, you may be charged for plagiarism. One way of ensuring privacy in e-learning is encryption. Universities are resorting to e-learning to provide instruction online. While many advances have been made in the mechanics of providing online instruction, the needs for privacy and security have to-date been largely ignored. At best, they have been accommodated in an ad-hoc, patchwork fashion. Privacy can be described as a learner's ability to maintain a "personal space" within which the learner can control the conditions under which personal information is shared with others.

Security examines ways and means for implementing data integrity and protection policies for organizations involved with e-learning. This chapter examines privacy and security issues associated with e-learning. It presents the basic principles behind privacy practices and legislation. It investigates the more popular e-learning standards to determine their provisions and limitations for privacy and security. Privacy requirements for e-learning systems are explored with respect to the "Privacy Principles." The capabilities of a number of existing privacy enhancing technologies, including methods for network privacy, policy-based privacy/security management, and trust systems, are reviewed and assessed.

Student Training

The researcher suggested that students must be taught about e-learning benefits and disadvantages

so that they can decide whether to study using e-learning or use classroom learning. Further more, universities and the government should introduce projects that will teach students in primary and secondary school about this technological ways of studying so that when they reach tertiary they already know about this things.

Securing E-Learning

El-Khatib (2003) states that security examines ways and means for implementing data integrity and protection policies for organizations involved with e-learning. The researcher recommended that security in e-learning be taken serious. At best, they have been accommodated in an ad-hoc, patchwork fashion.

Infrastructure

The researcher suggests that for a university to offer e-learning it has to upgrades its resources.

Verification

The researcher recommends that universities need to come up with special tools and techniques that can ensure user verification. So that one can be sure that the right candidates is doing the work. In the case where it is not possible to verify whether the right candidate is doing the work, Universities can set exams centres around the country to ensure that the right candidates is writing the exams.

User Accounts and Passwords

The study show that many students they use the same passwords for different accounts, the password they were given by the university for their log in at the university they also use it in other accounts.

Government Involvement

The government must set rules, standards, and policies that institutions must meet before they can be allowed to offer e-learning.

RESEARCH QUESTIONS

How Will Students Benefit from E-Learning?

Students leave universities with degrees but with no working experience, these leads to a high percentage of unemployed graduates. With e-learning students can study and work at the same time so by the time they have finished studying they will be having work experience and qualification. There are many other ways students can benefit from e-learning and they are listed next:

- Class work can be scheduled around work and family.
- Travel time and travel costs are reduced for off-campus students.
- Students may have the option to select learning materials that meets their level of knowledge and interest.
- Students can study anywhere they have access to a computer and Internet connection.
- Self-paced learning modules allow students to work at their own pace.
- There is flexibility to join discussions in the bulletin board threaded discussion areas at any hour, or visit with classmates and instructors remotely in chat rooms.
- Instructors and students both report e-learning fosters more interaction among students and instructors than in large lecture courses.

E-Learning

- E-learning can accommodate different learning styles and facilitate learning through a variety of activities.
- Knowledge of the Internet and computers skills are developed that will help learners throughout their lives and careers.

What can be Done to Make Students Feel Comfortable with E-Learning?

According to the findings of this study student from technological disadvantaged places turn to reject e-learning. They prefer traditional way of learning one of the reasons that make student to reject e-learning is that they come to universities with out any computer skills yet e-learning require one to have certain computer skills. Secondary schools need to teach computer courses so that student can .

Is Government Involvement Necessary in the Implementation of E-Learning?

The government can play an important role in e-learning by setting rules, standards, and policies universities need to follow before they can engage in e-learning. This will improve the standard of e-learning as universities will have to meet certain standards before they can be allowed to offer e-learning.

CONCLUSION

Context may be the most important element that can help one to determine the success of an e-learning initiative. An in-depth analysis of the context should be the departure point of every e-learning design effort. To consider the context, take into account learner characteristics, including:

- **Physical features:** Age, gender, disabilities
- **Education:** Fields of study, degrees earned, computer literacy

- **Cultural background:** Language, place of origin, traditions, sensitive subjects
- **Employment background:** Experience, time in current job, relationships with other participants
- **Expectations:** Reasons for attending the course, expected results

More than 85% of students will love to see UKZN (Westville campus) engaging in e-learning. Sixty percent of the students will love to see their course being 100% online. From the previous information, one can conclude that there is a need for e-learning at the University of KwaZulu-Natal (Westville campus) in the department of information systems and technology.

Chapter 4.24

Guiding Our Way: Needs and Motivations of Teachers in Online Learning Modeling Responsive Course Design

Kathleen P. King

Fordham University, USA

Frank J. Melia

Fordham University, USA

Marlene D. Dunham

Howard Everson & Associates, USA

ABSTRACT

Increased accountability for student outcomes among teachers led to an examination of the needs and motivations of 324 K-12 educators who participated in 6-week online professional development (PD) modules of study. This research was conducted through focus groups and an online survey. The most telling findings indicate four themes regarding teacher online PD: learner expectations, learner support and access, incentives and content. This project illuminates issues

that arise in formal education online learning environments as we continue to discover how to best serve educators' learning needs. This two-step study uses surveys and focus groups to empirically identify critical factors in instructional design and implementation. It benefits from large samples and the application of knowledge derived from Group A experiences to Group B. Follow-up research of 944 participants at year four of the project provides additional insight into technology use and motivation.

INTRODUCTION

Accountability means teachers must implement standards-based instruction and raise student achievement. The Anytime Anywhere Learning PD School (AALPDS) partnership developed a distance learning PD model to address this problem as it was emerging on the United States (U.S.) national educational horizon in the year 2000. Today, in 2006, it is clear how this need extends to the classroom, as teachers and schools, faculty and educational institutions face increased and incessant demands to integrate technology into teaching and learning, raise student test scores, and meet or exceed academic and content-area standards. This robust distance learning development, training and research project spans the years 2000-2005 and explores how online PD can offer a valuable vehicle for convenient, 24 hours-a-day/7-days-a-week access to a PD community and content that can address these challenges. Timing for the field of education to learn how online learning and hybrid learning can help advance these needs is at a critical stage.

AALPDS is an extensive online course delivery system of multiple 6-week courses. Each course passes through stages of development, implementation, evaluation and revision in a cycle of continual improvement. This distance learning project was funded by a U.S. Department of Education Fund for the Improvement of Postsecondary Education (FIPSE) Learning Anytime Anywhere Partnership (LAAP) grant.

The project set out to (1) design a system of PD that applies current national standards of PD, (2) adapt PD courses to local standards of learning, and (3) increase the capacity of local educators to implement and evaluate their own school-based PD programs. The strategy was to use emerging distance learning technologies to scale up the PD efforts required by standards-based accountability demands. By using Web-enabled technologies, the AALPDS project sought to relieve participating school districts from the burden of creating the PD

courses, managing the technology—the networks and systems—needed to deliver the instruction. The earliest phase was directed at organizational alignment and restructuring, and was followed by a more extended period of course development and online implementation. The project created AALPDS, which served educators in 32 states even as the project evolved.

This project is distinctive because of its focus on the needs of teachers as adult learners, the development of local and distant learning communities, and unique content in the areas of standards-based teaching, online learning, adult learning and high-performance classrooms. The online courses consist of instructor-guided, interactive, asynchronous formats that present in-depth material, promote the application of technology-based learning in teachers' classrooms and facilitate teachers' critical reflection and collaboration in online threaded discussions and group projects. The project sought to assist experienced as well as new teachers in the implementation of high-quality, standards-based instructional programs in a climate of increased national, state and local demands for improvement and accountability.

Since the project's inception in 2000, and going live with its first class in March 2001, we have experienced many changes in partnerships and a significant formative reorientation of our direction and implementation.

While the primary goals of the PD school have remained the same, the path of implementation has shifted based on formative evaluation data collected through online surveys and focus groups. For example, the survey data showed that the 8-week duration of the first series of online modules was too long to sustain learner participation. Online learners stated a preference for shorter modules as evidenced by the higher completion rates with the 6-week format. With the collaboration of the entire project team, all of the modules were revised into 6 weeks, leading in turn to subsequent revisions in plans for additional courses and content. It is from this

perspective that this chapter offers a discussion of two especially important research questions: What characterizes the strength of this distinctive online learning format? and What needs do teacher education and PD face within online learning environments?

LITERATURE REVIEW

In considering the needs of educators in online PD, two areas of the literature in particular inform our discussion: PD from an adult learning perspective and distance education. The project built on a unique framework and depth of understanding that adult learners would respond to; a system that recognized PD is a valuable opportunity for building reflective perspectives and practice.

PD

In considering the needs of educators in their ongoing PD, one salient perspective is to recognize them as adult learners (Cranton, 1996; King, 2002a, 2005; Lawler & King, 2000). The growing literature in this area brings to the forefront characteristics of adult learners that are especially meaningful in cultivating a climate of respect, building on prior experience, learning for application, encouraging active participation, using collaborative learning and empowering participants (Lawler & King, 2000). These broad principles are then interpreted for and applied to the PD context more specifically.

Rather than focusing on “skills” and “methods,” the approach envisioned learning opportunities that evaluates the past, looks at new possibilities and carefully develops approaches to teaching and learning that incorporate new learning and perspectives. Online learning formats were designed with this perspective and incorporated Web-based bulletin boards and online journals as tools for in-depth individual contemplation and group dialog about teaching,

learning, philosophy and practice (Beyerbach & Walsh, 2001; Hawkes, 2001; King, 2001, 2002c; Paloff & Pratt, 2001; Twigg, 2001).

The climate in which educators work is critical in forming perspectives of teaching and learning. When educators work within an environment in which they are highly valued and in which they are addressed as professionals, they can develop responsibility for and invest time in their PD. Intrinsic motivation is a stronger determinant of success than extrinsic rewards, and can be communicated through the organization, individual relationships and the manner in which PD is planned and delivered.

Similarly, building on prior experience enables educators to scaffold their learning and advance in thought and practice while validating their expertise (Lawler & King, 2000). This approach emphasizes transfer of learning and immediate application while also encouraging reflective practice.

Such learning is well received when educators interact with the content and one another through multiple instructional strategies (King, 2002b). Collaborative learning offers one way to cultivate this interaction with experience, content and application and build opportunities for reflection, application and dialog, which can become increasingly “transformative learning opportunities” (King, 2005). Online learning is increasingly used to foster collaborative discussions and can be used to explore and develop ideas and application (Simonson, Smaldino, Albright, & Zvacek, 2003).

Ultimately, these adult learning strategies can move PD initiatives towards empowerment of educators. Rather than PD stopping when an in-service program ends, educators have the opportunity to continue learning both individually and together when their organization supports and validates their learning, experience and collaboration.

Several authors build on this view of educators as adult learners to recognize that PD is a valuable

opportunity for building reflective perspectives and practice (Brookfield, 1995; Cranton, 1996; King 2002a). Rather than focusing on “skills” and “methods,” the approach envisioned learning opportunities that evaluate the past, look at new possibilities and carefully develop approaches to teaching and learning that incorporate new learning and perspectives.

Online learning formats were designed that incorporated this perspective and included Web-based bulletin boards and online journals as tools for in-depth individual contemplation and group dialog about teaching, learning and philosophy, and practice (Beyerbach & Walsh, 2001; Hawkes, 2001; King, 2001, 2002c; Paloff & Pratt, 2001; Twigg, 2001).

Distance Education

With the advent of online learning via Internet, and specifically the World Wide Web in the early 1990s, a new wave of possibilities emerged for distance education (Eastmond, 1995; Palloff & Pratt, 2001; Simonson et al., 2003). Instructional design concerns took new capabilities of user-friendliness, and interactivity emerged. The Web’s graphical interface, increased options for Internet connections and decreased costs of Internet-ready computers played important parts in building a base of users who could engage in online learning.

Building on the view of educators as adult learners, critical issues that emerge in this literature are climate, expectation, experience and interactivity. The widespread adoption of the Web as a major source of information, news and entertainment has brought the use of the Internet into the mainstream. This culture and climate of online dependency is critical in introducing and sustaining the viability of online learning. In the corporate sector, a large portion of PD is being moved to distance modalities and, more specifically, online (Berge, 1998). Online learning

platforms are likely to foster such collaborative discussion and can be used readily to facilitate further exploration and development of ideas and application (Hawkes, 2001; King 2002c, Simonson et al., 2003). The emerging instructional technology of online platforms held out the promise of fostering positive climates for learning, raising teachers’ expectations of themselves and their students, and providing an environment for richer interactive learning experiences (Alexander & Boud, 2001).

These dynamics create expectations within organizations and among individuals that need to be addressed in online learning programs. The literature has shown that online learning usually takes considerably more time than learners expect and, despite their experience with using online resources for other purposes, until they engage in online learning, learners do not fully comprehend the dynamics, possibilities and responsibilities (Palloff & Pratt, 2001).

Additionally, experience and interactivity can be incorporated successfully in online learning. These issues necessitate careful planning that considers a variety of online instructional strategies, pedagogical issues, learner needs and program/course objectives (Palloff & Pratt, 2001). Online learning offers opportunities to draw out learner experience in not only instructor-learner dialog, but also peer-to-peer dialog (King, 2002b). Indeed, these limits and interactivity can be extended so far that educators and learners alike may need to set boundaries for their own participation (Palloff & Pratt, 2001).

All of these dynamic possibilities have continued to develop a challenging pathway for online learning and workplace training as the possibilities and limitations of this multifaceted, still evolving delivery mode is experienced, pressed to new limits and tested under new changing educational, economic, technological, sociological and political conditions. This discussion serves as a brief representation of the wide base of support

for this research as it approaches online learning from adult learning principles, online technology, distance learning and PD.

Methodology

This research integrates two modes of data collection—focus groups and online surveys—within a mixed, quantitative and qualitative design (Creswell, 2003). This mixed design allows researchers to include a broad base of participants, as in the online survey (N=324), and also to explore a greater depth of experience through qualitative methods, such as questioning techniques in focus groups (N= 13, 8). Findings that are particularly relevant to faculty teaching, evaluation and development are presented here. This research and development project consisted of two phases over its first 2 years, according to the method and type of information collected.

During Phase One, the first 8 months, findings were discussed informally and frequently, and adapted as appropriate into project design. Phase Two began in the 9th month, as data collection became more routine and project management shifted from a development phase to a schedule of project coordination and monitoring. In Phase One, focus group findings were based on participant experience with one course offered at the earliest part of the project. During Phase Two, data were gathered through focus group findings and the online survey.

Online Survey. The more quantitative study consisted of an online survey. The 128-item online survey was voluntarily completed by learners within the 4th-6th weeks of their online course. Learners were notified when and how to access the survey by course facilitators. Respondent identity is kept confidential through passwords devised by each participant through a set formula that utilizes their user name. Then, one program administrator who does not have access to the responses of participants forwards those passwords to the evaluator, who accesses the responses without

knowing who the participants are. The survey is a combination of multiple choice, Likert items, and free responses that cover nine broad topics: demographics (7), satisfaction (4), motivation (23), course and course impact (45), online learning (23), technology experience (2), access (12), barriers (5) and contacts (7). This chapter focuses on the data collected from 34 items concerning demographics, satisfaction and motivation.

We instituted a Web-based survey that enabled us to utilize learner feedback to modify and adjust the program of courses to better meet the needs of teacher learners. The survey was developed by the external evaluation team, with a review and revision process that included input from program directors and course content specialists. Pilot testing of survey questions were distributed to the first focus group in person and via e-mail. A survey response rate of 33% (N=324) was achieved from among those who completed the courses.

Participants. All participants were enrolled in the project courses. Contact with the largest group of participants was primarily through the Web-based online survey, because courses are available to any educators in participating districts or who are members of Classroom Connect's total learner community (80,000 Web visitors annually). All courses were delivered exclusively online.

Survey. Among the 324 participants, 287 were female and 35 male. Regarding background, 279 were self-identified as White, 13 as African American, 8 as Hispanic and 5 multiethnic. Teaching experience of the participants ranged from 0 to 16 years and more: 100 had 16 or more years, 149 had 6 to 15 years, 65 had 1 to 5 years; and 2 had no teaching experience. For 102 (31.5%) respondents, this was their first online course.

Based on responses to descriptors in the survey, participants identified themselves as follows: 158 (48.8%) early adopters—first to try something new; 152 (46.9%) like to try technology after it's been tried by others; 7 (2.1%) resist using technology; and 7 (2.1%) no response. Additional findings includes 207 (63.9%) who describe themselves

as advanced technology users; 85 (26.2%) with some experience; and 25 (7.7%) as beginners. Furthermore, 32 (9.9%) were enrolled in a degree program and 11 (3.4%) indicated that the course was part of the requirements for that program.

The majority of survey respondents were female (88.6%) and non-minority (86.1%). The majority also lived in suburban communities 168 (52%); 65 (20.1%) had more than 21 years of professional educational experience, and nearly two-thirds, 201 (62%), held a master's degree. Less than one-fourth of the respondents, 77 (23.8%), lived in rural areas and less than one-fourth lived in an urban location 71 (21.9%). Studies indicate that there is a large economic and racial gap between users and non-users of the Internet, and our respondent demographics appear to confirm this gap for our online learners (Burdenski, 2001).

Focus Groups. Two focus groups were conducted by the project evaluation team at two critical points in the project: (1) at the initial implementation phase, and 2) when the project had been underway for 9 months. These on-site focus groups were conducted in the learners' school communities and included refreshments. Major differences between the two sessions were evident at these different points in time: first, the format of the session; and second, the availability of course offerings (as a result of maturation/development of project). The first focus group of 13 teachers occurred when they had been exposed to the first online course available (1 month after the project began in March, 2001). The 2-hour afternoon session consisted of a presentation by the project director, followed by an open question-and-answer session. The project evaluator was present and distributed written surveys at the close of the session. Data were gathered through observation and notes by evaluator and journal notes of the project director. The session was held at a local community college, in a major urban area.

The second focus group of eight learners occurred in the evening at the district office in a large suburban district. Over 3 hours, discussion

revolved around 15 questions developed by the district coordinators of the program. Discussion was audiotaped. The project evaluator recorded the discussion by question and tabulated responses.

Focus Group One. Thirteen participants (all female) attended the first focus group, among which 10 were African American, 1 Hispanic and 2 white. Eleven had taught for 16 or more years. Although they were all "technology" teachers, all had far less technology experience than teaching experience. Most had less than 5 years' experience in technology and rated themselves as "no experience," beginners and limited experience. This course was their first online course. All the teachers had been required by their school or district to participate in the PD activities. All were required, by the district administrator, to come to the focus group.

Focus Group Two. Ten participants, 9 females and 1 male, attended the second focus group. They were invited to the focus group by the district administration, but not required to attend. Ethnic identification was 2 African American and 8 White. The group represented various positions in five district schools and the district office: one was a high school computer teacher; one worked in the high school guidance office, three were elementary teachers, three were experienced media or resource specialists working in two elementary schools, two were district technology coordinators. Their range of technical expertise extended from "needing help with e-mail," resisting using technology to experienced. For half of the group (5), this was their first online course, as they had been selected by their district to participate and were characterized by intrinsic motivation, curiosity and determination.

Analysis. Objective survey responses were tabulated and coded for frequencies, percentages and correlations. Focus groups and discussion board transcripts and survey free responses were coded by constant comparison, as themes were determined from the data and then the data tabulated and grouped within those themes (Cre-

Guiding Our Way

swell, 2003). Gathering data from several sources provided a broad view of the online experience among these educators.

As commonly used in mixed design research, the multiple sources of data provide support for the validity of the data (Creswell, 2003). Survey items consisted of attitude scales and open-ended free-response answers. The focus groups and discussion boards served to validate the survey responses, as these participants had participated in both modes and the responses could be compared to one another. Construct validity of the survey instrument was a priority for the survey designers, as each section had multiple items relating to the construct being used to ensure fit with the purposes of the survey and the population being surveyed. Hypothesized relationships among different sections of the survey instrument were tested with empirical observations in focus groups. Items covered both negative and positive responses; for example, the items about assistance in accessing the computer was balanced by items about barriers to access. Both items had write-in responses, also. The internal consistent reliability of the rating scales were tested using coefficient alpha, showing reliability of .8581. Both validity and reliability were priorities for the instrument designers, and several items were written and some items were not used after pilot results were evaluated. The online survey system prevented redundancy of respondents because individual, unique, single-use passwords had to be developed for each participant each time they took a course, thereby preventing any individual learner “stacking” the responses with multiple entries.

Procedures. All teacher responses in the data collection process are coded and remain anonymous, and responses regarding individual teacher demographics, teaching experience and teacher opinion are kept confidential. Prior to completing the online survey, participants are informed that the project courses are being studied to assist in course development and to learn more about on-

line learning. Learners may decline to participate without negative consequences.

FINDINGS AND DISCUSSION

Four major themes emerged as the data from the focus groups, online surveys and hybrid classes were analyzed. The subjects and topics that occurred repeatedly in each method of data collection were: (1) learner expectations, (2) learner support and access, (3) incentives, and (4) content. Each theme will be discussed within the context that they were gathered.

The focus groups provide the best indication of the effects on the adult learner of district-mandated implementation of online PD programs. The first focus group discussions centered on obstacles to participation and effective implementation in District A, shedding light as to the practicability, usability and efficacy of a district-required, online PD program. The second focus group, District B in the suburbs of a large metropolitan area, provided information after 9 months of implementation. District B’s district technology coordinator facilitated teacher participation, assuring familiarity with school organization and procedures. This embedded familiarity was critical to the pre-implementation stage to correct assumptions about teacher motivation and usage, and was influenced by changes made as a result of District A’s feedback.

Two tables summarize findings from the focus groups. Table 1 captures the differences in both the individual characteristics of focus group participants and the differences in district implementation and support of the online learning courses. Two contrasting district styles as well as two dissimilar groups of learners emerge in Table 2. Although the focus groups are not comparable, the findings help describe characteristics of successful implementation for both the adult learner and the district/school. We need to remember that

these are results for two unique districts and we need to exercise caution in generalizing these themes.

Learner Expectations

Learner expectations prior to and during the courses surfaced repeatedly in the focus groups and were directly influenced by district/school/administrator communication about the program, the learner's level of technical proficiency and lack of experience with online courses. The context raised issues of technology placement and use; the social networks that developed between and among teachers and school leaders; and the time-frames, budgets and incentives governing use of the PD programs in the schools.

In District A, sometimes information was miscommunicated or not communicated, leading to unrealistic expectations for learners. For example, the purpose and expectations of participating in the courses was incorrectly conveyed to the teachers by district administration. Communicating accurate information to learners was difficult for the Web-based course deliverers, whether by the technical team or the course guide/facilitator. Many of the learners were novice technology users whose lack of understanding led them to repeatedly delete e-mails without reading them.

In District B, participating teachers included resource coordinators and teachers from different schools in the district. Communication was handled better and learners felt "honored and privileged" that they were asked to participate. The level of basic technology skills and lack of understanding about online learning was not an issue for most of these teachers. However, sometimes teachers (even those who had taken previous online courses) found the workload to be greater than expected. This mismatch of expectations may be seen in District B, where learners, although highly motivated, sometimes found they could not continue a course.

Learner Support and Online Access

The need for learner support is multifaceted and far-reaching in online PD. The focus groups indicated the need for ongoing district support for adult learners in mandated PD programs, especially when the users are novices in technology and online course-taking. The focus groups revealed the lack of district support in these areas: (1) a clearly articulated initial introduction with explanatory materials, and (2) a continuous PD program that follows up with teachers, troubleshoots and resolves problems. If such a support system had been in place in District A, teachers may not have been deleting e-mail due to lack of training. During focus group, it was the research team (not the district) that was able to determine (from participants) that greater technical expertise was needed among the learners. This valuable information focused our recruitment for participants and further support efforts, but it was too late to prevent the frustration in District A. In District B, training in how to submit online projects might have prevented the loss of a learner's paper and subsequent frustration.

In an online learning system that is not district based, learner support is primarily provided by the technical online course team. A district's support of an online learning program should include initial communication, training and follow-up with participating learners. Even though these courses included online, e-mail and toll-free telephone support, the novice learners still struggled greatly, including problems with the course registration process.

Discussion with teachers from District A revealed that teachers were unaware of the extent of the Web site and the course offerings, even though they are using the system. District A teachers demonstrate the need for ongoing structured and formalized support and training in the basics of how to use the system. When these novice learners were further oriented to the online course

Guiding Our Way

Table 1. The learner in the district

Implementation in Two Districts: Comparison of Focus Group Learner Characteristics and Support Provided by District		
Learner Background	District A	District B
Previous online learning experience	None	50% had previous experience
Learner attitude and motivation	Felt imposed, not enough time, already too busy	Privileged, honored, curious, personal growth motivation
Technology experience/Proficiency	All were inexperienced	Moderate and advanced experience (50%)
Computer access	50% had computers a home. All had computers at work.	All had computers at home. All had computers at work.
Web-based learning style	Not comfortable reading screens; download and print all information	Comfortable reading screens; sets priorities/identifies materials to download
District/School Support Provided		
Online learning policy implementation strategy	A district mandate: Teachers required but not enforced	Invited. Level of implementation varied by school
Introduction of system, initial and continuing communication to teachers	Severely limited. District level only.	Better at district level; varied by school
District support team providing ongoing support to teachers at implementing sites	Inactive and inexperienced	Active and experienced
Training to use system	None	None
Goals and follow-through	Unclear	Goals and follow-through set by district.

Table 2. Summary of themes that emerged in the focus groups

Needs for Successful Implementation of Online Instruction for Adult Learners in the Public School Setting		
Learner Expectations	District A	District B
Materials and content: relevance to professional work	Perceived as interesting, but not relevant	Perceived as relevant and interesting
Perception of time required	Took more time than expected	Courses varied; some took more time than others
Reason for not completing course	Time, lack of meaningful incentives, did not know how to use, not relevant	Courses more work than expected; would be easier fit into schedule; too much reading; too much intensity
INCENTIVES		
Incentive/Reward for participation	None felt by participants	Identified by participants
SUPPORT		
Communication, training and support	Severely limited; teachers on their own	Better, but teachers still on their own
Use of support provided: Web, e-mail, toll-free telephone	None used; some deleted pertinent e-mails, not knowing they were about the class	Used support

environment and Web site, they expressed greater interest in continuing and learning more.

Incentives

The role of incentives emerged as one of the most important needs among educators in this environment. Intrinsic incentives as well as extrinsic incentives need to be included, based on learners' comments. Online learning takes such great a time commitment amidst such overburdened teacher schedules that there has to be great motivation to pursue such efforts.

The most favored extrinsic incentive mentioned in the focus groups was financial, followed by academic credit incentives, such as graduate credit, continuing education units (CEUs) or certification that would result in financial rewards, and public or professional authority recognition for work accomplished. Teachers expressed that they are motivated by a combination of incentives, including personal and professional incentives, such as the desire to use technology and apply learning to their classrooms, and developing the content standards knowledge that would result from course participation.

District A is an example of how incentives affected the direction of the initiative, as the teachers would not gain financially (salary increments). The primary incentives were personal knowledge gain and CEUs. The learners made it very clear that personal knowledge was not sufficient. In District B, all the learners were interested in implementing new technology and saw enrolling and completing the course as a personal goal. The focus groups provide evidence that teachers lacking intrinsic and extrinsic motivation withdrew from participation.

For some teachers, personal satisfaction and learning are enough, but for others, incentives ought to include a combination of indirect or direct financial rewards. In other situations, the learner is a source of his or her own support and motivation. Without district mandates, incentives

and support, teacher perseverance to complete the course was dependent on personality style, time management and learning style. District B's focus group tended to be interested in implementing new technology and they set enrollment and completion as personal goals. District A teachers felt the program was imposed on them as a district goal – not an individual goal-- and combined with their lack of technology skill, they were not able to get as much out of the courses. Personality style and learning style vary, as learners appear to be very individualistic and idiosyncratic. We have more to learn about how variation in learning style impacts course completion.

Content

In online learning, the role of course content is critical, particularly that it is perceived by the learner as interesting and, even more importantly, relevant to the learner's professional work. Content surfaces as a priority because the learning experience relies so heavily on the course itself rather than spontaneous discussion, explanations or sample examples and applications. Both focus groups clearly illustrate that the curriculum content must satisfy the needs of learners or it will lose them.

District A was eager to begin, and enrolled the technology teachers in the first available course, Introduction to Online Learning. However, the learners were not interested enough in the content area, seriously hampering their continued involvement. Consistent with characteristics of other adult learners, these teachers wanted a course that could directly apply and immediately relate to their teaching in the classroom.

In contrast, District B began to participate when the project was almost a year underway and knew the entire scope of courses available. Several teachers in the District B focus group had participated in two or three courses, and were planning to participate in more, as they were quite enthusiastic about the courses with standards con-

tent. As they expressed, it was the first time they were able to see standards information presented in an organized and helpful manner.

Teacher needs and content need to match in a district implementation, as the choice of who is offered participation must match the courses being offered. District A used novice technology teachers instead of teachers who would be directly involved with implementing standards in the classroom. District B selected technology and resource teachers and teachers involved with implementing standards in the classroom. As additional districts have participated, they were informed of the recommendations below as ways to encourage greater participation and course completion.

Teachers and administrators face many demands in our high-stakes assessment climate. Even as many stakeholders remain critical of public education, this model of PD offers opportunities for new and veteran teachers to improve their effectiveness and meet some of these demands. For example, the threaded Web boards of each course enable teacher/learners to share their insights and expertise across the nation as they develop and increase their own knowledge and skills.

SUMMARY

We learned much about personal online experiences and district support systems for online learning from the participants in the focus groups. These adult learners were located in specific district PD implementation projects. Next, we look at the respondents to the Web-based survey, who are adult learners primarily from the larger Connected University (CU) community. They are not connected to a specific district and the primary way of contacting them is via the web.

Online Survey

From the 324 survey respondents, we compiled a profile of the successful learner in these courses. Though respondents comprise a non-diverse group, we are presented with the opportunity to increase the diversity of learners online. Online educators and learning providers should consider addressing the needs that surface in the emerging profile of the potentially successful learner: (1) diverse learner expectations, (2) learner support and online access availability, (3) incentives, and (4) rigorous content. Each of these areas is discussed in depth below.

Learner Expectations

Many potential and participating online learners have false preconceptions of online experiences. The reality is that quality online learning takes a substantial investment of time: Learners spent 140 minutes every time they logged in. Most respondents allocated minutes: 20 minutes reviewing assignments; 10 downloading information; 30 searching the Internet; 30 reading the forum; 15 posting on the forum; 30 working on course project and reading e-mail; and 5 reading public postings. Learners logged onto the course every week and 42.9% (139) said they logged in “once every few days.” Just more than 100 (105, 32.4%) said they logged in every day, and 114 (35.2%) respondents thought the course took more time than they expected. Very few, 13 (4.0%), thought it took less time than they anticipated. As shown in Table 3, survey respondents came to the online format from a wide range of professional experience.

Learner Support and Online Access Availability

We find that the potentially successful online teacher-learner needs to be a self-directed learner,

Table 3. Professional experience of respondents to AALPDS online surveys

Years of Professional Education Experience	% Total Respondents
One to five	19%
Six to ten	26%
11 to 15	20%
16 to 20	14%
21 or more	18%

Table 4. Experience using computers in the classroom

Years Using Computers in Classroom	% Total Respondents N=944
0-2	10%
3-5 years	26%
6 plus years	62%

Table 5. Motivating factors (N=944)

Motivating Factor	% of Total number of respondents
Topics are of interest to me.	88%
More convenient (time-wise) than attending a college or university. Convenience was a motivating factor, as many of the respondents said they had families and were looking for time-saving learning options.	83%
Thought it would be intellectually challenging.	83%
Thought it would be rewarding to communicate with other professionals across the country.	71%
Thought the course would be fun.	72%
Wanted to meet interesting people in my class.	38%
Required as part of my program/school.	19%
Live in a location where access to PD is difficult.	22%

Guiding Our Way

self-disciplined and have minimum technology proficiency of Internet searching, e-mail skills and Internet usage. In our initial survey of 324 teacher-learner participants, almost three-quarters, 237 (73.2%), reported they had had 3 or more years' experience with computers, and almost half of the respondents, 149 (46.0), had 6 or more years' experience. About half of the learners, 158 (48.8%), described themselves as "early adopters who are one of the first to try new programs or software." Only a small percentage, 7 (2.2%), said, "they resist using technology," and when they rated their technology expertise, two-thirds, 207 (63.9%), said they were "intermediate" and just more than one-fourth, 85 (26.2%), rated themselves as "advanced." Less than 10%, 25 (7.7%) said they were "beginners." When self-direction, self-discipline and comfort with technology are not present, numerous problems arise that may become insurmountable and learners may drop out of their course.

In a follow-up survey taken about 1 year later, the base of teacher learner participants expanded to 944. This larger group responded to the same question about classroom-based usage of computers, and the results are shown in Table 2. It is interesting to see that with the passage of time and the increased experience level of those responding, it appears that the more experienced the teachers, the greater the use of computers in the classroom. This also may reflect the increased market penetration of computer technology in schools.

In that same follow-up study of 944 teacher learners, we asked teachers what motivated them to enroll in an online PD course; the responses are summarized in Table 5. Though convenience appeared to play an important role, interest in the topics and the intellectual challenge appear to be almost as important factors. School or program requirements did not motivate more than one-quarter of respondents. It is also interesting to note that the potential remoteness from PD did not draw much more than one-fifth of the learners.

The focus groups indicated that lack of very basic technology proficiency made simple instructions and Web interface daunting. What the developers had defined as "basic skills" was considered intermediate-advanced skills to most of these teachers in 2000-2002. Of course, these definitions are dictated somewhat socio-historically, culturally and geographically and are changing rapidly, so in 2005 our definition of a novice user is different still. The lesson learned is to enumerate the skills needed.

While we do not know the economic status of our learners, we do know that 212 (96.3%) had computers at home, 299 (92.3%) had classroom access and 275 (84.9%) had access to a school computer lab. The most frequent responses regarding barriers that prevented them from accessing the course were: "personal time issues" (241, 74.4%) and "slow computer connections" (119, 36.7%).

Finally, regarding support and access, home computers appear to be the almost universal commonality of all the learners. We suggest it is essential for the successful online learner (Palloff & Pratt, 2001). When we combine these findings with the demographic profiles of our learners, it raises questions about equity and access, including attention to the economic issues of hardware, software and Web connection fees.

Incentives

We learned much about intrinsic incentives from the survey. The third most-frequent response regarding motivation was convenience (269, 83.0%). The most frequent write-in responses were convenience (112/227, 40.4%), freedom (54, 19.5%) and flexibility (46, 16.6%). The most frequent reward for posting in the Web-based asynchronous forum was that online peers were interesting and engaging (306, 94.4%); secondly, it was rewarding to communicate with peers across the country (290, 89.5%); and thirdly, they enjoyed positive feedback (286, 88.3%).

Content

Fourth, substantial and relevant content is needed in developing online courses. Educators and other Internet users look for courses that have new information, perspectives and application. The AALPDS courses are in several areas, including content areas of reading, writing and mathematics at three levels: K-2, grades 3-5 and grades 6-8. Another area is courses about creating high-performance classrooms, and courses were added in science, grades 3-5; social studies grades 6-8; educational technology; and online learning.

Tying back to motivation, educators, like other adult learners (Brookfield, 1995, King, 2002a), look to learn what they can use in their work, their classroom. Most of the respondents (291, 89.9%) were motivated to enroll in the course by intellectual challenge (277, 85.4%) as a secondary motivating factor. Two hundred twelve (65.5%) believe an online course is more current and 175 (54.0%) believe an online course is more interesting compared to other types of PD. About one-third, 109 (33.6%), believe these courses are more rigorous than other types of PD.

These findings demonstrate how online teacher PD confirms the centrality of felt needs and relevance. Focusing online course content can guide online PD efforts and resources. Courses will draw teacher learners if they hold promise for providing rich, interesting and relevant content, as well as offering means of learning that are more easily personalized, flexible and adaptable to learner needs. The findings demonstrate how online teacher PD courses—developed around clear content and taught with rigor—can strengthen the centrality and relevance of PD efforts and investments.

RECOMMENDATIONS

Online PD programs can benefit from building on the strengths of this program. Seven major recommendations are offered here.

1. **Clarity of expectations:** Online developers need to be familiar with district school procedures and expectations to prevent communication issues that may hinder effective implementation.
2. **Intrinsic motivation:** District and teacher motivation are often two separate issues, and mutually agreed-upon goals must be reached for teacher-ownership. For some teachers, personal satisfaction and learning are enough; but for others, this must be combined with either an indirect or direct financial reward. This is especially the case in highly formalized settings in which any activity out of the “contract” may be tied to a demonstrable incentive.
3. **Supports are needed to enhance technology skills:** District initiatives should provide both initial and ongoing opportunities to extend and support teachers with fewer technology skills. An introduction to the use of computer technology may be an appropriate enhancement for novices interested in adapting technology for their learning. Even teachers in the position of “technology teacher” may need more technology expertise.
4. **Using content as a powerful motivator:** Addressing felt needs of teachers in content supports intrinsic motivation by offering a variety of courses, especially courses that directly apply to the classroom.
5. **Exploring collaborative learning further:** To maximize online PD efforts, local support and collaborative groups would be beneficial. Hybrid models support teachers as learners by incorporating face-to-face sessions in support of online components.
6. **Building on the momentum of Leave No Child Behind (NCLB) legislation and initiatives:** This project stands as an example of the benefits of the scalability of delivering high-quality, instructor-led, online courses on the subject of standards-based curriculum and focused on teaching practice.

7. **Teaching, learning, technology and research:** Each decade brings new discoveries, curricular innovations, technological breakthroughs and philosophical favorites; this project, and others like it, demonstrate how teaching, learning, technology and research can be used to assist educators in the future.

ENDNOTE

¹ The project has continued to mature after this study was completed. More learners have completed the courses, and additional programmatic results were realized. Revisions to the text reflect these facts with insights regarding (1) needed PD incentives, (2) changes in content, (3) recommendations

that link to current trends in education, and (4) recommendations regarding research and technology innovation.

² This research and development project was a partnership funded by a U.S. Department of Education FIPSE/Learning Anytime Anywhere Partnership (LAAAP) grant to develop and extend innovative capacity for online teacher PD. It began in 2000 and has served more than 2,000 educators across the U.S. as of December 2005. Additional information may be found through Fordham University's Regional Educational Technology Center, www.retc.fordham.edu.

Chapter 4.25

Computer–Based Health Information Systems: Projects for Computerization or Health Management? Empirical Experiences from India

Ranjini C. R.

Lancaster University, UK

Sundeep Sahay

University of Oslo, Norway

ABSTRACT

Large investments are being made to reform the health sector in developing countries as the potential of ICTs in achieving health goals is being increasingly recognized. However, there have been various reports that indicate this potential of ICT is not being fully realized on the ground in particular settings. In this chapter, an empirical investigation of the introduction of health information systems in the primary health-care sector in

India is reported. Three cases—the India Health Care Project, Family Health Information Management System, and Integrated Health Information Management Systems—are presented. The authors argue against adopting a technocentric approach during the development of the HIS and suggest that these efforts should be sensitive to the sociotechnical context. Furthermore, a variety of constraints are identified. The chapter concludes with a discussion on the potentials of integration to address some of the identified constraints.

INTRODUCTION: THE CHALLENGES OF HIS IN DEVELOPING COUNTRIES

The plural of datum is not information.
~ Anonymous

Information and communication technologies in primary health-care settings offer a number of opportunities to enhance the efficiency of administration and improve the delivery of health-care services. Health information systems (HISs), geographic information systems (GISs), telemedicine, Web-based initiatives, and the development of health-care databases (see Bodavala, 2002) are examples of a few ICT-based initiatives currently ongoing in the primary health sector in India, and also in other developing countries. Despite the undoubted potential that ICTs provide, obtaining their practical benefits on the ground is a very complex undertaking, and there are various reports of total, partial, sustainability, and replication failures (Heeks, Mundy, & Salazar, 2000). Contributing to this unrealized potential are a number of complex interrelated issues such as inadequacies in both the computer-based infrastructure (for example, Nhampossa, 2004) and physical infrastructure of roads and transportation, which are required for the transmission of reports (Mosse & Nielsen, 2004); that is, there is a lack of proper network infrastructure, the persistent presence of legacy systems embroiled with different institutional interests (Nhampossa), weak human-resource capacities both in numbers and skills (Chilundo, 2004), heavy workload of health staff who need to give priority to providing care over administrative tasks like reporting (Mosse & Sahay, 2003), and a culture of information use that sees periodic reports as primarily fulfilling the needs of the bureaucracy rather than using the information to support action (Quraishy & Gregory, 2005). All these contextual influences make the challenge of

introducing ICTs in the health-care sector a very difficult one in practice (Sahay, 2001).

The critical role that HISs can play in public health has been emphasized since the early 1980s in attempts to integrate data collection, processing, reporting, and use to strengthen management at all levels of health services (Lippeveld, Sauerborn, & Bodart, 2000). HISs in most developing countries have been described by researchers and also policy documents emerging from international agencies as being grossly inadequate (for example, Lippeveld, Foltz, and Mahouri, 1992; World Health Organisation [WHO], 1987). Sauerborn and Lippeveld (2000) argue that this ineffectiveness stems from various reasons including the irrelevance and poor quality of data being gathered, duplication and waste among parallel HISs, lack of timely reporting and feedback, and poor use of information. As a result, what we typically find is HISs that are data led rather than action led (Sandiford, Annett, & Cibulski, 1992); in this sense data is an end in itself rather than a basis for planning, decision making, and evaluating interventions. Institutionally, HISs in developing countries are situated in rather centralized structures (Braa, Heywood, & Shung King, 1997; Braa & Nermukh, 2000; Braa et al., 2001) in which local use of information is not encouraged (Opit, 1987). This has led Sandiford et al. to comment that what is needed is not necessarily more information but more use of information.

While as a part of various health reform efforts, including HIS, ICTs are being actively introduced by international agencies and national and local governments, what is often found is that the focus of such efforts are primarily on the means, computerization, rather than the ends of what needs to be achieved: strengthening information support for health management. Introducing ICTs in the development of HIS is not necessarily the silver bullet that solves the efficiency problem of the health services (Sandiford et al., 1992), and over the years research has emphasized that critical

issues to be addressed in the implementation of IS are social and organisational, not solely technical (Anderson & Aydin, 1997; Walsham, 1993). As Helfenbein et al. (1987) have argued, changing the way information is gathered, processed, and used for decision making implies making changes in the way an organisation operates. They also suggest that producing and utilizing information more effectively will affect the behaviour and motivation of all personnel.

Policy makers (for example, under the sector-wide approach policy) and also researchers (for example, Piotti, Chilundo, & Sahay, 2005) propose that the integration of an HIS provides mechanisms to address some of the existing inefficiencies of HIS and to develop new forms of health data analysis. For example, the management of HIV programmes requires data from various sources such as the mother, child, and HIV-specific programmes. Rather than developing new HISs, it is argued that the existing systems should be effectively integrated. However, integration of HIS is a complex task. In a study on a national STI (sexually transmitted infections)/HIV/AIDS programme in Mozambique, Piotti et al. (2005) analysed the multiple reporting systems that were in place. Systems for the prevention of mother-to-child transmission, volunteers, counseling and testing, blood-transfusion services, AIDS patients under follow-up for the treatment of infections and/or antiretroviral therapy, rural-district AIDS inpatients, and AIDS patients under follow-up for home-based care were among the many reporting systems that they identified. Despite formal instruments to support the reform efforts to integrate the HIV/AIDS HIS, the multiplicity of reporting systems continued to exist, each with its own practices and processes. The integration of the HIS is not merely a technical or social task, but it is sociotechnical in nature.

We argue that taking a technological determinist perspective on HIS development implies a lack of sensitivity to the sociopolitical and institutional context, and contributes significantly to the un-

realized potential of the computerization of HIS in developing countries. There is an urgent need to shift this focus from computerization itself to the question—What is it that we want to achieve through computerization?—in order to strengthen these HIS-focused reform efforts. Analysis of this question helps to develop an argument against the adoption of a technocentric approach to the development of HIS and to instead approach this effort with a focus on integration and sensitivity to the sociotechnical context. Introducing computers does not in itself lead to better handling and use of information, and the challenge is to initiate a parallel informational reform process where information is seen as a resource for action rather than for fulfilling the needs of the bureaucracy.

The present chapter analyzes empirically some of these challenges, drawing upon a study of three specific HIS initiatives introduced in primary health-care settings in Andhra Pradesh (AP; a state in southern India): The India Health Care (IHC) project, the Family Health Information Management System (FHIMS), and Integrated Health Information Management Systems (IHIMS). In the following section, we provide a brief summary of the broad context of the health sector and HIS in India. We next describe the research setting followed by a narrative of the HIS projects. Later, we present our analysis and discuss the challenges and opportunities inherent in shifting the focus of HIS efforts from computerization itself to how it can support health management. Finally, some brief conclusions are presented.

THE INDIAN HEALTH SECTOR CONTEXT

The goal of health policy in India has been stated as supporting universal and free primary health care for all (Gupta & Chen, 1996). A primary health centre was conceived in India as an institutional structure to provide integrated preventive, promotional, curative, and rehabilitative services

for the entire rural population. The primary health sector includes primary health centres (PHCs), subcentres (SCs), community health centres, and upgraded PHCs in some areas. Each PHC is expected to provide health care for a population of about 30,000, whereas in practical terms, this ranges from 20,000 to 70,000. More details on the health sector in Andhra Pradesh are provided later.

The health staff in the PHCs and SCs generate considerable amounts of data about the services that they render, collate them on a weekly or monthly basis, and report them in prescribed formats, sometimes duplicating the same report format to different departments or programme managers. These informational activities take up a considerable amount of the health staff's time. Moreover, frontline health assistants are mere producers of data rather than its users. While the focus on reporting serves to fulfill the needs of the bureaucracy and their dependencies on international aid agencies, and the potential need for epidemiological analysis, information is rarely ever used to guide local action at the level at which the data are collected (Sahay, 2001). There are also quality-related issues that inhibit the active use of data. For example, data collected at every level are aggregated, and by the time these data reach the higher levels of the health system, the specific situations in the peripheral areas are completely masked (Quraishy & Gregory, 2005). The flow of data is largely unidirectional from the lower levels to the higher ones (see Figure 1), with very little constructive feedback being given to the local levels to strengthen their work processes. Instead, often the only feedback is in the form of a reprimand, where health staff are pulled up for not meeting their (rather unrealistic) targets. Mechanisms to facilitate mutual exchange of information are also minimal.

Acknowledging these limitations of the existing HIS during the launch of a new programme named the National Rural Health Mission, the prime minister of India, Dr. Manmohan Singh,

called for reorienting the HIS to support local action (April 12, 2005):

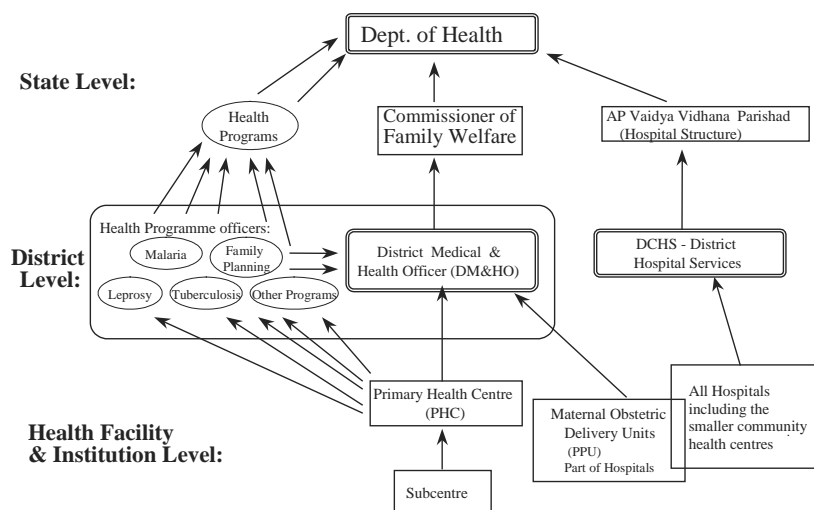

The monitoring systems have to become oriented outward towards the community and not upward towards the bureaucracy. For example, so far the health information we have in our country through the National Family Health Services Reports are seen at State and Central levels and hardly ever at district and below district levels. If information is to lead to action, it should be available and used at the local level. We must reorient the information system to support an accountability-structure by developing district health reports, state health reports and so on.

While the challenges to HIS reform are now being recognized at the policy level, the harder task is to address them on the ground. With this as the backdrop, we now shift to describing the specific research setting and the particular HIS implementation efforts.

The empirical material reported here is derived from a situational analysis of the implementation of three HIS projects in AP, a state with a population of 75.7 million (<http://www.censusindia.net>). Figure 1 provides a broad structure of the health-sector network and an overview of health information flows in Andhra Pradesh.

Subcentres have been established under the PHCs at a rate of one for every 5,000 people in rural areas, and one for every 3,000 people in tribal areas. One or two health assistants (auxiliary nurses and midwives) work at the SCs and are responsible for outreach programmes. They travel from one village to another to provide services such as immunisation, antenatal care, family planning, information and education activities, and school health programmes to the rural population. PHCs serve as the hub for implementing national programmes such as population control, and disease-control programmes like malaria, tuberculosis, leprosy, and gastroenteritis among others. Mainly, however, the PHCs are

Figure 1. Health Information Flow (Source: Sahay & Walsham, 2005, p. 44).

the cornerstone of the maternity and child health programme, now integrated into the reproductive and child health programme.

For example, one district, Chittoor, has a population of about 3.75 million served by 84 PHCs, each theoretically catering to a population of about 30,000. Each PHC has under it about four to seven SCs, each of which in turn is supposed to cater to a population of about 5,000. In practice, the PHC population varies from 25,000 to 40,000, and the SCs from 4,000 to 8,000. The state has about 1,386 PHCs, of which 470 PHCs are expected to provide round-the-clock services for safe deliveries. There will also be 268 hospitals, dispensaries, community health centres, and mobile units, and 10,568 SCs spread across 23 administrative districts, covering an area of about 246,793 sq km. In Andhra Pradesh, there are about 2,848 medical officers, 506 community health officers, 1,686 multipurpose health extension officers, 1,621 female multipurpose health supervisors, 614 public health nurses, about 11,000 multipurpose health assistants (also called auxiliary nurses and midwives), and 500 other administrative staff at

the primary health centre level (family welfare [FW] departmental manual).

RESEARCH SETTINGS: ONGOING HIS INITIATIVES IN ANDHRA PRADESH

Over the last few years, HIS projects have been initiated in the Family Welfare Department (FWD) in AP to help provide electronic support tools to the health staff at different levels of the organisation. These HIS efforts of the state government were initiated with the backdrop of larger good-governance reform policies initiated by the former chief minister Chandrababu Naidu within the framework of SMART governance (Simple, Moral, Accountable, Reliable, and Trustworthy). As a component of this ambitious good-governance policy, the chief minister drew up vision statements for every government department. The government's IT vision states, "Andhra Pradesh will leverage Information Technology to attain a position of leadership and excellence in the

information age and to transform itself into a knowledge society.” The vision document also established ambitious and demanding goals for the health department to be achieved by the year 2020. These goals were, among others, to achieve infant and child mortality rates of 10 per 1,000 (live births) and 20 per 1,000, respectively, a total fertility rate of 1.5 (average number of children per woman), and population growth of 0.8% a year. Good governance and the use of ICTs in public administration were emphasized to help achieve these goals.

In January 2002, the government of Andhra Pradesh brought out a strategy paper on governance and public management that forms the basis for governance reform activities in the state. In the book *Good Governance Initiatives in Andhra Pradesh* (Mohanty, Jones, & Rao, 2004), 28 projects have been documented to disseminate examples of good practices in the field of governance and public-sector reforms. The introductory chapter notes that:

governance involves mechanisms, processes and institutions, through which people articulate their characteristics of good governance to include: rule of law, participation, transparency, responsiveness, consensus, equity and inclusiveness, economy, efficiency and effectiveness, and accountability...The government of Andhra Pradesh has adopted an approach of combining knowledge, technology and citizen-centricity as the key strategy to improve governance in the state. (p. iii)

This focus on good governance to reform public services is indeed welcome. However, there is a need to shift the focus from merely elaborating on the content of reforms to the feasibility of implementing them on the ground. Implementation of these modern and managerial models to support good governance and best practices is complex and problematic (Madon, Sahay, & Sahay, 2004). Given the excessive focus on the

provision of infrastructure rather than on implementation and use, asymmetries exist between macro-level governance policies and the micro-level implementation of particular ICT projects (Madon, Sahay, & Sudan, 2005).

Toward a Computerised Health Database: Vision and Reality

In Andhra Pradesh, toward achieving Vision 2020 and the SMART objectives, the government undertook a number of IT initiatives, some of which have had direct implications for the health initiatives under study. One such initiative was the Multipurpose Household Survey (MPHS).

The MPHS was an ambitious project of the government of Andhra Pradesh to build a massive name-based database of 75.7 million citizens and 76.5 million land records to help provide a social-security identification number for every citizen of the state. The survey was originally compiled in 1995. It was later computerised and the data was hosted on a central server for public access. The citizen's database with about 130 data elements has been installed in 1,125 mandal¹ revenue offices. Although this database was created by the state revenue department for its own purposes, the government passed a directive that MPHS should be used as a standard database by all government departments and other agencies in an attempt to prevent multiplicity of databases. In order to comply with this directive, other departments started to add data from their own databases to the MPHS.

Creating a name-based database with various socioeconomic indicators for a population of 75.7 million is a challenging task. A consultant in the revenue department explained that this database was compiled in 1995 by conducting a household survey, and subsequently between 1998 and 2003 two private companies were given contracts to update these data and also to include other data such as deaths, births, migration, and so forth. Additional data (such as the number of school-go-

ing children and the number of working children in the age group 6 to 14) from another survey called the Human Development Survey (HDS), which was conducted by the planning department, was integrated with the MPHS data in January 2000. Integrating the data from the HDS into the MPHS database had inherent problems because the basic unit for the MPHS was the village and that for the HDS was the habitation.² In the HDS, data were collected on total numbers and not on the details of all individuals in a family. For example, details about a family included the total number of children in the age group of 0 to 5, the number of illiterates above 15 years, and the number of family members above 65 years, while in the MPHS, data were collected about every individual member. There were commissions and omissions because of the migration of people, and also because some people were reluctant to give their details for the survey. There were also quality issues raised about the HDS data as they had been collected by school children. As a result, the database was not accurate, and the quality of data was very poor.

In addition, with regard to our main concern here, the HIS, the PHC as the fundamental unit for the state health department did not match with the fundamental unit of the revenue department (the owners of the MPHS), the village. As a result, many of the health parameters necessary for health services were not included in the MPHS database, and it had to be updated with these data subsequently.

Around the time that the MPHS was being upgraded, in June 2000, Infodev (the Information for Development Programme), an agency of the World Bank, granted \$250,000 in funding for the first of the projects under study here: the IHC project. The key objectives of the IHC were to reduce or eliminate the redundant entry of data prevalent in paper registers, to generate monthly reports automatically for health assistants, and to make data electronically available for further analysis and compilation at higher levels of the

health-care system. The project was eventually implemented in 200 subcentres (spread across 32 PHCs). The larger objective of the initiative was to reduce infant mortality and maternal mortality by improving the quality of antenatal care and child health through improved information management.

The second project under study here, the FHIMS, was an offshoot of the IHC project. One district, Nalgonda, out of the 23 districts in the state was selected to pilot this project. It took off simultaneously in all 67 PHCs in the district in 2002. The information needs at different levels forced the family welfare department to embark on a more elaborate project to have information systems not just at the PHCs, but also in the district offices and the state office. The overall aim of the project was to “computerize the activities of the PHCs as a whole to take care of (a) Family Welfare needs (b) control of communicable diseases and (c) PHC management” (CFW, Office of the Commissioner of Family Welfare, 2003).

As already mentioned, during the initial days of the IHC project, it was decided that MPHS should form the basis for a name-based health registry, and that instead of conducting a new survey, the health staff should update the MPHS. The survey data were crucial for both the projects because they were to be the foundation of the name-based IS. This name-based system (with details such as, for example, who has malaria) was to replace the earlier one in which data were collected based on numbers (for example, how many cases of malaria in a region). In the FWD, the family or household was the basic unit of analysis, and it was expected that the database would maintain this unit of analysis, along data on births, marriages, family planning methods, antenatal and postnatal cases, immunisation of children, deaths, and diseases. It was argued by the proponents of the name-based system that it was necessary to provide targeted health care, especially in following up with antenatal cases, immunising children over a period of time, and in

tracking patients. While the officially stated aim of the FHIMS was to improve patient-specific care, in practice, as one doctor said, the rationale underlying FHIMS was to try and “prevent the manipulation of figures by the health staff, since with names it is easier to track whether or not the right numbers have been filled.”

Apart from these data-related issues, there were also software challenges. A consultant in the revenue department explained:

Quality problems with the software are because each department hires an agency on its own to get the necessary fields from the MPHS. That company may not know the design of the MPHS data completely. They are given a very short time, say a month or so, to deliver the product. Understanding a huge database and to know how to do it takes time. Quality suffered because of this.

Another software programme was developed to download the MPHS and print the MPHS data on habitation in the form of a household register. A software engineer of the IT company that had been involved in the development of the software for the FWD said, “Nobody knows about the accuracy of the data. The survey was initially done for the revenue department. We did not know the software codes because it was done many years back. We cannot assure the accuracy of the data.”

The development of the FHIMS software was contracted to an IT company located in the state capital at a cost of about \$68,500, and the requirements included 17 modules (such as family welfare activities, tuberculosis control, leprosy eradication, budget monitoring, personnel information, etc.). The software was developed on an Oracle back end using Visual Basic. Although the project itself was delayed (because the household survey, which was expected to be completed by December 2003, was still ongoing in March 2004 in many PHCs), the software was expected to be deployed toward the end of 2003. The health department mobilised about \$7.3 million for the project through

a consortium of funding agencies including the World Bank to buy about 1,500 computers and install it in every PHC and district office, and in the state office, and load the computers with Oracle software (with a license fee of about \$200 per computer) and Microsoft software.

The idea of computerization was that the MPHS data would be loaded in the FHIMS software, and using this health survey, data could be entered (based on names). It was soon realized, however, that the MPHS data was unsuitable because of quality issues and the fact that the data did not match the needs of the health department. As already mentioned, this was because the MPHS was conducted by the revenue department and hence did not have all the data that were necessary for the health department.

This process of collecting data for such a massive population, as can be imagined, was a complicated task and involved multiple challenges. When the health staff took the MPHS survey books to their respective habitations, they found them afflicted with many errors. Many health assistants complained that names were missing or inaccurate, ages of family members were wrong, or sometimes data on entire habitations were missing. Sometimes there would be a Muslim name for the head of the household, and the family members would have Hindu names (a quite unlikely possibility!). In another instance, the same name (of a head of the family) was in all the families in a particular habitation. Also, since house numbers were not arranged in an order in many villages, the health assistants had to rely on the names of people to locate their families.

Health assistants were expected to do the survey in addition to their regular work. Some of the health assistants said they were ordered to conduct this survey at their own cost and time. However, higher officials disagreed and said doing such surveys is part of their job. The health assistants would go in the evenings after work to conduct the survey, and had to be accompanied by their husbands because they had to travel after dark.

Also, as the list of names in the forms (printed from the FHIMS database) given to them did not match the people who were physically located in the habitations, they found it easier to buy new books and write the names by pen themselves. However, in the absence of any financial support, the health staff had to buy these books at their own cost. Because of time constraints, and the fact that they had to enter whether a person had (or had not) a list of about nine diseases and particulars of physical disability (six types) in code numbers, the assistants would typically simply enter “no” for all. A project coordinator of the FHIMS explained some of these difficulties experienced by the health assistants while conducting the survey during the pilot phase of the project as follows:

The other big difficulty that our staff faced is that they were given registers...per habitation, per village like that. Each book runs, depending on the size of the habitation, anywhere between 500 and 600 pages. Some habitations are really big and have 10,000 people. Our health assistants have to go to the field with these registers, not knowing on which page the family they have to survey is on because the books do not have any index. Addresses are not printed in a serial order as to how they are located nor are the names listed in an alphabetical order. So the health assistant practically had to turn all the 600 pages or 10,000 pages every time to locate a family. And she couldn't just tear all the pages and arrange it one after the other...She knows perfectly well which house comes next to which... That was also not possible because in one sheet we had two to three families. Later, in replication phase we have made sure we get only one family per page and we now have an index for every bound book...in an alphabetical order.

After the house-to-house survey, the next stage of the project was to enter the data into the computerised database, which was a time-con-

suming and arduous task given the already heavy workload and time constraints of the health assistants. The data entry into the household database, which would then be imported to FHIMS, was outsourced to a private party. This private agency further recruited data-processing operators (data operators; at a salary of about less than \$100 per month) to do the data entry.

During the pilot phase of the FHIMS project involving data entry, there were many omissions because the work of the data operators was not well monitored. While the health assistants were instructed to be present with their registers when data were being entered by the data operators to oversee the process, the health assistants would simply leave their registers with the data operators and go away to fulfill other duties. The data operators, for their part, found it difficult to make out the handwriting of the health assistants and the variety of informal symbols they had made in the registers. A retired district officer, who was appointed as a consultant for the project, explained why this lack of oversight of the data-entry process occurred as follows:

On many occasions health assistants were not present when the data entry was done. If the health assistant sat with the data operator with her register, that would slow down the data operator because his work would be constantly double-checked. On the other hand, work would proceed faster when the health assistant was not present because the data operator would worry less about whether he was entering the records correctly or not. Remember his payment was based on the number of records he entered per day. So naturally, his interest was not whether data he entered was right or wrong, his interest was to enter as many records as possible in a day and collect his money. The health assistants were not able to sit with the data operators, oversee and clarify, because she had so many other priorities. Moreover, that sort of accountability and sense of responsibility was not there among most of

the field staff. So, in effect, the data entry was not done in a systematic manner.

As the project expanded, data entry was moved to the respective PHCs. Now, a new set of problems caused delays in the process. Multiple software bugs, especially due to software incompatibility between the household survey module and the FHIMS database, were some of the problems encountered. The result was that certain data, for instance, data on antenatal women who did not reside in habitation or data on pregnancies leading to abortion or medical termination, could not be entered into the database. In some PHCs, the household survey module could not be linked to FHIMS database, leading to discrepancies between the population figures that were entered and what was actually displayed in FHIMS. In fact, although it was claimed that all the data had been entered, close examination revealed later that data entry was done only for the FWD module and even then for only a portion of it.

The India Health Care Project

The IHC project was started as a pilot in three health centres in the Nalgonda district where health assistants were given personal digital assistants (PDAs) and another health centre was selected to pilot the same application on a desktop computer. Subsequently, PDAs, which are mobile computing devices, were given to about 200 women health assistants. Typically, health assistants spend a considerable amount of time collecting, collating, and reporting health data to different officials. This paperwork is time consuming and cumbersome, and historic data are difficult to manage, retrieve, and use. The health assistants submit several reports of the services they have offered to the supervisors and medical officers at the weekly and monthly meetings, generally organised at the PHCs. At times, they also submit reports on different health programmes to different functionaries and agencies. The stated

objectives of the project were to reduce manual paperwork and eliminate redundant data entry, and thereby free up assistants' time for health-care delivery. The application was also expected to facilitate the generation of schedules with information pertaining to immunization and antenatal services for the health assistants, which would help them to geographically identify antenatal cases to be visited and children to be immunized. The system was also supposed to help the health assistant in tracking the history of the patients and enable her to take preventive measures such as treating high-risk pregnant women or giving timely vaccinations to children. The schedules also highlighted pending cases and those who had been missed by her in previous visits. This was supposed to help the health assistant to prioritise her work so that she could attend to cases that needed immediate attention. The PDAs were expected to eventually replace paper registers. Thus, the use of these mobile computing devices was projected as providing ample opportunities for assisting health staff in their routine work. At the PHC level, it was expected that the data from PDAs would regularly be transferred and uploaded onto desktop computers located at the PHCs and support the routine HIS.

However, the use of the PDAs was largely unsuccessful for a variety of reasons. For one, the memory supplied was insufficient (16MB). There were problems with charging the batteries in the rural areas. Many health assistants said the device was slow, and since using the device while on the job was time consuming, a few health assistants would do the data entry later in the bus on their way back from work or at home. One health assistant said she would ask her children to do the data entry at home. Those health assistants with eye-sight problems complained that they found it difficult to read small letters on the black and white screen, and said that a colour screen would have been better. Also, while standing with the PDAs in the sun made it difficult for the health assistants to see the screen clearly. Since they had

Computer-Based Health Information Systems

to deal with long lines of people waiting to get their attention, they found it troublesome to spend time trying to enter data into the PDAs. Added to the poor quality of the MPHS and the database, there were technical problems during the uploading of data into the database. The PDAs were perceived to be costly, and the health assistants were scared that they might lose them and they would have to pay for it from their pockets. Due to these and other problems, PDA use has now stopped. A health worker shared her experience:

The PDAs which were supplied were low in memory. When we started using PDAs it was taking a lot of time to search the name, or open the screen or save the entry. When we had a long queue of patients, mothers holding their small children waiting for us to give the children immunization shots, if we were operating a PDA which was slow, the patients would be frustrated. If I don't attend to them, they will go away. So, very soon I realised this PDA was not much of use when I was on the job. So I resorted back to writing in my old book. What I did was I would go home and then again enter all the day's entry into the PDA. To tell you frankly, though it has helped me in getting schedules, it has also increased my work load.

A doctor working at a health centre also shared a similar opinion on the reasons for nonuse of the devices:

The health assistants are reluctant to use PDAs because the operating system is such that if the power is discharged or if a health assistant forgets to recharge it, all the data will vanish. She has to come to the PHC and upload the data from the desktop to the PDA. In this division, the reason for reluctance of health assistants to use computers is that we got the PDAs first and desktops later. So whenever data vanished, the software engineers would take the PDAs to Hyderabad

(the state capital) and would feed the data there into the PDA. The second problem was memory. Third problem is when we said the memory is not sufficient, they changed the software so only the target population is there in the PDA. There are many software problems because of this. The health assistants who are really interested even today are not able to use them because some records are not captured properly.

Another doctor who was involved in training and supervising the project said both technical and nontechnical factors contributed to the failure of the PDA project:

The processing capacity of the PDA was slow. The intention of giving PDAs was that the health worker would give immunisation and immediately enter that data in the field. But that did not happen in practice. People won't wait. So they wrote manually in their registers. Once the immunisation session was completed, the health workers would have to again enter the data, come to the health centre and then upload the data (into the desktop). Only after that could they get the schedule. In that schedule few names would be missed because some records would be rejected. So due to all these issues health assistants were not able to use the PDAs comfortably. If these technical problems could have been solved, the percentage (of health assistants using the PDAs) would have been about 70-75%, but not 100%, because you cannot make everyone use that device. Also, battery has to be replaced after every two years or so. All these issues were not taken into consideration.

The reason to do a pilot is to try out a technology on a small scale in order to identify problems and resolve them before making a large investment. However, about 200 PDAs were brought by the IT company all at once. The consultant of the IHC project said:

The irony of it is we started the project in three PHCs initially as a pilot. So they could have procured the PDAs only for those 3 PHCs. When we raised this problem of memory they could have procured higher memory PDAs later. After having gained experience during this pilot phase they could have bought the rest of the PDAs. Anybody would do that. But the software company said they have bought all the PDAs at once. For half of the district, it was 200+ PDAs.

The poor quality of the survey database, recurring software problems, insufficient memory capacity, and the absence of timely and ongoing technical support and maintenance gradually led to nonuse of these devices on the job. The health assistants who were trained and were enthusiastic initially gradually lost interest and reverted back to their earlier manual system of recording health data. The project was neither sustainable nor was it scalable because of the costs involved. Out of 200, only about 9 health assistants were using PDAs in March 2004 during a field visit by one of the authors. During the visit, the health staff took out the PDAs from locked cupboards and showed the researcher blank PDAs that had not been used for months. In some other PHCs, we saw the children of the health assistants playing with these devices.

The aim of the project was to provide support tools that would allow health assistants to reduce the time spent doing paperwork. However, in practice, it actually increased their work. The second aim was to increase the accuracy of the data flowing up from the health assistants; however, this could not be achieved because the quality of the multipurpose survey data itself was poor. The third aim was to provide a means for getting health-care data at the village level into electronic form and generate reports. This was too ambitious to achieve because shifting from a manual to an electronic form was difficult for the reasons cited above. Finally, the project aimed to provide health assistants with information that

allowed them to provide more targeted and effective services to the people. Health assistants need more than just support tools, however, but also support to use those tools. In the absence of this, they were not able to use these devices effectively. As the consultant said, “it works only if the supporting staff trouble-shoot problems promptly and in a reasonable period. But this did not happen, so gradually the health assistants lost interest and developed a negative attitude towards computers.” So when plans to expand the computerisation project to the whole state were being drawn, it was decided not to opt for PDAs because of these problems, and also because it was considered too expensive.

Family Health Information Management System

The FHIMS project was conceived based on the experience of the IHC project. While the IHC project covered only one aspect of the work of the health assistants (family welfare services), it was decided by the FWD that a comprehensive HIS was necessary, and that it should include the different activities of PHCs including family welfare services, various health services (disease control, for example), and administrative aspects (such as budgets and logistics support). The department in its official circular (CFW, 2003) outlined the key objectives of this project as follows:

- To provide a name-based follow-up of family welfare services including antenatal services and immunization, and the early identification and timely referral of high-risk antenatal cases
- To improve the full immunization rates and thereby contribute to the reduction of infant mortality rates and maternal mortality rates
- To facilitate the health assistants to easily get schedules of services to be rendered in each habitation during a month; that is, to

provide schedules on pregnant women and children to be visited by the health assistants in their respective subcentres

- To reduce the burden of manual record keeping by the field staff and all the higher levels
- To contain the spread of communicable diseases and blindness by tracking incidences of diseases
- To improve the functioning of PHCs by facilitating effective service delivery
- To streamline inventory and infrastructure management at the health centres
- To manage career and training issues of field personnel

The project was conceived over the following phases: the pilot at the Nalgonda district (December 2001–November 2002), and the state-wide replication (June 2003–ongoing). We discuss these two phases followed by a summary of the identified implementation challenges.

The Pilot Phase of FHIMS at the Nalgonda District

The pilot phase of the FHIMS project was started in 67 PHCs in December 2001 about a year after the IHC project in the same district. A software engineer who had been involved throughout the design and development of IHC and also FHIMS explained that elaborate consultations were held with health officials at different levels, including health assistants, during the design of the software. However, when we spoke to many doctors, they typically said that the process had been largely top down with limited involvement of PHC-level doctors.

After the software was installed in all the PHCs, the department appointed data-processing operators (data operators) on a temporary basis for a period of 9 months to do the data entry and to train the staff during this transition period.

Although data operators initiated the data-entry process, they did not seem to have the capacity to take on the role of change agents and to motivate the health staff. Although the district administration had instructed every PHC to identify a competent person as a system administrator who could act as a leader and be trained by the data operators from the beginning, this did not happen. Also, the role of systems administrators was not clearly defined, and adequate guidelines were not given to them on how to manage their regular work (for example, as lab assistants) with these additional responsibilities. Additionally, no incentives were provided to concurrently carry on both this task and that of a system administrator. The system administrators also complained that the training that was provided was inadequate and focused primarily on computer awareness with hardly anything on the FHIMS and nothing on health management itself. A coordinator for FHIMS who was involved in conducting training sessions confirmed this exclusion:

Initially, all the cadres were trained in all the modules. That was not really useful. For example, a health assistant need not know about the budget module, or vehicle or personnel module. If she knows about the family welfare module and one or two national health programmes, that should be enough. Similarly, a pharmacist need not know about budget or family welfare modules. If he knows about his stores, inside out, it is more than enough. It won't take more than 2 days. He will be more than happy if he is thoroughly trained for 2 days on his module. But they were called for 5 days and were taught all the modules. By the time they came to their module, they had probably lost interest.

The doctors said they were not fully involved in the project from the beginning and were unaware about the aims of the project. A FHIMS coordinator, who is also a doctor said:

From the beginning, the doctors did not have ownership of the data... since the time the survey started. Training on updating the registers was given only to the health assistants, and the doctors did not know what the training was about. Had the doctors at the PHCs been told about the registers, all about the project, and given guidelines as to how a health assistant has to go about her work, this is where you as a doctor have to guide them...then things would have been different. However, the doctor was bypassed. The data entry was done at a central point (not at PHCs). The doctor lost track there again. That's how they drifted slowly. They could have probably fallen back on track when the software was installed, but that didn't happen due to many reasons. Hence the doctors did not own the project.

Online data transfer took place initially for sometime, but then stopped. The coordinator of FHIMS explained why:

Online data transfer was going on in 50% of the PHCs for sometime. But the thing is, the district administration is still taking only the manual reports. It is not taking the reports generated from FHIMS because all the data are not being entered into FHIMS. So, whatever report you get from that (software), it is not complete. We can generate only one report, Form B from FHIMS. But that had a few errors. And even if you could correct one or two errors with a pen, you need the other data. And where will the other data come from?

In March 2003, the authors visited 12 PHCs, one community health centre, and the district office. The health staff complained that many software- and system-related problems were identified but not addressed. In many PHCs, the health staff did not know the passwords, and did not know how to burn CDs and save the data. At the time of our visits, a majority of the health staff were not using the computerised system, were not

entering and updating the health data regularly, and hence were not generating computerised schedules or reports. The projects in most PHCs had stopped when the data operators left after their temporary tenure.

STATE-WIDE EXPANSION OF FHIMS

State-wide replication of the project involved the extension of the Nalgonda project to all the other 22 districts and 1,319 PHCs. The expansion phase of the project, which started in 2003, involved the computerisation of all the PHCs, district medical and health offices (DM&HOs), and the offices of the Director of Health and the Commissioner of Family Welfare at the state level (Circular I, CFW, 2003, p. 1). The replication involved the conduct of a household survey (to replace the MPHS data as was done in Nalgonda), the installation of computers and the FHIMS, the entering of survey data, training for the health staff, and the initiating of the other activities (such as identifying private agencies for printing MPHS books or team building) necessary for starting the project.

Based on the experience of the pilot, many changes were made during the replication phase. Survey registers were printed with an index and in alphabetical order. A team of 16 people were trained in each district, who in turn trained the health staff at the district level on how to conduct the household survey. Doctors were involved and system administrators were identified. Videoconferencing facilities were used regularly by the commissioner to coordinate and give instructions to health officials in the district, and to obtain status reports on the data-entry process. A number of circulars were sent to every PHC regularly, giving detailed instructions at different stages of implementation.

The computers were introduced in September 2003 in the PHCs, and the initial plan was to start the project by December 2003. In July 2005, one of the authors and his team conducted a situ-

ational analysis of the status of the implementation of FHIMS in 84 PHCs in another district (called Chittoor). This evaluation report, which was provided to the collector of the district, the DM&HOs, and the state-level authorities, identified a number of ongoing problems in the implementation of FHIMS contributing to it being far behind schedule. The evaluation identified that all the PHCs had reported software bugs of varying levels of complexity. Although household data had been entered, service data remained grossly incomplete. None of the PHCs were generating any of the reports that were needed to be sent to the district. This was because, except for one report, other reports could not be generated through the FHIMS. Although in a few cases schedules for health assistants were being printed, the demand for these schedules did not come from the health assistants themselves, but the schedules had been printed by the data operators (before they had left) and given to the health assistants. The study also revealed that on average only three or four people per PHC had received training in computer awareness through the 5-day training programme. No formal training was given to the PHC staff on FHIMS. In some cases, the data operators had provided some basic training to the system administrators. In more than 50% of the PHCs, none of the staff knew the username and password to enter the FHIMS modules after the departure of the data operators.

In summary, various factors have been identified that have impeded the implementation of the HIS initiatives discussed. These complexities are sociotechnical in nature. While some of these problems are expected given the extreme complexity of the projects, some, we believe, can be addressed by providing increased care and attention to the sociotechnical issues. In Table 1, we summarize some of these key challenges, and in the following section, we discuss how they were addressed.

DISCUSSION

One of the key recommendations of WHO (2005) in *Health and the Millennium Development Goals* is to improve the information basis on which health management decisions are made. The report notes, “making available information concerning the location, functioning, and performance of health services should also improve transparency and accountability in the management of the health sector” (p. 79). Accurate information can support better management and enhance the efficiency of health-care delivery. HIS can contribute to human development by supporting health management. Jacucci, Shaw, and Braa (2005) argue that the overall sustainability of a standards-based HIS is dependent on the quality of data and the skillful use of data at the level of collection. Local sustainability of the HIS requires the information to be of relevance not just for the managers, but also at the local level. This requires training health staff not just on the mechanics of using software, but also on public health-related topics of information use, data quality, significance of health indicators, validation, analysis, and interpretation of data, and linking these with interventions on the ground.

The implementation of HIS is not just a matter of introducing technology, but is also dependent on the social, organisational, and political issues that need to be addressed on an ongoing basis. Several authors have emphasized the need to understand and analyse information systems from a sociotechnical perspective (Coakes, Willis, & Lloyd-Jones, 2000; Kling & Lamb, 2000; Walsham, 1993). For example, Kling (1987) and Kling and Scacchi (1982) utilize Web models to take into account the social relations between the set of participants, the infrastructure available for its support, and the previous history of commitments in the organisation around computer-based technologies. Walsham (1993) provides an analytical framework for understanding the mutually shaping linkages that exist between

content, social context, and social processes of IS. Over the years, several authors have both applied Walsham's structural framework and also expanded it by including various facets of the economic, cultural, and political context (e.g., Avgerou & Walsham, 2000; Jarvenpaa & Leidner, 1998; Madon, 1993; Sahay, 2000; Walsham, 2001). Avgerou and Madon (2004) argue "for broadening of the perspective of situated research to make explicit the contextual origins of the meanings, emotional dispositions, and competencies actors bring to bear on the interactions that constitute these processes" (p. 176).

Even though a participatory approach was stated to have been adopted to a certain extent during the design and implementation of the FHIMS, in practice, this did not evolve into effective and sustainable partnerships resulting in end users owning the new system. As an example, the HISP team conducted a situation analysis in the 84 PHCs of the Chittoor district in August 2005 after the contracts of the data-processing operators responsible for the FHIMS implementation were discontinued. The analysis revealed that in about 50 of the 84 PHCs, the FHIMS system had not been used since the departure of the operators because the PHC staff did not even know the password to log into the system, indicative of the absence of a partnership between the implementing team and the end users, and the lack of local ownership of the system. This raises the need to adopt complementary or alternative approaches that can facilitate the creation of local capacity and ownership. This requires the trainers to play multiple roles from building technical capacity to motivating the staff, and facilitating the change processes at multiple levels (Tomasi, Facchini, & Maia, 2004). Building these capacities is a slow and gradual process, but they are crucial and fundamental for the collective ownership of the project. This requires the need to shift the focus from being primarily on technology to the various surrounding processes required to strengthen the informational basis of health management.

Some ways in which these challenges are being addressed in the FHIMS case is now discussed.

Shifting Focus from Technology to Information: Empirical Experiences from IHIMS

In order to address the various implementation challenges, the State Health Department endorsed in July 2005 a project called Integrated Health Information Management System (IHIMS) through a Memorandum of Understanding (MoU) with HISP India³ (a not-for-profit society set up by the University of Oslo). HISP is an ongoing, large-scale action research initiative that operates as a global network across a number of developing countries. HISP was started in India in December 2000, and was operating in some limited areas parallel to the FHIMS project, which had a state mandate. Since FHIMS was the official state project, and HISP was seen primarily as a university research and development project, HISP was always vulnerable to being terminated by the state in favour of FHIMS. As a strategy to protect itself against such an event, the HISP management proposed to the state the IHIMS project, which would integrate the individual capabilities of the FHIMS and HISP projects and develop synergies to contribute to the overall health information management in the state. The integration logic argued by HISP was informational rather than technological. While FHIMS was a name-based software, the District Health Information Software (DHIS), a not-for-profit customised open-source software developed by HISP, was a facility-based system. By linking the two technological systems, it was argued that an integrated informational analysis could be carried out both at the level of individuals and health facilities. Also, since the DHIS was linked to the Web and GISs, the integrated system could provide visual representations of the information on the Web and maps, something not currently possible with FHIMS.

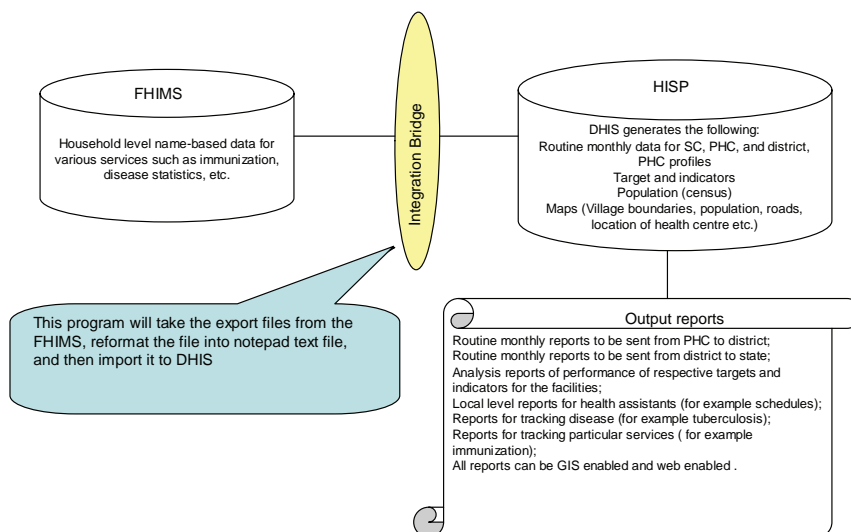

Technically, the integration was developed in the following way. With its focus on name-based data, FHIMS was capable of generating subcentre-based reports and schedules to help the health staff identify which households to visit and when. The name-based household data was entered into the FHIMS, through which the subcentre-based reports were generated. The data were then aggregated and imported into the DHIS by facilities (subcentres) and processed, which resulted in the generation of various analysis reports, including on the GIS and Web. The integration was thus proposed to convert some of the raw (household based) data into useful information through the use of analytical tools, and to improve the representation of the data using GIS-generated maps. In arguing for the integration, the HISP team emphasized that map-based reports would be useful for district- and state-level officials, for example, in resource-allocation decisions (such as opening a new facility or buying an ambulance). The conceptual schema of the integration proposed, and subsequently accepted, through the MoU under the IHIMS project is depicted in Figure 2.

The IHIMS implementation commenced in August 2005, and the first phase of the project

was a situation analysis to try to understand the status of the earlier FHIMS implementation and the underlying challenges. A key problem identified was that the operators who had been working previously in the PHCs under the FHIMS project had operated as independent islands and had not involved the health assistants in the PHCs. As a result, there was little development of local expertise and ownership of the system. As mentioned earlier, in nearly 50 of the 84 PHCs, even the passwords to log on to the system were not known to the staff in clinics there. In contrast to the approach of the operators whose focus was on data entry, the HISP's emphasis was on system facilitation whereby the data entry and report generation was not done by the trainers, but by the health staff themselves, supported and facilitated by the trainers. Also, there was a difference in the focus of the training content, which was not limited to the mechanics of the software, but also to issues of how information can be made useful to support local action.

After the situation analysis in August, the HISP trainers were assigned to a cluster of four to five PHCs and were responsible for providing ongoing support to the staff on site in each of the

Figure 2. The FHIMS-HISP integration

PHCs. This on-site training approach was radically different from the earlier FHIMS training strategy of one large district-level 3- to 5-day training programme followed by literally no support to the staff in the course of their everyday work. From August to November, a key focus of the IHIMS project was on completing the huge amounts of backlog in data entry in the FHIMS database, and trying to change the mindsets of the health staff from FHIMS to IHIMS, which included both DHIS and FHIMS. At the end of November 2005, an evaluation of the IHIMS indicated that 68 of the 84 PHCs had completed the backlog of data entry, and they had generated the Form B, mother and child report, and also the Forms A and C, for communicable diseases and other health services. The way IHIMS worked was that data for the Form B was entered into the FHIMS, and the report accordingly generated. However, the data required to generate Forms A and C were directly entered into the DHIS database, and the reports were generated through the DHIS. The FHIMS technically was not capable of developing the Forms A and C, but through the integration of the two systems, the whole suite of reports could be generated. Another evaluation at the end of December indicated that the number of PHCs that had generated the Forms A, B, and C was now 75, and the remaining 9 had serious structural problems (lack of staff or very large PHCs). Also, some of the PHCs, in addition to the routine reports of Forms A, B, and C, had also started to generate some analysis reports such as those for conducting inter-subcentre comparison. The HISP's training focus in the future was to be increasingly on the analysis reports and the use of information for action.

The relative success of the IHIMS programme can be attributed to three key reasons. First, by linking up the FHIMS and DHIS, the state government gave opportunities for the different people involved to pool their strengths and capacities rather than fight with each other. Second, the

individual capabilities of the two systems could be innovatively combined so that the FHIMS software was used for generating subcentre-based reports while the DHIS provided the facility-specific reports and also incorporated different forms of representation including the Web and GIS. Third, alternative training approaches could be included through the integration. Unlike the FHIMS project, in which training focused primarily on the use of computers, HISP emphasized the use of information, including the generation of reports, the analysis of data, and the use of GIS to make visible spatial correlations in health data. Also, HISP tried to develop the capacity of the health assistants and other staff at the PHC in the local use of information. This effort is part of a larger and long-term process of developing an information culture where data is not just seen as a mindless effort to fulfill the needs of an uncaring bureaucracy, but a resource that can strengthen the everyday local work. This approach is compatible with Sandiford et al.'s (1992) argument:

the ability to analyse and interpret data is indispensable but insufficient to overcome the inertia of the status quo to ensure that the information is translated into decisions and action....The need to tailor the presentation of information to the intended audience must be recognised. (p. 1085)

The analysis capabilities of the DHIS could be emphasized through various preprogrammed tools that provided the user with the ability to make comparisons and present data in the form of graphs, charts, and maps. Similarly, GIS provided particular analytical tools that enabled the mapping of health status and diseases, programme planning, displaying health-care coverage, planning health infrastructure and maintenance, and comparing performance indicators across PHCs (Sauerborn & Karam, 2000).

Prior research in the domains of IS and HIS, both in developed and developing countries, has

emphasized that integrating systems is no easy task as it involves aligning social, technical, and political linkages, and fostering coalitions and building synergies (Chilundo, 2004; Hanseth, Ciborra, & Braa, 2001). We agree with Chilundo, who has argued that the integration of ISs is not only a technical exercise, but involves the creation of a heterogeneous network comprised of various groups of people, technological artefacts, medical practices, and different information systems. While, at one level, integration can be seen as an attempt to reduce some of the heterogeneity in the system arising from a multiplicity of information systems, by adopting a modular approach to integration, heterogeneity can be encouraged rather than neutralized. While both the DHIS and FHIMS were capable of operating independently, in combination they were able to produce the whole set of reports required by the health department. Integration of not only the technical systems also implied bringing together different training approaches and also the pooling of financial and human resources. For example, the system administrators, a post created to support the FHIMS implementation, now were made the focal persons under the IHIMS and became responsible for the generation of the reports from both the DHIS and FHIMS systems.

In summary, we argue that the integration of systems can provide potential opportunities to address some of the implementation challenges discussed earlier. However, the philosophy underlying the integration attempts should not be to neutralize or eliminate one system, but to see how synergies can be created through drawing upon the positive aspects of both the systems and associated resources. For example, through IHIMS, the positive aspects of FHIMS, which were the name-based service schedule and summary reports, and DHIS, which was the facility-based reports, could be meaningfully incorporated toward the broader goals of health management.

CONCLUSION

The case studies presented earlier provide evidence of the importance of adopting a sociotechnical and integrated approach to the development of HIS. Too often, the introduction of ICTs is equated with development as an end in itself rather than as a means for supporting health management, which can in practice support development. These projects end up as largely computerisation projects and unsuccessful ones at that, rather than effective health-management initiatives. The introduction of computers, and the development and implementation of HIS in itself are not sufficient. Rather, the focus should be on how to develop and improve the informational base whereby information comes to be seen as a resource at all levels—at the local, district, state, and national levels—rather than just for bureaucracy.

There is typically an overemphasis on technical aspects during the implementation of HIS, and a relative neglect in addressing problems of information support that is necessary for better health management. The challenge is to move away from this pattern and to adopt a more integrated, holistic, and comprehensive approach to reforming informational and organisational practices. Introducing a HIS, particularly a name-based system, without addressing issues related to information generation, management, and use (analysis, interpretation, and evidence-based decision making) does not solve existing problems of poor quality of data, or the manipulation of figures, because health staff working in the field may have their own logic, stakes, and priorities that might not align with the goals of the promoters. That is, introducing information technology and systems does not in itself necessarily lead to better information practices or better health management. The challenge is not just to have adequate information, but to make better use of it and have a greater ability to act on it.

A grand vision to have a unified system (one-for-all purposes), as in the case of MPHS and FHIMS, may be attractive, but it brings with it numerous problems and is difficult to put effectively in practice. Instead, a more realistic approach should attempt to recognise what exists, what works well, and at what costs new systems are being built. While the name-based approach of the FHIMS is useful at the community level to track patients and provide targeted health care, HISP emphasizes the use of analytical tools for better health management and for capacity building of health staff. Initiating synergies between the FHIMS and DHIS through an integrated approach, as is being empirically attempted, provides opportunities to develop more sustainable health information systems that either of the systems by themselves cannot provide. These opportunities come through increased technical functionalities to serve different needs, a pooling of financial and human resources, and the incorporation of different and complementary training approaches.

ACKNOWLEDGMENTS

The authors would like to thank Professor Lucy Suchman for her helpful comments on previous drafts of this chapter. We would also like to thank the officials at the office of the Commissioner of Family Welfare, Andhra Pradesh, all the health staff and members of HISP India, and the FHIMS team for their support.

Chapter 4.26

Current and Future State of ICT Deployment and Utilization in Healthcare: An Analysis of Cross-Cultural Ethical Issues

Bernd Carsten Stahl

De Montfort University, UK

Simon Rogerson

De Montfort University, UK

Amin Kashmeery

University of Durham, UK

ABSTRACT

The ever-changing face of ICT can render its deployment rather problematic in sensitive areas of applications, such as healthcare. The ethical implications are multifaceted and have diverse degrees of sensitivity from culture to culture. Our essay attempts to shed light on these interplaying factors in a cross-cultural analysis that takes into account prospective ICT development.

PREAMBLE

Satisfactory provision of healthcare is central to our quality of life. At the same time, healthcare is a central cost factor in our personal as well as public expenditure. Healthcare systems in different countries face different challenges and provide different levels of services. It is probably fair to say that there is no one model that can address or overcome all issues. It is probably also fair to

say that most healthcare systems are trying to use technology in order to address some of the problems they are facing. Among these problems, one can find issues of cost minimization, consistency of care provision, quality control, labor saving, and a variety of others. This chapter will explore the relationship of culture, ethics, and the use of information and communication technology (ICT) in healthcare. As this suggests, we will not be able to do justice to the intersection of these four topics. Instead, the chapter will attempt to identify some dominant issues that are of relevance today.

The main purpose of this chapter is to develop a framework that will allow us to understand how culture can shape the perception of the ethicality of the use of ICT in healthcare. It is meant to provide the foundation upon which we can build valuable empirical research. We are interested specifically in the question whether there are cultural differences with regard to the perception of ICT in healthcare between individuals from cultures in a non-Western setting and those from European, specifically British, culture.

Given the size and complexity of the topic, we will use this chapter to outline some of the relationships among the main concepts and to identify areas worthy of research. Following basic definitions of pertinent concepts, the chapter will start by discussing the relationship between culture and health informatics and then proceed to describe some of the ethical issues of health informatics. These two strands of thought then will be combined to develop the concept of cultural influence on the perception of the ethics and morality of health information systems. We then will describe several scenarios that will render it clear what kind of issues we believe to be likely encountered. Establishing the descriptive and theoretical part of our topic will pave the way for developing methodological considerations that are pertinent to empirical research and to the cultural impact and ethics of ICT use in healthcare.

Ethics and Morality

It long has been established that, for the sake of practicality and application, a distinction should be made between ethics and morality. Morality can be defined as the set of acceptable social rules that are adhered to in a given community. Following this, one can define ethics as the workable scheme for the theory of morality. Ethics then can be used to describe, define, and justify morality. This distinction is not required by the etymology of the concepts, and it is not always used in English language writings on ethics. It is more widely adhered to in continental European philosophy (Stahl, 2004). We nevertheless believe it to be useful because it can help us distinguish between fundamentally different issues. Morality is a social fact and can be observed through the use of established social science methods. For example, we can observe patients in hospitals and find out whether they believe that a certain action is good or bad, whether they believe that a certain use of technology is acceptable or not. This question is fundamentally different from the ethical question of why the use of a technology is good or bad. While most individuals follow a morality of which they are aware, many of us rarely engage in explicit ethical reflection. That means that patients' ethical convictions, while important for their moral attitudes, often are implicit and much harder to determine. This has methodological consequences that will be discussed later.

Another reason the distinction between ethics and morality is important for our project is that it roughly corresponds to the difference between descriptive and normative research. One can undertake purely descriptive research on the social fact of morality, but when it comes to ethical justifications and normative suggestions, one changes the level of analysis. This is important for researchers to reflect on, and the conceptual distinction will make it easier for us to do so.

CULTURE AND INFORMATICS

This section will briefly review the relationship between culture and health informatics. For this purpose, it is useful to state why we are speaking of health informatics rather than information systems, software engineering, or computer science. The reason is that the term *informatics* is more inclusive and aims at use and social context rather than at the technical artefact itself. This is particularly pertinent, given that technology applications in healthcare are never ends in themselves or pure gadgets, but are always there to facilitate the aims of providing care. Such care also is always embedded in situations, cultures, and communities, which must be reflected by the technology. The very term *informatics*, therefore, indicates that we are looking at a wider picture. Interestingly, a large part of academic and practitioner publications dealing with ICT in healthcare use the term. Having thus explained the use of the term *healthcare informatics*, this section now will discuss the concept of culture and its relationship to health informatics.

Culture

Culture is a multifaceted concept that is hard, if not impossible, to define. For our purposes, we can start with an understanding of culture as the totality of shared meanings and interpretations of a given group. This repository of shared understandings and interpretations of the word is represented by emblems whose meanings and interpretations members of the same culture share (Castells, 2000; Galtung, 1998; Ward & Peppard, 1996). The exchange of meanings and the agreement on appropriate interpretations of emblems breed skills of communication, which begin with primitive means but evolve the more the communities develop. Eventually, communities become communication aficionados to the extent that the very existence of the culture depends on it. The nature of the culture will be reflected in

the nature of communication with information or meaning being implicit or explicit. This often is referred to as low context communication and high context communication (Nance & Strohmaier, 1994). This, in turn, underlines the social nature of cultures.

This is a rather wide understanding of culture that requires further specification. It is useful, however, because it allows an understanding of culture as a multiple phenomenon with areas of overlap and frequent change. For example, it facilitates cultures of different reach, such as organizational culture and national culture. Most organizations will have some particularities that are meaningful to their members and that outsiders cannot access easily. This is particularly so within a culture of collectivism (Nance & Strohmaier, 1994). They thus fulfill the definition of culture, and they arguably require a culture in order to facilitate their long-term survival (Robey & Azevedo, 1994). A similar description can be found for national cultures; namely, that they are the collection of things, ideas, and techniques, including institutions, which a society needs to persist (Gehlen, 1997). It should be clear that such a definition of culture will not allow easy delimitations and distinctions. Most individuals will be members of a variety of cultures (e.g., work, sports clubs, ethnic groups, families, nations, and regions). These memberships may be mutually reinforcing, but they also may be contradictory.

An important aspect of culture is that it has a normative function. This means that cultures contain an idea of how things should be and how its members are expected to behave. This means that they are inherently utopian and imply a good state of the world (Bourdil, 1996). There are different ways in which the normative character of cultures is transmitted. One of these ways is what we usually call ethics or morality. These refer to the norms that are accepted in a given culture and the justification of such norms. This also can be translated in terms of values that are

implicit in all cultures. Therefore, one can say that culture is a “value-concept” (Weber, 1994, p. 71). A related and very important aspect is that of tenet. Tenets and creeds constitute what we call meta-ethics. Their essence, usually imposing values and principles on communities that share belief in them, is normative guidance. Some religions are so comprehensive that their creeds and tenets can collectively govern all aspects of life of individuals, including their interactions with other members of the community. To these communities, ethical rules that they would abide by are only those ordained by their religion.

All of this should render it clear that cultures are linked deeply to questions of identity. On an individual level, identity as the answer to the question “Who am I?” is answered by a collection of narratives. These narratives draw on the cultures of which the individual is a member. Despite wide debate of a classification nature between relativists, utilitarianists, teleologists, and deontologists, it remains a fact of life that basic morality in the human species that commands decent conduct (i.e., do not lie; do not steal; do not deceive; etc.) are connate and *natura insitus* and, therefore, for that part universal. Culture, one thus can claim, is a universal ingredient of human existence. Clashes of cultures can evolve when interests conflict and desires intersect. In ramifications of the perplexity of today’s modern life, including those of technological applications, paradigm shifts might redefine postulates. When that happens, some cultures might tend to impose their compromised values on others, thereby leading to contradictory influences on identity and to cognitive dissonance, which can lead to pathological developments.

This point will be addressed in this chapter, since description of distorted cultural values and their influence on the perception of ethics health informatics constitute part of an ongoing debate.

Culture and ICT

The last section indicates that there is a close link between culture and technology. If culture imposes necessary conditions for reproduction, for instance, then it would become clear that reproduction technology and culture will be mutually dependent. By analogy, understanding technology as a rational approach to the environment, which typically uses artifacts for the subordination of nature, we are safe to say that culture is one of the human constants.

The close link of technology and culture extends to different types of technology but, most notably, to the most important and prominent technologies of a given culture. Early agricultural cultures can be characterized by their use of ploughs or other technologies that allowed them to develop agricultural production. Similarly, the cultures we live in today are characterized by their relationship to ICT. Talk of the “information society,” the “global village,” or similar constructs indicates that we are aware of the importance of ICT for our culture. ICT also is linked to the other defining technologies of our age, such as biotechnology and nanotechnology, but also to modern developments of more traditional technologies such as mechanical production technologies.

ICT thus allows the functioning of social institutions in Western societies such as the UK. Public administration and economic activities would look different without it. On the other hand, the social institutions we find in our cultures allow the use and development of ICT. Apart from this high level of interdependency between culture and ICT, there are also links that are less visible but as important. If we go back to the definition of culture as a set of shared meanings, norms, and interpretations, then we will see that culture strongly influences our perception of ICT and of the uses we believe to be acceptable. Again, this is a two-way relationship in which technology also affects the repository of available signs and their

interpretations. For example, we find it normal to speak of humans as information processing machines and to compare our cognitive functions with those of a computer. This indicates that technology has found its way into the set of symbols and metaphors that we believe to be meaningful. The issue becomes more complicated when culture and, consequently, ethics plays on several notes or acts on a multitude of fronts. Ethics of ICT in healthcare demands macro- and micro-analyses of not only the impact of ICT application on societal values but also the product of associated impacts of the combined forces interplaying in the overlapping parts of ICT and healthcare domains.

ETHICS AND HEALTHCARE

Healthcare procedures touch most of us on many different occasions. They are there during the most existential moments of our lives, from birth right across to death. They can affect our well being directly by providing remedies and alleviating pain and indirectly by offering us the certainty that we will be taken care of when needed. In light of the importance of healthcare for our physical and mental well being, it is easy to say that healthcare and ethics are closely related. But, nevertheless, it will be helpful to clarify the concepts used and to indicate some of the areas that we believe to be of relevance to our research.

Value-Based Practice (VBP) vs. Evidence-Based Practice (EBP) in Healthcare

Contemporary applications of ICT expand across the spectrum of healthcare fields. New developments in areas such as ICT are still unfolding and will continue to do so for some time to come. This situation usually creates what could be described as a policy vacuum (Moor, 1985). Applications of

ICT in healthcare systems lead to yet a further step of ambiguity and uncertainty. This is because a policy vacuum breeds an ethics vacuum. In order for action policies to be formulated, a conceptual framework needs to be created through appropriate analysis of the situation in question. This is very much the case in healthcare. In healthcare settings, current and future extensive use of ICT undoubtedly would result in a new state of affairs, which needs to be conceptualized in order for it to be given the legal, moral, and ethical codes that would keep its deployment in an acceptable manner—legally, morally, and ethically.

Over the past five decades, the world has been going through the initial, introductory phase of communication technologies, followed immediately by a boom in information technology applications and then a convergence of computing, communication, and media technologies. We currently are witnessing the new phase, which is still pervading diverse aspects of our lives in an unprecedented interfusion. Thus, this phase merits the title *permeation stage*. The ethical dimensions of healthcare ICT deployment under such circumstances can best be elucidated, if investigations covered areas, where vulnerable groups constitute the matrix. These mainly include neonates and infants, the elderly, palliative care, and mental illness patients. ICT could transform our concepts to the extent that the question is not anymore “Would it enhance healthcare?” but rather “What is healthcare?” When that happens, we then will realize how intangible healthcare has become. It is in such areas that ambiguity is evident as to whether health decision making should be the product of values or facts.

In terms of systematic categorization, recent researchers divide this domain into two distinct major subsections; namely, values-based practice (VBP) and evidence-based practice (EBP). Bill Fulford, one of its prominent advocates, defines VBP as the theory and skills base for effective healthcare decision making, where different (and,

hence, potentially conflicting) values are in play (Fulford, 2004). On the other side of the debate, Ronald Levant, an advocate of EBP, describes their initiative as a movement that strives to achieve accountability in medicine, psychology, education, public policy, and even architecture. He maintains that professionals are required to base their practices to whatever extent possible on evidence (Levant, 2005).

How Relevant is the VBP/EBP Debate to Health Informatics?

Values in a broader sense are “standards of behaviour” (Waite, Hawker, & Soanes, 2001). But this definition falls short of giving even a framework, if values were to be used for applied purposes, such as healthcare practice. In that sense, Sackett, Straus, Scott-Richardson, Rosenberg, and Haynes (2000) maintain that specifically patients’ values mean their unique individual preferences, concerns, and expectations. In practical terms, what these bring to clinical encounters should be integrated for the purpose of making sound, clinical decisions that would serve these patients’ interests. Combining the two definitions, it would appear that standards of behavior can become a function of preferences, concerns, and expectations; in short, the interests of all parties involved. Other definitions go as follows, singling out people’s interests: Value-based practices (VBPs) are practices that are grounded in people-first values, such as choice, growth, personhood, and so forth (Anthony, 2004).

Seedhouse (2005) in his recent work sets out his vision for a democratic future for healthcare decision making in which values of all stakeholders in the healthcare system will be taken into consideration. Values, being a subjective domain, require practice skills and methods of delivery when applied as a tool for healthcare decision making. Interaction between patients and providers is an essential part of the healthcare process. Value-based practice takes such activity

into account and considers its proper application a responsibility that the provider should strive to achieve. Among subheadings relevant to informatics and ICT, *knowledge* and *communication* stand out in this context. These are two terms used for information retrieval, acquisition, and accumulation. Information usually is acquired through first-hand narratives, polls, surveys, and media reports. In order for communication to be effective in terms of value-based practice in healthcare, the human factor is indispensable. Elements, such as attentive listening, empathy, sympathy, and reasoning, are attributes only of human beings. Methods such as Internet polls, postal surveys, and camera surveillance are potential recipes for communication failure, which, by the same token, will impact the value-based assessment and decision making. The knowledge thus acquired might have a wider impact of a negative nature not only on the users (patients) but also on other groups involved in the process, such as managers, social workers, insurers, and so forth (Colombo, Bendelow, Fulford, & William, 2003).

As interests vary from person to person and from group to group, the question as to how conflict is handled becomes inevitable. In fact, this is the paradox of value-based practice in healthcare. Therefore, the term *value* ought to be analyzed further into its micro-dimensions, which constitute a spectrum ranging from the abstract sense of ethics and over self-fulfilment criteria (wishes, desires, needs, etc.) right up to principles and beliefs. Another feature that renders the value concept problematic is the fact that values are not static; they change with time and can be modified under certain circumstances. This situation is exacerbated by the fact that some cultures allow such changes to take place, and others allow that to happen only within a very narrow margin. Also, the attitudes toward such changes can bear different connotations. They can be defined as developments in the positive

sense of the word, but they also can be defined as degradation.

Evidence-based practice, on the other hand, can be executed with the least reliance on the human factor. Artificial intelligence, expert systems, and diagnostic software are vivid examples. When sufficient material for decision-making precursors is at hand, opinions based on facts and evidence come into play. As mentioned above, EBP advocates concentrate their concern on accountability and pursuit of fact and evidence to verify it (Levant, 2005). Others have their own agenda for EBP implementation, which, in their view, should be guided by the recovery-oriented process and its values (Stultz, 2004), a matter that would transform EBP into VBP as well.

It is worthwhile to briefly considering the status of these considerations in terms of ethics and morality as outlined previously. If morality consists of the accepted norms and if ethics are the justifications, then values would seem to be part of both areas. Values are those things that we value and, thus, can be immediate generators of moral norms. On the other hand, values also can be part of the justificatory context of morality. The introduction of the term *value* to the debate also raises another issue: What are we to do if values contradict? As already stated, basing medicine on evidence is an immensely value-laden starting point. It implies assumptions on the nature of reality and of our abilities to access this reality. Evidence-based practice is thus value-based, even if this is not often recognized. Another problem of the concept of values refers to competing and contradictory values. When we speak of value-based medicine, we should realize that there is no single value and no coherent set of values that could guide this. The question thus appears—which values to choose among competing ones? An answer to this question would lead us beyond the current chapter and would have to go back to ethical theory. Very briefly, one solution could be the introduction of a hierarchy of values that would help us to identify

which values we should prefer in case of a value conflict (Stahl, 2003).

Is Ethical Impact Proportional to Technology Sophistication?

In order to answer this question, it would be sensible first to define sophisticated ICT applications in healthcare and what degrees of sophistication are meant. Two broad areas frequently are being identified by prominent bodies such as UNESCO: telehealth and telemedicine. “The former ... [includes] health services, education and research supported by ICT, while the latter refers more specifically to medical care and procedures offered across a geographical distance and involving two or more actors in collaboration, often in interdisciplinary teams” (UNESCO, 2005) As such, both are seen as related to healthcare informatics.

Equity, as a basic concept in all aspects of life, is a value that should be observed by all parties involved in any given setting in which spheres of interests overlap and lines of rights intersect. It is particularly so in healthcare systems. If we consider the situation of healthcare in a third world setting, inhabitants of remote rural areas who hardly have any care at their disposal would find equity a luxury that they cannot afford. ICT can benefit people who inhabit these isolated areas. In terms of observing, for example, the value of equity in healthcare under such circumstances, telemedicine applications are of particular benefit in that they do the following:

- Enhance access to better diagnosis to all people through computerized techniques.
- Enable online consultation with specialists, thereby reducing cost to the benefit of care providers.
- Enable follow-up through easy feedback on the efficiency of the prescribed treatment.
- Allow a chance for local medical professionals to receive training without having to move to more urbanized areas.

- Allow the establishment of databases for easy access to medical records.

Operations such as this could expand to an international level reaching as far as the technology can geographically go, thereby surpassing limits beyond which control becomes increasingly difficult. It is this degree of sophistication that could cause concern. Amidst these vast operations, it would become obvious that values such as confidentiality would be liable to breach with less and less control possibilities. Confidentiality as a personal requirement, however, is being dwarfed in comparison to security at a national or communal level.

An explanation might be that wide-scale research, such as clinical trials, can yield an enormous amount of information. If such information compiled by research conducted on whole communities is of a sensitive nature, such as DNA and genes, the breach of information confidentiality can become alarming. Genes can carry information that reveals traits common in the genetic pool of the whole community to the extent that their very existence could be at risk. Future bio-weapons fall into this category. This is supported by the fact that pharmacogenetics is a reality, which means that certain individuals, groups, or communities are more ready to respond to certain drugs than others, depending on their genetic makeup. This is being vigorously researched under the pharmaceutical domain for enhancing therapeutic and medical treatment. By the same token, however, individuals, groups, or whole communities can be inflicted specifically by disease through certain drugs or chemicals, depending on their genetic makeup. This is very much the case in societies whose building blocks are tribes or clans. We will explore this aspect further later on.

CULTURAL INFLUENCE ON THE ETHICS OF ICT USE IN HEALTHCARE: PARADOXES FROM WESTERN AND NON-WESTERN SETTINGS

In this section, we will have to choose some pertinent characteristics of the cultures that we hold to be representative and contrast them with certain uses of technology. It will end up with a collection of scenarios that will elucidate some issues of concern and shed more focused light on their complexity.

Issues in British Culture

British culture, as a vivid Western example of dynamic liberalism and utilitarianism, can serve the purpose of contrasting Western vs. non-Western settings. The liberal tradition translates into a high regard for the individual and the belief that social phenomena can be reduced to the sum of individual ones. This is important for healthcare, because the individual's rights are considered of primary importance, whereas collective considerations tend to be viewed as secondary. At the same time (and closely related to liberalism), British culture is influenced strongly by utilitarianism. This means that it is a generally accepted ethical principle to sum up all utilities and disutilities of a given act and to make decisions according to the comparison of the aggregate utility of an act. Utilitarianism often is vulgarized into a cost-benefit analysis in which the methodological problem of measuring utilities is replaced by measuring financial costs and benefits. This means that cost-benefits considerations are deemed appropriate in ethically charged situations. It also means that there is an intrinsic contradiction between the two main pillars. While utilitarianism is based on a methodological individualism and,

thus, compatible with liberalism, it is also deeply collectivist, because the rights of the individual can be (morally) overwritten by the overall collective utility.

Another aspect of mainstream British culture is that it is modernist, meaning that it relies on and trusts reason and science. While there is some resistance to this modernist view, it probably is safe to say that in mainstream British discourses, scientists are regarded as reliable and trustworthy, and the results of scientific research are seen as valid. This links to utilitarianism, which can be seen as the attempt to render ethics scientific. Science is justified, because it will help bring about a greater sum of happiness. It also means that there is an intrinsic bias toward evidence-based medicine and by association healthcare, because this is based on the scientific approach. Considerations of value are not seen as equally valid.

Examples of Issues in British Culture

On the basis of liberalism, utilitarianism, and modernism, British culture is fundamentally appreciative of new technologies. This is true for technology in healthcare as well. New healthcare technologies generally are described as positive and benevolent. There is, however, a stream of literature and research that looks at the intrinsic contradictions that grow out of the traditional view of technology in healthcare. Berg, whose work was done in the Netherlands and is transferable to the UK, describes some of these issues. The modernist view of ICT assumes that there is one governing rationale and that technology can be used accordingly to further the well being of patients. Doctors use technology to help and heal patients. This overlooks that modern societies are much more complex. One explicit reason for the use of ICT is thus to support organizational issues (Berg, 1999). Such an approach overlooks that healthcare is a complex system with a multitude of conflicting actors and interests. But even if it works, ICT then can be used to change the

way in which healthcare workers and patients interact. Technology can lead to disliking doctors and nurses. On the other hand, it also can widen the access to health services. Technology, which formally structures processes, also will lead to bureaucracy, which produces costs and, thus, is not always desirable from the utilitarian point of view.

Another interesting problem can be found in the intersection between healthcare, technology, and rationality. The modernist view of linear and individual rationality that objectively can determine desirable solutions (which is also the basis of evidence-based medicine) is not just problematic, because it underestimates the complexity of organizations. It is, to some degree, self-contradictory because it requires the very ad hoc and pragmatic activities to survive that it sets out to replace (Berg, 1997). More importantly, it also can be seen as an ideology that promotes particular interests. Using the case of a new online service, NHS Direct, Hanlon, et al. (2005) argue that “the supposed dominance of this technocratic consciousness hides class, gender and jurisdictional struggles” (p. 156). The Electronic Patient Record is a good example of these issues. Fairweather and Rogerson (2001) argue for a morally appropriate balance between the various moral standards that are in tension in the field of electronic patient records (EPRs). EPRs can facilitate doctor-patient relationships. However, at the same time, they can undermine trust and so harm the doctor-patient relationship. Patients are becoming increasingly reluctant to tell their own doctor everything that is relevant. A number of moral principles and the question of consent to release records need to be considered.

Issues in Non-Western Culture

Social norms differ from one community to another in different parts of the world. What is acceptable and permissible somewhere might not be so somewhere else. Therefore, healthcare

planners and strategists must have a clear vision of what would and what would not trigger sensitivities in the process of healthcare delivery and decision making. For instance, the vital communication element previously mentioned for good value-based practice can become totally defective if carried out, for instance, in a male-to-female setting in which social norms do not accept it. A similar attitude is expected in situations such as vaginal swabbing or artificial insemination, the meta-ethics being tenet-rooted. It is against the social norms and religious codes of many world populations. Muslims, for example, who constitute just over a quarter of the world's population (<http://www.islamicweb.com/begin/results.htm>) have attitudes that are overwhelmingly governed by Shari'a codes of conduct. These ordain many aspects of life, including those that fall within the sphere of healthcare. Questions concerning issues such as permissibility of a male healthcare provider to examine a female patient (or vice versa) are hot debate topics. This will be investigated further in the scenarios given next.

The influence of culture on the perception of health information and communication technologies are issues in a Middle Eastern setting (women, tribal structures, etc.). Further, to points mentioned previously, issues of ethical dimensions can be exacerbated by cultural influences. In the following section, we will try to take the reader through selected scenarios, some hypothetical and others compiled from real life in parts of the world that have entirely different attitudes toward practices seen in Western settings as acceptable—the effect being cultural.

Some Scenarios

Scenario 1: Outcry to the King

Ali takes his wife, who is in labor, to a university teaching hospital. Shocked to learn from the receptionist of the obstetrics and gynecology department that the attending physician is male, not

female, he reluctantly leaves the hospital to send a bitter letter of complaint through the media to the highest authority in the country: the king.

Let us imagine how the situation would be if this scenario were repeated, and the wife had complications and would require consultation and on-air monitoring via telemedicine.

Scenario 2: 30 Years in Pursuit of a Female Orthopedist

Yassir writes on May 18, 2005, to a medical forum asking for help. His mother has been suffering from debilitating orthopedic problems for 30 years and is reluctant to be seen by a male orthopedist; there is no female specialist in the area where they live.

Yassir's mother could not be helped, even by telemedicine intervention, so long as the hands that would touch her were those of a man, as she put it. The patient received numerous messages of support and sympathy.

Scenarios 1 and 2 are in total compliance with the Islamic code of conduct. The Islamic Jurisprudence Council of the Mecca-Based Muslim World League issued in its 14th session, convened in January 1995 in Mecca, its Fatwa (dictum) emphasizing the impermissibility of healthcare professional attending patients of the opposite gender. The Fatwa allowed for a margin of permissibility only under circumstances of absolute necessity. As is the case in all other similar situations, the degree of necessity is left to the individual to evaluate. In our two scenarios, the persons in question did not categorize their situation as absolute necessity and, therefore, abided strictly by the given Fatwa.

Scenario 3: Miss L. and the Monitoring System

Miss L. is admitted to the hospital in the summer of 2003. During her stay in a single room on the surgery ward, a young male in a professional

outfit made frequent visits to her, paving the way for a relationship to develop between the two. Eventually, kissing and hugging took place. Without realizing that the monitoring system was active, she enjoyed it. Soon, another man appeared and showed her photographs of her intimate encounters, threatening to make them public on the World Wide Web, unless she gave in to his demands, which turned out to be sheer sexual blackmail.

Scenario 3 is a typical example of the abuse that technology could undergo as a powerful tool with which opportunistic people might fulfill their desires. The perpetrator knows that Miss L. faces a very difficult situation, as cultural and social values of her society would not approve of her behavior.

Scenario 4: Mr. A.F. and the Monitoring System Again

Mr. A.F. was admitted to the hospital as a private patient and stayed in a private, luxury room for two weeks for pulmonary infection treatment. On one occasion during the convalescence days, his wife, who was visiting him at the time, happened to be with him alone in the room. He locked the door and had a very steamy, intimate encounter with her, without realizing that the monitoring system was active. The hospital management, while reiterating the fact that they were doing their job, soon acknowledged the unfortunate incident, offered an apology, and promised to destroy the film that carried the embarrassment, reminding Mr. A.F. that the essential function of hospital rooms is healthcare and receiving visitors for the purpose of the patient's welfare, but nothing beyond that. Mr. A.F. was adamant in not accepting the apology and insisted on suing the hospital. His argument was based on the conviction that his welfare extended to the activity he performed and that the hospital should have warned him beforehand of the monitoring system and what activities they had in mind for monitoring. He also maintained that

had the monitoring system been run by a human being, he or she would have stopped filming the action immediately. Leaving it up to a machine led to the embarrassment, for which the hospital should be held responsible.

Scenario 5: Genetic Screening and the XL Clan of the LL Tribe

Tribes in Middle Eastern regions and in some other parts of the world constitute the main building blocks of many societies extending across geographical boundaries and trespassing political borders. They share common ancestry and, therefore, a gene pool. The chronicle of this ancestry extends deep in history. Qahtani tribes, for instance, are named after Noah's descendant Qahtan, and Adnani tribes after Adnan, one of the descendants of Ishmael son of Ibrahim. Their branches and subsections are numerous and extend throughout the Arabian peninsula and beyond. For instance, about 70 tribes can now be identified in the UAE alone. Through the tribe and its hierarchy, the individual has the right of protection of the tribe and is obliged to abide by its rules. Disputes among members of the same tribe are dealt with by heads of clans, leaders of the subtribes, or the chief (sheikh) of the tribe. Verdicts and rulings thus formulated are binding to all parties. These stem from traditional tribal conventions and practices (urf), known to everybody. The traditional tribal system even makes a young man's own choice of his bride largely immaterial, as it strongly advocates first and second cousin marriages. The first option is usually the daughter of his paternal uncle. It is, therefore, not surprising that some of these clans who have been living in isolated, remote areas for millennia have an exceedingly high rate of consanguinity and, hence, are expected to have a reasonably distinct genetic makeup (<http://www.al-bab.com/yemen/soc/maneal.htm>).

This is dependent on population frequencies of specific alleles, though not to be taken as race-

specific, as no extensive studies have been made available thus far to define race based on genetics. It also should be made clear that the tribes in question at the writing of this chapter have not been subject to studies within the population genetics domain that clearly point out 1% frequencies of certain alleles, which is by definition a polymorphism.

Under such conditions, culture can put into action factors that are not reckoned with in the West. The sensitivity of information in a healthcare setting, such as patients' records and stigmatization, can form a combination of devastating effects in that culture. Saudi Arabia, for example, recently has introduced nationwide mandatory premarital screening tests, the impact of which on the social level is yet to unfold with a possibility of an unpleasant outcome if the tribal structure of the society is taken into consideration. The positive side of these tests is self-explanatory. In recognition of the high incidence rates of genetic diseases such as sickle cell anemia and thalassaemia in some regions of the country, such measures no doubt would reduce these rates. However, in the long run, with the accumulation of more and more genetically related information, whole clans and tribes could be stigmatized and girls with certain genetic traits victimized (in terms of spinsterhood), if procedures are not properly executed and/or information systems are not efficiently run and managed (Kashmeery, 2004). Our scenario is hypothesized for future projection.

The XL clan extends across the borders of three neighboring countries. Their branch on the western side of the borders had in abundance by genetic screening rules set by their government to consider allowing such tests to be performed on its members. Within a few months, a trend was established from the compiled data that the clan members have a NOTCH4 gene triplet repeat polymorphism. Without realizing the significance of the finding, the medical record facility did not impose tight security measures on the results. An abstract leaked in a bona fide manner to the

local media, which published a layman report on the procedure and praised its underlying policy. In academic circles, the impact was different. This polymorphism was known to have some association with a serious psychological defect: schizophrenia (Wei & Hemmings, 2000). Rumors spread swiftly, blowing the issue out of proportion. The chief on the top hierarchy of the tribe on the eastern side of the border got upset by the news that reached him anecdotally and ordered the XL clan chief not to cooperate with the genetic screening scheme. XL clan, chief, and individuals have their loyalty to the tribe more than to the state. They all decided overwhelmingly to boycott the screening schemes, current and future ones, and thereby came into conflict with local authorities, who stood by their agenda and work plans. The issue assumed national proportions, following confrontations and arrests. Social unrest began to reach police records wherever members of the XL clan were engaged, at work or social activities. XL clan becomes more and more isolated and alienated, with intermarriage rates with other groups of society falling rapidly, leaving stigmatized women haunted by the state of spinsterhood, which is a woman's nightmare in that society. The impact of these developments spilled over the borders to the east and south where other subsections of the same tribe live, and the scenario repeated itself, forcing members of the LL tribe to go through the same ordeal.

Scenario 6: The Bed-Ridden Elderly in the Care of Extended Family

At the age of 82, Mr. S.K. had been bed-ridden for three years due to leg muscular dystrophy. He also was diabetic and hypertensive and, therefore, needed close health and nursing care. Values, culture, and tradition would not allow his family even to discuss the principle of admitting him to a nursing home. The social norms where Mr. S.K. lived demanded that he be looked after by his nearest of kin. To facilitate such a stipula-

tion, members of the extended family usually live together in large premises. Mr. S.K.'s three sons were living with him in such a setting and managed to share the responsibility of his care. They were grown up professionals engaged in diverse occupations ranging from diplomacy and university professorship to high-ranking civil service. None of them was ever heard complaining or expressing the least bit of discontent, except for their admitted lack of expertise in some aspects of the care they were practicing.

Despite their continuous pursuit for knowledge from physician friends of theirs, they have always felt that the scheme would have worked more efficiently had there been a handy, simple software that gave guidelines for executing their tasks in a more professional way.

Their worries always peaked during the night when they were in their rooms and while they all were away at work, for fear of not being there for help, if needed. They used to hypothesize an emergency situation and have always felt that an adequate monitoring system, connecting them simultaneously to the patient's healthcare professionals who could intervene in the right moment, would have perfected the scheme.

These shortcomings were dwarfed in relation to the great advantage of having their father looked after in the comfort of his own home surrounded by members of his own family, who would do anything to please him, reiterating to him time and again that they do that with pleasure and passion.

Of course, he did not know that there are millions of parents in other parts of the world who go through the ordeal of leaving their homes and their loved ones when they desperately need them, and of losing their property in order to cover the expenses of nursing homes, where they might face a fate they frequently read about in the media. He didn't know that. But what he knew very well was that looking after him and preserving his dignity, no matter how demanding that might be,

are ordained by tenet and are a debt carried with pride from generation to generation.

EPILOGUE

Given the review of the literature and the scenarios just elaborated, the reader should have an idea of what sort of issues we expect to find. The reader also will realize that the research we are suggesting is at the crossroads of a number of disciplines and theories. So far, this chapter contains a collection of thoughts that is meant to support the contention that research in the cultural aspects of the ethical properties of ICT in healthcare is desirable. We have refrained from developing a specific theory that will explain the relationship between culture, ethics, and ICT in healthcare. Instead, we intend to investigate these matters from the starting point outlined previously, but we will keep an open mind to issues that have not yet been raised. To some degree, we thus propose to follow a grounded theory approach that aims to develop theory inductively from observation (Glaser & Strauss, 1967).

The purpose of this chapter was to outline an area of research between culture, ethics, and ICT. We hope that the chapter succeeded in persuading the reader that such a project is worthwhile. Given the early stage of the research, we expect the chapter to provoke vigorous debate and hot discussion about this topic—something that will help us to develop these considerations further. It is also a call for other researchers with similar interests to contact us in order to develop collaborative ties.

Section 5

Organizational and Social Implications of Information Communication Technologies

This section includes a wide range of research pertaining to the social and organizational impact of ICT around the world. Chapters introducing this section illustrate the intersection of ICT and culture and the impact this has upon individuals and entire communities. Other contributions discuss ICT's potential for empowerment among disenfranchised individuals and societies as well as the ways in which ICT can transform education and the modern workplace. Particular selections debate the use of ICT for web-based learning, while others discuss how ICT has been utilized in the field of tourism. The debates and inquires presented in this section offer research into the integration of global ICT as well as implementation of ethical considerations for all organizations.

Chapter 5.1

Convergence of ICT and Culture

Matthew Mitchell

WSU Center to Bridge the Digital Divide, USA

INTRODUCTION

Participants in development projects and programs that strategically utilize information communication technologies (ICT) are engaged in activities that have culturally-relevant impacts. At local and regional levels, there may be approaches to implementing ICT-based development projects that are appropriately contextualized for different socio-cultural systems. Such approaches need to look beyond short-term outputs and mid-term outcomes and give adequate focus on long-term impacts. It is possible to analyze the long-term impacts of ICT-based development projects through a number of different lenses, one of which is the concept of “convergence.”

The basic idea of “convergence” is the phenomenon of different states of being becoming one. Certainly the concept of culture converging with technology is not new; however, what is new with the convergence of ICT and culture is the accelerating pace of change on regional and international systems. This article describes diverse perspectives of “convergence” that may help provoke thought about and possibly inform

the successful application of ICT for regional and international sustainable development.

Leveraging ICT to achieve socio-economic development goals is an approach that warrants reflection on the convergence of technologies and cultures. Awareness of the interactive dynamics between culture and technology can enable leaders, researchers, innovators, practitioners, and stakeholders to be more successful in facilitating sustainable “ICT for development” programs. Three views of convergence provide insight on the possible implications of “ICT for development” programs include: structural, technological, and cultural.

STRUCTURAL CONVERGENCE

From a historical perspective, the concept of structural convergence describes the phenomenon where societies in less-developed countries (LDCs) assimilate the processes and practices of more developed countries through technological transfers (Inkeles, 1998). This is often made possible through aid-funded projects in sectors such

as agriculture, education, finance, transportation, and communications. In this perspective, convergence is normally non-reciprocal, meaning that the transfer of technology is unidirectional and only the recipient is impacted. This type of convergence involves the establishment of social and economic structures that are designed by and for developed nations. As evidenced throughout the 1900s, societal structures in LDCs such as finance, agriculture, education, government, and so forth, have become more similar to those structures found in developed countries (Aghion, Howitt, & Mayer-Foulkes, 2004). This structural convergence has a direct result on cultural content. Also seen during the previous century were numerous development projects in LDC's as well as developing countries that failed to produce intended results due to an inadequate consideration of the local environment, political reality, and culture (Howe & Dixon, 1993). Informed by lessons learned by others, current and future ICT-based development projects that affect the processes and practices in developing regions may be able to shape the impact of structural convergence to be more appropriate for a given socio-cultural system and perhaps increase its chance for success (Moore, 1998).

TECHNOLOGICAL CONVERGENCE

Distinct from the structural view, the "technological convergence" perspective describes a phenomenon where technological systems come together to create new systems. A widely recognized example of this type of convergence is the Internet where computers are interlinked using new and existing network infrastructures along with packet switching protocols (OECD, 1996). The World Wide Web (WWW), an aspect of the Internet, is a further example of convergence in that the digitally-mediated GUI environment of cyberspace has been merged with activities normally conducted in specific physical locales

(i.e., shopping, banking, learning, working, etc.). A narrower example of this type of convergence is Voice over Internet Protocol (VoIP), which has the potential to significantly influence the future structure of global telecommunications.

Driven by the acceleration of diverse technologies being synthesized into new technologies, the phenomenon of "convergence of technologies" is pressuring the privatization and liberalization of laws, policies, markets, and economies (Blackman, 1998). Similar to structural convergence, the spread of technology is creating cultural impacts that affect the recipient's culture more than the culture in which the technology was developed. Participants in "ICT for development" programs should be cognizant of this dynamic.

CULTURAL CONVERGENCE

Structural and technological convergences explain aspects of globalization and clearly represent a powerful influence on socio-cultural systems. Perhaps both an influence and an impact to technological convergence, "cultural convergence" is a constantly changing dynamic that serves as an engine for the evolution of broad social domains such as language, values, beliefs, behavior, and artifact. The process of cultural convergence reflects how culture changes through intra- and inter-cultural interactions. Some observers note that the quickening pace of convergence in ICT and the digital tsunami of media content may be detrimental to the integrity of the recipient's culture.

CONVERGENCE OF ICT AND CULTURE

Attempting to understand the convergence of ICT and culture is messy but imperative to the effectiveness and sustainability of development activities. As mentioned earlier, neither the con-

vergence of culture and technology nor awareness of the phenomenon is new. What makes the convergence of ICT and culture notable today is the speed at which these technologies have (and will likely continue to) spread and impact ICT can have on all social systems. The diversity in views of convergence clearly pertains to how ICT is used for development and may account for the difference in how “ICT for development” programs are perceived by stakeholders and “donor” and “recipient” populations.

Given the nature of technological convergence, it might appear as if LDCs are bound to be subjected to cultural change determined by external cultural forces (Huntington, 1993). Indeed, this asymmetric phenomenon can be seen in television programming, WWW content, software licensing, and the establishment of technological standards (Foulger, 2002). Because convergence is complex and causes unintended consequences, some perceive that cultural imperialism is a malignant by-product of development efforts based on technological transfer (James, 2003). However, it may be more than a by-product; it may be a direct result of trends set in motion by historical oppression and subjugation compounded by economic inequities (Senghaas, 2002). It is not exactly a coincidence that most LDCs are former colonies and perhaps understandable why citizens in the post-colonial developing world are much more sensitive to the issue of cultural imperialism than are citizens from more developed countries. Donors, practitioners, and stakeholders in initiatives that leverage ICT for social and economic development are necessarily involved in a process of technological and cultural convergence. This process does not have to include side effects such as hegemony and cultural homogenization. There is some control in the design, organization, degree of inclusion, implementation, and assessments of “ICT for development” programs that can balance the realities of convergence with the imperative of promoting cultural integrity. Due to the converging forces of globalism, there is probably

no way to avoid the impact of ICT on culture; as some say, “the genie is out of the bottle.” However, through adequate awareness of long-term impacts, a degree of control may be possible. For those involved in the design and implementation of ICT-based development projects that are aimed at either local or regional levels, they should take care to find effective ways in shaping the impact of ICT on the recipient social systems to be appropriate and beneficial. Careful implementation of convergence is not only an important condition to sustainable socio-economic development; it is consistent with the fundamental objective of any development activity to help bring about beneficial change while minimizing harm.

KEY TERMS

Convergence: The process of coming together or the state of having come together toward a common point.

Culture: Integrated system of spiritual, material, intellectual and emotional features of society or a social group that encompasses, among other things, art and literature, lifestyles, ways of living together, value systems, traditions and beliefs and artefacts.

ICT-Based Development Projects: Development projects that employ information communication technologies as a strategic tool or approach for achieving desired outcomes.

Information Communication Technology: The technology required for information processing. In particular, the use of electronic computers and computer software to convert, store, process, transmit, and retrieve information.

Chapter 5.2

Addressing the Cultural Dimensions of E-Learning: Where to Begin?

Andrea L. Edmundson
eWorld Learning, USA

ABSTRACT

In an exploratory study, the researcher examined the effects of cultural dimensions on e-learning outcomes for employees in functionally equivalent jobs in Western and Eastern cultures. Participants from the United States (U.S.) and India completed a Level 1 e-learning course designed in the U.S. In addition, randomly selected completers then reported their interactions with the e-learning course in a survey. Learners from the two cultures achieved equitable learning outcomes, suggesting that characteristics of Level 1 e-learning courses mitigate the effects of culture. In addition, while cultural dimensions did appear to affect learners' preferences for and perceptions of e-learning, both Eastern and Western participants were willing to try new approaches to learning that did not align with their cultural profiles. Based

on these results and practical usage, the revised (v.2) cultural adaptation process (CAP) model is presented as a guideline for adapting e-learning courses for other cultures.

INTRODUCTION

The term *globalization* gained currency in the 1970s as Western corporations rapidly expanded into other parts of the world (Jarvis, 2002), accelerating cultural exchanges (Walker & Dimmock, 2002). Industrial anthropologists have identified *cultural dimensions*—categories of characteristics across which cultures can be compared and contrasted, such as how members of a culture communicate, perceive time or view themselves in relation to the environment. As e-learning options proliferate and globalization continues,

an expanding audience of learners is more likely to encounter courses created by another culture. Most e-learning courses are designed in Western cultures; however, the largest and fastest-growing consumer groups live in Eastern cultures, such as China, Japan and India (Van Dam & Rogers, 2002). “Over the next 20 years, the global market for online learning is estimated to exceed \$215 billion, with rapid growth expected from cross-border delivery of higher education (an institution in one country delivers courses to students in other countries)” (Hezel & Mitchell, 2005, para. 1). Educators thus will be challenged to provide e-learning opportunities that result in equitable learning outcomes for new groups of learners from other cultures.

Learning outcomes were defined by Henderson (1996) as any results that reflect the acquisition of skills and knowledge, the effectiveness of instructional techniques and students’ perceptions or attitudes. Educational practitioners have begun to apply the concepts of cultural dimensions to instructional design, presuming that selecting or adapting courses to suit the cultural profiles of learners will generate equitable learning outcomes. However, empirical research has neither conclusively supported nor disproved them. The purpose of this study was to understand better the effects of cultural dimensions on e-learning in the globalized environment.

The problem is: “Are e-learning courses designed in a Western culture equally effective when used in an Eastern culture?” The research questions used to address this problem were as follows:

1. When taking an e-learning course designed in a Western culture, do participants from Eastern and Western cultures experience *equitable learning outcomes*?
2. Do they have different *preferences for or perceptions of e-learning*?
3. If there *are* strong similarities or significant differences in learning outcomes between

the two cultures, in participants’ use of features or in their preferences or perceptions, are these similarities or differences *related* to the cultural dimensions described in the literature?

Importance

According to a United Nations Development Program report (UNDP, 2001), the most developed, progressive and economically stable countries in the world are those that are technologically advanced. Technological change and the building of human capabilities are interrelated: Each requires the development of the other for success. Thus, the UNDP report (2001) promoted “rethinking educational systems to meet the new challenges of technology” (p. 84) through improved technology and technological education at a global level. Interest in promoting education and technologies continues to be addressed by the U.N. Millennium Development Goals (United Nations, 2005). Domestically, “At a time when many institutions in the U.S. must explore new markets for enrollment growth, other countries face a shortage of higher education campuses and student seats” (Hezel & Mitchell, 2005, para. 3).

From an instructional point of view, incompatibilities between the cultural characteristics of e-learning courses and learners could cause inequitable learning outcomes (Henderson, 1996). For example, members of cultures may prefer to learn in a particular manner (Gardner, 1989; Horton, 1999), or they may have specific approaches to problem solving (Lave, 1988; Soh, 1999) and creativity (Gardner, 1989). Or, a pedagogical paradigm espoused by one culture could alienate or confuse targeted learners (Hall, 1981), as could unintentional cultural biases in instructional design (McLoughlin, 1999). Learning styles may also be influenced by culture. Through their use of research on cultural dimension, practitioners propose that e-learning be designed to match to the cultural profiles of the targeted learners (Marcus & Gould, 2001; Marinetti & Dunn, 2002).

Theoretical Foundations

Hofstede (1984, 1997, 2001), Trompenaars and Hampden-Turner (1998) and Hall (1953, 1981) identified and characterized cultural dimensions at the national level, primarily with respect to corporate business and communication. While they posited the probable effects of many of these dimensions on education, researchers Gardner (1983, 1989), Henderson (1996) and others have explored similar concepts within the discipline of education. Jaju, Kwak, and Zinkhan's (2002) study related learning styles and preferences to cultural dimensions, a step towards confirming a definitive relationship of culture to e-learning and its importance.

Hofstede and Cultural Dimensions at the National Level

Hofstede (1984, 1997) established the practice of using *national cultures* in quantitative studies: Samples of people living and working in the same country are reasonable representations of the national culture. He gathered data from questionnaires administered to 116,000 participants in 50 countries and three regions, identifying five cultural dimensions that he portrayed as continua bounded by polar extremes. He calculated indices of these dimensions for each country, described below, across which cultures could be compared and contrasted.

Power Distance Index (PDI)

The PDI—"the extent to which the less powerful members of institutions and organizations expect and accept that power is distributed unequally" (Hofstede, 1997, p. 27)—has ramifications in educational organizations. In nations with low PDI scores, such as the U.S. (PDI = 40), teachers and students tend to be perceived as equals. Teachers are facilitators of student-centered education rather than authoritative subject matter experts

(SMEs). Students are expected to show initiative, solve problems, build their own knowledge base, question teachers and initiate discussions. In high PDI nations, such as India (PDI = 77), relationships between teachers and students are accepted as inequitable: Teachers are authorities and SMEs; thus, students tend not to question their knowledge (Hofstede, 1997).

Individualism Index (IDV)

Hofstede (1997) defined individualistic societies as those "in which ties between individuals are loose" (1997, p. 51). By contrast, collectivist societies are those "in which people from birth onwards are integrated into strong, cohesive *ingroups*, which throughout people's lifetime continue to protect them in exchange for unquestioned loyalty" (Hofstede, 1997, p. 51).

Members of collectivist societies tend to rely on their *ingroups* to determine social relationships in educational settings, and may even expect differential treatment dependent on their social class. In contrast, students in high-IDV societies expect to be treated as equals among peers and faculty. They prefer to work as individuals and expect recognition for individual merit.

Globally, collectivist societies are predominant (Hofstede, 1997). From the perspective of education, this represents an important consideration. The U.S. and other high-IDV countries produce most instructional artifacts, including e-learning. Characteristics of these courses could significantly conflict with the values of collectivist societies that import them. The U.S. has the highest IDV (91) in Hofstede's study, while India has a much lower IDV of 48 (Hofstede, 1997).

Masculinity Index (MAS)

Hofstede (1984) defined the dimension "masculinity vs. femininity" in terms of how a culture socializes its members to perform gender roles. In a masculine culture, men are expected to be

tough and assertive, while women are perceived as tender and modest. In a feminine culture, men and women are more likely to have similar roles; both are expected to be tender and modest, even if men also express some assertiveness.

Hofstede (1997) contended that, in high-MAS countries, students compete openly, are achievement conscious and are disappointed by failure. An instructor's academic excellence and reputation are important. In a low MAS culture, teachers and students have more relaxed expectations. The U.S. and India yielded similar MAS indices in Hofstede's work (62 and 56, respectively).

Uncertainty Avoidance Index (UAI)

Uncertainty avoidance is "the extent to which the members of the culture feel threatened by uncertain or unknown situations" (Hofstede, 1997, p. 113). Uncertainty avoidance is not risk avoidance; rather, it refers to a pattern of reducing ambiguity.

Hofstede (1997) felt that, in a high-UAI environment, the teacher is an expert and unquestionable authority. Students prefer a structured learning environment, precise objectives, strict timetables, precise answers and rewards for accuracy. In contrast, in low-UAI cultures, teachers act as facilitators of learning. Students are comfortable with vague objectives, loose timetables and multiple solutions to problems, and they seek to be rewarded for originality. The U.S. and India have similar, mid-range UAI scores of 46 and 40, respectively.

Long-Term Orientation (LTO)

Hofstede's fifth cultural dimension, "short-term vs. long-term orientation to time," was theorized after his original 1984 study. In general, Hofstede found that Eastern countries had relatively high LTOs, while Western countries yielded relatively low LTO scores. Hofstede did not propose specific ramifications of the LTO dimension on education, and it was not included in this study.

Trompenaars and Hampden-Turner's Cultural Study

Trompenaars and Hampden-Turner (1998) also researched cultural dimensions at the national level; like Hofstede, they were primarily interested in the effects on business. Their analysis of surveys (more than 30,000 corporate managers from more than 100 countries) identified eight cultural dimensions, some of which were similar to Hofstede's. Each of their dimensions, like Hofstede's, was described as a continuum bounded by two extreme, opposing characteristics. However, in contrast to Hofstede, they held that in practice, cultural groups display both extremes of all dimensions but show a preference or tendency toward one extreme in most situations. Unlike Hofstede, they rarely speculated on the implications of cultural dimensions in education.

In the first category, "relationships and rules," Trompenaars (1998) identified five dimensions across which cultures could be compared and contrasted. *Universalism vs. particularism* relates to the balance between rules and relationships. Universalists tend to adhere to rules. In a particularist society, rules are flexible guidelines over which relationships always take precedence. This dimension is not dissimilar to those delineated by Hofstede; however, attitudes towards relationships and rules could prove to be important in an educational environment. For example, a teacher from a universalist culture conforms to the rules: "You did less than C average work; thus, you have earned the failing grade." However, a teacher from a particularist society might bend the rules to allow the student to pass, acknowledging that the student has put forth effort; or the teacher might be more lenient if he or she is acquainted with the student's family.

The *individualism vs. communitarianism* dimension, similar to Hofstede's IDV index, refers to the tendency to perceive oneself primarily either as an individual or as a member of a group. In an individualistic culture, members value personal achievement and responsibility. The

communitarian society, meanwhile, privileges the achievement of group goals. They frequently make decisions via consensus or defer decisions to an authoritative entity.

Members of *affective vs. neutral* cultures may be, respectively, emotionally expressive or emotionally detached and objective in verbal or non-verbal communication. This dimension is reflected in communication through forms of humor, styles of speaking, tone of voice, frequency and type of touch, amount of eye contact and the ratio of nonverbal (contextual) to verbal (content) communication. Characteristics of this dimension are similar to those described by Hall's (1981) concept of high-context vs. low-context cultures and could, conceivably, affect learning preferences or outcomes.

Specific vs. diffuse relates to "the degree to which we engage others in *specific* areas of life ... or *diffusely* in multiple areas of our lives" (Trompenaars & Hampden-Turner, 1998) and accounts for the degree and level of interaction between people. In *specific* cultures, for example, the "boss" is the authority in the office, but beyond that environment, he or she is no longer granted the same deference. Conversely, in *diffuse* cultures, members confer authority to superiors across most environments. Members of specific cultures tend to use direct and purposeful communication, while diffuse cultures tend to be less direct, often to the point of appearing evasive. Such differences in communication could, conceivably, interfere with learning in a globalized environment.

The *achieved status vs. ascribed status* dimension relates to whether a culture determines status according to accomplishments or according to markers of group membership. In achievement-oriented cultures, according to Trompenaars and Hampden-Turner (1998), authority is tied to one's task or job, whereas in an ascription-oriented culture, titles clarify status. This dimension shares characteristics with Hofstede's PDI.

Trompenaars and Hampden-Turner (1998) also identified two dimensions in the category

"attitude toward time." *Orientation to past, present and future* reflects to how cultures perceive the importance of each of these periods. The dimension *sequential vs. synchronic* is related to whether time is perceived as linear and composed of discrete events or as circular and composed of integrated, overlapping events.

Lastly, Trompenaars and Hampden-Turner (1998) categorized "attitudes toward the environment." Members of *inner-directed* cultures believe they have significant control over the outcome of events, aggressively trying to manage situations; whereas members of *outer-directed* cultures believe they are subject to an external locus of control, and thus are more comfortable and flexible when confronted with change.

Hall's Perspectives of Cultural Differences

In Hall's (1981) words, "culturally based paradigms place obstacles in the path to understanding because culture equips each of us with built-in blinders, hidden and unstated assumptions" (p. 220). Hall envisioned cultural differences as poles on opposite ends of continua that resemble the indices and characteristics, respectively, of Hofstede (1984, 1997) and Trompenaars and Hampden-Turner (1998).

According to Hall (1981), members of *M-time* (monochronic) cultures tend to emphasize schedules, promptness and segmentation of activities. Their communication is low context, depending more on direct language than on subtle signals. In contrast, members of *P-time* (polychronic) cultures engage in multiple activities simultaneously and tend to focus on relationships and the completion of transactions rather than on scheduled events. Their communication is high context, as it is dependent on what they already know about their culture.

According to Hall (1981), American education tends to be linear, compartmentalized and lacking in creativity and problem-solving techniques. As

members of a low-context culture, Americans tend to use sparse communication, especially in technologically driven environments. However, such direct communication may be advantageous in globalized e-learning.

Applications of National Level Cultural Dimensions in Education

Educational researchers and practitioners have begun to incorporate the findings of national-level studies into e-learning. Marcus and Gould (2001), for instance, proposed redesigning the user interface of Web pages to match the known cultural dimensions of the target culture as described by Hofstede (1997).

Marinetti and Dunn (2002) proposed adapting courses of varying complexity to the cultural dimensions of learners as identified in the literature to accommodate the presumed preferences of different groups. Their adaptation strategies are summarized in Table 1. For the purpose of discussion, each level of course complexity has

been assigned a number, ranging from Level 1 to Level 4, also indicating the level of cultural influence on the course design.

For example, based on their table, for Level 1 courses, simple *translation* of content would be adequate as a cultural adaptation technique, because the content and method of presentation is straightforward, indicating little if any cultural impact. Translation could encompass simple conversion to ‘global English’ or to British English, or to full-scale translation to another language. For Level 2 courses, in which content or tasks are more complex but universally familiar, in addition to potential translation, *localization* could ensure that concepts and technical tasks are achievable by the targeted culture.

Localization may be described as “the process of converting material ... into a format that is technically, linguistically and culturally appropriate for countries outside the original market” (Transware, 2002). These superficial changes, called *soft-multiculturalism* by Henderson (1996), include slang, humor, gestures, units

Table 1. Descriptions of course levels 1-4 (Marinette & Dunn, 2002)

Complexity Level	Level 1	Level 2	Level 3	Level 4
Content Type	Simple information, knowledge, news	Low level, cognitive “hard skills”; simple knowledge and core concepts	Some soft skills; complex knowledge, such as regulatory or financial information; business strategy and most business skills	Mostly “soft skills,” such as attitudes and beliefs; many complex management skills
Content Examples	Product knowledge, company procedures	Application software, other electronic skills	Project management, presentation skills, marketing strategy	Negotiation skills, motivation, teamwork, conflict resolution
Content Adaptation: What people learn	Translation only; content and context culturally neutral	Translation plus context adaptation, examples as required	Translation plus context adaptation, examples and some modular content	Significant proportion of content and context is unique per culture
Instructional Strategy Adaptation: How people learn	None	Minor changes	Required at key points; re-ordering information, representation of concepts, alternative media, etc.	Significant proportion unique per culture; may require alternative course architectures
Adaptation Strategies	Translation	Localization	Modularization	Origination

of measure, law, taboos, etiquette and so forth. For Level 3 courses, Marinetti and Dunn (2002) proposed *modularization*. Modularization entails adapting only those components of the e-learning course that vary between the designing and recipient culture, and that could affect learners' outcomes. These components, referred to as *reusable learning objects* (RLOs), may also be called *cultural learning objects* (CLOs) in this context (Alberta Online Consortium, 2004) or cross-cultural learning objects (XCLOs). Finally, for course content that is complex or culturally differentiated, Marinetti and Dunn recommended *origination*—creating a new course with the full participation of the target culture to meet its very specific needs and preferences.

Any of the above techniques, singularly or in combination, could simplify the adaptation process and reduce the costs of redesign, subsequently improving the cultural compatibility of e-learning courses. However, the presumed need to adapt e-learning courses to the cultural dimensions of targeted learners remains unproven by research. In addition, the possibility that a cultural group could accept or adapt to the dimensions of the culture in which an e-learning artifact originated remains unexplored.

Cultural Dimensions in Education

At a high level, culture influences multiple aspects of education, from the obvious, such as educational structures, governance, delivery systems and teaching styles (Thomas, 1990), to the subliminal, such as values or the purpose of education (Gardner, 1989; Mosa, 1999; Jarvis, 2002).

Gardner (1983) argued that cultures value different types of intelligence and different forms of knowledge. These intelligences are not cultural dimensions per se, but Gardner's theory of multiple intelligences suggests that one culture could prefer one cluster of intelligences to another, and that education could be designed to accommodate those intelligences. In another study (1989), he

found that the Chinese prefer a *mimetic* approach to education: Teachers (and educational materials) are treated as unquestioned repositories of knowledge. In contrast, Americans were moving toward a *transformative* approach to education: Teacher act as coaches, eliciting desired qualities from students.

Henderson (1996) proffered a comprehensive *multiple culture model* (MCM) specifically for investigating cultural characteristics in education, with 14 dimensions represented as continua with polar extremes, reminiscent of those used by Hall (1981), Hofstede (1984, 1997) and Trompenaars and Hampden-Turner (1998). In the model, the course features and characteristics represented on one side reflect the objectivist-instructionist pedagogical paradigm, while those on the other side reflect the constructivist-cognitive paradigm, bearing similarities to the descriptions of Level 1 through Level 4 courses (Marinetti & Dunn, 2002).

STUDY METHODOLOGY

For this study, the 14 dimensions on the MCM were reduced to nine, thereby creating the *simplified multiple cultural model* (SMCM) (Edmundson, 2004):

1. **Pedagogical Paradigm:** *Instructionist/Objectivist – Constructivist/Cognitive*. Four closely related dimensions—*Epistemology, Pedagogical Philosophy, Underlying Psychology* and *Goal Orientation*—were combined to create a singular dimension, Pedagogical Paradigm.
2. **Experiential value:** *Abstract – Concrete*. When instruction has abstract experiential value, learning is removed from reality. Instruction with concrete experiential value integrates the learning process with the learner's world.

3. **Teacher role:** *Didactic – Facilitative*. A didactic exposition of knowledge, such as a lecture, contrasts with facilitative pedagogical techniques that enable exploratory learning without controlling outcomes.
4. **Value of errors:** *Errorless learning–Learning from experience*. Under an errorless learning paradigm, students learn until they generate no mistakes, or the instructional method does not allow for errors. In contrast, the learning from experience approach to instruction uses errors in the educational process.
5. **Motivation:** *Extrinsic–Intrinsic*. Extrinsic motivation originates from factors outside the learner, such as the need for high grades or the presence of engaging materials. Intrinsic motivation comes from an internal desire to learn.
6. **Accommodation of individual differences:** *Non-existent – Multifaceted*. In some contexts, learning and knowledge are structured so that there is no need for accommodation of individual differences. When accommodation of individual differences is existent, on the other hand, knowledge and learning are presented in a variety of ways so that learners can utilize the tools that most suit their preferences.
7. **Learner control:** *Non-existent – Unrestricted*. In this dimension, the student either learns along a predetermined path or by independent discovery.
8. **User activity:** *Mathemagenic–Generative*. A mathemagenic approach permits learners to access the same content in different ways, while a generative approach encourages learners to engage in the process of creating and elaborating content.
9. **Cooperative learning:** *Unsupported – Integral*. In this dimension, learners work independently, or learning is encouraged through cooperative activities.

Certain SMCM dimensions (e.g., cooperative learning) may be manifestations of cultural dimensions at the national level, while others may simply reflect learner preferences or subliminal effects of culture. To date, however, relatively few studies have examined cultural dimensions within e-learning courses. Likewise, few researchers have administered an e-learning course designed by one culture to individuals in another culture with the intention of measuring potential differences in learning outcomes.

THE STUDY

The experimental design best suited to part one of this study was the posttest-only control group design (Campbell & Stanley, 1963; Leedy & Ormrod, 2001; Tuckman, 1978) diagrammed in Figure 1.

Pre-testing was neither desirable nor useful in this study, as the researcher was interested in the differences between learning outcomes caused by the culture, rather than the knowledge or skills generated by the e-learning course.

Seven hundred fifty-seven technology workers in functionally equivalent roles were required by their company to take a western-designed e-learning course. The Software Upgrade Tutorial was designated as a Level 1 course, according to the criteria described by Marinetti and Dunn (2002). From this group, 250 were randomly selected (for a confidence interval of 95%) to participate in the study: 204 from a Western culture (U.S.) and 46 from an Eastern culture (India). Data on learning outcomes were analyzed using students' *t* tests for unequal *n* using StatDisk (Triola, 2001).

In part two of the study, the 250 participants were invited to complete an online post-course questionnaire, which included questions based on the SMCM dimensions, to identify (a) learning outcomes not recorded by the learning management system, and (b) the participants' preferences for and perceptions of e-learning, based on potential

Figure 1. Posttest-only control group design

R1	X	O1
R2		O2

Note:

- R = randomly selected members of the groups under study
- X = the treatment (i.e., the culture of each of the two groups)
- O = the observations or measurements of differences between the two groups (i.e., tutorial results and questionnaire responses)

cultural differences and their overall experiences with the genre. The students' mean (coded) responses were analyzed using students' *t* tests for unequal *n* using StatDisk (Triola, 2001).

Finally, the researcher explored possible relationships between the learning outcomes and participants' preferences and perceptions to the cultural dimensions described in national-level research.

SUMMARY OF FINDINGS

Members of both groups, completing a Level 1 course, achieved equitable learning outcomes when they took the Software Upgrade Tutorial. There were no significant differences ($\alpha = .05$) between learning outcomes (number of attempts needed to complete the course, scores of each attempt and time needed for each attempt). Responses on the questionnaire provided additional information on how they navigated and used the course and their perceptions of its effectiveness. Both groups needed no more than three attempts to complete the course. An average of 85% of the participants completed the course on the first attempt in an average of 68 minutes, with an average score of 85.5%. While the U.S. participants

felt that the tutorial did not completely meet its objectives, both groups agreed that they had *applied* most of what they had learned to their work. Both groups used the course features, in the form of simple media (demonstrations, handouts and navigation tools), in the same manner, although Americans tended to print more handouts than Indian participants. Both groups acknowledged that they had experienced confusion in the past with language and format in e-learning, which indicated that they had taken e-learning courses more complex than the Level 1 tutorial used in this study.

Participants expressed equal acceptance of the course characteristics manifested in behavioral/objectivist and cognitive/constructivist paradigms. This acceptance may have been related to characteristics of this particular group, but should be considered when working with members of other cultural groups, as well. With respect to those features and characteristics, participants preferred that the instructor/course designer manage the design elements; establishment of course objectives; selection of activities, instructional methods; examples; and determination of the best path to learning. These features are typically selected during the *design process*.

Participants also indicated that they preferred being guided by a facilitator rather than instructed

by an expert, controlling the pace of learning, testing themselves by experimentation, learning from their mistakes, and applying course knowledge and skills to their own activities. In other words, participants expected to control *how they interacted with the course*, although both groups indicated that they would be open to trying other approaches to learning.

Participants' responses indicated that two of the nine dimensions of the SMCM are related to certain cultural dimensions described at the national level. The dimension of *cooperative learning* on the SMCM shares characteristics with Hofstede's IDV dimension, Trompenaars and Hampden-Turner's individualism vs. communitarianism dimension, and Hall's M-time vs. P-time dimension (M-time stressing independence and individualism). The *origin of motivation* on the SMCM shares characteristics with Hofstede's IDV and MAS dimensions (why students chose to participate and achievement consciousness, respectively), as well as to Trompenaars and Hampden-Turner's individualism vs. communitarianism dimension (motivation toward personal achievement or group goals).

Two other SMCM dimensions seem potentially related to those identified at the national level, though not as strongly as *cooperative learning* and *origin of motivation*. *Teacher role* from the SMCM appears to share characteristics with Hofstede's MAS dimension (teacher's status) and with Trompenaars and Hampden-Turner's specific vs. diffuse dimension (the range of authority conferred). *Learner control* on the SMCM appears to share characteristics with Hofstede's PDI (degree of authority or control conferred) and Trompenaars and Hampden-Turner's inner-directed vs. outer-directed dimension (one's need for control over the environment). *Value of errors* on the SMCM seemed weakly related to Trompenaars and Hampden-Turner's universalism vs. particularism, the dimension encompassing the value of rules.

Thus, while this study did not explore statistical correlations between cultural dimensions and learner preferences, there appear to be potential relationships between at least four dimensions of the SMCM and dimensions identified by other researchers. These findings suggest the need for studies of cultural dimensions in Level 1 to 4 courses, as greater course complexity may trigger stronger responses, indicate more cultural preferences or infer more obvious relationships to national-level cultural dimensions.

RESULTS

New Perspectives on E-Learning

The findings in this exploratory study offer five new perspectives on the e-learning environment that could change how instructors/designers create courses, how consumers adapt and/or export Western-designed e-learning courses and how Level 1 e-learning can be used to promote global education and economic development.

First, the features of Level 1 courses appear to create a learning environment conducive to equitable learning outcomes, as their low-context nature introduces the fewest cultural effects: Communication is minimized; interaction is nonexistent; and language is blunt, technical and sparse (Hall, 1981).

Second, learners seem to differentiate between the features of courses generated during the design process (and are thus beyond their control) and those that drive learner interaction with the course, which they prefer to control. This ability to differentiate may be a reflection of a certain level of technical sophistication within these groups of learners; however, knowing this, course developers should expect, at the least, to determine e-learning course goals and objectives, types of learning activities, instructional method(s) and the overall "path" to learning. At the same time,

they should expect that learners would prefer facilitation of learning rather than authoritative instruction, control of the pace of learning, learning from experimentation or mistakes and application of learning to their own needs.

Third, since members of both cultures were amenable to trying course features representing contrasting pedagogical paradigms, there is

potential to introduce an *eclectic paradigm*—a combination of instructivist/objectivist and constructivist/cognitive, as suggested by Henderson (1996)—to other cultures.

Fourth, certain SMCM dimensions appear to affect e-learning preferences and outcomes. The dimensions of cooperative learning and origin

Figure 2. The CAP model, v.2.

	Level 1	Level 2	Level 3	Level 4
Step 1: Evaluate type of content (see examples.)	Simple information, core knowledge, news or updates, such as product knowledge, company procedures	Low-level, cognitive hard skills; simple knowledge and concepts, such as those used in application software; most computer-related skills	Some soft skills; complex knowledge, such as project management, presentation skills, marketing strategy	Mostly soft skills; attitudes and beliefs, such as negotiation skills, motivation, teamwork, conflict resolution
Step 2: Identify media	Lecture, handouts, simple demonstrations (no actual interaction among learners or between instructor and learners)	In this range, several media options are available, but HOW they are used is the important factor. For example, media can provide active or passive access to other learners or to the instructor. Visual Media—Satellite broadcasts, audio conferencing, recordings, television, etc. Text-Based Media—Threaded discussions, list servers, online chat, e-mail, etc.		Videoconferencing, Web-based training, streaming media and Web conferencing (real time or simulated interactions among learners or between learners and instructor)
Step 3: Identify pedagogical paradigm (via instructional methods, etc.)	Instructivist-objectivist, with behavioral objectives and sharply-focused goals; low-context communication; mimetic	More closely related to instructivist-objectivist than constructivist-cognitive paradigm	More closely related to constructivist-cognitive than instructivist-objectivist paradigm	Constructivist-cognitive with cognitive objectives, unfocused goals; high-context communication; transformative
Upon review of targeted learners' cultural dimension (Hofstede, Trompenaars & Hampden-Turner, Hall, etc.), relate learners' cultural profiles to <i>critical and assistive</i> characteristics of the course that may support or hinder learners' use or acceptance of course:				
Step 3 (a): Identify <i>critical</i> cultural characteristics of course	Unsupported ←	Cooperative Learning		→ Integral
	Extrinsic ←	Origin of Motivation		→ Intrinsic
	Non-existent ←	Learner Control		→ Unrestricted
	Didactic ←	Teacher Role		→ Facilitative
	Errorless learning ←	Value of Errors		→ Learning from experience
Step 3 (b): Identify <i>assistive</i> cultural characteristics of course	Mathemagenic ←	User Activity		→ Generative
	Abstract ←	Experiential Value		→ Concrete
	Non-existent ←	Accommodation of Individual Differences		→ Multifaceted
Step 4: Integrate current research findings				
Step 5: Adaptation strategies Such strategies can consist of design changes to the e-learning course itself, or to the e-learning environment.				
Step 5 (a): Design strategies	Translation	+ Localization	+ Modularization	Origination
Step 5 (b): Environmental strategies				
Step 6: Action planning and testing				

of motivation appear to have strong effects on e-learning preferences and, thus, may be characterized as *critical cultural dimensions*. Three dimensions—teacher role, learner control and possibly value of errors—have indeterminate impact, but are likely to matter and, until further research indicates otherwise, could be treated as critical dimensions. The remaining dimensions—user activity, experiential value and accommodation of individual differences—may be described as *assistive cultural dimensions*.

Finally, there appears to be a dichotomy between the cultural *profiles* of learners and their actual preferences. While several of the large-scale trends that define cultural groups may need to be accommodated in e-learning courses above Level 1, a significant number of these dimensions are best viewed as “possible preferences,” rather than as ultimate and final outlooks, and should be explored further. One way in which to do this is to use the cultural adaptation process (CAP) model.

The CAP Model: Version 2

The revised version of the original (Edmundson, 2004) CAP model (v. 2) in Figure 2 is proposed as a guideline for offering culturally appropriate e-learning courses (a) by evaluating existing e-learning courses, (b) by creating cultural profiles of targeted learners, and (c) by guiding testing of e-learning courses. This version is based on a synthesis of findings from this study, but it also incorporates findings on cultural dimensions from research in industrial anthropology (Hofstede, Trompenaars, & Hampden-Turner, Hall, etc.) and education (Henderson, Marinetti, & Dunn, etc.), as well as the practical experiences of the researcher (Edmundson, 2005).

The model provides a matrix in which, from left to right, course complexity is considered, and from top to bottom, the steps in adapting an e-learning course for a targeted culture are presented. Users of the model will need to know

the cultural dimensions of the targeted learners as they relate to cooperative learning, origin of motivation and, most likely, learner control, teacher role and value of errors. They will need to identify the level of the course they expect to use, adapt or create, and then analyze and evaluate the match of course characteristics to the cultural dimensions and preferences of targeted learners. Quantitative evaluations can be conducted to determine if targeted learners can achieve the intended learning outcomes. In addition, their learning preferences should be assessed, using focus groups, surveys or interviews.

Future research may indicate that other dimensions should be included in the model, that certain assistive dimensions should be rated as critical, or that current dimensions classified as critical are more aptly described as assistive.

The CAP model represents a new, but not complete, perspective on the cultural dimensions of e-learning courses and learners. Feedback from the use of the systematic model and further research would help fashion a reliable tool for consumers of e-learning.

Changes Made to the Model

Based on experiences using the original version of the model (Edmundson, 2004), several changes to the model were implemented (Edmundson, 2006). Summarized, those changes include:

1. Incorporate recent research into the model.
2. Conduct qualitative and quantitative evaluations of the effectiveness of the proposed changes using focus groups and pilot tests, as well as surveys to identify learners' preferences for methods and approaches, their use of course features and other relevant variables.
3. Show that adaptation solutions go beyond those proposed in the matrix (e.g., translation, localization, RLOs and origination).

Figure 3. The framework for using the CAP model, v.2.

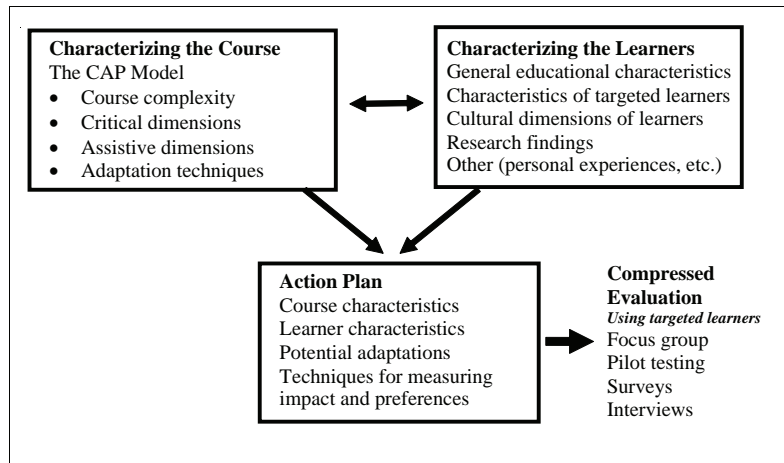

Figure 4. A sampling of potential adaptations to consider (based on a mock example).

Course characteristics	Learner characteristics	Potential adaptations to consider	How to measure or evaluate impact/preferences
Use of American English	Taught in schools with British English	<ul style="list-style-type: none"> • Change words, idioms, colloquialisms • Provide learners with a glossary • Do nothing 	Determine learner familiarity with American English and idioms, and other colloquialisms used in the course.
Use of American icons and brand names, such as Harley Davidson motorcycles	Highly educated, work for Americans and are frequently exposed to American culture through mass media, work, colleagues	<ul style="list-style-type: none"> • Replace with those known to Indian learners • Explain differences • Do nothing 	Determine learner familiarity with American icons, pop culture and other colloquialisms used in the course via focus group
Lacks cooperative activities and group work except through simulations and post-course communications	Prefer cooperative activities and group work	<ul style="list-style-type: none"> • Create RLOs to replace individualistic activities with more cooperative ones • Create and present a supplemental cooperative activity just for the Indian learners • Do nothing; learners may accept and/or adapt to individualistic activities 	Pilot test the course for equitable learning outcomes; survey participants about reaction to activities provided
Embodies cognitive-constructivist educational paradigm	More accustomed to instructivist-didactic approach to teaching	<ul style="list-style-type: none"> • Create a course based on paradigm to which learners are accustomed • Do nothing; learners accept and/or adapt to different paradigm 	Pilot test the course for equitable learning outcomes; survey participants about reaction to activities provided

Such solutions may include, but are not limited to, presentation options (e.g., how the course is marketed); provision of supplemental materials (e.g., glossaries); and creation of supportive activities (e.g., a cooperative discussion group) (Proposed Changes to the Model section, para. 1).

In version two of the model, all of these changes have been implemented so that the overall process can be envisioned using Figure 3.

Thus, the user of the model would be constantly comparing learner characteristics to characteristics of the e-learning course and, based on identified differences, would generate an 'action plan' (Figure 4) for investigating whether (and to what extent) those differences affected the learners' ability to successfully complete the course. In addition, as alluded to above, the design of the course does not necessarily require adaptation. Instead, as illustrated in Figure 4, the user might identify and consider multiple ways in which to make the e-learning course acceptable to the targeted learners by modifying the environment in which it is presented. Any proposed adaptations would be tested and measured for their effectiveness in a 'compressed evaluation' environment involving representative members of the targeted culture.

CONCLUSION

Based on findings in this study, the researcher proposed new perspectives on e-learning that could represent the means to effectively adapting or creating e-learning courses for use in other cultures. A revised version of the CAP model was provided as a guideline for culturally adapting e-learning. Such actions could increase access to technology education, improve technological literacy, and introduce new technologies across and between cultures, thereby increasing socio-economic development across the ever-expanding e-world.

Many factors point the way to success in global e-learning delivery. Learning those factors—both external market and internal capacity—and how the factors work in different countries will be essential to a sound strategy for international growth of [your] programs. (Hezel & Mitchell, 2005, Conclusion section, para. 1)

Chapter 5.3

Group Process and Trust in Group Discussion

Lorna Uden

Staffordshire University, UK

Linda Wojnar

Duquesne University, USA

ABSTRACT

Successful group discussion plays a crucial role in online learning. Teachers normally assume that students automatically transfer their learning of group process from group to group. Our experience found that for group discussion to be effective, it is important that we consider group process and the role of trust within groups. This chapter begins with an introduction to group process and trust, followed by a brief review of the benefits of group discussion for online learning. Then, we describe the role that teachers play in initiating environments that promote trust and group empowerment. Through our experience of the implications of group process and trust, we will discuss how this environment fosters trusting relationships. We will also discuss the value

of reviewing trust in the group process for each class before assigning group work. The chapter concludes with the outcomes of our experience and suggestions for further work.

INTRODUCTION

Students are taught at a very early age about group process, which includes teaching the importance and value of internalizing and distributing roles among group members to maximize the results of the task. Knowing that group process is taught in a specific grade level, succeeding teachers make assumptions that these students will automatically transfer their skills, and the teachers do not first check with the students to learn about what they do remember. Although some groups of students

Group Process and Trust in Group Discussion

may recall and follow the process as they were instructed, our experience showed that most of them do not. More importantly, when most teachers, who are quite experienced in teaching group process, become learners themselves, they, too, do not automatically follow the procedure of assigning roles to group members when working in groups. For group process to work effectively, it is also important to consider trust.

Group Processes

Tasks and activities performed in a group discussion generally can be known as a process. Group process is a crucial part of computer-supported collaborative work (CSCW) concepts that specify the goals and structure of the team, as well as the progress of the cooperation between team members (Borghoff & Schlichter, 2000). According to Borghoff and Schlichter (2000), a group process is the specification of information, activities and characteristics of an electronically supported team, including the context for group interaction. It usually consists of a static part and dynamic part. The static part describes the team and its environment for performing activities, whereas the dynamic part specifies the progress of the group work and its respective state. The static part of the group process consists of: goals, organization, protocols and environment of the group. On the other hand, the dynamic part is made up of shared documents, group activities, the current group state and group sessions (Borghoff & Schlichter, 2000).

Group goals describe the global goals to be achieved by a predefined team. Individual goals can differ from group goals. Group goals have priority over individual goals. Group organization describes team members according to profiles (their skills and competencies) and their position within the team and the organization in which the team is embedded. The role of the team within the group may depend on their roles within the organization. It may also change dynamically

as the group progresses. There are active and dynamic participants within a group discussion. The group protocol describes the way in which the team members cooperate and communicate with each other. Two types of protocols exist: technical and social. A technical protocol is based on hardware or software, while a social protocol is one controlled by team members. It helps to determine how the flow of conversation will occur during a session. Two approaches can determine the flow of the conversation: informal and formal. In the case of an informal approach, each participant can feel free to speak according to predefined rules. In the formal approach, a moderator is appointed. Group environment is determined by the context of the group work, and includes the hardware and software systems, room equipment and room layout.

Group documents belong to the dynamic part of the group process. A meeting session is one example where a group shares information and relates to a group process. Activities taking place during a group process can have temporal or causal dependencies on each other. It must be dynamically adaptable to new situations. Borghoff and Schlichter (2000) suggest that a group session is performed as part of a group activity. It can be both synchronous and asynchronous. Participants may include one or several or all team members. A variety of operations is performed within a group session. According to Borghoff and Schlichter (2000), group process is dynamic and passes through several stages during the group's life. It consists of two main phases: creation and consolidation, which are subdivided into seven phases:

- **Creation phases:**
 1. **Orientation:** This phase represents the beginning of the group process. Team members discuss the overall goals of the group and then ask, Why was the team created? What is the purpose of the team?

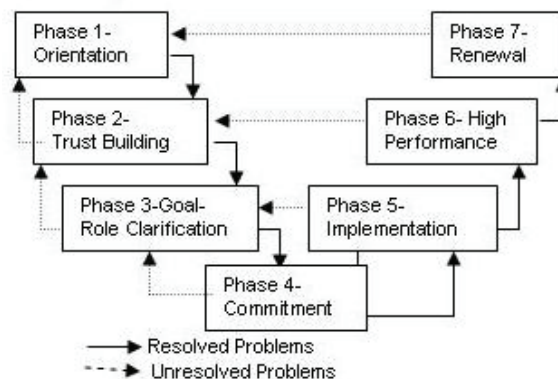

2. **Trust building:** Next, the integration of individual persons into the group process is of interest: What is expected of me? Who are my direct contacts? What amount of work am I expected to do? Trust building is important, because it leads to an open atmosphere and mutual respect. Disorientation or uneasiness of team members requires back-tracking to the previous phase.
 3. **Goal/role clarification:** In this phase, the goals and tasks of a group are defined.
 4. **Commitment:** The procedure for achieving group goals is outlined. Discussions are made with respect to problem structure and the assignment of resources. All team members must agree to support that procedure. Unresolved dependencies and responsibilities may require the group's return to Phase 3.
- **Consolidation phases:**
 5. **Implementation:** Individual tasks are assigned to people after team members have agreed on a problem. Temporal and causal dependencies during task execution must be taken into consideration. Conflicts between tasks and confusion

of team members could result in back-tracking to the goal/role of clarification phase.

6. **High performance:** When methods and procedures are defined, it is no longer necessary for the team to convene to discuss and determine each and every step. Instead, activities occur intuitively and flexibly.
7. **Renewal:** The high performance phase is only of limited duration. Team members become less motivated as time goes on.

The structuring of a group process into phases and interdependencies helps us pinpoint the potential of group work to support the tasks of the individual steps. The first two phases require direct contact (e.g., face to face) between team members. Synchronous conferencing systems or electronic meeting rooms are acceptable alternatives. A mixture of synchronous and asynchronous group work can support activities within the goal/role clarification phase. According to Borghoff and Schlichter (2000), fast communication is indispensable for mutual understanding. During the phases of commitment, implementation and high performance, focus is on the determined and agreed-upon group activities. For the renewal

Figure 1. Group process model of Drexler and Sibbet

phase, direct contact between team members is necessary.

Trust

Another important factor that contributes to the success of group discussion is that of trust. Trust is essential if teamwork is to be successful, especially in online learning, where group members are geographically separated. The level of trust between individuals, organizations and within society as a whole influences the nature of trust in online learning, both in terms of the contributions made by individuals and the productivity of the discussions within the learning environment.

There are different types of trust, depending on the length of time that the team members have known each other. These are (Jarvenpaa & Shaw 1998):

- **Identification-based trust:** The individuals are convinced that they have similar intentions and goals.
- **Deterrence-based trust or calculus-based trust:** Results from a fear of the consequences of behaving in an untrustworthy manner. Calculus process is where a trustor calculates the costs and/or rewards for another party to be opportunistic. In the prediction process, the trustor forecasts another party's behavior from historical data. The individual recognizes the consequences for not doing what he or she said he or she would do.
- **Swift trust:** The time available does not allow trust to be built up in the normal way, and team members simply assume that the other team members embrace similar values to their own.
- **Knowledge-based trust:** The individuals trust each other, as they know each other sufficiently well to be able to predict each other's behavior and have shared experiences. The trustor uses information about how the trustee has carried out tasks in the past to predict future action.
- **Transferred trust:** May occur when the trustor knows and trusts a person or institution that recommends the trustee. This is a form of swift trust.
- **Psychological or behavioral trust:** A predisposition towards having confidence that others will carry through on their obligations (Warrington, Algrab & Caldwell, 2000).
- **Technological trust:** A belief that technologies will perform reliably and will not be used for untoward purposes (Chiravuri & Nazareth, 2001).
- **Organizational trust:** The belief that an organization will carry through on its obligations (Cummings & Bromiley, 1996).
- **Situational trust:** Dependence on cues and clues in the immediate social environment when deciding whether to trust another group, organization or institution (Karake-Shalhoub, 2002).
- **Interpersonal trust:** An expectation that others will behave in a predictable way, and a willingness to be vulnerable during the trust relation (Dibben, 2000).

Shapiro and others (1992) identified three consecutive stages through which trust develops: calculus-based, knowledge-based and identification-based. In the beginning, calculus-based trust exists when neither party is familiar with the other. The knowledge-based stage is entered when information flow increases and behavior becomes more predictable, therefore adding more mutuality to the relationship. Finally, trust develops into the information-based stage. By that time, there should be complete empathy within the relationship and a full understanding of each other's needs, wants and intentions (Ashleigh, Connell & Klein, 2003).

According to Fukuyama (1995), trust is the expectation that arises within a community of regular, honest and cooperative behavior, based on commonly shared norms, on the part of the other members of that community. What is the role of trust in synchronous group discussion? We

believe that knowledge transfer in group discussion is embedded in a social context. Participation in the relevant social context is essential for the successful transfer of learning in productive synchronous group discussion. The very existence of a relationship between participants in productive group discussion exchange requires the presence of trust. The transfer of knowledge through education in group discussion requires trust between the teacher and the student. We also believe that trust, familiarity and mutual understanding, developed in a person's social and cultural contexts, are prerequisites for the successful transfer of learning in group discussions. Trust within and between members of the group can assist the dissemination of knowledge in group discussion. However, it is also important for us to recognize that issues of control and power also shape social interaction and, therefore, influence the processes of learning in group discussion. When a teacher structures the discussions, his or her control has an important impact on the participation and contributions of the learners.

Two types of trust are necessary for knowledge sharing: benevolence-based trust and competence-based trust (Levin, Cross, Abrams, & Lesser, 2002). Benevolence-based trust is one in which an individual will not intentionally harm another when given the opportunity to do so. Competence-based trust describes a relationship in which an individual believes that another person is knowledgeable about a given subject area. Both types of trust were necessary for students to work effectively and share knowledge.

BENEFITS OF ONLINE LEARNING: WITH RESPECT TO GROUP DISCUSSION

There are many benefits to online learning. For learners, benefits include easy access to global resources; learning at a time during the day, evening or night when learning is best for the learners;

learning at the place that is most convenient to the student without the need to travel to universities to attend classes; and learning without any interruptions to their work schedules, appointments or family events. For teachers, information and communications technology (ICT) embraces the design of learning environments that permit deeper learning using multimedia facilities. Teachers have an online location where they can add additional resources to meet the learning needs for all students, who learn through a variety of modalities. Given all the benefits, the heart of online learning is located in the online discussions. Online discussions facilitate learning on a scale not practicable in the past. In residential classrooms, while traversing the room from group to group, teachers can only listen to one group of students at a time. In some online learning systems, teachers have the ability to open and view the chat rooms for all of the groups at the same time, where they may take advantage of 'teachable moments' that occur in synchronous group discussions, to provide explanations when needed or to challenge students to think at higher levels while the discussions are in action. In most learning management systems today, online discussions are automatically archived. A benefit of an archived discussion is that the transcript could be viewed by students who were not able to take part in the discussion. Another benefit is that the chat logs from all of the groups could be posted to a discussion thread, where the entire class could access and learn from them, adding to the richness of the class. Online discussions provide the medium for teachers to observe the level of community building within in each group, within the entire class, and to add more scaffolding to move the community building to higher levels.

We believe that trust and performance are interrelated in online learning. The reason given is that much learning happens through social interaction. According to Sousa (2003), the trust students put in three main components of an online distance learning scenario is the common

Group Process and Trust in Group Discussion

denominator of several related problems, such as motivation, retention and technology difficulties, which normally lead to low academic performance. The three factors identified by Sousa and others (2003) are:

- Students' trust toward the teacher's interaction;
- Students' trust toward the virtual learning environments (VLE); and
- Students' trust toward the technology.

The work by Jarvenpaa and Leider (1998) also pointed to the relationship between trust and performance in online distance learning. They suggested that responses to positive trust building activities have an increasing trust in team members. In the paper *Trust, Safety and Confidence: Building the Foundation for Online Interaction*, Klecka (2003) shows that besides safety and confidence, trust is the basis for interaction in online learning. In her research, Klecka (2003) found that users need to establish trust before they feel confidence to participate in group discussion and sharing.

ONLINE LEARNING AT DUQUESNE

GITED516: Distance Learning Course Design is a graduate course purposefully designed for educators who aspire to teach online. This course was designed to place teachers in the role of a learner so they could experience and gain an appreciation of what it was like to learn online from a learner's perspective. In this blended course, learners meet residentially for a total of four sessions during the 15-week semester: two sessions at the beginning of the course and two sessions at the end of the course.

From the moment the students enter a class, when they meet the teacher and other students for the first time, they develop an intuition about how they feel about the culture of the class. Initial Online Trust (IOT) is the initial stage of a user's

trust in the online learning system. It inherits the essential nature of general trust. IOT is the trust that surfaces when parties first meet or interact. It is based on an individual's disposition to trust or an institutional cue that enables one person to trust another without firsthand knowledge (McKnight & Cummings, 1998). Initial trust is also the trust in an unfamiliar trustee, a relationship in which the actors do not yet have any credible, meaningful information about or affective bonds with each other. We believe it is important to identify the type of knowledge a trustor has before the first interaction. Differentiating users based on their knowledge is the first step to understanding their trust.

Even if students do not verbalize their thoughts, they enter a classroom concerned whether they are enrolled a safe risk-taking course, where they can trust the teacher and the students, where they can take risks, possibly even make mistakes, and still be accepted by others. In this course, during the first face-to-face session, the teacher took the first step in setting the tone of the environment. The teacher and the students briefly introduced themselves to the class, since one of the homework assignments for the first class was for the students to upload their autobiography, adding more details into the Learning Management System (Blackboard) than they shared in class. The bio is an important activity. Students from past courses frequently commented that they referred back to the photos and personal information about their peers several times during the course after they began to read each others' postings. Following the brief introductions, the students performed an activity where they completed an unannounced 1-minute typing test, using an authentic secretarial typing test, to identify their typing speeds. The purpose of this activity was to identify the typing speeds of each student so that the teacher could combine this information along with the knowledge learned from the students' bios, so that the teacher could place them in groups for the next two activities: an unstructured and structured synchronous chat. The ability to communicate can be hindered by

limited typing skills. Clear communication is essential for online teams to function effectively (Larson & La Fasto, 1989). Building trust fosters effective online communication. A synchronous chat is similar to on-ground small-group discussions, which happen in real time. The class was divided into groups consisting of no more than three to four students per group. As other previous GITED 516 classes, the average typing for this class was 30–40 words per minute. Once the groups were formed, the teacher shared this information with the class and then taught the class about the ‘mechanics’ of entering and posting their thoughts into a virtual classroom, called a ‘chat room.’ This is where the students only learned about the tool. Intentionally, information was shared with the students at this time.

The first synchronous activity was called an unstructured chat. In the unstructured chat, the teacher provided no rules of online etiquette (netiquette) and she did not provide any reference to group processes. The purpose of the chat was to observe the interactions of the group members, to witness whether their typing speeds were exchanged without prompting, to check for group organization and productivity, to observe for equal participation of all group members, and particularly to see whether the groups assigned roles. The teacher timed the activity to last 15 minutes. The group was tasked to answer two questions, which the teacher knew they could answer from their past experience. The two questions for this assignment were:

1. Discuss your most favorite teacher and the reason you remember the teacher so well.
2. Discuss what you either heard from others, experienced yourself or perceive about the characteristics and qualities of successful online students.

The teacher assured the students that there were no right or wrong answers to this activity, hoping that the students would be more willing

to express their thoughts in a public forum (but in a password-protected Learning Management System) to their peers they met that evening.

Once the unstructured chat was over, the students were allotted 15 minutes to discuss their unstructured synchronous chat experience. As with other classes, the groups said they felt like they were on a treadmill, where they had difficulty keeping up with reading and typing at the same time. Some students said they stopped participating in the discussion because of their limited typing speeds or because English was not their first language, feeling excluded because the American students used a lot of slang or local terminology they did not know. Following the discussion, the teacher spent the next 15 minutes reviewing the group process, structure, rules of netiquette and the group roles the students would be expected to assign for each succeeding synchronous chat. The five roles communicated to the students were: *Organizer, Communicator, Timekeeper, Recorder and Remediator.*

- **Organizer:** Monitors the group’s progression, keeps the group on task, and checks for accuracy in the posted information.
- **Communicator:** Substantiates that all participants in the group had an equal opportunity to voice their thoughts, opinions and ideas during the discussion and assures that the diversity of thoughts is respected. *Communicators* must know the typing speeds of each member to decrease the pace of the conversation, when necessary, to keep all members participating at an achievable level.
- **Timekeeper:** Monitors and manages the assigned tasks to assure that all questions or assignments have been addressed.
- **Recorder:** Reviews the online chat log following the discussion, summarizes the important points addressed, sends the analysis to all team members to be sure the summary is reflective of everyone’s thoughts, and posts

Group Process and Trust in Group Discussion

the summary to the discussion board for the other groups to read so that everyone in the class has the opportunity to learn from the discussions of all groups.

- **Remediator:** Recaps the group's agenda, tasks or assignments, updates the member briefly of the group's progress, and asks the member for his or her input.

From the author's experience, building trust within a community of learners (Phase 2: Trust in Borghoff and Schlichter's model, 2000) evolves within an eight-step hierarchical model. If teachers want groups to attain their highest levels of trust that leads to sustaining online dialog, the teacher's role must evolve from leading and directing the conversation to a facilitator's role, which becomes supportive and fosters group empowerment, culminating in the facilitator stepping aside, letting the group take the lead, and only intervening in the conversation on occasion and when appropriate. The eight-step hierarchical model to aid in sustaining online discussions and building trust involves:

- **Step 1:** Facilitator learns about the audience and sets everyone up for successful dialog.
- **Step 2:** Facilitator individualizes the setting—links content to the context and culture of the audience.
- **Step 3:** Facilitator sets up a risk-taking environment for the group to respect each others' thoughts.
- **Step 4:** Group depends on the facilitator to raise the comfort level of the group and begin the discussion, rarely taking risks when they speak.
- **Step 5:** Group begins the dialog, but superficially shares their thoughts. The group begins to formulate thoughts about the trustworthiness of the group. Learners are less vulnerable in conversations when they begin their dialog with the word "They."

- **Step 6:** Group leads the dialog, but increases their trust slowly—taking one risk at a time (Trust builds on small successes) and testing the trustworthiness of the group by taking more risks with the more acceptance they receive from the group. Learners are more vulnerable and generally progress from beginning their thoughts with the word "They" to the word "We."
- **Step 7:** Group sustains the dialog and shares deeper thoughts with the group. The group depends on each other to drive the dialog. This is where the learners are most vulnerable, and they generally begin their conversations with the word "I."
- **Step 8:** Group sustains the dialog and the group members speak with a unified voice, understanding each other when they speak. This level demonstrates that the highest levels of trust are evident. The group speaks openly and honestly, and refrains from group think.

Online dialog has the potential for groups to form deeper relationships, because in an online environment learners who do not speak (by typing their responses) are considered absent. Learners cannot remain passive in an online environment or no one will know they are present. The first four steps in the model described above are initiated and implemented by the teacher. The remaining four steps are led by the group members. Building trust evolves over time and is accomplished through a hierarchical approach. For example, when trust is breached, learners may regress at least one or two more steps. Depending on the learner's trust established in prior relationships, the length of time it takes for learners to trust the group members will vary. This factor must be taken into consideration in the group process. Some students will not openly share their thoughts until trust among the group members has been achieved.

One of the homework assignments for the first session was for students to answer a 20-question self-assessment questionnaire related to *Making Informed Decisions About Online Learning*. This survey was another tool that further assisted the teacher in learning more about the students before they worked online and outside of the residential setting. The questions below were selected from the survey because of their direct implication in providing more knowledge about each student's past experiences, which may impact their performance in the group. In the survey, students rated themselves using the metaphor of a traffic light, implicating their answers in a green (benefit), yellow (caution) or red (risk) category. For any markings in the yellow (caution) or red (risk) categories, students were asked to provide an explanation for their answers. Our experience has shown that many students rated themselves more critically than the teacher would have rated them. This survey was used to identify potential and proactive "red flags" that may indicate potential problems the students may experience in the course and group work. The questions most appropriate for this chapter and the students working in groups in general were:

- Rate your leadership skills;
- Rate your history of verbal participation in class;
- Rate your pattern of focusing and answering questions/dialoging on task;
- Rate whether you prefer to work in groups or to work alone;
- Rate your individual productivity completing group work;
- Rate your level of active listening during a conversation;
- Rate your level of comfort sharing your work with others; and
- Rate your ability to read carefully.

THE CASE STUDY

In this section we describe how the group process of Borghoff and Schlichter (2000) is used in our case study for our online learning course at Duquesne.

Phase 1: Orientation

Following the Best Practice Model of Online Teaching and Learning in the article by Wilcox and Wojnar, *Best Practice Goes Online* (2000), getting to know the audience is an important starting point to building trust and individualizing instruction for all learners. In this phase, the teacher and students met in a residential classroom. Meeting their peers in a face-to-face (on-ground) classroom before conducting online discussions in a virtual classroom, where the students were meeting online from various geographical locations, helped the students to feel more at ease with their peers. They were able to connect names with the faces of their peers they remembered from the first session. Online, students will be communicating in text-based synchronous discussions and asynchronous discussions. The instructor guided the students through the unstructured chat, the teaching portion of group process, expectations and netiquette guidelines, and then through the structured chat. For homework, students were tasked to complete a 20-question survey. The orientation aims to prepare the class for a problem-solving synchronous discussion the groups will conduct themselves, without the presence of the teacher, using the content of the *Six Thinking Hats* book by Dr. Edward De Bono in Session/Week 4.

Phase 2: Trust Building

Teachers and students evolve into communities of learners over time. Trust begins on the first day the teacher and students meet. In our model, the teacher facilitates the first four steps toward

Group Process and Trust in Group Discussion

building a community of learners. Steps four through eight focused on the group's role in this process. The goal is to keep increasing the levels of trust within the group so that the discussions will become rich and will be sustained by the group. *Trust is the most fluid and most critical level in the group process to keep learners involved in the learning process.* As long as group members continue trusting each other, by acquiring small successes to what they post and gaining acceptance by their peers, the members will be more willing to share their thoughts in a public forum, which in turn aids the progression of the dialog, where students are comfortable sharing their true thoughts without the fear of rejection. Facilitating and nurturing the process where students depend on each other, rather having them depend on the teacher to provide the knowledge and guidance they need to be successful in online discussions, assists students in taking ownership and responsibility for their own learning.

Phase 3: Goal-Role Clarification

The agenda for the group work is clearly articulated and understood by all group members. Discussions proceed smoother and on-task faster when one person in the group posts the objectives and tasks the group is expected to complete. It is important to review netiquette guidelines and assign roles to each member of the group. Initially, the teacher should assign the roles to the group members. The more clearly the objectives and tasks are articulated and understood at this time, the easier it will be for the group to begin to focus their thinking and move forward in their discussion.

Phase 4: Commitment

The teacher selected the groups. In this assignment, students were provided with a link to an online case study in advance of the discussion.

The entire class read the *Six Thinking Hats* book. The teacher assigned a different colored hat to each student. There were six students per group. Students were expected to lead the discussion when their group requested a response of the thinking of their colored hat to solve a problem. The group was tasked to problem solve a case study using all of the colored hats.

Phase 5: Implementation

The synchronous discussion took place over 1-1½ hours. Our experience has shown that a discussion lasting longer than 1½ hours causes a decline in the students' concentration and reading abilities, because the thinking and concentration of reading text online was so intense.

Phase 6: High Performance

Reports and comments from students have shown that this activity is very meaningful. Most of the students had been involved in work or life situations that required problem-solving skills. In prior situations, students had recognized they generally do their problem solving with some, but not all, of the colored hats. Because students found this activity so interesting and practical, they were able to see how this activity could transfer to problem-solving issues in their workplace. The group's concentration was very intense, but sustainable by the group.

Phase 7: Renewal

Limiting the time frame to conducting the discussion to a manageable time frame (no longer than 1½ hours), the group was able to sustain the momentum of the discussion without getting tired or becoming less motivated. In past classes, when the chat lasted more than 1½ hours, renewal time was required.

THE ROLE OF TRUST IN SYNCHRONOUS GROUP WORKING

How do we facilitate trust?

1. Creating a common understanding of how the online learning course works, we found it important to develop a common context or common understanding among students regarding the nature and goals of the course. Factors that were significant in building benevolence and competence-based trust include: a shared language and goals; and relating to the importance of building a shared view of how learning was accomplished, how it is measured and how it is ultimately rewarded. Creating this common understanding makes it easier to focus on mutually held goals and values. This helps to reduce the time and effort spent on individual issues and motivation.
2. Help build trust-building behavior. As teachers, we can influence the level of trust by modeling and recognizing trust-building behavior, such as receptivity and discretion.

Teacher support is vital to the success of online learning. Teachers should support their students at the start of their learning. What type of support is appropriate? It is our belief that support should include providing information, encouragement and resources to the students. Teachers should respond promptly to students' queries and provide direction to them, acting as an arbitrator and backing decisions of teams.

Until students get to know one another, the benefits of learning through group discussion may require a leap of faith. New online learners will not know whether what they are learning is of value until they fully experience several discussions. The ability to share a high degree of mutual understanding, built on a common appreciation of

a shared social and cultural context, is essential to building trust between individuals.

Trust is widely recognized as a major issue affecting the uptake of online learning. We know that although ICT can be used to facilitate the transfer of knowledge through online learning, it should also be capable of reinforcing trust by providing mechanisms of validation and protection through necessary regulatory and institutional framework. In addition, trust should also depend on the sharing of a set of socially embedded values, cultural institutions and expectations. This may be facilitated through the establishment and maintenance of a strong institutional culture. It is possible with the aid of ICT through the virtual learning environment of the discussion group to build a relationship of trust and mutual understanding.

While mutual goals are necessary, they are not sufficient to gain mutual trust for collaboration (Dodgson, 1993). With mutual trust, participants will reciprocate openness and sharing of information and knowledge over time. Other conditions that impact mutual trust are rivalries and occupational communities. We believe that it is necessary to understand the philosophy of group process with trust built in as part of the process.

It is our belief that cooperation is an essential part of online learning. Borghoff and Schlichter (2000) believe that cooperation in a group is both a repeated alternate between synchronous and asynchronous cooperation and a process during which subgroups constitute themselves for solving individual subprograms. For example, a seminar on a paper can exemplify alternation between the different cooperation modes, as shown in Figure 2 (Borghoff & Schlichter, 2000).

The synchronous environment demonstrates students' ability to demonstrate thinking using both preparatory and impromptu techniques (Wallace & Wojnar, 2002). In our case study, students were assigned a Universal Resource Locator (URL) to locate an article for their case

Group Process and Trust in Group Discussion

study. Students were expected to identify the issues and then to problem solve each issue using all six hats. Since students had time to prepare and formulate or process their thoughts, they used a preparatory technique. As the discussion continued and the group posed questions to each other, students responded to the questions without any prior preparation. This technique is called the impromptu question-and-answering technique. The asynchronous environment is more reflective than the synchronous environment and allows for students who are processors of information to think through and rewrite their original thoughts once they have had ample time to process the information. Incorporating both synchronous and asynchronous discussions in an online course are the closest means to replicating a residential learning environment. Residential classrooms are filled with rich discussions because they include both group and individual work.

During the 15 weeks the course was taught, there were only two synchronous discussions scheduled with each discussion lasting no longer than 1-1½ hours. Too many synchronous discussions during a course defeat the purpose most learners enroll in online classes—flexibility, leading to a fixed course schedule.

Learning is a social process involving teams of people working together. Building relationships for online learning is vital to the effectiveness of the team (DeNigris & Witchel, 2000). This is a positive link between member relations and team performance for both short-term teams and long-term teams (Druskat, 1996; Druskat & Kayes, 2000).

CONCLUSION

Group discussion is a crucial part of online learning. For effective group discussion, it is important that we understand group process and trust in collaborative work. According to Borghoff and Schlichter (2000), a group process is the specifica-

tion of information, activities and characteristics of an electronically supported team, including the context for the group interaction. Included in the group process is the issue of trust. Trust is vital if we want students to be fully active and participate in the group discussion. The outcome of the trust building process in the group discussion leads to a student's ability to learn from other each and from the teacher. Because students began to trust each other and their teacher, they became more open and able to share their thoughts without fear of being rejected. This allows them to learn problem solving from each other that will lead to solving related issues in their workplace. The trust that individual members develop within their team helps them to predict others' behaviors. The initial getting-to-know-you session encompasses sharing of cultural information. These individuals exchange information about shared values, assumptions, opinions and beliefs. There is also a sharing of personal information, such as hobbies, interests, family life, work life, personal expectations of team, equipment, resources and so forth.

Our experience has shown that for online discussions to be productive and goal oriented, teachers should review the group process with students before they assign group work. Students need to know the value and impact they have on making groups functional and high performing. Surveys that could identify past experiences within group work may help to identify "red flags" that may proactively make a difference between student satisfaction and frustration in online discussions. Trust is one of the most fluid yet critical elements that either led groups to share or to hold back their thoughts in any setting. By taking the time to explain the rules of online engagement, teachers will increase the probability that the discussion will be content-rich, productive and on-task, and meets or exceeds the objectives and tasks assigned, rather than being disappointing, non-productive and demonstrating no viable results.

Once students are skilled in the procedure for conducting online discussions, generally with secondary students or adult learners, teachers may empower their groups to monitor and manage a synchronous discussion without their presence. By carefully following the model of Borghoff and Schlichter (2000) from orientation to renewal, higher-quality and more productive discussions that actively engage all learners are possible. Students who have multiple classes together may be more inclined to experience all eight steps in our community building model. We have demonstrated in this chapter how we have utilized both group process and trust in our online course.

FUTURE RESEARCH

We would like to conduct further research in how group process and the issue of trust impacts online learning discussions, the limitations of the current model, the process of identifying the types of audiences that would be most suitable for online group discussion, online chat logs from the course to identify whether groups automatically assign roles to their group members and the group process they follow, and group online productivity through a variety of assignments.

Chapter 5.4

Community (Information and Communication) Technology: Policy, Partnership and Practice

Peter Day

University of Brighton, UK & Central Queensland University, Australia

ABSTRACT

This chapter illustrates the significance of developing a shared understanding of community, which is more than an adjective qualifying a certain type of ICT usage in a rapidly developing area of social practice and academic study — Community Informatics. Highlighting the importance of contextualising ICTs within their social environments, the chapter approaches Community Informatics from a human-centered perspective. It introduces a framework of democratic design criteria intended to assist the community planning and implementation processes of community technology initiatives. Examining the significance of community policy, community partnerships and community practice, the author invokes the need for interdisciplinary and cross-sectoral collaboration in Community Informatics and argues that community ICT initiatives should be grounded in the needs of local communities if they are to be utilised successfully as tools of community empowerment.

INTRODUCTION

Communication, in one form or another, has played a central role in developing and sustaining the well-being of geographic communities throughout history. Community Informatics, a fairly recent phenomenon of modern network societies, can be traced to the community communications pioneers of the late 1980s and early 1990s. In Europe, for example, community tele-service centres and community telecottages were being developed in Scandinavia and the UK, whilst in North America, the community networking movement emerged during the same period (Day, 2001). Since these early beginnings the primary purpose of such community technologies has been to utilise information and communications infrastructures, applications and services to empower and sustain the social capital of local communities (the networks, organisations, groups, activities and values underpinning community life). However, developing sustainable and effective community

ICT initiatives can be problematic and present significant challenges across a number of levels (Day & Harris, 1997).

This chapter seeks to address some of these challenges, not as a final solution of ‘one best way’ but as a stimulant to cross-sectoral dialogue and collaboration at community level. The main contribution to this dialogue is the presentation of a framework of democratic design criteria intended to assist the community planning, implementation and development processes of community technology. The framework is introduced within the context of community ICT policy, partnerships and practice — the 3Ps of Community Informatics. In this context the chapter is intended as an input to both the interdisciplinary academic discourse accompanying the emergence of Community Informatics as a field of investigation and the emerging cross-sectoral communications found in community ICT practice (Day & Schuler, 2000).

UNDERSTANDING COMMUNITY

In order to avoid interdisciplinary or cross-sectoral misunderstanding in this relatively new area of study and practice, it is worth spending some time developing an understanding of what is meant by the term ‘community’. To begin with, this chapter assumes communities to comprise both active community groups and individual citizens. However, in terms of essential characteristics such as socio-economic environments, culture, social norms and values, needs and behaviour, no one community is alike. There are commonalities but there are also differences. Communities are naturally heterogeneous and rather than attempt a hard and fast definition this chapter adopts a more flexible approach. Butcher’s three interrelated senses of community — descriptive community, community values and active community (1993) — not only provide a starting point for discussion but enable practitioners, researchers and policy-

makers to consider the characteristics, resources and needs of their own communities and plan community initiatives accordingly.

The notion of Descriptive Community, which draws on the word’s etymological origins of having ‘something in common’ provides us with our first sense of community. This ‘something in common’ might refer to a neighbourhood, village, or town, for example, but might also refer to other social determinants such as ethnicity, religion, and sexual orientation. It should be noted that communities based on location or interests are not necessarily mutually exclusive. Indeed geographic communities are often made up of diverse cultures and it is not uncommon for groups and individuals to share knowledge and draw from each other’s experiences, creating new forms of common interests as a consequence. Of course, the opposite can also be true and conflict can and does arise in and between communities, but for communities to be sustainable, especially where diversity of culture and social norms exists, Community Values are significant.

The second sense of community is found in the sharing of certain social values, i.e., solidarity, participation and coherence. Although community values are open to interpretation and can be contested, the principles upon which they are established provide the value base of community initiatives and policies. Solidarity inspires affection and loyalty in communities through mutuality and co-operation in relationships. Participation enables individuals to contribute to and engage in the collective life and aspirations of the community. Coherence connects individuals and community, facilitating an understanding of themselves and their social world. However, the potentially contested nature of community and modern society’s inherent diversity of cultures and belief systems require community members to respect and celebrate the social richness and diversity of community life if they are to co-exist in the same geographical space and share social experiences. This diversity distinguishes the in-

dividual from the collective whilst, at the same time, contributing to the collective.

That communal does not subsume individual might be regarded as paradoxical, but a balance between adequate amounts of privacy, autonomy and localism is required to shape Community Values. Shared public spaces, community associations and activities that provide the opportunity to engage with one another should be tempered with spaces offering both privacy and respect for the diversity of cultural principles.

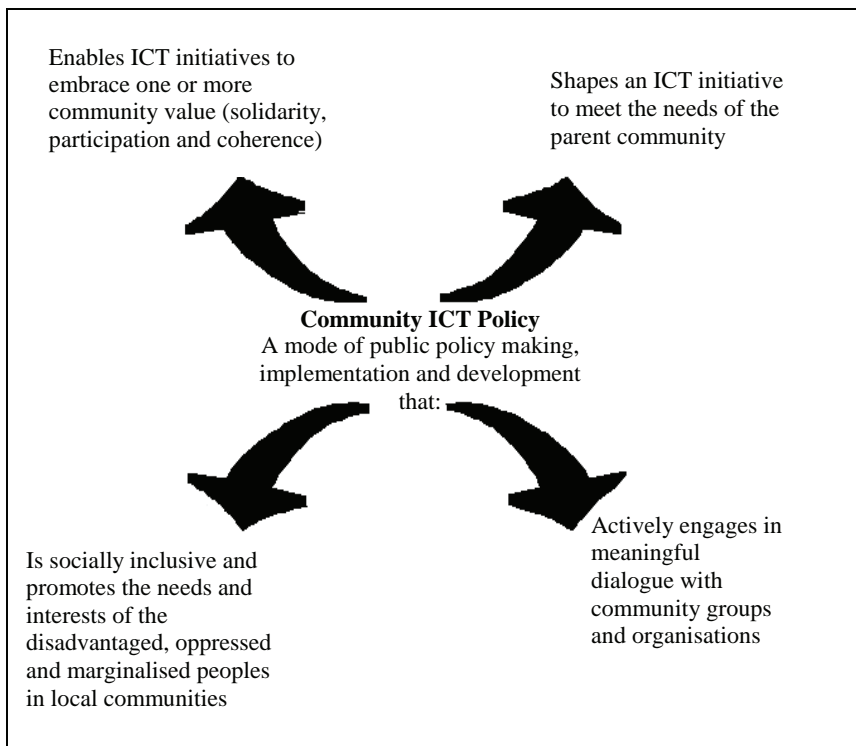

The notion of the Active Community provides the third sense of community and stems from community identity. It is through a sense of belonging to a local community that people engage in community activities. The Active Community refers to collective action by community members

embracing one or more communal values. Such activities are normally undertaken purposively through the vehicle of groups, networks and organisations, which is why the concept of social capital is of such import to any discussion of community. These community and voluntary sector organisations form the bedrock of community life, and although often under-resourced and over-stretched play a significant role in building and sustaining community.

COMMUNITY POLICY

The Active Community is based on the participation of community members, groups and organisations in shaping community life. How-

Figure 1. Community ICT policy (Source: Day, 2001)

ever, a shared value base between community and policy makers is crucial to the formulation of policies that build, develop and sustain active communities. In developing an understanding of what community means at the local level, it is possible to develop policies that are meaningful and relevant to people in those communities in the network society, and community ICT policy can be represented as shown in Figure 1.

THE PARTNERSHIP APPROACH

Partnerships have always played a central role in community policy, and this shows no sign of abating. In fact, if anything, the dependency on partnerships is on the increase today. Significantly, partnerships have also been crucial components of information society policy development and implementation since 1994 (CEC, 1994a) and are therefore of import to community informatics. However, they are complex social arrangements and their impact on the development of community technology, especially community ICT initiatives, is worthy of investigation.

Although partnerships can be both formal and informal arrangements to work together, Wilcox suggests that where a task is complex and long-term, such as a community ICT initiative, a formal partnership is the best approach (1994). He continues by suggesting that one of the first tasks of any partnership should be the clarification of issues such as joint purpose and values. However, although aims are usually identified early in the partnership life cycle, a key problem is that partners often have different social agendas and consequently differ in their interpretations of these aims, which are often deliberately vague so that all partners may feel comfortable with them. Rarely is time spent establishing common purpose and values through open and honest discussion (Day, 2001).

Public/Private Sector Partnerships

The traditional approach to partnerships is based upon the public and private sectors (CEC, 1994a). This model, through its concentration on economic and physical capital, overlooks the significance of social capital (Putnam, 1996) and is usually based on power. The private sector has economic power and the public sector has regulatory, administrative, legislative and some economic power. It is these powers that dictate and drive forward the development of local information society policy. The third sector¹ is excluded from such a scenario and is forced to exert whatever influence it might have through any available channel. Partnerships such as these tend to stimulate social exclusion by failing to include representation from local communities and individual citizens (Harris, 1996).

Cross-Sectoral Partnerships

In a call for a more inclusive attitude, Harris suggests cross-sectoral community partnerships should comprise local authorities, the private sector, and academic and voluntary sector agencies (1996). However, the disempowerment of citizens, found in traditional partnership models, can also be found in some cross-sectoral partnerships. Even where the not-for-profit, or third sector is included, the power of professionals and/or 'experts' (Street, 1997), together with a bureaucratised policy-making process can sometimes be observed (Sanderson, 1999). Where citizen input is sought, this often takes the form of consultation. Local people might be asked their views on a specific proposal and some slight amendments might even be possible but the purpose, budget, outcome, etc. have generally been predetermined. As Arnstein argues, such consultation is usually little more than tokenism (1969).

Tripartite Partnerships

Although cross-sectoral partnerships are now recognised as significant to modern policy-making (New Economics Foundation, 1998), a more equitable approach is required, one that transcends the inherently exclusive nature of traditional partnership models. Tripartite collaboration is posited as an attempt to build on cross-sectoral partnership mechanisms at local level (Day, 1996, 1998). Rather than being driven solely by the economic imperative of public and private sectors, the policy-making process should be based on respect, equity and mutuality between partners and embedded in community need.

The social development of local communities cannot be shaped by economics alone. The economy is only one element of the human condition in community life. Simply said, if the private sector has the right to make profits from the local community then it has the responsibility to contribute, in a meaningful and necessary manner, to the welfare and social fabric of that community. As an enabling authority, it should be the role of local government to oversee such community partnerships.

Collaborating in tripartite partnerships enables each sector to bring its own skills, expertise, experience and knowledge to the local partnership. The private sector is usually good at doing things efficiently. The third sector is good at articulating local views, communicating with users, and developing a sense of citizen ownership and identity. The public sector's² key strengths are its enabling ability, and ensuring that the broader public objectives are achieved by maintaining a strategic overview (Landry & Bianchini, 1995). The diversity of partners' contributions provides the foundation of tripartite partnerships. Diversity of experience, knowledge and skills, as well as more tangible resources should be regarded as partnership assets, i.e., social wealth.

Partnerships developed in this way can promote a more democratic approach to societal changes. However, to be successful they must encourage participation, so that joint purpose, common values and mutual understanding can develop. Enabling local communities to engage in the shaping and utilisation of community ICT initiatives is an important step towards a more inclusive society.

Tripartite Collaboration

Tripartite partnerships signify a major directional shift from the limitations of the partnership policies that underpin many information society development initiatives (Shearman, 1999). They point the way to a more collaborative form of community communications and decision-making in which the influence of social networks is emphasised. However, it should be understood that such collaboration requires changes to the existing social and cultural perspectives of many organisations and agencies. Fresh and open minds are requisite to addressing the needs of local communities and the challenges of collaboration.

The active involvement of the third sector in the policy process through tripartite collaboration also requires a re-examination of assumptions and practices relating to the power of administrators (Day & Harris, 1997). Without changes in the way bureaucracies function, authentic participation will be limited to experiments of academic interest only. Enabling administrators to become co-operative participants in a collective community dialogue will require a significant shift in values of the role of administrators and the organisational cultures of many local authorities. The development of more participatory and inclusive community policies requires research not only into ways of empowering and educating citizens but also into ways of re-educating administrators and enabling administrative structures

and processes to facilitate an effective dialogue between citizens, administrators and policy-makers (King et al., 1998).

Outlining the Need for Change in Partnership Approaches

Policies to meet the challenges of the network society will need to draw from the widest social knowledge base. The facilitation of flexible and fluid partnerships through tripartite collaboration will go a long way to meeting the needs of communities in a rapidly changing socio-economic landscape. By utilising such partnerships in the development of community ICT initiatives, a more accurate representation of the needs of local citizens can be achieved. The participatory and collaborative nature of tripartite partnerships is reflective of, and complimentary to, the networking potentiality of ICTs. However, ICTs do not solve societal problems (only social solutions can do that) but they can provide requisite platforms for the efficient support of effective solutions (CEC, 1994b).

Unfortunately, it is not often recognised by policy makers that richly diverse sources of social creativity exist in local communities. By providing the expertise, resources and support for the creative social processes of local communities through the tripartite approach, a bridge can be built between the formal institutions and the informal networks that characterise the everyday life of local communities.

Harnessing the knowledge and creativity of local communities with the professional skills and expertise of public agencies and, where appropriate, private companies, can facilitate and increase social innovation. Social innovation is defined in this context as social initiatives designed and driven by local people to meet the needs of the local community through the solution of local problems.

The scenario of an empowered citizenship utilising ICTs to address social needs through participatory community practice unfortunately receives little consideration at policy level. Yet it is precisely the potential for citizens to participate in a full and active manner in the network society; designing, implementing and developing initiatives, activities and services that democratically meet community defined social need that transcends the passivity that marks the current techno-economic paradigm.

If the only services available to citizens are those regulated and priced by the service providers of a commercially developed infrastructure, then issues of access, social inclusion and active citizenship are diminished in value because the role of citizen is reduced to that of passive consumer.

Universal Participation

The previous section of this chapter highlighted the role of the third sector in tripartite collaboration. However, whilst such an approach encourages citizens to be actively involved in community groups, etc. — by providing them with a voice in the policy making process — it is important to note that community groups, etc., are not the whole story in respect of communities. Indeed, there is a potential danger that groups or third sector ‘experts’ familiar with the process of local government can dominate participation and actually deter active citizenship (Wilson, 1999).

Similarly, contested values within communities can lead to conflict. This can also act as a deterrent to the involvement of those new to forms of civic engagement and can be used as an excuse for inaction by local authorities. However, where people feel valued by policy-makers as equal citizens and are able to act on this sense of worth, they are more likely to contribute to and participate in shaping their local community. Active participation is therefore related to issues

of social rights and empowerment, and local authorities have obligations to citizens to respect and respond to collective contributions, needs and aspirations (Higgins, 1999).

Consequently, if social inclusion is to be both achievable and sustainable within the network society, all citizens should, as a fundamental democratic right, have the opportunity to participate in its evolution. Universal participation should now be included as part of the network society universality debate, alongside universal service and universal access (Kubicek et al., 1997; INSINC, 1997). In this way, citizens of a network society can both empower themselves and enrich the quality of life of their local communities, and through aggregation, contribute to improving the quality of life at a societal level.

COMMUNITY PRACTICE

As the development of community policies is dependent on encouraging active communities, the implementation of community policies, as has been seen, requires a change in mind-sets, enabling new and distinctive methods and techniques to be embraced (Glen, 1993). Glen describes these processes as ‘community practice’, which may involve some or all of the following components:

- The sustained involvement of paid community workers;
- A broad range of professionals who are increasingly using community work methods in their work;
- The efforts of self-managed community groups themselves;
- Managerial attempts at reviving, restructuring and relocating services to encourage community access and involvement in the planning and delivery of services (Glen, 1993, p. 22).

Describing the symbiotic relationship between community practice and community policies, where each is related to and promotes the other, Glen identifies three community practice approaches:

- Community services approach
- Community development
- Community action³

The last two operate at grassroots level. Community development concerns itself with the empowerment of communities to define and meet their own needs. Community action consists of organising and campaigning to achieve community goals. The community service approach involves altruistic and compulsory forms of assistance to people in need⁴ (Glen, 1993). However, because of the wide range of agencies, organisations, groups, etc., involved in community practice, approaches may be ‘top-down’, i.e., promoted by local authorities or voluntary bodies, or emanate from within local communities, i.e., ‘bottom-up’.

Whatever the complexion of an initiative, community practice should not be viewed as a blueprint for best practice but as a framework of three interrelated elements that assist in the understanding and fulfilling of community need. A brief examination of each element within a Community Informatics context is now conducted.

Community Services Approach

The community services approach requires a great deal of resources and support for the various initiatives/projects. This is the process in which community-oriented organisations and services are developed to meet the identified needs of the community. In a community informatics context, examples of this might include: the provision of online information services, public access centres, low cost ICT provision schemes, and education and training programs.

Community Development

Community development focuses on the promotion of community self-help and empowerment. This requires a continuation of the community services approach but with a view to building the capacity of communities to sustain the initiatives. Stimulating dialogue, collaboration and mutual support within and between the social organisations and networks in a community (social capital) and engaging in a consideration of how ICTs might underpin such activities, e.g., through the design, implementation and development, or community planning processes of a community network, are key goals here.

Community Action

Once empowered, communities are in a position to campaign for community interests and to influence the shaping of community policies. The community services and development approaches are continued to maintain a social safety net, but communities have more autonomy in their own affairs. The aim here is sustainable community through democratic communicative action.

Whatever the partnership composition and balance between the three interrelated elements of community practice, a shared value base that prioritises the identification and realisation of community needs as the motivating force of a community ICT initiative is required if they are to be socially sustainable. Subordinating ICT systems and artifacts to the needs of people living in geographic communities is fundamental to this process. Drawing from Sclove's theory of democratic technology (1995), the next section presents a framework for the participatory planning and implementation of Community ICT initiatives.

A FRAMEWORK FOR THE DEMOCRATIC DESIGN OF COMMUNITY ICT INITIATIVES

This framework is structured in five sections. The first three are based on Sclove's organising principles of institutional setting and association in a democratic society: democratic community, democratic politics and democratic work, and are deemed as essential to establishing democratic community ICT initiatives. The fourth relates to criteria aimed at securing the democratic sustainability of initiatives whilst the fifth introduces criteria intended to perpetuate democratic participation.

Toward Democratic Community

- A. Seek initiatives embracing one or more community value (solidarity, participation and coherence).
- B. Promote community development through the empowerment of citizens to define and meet their own needs.
- C. Relate goals and outcomes to the needs of communities and their citizens.

Criterion A states that democratic community ICT initiatives should be based on one or more community value. As seen previously, solidarity inspires affection and loyalty through mutuality and co-operation in relationships, sustaining community members at an emotional level. Participation benefits individuals through the recognition of their contribution to collective life and self-development. Coherence connects individuals to the community, and leads to an appreciation and comprehension of self and situation that give meaning to and awareness of themselves and their social world. Stimulating and sustaining the community values of solidarity, participation and coherence has been a challenge exercising

Figure 2. Community ICT planning and implementation criteria (Source: Day, 2001)

Toward DEMOCRATIC COMMUNITY:

- A. Seek initiatives embracing one or more community value (solidarity, participation and coherence).
- B. Promote community development through the empowerment of citizens to define and meet their own needs.
- C. Relate goals and outcomes to the needs of communities and their citizens.
- D. Develop activities and services that meet community need identified through sustained and meaningful dialogue of citizens and service providers.
- E. Give priority to the needs and interests of a community's socially excluded citizens.

Toward DEMOCRATIC POLITICS:

- F. Avoid policies that establish authoritarian or elitist social relations.
- G. Ensure initiative independence to encourage participatory community action to achieve community goals.
- H. Contribute to a public space for shared communications that facilitate inter/intra-community conviviality.
- I. Recognise and celebrate diversity of opinion, beliefs, values and culture and avoid policies that promote intolerance and disrespect.

Toward DEMOCRATIC WORK:

- J. Promote self-actualisation through activities and services that stimulate lifelong learning and active citizenship in the community.
- K. Invest in social capital by promoting common community interests and concerns.
- L. Seek to stimulate both social and formal economies of local communities.

Securing democratic sustainability:

- M. Enable meaningful engagement with groups and organisations active within local communities through the development of tripartite partnerships.
- N. Promote social innovation by harnessing the indigenous knowledge and creativity of communities with the resources and expertise of public, private and third sectors.
- O. Develop a sense of community identity and ownership.

Embracing community participation:

- P. Promote universal participation.
- Q. Seek 'local' technological flexibility and 'global' technological pluralism.

the minds of community development workers for decades. It is no less of a challenge within a community informatics context, where, if community technologies are to be employed as tools for community empowerment, their design, as well as their implementation and development, need to be based on community values.

However, understanding that community technology processes are as important as the products or applications themselves is not, in itself, enough. Consequently, Criterion B calls for community ICT initiatives to promote community development by empowering citizens to democratically define and meet community needs. To fulfil criterion B, methods of inclusive and participatory needs analysis must be employed. Such tools must facilitate identification of both the scope and diversity of a community's needs and the appropriateness of community ICT applications to the local needs of a social environment (Criterion C). The development of community technologies that promote local autonomy whilst facilitating collaborative and co-operative action and interaction is crucial to community conviviality.

However, attempts at developing participatory methods that actively engage communities in identifying local needs and applying those needs to the design, implementation and development of community ICT initiatives are few and far between at the moment. Of course, a range of participatory tools and methods exists that are sometimes employed within community practice generally, e.g., citizens' panels, consensus conferences, scenario workshops, community appraisals and focus groups (New Economic Foundation, 1998), but to date few have been used in a community informatics context. Part of the reason for not exploring the potential of such participatory tools can be found in a misplaced but popular belief that the design, implementation and development of technology, and ICT in particular, is the domain of experts into which mere mortals and common folk should not wander.

Despite this conventional wisdom, there is growing evidence to indicate that given the opportunity, non-expert citizens are more than capable of grasping the complexities relating to ICTs in their social environments. In Denmark, for example, the Board of Technology organised a series of consensus conferences on issues ranging from food irradiation and genetic engineering to sustainable agriculture and educational technology. The consensus conferences not only resulted in a better informed Danish public in matters relating to technology but also enabled early public involvement in the development of technologies. To this end, they facilitated "more flexible, socially responsive research and design modifications, [which is a potentially] fairer, less adversarial, and more economic path of technological evolution" (Sclove, 1996).⁵

- D. Develop activities and services that meet community need identified through sustained and meaningful dialogue of citizens and service providers.
- E. Give priority to the needs and interests of a community's socially excluded citizens.

The implementation of community technology activities and services must be effective in meeting community need if such initiatives are to remain sustainable. Criterion D requires sustained and meaningful dialogue between 'experts' (social and technical) and the local community through the forging of democratic partnerships to ensure that initiatives continue to meet community needs. Whilst consensus conferences are useful in achieving and sustaining meaningful dialogue, the dialogue required for the participatory design of community ICTs can require a more dynamic and direct form of engagement between citizens and 'experts'.

Asset-based community technology and community building projects, such as the methodology employed in the low- to moderate income Camfield

Estate in Roxbury, Massachusetts, is an example of such an approach (Pinkett, 2002). The purpose of this project was not just to encourage community participation in the community building process but also to empower the community so that it became the central driver of the 'improvement process' through community technology. Dialogue in Roxbury was between 'experts' and community members as 'agents of change'. This differs from consensus conferences. In Roxbury the purpose was for the community to shape change directly, whereas consensus conferences are usually employed to inform policy so that change might be considered. The point here is not that one participatory method is better than another; both have their appropriate uses. However, their application should be dependent on the social context, i.e., the needs of the social environment in which they are being considered, and this can only be determined through meaningful dialogue. Building on this (Criterion E), priority must be given to the needs and interests of the disadvantaged and marginalised members of a community, if social inclusion is to be achieved.

Toward Democratic Politics

- F. Avoid policies that establish authoritarian or elitist social relations.
- G. Ensure initiative independence to encourage participatory community action to achieve community goals.

The important issue with respect to Criterion F is that ICTs should be harnessed to underpin democratic community. To achieve this it is crucial to select technologies that do not establish authoritarian or elitist social relations, either within partnerships seeking to develop a community technology or the community itself. For example, community initiatives with the best of social intentions, when run by a small number of self-appointed leaders, run the risk of developing

an atmosphere of elitism and being unrepresentative of community wishes. Although many initiatives are started in this way, there comes a time when their governance must be placed in the hands of the broader community, if they are to remain democratic. It is also essential that community ICT initiatives retain some degree of independence from funding agencies or partnership organisations. There may be occasions when the views of the community come into conflict with those of such bodies and some form of community action is required. Criterion G states that initiatives must be independent and free from the influence of vested interests if they are to be used by an empowered community acting to identify and achieve community goals.

- H. Contribute to a public space for shared communications that facilitate inter/intra-community conviviality.
- I. Recognize and celebrate diversity of opinion, beliefs, values and cultures and avoid policies that promote intolerance and disrespect.

Underpinning all community ICT initiatives should be a public space dedicated to open communications (Criterion H). Such a public space supports inter and intra-community communications. If community-driven ICTs are to underpin social activities within local communities by providing an extra forum of communication, then electronic public spaces should be afforded the same importance that sociologists give to 'actual' public spaces or 'third places' such as parks, community centres, civic squares, cafes and pubs. The utilization of ICTs to provide a public space for shared communications at both inter and intra-community levels supports participatory democracy and encourages the valorisation of diversity.

Modern society is both pluralist and multicultural. While this diversity enriches the human experience, it also produces complex social

problems. The many communities, groups, associations, etc., that comprise society often coexist quite peacefully. However, conflict also often exists within and between communities. Criterion I holds that community ICTs should both respect and protect society's diversity. They should not be used to promote views hurtful or damaging to the cultural heritage of others; for example, racist or sexist materials should not be stored or disseminated on community systems. The resolution of problems of conflict can only be achieved through democratic determination within or between communities.

Toward Democratic Work

- J. Promote self-actualisation through activities and services that stimulate lifelong learning and active citizenship in the community.
- K. Invest in social capital by promoting common community interests and concerns.
- L. Seek to stimulate both social and formal economies of local communities.

In this context, democratic work applies to activities engaged in as part of the social economy, but policies could be developed here that relate to telework and other forms of community-based revenue generation. Criterion J relates to awareness raising, training and education activities and services at community ICT initiatives, and states that they should enable self-actualisation and enable community capacity building. The development and application of skills through activities in the social economy enable citizens, through engagement, to contribute to community life in new ways. Consequently, facilitating self-actualisation and capacity building activities in community initiatives is a way for policy and practice to invest in the social capital of a community. It can be done by supporting common interests and concerns, as a recognition of the importance of a community's social wealth⁶ (Criterion K). By adopting more holistic approaches to the social

development of communities, a range of mutual community economic development activities can also be supported and/or identified (criterion L).

Securing Democratic Sustainability

- M. Enable meaningful engagement with groups and organisations active within local communities through the development of tripartite partnerships.
- N. Promote social innovation by harnessing the indigenous knowledge and creativity of communities with the resources and expertise of public, private and third sectors.
- O. Develop a sense of community identity and ownership.

Some form of cross-sectoral partnership often shapes the structure, function and organization of community ICT initiatives. This is because the highly competitive and profit motivated nature of modern capitalist society makes it difficult, if not impossible, for community-driven grassroots initiatives to survive without support of this nature. Partnerships, therefore, are an increasingly important component of civil life. Criterion M necessitates the establishment of tripartite partnerships to secure initiative sustainability. By harnessing the existent knowledge and creativity of communities with the resources and expertise found in the public, private and third sectors, social innovation can be promoted (Criterion N). Criteria M and N contribute to the development of a sense of community ownership and identity. This community identity and sense of ownership are essential if community ICT initiatives are to be sustainable (Criterion O).

Embracing Community Participation

- P. Promote universal participation.
- Q. Seek 'local' technological flexibility and 'global' technological pluralism.

Central to promoting democratic participation is the recognition that whilst policy must enable active community groups to participate in the three organizing principles of a democratic society, this in itself does not represent an inclusive approach to participation. Community groups, whilst important to active communities, do not constitute complete communities. The facilitation of universal participation, where every citizen that wishes to has the right to participate in these principles in some way (Criterion P) goes some way to achieving this. Clearly, it is impractical to enable full citizen participation in every stage of the design, implementation and development of community ICT initiatives. However, a range of participatory community methods exist that can be utilized within local communities where appropriate, e.g., consensus conferences, citizen panels and scenario workshops. It is important that the community socio-technical order remains flexible and democratic. If it becomes too rigid, social relationships become more inflexible and subsequent structural alterations prove difficult. Whilst flexibility is important at the local level, it is also significant globally. Valorising diversity by ensuring local flexibility in all communities ensures the preservation of cultural pluralism and affords communities and individuals the ability to communicate with and learn from other cultures (Criterion Q) in the network society.

CONCLUSION

Central to the examination of the relationship between community policy, partnerships and practice conducted in this chapter have been three fundamental propositions:

- Community policy, partnerships and practice should be embedded in and reflective of the needs of local citizens;

- As citizens, local people have the right to participate in the decisions that shape local communities;
- Within a Community Informatics context this often requires changes in the organisational cultures and mind-sets of partners in order to achieve the trust and mutuality necessary for successful community ICT initiatives.

Strategically, the development of equitable partnerships between the public, private and third sectors promotes a more human-centered approach to local policy making and addresses the concerns of many community initiative practitioners who regard the community policy process as unrepresentative of local needs (Day & Harris, 1997; Shearman, 1999). Operationally, identifying community need through participative methods, such as citizens' forums and consensus conferences, can lead to a more inclusive and holistic approach to community policy and practice in the network society.

The framework presented here is not intended as a blueprint to be imposed, by policy, on local communities. Its value lies in its applicability across the diversity of community ICT practices. With this in mind the intention of this chapter has been to provide an alternative to the techno-economic agenda often found in much of the network society discourse, by providing insights into Community Informatics from a social science perspective. The democratic community planning criteria presented here need to be supported by similar design criteria from the technological perspective. This is the challenge facing the community systems and software developers of the community informatics movement. The development of technical democratic design criteria is an area where important research can be conducted in the future. Synergy between the social and technical components of community ICT research,

practice and policy is crucial to building socially inclusive pathways to the network society.

ABSTRACT

The rapid incursion of information and communication technologies (ICT) into the classroom has meant that, within the space of a few years, computers have moved from being peripheral to being an integral part of the learning environment. However, our perceptions of a technology are affected by the age at which we encounter it. This chapter draws on the findings of a number of research projects at the University of Sheffield. These findings are used to explore some

of the ‘generation gaps’ that arise from differing perceptions of learning technologies. The data discussed provide insights into the ICT-based generation gaps that currently exist between and within groups of students, teachers and parents. It is argued that a fundamental gap may exist between students differing in age by as little as 5 years. Results from a related project exploring Networked Information and Communication Literacy Skills (NICLS) are used to introduce a discussion on the nature of any skills gap that must be addressed in light of these generation gaps.

INTRODUCTION

The Sudden Rise of Computers in the Classroom

Computing technologies have been criticized by educationalists and educational philosophers, many of whom feel that they promote shallow learning, mindless copying and pasting, and the decontextualized acquisition of definitions and facts. In short, they are dismissed as being a tool for:

“jogging the memory, not for remembering ... [providing students] with the appearance of intelligence, not real intelligence ... they will seem to [have] wide knowledge, when they will usually be ignorant.”

The quotation above however, is not from a modern educationalist, mistrustful of new technology, but is adapted from Plato’s ‘Phaedrus’ (p. 69), in which the author recalls Socrates’ criticisms of writing.

It is easy to forget that reading and writing are ICT and, like all technological innovations, would have been subject to reactions ranging from unquestioning enthusiasm to reactionary scepticism. Reading and writing, however, permeated society over hundreds of years, so systems could adapt gradually. ICT has had a much more sudden impact.

Douglas Adams (1999) observed that our attitude to technology is determined by the age at which we first encounter it:

1. Everything that’s already in the world when you’re born is just normal;
2. Anything that gets invented between then and before you turn 30 is incredibly exciting and creative, and with any luck you can make a career out of it;
3. Anything that gets invented after you’re 30 is against the natural order of things and

the beginning of the end of civilization as we know it, until it’s been around for about 10 years, when it gradually turns out to be alright, really.

Madden, Nunes, Ford, McPherson, and Miller (2003b) looked at the development of various computer technologies in light of this analysis. Adams, somewhat arbitrarily, selected 30 as the age above which technological developments cease to be readily acceptable. Madden et al. considered developments in computing in the 30 years prior to their report. It provided a useful reminder of the speed with which computers have impacted on society.

30 years: 1973 saw the first appearance in print of the term ‘microcomputer’; Wang unveiled its ‘word-processing’ system; and IBM introduced the Winchester hard disk (Professional Software Systems, 2004). Computers were expensive and delicate machines, to which only highly trained personnel had access.

20 years: In 1983, Time magazine nominated the IBM PC (released in 1981) as its “man of the year”; Microsoft released Word 1.0; and the first IBMPC-based graphics program, PC-Draw, was introduced (Professional Software Systems, 2004). Ten million computers were in use in the United States (US): They were beginning to appear on desktops in the workplace. Few people would have had access to them, however, until they began work or entered higher education. The youngest of teachers in 2003 were 3 years old.

10 years: By the end of January 1993, there were 50 World Wide Web servers known to exist. Later in the year, Mosaic, the first graphic browser (on which Netscape came to be based) was introduced; and the Pentium processor was released (Professional Software Systems, 2004). Encarta 1993 made no mention of the Internet, and dedicated just 62 words to ARPANET. PCs had

Mind the Gap!

become familiar sights in universities and offices around the country, and were beginning to become commonplace in schools (although access was restricted). In 1993-'94, the average secondary school in England had one microcomputer per 10 students: Only 30% of these were capable of supporting a Graphic User Interface (GUI) (Department for Education, 1995). Use of computers in schools was limited to specific lessons in subjects, such as science and math. Although the National Curriculum (which required the incorporation of ICT) had been in place for 5 years, limitations in ICT usability and availability severely restricted the use to which computers could be put across the curriculum (Opie & Katsu, 2000). For most lessons, therefore, the educational technologies used to teach students in 1993 were the same as those that had been used for teaching their parents.

Since 1993: In the intervening years, the learning landscape has changed markedly. GUIs, such as Windows, have become standard; so computer technology has become more intuitive, making it easier for schools to adopt ICT across the curriculum; a factor that presumably has contributed to the rapid growth in computer numbers, as shown in Table 1 (Department for Education and Skills (DfES), 2002a, 2004). These figures are somewhat misleading, since many of the computers in the

early 1990s could not have supported GUIs; but this proviso makes the growth in primary schools all the more noteworthy. Even more remarkable, though, has been the rate at which schools have been gaining access to the Internet.

A Practical Educational Technology

The brief history above provides a reminder that, for most teachers, the idea of using ICT in their teaching would have been impractical until very recently. Furthermore, they could not have used their own childhood experience of school as a model to guide them.

Teachers in secondary schools and in Further Education¹ have had a little longer than their primary school colleagues to become accustomed to the incursion of computers into the classroom. In 1999, Selwyn (p. 163) predicted that:

Smaller schools catering for younger learners ... are probably going to attract less ... funding per learner.

Statistics from the DfES (2002b) (Table 2) confirm the accuracy of this prediction. On average, secondary schools in England have 4.2 times as many full-time students as primary schools. In 1998, shortly before Selwyn published his prediction, average expenditure on ICT in secondary

Table 1. Statistics relating to primary and secondary schools in England (DFES, 2002a, 2004)

	Mean no. of students per computer		Percentage of schools connected to the Internet	
	Primary	Secondary	Primary	Secondary
1994	23.0	10.0		
1996	19.0	9.0	5	47
1998	17.6	8.7	17	83
1999	13.4	8.4	62	93
2000	12.6	7.9	86	98
2001	11.8	7.1	96	99
2002	10.1	6.5	99	99
2003	7.9	5.4	-	-

Table 2. ICT expenditure in English schools (DfES: Survey of Information and Communications Technology in Schools, 2002)

	Average expenditure/school (£)					Increase in computing power between 1998 and 2002 (by Moore's Law)	
	1998	1999	2000	2001	2002		
Primary	3600	7000	8300	10300	15400	68.444	
Secondary	40100	45400	50100	60300	76900	30.683	
Ratio	11.139	6.486	6.036	5.854	4.994		

schools was more than 11 times greater than expenditure in primary schools. Since then, however, ICT spending in primary schools has risen far faster than in secondary schools. The gap has now closed; and in 2002, secondary schools spent five times as much on ICT as primary schools.

More Powerful Computers

The impact of increased expenditure is even more remarkable when Moore's Law is taken into consideration. In 1965, G.E. Moore, co-founder of Intel, observed that:

The complexity for minimum component costs has increased at a rate of roughly a factor of two per year... (p. 115)

In practical terms, this means that a computer designed in 2006 will have twice the processing power of a computer designed in 2005; four times the power of those designed in 2004 and so forth. Assuming that the cost of a new computer remains constant, then, if a school has as much to spend on ICT this year as it did last year, that same sum of money can buy approximately twice as much computing power. In other words, according to the data in Table 2, secondary schools in 2002 could afford 31 times as much computing power as they could in 1998, and primary schools could afford 68 times as much.

This rise in processing power has played a large part in making the PC a practical tool in

the classroom. It has allowed GUIs to become universal, making PCs easier to use; it has accelerated performance, thereby decreasing user frustration and reducing the risk of students repeatedly pressing buttons on the grounds that "it didn't work last time"; and it has allowed drawing packages to become ubiquitous.

This last point is significant because many primary school students are still coming to terms with reading and writing; so any text-based activity on the PC will have difficulties associated with it that have nothing to do with the technology. It is not surprising, therefore, that drawing is the preferred activity on computers among primary school students (Selwyn & Bullon, 2000; BECTa, 2001a).

Younger Users

Because of the rise in expenditure on ICT in education, the age at which students have routinely come into contact with ICT has dropped rapidly over the last 10 years. Ten years ago, students were unlikely to make regular use of ICT until they went to work or college. One of the much publicized aims of the United Kingdom (UK) Labour Party when it entered government in 1997 was the promotion of ICT in schools. On coming into office, it announced that it was going to make available £700 million to upgrade ICT resources in schools and to connect schools in a National Grid for Learning (NGfL). A further £230 million (New Opportunities Fund) was provided to train teachers to use the new technology.

Mind the Gap!

The figures in Table 2 show that secondary schools were the first to benefit from this initiative. Where ICT was used in primary schools, it often served the function of a 'pacifier,' used to provide an activity for students who finished a task before their peers (Selwyn & Bullon, 2000). Students arrived from primary school to find substantially better ICT resources than they had previously encountered and, in most cases, teachers could confidently treat them as ICT beginners. Increasingly, however, this is changing, and students arrive at secondary school with ever greater ICT skills (Madden, Bates, White, & Apthorpe, 2004), resulting in teachers feeling more and more left behind.

The Skills Gap Between Teachers and Students

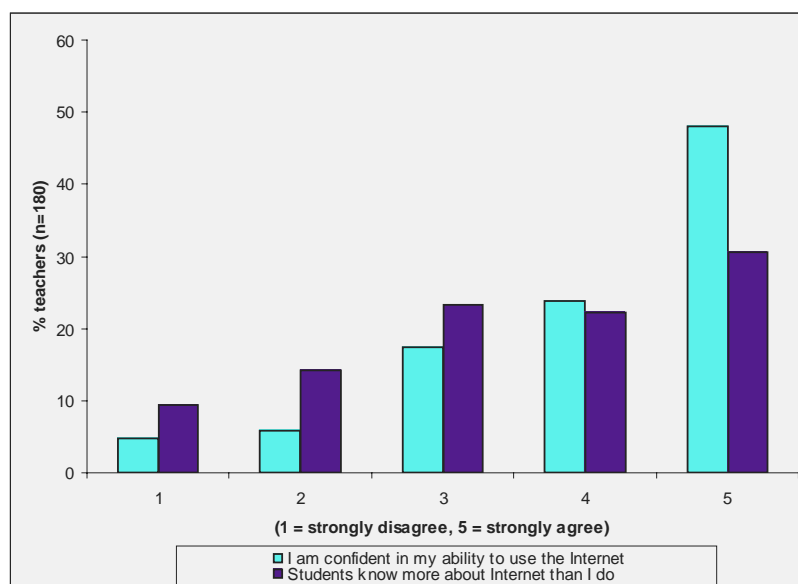

A recent project, funded by the UK's Arts and Humanities Research Board, looked at aspects of the impact of the Internet on education in English schools, and revealed clear differences between the abilities of teachers and students to

work with the new technologies. Eighteen semi-structured interviews were carried out in January and February 2002 with staff at The City School in Sheffield (Madden, Ford et al., 2003). The City School was selected for the project because of the excellence of its ICT facilities and the experience of its staff in using ICT in their teaching. Nevertheless, many interviewees commented that their ICT skills were more limited than those of their students. One head of department confessed to having supervised classes of students using the Internet, despite never having used it himself. Others recognized its value, but were conscious of being less competent users than their students. Examples of the type of comments made by interviewees are as follows:

The kids are ahead of me [in using ICT] ... I wish I was better at using it.

I haven't experienced [problems with students lacking technical skills] ... I think it's the opposite; I think it's the staff sometimes that don't have the technical skills ...

Figure 1. Teacher's responses to questionnaire statements

I have learnt a lot from kids in the past about what to do [on the computer] ...

I always say at the beginning 'Look—I'm an old teacher—I don't know as much about computers as you—I know how they can be used, I know how they're useful, I know how important they are.

These interviews were used to generate a questionnaire that was sent to the heads of departments in all the state-funded secondary schools in Sheffield (Madden, Ford, Miller, & Levy, 2005). The questionnaire comprised a series of statements with Likert scales of 1-5. Two of the statements were as follows:

1. I am confident in my ability to use the Internet.
2. Students know more than I do about the Internet.

A Spearman's Rank Correlation showed responses to these two variables to be significantly negatively correlated ($p=0.01$), suggesting that the more confidence teachers have in their ability to use the Internet, the less likely they are to feel that students know more about the Internet than they do. This finding is much as would have been expected. Despite the correlation, however, most teachers (52.9%) still feel that students know more about the Internet than they do (Figure 1), including a large minority (29.6%) who feel confident in their own abilities (Table 3).

The Skills Gap Between Parents and Children

Evidence for a skills gap between parents and children arose from a project carried out by Sheffield University and The City School (Project 2). In September 2002, a questionnaire was circulated among parents of students newly arrived from primary school. Among other things, parents were asked to assess their own ICT skills and those of their children on a five-point Likert scale. Shortly afterwards, students were given an online test designed by a member of the school's ICT department to assess their ICT skills. Two measures of student ICT ability, therefore, were available:

1. Based on parents' observations and their understanding of ICT skills
2. Based on results of a test developed by the school's ICT department.

The school's ICT test correlates significantly with measures of performance in math, English and science taken at the students' primary schools (Table 4); and with parents' assessment of their own ICT skills. Parental assessment of their children's ICT ability is unrelated to the schools' measures, but is significantly correlated to the child's sex ($p<0.05$: boys are considered more skilled) and with the perceived standard of school resources ($p<0.001$) and teaching ($p<0.01$) in a child's primary school. It seems reasonable

Table 3. Percentages of teachers agreeing with both statements

		Students know more than I do about the Internet.		
		(Likert score)		
I am confident in my ability to use the Internet.		4	5	Total
(Likert score)	4	8.5	6.9	15.3
	5	9.0	5.3	14.3
Total		17.5	12.2	29.6

Mind the Gap!

Table 4. Factors significantly correlated with assessments of students' ICT skills

Student skills (as assessed by parent) correlate with:	
Student sex (boys' skills rated higher than girls').	1% significance, n=65
Perceived standard of primary school resources.	1% significance, n=65
Perceived standard of primary school teaching.	1% significance, n=63
English Key Stage 2.	1% significance, n=57

Student skills (as assessed by school's ICT test) correlate with:	
Parents' perception of their own ICT skills.	1% significance, n=65
Level of ICT concern.	(Negative correlation) 1% significance, n=65
English Key Stage 2.	0.1% significance, n=57
Maths Key Stage 2.	0.1% significance, n=58
Science Key Stage 2.	0.1% significance, n=57

to assume, therefore, that the parents surveyed were not in a position to assess the ICT skills of their children.

The Skills Gap Among ICT-Literate Adults

Evidence of another skills gap emerged during the development of a part-time Continuing Professional Distance Education course designed to lead to a master's degree in IT Management (MA in ITM) (McPherson & Nunes, 2004). This MA is delivered via a combination of face-to-face and online learning materials.

In the process of developing the MA, it became apparent that technical skills on their own are not sufficient for a student to make successful use of ICT in learning: A range of social and information skills is also required.

The MA ITM course is designed for professionals in the Information Technology (IT) sector. Initially, it was assumed that, because of the students' technological background, no particular training was required to use the online facilities provided for those on the course (Nunes, McPherson et al., 2000a). However, studies of the usage of these facilities revealed a number of problems. Early intakes of students did not make full use of the available resources; and where use was made,

it was often inappropriate. Many students, for example, showed behaviors incompatible with the purpose for which the system was designed (e.g., flaming and lurking).

By contrast, according to teachers at The City School, their students are enthusiastic users of online communication:

I can go into a room and see youngsters who are supposedly getting information from the Internet—you find them on the chat line.

This is despite the fact that they have received no formal training:

... we've never taught chat in school. We've never taught them to log into chat rooms, or anything else, but ultimately, if you gave them 5 minutes, then you find them on Music Channel Chat room ...

It is also in opposition to the wishes of teachers:

I don't like them going in there, so I keep them out of there, but that's another way of communication which gets them on to a computer and once they see that, that excites them.

DISCUSSION

The three projects referred to above provide evidence of gaps, both in technical skills and in perceptions of technology, between different interested parties in education. These gaps occur not only in the obvious areas—between adults/children and teacher/student—but also between students with differing experiences of ICT in education. The consequences of these gaps are discussed in further detail below.

The Impact of ICT on Learning

In the survey of Sheffield teachers mentioned above, department heads were asked to respond to the following statement:

I am under no pressure to use the Internet in my teaching

Fifty-two percent (n=169) did not agree with the statement. The majority of teachers, therefore, either disagreed (25%) or were ambivalent (27%). Clearly, therefore, many teachers not only feel that that they may be under pressure to use the Internet, but they also believe that their students know more about it than they do. Such a combination of circumstances could result in educationalists failing to recognize the potential of ICT within the learning environment, leading to under usage and inappropriate usage.

Old Teaching and New Technology

Teachers often use new technologies as though they were something old and familiar. That way, they can satisfy any requirement to use the technology without needing to amend their teaching methods. An example of such use is the numerous computer assisted learning (CAL) programs that are little more than electronic books.

Such superficiality in the use of ICT has long been criticized. In 1971, a 2-day symposium

was organized by the Science Research Council and the Social Science Research Council. At the symposium, CAL was criticized on the grounds that:

using computers for pre-stored material, that is, computerized programmed learning, combined inordinate expense with a very superficial philosophy of learning. (Annett, 1976)

Similar concerns were voiced 25 years later, in the report on the evaluation of the Teaching and Learning Technology Programme (Coopers & Lybrand, 1996), where it was felt that the projects would have benefited from:

... a more serious and helpful attempt to encourage projects to engage with pedagogic issues (para 283)

More recently, in a report on the use of interactive whiteboards (IW) in teaching, students are reported as expressing:

... disappointment and frustration with some approaches to using the IW, particularly when they consider that its capabilities are being under-exploited. For example: 'If teachers are going to use them [as a traditional whiteboard], then I wouldn't bother wasting all that money'. (Levy, 2002, p. 17)

Students, therefore, are clearly better able to appreciate the opportunities afforded by ICT than their teachers (Madden, Ford, Miller, & Levy, 2006).

Networked Literacy

Such usage of ICT in teaching neglects not only the 'added value' that new educational technologies can bring, but it also ignores the fact that, to obtain that value, students need to acquire new skills.

Mind the Gap!

As was learned from the experience with the MA ITM, technical knowledge, though necessary, is not sufficient. Many other skills are required by students learning online using computer-mediated technologies. Nunes, McPherson and Rico (2000a) have described such skills as NICTS.

Networked literacy complements traditional basic skills with a new set of information and communication literacy skills. Information literacy requires students to recognize their information needs; to identify ways of addressing gaps in their knowledge; to construct strategies for locating information; to locate and access information; to compare and evaluate information; and to organize, apply and synthesize information (Webber & Johnston, 2000).

In addition, if successful communication is to take place online, learners must change their behavior. The skills required when communicating online form what can be considered communication literacy. NICTS (Nunes et al., 2000b) include information literacy skills (as described above), and online collaboration and cooperation skills. These latter comprise:

- **Technical aspects**, including the skills needed to use computer-mediated communications (CMC) in an online learning situation
- **Social aspects**, needed to compensate for the unavailability of social cues traditionally delivered by auditory and visual channels.

The technical aspects of NICTS are relatively easy to address, but the social aspects have often been overlooked (Nunes, McPherson & Rice, 2000b; Hara, 2000; McDowell & Pickard, 2000). As a result, experiences such as those in the MA ITM course are common: Communications are misinterpreted, causing unintended offence and provoking inappropriate hostility. Students, therefore, need to be aware of crucial social issues involved in using CMC technologies (Webber & Johnston, 2000).

NICTS at School

Another relevant statement in the AHRB survey of school teachers is as follows:

Figure 2. Percentage of teachers of differing ages agreeing with the statement: 'My Internet skills were acquired informally (e.g., self-taught, learned from friends/colleagues etc.), rather than on a taught course.'

My Internet skills were acquired informally (e.g., self-taught, learned from friends/colleagues, etc.), rather than on a taught course.

Eighty-five percent of respondents (n=188) agreed with this statement; 67% agreed strongly. As can be seen in Figure 2, for teachers younger than 55 years, age seems to make little difference. The youngest respondent was 24 years old; she agreed with the statement.

As stated above, the technical aspects of NICLS are relatively easy to address. However, of the teachers who responded to the survey, more than 95% never used chat rooms: The importance of the social aspects of NICLS, therefore, is likely to be unrecognized among them. E-mail was used, at least occasionally, by 70% of responding teachers; but as is the case with interactive whiteboards, e-mail can be related to an existing technology (mail) with which the teachers are already familiar. Two interesting questions, therefore, emerge:

1. What, if any, online social skills are evolving among school children who appear to be enthusiastic users of chat rooms? Are there misunderstandings similar to those encountered on the MA ITM and, if so, how are they dealt with?
2. Does the age at which e-mail skills are acquired affect the nature of e-mails? In particular, do students who learned to write letters before they learned to write e-mails produce more formal and more carefully worded e-mails?

NICLS Post-1997

The statistics cited in Tables 1 and 2 show how recently ICT resources became widely available in schools. It could reasonably be argued, therefore, that, prior to 1997, it was not practical to teach many of the NICLS identified by Nunes et al. (2000a) until students moved to further or higher education. As a result, the nature and range of information sources to which today's students

have access is markedly different from those used by students finishing school prior to 1997.

Another significant development took place in the 2003-'04 academic year. DfES (2003) introduced amendments to the teaching of ICT in English schools. The new ICT course is designed to emphasize the relevance of ICT to all national curriculum subjects. If successful, many more students will leave school with NICLS. In all probability, however, for reasons discussed above, they will have been taught the technical aspects of NICLS, but will have evolved the social aspects by experimentation with their peers.

ICT Generations and the Resulting Gaps

The title of this chapter refers to a new generation gap: In fact, there may be several generation gaps, arising not only from the introduction of technology, but also from the successful incorporation of NICLS. The rapidly changing ICT environment within the class will lead to different generations of students having very different experiences at school, as follows:

- **Pre-1997:** ICT resources, where available, are just used for the teaching of subjects relating to math, science and technology. Teaching and learning are largely unaffected, otherwise. Some students acquire technical skills, but there is little opportunity to use computers as a tool for communication. Most students only become familiar with the Internet after leaving school.
- **1997-2003:** ICT resources become widely available. Pockets of expertise in the application of ICT to teaching begin to develop, but most teachers apply the technology cautiously, if at all. Students increasingly make use of ICT (particularly the Internet) as a learning resource. Many teachers (and parents) regard such usage with suspicion. NICLS are acquired rather than taught.

Mind the Gap!

- **2003-2008:** ICT is increasingly embedded within the national curriculum. Teachers need to demonstrate their usage of it, but often it is employed as though it was an extension of existing technologies (e.g., electronic book) and it is under used. Students begin to learn ICT in primary school, along with reading and writing. More systematic teaching of NICLS begins.
- **Post-2008:** Schools begin to employ newly qualified teachers who grew up with ICT. It was a natural part of their learning environment, so they have no qualms about their students using it. Formalized instruction in the social aspects of NICLS begins.

Consequences of the ICT Generation Gap

The versatility of ICT and its potential value as an educational technology make it probable that, in the future, it will be ubiquitous at all levels of education. Adult learners, therefore, must acquire NICLS if they are successfully to complete any course of which online learning forms a significant component. Failure to do so will result in much frustration for the students, and eventually to lower levels of success (Hara & Kling, 1999).

Such frustrations are unlikely to be experienced, or even understood, by students who became familiar with online learning environments during their formative years. Zafeirou, Nunes and Ford (2001) provide an example of a divide based on varying levels of NICLS, when they describe the problems some students encountered due to lack of typing skills. When using a Virtual Learning Environment (VLE), they experienced what amounted to a virtual speech defect, which severely hampered their efforts to communicate with fellow students.

Further inequities could arise where teachers fail to appreciate the potential of a technology. When home computers first became affordable, teachers were often impressed by well-presented,

word-processed assignments. They quickly came to recognize the signs of 'cut-and-paste' essays; but before they did so, many students received high marks for work that owed more to their ICT skills than their understanding of the subject material.

Social Impact

The consequences referred to above are fairly obvious. Other, more subtle and more profound consequences may also arise, which may be as great as the impact of literacy on education in ancient Greece. It is hard to appreciate exactly what this might have been, because records of educational methods among pre-literate ancient Greeks are textual and, therefore, were made by practitioners of the new technology. Nevertheless, in "Preface to Plato," Havelock (1963) identifies numerous profound changes arising from the development of writing. According to Havelock, the orally based educational regime of pre-literate Greece was based on rote learning of rhythmically structured patterns that were recited and repeated without analysis (which is somewhat ironic, given Socrates' criticism of writing). Their role was, arguably, to stamp on learners the world view of their community. But then:

... at some time towards the end of the fifth century before Christ, it became possible for a few Greeks to talk about their 'souls' as though they had selves or personalities which were autonomous and not fragments of the atmosphere nor of a cosmic life force, but what we might call entities or real substances. (p. 197)

The change is attributed to the spread of writing. In due course, this made it possible for learning to transcend the immediate community. Groups of people, making "... parallel use of texts, both to structure the internal behavior of the groups' members and to provide solidarity against the outside world" are described as 'textual communities' (Stock, 1983).

The spread of reading and writing, therefore, affected individuals, communities and, indeed, the evolution of world culture (Madden, 2004) in ways that would probably have been inconceivable to Socrates and his contemporaries.

CONCLUSION

It took hundreds of years for literacy to become commonplace. Its effects, therefore, took many generations to permeate through communities and cultures. By contrast, ICT has the potential to change education radically in a fraction of a generation.

Some issues arising from the use of ICT in learning and teaching may be subtle and far-reaching. If writing made it possible for ancient Greeks to begin thinking of themselves as individuals, what could be the impact of increasingly sophisticated virtual learning zones?

Questions such as this are impossible to answer without greater experience and additional research, but the kind of meta-analysis of related projects that has been presented in this chapter has allowed a better understanding of the ICT generation gap.

As the 'new' literacies discussed earlier cease to be new but become incorporated in the educational system, the generation that has already passed through that system may be excluded from an increasingly important sector of the education market. Planning, therefore, is necessary to ensure that their needs can be addressed by life-long learning and Continuing Professional Development programs.

In the UK, perhaps one of the most significant developments in the use of computers as an educational technology has been adoption of the acronym ICT in place of IT. The emphasis on communication as well as information is an indication of the growing awareness of the new technology's role in facilitating exchanges and discussions, thereby addressing the shortcomings

that Socrates noted arising from use of the (then) new technology of writing. Properly used, ICT allows students to move from being "hearers of many things" to being active processors of their readings and discussers of many things. In other words, ICT has the potential to enrich the learning process, facilitating an education based on interaction and social negotiation of meanings. Had Socrates been able to use ICT, he could still have subjected students to his methods.

ABSTRACT

One possible consequence of information and communication technology's rapid rise will be a new 'generation gap' arising from differing perceptions of the learning technologies. The nature, causes, and consequences of this gap are of interest to educational practitioners and poli-

cymakers. This article uses data from an ongoing project, together with a synopsis of research, to describe the ICT-based generation gap that currently exists between students and their teachers and parents. It is argued that this gap may exist between students differing in age by as little as five years. Results from a related project exploring Networked Information and Communication

Literacy Skills (NICLS) are used to introduce a discussion on the nature of any skills gap that must be addressed in light of this generation gap.

INTRODUCTION

It is often the case that the findings of discrete projects in information and communication technologies (ICTs) in teaching and learning, when analysed and discussed together, will produce findings that would not have been apparent from the separate projects.

This article emerged from discussions that took place between researchers involved in three projects addressing different aspects of ICT in teaching and learning at various levels of education in the UK. As a result of these discussions, issues relating to skills gaps between different stakeholders in the education process became apparent. The full extent of this phenomenon and associated implications were not immediately obvious from the findings of the individual projects and resulted in this article, which has the following purposes:

1. to serve as a reminder of just how recently ICT has become commonplace within education and how exaggerated expectations have led to undue pessimism;
2. to present findings from research at the University of Sheffield concerning the views that teachers and parents have of ICT and its use by children; and
3. to identify problems that may arise when using ICT in post-16 education, as a result of students having differing experiences with the technologies.

Thus this article is not a traditional reporting of one individual research process, but a cross-discussion of the findings of the following projects:

- A three year project, titled “Education for Evidence-Based Citizenship: Improving Pupils’ Information Seeking Skills,” funded by the UK’s Arts and Humanities Research Board (AHRB). This collaboration between the Department of Information Studies and the City School in Sheffield seeks to explore aspects of Internet usage in English schools.
- Research funded by the British Educational Communications and Technology Agency on the teaching of ICT to students in transition from primary (ages five to 11) to secondary (ages 11 to 16) education in England. The research was carried out at The City School in Sheffield, and drew on the AHRB project referenced above.
- A seven-year action research process to design and develop a part-time Continuing Professional Distance Education (CPDE) program leading to an MA in IT Management (MA ITM) (McPherson & Nunes, 2004). This MA is delivered via a combination of face-to-face and online learning materials.

REVIEW OF THE LITERATURE

The Sudden Rise of Computers in the Classroom

Computing technologies have been heavily criticised by educationalists and educational philosophers as a vehicle to promote shallow learning, mindless copying and pasting, and de-contextualised acquisition of definitions and facts. In short, a tool for:

“jogging the memory, not for remembering... [providing students] with the appearance of intelligence, not real intelligence...they will seem to [have] wide knowledge, when they will usually be ignorant.”

A New Generation Gap?

This quotation, however, is not from a modern educationalist, mistrustful of new technology, but is adapted from Plato's 'Phaedrus' (p. 69), in which the author recalls Socrates' criticisms of writing. It is easy to forget that reading and writing are information and communications technologies and, like all technological innovations, would have been subject to reactions ranging from unquestioning enthusiasm to reactionary scepticism.

Reading and writing, however, permeated society over hundreds of years, so systems could adapt gradually. ICT has had a much more sudden impact. Douglas Adams (1999) observed that our attitude toward technology is determined by the age at which we first encounter it. Specifically:

- everything that is already in the world when you are born is just normal;
- anything that gets invented between then and before you turn 30 is incredibly exciting and creative, and with any luck you can make a career out of it; and
- anything that gets invented after you are 30 is against the natural order of things and the beginning of the end of civilisation as we know it until it has been around for about 10 years when it gradually becomes alright.

Madden et al. (2004) looked at the development of various computer technologies in light of this analysis. Adams, somewhat arbitrarily, selects 30 as the age above which technological developments cease to be readily acceptable. It provides a useful starting point, however, for contemplating the speed with which computers have impacted on society.

Thirty years ago: The year 1973 saw the first appearance in print of the term 'microcomputer'; Wang unveiled their 'word-processing' system; and IBM introduced the Winchester hard disk (Professional Software Systems, 2004). Thirty years ago, computers were expensive and delicate machines to which only highly trained personnel had access.

Twenty years ago: In 1983, Time magazine nominated the IBM PC (released in 1981) as its "man of the year"; Microsoft released Word 1.0; and the first IBM PC-based graphics program, PC-Draw, was introduced (Professional Software Systems, 2004). Twenty years ago, 10 million computers were in use in the USA: they were beginning to appear on desktops in the workplace. Few people would have had access to them, however, until they began work or entered higher education. The youngest of today's teachers were three years old.

Ten years ago: By the end of January 1993, there were 50 World Wide Web servers known to exist. Later in the year, Mosaic, the first graphic browser (on which Netscape came to be based), was introduced; and the Pentium processor was released (Professional Software Systems, 2004). Ten years ago, PCs were familiar sights in universities and offices around the country. They were beginning to become commonplace in schools, but access was restricted. In 1993-1994 the average secondary school in England had one microcomputer per 10 students. Only 30% of these were capable of supporting a Graphic User Interface (GUI) (Department of Education, 1995). Use of computers in schools was limited to specific lessons in subjects such as science and maths. Although the National Curriculum (which required the incorporation of ICT) had been in place for five years, limitations in ICT usability and availability severely restricted the use to which computers could be put across the curriculum (Opie & Katsu, 2000). For most lessons therefore, the educational technologies used to teach students 10 years ago were the same as those that had been used for teaching their parents.

Since 1993: In the intervening 10 years, the learning landscape has changed markedly. GUIs, such as Windows, have become standard, so computer technology has become more intuitive, making it easier for schools to adopt ICT across the curriculum — a factor that has presumably contributed to the rapid growth in computer num-

bers in primary and secondary schools (DfES, 2002a). These figures are somewhat misleading since many of the computers in the early 1990s could not have supported GUIs; but this proviso makes the growth in primary schools all the more noteworthy. Even more remarkable though, has been the rate at which schools have been gaining access to the Internet.

FINDINGS

A Practical Educational Technology

The brief history above provides a reminder that, for most teachers, the idea of using ICT in their teaching would have been impractical until very recently. Furthermore, they could not have used their own childhood experience of school as a model to guide them.

Secondary school teachers have had a little longer than primary school teachers to become accustomed to the incursion of computers into the classroom. In 1999, Selwyn (p. 163) predicted that:

“smaller schools catering for younger learners...are probably going to attract less...funding per learner.”

Statistics from the DfES (2002b) confirm the accuracy of this prediction. On average, secondary schools in England have 4.2 times as many full-time students as primary schools. In 1998, shortly before Selwyn published his prediction, average expenditure on ICT in secondary schools was over 11 times greater than expenditure in primary schools. Since then, however, ICT spending in primary schools has risen far faster than in secondary schools. The gap has now closed; and in 2002, secondary schools spent five times as much on ICT as primary schools.

More Powerful Computers

The impact of increased expenditure is even more remarkable when Moore's Law is taken into consideration. In 1965, G.E. Moore, co-founder of Intel, observed:

“The complexity for minimum component costs has increased at a rate of roughly a factor of two per year...” (p. 115).

In practical terms, this means that a computer designed in 2003 will have twice the processing power of a computer designed in 2002, four times the power of those designed in 2001, and so forth. Assuming that the cost of a new computer remains constant, if a school has as much to spend on ICT this year as it did last year, that same sum of money can buy approximately twice as much computing power. In other words, according to the data, secondary schools in 2002 could afford 31 times as much computing power as they could in 1998, and primary schools could afford 68 times as much.

This rise in processing power has played a large part in making the PC a practical tool in the classroom. It has allowed GUIs to become universal, making PCs easier to use; it has accelerated performance, thereby decreasing user frustration, and reducing the risk of students repeatedly pressing buttons on the grounds that “it didn't work last time”; it has allowed drawing packages to become ubiquitous.

This last point is significant because many primary school students are still coming to terms with reading and writing; so any text-based activity on the PC will have difficulties associated with it that have nothing to do with the technology. It is not surprising therefore, that drawing is the preferred activity on computers amongst primary school students (Selwyn & Bullon, 2000; BECTa, 2001a).

Younger Users

Because of the rise in expenditure on ICT in education, the age at which students have routinely come into contact with ICT has dropped rapidly over the last 10 years. As was stated earlier, 10 years ago, students were unlikely to make regular use of ICT until they went to work or college. One of the much publicised aims of the UK Labour Party when it entered government in 1997 was the promotion of ICT in schools. On coming into office, it announced that it was going to make available £700 million to upgrade ICT resources in schools and to connect schools in a National Grid for Learning (NGfL). A further £230 million (New Opportunities Fund) was provided to train teachers to use the new technology.

Secondary schools were the first to benefit from this initiative. Where ICT was used in primary schools, it often served the function of a ‘pacifier’, used to provide an activity for students who finished a task before their peers (Selwyn & Bullon, 2000). Students arrived from primary school to find substantially better ICT resources than they had previously encountered,; and in most cases teachers could confidently treat them as ICT beginners. Increasingly however, this is changing, and students arrive at secondary school with ever greater ICT skills (Madden, Bates,

White, & Apthorpe, 2004a), resulting in teachers feeling more and more left behind.

Skills Gap Between Teachers and Students

The AHRB project referred to in the introduction (Project 1) looked at aspects of the impact of the Internet on education in English schools, and revealed clear differences between the abilities of teachers and students to work with the new technologies. Eighteen semi-structured interviews were carried out in January and February 2002 with staff at the City School (Madden, Ford, Miller, & Levy, 2003). The City School was selected for the project because of the excellence of its ICT facilities and the experience of its staff in using ICT in their teaching. Nevertheless, many interviewees commented on the fact that their ICT skills were more limited than those of their students. One head of department confessed to having supervised classes of students using the Internet, despite never having used it himself. Others recognised its value, but were conscious of being less competent users than their students.

These interviews were used to generate a questionnaire that was sent to the heads of department in all the state- funded secondary schools in Sheffield (Madden, Ford, Miller, & Levy,

Table 1. Percentages of teachers agreeing with both statements

		Students know more than I do about the Internet.		
		(Likert score)		
I am confident in my ability to use the Internet.		4	5	Total
(Likert score)	4	8.5	6.9	15.3
	5	9.0	5.3	14.3
Total		17.5	12.2	29.6

2004b). The questionnaire comprised a series of statements with Likert scales of 1-5. Two of the statements were as follows:

1. I am confident in my ability to use the Internet.
2. Students know more than I do about the Internet.

A Spearman's Rank Correlation showed responses to these two variables to be significantly negatively correlated ($p=0.01$), suggesting that the more confidence teachers have in their ability to use the Internet, the less likely they are to feel that students know more about the Internet than they do. This finding is much as would have been expected. Despite the correlation however, most teachers (52.9%) still feel that students know more about the Internet than they do, including a large minority (29.6%) who feel confident in their own abilities (Table 1).

Skills Gap Between Parents and Children

Evidence for a skills gap between parents and children arose from a project carried out by Sheffield University and The City School (Project 2). In September 2002 a questionnaire was circulated amongst parents of students newly arrived from primary school. Among other things, parents were asked to assess their own ICT skills and those of their children on a five-point Likert scale. Shortly afterwards, students were given an online test designed by a member of the school's ICT department to assess their ICT skills. Two measures of student ICT ability were therefore available: (1) assessment based on parental observation and understanding of ICT skills, and (2) assessment based on results of a test developed by the school's ICT department.

The school's ICT test correlates significantly with measures of performance in maths, English,

and science taken at the students' primary schools and with parents' assessment of their own ICT skills. Parental assessment of their children's ICT ability is unrelated to the schools' measures, but is significantly correlated to the child's sex ($p < 0.05$: boys are considered more skilled) and with the perceived standard of primary school resources ($p < 0.001$) and teaching ($p < 0.01$). It seems reasonable to assume therefore, that the parents surveyed were not in a position to assess the ICT skills of their children.

Skills Gap Among ICT-Literate Adults

Evidence of another skills gap emerged from Project 3. In the process of developing the MA ITM referred to above, it became apparent that technical skills on their own are not sufficient for a student to make successful use of ICT in learning; a range of social and information skills is also required.

The MA ITM course is a distance-learning programme designed for professionals in the information technology (IT) sector. Initially it was assumed that, because of the students' technological background, no particular training was required to use the online facilities provided for those on the course (Nunes, McPherson, & Rico, 2000a). However, studies of the usage of these facilities revealed a number of problems. Early intakes of students did not make full use of the available resources; and where use was made, it was often inappropriate. Many students for example, showed behaviours that were incompatible with the purpose for which the system was designed (e.g., flaming and lurking).

By contrast, according to teachers at The City School, their students are enthusiastic users of online communication:

"I can go into a room and see youngsters who are supposedly getting information from the Internet — you find them on the Chat line."

A New Generation Gap?

This is despite the fact that they have received no formal training:

“...we’ve never taught Chat in school. We’ve never taught them to log into Chat rooms, or anything else, but ultimately, if you gave them five minutes, then you find them on Music Channel Chat room....”

It is also in opposition to the wishes of teachers:

“I don’t like them going in there so I keep them out of there, but that’s another way of communication which gets them on to a computer, and once they see that, that excites them.”

DISCUSSION

As argued, the three projects provide evidence of gaps, both in technical skills and in perceptions of technology, between different interested parties in education. These gaps occur not only in the obvious areas, between adults/children, and teacher/student, but also between students with differing experiences of ICT in education. The consequences of these gaps are discussed in further detail below.

The Impact of ICT on Learning

In the survey of Sheffield teachers referenced above, heads of department were asked to respond to the following statement: “I am under no pressure to use the Internet in my teaching.” Fifty-two percent (n = 169) did not agree with the statement. The majority of teachers therefore, either disagreed (25%) or were ambivalent (27%). Clearly therefore, many teachers not only feel that they may be under pressure to use the Internet, but they also believe that their students know more about it than they do. Such a combination of circumstances could result in educationalists

failing to recognise the potential of ICT within the learning environment, leading to under-usage and inappropriate usage.

Old Teaching and New Technology

Teachers often use new technologies as though they were something old and familiar. That way, they can satisfy any requirement to use the technology without needing to amend their teaching methods. An example of such use is the numerous Computer-Assisted Learning programs that are little more than electronic books.

Such superficiality in the use of ICT has long been criticised. In 1971, a two-day symposium was organised by the Science Research Council and the Social Science Research Council. At the symposium, CAL was criticised on the grounds that:

“using computers for pre-stored material, that is computerised programmed learning, combined inordinate expense with a very superficial philosophy of learning.” (Annett, 1976)

Similar concerns were voiced 25 years later in the report on the evaluation of the Teaching and Learning Technology Programme (Coopers & Lybrand, 1996), where it was felt that the projects would have benefited from “a more serious and helpful attempt to encourage projects to engage with pedagogic issues” (paragraph 283).

More recently, in a report on the use of interactive whiteboards (IW) in teaching, students are reported as expressing, “disappointment and frustration with some approaches to using the IW, particularly when they consider that its capabilities are being under-exploited. For example: “If teachers are going to use them [as a traditional whiteboard,] then I wouldn’t bother wasting all that money” (Levy, 2002, p. 17). Students therefore may be better able to appreciate the affordances of ICT than their teachers.

Networked Literacy

Such usage of ICT in teaching neglects not only the 'added value' that new educational technologies can bring, but it also ignores the fact that, to obtain that value, students need to acquire new skills. As was learned from the experience with the MA ITM, technical knowledge, though necessary, is not sufficient. Many other skills are required by students learning online, using computer-mediated technologies. Nunes et al. (2000a) have described such skills as Networked Information and Communication Literacy Skills (NICLS).

Networked literacy complements traditional basic skills with a new set of information and communication literacy skills. Information literacy requires students to recognise their information needs; to identify ways of addressing gaps in their knowledge; to construct strategies for locating information; to locate and access information; to compare and evaluate information; to organise, apply, and synthesise information (Webber & Johnston, 2000).

In addition, if successful communication is to take place online, learners must change their behaviour. The skills required when communicating online form what can be considered communication literacy. Networked Information and Communication Literacy Skills (Nunes et al., 2000b) include information literacy skills (as described above), and online collaboration and co-operation skills. The latter comprises technical aspects, including the skills needed to use Computer-Mediated Communication (CMC) in an online learning situation, and social aspects needed to compensate for the unavailability of social cues traditionally delivered by auditory and visual channels.

The technical aspects of NICLS are relatively easy to address, but the social aspects have often been overlooked (Nunes et al., 2000b; Hara, 2000; McDowell & Pickard, 2000). As a result, experiences such as those in the MA ITM course

described above are common: communications are misinterpreted, causing unintended offence and provoking inappropriate hostility. Students therefore need to be aware of crucial social issues involved in using CMC technologies (Webber & Johnston, 2000).

NICLS at School

Another relevant statement in the AHRB survey of school teachers is as follows:

"My Internet skills were acquired informally (e.g., self-taught, learned from friends/colleagues, etc.), rather than on a taught course."

Eighty-five percent of respondents ($n = 171$) agreed with this statement; 67% agreed strongly. Seventy-one percent of teachers over 50 ($n = 48$) agreed. Among the under 50s, age made little difference, with 88% of teachers agreeing. The youngest respondent was 24 (she agreed with the statement).

As was stated above, the technical aspects of NICLS are relatively easy to address. However, of the teachers who responded to the survey, over 95% never used chat rooms; the importance of the social aspects of NICLS are therefore likely to be unrecognised among them. E-mail was used, at least occasionally, by 70% of responding teachers; but as is the case with interactive whiteboards, e-mail can be related to an existing technology (mail) with which the teachers are already familiar. Several interesting questions therefore emerge. What, if any, online social skills are evolving amongst school children who appear to be enthusiastic users of chat rooms? Are there misunderstandings similar to those encountered on the MA ITM, and if so, how are they dealt with? Does the age at which e-mail skills are acquired affect the nature of e-mails? In particular, do students who learned to write letters before they learned to write e-mails produce more formal and more carefully worded e-mails?

NICLS Post-1997

The statistics cited in this article show how recently ICT resources became widely available in schools. It could reasonably be argued therefore that, prior to 1997, it was not practical to teach many of the Networked Information and Communication Literacy Skills identified by Nunes et al. (2000a), until students moved to further or higher education. As a result, the nature and range of information sources to which today's students have access is markedly different from those used by students finishing school prior to 1997.

Another significant development takes place in the academic year 2003-2004. The Department for Education and Skills (DfES, 2003) is introducing amendments to the teaching of ICT in English schools. The new ICT course is designed to emphasise the relevance of ICT to all national curriculum subjects. If successful, many more students will leave school with Networked Information and Communication Literacy Skills. In all probability, however, for reasons discussed above, they will have been taught the technical aspects of NICLS, but will have evolved the social aspects by experimentation with their peers.

ICT Generations and the Resulting Gaps

The title of this article refers to a new generation gap; in fact there may be several arising, not only from the introduction of technology, but also from the successful incorporation of NICLS. The rapidly changing ICT environment within the class will lead to different generations of students having very different experiences at school, as follows:

Pre-1997: ICT resources, where available, are just used for the teaching of subjects relating to maths, science, and technology. Teaching and learning are largely unaffected otherwise. Some students acquire technical skills, but there is

little opportunity to use computers as a tool for communication.

1997-2003: ICT resources become widely available. Pockets of expertise in the application of ICT to teaching begin to develop, but most teachers apply the technology cautiously, if at all. Students increasingly make use of ICT (particularly the Internet) as a learning resource. Many teachers (and parents) regard such usage with suspicion. NICLS are acquired rather than taught.

2003-2008: ICT is increasingly embedded within the national curriculum. Teachers need to demonstrate their usage of it, but often it is employed as though it were an extension of existing technologies (e.g., electronic book), and it is under-used. Students begin to learn ICT in primary school, along with reading and writing. More systematic teaching of NICLS begins.

Post-2008: Schools begin to employ newly qualified teachers who grew up with ICT. It was a natural part of their learning environment, so they have no qualms about their students using it. Formalised instruction in the social aspects of NICLS begins.

Consequences of the ICT Generation Gap

The versatility of ICT and its potential value as an educational technology make it probable that, in the future, it will be ubiquitous at all levels of education. Adult learners must therefore acquire NICLS if they are successfully to complete any course of which online learning forms a significant component. Failure to do so will result in much frustration for the students, and eventually to lower levels of success (Hara & Kling, 1999).

Such frustrations are unlikely to be experienced, or even understood, by students who became familiar with online learning environments during their formative years. Zafeirou, Nunes, and Ford (2001) provide an example of a divide based on varying levels of NICLS, when they

describe the problems some students encountered due to lack of typing skills. When using a virtual learning environment (VLE), they experienced what amounted to a virtual speech defect, which severely hampered their efforts to communicate with their fellow students.

Further inequities could arise where teachers fail to appreciate the potential of a technology. When home computers first became affordable, teachers were often impressed by well-presented, word-processed assignments. They quickly came to recognise the signs of 'cut and paste' essays; but before they did so, many students received high marks for work that owed more to their ICT skills than their understanding of the subject material.

Social Impact

The consequences referred to above are fairly obvious. Other, more subtle and more profound consequences may also arise, which may be as great as the impact of literacy on education in Ancient Greece. It is hard to appreciate exactly what this might have been, because records of educational methods among pre-literate Ancient Greeks are textual and were therefore made by practitioners of the new technology. Nevertheless, in his Preface to Plato, Havelock (1963) identifies numerous profound changes arising from the development of writing. According to Havelock, the orally based educational regime of pre-literate Greece was based on rote learning of rhythmically structured patterns that were recited and repeated without analysis (somewhat ironic, given Socrates' criticism of writing). Their role was, arguably, to stamp on learners the world view of their community. Then:

“At some time towards the end of the fifth century before Christ, it became possible for a few Greeks to talk about their ‘souls’ as though they had selves or personalities which were autonomous and not fragments of the atmosphere nor of a cosmic

life force, but what we might call entities or real substances.” (p. 197)

The change is attributed to the spread of writing. In due course, this made it possible for learning to transcend the immediate community. Groups of people, making “parallel use of texts, both to structure the internal behaviour of the groups' members and to provide solidarity against the outside world” are described as ‘textual communities’ (Stock, 1983).

The spread of reading and writing therefore affected individuals, communities, and indeed the evolution of world culture (Madden, 2004), in ways that would probably have been inconceivable to Socrates and his contemporaries.

CONCLUSION

It took hundreds of years for literacy to become commonplace. Its effects therefore took many generations to permeate through communities and cultures. By contrast, ICT has the potential to change education radically in a fraction of a generation.

Some issues arising from the use of ICT in learning and teaching may be subtle and far-reaching. If writing made it possible for Ancient Greeks to begin thinking of themselves as individuals, what could be the impact of increasingly sophisticated virtual learning zones?

Questions such as this are impossible to answer without greater experience and additional research, but the kind of meta-analysis of related projects that has been presented in this article has allowed a better understanding of the ICT generation gap.

As the ‘new’ literacies discussed above cease to be new, but become incorporated into the educational system, the generation that has already passed through that system may be excluded from an increasingly important sector of the education market. Planning is therefore necessary in order

A New Generation Gap?

to ensure that their needs can be addressed by lifelong learning and continuing professional development programmes.

In the UK, perhaps one of the most significant developments in the use of computers as an educational technology has been the adoption of the acronym ICT in place of IT. The emphasis on communication as well as information is an indication of the growing awareness of the new technology's role in facilitating exchanges and discussions, thereby addressing the shortcomings that Socrates noted arising from use of the (then) new technology of writing. Properly used, ICT allows students to move from being "hearers of many things" to being active processors of their readings and discussers of many things. In other words, ICT has the potential to enrich the learning process, facilitating an education based on interaction and social negotiation of meanings. Had Socrates been able to use ICT, he could still have subjected students to his methods.

EDITOR'S NOTE

The authors generously offered an expanded discussion of this research, as well as the tables and figures that graphically represent its findings. Chapter 5.7

Behavior Change through ICT Use: Experiences from Relatively Healthy Populations

Marieke W. Verheijden

TNO Quality of Life, The Netherlands

ABSTRACT

New communication technologies have made an impact on several areas of our everyday life, including the areas of health and health promotion. The Internet provides opportunities for personalized interactive health communication at a much larger scale than is possible in face-to-face communication. It has been suggested that only interactive health-behavior-change Web sites that advise, assess, assist, provide anticipatory guidance, and arrange follow-up have the potential to lead to successful behavior change. Additional factors that may affect the success rate of behavior-change programs are the reach of and the exposure to such programs. This chapter elaborates on all of these factors.

INTRODUCTION

Rapid developments in information and communication technologies have made a plethora of computer-based applications affecting our everyday life available. Not surprisingly, these applications have also been taken up in health-related areas. Electronic medical records, computerized reminders for preventive services, and computer-aided diagnosis of tumors are examples of this. Examples can also be found in the area of health-behavior change. New communication technologies are increasingly used as a replacement for and supplement to traditional health education and health-behavior-change programs. In addition to searching for health information, large groups of Internet users have received infor-

mation from tailored health-promotion programs through interactive health communication and/or have participated in online surveys (Sciamanna, Lewis, Tat, Napolitano, Fotheringham, & Marcus, 2002).

Evidently, the ultimate goal of Web-based health-promotion programs is to make an impact on public health. The extent to which such programs have an impact on public health is determined by two components: the reach and the efficacy (Abrams, Emmons, & Linnan, 1997). This chapter will discuss the following components in more detail: the Internet as a communication channel, potentials and minimum requirements of Web-based behavior-change programs, the delivery and reach of and exposure to Web-based behavior-change programs, and the feasibility and effectiveness of Web-based behavior-change programs. This chapter focuses specifically on relatively healthy populations as opposed to patient populations. Koelen and Van den Ban (2004) discussed that conventional mass media generally focus on new discoveries about diseases and their treatment. Much less attention is focused on disease prevention, health behavior, or early detection. This is in sharp contrast with the general idea that an ounce of prevention is worth a pound of cure, and stresses the need for a focus on applications for relatively healthy populations. This is particularly challenging because (otherwise healthy) at elevated risk for cardiovascular disease stated that they were more interested in using Web-based health-promoting programs for information when confronted with a direct medical condition than for prevention purposes (Verheijden, 2004).

COMMONLY USED BEHAVIOR-CHANGE THEORIES

Changing health behavior is challenging, and it is widely assumed that to be successful one needs to understand the determinants of behavior and be-

havior change. To help increase this understanding, several models have been developed. It is beyond the scope of this chapter to provide a full overview of health-behavior (-change) models. Therefore, this paragraph only briefly touches upon some of the most frequently used models: the theory of planned behavior and theory of reasoned action, the health belief model, the social cognitive theory, and the stages-of-change model. According to the theory of planned behavior, intention is the basis for any behavior change. Intention in turn is a function of attitude toward the behavior (change), the perception of the social pressure from other people (subjective norm), and perceived behavior control (self-efficacy). The health belief model postulates that health behavior is determined by the belief in a personal health threat combined with the belief in the effectiveness of a healthy behavior, provided that there is an internal or external cue to action, such as an article in a newspaper or a close friend having a heart attack. The social cognitive theory proposes that interrelated personal, environmental, and behavioral factors determine behavior. The stages-of-change model is one of the very few models specifically developed to address behavior change (as opposed to addressing merely the behavior itself). The stages-of-change model postulates that individuals can be classified in one of five stages of change based on their current behavior and on their intentions to change in the (near) future. Progressing through the stages of change thus reflects behavior change. The model also explicitly states that behavior change is not a watershed event. Instead, it is a spiraling progress and regression to earlier stages of change is possible (Ajzen, 1991; Bandura, 1986; Koelen & Van den Ban, 2004; Mullen, Hersey, & Iverson, 1987; Prochaska & DiClemente, 1983; Prochaska & Velicer, 1997). Especially in recent years, the models are increasingly used as a theoretical basis for all sorts of health-promotion practices, including Internet-based programs.

THE INTERNET AS A COMMUNICATION CHANNEL

Communication is essential to inform people about health and to keep health issues on personal and public health agendas. New technologies provide the means for interactive health communication. This was defined by the Science Panel on Interactive Communication and Health (SciPICH) as “the interaction of an individual—consumer, patient, caregiver, or professional—with or through an electronic device or communication technology to access or transmit health information or to receive guidance and support on a health-related issue” (Robinson, Patrick, Eng, & Gustafson, 1998). Electronic applications that focus exclusively on administrative, financial, or clinical data were excluded from this definition. The SciPICH identified six specific functions of interactive health communication: to relay information, enable informed decision making, promote self-care, manage demand for health services, promote peer information exchange and emotional support, and promote healthful behaviors. All aspects can be valuable in health-behavior-change programs.

The outcome of health communication is determined by characteristics of the source, message, channel, and receiver. The word channel refers to the way the message is brought across from the source to the receiver. Evidently, health-promotion messages can be transferred using a number of channels. These channels may vary in the extent to which the receivers are at liberty to interpret the message to their own views, in the extent to which feedback is possible, and in the extent to which group interaction is possible. Channels can also be placed on a continuum ranging from one-way flow of information (e.g., mass media) to active two-way exchange (e.g., an in-person conversation). Channels that typically possess characteristics from both sides of the continuum, such as interactive computer technologies, are usually referred to as hybrid media (Koelen & Van den Ban, 2004). These hybrid media potentially reach large numbers of people and support a level of interactivity that is impossible with conventional mass media. Table 1 (see also Leeuwis & Van den Ban, 2004, for a more detailed discussion) presents characteristics of hybrid media in applications for health-promotion programs.

Table 1. Characteristics of hybrid media for health-promotion programs

Reach	Potentially large
Push and pull	Pulled delivery of information, potentially large information overload. Limited insight in the actual reach of the intended target audience
Tailoring and personalization	Possible, but only using preprogrammed structure. Less direct than interpersonal communication
Social support	Particularly promising for stigmatizing topics when people prefer to be anonymous. Possibly difficult to establish relationships
Space and time dependence	At convenience of users, no geographical boundaries. Equipment is still largely tied to locations.
Speed	Content can easily be updated in the event of new developments.
Costs	Development costs (particularly of advanced applications) can be high. The cost per person may end up being relatively low because of potentially large reach.

POTENTIALS OF BEHAVIOR-CHANGE PROGRAMS THROUGH THE INTERNET

The increasing research interest in behavior-change programs through the Internet is due in part to the increasing numbers of people at risk for non-communicable lifestyle-related chronic conditions. While individual approaches have shown to be effective for many different health behaviors in many different target groups, they are very expensive, thus limiting their applicability for reaching large groups of people. When targeting large groups of people, most approaches use the same generic information for all members of the target group. This information is oftentimes action oriented and may thus fail to be of interest and relevance to the majority of the target group. As discussed previously, hybrid media may provide a solution to this.

There are also other potentials of new communication technology that may be used for health-promotion programs. In addition to the characteristics discussed in Table 1, using new communication technologies for health-behavior change also has several other advantages related to interactivity, appeal, and engagement. Tailoring and instantaneous feedback based on the responses of the participants, for example, may increase the interactivity and improve the personal relevance of the content. Wantland, Portillo, Holzemer, Slaughter, and McGhee (2004) also suggested that “interactivity may help reduce attrition and provide benefits in producing positive behavioral change.” The appeal of health-behavior-change programs can be increased by giving convenient access to the program and by allowing participants to choose what material they receive, when, and how often. Some target groups may also prefer computer-delivered programs over other delivery methods. Finally, computer-based health-behavior-change programs may have advantages over traditional programs in terms of engagement, for example, by facilitating open communication,

particularly on sensitive issues. Furthermore, multimedia interfaces may reduce the level of literacy required to work with the materials, and they allow for role-playing in a virtual environment (Owen, Fotheringham, & Marcus, 2002).

De Nooijer, Oenema, Kloek, Brug, De Vries, & De Vries (2005) conducted a survey among 15 experts involved in the development and evaluation of health-promotion interventions on the Internet. The experts unanimously stated that a solid theoretical base is essential for the success rate, however, the extent to which the large numbers of available Web-based health-promotion interventions are sufficiently theory based may be limited at the present time (Evers, Prochaska, Prochaska, Driskell, Cummins, & Velicer, 2003). Notably, most experts were involved in interventions based on frequently used theories in health-behavior change, such as the social cognitive theory and the stage of change model. Apart from the benefits for the users, the experts also benefits for designers and researchers. These benefits include easy access to information, the reach of potentially large groups of users, low costs for dissemination of information, the possibility to keep the information up to date with relative ease, the possibility for follow-up, integrated questionnaires and feedback, tailored questionnaires, and central data management.

The experts also mentioned several disadvantages of Web-based health-promotion programs. One of the major concerns is related to the actual reach of the target audience. As of yet, it is unclear how experts can assure that the intended target audience knows about the availability of the site, that they will actually access the site, and that they will stay on the site long enough to receive the message. Furthermore, the Internet provides health workers with much less influence on (or control over) what people do with the information that is presented to them. Another concern that was mentioned is the lack of quality control on Web-based information and the large numbers of sites containing false and possibly dangerous

information. Limited personal communication and the possibility that health-related information may easily be overlooked or disregarded in view of the large numbers of e-mails and Web sites people are exposed to were also mentioned.

MINIMUM REQUIREMENTS OF WEB-BASED BEHAVIOR-CHANGE PROGRAMS

Several instruments to rate the quality of Web sites are available (Commission of the European Communities, 2002; Gagliardi & Jadad, 2002; Gattoni & Sicola, 2005; Griffiths & Christensen, 2005; Risk & Deznawagis, 2001). However, very few of these instruments are applicable to the interactive Web sites that are used for health-behavior-change programs (Evers et al., 2003). It was therefore attempted to extrapolate clinical-practice guidelines for face-to-face counseling to guidelines for Web sites that provide interactive health information. These guidelines for Web sites can be summarized using six As, which provide a minimum set of criteria for a Web-based program to have the potential to change behavior (Cummins et al., 2003; Evers, Cummins, Prochaska, & Prochaska, 2005). Notably, meeting all criteria does not guarantee successful behavior change.

The initial criterion in face-to-face counseling is to *ask*. In this step, the behavioral concerns of the patient are assessed. Because it was assumed that

people only visit sites on topics they are interested in or concerned about (e.g., people visiting a site on smoking cessation want help to quit smoking for themselves or for someone close to them), this criterion was not included in the Health Behavior Change on the Internet (HBC-I) screener. The five criteria that were included are to advise, assess, assist, provide anticipatory guidance, and arrange follow-up (Table 2). These strategies will be discussed in more detail below.

Evers et al. (2005) reviewed almost 300 Web sites targeting alcohol use, diet, exercise, smoking, and three disease-management programs using the five As. Less than 10% of the Web sites met all five criteria. The criterion that the fewest Web sites met was anticipatory guidance. The assess criterion was met most frequently (slightly over half of the sites). Sites on smoking cessation, diet, and exercise relatively frequently met four to five of the criteria.

Advise

The first criterion includes advising individuals about behavioral risks and about the need to change this behavior. This may be done in part by using (self-) assessment approaches that will be discussed under “Assess.” It is also recommended that the purpose of the Web-based program (i.e., to initiate and sustain behavior change) is made clear to the users.

Table 2. The five As for Web sites providing interactive health information

Advise	Create sense of urgency about the need to change
Assess	Assess (determinants of) behavior
Assist	Provide (tailored) feedback on assessments, suggest strategies for change, support behavior-change efforts
Anticipatory guidance	Manage tempting situations, provide relapse prevention, maintain motivation
Arrange follow-up	Specify time frame, encourage continuous participation

Assess

People who are unaware of the problem behavior and the need to change will most likely not be interested in any information on behavior change. This makes (self-) assessment of the problem behavior to create a sense of urgency an obvious criterion. Assessment is also important because it provides the basis for tailoring feedback messages. Unfortunately, Anhøj and Jensen (2004) showed that patients were more likely to trust their own (oftentimes incorrect) perception of dietary and physical-activity habits than the outcomes presented to them by a computer program. Similar findings were found in other studies (Anhøj & Nielsen, 2004; Brug, 1999). This complicates the feedback that can be given on self-assessment tools. Yet, as Verheijden, Jans, and Hildebrandt showed that people's belief that their lifestyles are healthy already is one of their major arguments for limited interest in Web-based behavior-change programs, misconceptions about people's actual behavior need to be taken away as much as possible.

A variety of outcomes may be assessed. One may think of weight, BMI (body mass index), exercise levels, fitness levels, nicotine dependence, and so forth. Patients' willingness to change is also frequently assessed (Evers et al., 2003). Several theoretical frameworks to do so are available (e.g., the stages of change model, the precaution adoption process model, the theory of planned behavior). Bensley et al. (2004) presented three behavior-change projects based on the e-health behavior-management model. This model integrates several commonly used behavior-change concepts to assess and affect people's readiness to change behavior. The model subsequently directs the user to stage-matched information that is available on the Internet (as opposed to most tools designed for research purposes that refer people to information specifically designed for the study). Bensley et al. argued that using preexisting information sources reduces costs compared to developing

new computerized expert systems. However, all existing sources people are directed to do need to be reviewed and approved for credibility and appropriateness. The ever-changing nature of the content of Web sites may therefore impose serious constraints on the applicability of this approach. The HBC-I screener also suggests to assess other psychosocial variables that can affect behavior change, such as attitude, self-efficacy, and subjective norms. Collecting data on these variables may be interesting from a research perspective, but their value in behavior-change practice may be limited, as research on dietary behavior thus far has shown no added value of tailoring to psychosocial variables in addition to feedback on food-consumption levels (Brug, Steenhuis, van Assema, Glanz, & De Vries, 1999).

Assist

The assist criterion includes providing support, reinforcement, and understanding; providing people with intervention options and negotiating an intervention approach; and providing assistance during the change process. One may think of increasing knowledge, offering nicotine-replacement therapy, setting realistic goals, developing skills, getting social support, and so forth. Interestingly, while Web-based behavior-change programs allow for interaction with health professionals as well as with peers, the evidence suggests that when given access to both, subjects tend to rely more on communication with health professionals than on peer support (Nguyen, Carrieri-Kohlman, Rankin, Slaughter, & Stulbarg, 2004).

Tailoring may play an important role in the assist criterion. In tailoring, the information that is presented to people is a selection of all available information based on their socio-demographic, behavioral, motivational, psychosocial, and physical characteristics. In this respect, communication through new interactive-technology applications mimics the level of tailoring that can take place

when an individual is given a face-to-face consultation with a health worker. In addition, interactive health communication may also be personalized. The underlying assumption for tailoring the behavior-change program to individuals' characteristics is that this will increase the personal relevance of the message, thus increasing people's attention and the subsequent motivational and behavioral impact (De Vries & Brug, 1999; Dijkstra & De Vries, 1999; Kreuter, Farrell, Olevitch, & Brennan, 2000; McGuire, 1985; Petty, Barden, & Wheeler, 2002). Furthermore, the tailoring process assures that no redundant information is presented to the participant. This saves people time on deciding what they should and what they should not read (see Textbox 1 for a brief description of computerized tailoring).

Anticipatory Guidance

It is generally accepted that behavior change, once successfully initiated, may be difficult to sustain, especially when facing difficult situations. The HBC-I screener therefore includes anticipatory guidance: counseling and support for anticipated barriers and for relapse prevention. This may be done by specifically addressing frequently occurring barriers for behavior-change maintenance. Other possibilities include providing guidance on managing tempting situations or relapse prevention. Evidently, including anticipatory guidance in Web-based behavior-change programs does not guarantee successful maintenance of the desired behavior. However, the frequent relapses that occur in behavior change more than justify

Textbox 1. Computerized tailoring

The first-generation computer tailoring programs produced print communications. This print was in many ways similar to the traditional brochures that were used in non-tailored print approaches, but we presented people with a selection of the information as opposed to including all possibly relevant information. Later generations were available online and provided instant feedback. Interactive Web sites and the delivery of programs through personal digital assistants (PDAs) are examples of this approach (Owen et al., 2002; Redding et al., 1999).

Computer tailoring of health-promotion programs tends to take place in two steps. In the initial step, people complete an assessment instrument to assess (determinants of) the behavior of interest. In the second step, a computer program (sometimes also referred to as an expert system; see, for example, Redding et al., 1999) selects relevant message segments that are combined into tailored feedback on the outcomes of the assessment phase. The feedback often includes personal, normative, and ipsative feedback. This provides the respondent with information relevant to their current behavior (in itself and in relation to their prior behavior), and relevant to their behavior in relation to a reference group of peers (Owen et al., 2002; Redding et al.). Expert systems thus combine the individual matching that can be obtained in an individual clinic-based intervention with the relatively low costs associated with a public health approach. They also have the following additional benefits: ease of documentation, ease of transfer to multiple sites, increased consistency in decision making, increased potential for replicable results, permanence, and low costs (Waterman, 1986). A combination of personal contact and a computerized expert system is also possible, for example, when the health-promoting actions of a health professional are guided by information provided by an expert system (Velicer et al., 1993).

inclusion of this strategy in the HBC-I screener. Unfortunately, as was shown in the study by Evers et al. (2005), anticipatory guidance is infrequently included in health-behavior-change programs.

Arrange Follow-Up

Most researchers and practitioners agree that behavior change is a process that occurs over time rather than a watershed event. To maximize the likelihood of successfully affecting health behavior, repeated efforts are expected to be necessary. These continuous efforts may build on people's motivation levels, or they may help prevent relapse. As a result, the provision of a follow-up, either in the program itself or by referring people to other sources of follow-up interventions, is also part of the HBC-I screener (Evers et al., 2005). In practice, this may take place using daily or weekly e-mail reminders to keep users in touch with the program. Follow-up in person, for example, through telephone calls is also possible. Repeating the assessment tends to be a good trigger for people to participate in follow-up programs.

In addition to the As, health-behavior-change Web sites should be designed to assure sufficient security of potentially sensitive health information by preventing unauthorized access. Password registration and members-only access are examples of this. Evers et al. (2003) found that many behavior-change programs had a privacy-policy statement and provided information on how the data collected from users was used.

DELIVERY OF WEB-BASED PROGRAMS TO PROMOTE A HEALTHY LIFESTYLE

As Abidi and Goh (2000) suggested, "healthcare information should be personalized according to each individual's healthcare needs and it should be pro-actively delivered, i.e., pushed towards the

individual." The need for pushed (as opposed to pulled) delivery may be particularly crucial for lifestyle programs. Yet, as was also discussed by Van Woerkum (1997), the main consequence of using new media for communication is that the role of senders and receivers in the process changes. Traditionally, health professionals and/or knowledge institutions sent messages they deemed useful to the intended users. The initiative for knowledge transfer was thus on the side of these parties. New communication technologies have gradually moved the initiative to the users, who are looking for information on demand to answer any question they may have. Many people have incorrect perceptions of their lifestyle; they underestimate their intake of energy and fat, and they overestimate their physical activity levels. As a result, people may mistakenly perceive themselves to have a healthy lifestyle and may therefore not be interested in programs telling them how to improve their behavior. Pushed delivery of programs with fast and easy self-assessment tools may help to achieve the self-awareness that is crucial to initiate health-behavior change. Evidently, the challenge is to develop a strategy for pushed delivery of such self-assessment and counseling tools. Edutainment (education entertainment) may be a useful approach in this respect. Edutainment uses an entertainment approach (games, quizzes, TV shows, etc.) to make something of an otherwise possibly dull learning experience. *Sesame Street* is one of the clear examples of this strategy. Positive experiences with edutainment in health, for example, in diabetic children have been shown (Aoki et al., 2004). Fewer generally known examples exist for adults. Edutainment, however, has been successfully applied in several health-related areas such as drug abuse, drunk driving, HIV/AIDS, family planning, and nutrition. One of the examples that are currently available for adults in many countries throughout the world is the RealAge test (<http://www.realage.com>, RealAge, Inc.). RealAge provides personalized health information and health-management

tools. Their flagship product, the RealAge test, compares biological vs. calendar age based upon people's answers to several questions on topics that affect the rate of aging. An interesting feature of the RealAge test is that it uses tactics based on the net-present value theory (see Allegrante & Roizen, 1998) to express expected health benefits later in life (a relatively abstract long-term benefit) in life years (a more concrete benefit that makes sense to people in the present). The RealAge test is available through the Internet and is supported by mass media activities such as TV shows.

Reaching the Target Group

One of the important challenges in health promotion is to reach the intended target audience. It has been postulated that the reach and impact of health-promotion programs are likely to be much larger when the target groups' desires are taken into consideration early in the development and planning process (e.g., in the precede-proceed model by Green & Kreuter, 1999). Indeed, as with any other health-promotion activity, the desires and needs of the target audience should be taken into consideration when designing, testing, and implementing Web-based health-promotion programs. At present, the content, style, and graphic design of the health-promotion programs are often based on the message health workers want to convey and on the personal preferences and skills of the Web designers. Yet in the end, the users decide what they like or dislike and can leave a site full of relevant information with one simple mouse click. When users visit a site, they decide in 5 to 10 seconds whether or not they will stay. This decision process tends to be based on the home page and possibly one additional page. This decision is personal and largely emotional, based on several satisfiers and dissatisfiers (ZBC Consultants B.V., 2004). Unfortunately, most programs tend to be designed top-down, which reduces the odds of programs meeting these satisfiers and dissatisfiers.

An alarming notion to add to this is the tendency that "to those who have (information), to those will be given" (Koelen & Van den Ban, 2004). Indeed, Verheijden (2004) conducted a non-response survey and showed that participants in a Web-based tailored nutrition counseling program were a relatively well-educated and healthy sub-sample of the target audience. It was also suggested by Brug, Oenema, and Campbell (2003) that interactive health communication may be particularly appealing to highly educated, motivated women. However, there is also evidence that interactive health communication can be as effective among people with lower education as among higher educated people. The appreciation and exposure may even be more positive among the lower educated people. This is in line with the idea that the ability to adapt the pace of learning to one's personal interests and skills (which characterizes interactive health communication) may be particularly beneficial to lower educated people. Evidently, a crucial factor related to access that needs to be addressed is the possibility that people do not use the Internet because they do not want to use it or because they see no need to use it (Bush, Bowen, Wooldridge, Ludwig, Meischke, & Robbins, 2004). Efforts to counteract this phenomenon need to be made simultaneously with current efforts to reduce the digital divide (see below), which are largely focusing on providing people with access to computers and the Internet and to training in the use of hardware and software.

One of the complicating factors related to the reach of the target group is the digital divide between those who do and those who do not have access to information technology. As discussed by Bush et al. (2004), the term Internet access is used in a variety of meanings in different contexts (see also Leeuwis & Van den Ban, 2004, for a discussion on factors determining the availability of information technology). Based on an extensive search of overlapping information sources, they suggested that issues of Internet and Web access

can be either connectivity issues (for example, availability, capability) or human interface issues (for example, literacy; language; education; race, ethnicity, and culture; income; disability and age; experience and familiarity; skill and training). Although the socio-demographic characteristics of the advantaged and the disadvantaged groups may vary to some extent, younger, well-educated, employed men generally seem to be on the right side of the digital divide. Evidently, the digital divide also limits the rise of Web-based applications in less developed countries. Four successive phases in access to information technology have been suggested: (a) motivation, (b) possession of or access to hardware and software, (c) skills, and (d) actual use (Van Dijk, 2005). The digital divide is believed to be narrowing, but evidently access remains a barrier for some groups, such as the elderly, illiterate, and physically or mentally handicapped people. As a result of this, the use of certain media in health-promotion interventions can have political implications because they have benefit for some but are unavailable to others. Despite the advantages of interactive Web-based behavior-change programs, it has been suggested that communicative intervention programs should use a combination of different media, either simultaneously or in succession. Combining multiple media approaches may increase the likelihood of a program being effective because different members of the target audience may have preferences for and/or access to different media. Furthermore, different media have different qualities that may be combined to form an optimal intervention mix (Leeuwis & Van den Ban).

Data on the reach of Internet-based health information are not readily available. Over the past few years, almost 75% of the Dutch Internet users used the Internet to obtain health-related information. Estimates based on 2002 state that 73 to 110 million American adults used the Internet to look for health information for themselves or for others (Nguyen et al., 2004). U.S. data on use of the Internet for health information by the chronically

ill showed that 46% reported using the Internet to seek for health information or advice in the past year (Wagner, Baker, Bundorf, & Singer, 2004). Over 10% reported at least monthly use. The likelihood of using the Internet for health information was higher among people with multiple chronic conditions than among people with hypertension, cancer, or heart problems only.

A recent study among members of a Dutch Internet panel showed that 28% of the respondents had participated in Web-based tailored lifestyle programs; 57% expressed an interest in such programs, and 15% expressed no interest (Verheijden, Jans, Hildebrandt, 2006). People who were interested in or had participated in such programs were younger and more frequently female than people who expressed no interest. People most frequently reported a general interest in their own lifestyle and in online tests as reasons to participate. Much less frequently, people were interested in possible improvements in their lifestyle. The main reasons for people not to be interested in Web-based tailored lifestyle programs was their preference to discuss lifestyle and health issues with (primary care) physicians or other health professionals. They also did not want to worry about their lifestyles, or believed there was no need for them to participate in Web-based tailored lifestyle programs because their lifestyles were already healthy.

Evers et al. (2004) and Evers et al. (2005) collected similar data in a longitudinal study among a sample of American Internet users on the use of Web-based health-behavior-change programs. At baseline, approximately 25% of the respondents used the Internet for health-behavior-change or disease-management programs. The vast majority of the remaining respondents had no intention to start using such programs. At follow-up 1 year later, most people who were initially using health-behavior-change programs were no longer doing so. This may be explained by the consistently high level of cons across all levels of motivation to use the Internet for health-behavior change that

were found. Other explanations may be that some programs were no longer available through the Internet, or that the programs had a fixed duration of less than 1 year. Whatever the exact reasons, it is safe to conclude that even with continued use, the disadvantages of using programs on the Internet are prevalent, and that users are at risk for discontinuing use (Evers et al., 2004).

EXPOSURE TO WEB-BASED HEALTH-PROMOTION PROGRAMS

The central route of the elaboration likelihood model (Petty & Cacioppo, 1986) suggests that the extent to which people are persuaded to change their behavior depends on the time they spend elaborating on the topic. In Web-based health promotion, one might thus hypothesize that increasing the amount of time individuals spend reading or thinking about content on a Web site increases the likelihood of behavior change (Sciamanna et al., 2002). Future research and practice would therefore benefit from more data on exposure to (specific parts of) interventions. Sciamanna et al. and Leslie, Marshall, Owen, and Bauman (2005) suggested that people with low levels of motivation to increase their physical activity levels use other parts of intervention Web sites and have other preferences than people with high levels of motivation. Unfortunately, data on exposure to intervention programs are hardly ever presented despite the fact that the use of a Web site, visits to specific pages on a site, the use of links, and so forth can all be monitored in contemporary Web-based health-promotion programs. Only 5 of the 22 studies in the review by Wantland et al. (2004) reported measures of intervention exposure. Oenema, Brug, and Lechner (2001) increased the likelihood of high exposure to the intervention program by installing it on a local hard disk, thus preventing people from browsing the World Wide Web. Marshall, Leslie, Bauman, Marcus, and Owen (2003) conducted an 8-week in-

tervention with repeated reminders to use the site. They found that less than half of the participants used the site. Only 26% of the participants used the site more than once. An 8-month intervention program on nutrition counseling (Verheijden, 2004) was used by only 33% of the study participants (median site-use frequency among users was one time). Participants from different study populations were asked to report reasons for their relatively infrequent site use. Barriers that were reported included lack of time, lack of interest in the topic, limited access to computers and/or the Internet, and low expected benefits (Sciamanna et al., 2002; Verheijden, 2004).

CURRENT WEB-BASED BEHAVIOR-CHANGE PROGRAMS

Large numbers of Web sites currently offer people the possibility to participate in behavior-change programs. These sites vary largely in content and quality (Evers et al., 2003). They also vary in the number of health behaviors that are addressed and in the freedom of choice participants have in terms of the topics they would like to work on. Verheijden et al. (2006) showed that possible users of health-behavior-change programs differ in their views about what lifestyle topics should be addressed. Roughly half of the participants said they would like to decide for themselves which behaviors to focus on. The other half stated that Web-based behavior-change programs should address all relevant lifestyle issues. Very little evidence exists about addressing multiple lifestyle issues simultaneously. Evers et al. (2003) found that the vast majority of Web sites cover more than one behavior. Some of these combined programs integrate the five As for all behaviors involved. Others offered a modular approach in which the five As were kept separate. Research by Vandelanotte, De Bourdeaudhuij, Sallis, Spittaels, and Brug (2005) showed that the simultaneous approach may be more effective in certain groups of people than a sequential approach.

THE FEASIBILITY AND EFFECTIVENESS OF WEB-BASED HEALTH-PROMOTION PROGRAMS

As for any other health-promotion tool, a major prerequisite for large-scale implementation of Web-based health-promotion programs is a solid evidence base for their (cost) effectiveness. Conducting feasibility and pilot studies is an important first step in the evaluation of Web-based health-promotion programs (De Nooijer et al., 2005). Unfortunately, there is very little literature available on this topic. This is likely the result of journal editors being more interested in randomized controlled trial on the effectiveness of the final programs. As a result, publishing pilot studies is relatively low on researchers' priority lists. However, to prevent the wheel being reinvented over and over again, the field would benefit from the publication of the successes and failures in pilot studies, such as was done by Anhøj and Jensen (2004). They conducted a feasibility study on a Danish Internet application for lifestyle changes in diet and physical activity among five general practitioners (GPs) and 25 patients. Data were collected rather randomly from different sources and participants were likely a convenience sample. Nevertheless, the results from this study provide some valuable insights for the design of future behavior-change programs. One of the important outcomes of this study is that patients seemed to give a high value to personal relations with a health-care professional. All patients agreed that "the use of the program did not provide the necessary support in their struggle towards a healthy lifestyle." They said that the program itself was merely a tool and that it could never replace support from a health-care professional. It was also reported by both patients and GPs that the program needs to allow for frequent interaction, especially in the beginning, to prevent patients' loss of interest. Anhøj and Jensen (2006) suggested breaking up advice messages into small fragments delivered on a daily basis. They also

suggested allowing patients to complete dietary assessment instruments on a regular (possibly even daily) basis, despite the fact that these instruments may have been developed to assess dietary intake patterns over the past month. Evidently, the latter limits the reliability of questionnaire results and the content of advice, which is one of the other key issues that needs to be addressed for similar programs to be successful in bringing about patients' lifestyle changes.

However, aside from a number of position papers indicating the potential of these programs and a few studies with varying external validity, very little evidence is available. Wantland et al. (2004) reviewed behavioral-change outcomes in Web-based vs. non-Web-based interventions for (amongst others) weight control, weight-loss maintenance, nutrition, physical activity, and the secondary prevention of heart disease. They concluded that there was substantial evidence that use of Web-based interventions improves behavioral-change outcomes. De Nooijer et al. (2005) conducted a systematic review on the effectiveness of Web-based health-promotion programs in the areas of smoking, physical activity, nutrition, weight loss (maintenance), safe sex, alcohol, and drugs. They found favorable effects (part of which were significant) on knowledge, awareness of actual consumption levels, self-efficacy, and intention to change behavior. The evidence on behavioral and biomedical outcomes was conflicting, and effect sizes were predominantly insignificant. Werkman, Kroeze, & Brug (2005) conducted a systematic review of the effectiveness of computer-tailored education on physical activity and dietary behaviors. They found most consistent evidence for tailored interventions on fat reduction. There was very limited evidence to support computer-based tailored programs for physical activity. Textbox 2 briefly presents examples of computerized health-behavior-change programs in the area of physical activity (Marshall et al., 2003), smoking (Velicer et al., 1993), and diet (Block, Block, Wakimoto, & Block, 2004).

Textbox 2. Some examples of computerized health-behavior-change programs

Expert System for Smoking Cessation

Velicer et al. (1993) tested a computerized expert system for smoking cessation in 870 smoking volunteers. People were randomized into one of four groups: (a) standard treatment using self-help manuals and booklets, (b) individualized treatment using manuals based on all constructs of the trans-theoretical model, (c) interactive individualized treatment using manuals based on all constructs of the trans-theoretical model and three printouts of computer-generated reports on people's responses to mailed questionnaires, and (d) extensive interactive, individualized treatment using manuals based on all constructs of the trans-theoretical model, three printouts of computer-generated reports on people's responses to mailed questionnaires, and a series of short calls from counselors to provide personalized feedback. Self-reported smoking abstinence was measured in a pretest and after 6, 12, and 18 months. Individualized treatment and standard treatment led to similar abstinence rates through 12 months. At 18 months, individualized treatment outperformed the standard treatment. Interactive, individualized treatment outperformed standard and individualized treatment at all time points; quit rates were roughly twice as high. The extensive interactive, individualized treatment was slightly less effective than the regular interactive, individualized treatment.

E-Mailed Nutrition Intervention Program

Block et al. (2004) conducted an experiment in which employees at a corporate work site were offered the opportunity to work with the e-mailed Worksite Internet Nutrition (WIN) program. Some of the principles in the WIN program were relevance to the employee, tailoring, flexibility and individual choice, skill facilitation, commitment and goal setting, reminders and reinforcement, and multiple strategies and channels. Eighty-four of the 230 employees participated in the program. No control group was included in the study. The participants increased the frequency of fruit and vegetable consumption by 0.73 times per day and decreased the frequency of fat consumption by 0.39 times per day. Participants found the program helpful (93%) and all of the participants who admitted not to be health conscious at baseline would recommend the program to others.

Web-Site Physical-Activity Program

Marshall et al. (2003) conducted a study among 655 participants who were recruited from an Australian regional university. Participants were randomized to receive either a print-based or a Web-based active-living program. Most people preferred the Web-based program. However, 36% of the participants in the print-based group had kept the intervention materials for future reference, while only 12% of the participants in the Web-based group reported to have bookmarked the Web site. There was a trend for participants in both groups to participate in more physical activity after the intervention, but there were no statistically significant differences within or between study groups.

These examples were chosen because they represent different options in computerizing: Web sites, e-mails, and computerized expert systems. Several methodological drawbacks characterize some of the studies included in the reviews described above. For example, one needs to be cautious when interpreting studies in which a Web-based program (i.e., increasing access to information) is compared to a no-treatment control. The difference in exposure to intervention may be a co-intervention to such an extent that the effects of the use of new media cannot be assessed properly (Nguyen et al., 2004). A nice series of studies in which this was not an issue was conducted by Harvey-Berino, Pintauro, Buzzell, et al. (2002), Harvey-Berino, Pintauro, Buzzell, and Gold (2004), and Harvey-Berino, Pintauro, and Gold (2002). They compared weight-loss maintenance programs, one of which was delivered via the Internet. The studies provided conflicting evidence on the effectiveness of Internet interventions for weight-loss maintenance; the Internet intervention was at best slightly (yet insignificantly) better than other treatment modalities. Generally, the attendance of meetings was lower in the Internet intervention and patients tended to prefer the in-person intervention.

A study by Consoli, Ben Said, Jean, Menard, Plouin, and Chatellier (1995) showed that knowledge scores among hypertensive patients increased significantly more when standard education by physicians, nurses, dieticians, and pamphlets were supplemented with one computer session using an expert system. Some positive experiences were also reported for other conditions, such as heart failure and asthma (Krishna, Francisco, Balas, Konig, Graff, & Madsen, 2003; Stromberg, Ahlen, Fridlund, & Dahlstrom, 2002). It has been suggested, however, that these findings cannot simply be extrapolated to the effectiveness of computerized behavior-change programs in general because the sense of urgency to participate in such programs is much larger for people who have been diagnosed with chronic conditions than

for people who need to make behavioral changes in the prevention of chronic conditions. This may be partly the result of the fact that people can expect benefits from participating in such programs in the long term, while the effort needs to be put in at present (Allegrante & Roizen, 1998).

POTENTIAL FOR HARM

Initially, many interactive health communication systems were available under supervised conditions in academic research settings only. More recently, however, many systems have become available to the general public. There is even less evidence available on these publicly available products than on the academically available ones, and monitoring occurs rarely. As SciPICH (Robinson et al., 1998) already stated, this should raise legitimate questions about their quality, cost, and potential to cause harm. The risks of direct and indirect damage to people's health as a result of health-promotion programs through interactive health communication may be considerable. This may be the result of inappropriate treatment or delays in seeking necessary medical care. The expert panel in the study by De Nooijer et al. (2005) that was discussed previously also expressed concerns about places people can turn to when they need more information after they have read misleading or terrifying information on the Web. Other examples include damaged trust in health-care clinicians and misleading claims for health products. SciPICH strongly equal for the active involvement of health-care professionals in assessing and assuring the quality of interactive health-promotion tools and in contributing to the development and implementation of such tools. It advocated that this approach would lead to much better outcomes for both health-care providers and health-care consumers than an approach in which professionals ignore or disparage such tools.

CONCLUSION

New communication technologies provide many opportunities for health-promotion programs, but they also have some considerable limitations. The ultimate proof of the pudding, of course, is in the eating. As Evers et al. (2005) already stated:

Until the field solves the problem of helping significant percentages of populations toward effective action and maintain such action, Internet programs will not be able to realize their potential to be the lowest cost modality for delivering tailored communications that can have the highest impact on health promotion, disease prevention, and disease management.

It is a challenge for all those involved to make the best possible use of the new technologies for programs that were originally designed for face-to-face or print strategies, as well as to develop new programs specifically designed in a new media format. However, to make full use of the possibilities of face-to-face and computer-based interaction in health communication, the World Wide Web should never fully replace consultations and clinical examinations by health professionals. Depending on factors such as the available resources (time, space, staff, etc.) and the personal preferences of all individuals involved, an ideal mix of intervention approaches may be composed.

INTRODUCTION

The most common definition of the information society lays emphasis upon spectacular technological innovation and the transformative effects of new information and communication technologies. The key idea is that breakthroughs in information processing, storage, and transmission have led to the application of information technology in virtually all, public and private, sectors of society (Webster, 1995). By the 1990s, to admire and indeed enthuse over new ICTs had become highly fashionable and popular. Such technological enthusiasm has become so pervasive that it has seeped not only into political and policy

discourses, but also into the whole spectrum of the media and fora of public communication (Preston, 2001). In addition, discourses of the information society are often dominated and shaped by male commentators (e.g., Castells, 2000; Gates, 1995; Kelly, 1999; Negroponte, 1995). For example, when compiling a collection of the dominant players of international information-society discourse, Cawley and Trench (2004) were hard-pressed to find female commentators, succeeding only in finding 3 out of a total of 18 critics.¹

We argue that the focus on the artefact, and thus technological celebration, takes precedence over the largely ignored field of technological uses and consumption issues. Hence, we present

a study that analyses the individual user experiences to challenge the stereotypical user traditions represented by the information-society discourse. We wish to present a counternarrative that shifts the emphasis from technical expertise, and technological and transformative benefits of artefacts to more individual-user-focused narratives.

As a result, this brought about a dual-narrative process through which the respondents described their experiences. We found that when people described their uses, consumption patterns, and domestication² experiences of ICTs, they tended to do so by employing contrasting frames of reference. These frames of reference we have termed the objective lens (or narratives) and subjective lens (or narratives). Through what we term objective narratives, we found that some respondents would describe their use through official and technical frames of reference. For example, they employed primarily dominant information-society jargon to frame how they made sense of technologies and their use experiences. Through subjective narratives, we found that respondents would describe their use and experiences from primarily a personal perspective to explain how the technology fitted their lives, the role it played in their everyday routines and habits, and the associated meaning and significance of the artefact.

While these contrasting narratives are not mutually exclusive or contradictory, it became clear from the interviews that a pattern of use narratives was emerging. We found that such narratives slightly reinforced traditional gender roles in which men tend to talk about technologies in highly technical terms of reference, while women portray themselves as technologically helpless or ignorant (Gill & Grint, 1995; Gray, 1992; Lie, 1995). Although we did not look for or find stable gender categories, the emergent gender narratives seem to renew the existing gender roles that link masculinity and technology (Vehviläinen, 2002).

With the development of computer technologies, we have witnessed a shift from IT to ICTs.

This has resulted in a redefinition of the computer as an artefact: from a mere computational device to the newly emergent multimedia-enhanced computers, or what Paul Mayer (1999, p. 1) calls a “meta-medium.” Today, the conceptualisation of the computer is more problematic. It may be thought of as the Web or Internet, computer games, CD-ROMs (compact disc read-only memory), reference works, e-mail, and a diverse range of applications for displaying and manipulating text, images, graphics, music, databases, and the like. Spilker and Sørensen (2000, p. 270) argue that computers are no longer “primarily about programming, systems, control and calculation,” but instead “a gateway to communication and cultural activities.” The shift in identity has opened up or unlocked the conceptualisation of the computer. Therefore, it is possible for wider audiences and previously excluded groups (such as the elderly and women) to translate the computer into something meaningful in their everyday lives. As a result, we were not solely focused on the computer as a separate technology, but instead on the wide range of information and communication technologies that are available in the domestic setting.

BACKGROUND

While the concepts of objectivity and subjectivity are not novel terms to describe contrasting positions, we have used the concepts to facilitate the understanding of how our respondents talk about their experiences and uses of ICTs. Orlikowski and Robey (1991) have employed this approach to address the relationship between information technology and the structuring of organisations. The authors argue that the essence of both social reality and ITs can be described by using objective and subjective perspectives. In Orlikowski and Robey’s approach, the objectivist relationship to technology underlines the importance of the material characteristics of the artefact, while the subjectivist approach focuses on the

importance of the subjective human experience in the interpretation, creation, and modification of the social world.

Although Giddens' (1976) theory of structuration bridged the gap between the objective and subjective social reality in academic circles, and in particular technology studies, the emphasis lies firmly in the objective approach (Orlikowski, 2000). We argue that one must consider both subjective and objective approaches to ICT discourse. The division is maintained in this article as it is constructive and valuable in the ways it enables us to discuss how and why the objective approach to articulating ICT use is publicised, overvalued, and hyperbolised. On the other hand, the subjective approach is often neglected and confined to private, domestic, and unofficial realms. The aim of this article is not to merely point to the existence of both discourses of ICT use, but instead to argue that it is important to locate the common ground between the discourses in order to provide a grounded and holistic picture of the ways people talk about their ICT use.

NARRATIVES OF ICT USE

The data for this article are drawn from a larger study of Finnish families looking at ICTs in everyday life and the use of electronic services.³ The objective-subjective theme discussed here emerged while analysing the ways family members talked about their ICT use. For the purpose of this article, we draw on selective excerpts from the interviews to illustrate the contrasting narratives.

Pure Objective Lens

The dominant narrative of information-society discourse presents ICT use in a normative way, for example, by urging universal access and consumption, which is mirrored through official discourse in the ways everyday users express their

personal experiences. This way of describing ICT use was also reproduced by several respondents, as can be observed in the following quote.

Ville: We had our first computer ... [it] was 2-8-6 ... quite interesting. We have it actually still somewhere; I don't know where.

Interviewer: Was it about when ... [W]ere you still in school?

Ville: Well, it was when [it] cost thirty grant[s] of old money.

Here, Ville was asked about his early memories of the family's first computer, and he replied listing only the technical particulars and the price of the machine. The quote gives an interesting insight into how male respondents often shied away from using personalised or subjective narratives to articulate their everyday use of or relationship with the artefact. Instead, they preferred to employ objective or dominant information-society narratives to describe their relationships with ICTs. We found male respondents would employ such narratives even when discussing Internet use.

Information-society discourse, as we stated earlier, adopts the classic determinist position whereby technical advances are celebrated using hyperbolic expressions (Preston, 2001). This technical enthusiasm is picked up by ordinary users (mostly male) who tend to reproduce these official narratives to describe their own use.

Pure Subjective Lens

We also identified another narrative used by the respondents to describe their use in a more personal or subjective fashion. To illustrate this alternative narrative, we present one example of a female respondent who expresses her use and consumption of the Internet by relating its use to her everyday routines and habits. Here we notice a shift in the respondents' narratives from objective

discourses of use to narratives of personal and individual ways of describing how the artefact fits into everyday life.

[On the Internet] there is lot of instructions, people's gardens, advice. Then there is from these willow works. You find really those instructions, real illustrated, and they talk [on Web pages]. I just devour those. (Helena)

When talking about her use of the Internet, she gives very practical (or subjective) descriptions of her Internet habits, incorporating emotive and expressive language to articulate her use patterns: "and then I can manage without [the] machine [computer], but it is nice to visit [Web pages] if I just can."

She also makes it clear that using the Internet is not an overwhelming activity for her, but one she can do well without. This she explains partly due to the everyday situation in the family, as access to the computer is compromised due to other family members being active users.

Mixed Objective and Subjective Lens

Helena's husband Heikki gives us a very useful insight into the dilemma users face when trying to balance the objective and subjective relationships with the computer. He explains,

I don't really like [to] use it much then ... I don't know if it's character or what, but I feel bad if I'm not working; then when I'm by [the] computer ... I feel I'm wasting my time ... but I do sometimes [on] weekends. (Heikki)

In this quote, we get a sense of how users strive to reconcile the work-related or non-hobby-related uses of the computer and the Internet (objective) with the leisure or entertainment features and functions, and perhaps even communicative elements of ICTs (subjective). Objective discourses tend to focus on "worthy" or beneficial uses of

ICTs while perhaps overlooking the everyday uses such as music downloading, game playing, surfing, and e-mailing. It is only through a subjective discourse analysis that we get a sense of the reality of everyday uses of ICTs and accordingly develop an understanding of the meanings and significance users assign to them.

TRADITIONALLY GENDERED OR GENDERED TRADITIONS?

This section will explore whether gender differences between masculine and feminine users are reinforced, reproduced, or challenged. Ostensibly, there existed some gender differences in describing one's own ICT use. It became apparent during the respondents' narrations that both men and women appeared to adhere to traditional gender stereotypes, in which men are presumed to be technologically oriented and women technologically helpless, or at least not interested in technology (Gill & Grint, 1995). In doing so, they do not just express their own interpretations, but they appear to also confirm and renew the connection between technology and masculinity.

However, on deeper analysis, we found some interesting similarities between the male and female approaches to describing ICT use. We suggest that the presence of such similarities can be argued perhaps as a weak indication that signals the diminishing traditional bond between technology and masculinity (Lie, 1995).

In our interview material, the men, Pekka, Heikki, and Ville, used all three narratives (objective, subjective, and mixed narratives). In spite of this, there also emerged some crucial differences between the men as Ville employed almost exclusively the objective narrative, even as he presented his individual ICT experiences. The other men, Heikki and Pekka, employed mixed narratives when articulating their ICT use. This reinforces the position held by Lie (1995), who argues that "the connection between technology and masculinity

does not imply that all men are equally attached to technology, or that one can prove empirically that majority of them are” (p. 382).

Alternatively, the interviewed women, Paula, Helena, and Leena, employed subjective and mixed narratives. Significantly, they did not employ objective narratives at all. It became apparent that Leena was more aware of the objective discourse, but chose instead to articulate her ICT use in more subjective tones. Paula was quite enthusiastic about computer use and the potential benefits of the information society, using objective narratives to express her opinions. But when she described her individual role as an ICT user, she presented herself as “not the good and legitimate user,” which can be seen as reverting back to subjective narratives. In essence, the female respondents knew of the dominant narrative of information-society discourse, but they used it as a mirror to present their own subjective experiences.

FUTURE TRENDS AND CONCLUSION

Although the objective lens continues to be used as the dominant narrative, we believe the subjective lens will become increasingly pervasive with more user- and consumer-focused research (such as Hartmann, 2003; Miller & Slater, 2000; Ward, 2003). This type of research mirrors the changing faces of ICTs from highly technical artefacts (bound up with programming and networking identities) to technologies with everyday uses for domestic users (with communicative and interactive functions). This shift brings about opportunities for ordinary users to articulate their own subjective relationships with ICTs while lessening the need for dedicated technical expertise and skills to operate information technologies. From a cultural- and media-studies perspective, Silverstone, Hirsch, and Morley (1994) view the “double articulation” of ICTs—both technological

texts and media texts—as having an influence on relationships with ICTs, and in the case of this article, on the discourses people use to describe those relationships. As a result, ICTs are not solely studied from a technological perspective, as by computer scientists, but also from social and human-centred perspectives (e.g., Castells, 2000; Hine, 2000; Lie & Sørensen, 1996).

Furthermore, the scientific paradigm is recognising this shift as studies become less positivist in nature and instead focus more on areas such as interpretive studies (see Walsham, 1995, 2005). In the information-systems field, interpretive studies provide space to consider alternative explanations of ICT use and practice, in particular in new gender studies where the focus is not typified by the differences between the genders but instead on subjective differences, for example, between women’s use of technology. Therefore, we suggest that the subjective analysis of technology use and its discourse should be considered a valuable insight into how users construct individual interpretations of ICTs. In cultural and media studies, the concept of domestication is employed to achieve insights into the experiences of individuals as they tame wild technologies and make them fit into their everyday surroundings, routines, and patterns. Domestication, as an analytical tool, gives scope to researchers to consider the technological and social characteristics of technology and the social factors that influence its use and identity. This approach to technology and everyday life marks a move away from the understanding that technologies appear in society ready to use, to an understanding of technologies as unfinished artefacts. It provides a very useful way of exploring the social complexity of how people experience ICTs beyond any simple idea of the benefits and uses of technology.

In conclusion, as ICTs become more a part of everyday life, we believe the stereotypical connection between technology and masculinity will focus less on male users and female nonusers, but will focus more accurately on the kinds of

uses there are and how those uses are articulated. We posit the technology-orientated male will be replaced, for example, by the sophisticated image and narrative of the open-source programmer, with all the superfluities of high technical expertise. Meanwhile, the technologically helpless female is interchangeable with representations of unsophisticated use or everyday uses of information and communication technologies.

Interviews

The interviews conducted in South Ostrobothnia, Finland. Names of the interviewees have been changed:

Heikki, interviewed June 2, 2003, by E.-R. Koivunen

Helena, interviewed June 2, 2003, by M.-K. Paakki

Leena, interviewed June 24, 2003, by M.-K. Paakki

Paula, interviewed July 16, 2003, by M.-K. Paakki

Pekka, interviewed July 16, 2003, by E.-R. Koivunen

Ville, interviewed June 25, 2003, by E.-R. Koivunen

APPENDIX

Two of the project members, researchers Koivunen and Paakki, collected the empirical material and interviewed the respondents in the summer of 2003. The interviews were conducted in a South Ostrobothian village in Finland. In the village, there are 400 inhabitants, a school, a shop, a bank, and a church. The interviewees are members of two extended families (see Figure 1).

Family 1 is comprised of the households of two brothers and their families living next to each other. The brothers, for whom we use the pseudonyms Heikki and Pekka, are both married and have young children. Heikki and Helena have two daughters, while Pekka and Paula have four daughters. In these families, all members use the computer and the Internet. We interviewed the brothers and their wives. These interviews took place at their homes.

Family 2 includes a grandmother, grandfather, father, mother Leena, and a 20-year-old son, Ville.

They all live on the family farm. From this family, we interviewed only the mother and the son, who are both known in the village as active and innovative users of ICTs. The other members of the family do not use the computer or Internet. Leena was interviewed at her workplace, which she called her second home, while Ville was interviewed at home.

KEY TERMS

Domestication: Domestication refers to the process whereby technological artefacts are fitted into the routines and practices of the everyday lives of users. It is a process whereby technologies are consumed within specific and localised contexts and become inscribed with meanings, while reproducing values and transforming relations.

Dominant Narratives: Dominant narratives are part of our shared cultural knowledge about standards, which we refer to in explaining our

Figure 1. The interviewees and their family relations

Articulating ICT Use Narratives in Everyday Life

acting, knowing, and thinking, and they are produced and reproduced in the discourses of everyday life.

Double Articulation: Double articulation refers to the concept that media lead double lives as both communication media and artefacts. Technologies are doubly articulated in the ways we need to address responses to particular texts or genres brought to us by the media and, on the other hand, the significance of media technologies themselves.

ICTs: Information and communication technologies such as televisions, telephones, the Internet, computers, and so forth.

Information Society: This concept is characterised by a new kind of information-led, service-oriented society that will replace the industrial-based model that had been dominant in the West in the 19th and 20th centuries. Information, and

those who know how to create, assemble, and disperse it, is deemed more valued than labour.

Objective: The objective is nonsituated, impersonal, and not dependent on or influenced by personal opinions or prejudices.

Subjective: The subjective is based on thoughts or feelings derived from individual experiences and personal interpretations.

ENDNOTES

- ¹ Those female commentators are Sherry Turkle, Esther Dyson, and Robin Mansell.
- ² Domestication here refers to the process of rendering new technologies as tame as they enter the domestic setting.
- ³ See Appendix for an extended account of the empirical data sample.

Chapter 5.9

ICT, CoLs, CoPs, and Virtual Communities

Antonio Cartelli
University of Cassino, Italy

INTRODUCTION

Every day, information and communication technologies (ICT) are extending their influence on knowing and transmitting knowledge. They act on humankind at different levels: the individual, the society, and the community/organization. The Internet more than other instruments in the past is changing human customs and knowledge strategies mostly due to the online information systems developed during last few years.

BACKGROUND

The experiences described below were from the author in cooperation with M. Palma (professor of Latin paleography) while working on special Web sites to be used in paleography for research and teaching. The Web sites were not e-learning platforms but were used as content management systems (CMS), learning management systems (LMS), computer-supported collaborative learn-

ing systems (CSCLS), and knowledge management systems (KMS).

The use of the above systems is based on the hypothesis the author shares with M. Palma: that ICT and especially the Internet cancelled the temporal gap existing between research and teaching time (at least in paleography). Due to the Internet, in fact, scientists can immediately publish the research results; it becomes, then, more and more difficult to separate the proposal of new scientific paradigms from their translation into educational and didactical materials.

Web Site “Didactical Materials” for Latin Paleography

In the Middle Ages different scripts were used for handwriting documents and their study is based on the analysis of charters and manuscripts. The main problem scholars and students have today is often the simple access to these materials due to security and preservation reasons. Furthermore, proceedings of conferences and meetings are

usually printed some years later and it is very difficult, if not impossible, for scholars, to report the meaning of a hypothesis or the relevance of a discovery to their students, contextually to their proposal.

To respond to the above problems, a Web site was planned to make available the following:

1. Didactical materials for a course on Latin paleography, that is, the plates reproducing the pages of manuscripts and the transcription of their texts.
2. Texts freely extracted and translated from printed or electronic documents, or made available from the authors, and collected in various sections: from codicology to cataloguing and preservation, and so forth.

It has to be noted that the experience of the didactical materials' Web site is mostly unique, not only for the systematic nature of the plates and for the presence of their transcriptions, but also for the documents reported among the texts; many of them are, in fact, papers concerning recent research topics, produced for special events (i.e., mainly conferences) and made available from the authors for didactical purposes.

The Web Site "Women and Written Culture in the Middle Ages"

The main aim of this dynamic Web site (Cartelli, Miglio, & Palma, 2001) was the systematization of the data emerging from the research while leading to an instrument helping scholars to find new elements for further studies.

Data appearing relevant to the scientific community were:

- For the Scribes: (a) the name of the woman as it appears in manuscripts, (b) her qualifications (i.e., if it is known whether she was a nun or a layperson), (c) the date or the period she belonged to (up to the 15th century)

- For the Manuscripts: (a) their shelf marks (i.e., town, library, and number of the manuscript), (b) the place and the country where they were written, (c) the date or the period they belong to, (d) the authors and titles of the texts, (e) the bibliography or its source of information.

Furthermore it appeared important to show for each woman the manuscript(s) she wrote and vice-versa, and if possible and available, at least an image of the copyist's hand.

The site has two separated sections: one being operated only by editors (to insert, modify, delete the data stored in the database), thus ensuring the scientific validity of the information reported; the other is at everyone's disposal to obtain the list of all women and manuscripts in the database, or to make queries concerning women and manuscripts with specific qualifications.

The Open Catalogue of Manuscripts and the Martyrology of Arpino

At the basis of the Open Catalogue of Manuscripts are the results of recent studies concerning the use of the Web for the publication of catalogues of manuscripts (Cartelli & Palma, 2003b). In its final structure, it is an information system devoted to the management of documentary information in ancient libraries and it is based on the use of the Internet and especially of the Web for managing and accessing data. It is composed of five sections: (a) the first one contains documents explaining the history of the library and of its manuscripts; (b) the bibliography ordered by shelf mark and, eventually, alphabetically and chronologically, is housed in the second section; (c) in the third section are the descriptions of the manuscripts; (d) the fourth section is devoted to the images of the highest number of manuscripts in the library (potentially all); (e) the fifth and last section consists of a communication subsystem granting the

easier acquisition, writing, and editing of texts (Cartelli & Palma, 2002).

In Italy the Malatestiana Library in Cesena, an ancient library founded in late 15th century decided to adopt the Open Catalogue for its 453 manuscripts and their catalogues and activated all the sections the author hypothesized for its structure.

On another hand the Martyrology of Arpino, as a single manuscript kept in the church devoted to Our Lady in Arpino (a small town in central Italy), had the suitable features for the creation of an Open Catalogue (Cartelli & Palma, 2003a) made by a single manuscript and a special site for it was carried out in the Faculty of Humanities.

The Bibliography of Beneventan Manuscripts

The BMB experience (Bibliografia dei Manoscritti Beneventani—Bibliography of Beneventan Manuscripts) started in 1992 with the main aim of collecting the quotations of Beneventan manuscripts (i.e., medieval books written in the South Italian national script) by means of a program called BIBMAN. In 1997, the first Web site was developed to make it faster and easier for scholars to download new bibliographic data (nearly monthly).

Recently many problems with the BIBMAN program resulted in a plan to carry out a new Web site: the BMB online (Cartelli & Palma, 2004). It is an information system where various people with permission can store the quotations of Beneventan manuscripts and it can be freely queried by general users. Persons entrusted with the task of collecting the quotations of Beneventan manuscripts are grouped into three categories:

1. contributors, who can write, modify, and delete bibliographic data for the materials assigned to them
2. scientific administrators, who can manage all data and write, modify, and certify biblio-

graphic materials (this last operation being done only once because certified records cannot be accessed for revision)

3. system administrator, who is allowed to do all operations including the modification or deletion of certified data

The access to certified bibliographic materials is possible according to different query pages: (a) by author, (b) by manuscript, (c) by contributor, (d) by one or more words or part of them concerning the title, location, or bibliographical abstract of a given publication.

It has to be noted that in the system are also implemented: (1) a closed communication subsystem made by an electronic blackboard guaranteeing an easy exchange of messages among contributors, (2) some special functions, available only to system administrator, for the production of the printed version of the yearly collected data.

ICT, COLS, COPS, AND VIRTUAL COMMUNITIES IN PALEOGRAPHY

The systems and Web sites described above were carried out by the author at different times but were suddenly introduced in everyday teaching and research work. The effects they produced are analyzed in what follows:

- The students attending the paleography course found the plates on the Web site of Didactical Materials (both for the analysis of the scripts and for training themselves in the transcription of the texts) very useful and were instantaneously led to the themes of most recent research studies and to the debates in the paleographic community. Furthermore, after a very short starting phase, during which people had to be repeatedly invited to submit materials for publishing on the Web site, the number of scholars who autonomously propose the publication of

their works is now growing. At last it has to be noted that many students in other Italian universities use the same materials and ask for explanations via e-mail, thus creating a virtual community on paleography studies.

- Many students not only used the materials reported in the Women Copyists Web site, but were also involved in the description of manuscripts and in the collection of the plates reproducing texts written from women (i.e., they learned to distinguish the different hands of women copyists and their way of writing manuscripts). With time the number of bibliographic notes increased from scholars all over the world. As a consequence the project of an information system which allowed people to autonomously manage the bibliographical data and an enhancement of the virtual community (it is also a community of practice) working on women copyists have been planned,
- Some students were involved in the description of manuscripts of the Malatestiana Library and accessed the communication subsystem of its Open Catalogue so that they could share with the subscribers of the newsgroup the texts they wrote. It has to be noted that the Malatestiana Library staff reports of an increasing number of scholars and students asking for access to the communication subsystem of the Open Catalogue and of a continuously growing number of reports and discussions concerning the manuscripts in the library. By comparing the above results with what is already known on CoPs and virtual communities, it seems that people involved in the Malatestiana Open Catalogue have all the typical features of those kinds of communities.
- The Martyrology of Arpino, on another hand, has been used for teaching as follows: (1) some make-up courses centered on it were

designed for students with gaps in their basic knowledge of History and Latin (i.e., the manuscript was used as a chronicle from 14th-16th century and the historical events reported there had a counterpart in relevant events of that period); (2) students were directly involved in the production of the Web pages of the Martyrology site (with the acquisition and editing of texts and images), in the description of the manuscript and in the transcription of the text. As a result, the students involved in the digitization of the pages of the Martyrology and in the editing of its texts had fewer problems than their friends in learning computer use and there were no cases of rejection of its use as often happened in institutional computing courses in the Faculty.

- Many students, after having attended the basic courses on cataloguing, were asked to become contributors for BMB online and to produce bibliographic materials. The discussions they had with administrators, professors, and among themselves, the use they made of the electronic blackboard and of the e-mail services for the exchange of messages, and last but not least, the chance of working in little groups on the same problems helped them very much in the acquisition of the knowledge and development of the skills they would need (as paleographers) in their everyday work.

CONCLUSION

In the author's opinion the effects induced on knowledge construction/sharing processes can be analyzed from three different points of view:

1. The first one concerns the communities of students involved in the experiences described above and what we know on CoLs. It has to be noted that the groups of

students involved in the experiences (a few elements each time and in the best case no more than 19 subjects) really had the features of CoLs or FCL as described by Brown and Campione (1996). Furthermore the students were satisfied with the new approach to the discipline and got better results in their exams, that is, they had better scores and developed better skills than their counterparts in traditional courses (as it was recognized by the professors). Some new effects never observed before were also detected in the following skills: working in a group (in traditional courses it is a very rare experience), easier facing of complex tasks (thanks to the help each student could have from their colleagues), and raising of the individuals' peculiarities within the community. The ICT also had a great role in all experiences because they helped students in experimenting a metacognitive environment and cognitive apprenticeship strategies, involved them in the discussion and evaluation of the procedures they took part in, and let them experiment with meaningful learning (Varisco, 2002).

2. The second point of view is the one of the communities of practice (CoPs). But is it suitable to look at groups of students as CoPs? With respect to corresponding communities in organizations and corporations, which are autonomously created and have no hierarchies, the presence of a hierarchical structure has to be noted (professors and their collaborators organize the work, suggest what to do, support everyday activity, etc.). Further differences between groups of students and CoPs are (a) community skills are mostly induced/transmitted by professors and not freely shared among individuals, (b) community memory is not made of the repositories of expertise but it is made of the data in the Web pages and in the databases (i.e., it is mostly represented

by the scientific knowledge available from sites browsing and database querying).

Nevertheless, in the author's opinion, the answer to the above question must be affirmative because (a) there is a common task shared among all community members, (b) there is a reciprocal commitment regulating interactions and sharing of experiences among the subjects in the community, (c) there is a shared repertoire of knowledge, instruments and methods by means of which common knowledge is preserved and transmitted (Wenger, 1998).

3. The third and last point of view is the one of virtual communities. It has to be noted that many scholars cooperated in the various projects via the Internet (by sending papers or other texts for the Didactic Materials, by intervening in the discussion groups of the Open Catalogue, or by compiling bibliographic cards as contributors of the BMB online) and often they did not know people carrying out those projects or other people working on them. Nonetheless their contributions were very important for students and for the construction of the community memory. In the author's opinion it can be deduced, at least in the case of paleography, that virtual communities can act as CoPs without needing presence meetings, thus contradicting the third law of Denning (2000). From what has been reported until now, it seems that the overlapping of virtual communities and CoPs features are possible if people joining them have the same highly specialized skills and agree on the target to be hit (also if they do not know one another).

FUTURE TRENDS

From what has been said until now some hints for future research seem possible:

1. If, as emerged above, the contribution to problems analysis and solution coming from different kinds of communities seem to produce better results with respect to the ones coming from individuals or single types of communities, further research has to be carried out on the relationships existing among them and on the consequences that the presence of the same individuals in more than a type of community has on knowledge construction processes.
2. If, at least in the case of paleography, the presence of a virtual community contributes in increasing scientific knowledge construction (and not only teaching), other best practices have to be encouraged and the opportunity for academic and research institutions of making stable and durable their intervention in problems analysis and solution has to be analyzed.

KEY TERMS

Cognitive Apprenticeship: It is originated from traditional apprenticeship, which has the following well-known features: modeling, coaching, scaffolding, and fading. When it is applied to educational and research situations, the new features of articulation, reflection, and exploration must be added to the ones above.

Community of Learners (CoL): It is a community of students, teachers, tutors, and experts marked by the presence of the following elements: (1) multiple ZPDs (the zones of proximal development of the subjects in the CoL); (2) legitimated peripheral participation (the respect of the differences and peculiarities existing among the various subjects in the community); (3) distrib-

uted expertise; (4) reciprocal teaching and peer tutoring; (5) various scaffoldings; (6) cognitive apprenticeship; and (7) metacognition.

Community of Practice (CoP): It is a community of individuals having the following elements in common: a) a joint enterprise, as understood and continually renegotiated by its members; b) a mutual engagement binding members together into a social entity; and c) a shared repertoire of communal resources (routines, sensibilities, artifacts, vocabulary, etc.) that members developed over time.

Information System: It is the set of all human and mechanical resources needed for acquisition, storing, retrieving, and management of the vital data of a given system. With human resources are usually intended both the individuals involved in the use of the system and the procedures they have to carry out. With mechanical resources have to be intended both the hardware and software instruments to be used for the management of data.

Online Database: It is a special Web site interfaced with a database (usually relational). Special languages have been developed to make easier for programmers the creation of Web pages for the updating and querying of databases.

Paleography: It is the discipline studying the ancient script from 9th to 15th centuries (until first printing of documents). Dating and localizing a medieval script, as well as identifying a scribe, are the paleographer's essential tasks on which all historical speculations are founded.

Virtual Community: It extends the sociological definition of community by including the groups of subjects who can never meet themselves or physically know one another but who use the Internet for their interpersonal communication, that is, for sharing information, building new knowledge, and socially interacting.

Chapter 5.10

“You’re In My World Now.”TM

Ownership and Access in the Proprietary Community of an MMOG¹

Sal Humphreys

Queensland University of Technology, Australia

ABSTRACT

This chapter considers how the interactive and social nature of massively multiplayer online games (MMOGs) presents challenges to systems of organisation, control, and regulation used for more conventional media products. It examines how the interactive structures of games cast players as producers of content, not merely consumers. This productive role creates a distributed production network that challenges the ideas of authorship which underpin copyright and intellectual property. The role of the publishers is shown to encompass community as well as intellectual property management. The communities generated within these games are a key source of economic benefit to the publishers. The contract that determines the conditions of access and the forms of governance inside proprietary worlds is considered in light of this newly intensified relationship between commerce and community. Questions are raised about the accountability of

publishers, the role of the market, and the state in determining conditions of access.

INTRODUCTION

MMOGs are a form of new media that challenge, and will reshape, many of the conventional practices associated with media. These intensely social games, in which hundreds of thousands of players create communities and content with each other, exceed many boundaries associated with the organisation, regulation, and control of media. In particular players help constitute these games through their production of game play, derivative works, secondary economies, and strong social networks. This disrupts some of the key foundations underlying other media. For instance, productive players challenge both the institutions of intellectual property and discourses of consumer rights. The creation of ongoing communities inside proprietary worlds raises

issues about the terms of access and the recourse to justice such communities have. The role that contract law takes in determining the rights of players has implications for a much broader set of online applications which can be defined as social softwares.

In this chapter I will explore the structure of MMOGs, looking at how the emergent quality of these games necessarily means that authorship resides in part with the players. The ceding of some control to the players leads to contention and disagreement. Dialogue between developers, publishers, and player communities indicates an ongoing struggle for power in some areas. I will explore how the rise of active fan and mod communities (players who modify games in various ways or create new artwork and other content for games) has led to the development of new business models, where publishers seek to harness the innovative and creative capacities of players. Who should own the results of players' labours, who can exploit the intellectual property in fan-created items is very much dependent on the type of business model being employed by the publisher. These distributed production networks present some major challenges for all stakeholders in the process.

However, fan-based creation of new game objects is not the key focus of this chapter. The even more interesting feature of MMOGs, and the one that presents an even greater challenge to current practices, is the value of the social networks. MMOGs rely on subscription-based models for revenue, and as such, the ongoing and long-term involvement of players is key to their success. The ways in which social networks are facilitated through the structures of the games are explored, and it becomes clear that the commercial success of these games is very much bound up in the affective investments of players. The stronger the social ties within the game, the longer the player will subscribe. This intensified relationship between commerce and culture raises interesting and contentious issues.

If players conduct large parts of their social lives inside the proprietary spaces of game worlds, the terms of access to those spaces become very important. Access is not only to the content created by the developer, but to the other players and to their own electronic identities. The end user licence agreements (EULA) and terms of service (TOS) to many games are one-sided contracts that work to the benefit of the publishers. As managers of intellectual property, publishers are used to dictating terms which work to the benefit of themselves and the authors of the works they are managing. With social applications such as MMOGs however, they have become managers not only of intellectual property but of communities as well. The level of accountability publishers have with regard to their player communities is shown to be very low. Decisions to ban players and deny them access to their communities and their own electronic identities are made without any requirement of a neutral point of view or fairness. With no appeal mechanisms in place, the contracts institute an unseemly high level of power for the publisher over players' affective connections and identities.

I argue in this chapter that commonly used neo-liberal discourses of the empowered consumer, which hold that players, as consumers, have the power to exit from the product if they find the management of the service unfair, ignore players' role as producers, as well as the high cost of exit. I also argue that understanding MMOGs in terms of more conventional media properties, and thus in terms of intellectual property, ignores the role of affect in the production of value in MMOGs.

Finally, I look at the ways in which the unruly player populations challenge and circumvent the various formal and legal restrictions imposed by publishers. Player productivity and agency may well lead to individual experiences of empowerment through these games. However the terms of access ultimately rest with the publisher and as such represent the power to terminate such experiences of connection and empowerment.

Thus the contracts which determine the terms of access are set to become major areas of contention and dispute.

MMOGS

Computer games are an immensely successful form of media, rivalling Hollywood box office in industry annual turnover (Newman, 2004, p. 3; Prensky, 2001) and achieving a high level of penetration into the entertainment market in many countries. In the U.S., sales figures of video and computer games in 2003 were \$7 billion (Entertainment Software Association, 2004). Comparably high figures apply in the UK, Europe, South Korea (where broadband accessibility has enabled network play); and increasingly, China and other Asian markets. Unlike other, more narrative based media, computer games exploit the cybernetic feedback loops available through the technology to deliver a form of content that allows the user to do things with the text. Computer games of all types establish a relationship between the player and the game that is different from the conventional narrative text's construction of the relationship between reader and text. Because of the goal-driven nature of games, the emotional engagement with the text comes, not from the engagement with characters and events such as occurs in conventional narratives, but because the player is an actor themselves. The engagement comes because the player is the performer, and the game evaluates the performance (Juul, 2001). Crucially the game can assess a player's performance and adapt according to that performance. This means the game can present greater challenges to the player as their skill improves (typically implemented through a levels-based structure). This adaptability is often key to a game's success. It represents responsiveness to the player's actions or performance. How games work as texts is very different from conventional narrative texts.

What is implicated in these observations is the issue of control. In a conventional narrative, although the author is not in control of the many interpretations of the text that will occur, he or she is in control of the crafting; the structure; the order of events; the building of tension; the withholding and revelation of information; and so on (Cameron, 1995; Ryan, 2001). In a game some of this control is ceded to the players, who determine to a greater or lesser extent what will happen next. Control for the developer is asserted through the structures of rules, the coding of object behaviours, and the parameters of the game world they create. Players will construct their own trajectories and game play with more or less freedom depending on the tightness of the control imposed by the developer. But the power dynamic in the dialogue between player and developer is quite different from the negotiations between author and readers of a more conventional narrative text.

MMOGs, as a subgenre of the computer games field, represent a particularly interesting case of the negotiation for control of the text. MMOGs can be cast as emergent texts. Unlike some often single-player games which dictate narrow pathways through a game along a particular trajectory, MMOGs are emergent—the rules and parameters of the games are set, and to some extent shape the possible game play—but the direction of play and the events that unfold are largely determined by the players themselves.

The more this quality of emergence is incorporated into media environments, the more the issues of control and authorship will arise. What is implied in the practice of interactivity, in the construction of emergent environments, is that the users will be creators in a distributed production network. As Leadbeater (2000) has pointed out:

The more knowledge-intensive products become, the more consumers will have to be involved in completing their production, to tailor the product to their needs ... In a knowledge driven economy, consuming will become more a relationship than

an act ... with the consumer as the last worker on the production line ... (pp. 32-33)

The importance of this consumer creativity cannot be underestimated. A production shared between developers and players redefines the concept of authorship and this becomes problematic when dealing with conventional copyright and intellectual property laws which mobilise idealist notions of Romantic authorship. How can such a system cope with distributed production spread across not only paid workers in a development house, but also what have traditionally been thought of as consumers—the players. The more productive the players become, the more stretched these systems of understanding and regulating media will be (Humphreys, 2005b).

MMOGs are persistent worlds which allow players to meet and play inside shared environments online. Although console games are increasingly incorporating network play into their capacities, initial MMOGs have been PC-based Internet games. In South Korea, where broadband penetration is high, and where PC Baangs (Internet gaming cafés) are very popular, MMOGs have attracted large populations of players. Lineage was the most successful of the initial raft of MMOGs, with over 3 million subscribers in South Korea and a further 1 million in Taiwan (Herz, 2002a). In the Western world, EverQuest was for many years the most successful, at one time holding a subscriber base of 450,000. Other notable early Western MMOGs were Ultima Online (which was the first MMOG to really develop a large and persistent player base) and Star Wars Galaxies. More recently the publisher Blizzard’s World of Warcraft achieved figures of over 1 million subscribers in July 2005 (Blizzard Entertainment, 2005).

Players tend to be dedicated, and given the complexity of game play in most MMOGs, casual play is difficult. Surveys carried out by Kline and Arlidge (2002) and Yee (2001) put the average playing time of EverQuest players between 20-24

hours per week, with “hardcore” players spending up to 40 hours or more a week inside the game. It is the role of these players in producing value for the games that I want to examine now.

REDEFINING CONTENT IN AN INTERACTIVE ENVIRONMENT

Many computer games have generated very active communities of fans who create their own artwork and objects to import into their game and to share with other players. These mod (after modification) communities of fans bear some resemblance to the fan fiction writer communities that have sprung up around films and television series (Hills, 2002; Jenkins, 1992). They create new skins (artwork including customised clothing) for their characters or avatars, new levels (environments) to play in and sometimes new AI (artificial intelligence characters to play against) for importing into their games. Occasionally players create entirely new games using the game engine from a favourite game. The very successful game Counter-Strike is the product of a team of hardcore players who collaborated to make a new game using the Half-Life game engine. Counter-Strike has won numerous player and industry awards. Some developers and publishers have been quick to harness this creative and often innovative activity, releasing tools for players to use to create extra content for games and facilitating the uploading and swapping of such content between players (Banks, 2002; Herz, 2002b).

Indeed some companies have moved to a business model where they release a platform and rely on players to create most of the artwork/content. The role of the developer and publisher becomes one of service provider and community facilitator (Humphreys, Fitzgerald, Banks, & Suzor, 2005). Auran for instance, the developer and publisher of a train simulation game, Trainz, relies on fan groups of dedicated train enthusiasts around the

world who create trains and tracks modelled on their local railway systems. Thus there are content developer groups for Trainz in the UK, the U.S., Sweden, Australia, and numerous other countries, all keen to create detailed representations of their favourite local trains and tracks. These fans swap their content and their knowledge on how to build them—sometimes for free and sometimes for money, depending on the motivations of the player-creator. Whether player-creators are allowed to own the intellectual property in their own creations depends on the business model and attitude of the publisher. Auran allows players to own their IP and to trade their content commercially. Other publishers claim all IP in the player-created content and disallow commercialisation of it by the players. The Sims is another example of a game heavily reliant on player-created content (up to 90% of content is created by players according to Herz [2002b]), but Electronic Arts, the publisher, does not allow commercial trading of content created for the game by players.

Many of the MMOGs do not have the facility that allows players to upload their own objects and artwork into the game. There are some straightforward practical reasons for this. In a persistent dynamic world, which may host up to 10,000 players on a single server, and run 50 servers or more, ensuring the smooth technical running of a server becomes much more difficult if new, player-created objects need to be constantly integrated into the world, not only for that player but for every other player on that server as well. Second Life, which is a persistent world (but not a game—it is an environment but lacks the goals and built-in rewards and rules of a game), allows users to create their own objects in the world. This is the exception rather than the rule for persistent virtual worlds. Second Life TOS are such that the players own the intellectual property in their creations. Linden Labs, the publishers, have implemented Creative Commons licencing for their users in an effort to enable smooth interchange

of objects between players. Linden Labs are very clear that they see the main source of innovation and creativity in their world as emanating from the users (Ondrejka, 2004).

Whether players and users are given the right to own the in-game objects, and whether the objects are created by the players or the developers, a secondary market has sprung up on the Internet in which these items are traded for real money (Castronova, 2001; Dibbel, 2004). Their status as property is not really under dispute any longer. Hunter and Lastowka (2004) assert in relation to games and game items that “...no obvious reason exists prohibiting the recognition of legal interests in intangible virtual properties” (p. 294). The issue then becomes what kind of access or exclusions are agreed to in relation to those objects by users/players and developers/publishers through TOS or EULAs. One option is for the publishers to claim all rights of ownership in the objects, and the rights to exploit the value in those objects. Implementing Creative Commons licencing is another. Or, as Benkler (2004) suggests, a further option is to implement the GNU Free Documentation licencing (the form of open source licencing adopted by wikipedia) that effectively creates no exclusions at all.

What I want to address now is the idea that content is more than the coded objects and artwork in these environments. The idea that Benkler (2004) raises, which I want to explore further here, is that it is not the digital objects that we should be focusing on. Referring to these online virtual worlds Benkler says: “... it is a form of social software, mediating a social relation among individuals...” (2004, p. 1). Benkler’s attempt to shift the debate away from who should own the virtual spoon or sword offers an opportunity to begin to understand online interactive environments as more than intellectual property.

When a player logs into an MMOG such as EverQuest what he or she engages with is much more than what the developer has created. The

world and the objects in it have indeed been coded by the developers. But game play is made not purely through engagement with these things. Game play happens through engaging with both the world and its objects and with other players. Solo play is not much fun in these games, although it is possible. However MMOGs tend to be structured to actively reward social play and discourage solo play. EverQuest for instance is not a game where you can fight other players (apart from on a dedicated player-versus-player server). The idea is to team up with other people and fight computer generated opponents. Most computer generated opponents after the early levels of the game are impossible to kill through solo play. The game rules and the game engine code both work to structure social play as the norm. The establishment of in-game communities is an integral part of a games' success.

Thus, while some of the engagement for a player may come from mastering skills inside the game, to a greater or lesser extent, the other source of engagement comes from interacting with other players. What constitutes content in the game is only partially created by the developer. Even in games where players cannot make their own objects for the game, they are still creating game play and content that other players engage with. There are a number of implications that arise from thinking about content in this way.

Firstly, it requires rethinking the model of production from the more conventional linear structure: a chain of events that begins with an author (or team of authors), who create and finish a text, which is published and distributed by a publisher to an audience under particular conditions of copyright. The MMOG product is not finished by the author. It continues to develop after publication. Furthermore, after publication the content is created by both the paid developers and the unpaid labour of the players. Rather than linear, the production model is recursive and networked. Rather than a single author (or

developer team known as author) there are multiple authors.

Thus, secondly, a networked or distributed production model brings into question the idealist conception of the romantic author upon which much copyright is based. How does intellectual property law articulate with collaborative social production? Is it an appropriate form of law to be applied in this context? The complexity of intersecting interests and rights in an environment that embodies social as well as property elements, and production as well as distribution issues, raises serious challenges to the paradigm of intellectual property. In a proprietary environment the implication is that in-game communities are owned and controlled by publishers. Rather than accepting the key terms of the debate, which tend towards arguments about who should own the intellectual property in particular works, it may be more pertinent to ask: Should some things be owned at all?

These are issues that have been explored in relation to indigenous, oral, and folklore cultures which have had to interface with economies based on individual property rights. Solutions for protecting the collectively held rights of those cultures in such contexts have tended to entail the introduction of new mechanisms (and displacement of old ones) for understanding them as property. But when social relations and processes become subject to a property regime they are reified—what was fluid becomes fixed, what was process becomes a thing, a commodity.

Coombe points to the ways in which copyright or IP law freezes:

... into categories what Native peoples find flowing in relationships that do not separate texts from ongoing creativity production, or ongoing creativity from social relationships ... (Coombe, quoted in Smiers, 2002, p.128)

Engagements with property law produce particular effects and kinds of truths about the

medium in question. Invoking property law can preclude other understandings and shape practices in particular ways.

In current contexts, it seems almost inevitable that intellectual property should be the lens through which this multi-user online medium is viewed. Intellectual property shapes the institutional practices surrounding it. But as Frow (2000) points out, the teleological assumptions that accompany arguments of inevitability need not be accepted. Institutional practices (for instance those of the publishing industries) are the result of a historic series of strategic moves made by the stakeholders and represent the enactment of particular power relations. These can be countered in equally specific and strategic ways. The framing of all issues pertaining to this area as property issues closes down other debates that might be had. As Coombe (2003; glossing an argument put forward by Vaidhyanathan) suggests:

... once all questions of authorship, originality, use, and access to ideas and expressions become framed in terms of property rights, discussion simply seems to end and maximum protection seems ordained; how can one argue in favour of theft? (p. 3)

If one looks at what constitutes content in an MMOG environment and understands it as being social interactions as well as bits and bytes of code, then it seems that questions about authorship and property may not be the right questions to be asking. Thus I want to turn now to the role of affect in producing value, and the issues raised by these new forms of interconnections between commerce and culture.

THE VALUE OF SOCIAL NETWORKS

Most MMOGs run as subscription-based games. As such, they rely on players having a sustained

interest in the game. Single player games more often involve a point-of-sale interaction between the publisher and the player. The player engages with the game until they have “cracked” it—mastered it—and then moves on to the next game. MMOGs do not have an end. Players may engage with an MMOG for upwards of 5 years. While the content supplied by the developer and publisher may be one of the reasons for this extended engagement, the key reason will be the strength of the social ties a player develops within the game. The stronger the ties, the longer the engagement, and the longer the monthly subscription rolls in for the publisher. The commercial value of the game is thus very much linked to the social networks generated within the game. This intensified relationship between commerce and culture is one which brings up interesting challenges and issues for both businesses and players.

Developers design their games to reward social play and discourage solo play. While the quality of emergence ensures they cannot predict with total certainty how a game community will unfold, they can structure into the rules and parameters of the game environment affordances which encourage social engagement. For instance, rewards may be greater when slaying a computer generated opponent (mob) in a full group than when slaying it solo. Some higher level mobs may be impossible to kill without a group. In games such as EverQuest slaying a higher level mob can require a raid of several hours and up to 70 players. The ability to organise a group of 70 players to be in one place and fight cooperatively against a joint opponent demands a strong, established network of social contacts as much as it implies strategic and fighting skills.

Most MMOGs offer some kind of infrastructure that allows people to form guilds, or clans—ongoing social groups—that can create the basis for networks that persist over time. Such structures might include: chat channels that allow easy communication between group members, even when not colocated in the game;

tags that identify players publicly as belonging to a particular group; locations within the game that “belong” to the group and where they can meet; tools for creating distinctive group emblems; and so on. These structures do not necessarily mandate the kind of social relations which are built, they more facilitate the building of ties.

My own research in EverQuest showed that guilds ranged in type from the ultra competitive, efficient, and dedicated über guilds that expected their members to raid five or six nights a week for four or five hours a night, to more “family” oriented guilds which focussed less on ultra high achievement and more on friendly, helpful social interaction. I interviewed one player who patiently worked his way through an 8 month admission process, attending five or six raids a week, to get into what he considered to be the most elite guild on his server. On the other hand, one guild I joined and stayed with for several years seemed to run more like a soap opera. Friendships and romantic liaisons were formed and broken; in-guild marriages celebrated; alliances with other guilds made and broken; bouts of group petulance and mass sulking were followed by an exodus of half the guild; recruitment drives were mounted; and various other ebbs and flows of goodwill and rancour kept the members engaged and active. The sometimes repetitive game play, which some of the players had mastered years ago, was made fun again by the social engagements required to pursue it. Raids could be completely absorbing; requiring concentration; coordination of players and groups; and skills on the part of individuals. They could result in triumphant teamwork or abysmal failure and “total mass wipeouts,” but as one player told me, you could bond with your group better if you had experienced adversity and obliteration together.

Given the amount of time many of the players spend inside MMOGs it seems clear that at least some are conducting their social lives within the game worlds. They are forming enduring relationships of one kind or another with other players.

Sometimes there is a crossover between online and off-line relationships, with players who know each other off-line playing together inside the game. Sometimes players meet off-line having initially met online. As such, the communities within the game can be seen to exceed the boundaries of the game. But on the whole, the communities conduct their main activities within the proprietary spaces of the publisher.

TERMS OF ACCESS

6. We may terminate this Agreement (including your Software license and your Account) and/or suspend your Account immediately and without notice if you breach this Agreement or repeatedly infringe any third party intellectual property rights, or if we are unable to verify or authenticate any information you provide to us, or upon gameplay, chat or any player activity whatsoever which we, in our sole discretion, determine is inappropriate and/or in violation of the spirit of the Game as set forth in the Game player rules of conduct, which are posted at a hotlink at www.everquestlive.com. (extract from the EverQuest EULA, emphasis added. Sony Online Entertainment, 2005)

The previous paragraph is taken from the EverQuest EULA that all players click through each time they log on. The agreement is some seven pages long, and if the player wants to understand some of the terms they must consult the EverQuest Web site (for instance the Rules of Conduct they agree to in the EULA are only found on the Web site, and consist of a further eight pages of text). It seems doubtful that many players read through the entire document. The contract is not negotiable. It is a manifestly one-sided contract which works in favour of the publisher and to the detriment of the players. Its terms may be changed without notice or negotiation at any time, it lays claim

to all player created content, and it allows the publisher to disclose information about players to government agencies and other private entities at its own discretion.

The EULA represents the point where contract law intersects with a number of other areas of law and renegotiates the boundaries. The right to determine what conditions of governance will exist in a particular game world are premised on ownership of that world by the publisher or developer. Taylor (2002) has noted:

... we increasingly live in a world in which opting out of technological systems is becoming more and more difficult ... and yet participation within them pushes us to accept structures we might oppose. (p. 233)

With the advent of online virtual worlds, we see an increase in the number of people conducting their community life and social relationships within proprietary spaces. The publishers wield power over players through both intellectual property and contract law. The power they exert has the capacity to limit the access people have to their own electronic identities and their communities. This power is based on, as Hardt and Negri (2000) point out, an increasingly abstracted concept of private property, coupled with contract law which is able to reset the terms of engagement between the parties. Contracts are often able to get individuals to waive their rights, and courts are increasingly allowing this to occur.

It is worthwhile highlighting here how contract law can individualise an arrangement, and thus override the collective rights that may be protected by law focused on a more “universal” public good. However, as parts of our lives are increasingly conducted in proprietary spaces, those spaces take on the characteristics of a public commons, and the role of the publisher begins to resemble that of a state. If the publisher is to usurp the state and its powers by redefining law through private contracts, perhaps it is time for the “real” state

to intervene and regulate what the terms of those contracts might be. Leaving this regulation to the marketplace is not an adequate solution, given the lack of real interest the marketplace has in citizen rights, justice, or equality.

The value of affect, of social and emotional investment and its relationship to economics is not easily articulated. Developers and publishers know that the social relationships and the emotional investments of players are the key to a successful MMOG. Businesses know about and utilise affect and cultural production as part of their economic strategies (Jarrett, 2003). Communities and social networks can create “site stickiness” on the Internet. Brand loyalty is a result of an affective process of creating and harnessing desire in consumers. The economic value of affect in the networked, knowledge economy is huge. The intangible nature of affect makes its commodification hard to measure. In a discussion of intellectual property in this context, affect is often ignored or erased—it has no place in a discourse of property. However, rather than ignore it, it may be time to broaden the range of discussion that occurs around interactive media products to encompass the role of affect. Does utilising affect for commercial gain come with any obligations or systems of accountability?

The creation of subscription-based virtual game worlds has generated the creation of communities. How are these communities to be managed? Do game participants hold all the rights of an ordinary off-line citizen—the right to the same protections and freedoms? Is a publisher under any obligation to treat the game world community fairly? For instance, in the EULA for EverQuest, cited previously, Sony Online Entertainment (SOE) reserves the right to ban players’ accounts (and therefore access to the game) on a number of grounds, including if the player plays “against the spirit of the game” (SOE, 2005). Such a catchall term in effect gives SOE the right to terminate the service for pretty much any reason it wants. There is no system for appealing such a decision.

This is the case with many other games and online environments, including various AOL, EA, and MSN services.

[I]t is disturbing to learn that online intermediaries (the companies who create online spaces—currently, games, but in the future, private internets) now have “ownership” of online identities. These providers may not be very accountable or transparent, and their rules may be effectively unreviewable by any terrestrial court or legislature. This means online intermediaries will be handing out “law”, whether we like it or not. Online intermediaries are a different source of law than those we are used to (such as courts and legislatures). (Crawford, 2004, p. 219)

Although it is clear that publishers need to be able to ban players from their games if they are “griefing” other players (cheating or being outrageously disruptive and antisocial)—there is no guarantee that all players operate with the same understanding of griefing (Foo, 2004) or that publisher decisions on this will be fair or right.

A private online intermediary has no particular legal requirement to be neutral as to viewpoints or actions of users. Courts will defer to extraordinarily broad (and ever-changing) terms of service for these online worlds. So the law of identity online is private, contractual law. The use of force online—the removal of identity—has been handed over to private parties. (Crawford, 2004, p. 221)

In current neo-liberal discourses of the empowered consumer in the marketplace, the consumer is seen as endowed with agency and the ability to make choices between products. If a player does not like the style of governance in a game they should change games. To a certain extent this is possible. However the role of affect comes into play here in significant ways. As discussed, players create communities within MMOGs. This entails

often significant investments of time and affect. And once embedded into a community, once many of a players’ friends are to be found within a game, then the cost of leaving the game is very high. Building friendships is a time-consuming process. Accruing social status, constructing networks, building reputations, are all activities that players invest time and affect in. The high switching costs for the player mean they are not free agents, able to move through the market at will. Changing games is not like changing your brand of jeans. Their agency and mobility is constrained by the affective elements of their investment in the game. And let us be completely clear about the fact that the investment of the players in this way is directly, economically beneficial to the publishers. It is the networks and communities that keep players’ subscriptions coming in year after year.

There are two key things of interest here. The first is that the affective and time investments of players create part of the content of the game—they are co-creators of the game with the paid developers. As such, it is limiting to conceptualise players as consumers. They not only consume, they also produce. As what they produce gives them a sense of ownership in the game (and at the very least a sense that they own their own identities online), and constrains to some extent their ability to leave, a discourse of consumerism which locates their power as residing in their exit power, fails to adequately encompass what is at stake. In fact it offers a very diminished position of power to the players. Thus the discourse of the players as consumers erases their role as producers. And we should not fail to notice that their productivity is very profitable to the publishers.

Second, because affect and social networks and communities are intangible, and not properly thought of as property, they are erased from discourses which frame these media products as intellectual property like any other media property. Interactivity and networking—the two key aspects that differentiate new media from more

conventional media thus raise serious challenges to such discourses. These characteristics highlight that in a new media environment, with actively productive users, what is produced bears little resemblance to the other products dealt with by intellectual property law. Not only is the process of production no longer linear, the authorship multiple, and the product never "fixed" like a conventional text, but the nature of networked, collaborative environments is such that communities and social relations are central to the product. The legal rights of people participating in proprietary worlds accessed through contracts need to be considered. The terms of the contracts currently are manifestly one-sided and seem to diminish participants' access to administrative justice at the very least.

THE CHAOTIC UNRULINESS OF PLAYERS

The previous discussion deals with the formal and legal structures associated with MMOGs. But as with any emergent and social environment, the actual practices of the players and the publishers differs somewhat from such formal mechanisms of control. As with any community, online or off-line, proprietary, public or private, behavioural norms are established and policed by the participants as much as by an outside body or institution.

Communities can be to a greater or lesser extent self-governing. Publishers cannot wholly determine every norm within the game through code and customer service policing. Any social group will have ways of establishing and policing community norms. Regulation of conduct can be enforced through a variety of social mechanisms. The public shaming of cheats—shouting the name of "loot stealers" through the zone for instance—can be a means of enforcing certain norms. Group norms vary across the different communities found within the same game. Some guilds are very hierarchical, others more like a

drunken party of equals. Some work towards cohesive team actions, some run like a primetime soap opera. Some groups may establish role-playing norms and others ridicule them. Clashes between groups with differing norms may cause more widespread discontent within the game.

Publishers have a great deal of latitude in how they choose to intervene in the communities. Decision making with regard to community governance can rest to a great extent with the players if that is how the game is designed. The MMOG *A Tale in the Desert* was an example of a game where players were able to suggest and vote on in-game rules and government, up to a point. The balance of power can shift according to the game, but to some extent will be reliant on the nature of the game itself and whether, for instance, having player populations vote on rule making in the game actually fits with the themes of the game.

In a series of interviews conducted in 2003, I encountered a variety of attitudes towards the role and conduct of customer service among players. Some were adamant they would rather seek their own solutions to in-game disputes—be they at the personal or the broader- and inter-guild level. They did not want any external, customer-service-based intervention in disputes. Others said they were quick to report to customer service what they perceived to be bad behaviour or violations of codes of conduct. Most had dealings with customer service over bugs and technical glitches that left them stranded in places they were unable to shift from themselves. I encountered a number of players who had stories about the perceived inconsistencies in the decisions meted out by customer service. Several told stories of being very confused as to what actually constituted an "exploit." Trouble seemed to arise around the finer points of when play is actually cheating and when it is just clever, expert play from someone who knows the game inside out. I heard stories of players who had warnings placed on their accounts or who had been banned for acts they

considered to be perfectly reasonable or to have been misinterpreted by the customer service team (Humphreys, 2005a).

The key issue here is not whether the player was right and the customer service team wrong, but that there is no dispute resolution system in place that can hold the customer service team accountable for its decisions. If a player feels their account has been banned unfairly, where do they go to appeal the decision? If there is misunderstanding about the rules, or differing interpretations of the rules, where can this be argued?

It is at this point, where there is uncertainty or ambiguity about the governance of the community, that the role of the publisher as community manager most obviously becomes problematic. Given the level of investment some players have in the game, and given the value that their investments add to the game for the publisher, is it enough to say "well, there are other games in the market, they can just move on to one of them instead"? Should a player be expected to wear the high cost of a poor decision made by a possibly overworked customer service team, or should they have access to a system of appeal? Should publishers be able to insist on such contracts without these mechanisms in place?

Many players circumvent the customer service team's efforts at policing—buying new accounts (against the terms of the EULA) at online auction sites. However this can be a costly process—high level characters cost many hundreds of U.S. dollars at the online player auction houses. The secondary economy surrounding MMOGs (in which players buy and sell in-game money, objects, and characters), is an indication of the ways players exceed the boundaries laid down in contracts. The trade being done in in-game items through auction houses—the secondary markets—was estimated to be worth \$880 million at the 2004 State of Play Conference at the New York University Law School (Salyer, 2004). Almost all MMOGs explicitly ban this kind of trade, although some publishers are beginning

to work out ways in which they can become the brokers in this market and make money from it themselves, but this model is currently still in its infancy. Whatever the arguments for and against such secondary economic activities, the practice of banned players going online and buying new high level characters still represents a cost to the player for an action on the part of the publisher that could be construed as unfair. The rebuilding of social status and identity is also implied in this process.

Players may be significantly empowered on a personal level through their playing of MMOGs. I conducted one interview in the course of my research with a woman whom I had encountered inside EverQuest. She was a guild leader in a guild with several hundred members. She played about 40 hours a week. She knew just about everything there was to know about EverQuest. Other guild members turned to her for advice and sought her expertise on many aspects of the game. She organised raids and led them a number of times a week. She had a range of characters, all of whom had "partners" online—some were married, others were strategic alliances, and others she characterised as mere flirtations. She held considerable status amongst her peers and was seen as competent and capable. When I travelled to meet this woman and interview her, she turned out to be disabled, limited in her mobility, and unable to get work outside the home. She lived in a basement flat with her husband and two children. She did not really like her husband, but felt unable to leave the relationship because of her financial and physical dependence upon him (she could not, for instance, tie her own shoelaces due to her disability).

For her, EverQuest was a place where she could access social status, recognition for her leadership abilities, romance, and friendships that were unavailable to her in her off-line life. That EverQuest was a source of empowerment for her could not be in doubt. There is, however, a difference between this kind of personal empowerment

and the structural power relationship that exists between her and the publisher. In this relationship, the publisher holds the power to deny her access to EverQuest. All the positive empowering aspects of creating and engaging with online social activities and social networks mean nothing if you cannot actually access them. Thus, I want to make clear the distinction between the kinds of power players that may develop within the game, and the kinds of power involved structurally between players and publishers around the issue of access.

Players have held protests inside games—for instance, in *Star Wars Galaxies* where a swathe of players were banned by customer service after a “duping” scam was implemented by one player. Rather than tracking down the source of illegally duped (duplicated through exploiting a bug in the code) items, any player who had bought one was banned by the customer service staff. These players were unaware of the duped status of the item they bought, but were banned nonetheless. A protest of several hundred players was held in a particular zone of the game. Players were transferred out of the zone by the customer service team and had their accounts warned (a flag that precedes banning).² It was an interesting event for the ways in which it became obvious that the customer service team were the holders of structural power—able to deny access with no accountability. The players held exit power—they could leave in protest and take their business elsewhere—but for many this represented too great a loss to contemplate. While many of the banned accounts were eventually reinstated, the customer service team were actually under no obligation to do so.

Thus while players can be seen to exercise a certain amount of agency within MMOGs, creating their own communities and game play and experiencing various forms of personal empowerment through their activities, there are ultimately structural limits on that agency. While it is in the interests of the publisher not to alienate the communities it is managing inside a game,

this constraint on their behaviour is not enough to ensure players are treated fairly and that access to their online identities and communities is maintained in an accountable manner.

CONCLUSION

MMOGs represent one of the most interesting turns that interactive media have taken—subscription based, interactive, emergent, social, networked—they exploit many of the features of “new media” that are new. They are much more than repurposed “old” media. They are an exemplary knowledge economy product. MMOGs embrace the productivity of their users and turn it to the advantage of publishers very successfully. But this new form also brings with it challenges to conventional publishing and legal practices. The regulation of such media is a complicated proposition, particularly in relation to the fair treatment of individuals and communities conducting their social lives within the game worlds. While it is probably simplest to argue for a free market solution to the questions of governance, I have argued that this latest interface between consumer/citizens and media corporations may require more complex treatment. If online identities and online communities are owned by a third party, the conditions of access to them become crucial. As we come to live more and more of our lives inside proprietary spaces, what role are governments to take in ensuring our fair treatment? Can we afford to let our commonly held public rights devolve into a series of one-sided contractual arrangements with corporations that work in the interests of profit above all else?

While MMOGs may seem like a fringe example in terms of the numbers of people they attract, the issues raised by their structure and the business models used to maintain them, will become important ones across a broad spectrum of applications which also utilise Internet-based social software. Their reliance on distributed

production and the value of social networking, with all the inherent contradictions with copyright and intellectual property laws, and their need for social governance, flag what will become major and complex issues for businesses, law makers, and users. The central role of affect and its intersection with commercial imperatives requires further consideration from all parties.

The users of such applications (be they games or other online environments) take a very active role in constituting the content and may in the future be less willing to accept the very uneven TOS currently on offer. But in a world of constrained choices, where the market does not in fact offer the kinds of terms users might wish for, the role for policy making and regulation will become clearer.

Chapter 5.11

Digital Petri Dishes: LiveJournal User Icons as a Space and Medium of Popular Cultural Production

Alek Tarkowski

Polish Academy of Sciences, Poland

ABSTRACT

Internet applications such as Web-based blogging and instant messaging tools or social networking sites often provide their users with the possibility of displaying small graphic elements. Such “pictures” or “icons” allow users to represent and mutually identify themselves. This text is an analysis of user icons displayed on the LiveJournal blogging site. I treat such a user icon as a medium with particular characteristics and patterns of usage. LiveJournal users use such icons to participate in what John Fiske (1992) calls popular culture. A case study of user icons discloses the life cycle of the media form, during which a medium with initial characteristics coded by its creators begins over time to support a wide variety of uses, innovation in usage, and active participation in culture. In this chapter, I consider user pictures and practices that are tied to them as an example of the manner in which popular culture functions in the digital age.

INTRODUCTION

LiveJournal is one of the more popular blogging tools, a Web-based application that allows users to run an online diary or journal. LiveJournal at its nascence was itself a result of user innovation. It was written by a 19-year-old programmer named Brad Fitzpatrick as a tool that would allow him to stay in touch with high school friends after leaving for college. LiveJournal’s user base has been constantly growing and in early September 2005 there were almost 8.2 million registered journals and 1.4 million users who have updated their journal in the preceding month. Although the exact historical data on LiveJournal growth is not readily available, such data is for the purpose of this chapter insignificant, despite the general hype surrounding the growth of blogging. Neither are these numbers quoted to prove the importance of the site, as cultural significance cannot be easily quantified into statistical figures. It is the scale of the phenomenon, which involves hundreds of

thousands of Web pages, users, and communities formed by them, that is important. It is the scale of a fair sized city, a size at which any phenomenon must be internally varied and heterogeneous.

As an online publishing system, LiveJournal is a tool that can be used for production, exchange, and reception of cultural content. Furthermore, this content and the interface with which it is produced forms an axis for communication and formation of social associations. LiveJournal's architecture is designed to support interaction, in particular by enabling the creation of "communities." These collectively written journals are spaces for discussion, similar to online forums. Each community, treated as a media form, is an anchor for a collective of users that expresses itself in the community's online space and is commonly thought of as a community as well. Posts and comments are both instances of personal expression and traces of interactions between users. They are shared and public because they have been archived by the system, while other aspects of these interactions remain invisible, as they took place in private spaces and channels or even beyond the Internet. Although LiveJournal is constantly being accessed in the present, its public space has a historical, archival character as it consists of content stored in LiveJournal servers. A community of users communicating through LiveJournal constructs in parallel a community as a media form, a record of own interactions stored as the system's content.

Defining LiveJournal as a blogging site has its consequences. Blogging is a phenomenon that is a prime example of what Woolgar (2002) calls the cyberbolic social studies of the Internet, based on "...synoptic, top-down (and often un-explicated) depictions of technical capacity and effect" (p. 4). We can instead think of LiveJournal as simply an online infrastructure for publishing content. It is a digital medium primarily designed to support textual communication and to remain open—it has few restrictions or even guidelines

regarding the produced content. There are almost no preferred themes, style guidelines, or editorial policies, except for the general standards of decency, to which users must adhere. The only significant limitation is the difficulty of publishing multimedia content, as LiveJournal does not provide users without paid accounts with server space for content other than text.

A distinction should be made between LiveJournal as either an application designed by its administrators or a material, technical artifact—and LiveJournal as it is perceived by its users. The relative simplicity of the application means that it is the content and not the medium itself that defines user's experience. While sharing the label "LiveJournal journal," individual sites can greatly vary and the system itself can have different meanings for different users. The heterogeneity of uses, themes and interests, or communities means that there is no "typical," model use of LiveJournal, no synoptic description it will fit into (Woolgar, 2002).

LiveJournal as a system has a border that is porous and only roughly relates to the symbolic limits of the livejournal.com domain, making it even more difficult to consider LiveJournal as a single medium and a homogeneous environment. At the level of code and content, users outsource the storage of visual content to other servers and service providers. Links from the site constantly direct the viewer beyond LiveJournal. At the social level, LiveJournal is but one tool and space in a wider digital environment. Users use this tool to varying degrees and ascribe to it varying degrees of importance. Activity at the LiveJournal site is for a vast majority of users only a part of their online activities, which in turn are only one aspect of their media-saturated lives. The porous character of LiveJournal means that its users and components "pertain to them by one side only, but through the other sides, ... escape from the world they constitute" (Tarde, 1999, p. 80).

USER ICONS IN THE CONTEXT OF THE LIVEJOURNAL SITE

A user picture or user icon is a graphic selected by the user and displayed on his/her journal. To some extent, it is designed as a visual counterpart to the username. According to the intentions of LiveJournal designers, these pictures serve to represent the user, disclose elements of his/her identity. The LiveJournal FAQ states that “[u]ser pictures are icons or avatars used to represent yourself, your moods or feelings, your interests, etc. They are displayed in numerous locations on LiveJournal ...” (asciident 2005). An icon appears on a user’s journal page, a user info page containing selected information about the user appears alongside posts and comments authored by the user.

When it comes to choosing an icon, system administrators provide only a limited set of guidelines that pertain solely to the technical and code levels of an icon. Each picture has to be a .GIF, .JPG, or .PNG file, not larger than 100x100 pixels and with a file size not greater than 40kb. While the definition of the user icon does suggest that the image should be iconic in nature, it is not explicitly stated that a user picture must be a picture of the user. The only limitations concern use of explicit content. LiveJournal FAQ informs users that their pictures, especially the default one, are freely accessible and therefore potentially available to any user. Thus the default picture cannot contain explicit content, while other user pictures can be of a more graphic nature.

A user with a free account is entitled to an icon pool of three different pictures, while with a paid account the number increases to 15 different icons. With an additional purchase, a user with a paid account can raise their total number to 100. Additional user icons are one of only a few extensions of the paid suite that a user can purchase. LiveJournal allows users to upload pictures, select the default one, and assign keywords, which

later are used to select a picture accompanying particular posts and comments.

LiveJournal FAQ provides little advice about creating an icon and formatting it so that the technical limitations are met. In order to do so, access to and at least basic competency with graphics or photography software is required. The FAQ states only that: “[y]ou have the option to create a userpic yourself. In order to do this, you will need an image-editing program. If you do not have an image-editing program, you may wish to use your favorite search engine to find one. You can also find a userpic from a website or from a LiveJournal community” (asciident 2005).

Therefore a user does not have to follow any rules or guidelines regarding the creation and usage of icons, and neither is much guidance given. Due to this lack of prescribed uses, and to minimal technical limitations (the size of the image being the only significant one), a user icon is an open tool. An analysis of user icons on LiveJournal shows that with time the way they were used went beyond the simple representation imagined by system’s designers. The ability to freely create icons is coupled with the possibility of selecting, from one’s icon pool, an icon appropriate for the given situation. This allows users to control both a user pool, which can be considered a way of visualizing their personality or identity, as well as the default icon displayed on a user’s journal and icons shown alongside posts and comments. In this manner a seemingly simple feature becomes a potentially versatile medium for not only representing, but also expressing oneself and communicating with others. As we will later see, the usage of icons commonly goes beyond displaying one’s photograph.

The user icon as a medium and a body of specific user icons are the subject of this chapter. An icon is a media species, as well as a population of individual icons. The species itself has its own life cycle, as uses develop and evolve over time and initially prescribed uses become but a

starting point for cultural innovation. It is through contact with users that an icon becomes a hybrid of initial assumptions or specifications and ever new practices, expectations, and imaginations. We can compare the difference that exists between prescribed and actual uses to the distinction between *langue* and *parole* made by De Saussure (1991). User icons can be understood as serving several purposes at once: (1) a tool designed by LiveJournal programmers to fulfill a certain function both within a single journal and in a system of hyperlinked journals; (2) a tool and medium made available to the users, who adapt it to their own uses and needs, transforming its function and potential; or (3) a body of cultural content stored by users on LiveJournal servers and displayed as user icons.

The user icon is a layered phenomenon. A tripartite layer model has been initially proposed by Benkler (2000), who distinguished the physical, code and content layers of the Internet. In the case of user icons, the influence of the physical layer is of secondary importance, as it does not directly affect the icon that exists in an environment formed by several sublayers of the code and content layers, such as the World Wide Web and the LiveJournal application. I therefore distinguish instead between the layers of code, content, and interaction. At the level of code, an icon is a field in an individual database entry, which can store a bit of content data that meets a set of requirements. At the content level, an icon is an image visible in the user's browser. At the interaction level, icons are material artifacts to which cultural practice and social behavior are tied.

The life cycle of an icon as a medium begins when the icon is a potential form with a prescribed usage defined in its code layer. At a later stage, the user icon turns into millions of existing images and displays a complexity and variety typical of the everyday life of LiveJournal users, in which these icons, as tools and objects of popular culture, are involved.

The use made of an icon by a user is influenced by several factors present at different layers of an icon. It is partially defined by the architecture of the icon's code, partially by a prescribed usage, which is a norm defined by LiveJournal's creators (and enforced not only through system's code), and partially by individual experience: by observing other's icons and uses made of them—a collective history of icon usage.

LiveJournal icons are an interesting cultural phenomenon for several reasons. Firstly, they constitute an opportunity to analyze the relation between an initially prescribed use and the actual use patterns developed by users. Or put in other words, to analyze the differences between the imaginations of the creators and users. Media designed as open and interactive have a potential to support cultural innovation. The end-to-end argument (Saltzer, Reed, & Clark, 1984) describes a telecommunication network like the Internet, which by remaining open and simple, effectively hands over control of the service to end users and thus fosters innovation of usage (Lessig, 2000). Alongside improved innovation, an end-to-end network has normative benefits: greater diversity of participating groups and weaker third party control or censorship (Sandvig, 2002). Uses that icons are put to become varied with time and grow beyond the frames set by LiveJournal's creators. Like the Internet, both the LiveJournal system and its user icons form a medium that does not discriminate against transmitted content. In each case, an open code layer supports a varied and vibrant culture at the content level. The Internet thus has a recursive structure and its parts display similar characteristics to the Internet itself. Embedded in the online media environment are media forms that serve as both containers for content and content-generating structures. Multiplicity and variation of forms that grow from a relatively simple and limited medium proves the hypertrophic nature of modern culture. The user icon is but one simple feature of a single

online application, yet it involves a wide number of users and supports varied and lively cultural production.

It is difficult to find direct parallels to user icon usage in off-line or predigital culture. The production of user icons depends on the ability to cheaply and easily find, copy, and transform content, offered by digital tools. When searching for similarities we can compare LiveJournal icons and their uses to:

1. fashion elements, such as pins, t-shirt designs, or patches;
2. scrapbooks with clippings from color magazines;
3. teenage bedrooms, filled with posters and photos;
4. graffiti, stencils, stickers, and other forms of individual expression in public space; and
5. ID documents or membership cards.

My analysis focuses upon icons as symbolic tools and the varied uses made of them. I am less interested in their content and avoid interpreting their meaning or significance. An accurate interpretation is difficult if not impossible and we should heed the warning of Barthes, who describes the “terror of uncertain signs” (Barthes, 1977, p. 39). The meaning of visual content is almost limitless and thus uncertain when they are placed out of context and not fixed by text information, as is often the case in digital media, characterized by an ease of recombining content.

First of all, it is often difficult not only to establish the origin and authorship of a given icon, but also to ascertain whether the given content is a product of the media industry or a popular cultural production. This is due to the fact that homemade, visual Web content can today be of similar quality as commercial content, especially in the case of objects that are relatively small and of low resolution. High levels of cultural competence are required to identify content and

to understand the web of allusions, parallels, and citations weaved by LiveJournal users. Secondly, a single icon is displayed in the multiple contexts of different Web pages, text, and other images. It has a different meaning when displayed alongside all of the user’s icons in the icon pool, different when present—like a digital crest—in a prominent place at the user’s journal and yet another when displayed alongside individual posts and comments. A researcher can also easily extract icons from the system and attempt to analyze them on their own. Following Barthes (1977), we should interpret the meaning of icons as only one layer in a wider web of meanings. However, this would quickly force us to deal with the complexity of analyzed environment, which I tried to avoid by focusing on the user icon as a single, simple feature. LiveJournal content in general, as experienced by the researcher, is separated from the everyday lives of its users and creators, it is but one aspect of a whole largely invisible to a student of online culture.

I believe though that we can also think of icons as a medium with which the researcher can visualize a given cultural phenomenon. While researchers of new media still lack tools for analysis and interpretation of online materials, the visualization of cultural phenomena through a focus on their visual aspect can be a valid method for dealing with encountered complexity. Bendyk (2002), in his analysis of the Bovine Spongiform Encephalopathy (BSE) epidemic, shows how public perception of the threat—an infectious particle known as prion—was changed by visualization techniques: “3D visualization software made the prion, until then an abstract concept for most people, come alive” (Bendyk, 2002, p. 154). Bendyk observes that visualization can provide insight that is imprecise or even false, but the same can occur when we try to grasp complex phenomena with concepts. The term translation (traduction) is used in Actor Network Theory to describe a process of reality construction, in

which a single actor speaks on behalf of others and imposes upon them his/her own description, and therefore construction, of reality. In the process, “identity of actors, the possibility of interaction and the margins of manoeuvre are negotiated and delimited” (Callon, 1999, p. 203). Translation involves opening and closing of phenomena, so they can either be disclosed as complex or made to look like simple “black boxes.” Cyberbolic analysis of new media is criticized by Woolgar (2002) as an example of translation that takes a complex phenomenon and translates it into a homogeneous system with uniform uses and effects.

User icons exist in a space where mass media content and popular cultural content, arising out of everyday life, meet. They therefore allow the researcher both to trace the boundary line and study interactions between the two spheres. We can see how the online lives of LiveJournal users, represented in digital traces such as user icons, are no longer part of the everyday, but are rather elements of the process of popular culture. LiveJournal icons are one of many tools through which people negotiate their relations with dominant cultural content and construct their mediated lives.

User icons are many things at once. They form interface spaces between a dominant culture produced by media industries and the everyday realities of users. They are also tools used by users to build identities with the help of dominant media products and they inject these identities into the shared cultural sphere. They are hybrids formed from cultural, media and technical elements.

POPULAR CULTURE IN THE PREDIGITAL ERA

LiveJournal user pics are a manifestation of popular culture. Fiske (1992) defines popular culture as the process, in which resources provided by a dominant cultural system are excorporated by subordinate users, who make their own culture

out of it. By focusing upon excorporation, rather than incorporation of people in the system, Fiske provides an alternative to a pessimistic approach to modern culture that has its roots in the works of the Frankfurt School. Fiske assumes that “[t]he people are not a passive, helpless mass incapable of discrimination and thus at the economic, cultural and political mercy of the barons of the industry” (Fiske 1987b). Attempts at incorporating them made by the dominant cultural system are a sign of popular vitality and creativity.

Popular culture is not pop culture and the adjective popular does not describe a popularity measured by top hits lists. Popular culture is an autonomous cultural sphere created by and for people at the interface between the dominant cultural industries and everyday life. According to Fiske (1992), cultural commodities circulate not in one, but two different and partially autonomous economies. They are produced in the financial economy of the dominant cultural industry, but later transfer to the cultural economy, in which consumers are also producers. In this second economy production is not for profit, and it is not the products of the dominant cultural industry but meanings and pleasures that are the most important circulating commodities (Fiske 1992). The dominant culture provides the popular culture with resources, but it only to some extent controls their later transformations. Popular culture is a sphere of active reception, interpretation, and transformation of content produced by dominant cultural industries, mainly the mass media. While in itself it is active and vital, popular culture is described by Fiske as always a reaction to the dominant culture. Some cultural commodities have the potential to trigger popular cultural activity. They have an open character and invite new uses or interpretations. Such cultural innovation can be based not only upon the acceptance, but also evasion or opposition to encountered meanings.

There are therefore different terms in which the relationship between dominant cultural industries and popular culture can be described. The major-

ity of metaphors used are based on the concept of conflict or combat. Eco describes activities that “restore a critical dimension to passive reception” or “urge the audience to control the message and its multiple possibilities of interpretation,” as semiological guerrilla warfare (Eco, 1987, p. 144). Michel de Certeau speaks of poachers, who encroach and steal cultural goods without being caught or even subject to the laws of the territory (De Certeau, 1998). Fiske (1992) writes that popular culture has to do with treachery, robbery, sleight-of-hand games played with the cultural industry: “To attract consumers is to attract tricksters; encouraging consumption encourages trickery, robbery, la perruque” (p. 41).

Jenkins (1998) suggests that metaphors of conflict account for only one stream of popular cultural activity, one which he calls “culture jamming”. He distinguishes it from “cultural poaching”. Cultural jamming is more radical and closer, as an intellectual position, to the pessimism of the Frankfurt School. Culture jammers define themselves as outsiders who attempt to liberate their own lives and the lives of others from the mass media that encroach and invade their lives. Cultural poaching in turn is rather a form of cultural symbiosis or parasitism that works not beyond the cultural system, but within its bounds. Poachers participate in the dominant culture, but see themselves as creators and reject the possibility of being marginalized to the position of passive receivers. Both strains of popular cultural activity thus attempt to fulfill the postulate of semiotic democracy, according to which in a good society each one should participate in the creation of meanings that circulate in a culture (Fisher, 2001; Fiske, 1987a). While both are forms of collective cultural action, jamming attempts to achieve what Melucci (1996) calls a breach of the limits of compatibility of the cultural system, while cultural poaching exists largely within the system’s limits. It is the latter of these two strains that the most popular cultural activities present at LiveJournal fit into.

Protest activities are traditionally understood as antagonistic, system-breaching, collective actions. Cultural poaching does not fit this definition, as it does not attempt to breach the system’s limits. Galloway (2004) believes that we need to redefine protest because of the changing nature of power, against which it is directed. Galloway describes a form of distributed, decentralized control, which has been gaining importance in the modern world. It is a procedural form of power exhibited for instance by protocols running at the code layer of the Internet. Resistance to distributed control cannot be based upon the traditional notion of protest, but the concept of hypertrophy: “The goal is not to destroy technology in some neoluddite delusion, but to push technology into a hypertrophic state, further than it is meant to go ... Then, during the passage of technology into this injured, engorged, and unguarded condition, it will be sculpted anew into something better, something in closer agreement with the real wants and desires of its users” (Galloway & Thacker, 2004). Popular cultural activity at LiveJournal is an example of such hypertrophic cultural activity.

DIGITAL MEDIA AND THE TRANSFORMATION OF POPULAR CULTURE

Fiske wrote *Understanding Popular Culture* in 1989, 2 years before the invention of the World Wide Web by Tim Berners-Lee and several years before rapid growth of Internet use began. Popular culture, according to Fiske, circulates in the context of three types of content: primary texts or original cultural commodities; secondary texts that directly refer to them, such as reviews, criticism, or advertisements; and tertiary texts that are the process of everyday life: conversations, patterns of dressing, acting, or dwelling.

In the dominant mode of popular cultural activity, people take ready-made products and replace

ready-made meanings with ones they themselves produce. Commodities that are reused later in the process of popular culture are according to Fiske (1992) poor in meaning, insufficient, “resources to be used disrespectfully, not objects to be admired and venerated” (p. 123). Popular culture takes these incomplete cultural objects and fills them with meanings that make them relevant in everyday life. In this manner, a contradictory culture is formed. It relies upon simple, even unimaginative resources provided by the dominant cultural industry and produces content characterized by “subtle complexity, dense texture of human sentiment and of social existence” (Fiske, 1992, p. 120). Popular culture uses all three types of content, but by itself produces only tertiary texts. Among these most numerous are conversations, through which viewers, readers, and listeners redefine the meaning of cultural commodities. It is also produced through dress styles, patterns of behavior, and lifestyle choices. Ephemeral manifestations of popular culture coexist with cultural commodities without displacing them. “With very few and very marginal exceptions, people cannot and do not produce their own commodities, material or cultural, as they may have done in tribal or folk societies. In capitalist societies there is no so-called authentic folk culture ...” wrote Fiske (1992, p. 27). Predigital times were a period of the Dark Ages for popular creativity (Lessig, 2001). The production of autonomous content, that is, content not derived from commodities produced by cultural industries, was marginal and its distribution was limited and local.

The relation between two segments of contemporary culture, as described by Fiske (1992) or De Certeau (1998), are based upon several key dichotomies: large and small; constant and in flux; and cumbersome and nimble. John Fiske explained the distinction between dominant and popular culture by describing the former as “places” built by the powerful and the latter as “spaces” temporarily set up in these places by the weak (Fiske, 1992). De Certeau (1998) describes

the powerful as cumbersome, unimaginative, and over organized. These traits allow “the weak,” or producers of popular culture, to dwell in dominant content, appropriate it, and to “speak [their own] meanings with their language” (Fiske, 1992, p. 36).

The difference between dominant and popular culture is related to the type of media at the disposal of the two cultures. The cumbersome and slow character of dominant culture is in part an effect of the relative stability and durability of media and objects, to which it is tied. Dominant cultural commodities often take the shape of relatively durable material artifacts like newspapers, books, DVDs, or toys. Otherwise they gain significance and importance as content is broadcast into—so as to almost saturate—the majority, if not the whole, of a society. Actor Network Theory uses the term *immutable mobiles* to describe objects that retain their shape and characteristics while moving through space and time (Law, 2000). With such objects, and thanks to their durability, power can be enforced and sustained at a distance. An analysis of popular cultural activities shows that such objects are not necessarily immobile. Cultural commodities enforce certain meanings, but at the same time are open to appropriation and reworking of carried meanings. “To be popular, the commodities of the cultural industries must not only be polysemic—that is, capable of producing multiple meanings and pleasures—they must be distributed by media whose modes of consumption are equally open and flexible” (Fiske, 1992, p. 158). In other words, with time and at a certain distance, they become mutable.

In contrast, the creators of popular culture are quick and nimble, unencumbered by products that need to be distributed or property that needs to be protected. Popular culture is not a cultural industry and does not need legal, distribution, or marketing apparatuses. Material artifacts of popular culture, if any, were distributed in circuits that were either local or marginal and in both cases informal and based upon a nonfinancial economy. Lacking

the capability to produce immutable mobiles, popular culture is unable to widely propagate its own meanings.

Digital media have transformed popular culture as much as they are changing the shape of the media market and cultural industries. Today, popular culture still exists at the borderline between dominant cultural content and everyday life, yet the growing popularity and diffusion of digital media in the society means that this interface space is, to a growing extent, digital and online. Mizuko Ito (in press) describes how contemporary popular culture is characterized by a coupling of collective imagination with digital technologies. These have revolutionized the popular production and distribution of symbolic goods by lowering the costs, time, and effort necessary to produce and distribute cultural products. Through these technologies, meanings that were until now ephemeral became anchored in relatively stable digital content.

Since the last decade of the 20th century, the growing influence and popularity of the Internet and other digital media transformed the conditions in which popular culture is both produced and distributed. Digital media gave popular culture the ability to distribute—at least potentially—content at a speed and range comparable to the capabilities of broadcast media. Most of these changes have by now been well documented, and the Internet is commonly described as capable of lowering all sorts of costs that hinder cultural production. Increased ease with which people can actively participate in their culture significantly affects the process of popular culture.

Yet the character of popular culture is most profoundly changed by the fact that digital media give people the potential to produce symbolic goods that are no longer ephemeral, scarce, and only locally available. Digital popular culture is capable of producing not only what Fiske defined as tertiary, but also secondary texts (Fiske, 1992). Potentially digital media enable people even to create their own primary texts, a body of auto-

nous cultural content that is closest to what Fiske calls “authentic folk culture” (Fiske, 1992, p. 27). Digital popular culture is thus able to acquire its own immutable mobiles, objects that can propagate in digital environments, allowing popular culture to grow in size and significance.

Predigital popular culture existed on a small scale, partially invisible to the dominant culture with its cultural industries, which it easily tricked, thus remaining beyond the latter culture’s scope of control (Bey, 1985; Fiske, 1992). This changed with the digital means of symbolic production and communication, when every operation involved making a copy (Lessig, 2004). Once ephemeral activities now produce relatively durable, immutable objects, and cultural poachers are now leaving traces of their own actions. Digital environments allow institutions that form dominant cultural industries to easily and efficiently monitor, track, and mine for data. In this manner, the circulation of materials can be controlled or measured, for instance to protect their own intellectual property or to provide data needed to adjust future production and marketing. They also facilitate reciprocal appropriation of popular cultural practices and aesthetics by cultural industries (Jenkins, 1998).

Cultural poaching has been explained as bricolage (Jenkins, 1998), the art of “making do with whatever is at hand.” Popular cultural production was the domain of the bricoleur: “someone who works with his hands and uses devious means compared to those of a craftsman” (Levi-Strauss, 1966, p. 16). A bricoleur works with a set of parts that is neither planned nor invented—but found, assembled, and appropriated in the conditions of relative scarcity.

Introduction of the digital media into the society has also improved the availability of “raw materials” needed for popular cultural production. In predigital times, before the Internet, cultural commodities could be received as push media broadcasts or had to be bought. The growing World Wide Web places, at the disposal of its

users, a rapidly growing body of digital content. Most of this content can be easily accessed and duplicated, albeit cultural industries attempt to an ever greater extent to curb uncontrolled usage through legal and technical means (Lessig, 2004). Content that is accessible on the World Wide Web is much greater than that available through push media, and access to it is often freed from financial constraints. In such conditions, time or attention span and not money become a crucial investment. In a condition of cultural plenitude, when a great range of materials is always at hand, popular cultural production resembles grazing more than poaching. Due to the vastness of contemporary culture, rational selection is not often possible. Due to limited attention spans we are more than ever choosing from but a thin slice of a culture as a whole. Popular cultural production still makes do with what is at hand, but in a digital era this is a strategy for coping with excess and not scarcity. Bricolage is a mode of experiencing and appropriating a culture characterized by complexity, in which no order is visible and whose elements cannot be “drawn together and properly assembled” (Law & Mol, 2002, pp. 14-15).

As a result of a partial transfer online of both dominant and popular culture, the two spheres began resembling each other to a greater extent. The changing conditions of popular cultural production and distribution weakened the distinction between cumbersome dominant culture and nimble popular culture. Online, all cultural phenomena begin coexisting in a single symbolic space, which furthermore is collectively imagined as a space in which the digital aspect of the process of everyday life is situated. Primary, secondary, and tertiary cultural texts coexist and interact in a relatively homogeneous space of the Internet and the World Wide Web, under protocological control of basic Internet protocols at the code layer of the medium (Galloway, 2004). Equally important are the decreased distance and difference between dominant and popular culture, as well as a mutual contamination occurring between these two

cultures and everyday life. This according to Lash and Urry (1994) is characteristic of what they call the post-modern condition, in which cultural forms increasingly form a part of social reality that is not distinguished as different or specific. In post-modernity, “an audience is sensitized to the reception of such cultural objects because of ‘semiotics of everyday life’ in which the boundary between the cultural and life, between the image and the real, is more than ever transgressed” (Lash & Urry, 1994, p. 135).

POPULAR CULTURE AT CODE AND CONTENT LAYERS OF LIVEJOURNAL

Predigital popular culture could have been imagined as existing in spaces temporarily established at the border or interface, with the dominant culture. In the digital era, the Internet and World Wide Web have provided an environment in which places—symbolic, but nevertheless real—of popular culture can be created. LiveJournal users are not poaching its online cultural resources, but rather producing popular culture in a place that in their imaginations can be inhabited, settled upon. It is a place where humans often dwell only temporarily, as proved by the majority of blogs left fallow by its creators. Still content dwells forever or at least until the death of the server. While our everyday lives remain in constant flux, their record on the Internet, or the objects of online popular culture, remain and are largely static. This is the “dark matter that gets left behind to molder in data vaults and arcane archives as we progress into a great digital future” (Nolan & Levesque, 2005, p. 35). LiveJournal is a place, not a space of popular culture. In this place, popular meanings are not injected into preexisting content by rogue actors, but constitute primary content produced there. Raw digital materials, that is, cultural commodities, are not produced on-site, but brought into the LiveJournal environment. However, to

fully understand the process of popular culture at LiveJournal, we should once again distinguish between the code and content layers. At the code level, users took an informational infrastructure crafted by LiveJournal's creators and adapted the relatively open tools to their own needs. The LiveJournal system itself is to an extent sluggish and unimaginative, dependent upon a certain path coded into its interface and database, a certain historic condition in which Brad Fitzpatrick decided to write the system, and a simple view of future uses imagined by the system's creators. These coded tools have been taken by users and appropriated for new uses. While the code remained the same, LiveJournal as a digital tool grew beyond its initial boundaries.

Furthermore, some of the new and innovative uses of LiveJournal have repurposed it as a tool for the digital production of popular cultural content. LiveJournal is also what Fiske (1992) calls a producerly cultural form. Although accessible and open, it has "gaps ... wide enough for whole new texts to be produced in them" (p. 104). With time, LiveJournal became a space in which popular culture could be performed. Elements of its coded infrastructure could be treated as tools for popular cultural production. LiveJournal user icon is one such tool, originally imagined as a method of personal representation that at some point started being used for popular reuse of dominant content.

THE LIVEJOURNAL USER ICON AS A SITE OF POPULAR CULTURE

User icon usage does not follow a single pattern, but is rather a family of uses that begins with a limited set of uses envisioned by system's creators and then evolves into a dynamic system of both conformist and innovative uses. The user icon was initially designed as an iconic sign that signifies its user based on the principle of similarity. It has been later redefined into a primarily symbolic

sign. The relation between the sign and the user became based upon an arbitrary, agreed convention. User icons contain faces and cropped facial details; celebrities, fictional characters, animated characters, and other people; animals and cartoon creatures; slogans and drawings; landscapes and objects; actors, musicians, and models; users, friends, and strangers. To some extent they retain their prescribed function, so that every image displayed can be interpreted as signifying a given user. Yet we must assume that in the case of many icons the representation of the user is neither the sole or primary goal. The sum of all LiveJournal user icons is a quite faithful visualization of culture as a whole, albeit divided into fragments the size of 100 pixels to a side.

While the interpretation of user icon content goes beyond the scope of this chapter, it is worth making several remarks in this regard. Such an interpretation is a daunting task and does not provide direct insight into the lives and identities of users, hidden behind "photo shopped" layers of images. Nolan and Levesque propose that it is never a real identity, but only an "identity map" (2005, p. 35) that can be recreated from online content—an approximation of the real person. It is worth adding that such identity maps are created not just by researchers and human hackers described by Nolan and Levesque, but by all users. An online persona does not have to take the form of a three-dimensional virtual visualization. More commonly, it is an imaginary actor constructed by others on the basis of available content relating to the given person.

If we treat the user icon as a tool for visualization of contemporary culture and society, then the icon suggests that we live in a reality in which the lines between mediated content and real lives became blurred. The space of user icons is an environment, in which representations of users coexist mostly with cultural commodities. The ecosystem of LiveJournal user icons is monotonous and depleted, inhabited by users, celebrity images, and other mass mediated content, texts,

and slogans and abstract or digital backgrounds. Given the possibility to freely represent and express oneself, users opt to rework cultural commodities and insert themselves into their mix. Other than photographs of oneself, there are few signs of primary cultural texts produced by users who do not choose to represent or express themselves with images of loved ones, favorite objects, or places that are part of their everyday, off-line existence.

As is the case with every medium, LiveJournal users are to a varying extent innovative in their use of icons. Of all users, two partially overlapping communities, fandom and icon makers, are most involved in innovative cultural production with the use of icons. Fans participate in a culture in a manner that is extravertous and hypersocial (Ito, 2005), active enthusiastic and partisan (Fiske, 1992). Fandom prefers cultural poaching to jamming, a mode of appropriation that is dialogic with the dominant culture and respectful of mainstream consumption of the media (Jenkins, 1998). Cultural poachers mainly care about the right to self-expression and reworking of cultural material for their own interests and pleasures. "Fans respond to this situation of an increasingly privatized culture by applying the traditional practices of a folk culture to mass culture, treating film or television as if it offered them raw materials for telling their own stories and resources for forging their own communities" (Jenkins, 1998). Icon making is a hobby, a form of digital craftsmanship and artistic production. For icon makers, a user icon is not just a medium, but also a popular art form. Both types of groups perform popular culture with the use of a user icon, a medium provided by LiveJournal's creators; dominant mass mediated content and a repertoire of techniques of icon creation. For fandom communities, style and techniques developed by icon makers are of secondary importance to playful appropriation of meanings and expression of attachment to their favored cultural commodities. Icon makers place greater emphasis upon cultural production

of icons as an artistic activity. In both cases, icons become a symbolic currency that circulates within these communities, used to express oneself, but also to sustain social relations and establish an individual reputation.

While practically every LiveJournal user is an icon maker, I reserve the term for those users that pay particular attention to this medium and furthermore self-define themselves as such. Icon making is hypersocial. It reflects "forms of sociality augmented by dense sets of technologies, signifiers, and systems of exchange" (Ito, 2005, p. 6), which according to Ito are characteristic of the popular culture of youth and children today. Online hypersocial relations are based in textual conversations taking place in makers' and communal journals, but are first of all sustained through the circulation of icons.

Icon makers have developed a specific aesthetic and style. User icons made by them are usually a collage of three elements: a human face or figure, a short text or slogan, and an abstract pattern or design serving as the background. Icons seem to have evolved into a form that most fully utilizes the limited resources at hand (in particular screen and server space) to perform digital popular culture—that is, to signify user's attachment, involvement, and interaction with cultural commodities.

Icon makers communicate through specialized journals and communities that can play several different functions. They can be: (1) virtual "shops," in which makers accept requests from others; (2) showcases of works; or (3) competition spaces with contests that establish the value of works and artists. Icon making is a social activity and icon makers usually compare their works, accept commissions, or allow others to copy and reuse their icons. It is a community based upon an economy of reputation and the circulation of user icons. A maker's reputation depends upon the quality of his/her works: aesthetic merit, ability to perform popular cultural appropriation, and technical skill.

The last factor seems especially interesting, as makers pay much attention to icon-making techniques. Icon making requires skills with two-dimensional graphics software; an understanding of disc space usage by graphic files and factors that affect their size; and know-how of appropriate digital brushes, fonts, and techniques. Many icon makers are distinguished by an understanding of the relation between displayed content and the code layer of an icon. Icon making is similar to the demoscene, a hacker subculture whose members competed to create short but intense digital graphics called demos. It also has parallels with the “5k contest,” a Web-design competition organized since 1999, in which designers create Web sites of no more than 5kb in size.

While icon makers naturally have varying skills and talent, some of them fit the description of what Leadbetter and Miller (2004) call Pro-Amateurs: “committed and networked amateurs working to professional standards” (p. 9).

Of all LiveJournal users, fans and icon makers are communities that have developed most unorthodox uses for the user icon. To give a final example, a text field set up in the system as a space for a short description of an icon has been used in icon-making communities to attribute the authorship of the author—a function that is crucial in a nonfinancial economy based upon reputation. In such a case, the original function of the icon—the representation of a user—is pushed beyond the icon’s boundaries. System’s administrators later introduced the possibility of commenting icons, possibly in reaction to this practice.

Ito (2004, 2005) describes popular culture of Japanese youth as a coupling of two “sociotechnical innovations”: the hypersociality mentioned previously, supported by digital communication and file-sharing networks, with what she calls “media mixes.” A media mix “integrates different media forms through licensed character content” (Ito, 2004, p. 31), a “heterogeneous but integrated web of reference” (Ito, 2004, p. 31) anchored in cultural commodities and technologies. Media

mixes, argues Ito, create relatively open and porous intertextual networks with which popular culture can interact.

The content reused at LiveJournal is part of wider media mixes, in which images of celebrities or fictional characters are present as well as videoclips, posters, movies, newspaper and magazine articles, t-shirts, DVDs, and so on. Yet LiveJournal seems detached from such mixes. Ito (2005) describes a process of constant negotiation that occurs between dominant and popular interests inside Japanese media mixes. Cultural industries are absent at LiveJournal and do not attempt to commodify or profit from popular cultural activities occurring on the site. LiveJournal is indeed, paradoxically, invisible to the powerful. We can only assume that the site itself retains its autonomous character only because the everyday lives of its users have already been colonized. Yet LiveJournal is not a site of a popular cultural rebellion directed at the dominant culture, but a space in which consumers decide to perform acts of cultural poaching and grazing.

CONCLUSION: PETRI DISHES AND DIGITAL FOLK CULTURE

A user icon is an empty “container”: a field in the database, a bit of space on a server, a space on a journal’s Web page. Such a container is itself a simple form that expresses minimal preferences regarding the content that it can store. We can compare it to a petri dish filled with a selective medium, upon which a bacterial culture can flourish. This metaphor accounts both for the robustness of activities rooted in a simple media form and for the organic manner in which patterns of usage develop over time. We can draw a conclusion from the case of user icons that popular cultural activities flourish when anchored in already existing content and structure. As long as the architecture is not too restrictive, users are drawn by the presence of some (not necessarily

optimal) interface and architecture, the presence of social and cultural conventions, and the presence of others. LiveJournal is like a city, whose “dwellers are not necessarily smarter than other human beings—but the density of space occupation results in a concentration of needs. And so questions are asked in the city that have not been asked elsewhere ...” (Bauman, 2003, p. 104).

I used the example of LiveJournal user icons to present the life cycle of a digital medium, characterized by a relation between a medium that is open at the layer of code and culture that flourishes at the level of content. As such, it is a case study of the robustness and capacity to innovate that is inherent in popular culture. I argue that the Internet is both filled with digital petri dishes of varying size and itself shares structural characteristics with the LiveJournal user icon.

Chapter 5.12

Competent Web Dialogue: Thoughts Linked in Digital Conversations

Eva Fåhræus

Stockholm University and Royal Institute of Technology (KTH), Sweden

Marianne Döös

VINNOVA, Sweden

ABSTRACT

Conducting a dialogue on the Web is a matter of linking thoughts in digital conversations. This article is intended to contribute toward learning qualities in such conversations. The term “dialogue” refers to a special kind of conversation, having structure, purpose, and learning qualities. The focus is on learning Web dialogues taking place in a course context using text-based, asynchronous meetings. An overview of factors that influence digital group conversations is presented together with a model for dialogue competence face-to-face. The dialogue potential of Web dialogues is highlighted. Course leaders and teachers wanting to create opportunities for learning Web dialogues, as well as the interlocutors themselves, need to wise up on the digital interchange of thoughts as a form.

INTRODUCTION

Conducting a dialogue on the Web is a matter of linking thoughts in digital conversations. Contacts and conversations via the computer are growing in volume. People are successively changing their understanding of what this kind of conversation is, and of its possibilities and difficulties. When conversing with others via the computer, we are moving in the border zone between solitude and company. In order to achieve learning qualities in these digital conversations, the interlocutors need to wise up on the digital interchange of thoughts as a form. This article is intended to contribute in that direction, partly by borrowing knowledge concerning group dialogue and dialogue competence in face-to-face situations. The focus of attention is on the dialogue in connection with the text-based, asynchronous meeting,

and in particular on digital group conversations in connection with courses, training programs, and university education. Often, though not always, these conversations are conducted with an element of examination or with a stipulation of presence and activity. Above all, though, they are meant to be good learning conversations, that is, conversations in which people learn with and from each other. The term “dialogue” as used in this article refers to a special kind of conversation, one having both a structure and a purpose (cf. Wilhelmson, 2006).

Digital technology has led us into new forms of conversation, and in some digital exchanges the similarity is so great that it has become natural to say that we are talking, even though we are actually writing. Different people have very different images of what communicating on the Web and at a distance implies. There are great variations of experience and competence. For example, there are generation differences, and the fact of our writing with completely different kinds of software and with different degrees of digital competence. The lack of common images, that is, similar understanding of what digital conversations can be, is an important basic precondition that will have to be taken into consideration for many more years to come. Dialogue does not come easily, even when people see and hear each other. A group dialogue requires practiced skills, but its learning potential, that is, the possibility it affords, in the company of others, of increasing one’s understanding and pondering one’s experience, makes it worth the trouble.

Two Digital Conversations by Way of Illustration

The participants in a distance course are given the task of conversing in writing with each other, by computer, about gender aspects of IT use. They are each to have read an article or a book chapter on the subject and are now to give their views on it and converse with each other in groups of about 10

people. This conversation is expected to continue for a fortnight in a conference system of the First Class type. In one group the conversation makes rather slow progress. When the participants have described the content of the article they have read, communication comes to a standstill. The course leader then intervenes to ask whether anyone has had personal experience of gender discrimination in connection with IT use, whereupon a number of participants describe experience of the kind, and others reply with affirmative comments on some of these contributions. Nothing much more happens after this.

In another group the communication gets off to a somewhat hesitant start but soon gets quite lively. In connection with describing the article, one participant relates personal experience of the subject. Another participant relates a similar experience, while a third objects that the reason must have been something other than gender discrimination. A lively conversation ensues as to what the reasons might have been. There are still some people who have not voiced an opinion, and so the person who was first to speak asks the “silent ones” to give their opinions. The conversation flows on and now gets quite heated. Someone writes that she feels insulted by the doubt cast on her story. The person who queried what she wrote apologizes and clarifies his meaning. The misunderstanding is cleared up, and the conversation continues on a frank and friendly basis.

What did the participants in the two groups learn from all this? Those in the first group presumably learned a certain amount from the articles they read and perhaps too from the summaries provided by other group members. No one, presumably, got much out of the Web talk. At worst, the participants may have come to the conclusion that electronic conversations are worthless. The other group probably learned quite a lot, both facts about gender issues and various possible perspectives on IT and gender. Perhaps they even changed their opinions about certain forms of IT use and saw greater opportunities for their own

part. We shall be returning to these examples later on in this article.

Factors Influencing Digital Group Conversations

There are a large number of factors influencing the way in which a group discussion on the Web develops and how much the participants get out of it. The nature and wording of the task, the choice of subject, the size and composition of the group, and the participants' private situation and attitude to the task make a difference to motivation and activity. This in turn makes a difference to what and how much different people learn and how they allow themselves to be influenced. Another important factor is the way in which the dialogue is conducted and how conscious the participants are of the role they themselves are playing in it. The electronic dialogue, like the face-to-face (f2f) variety, can be improved by the participants developing their dialogue competence (Wilhelmson & Döös, 2002). Ability to link thoughts together in digital conversations makes a substantial addition to learning, especially in the case of distance learning. As a participant in digital conversations, one needs, then, to cultivate the ability to conduct learning conversations and also think about creating good preconditions both for oneself and for others.

The person planning and conducting a course also has great possibilities of influencing how instructive the digital conversations become and the extent to which they attain qualities concerned with linking thoughts between and within the individuals taking part. This is primarily a question, not of intervening in the actual conversation, but rather of course planning, and of course leaders and teachers understanding why, and by what means, a digital conversation proves successful. In this way they can contribute toward positive opportunities and conditions in the form of tasks, group composition, and requirements.

When arranging dialogue group conversations f2f, one can speak of the importance of reserving "a bubble of time" affording scope and tranquility for reflection (Wilhelmson & Döös, 2002). A counterpart in dialogue on the Web could be concerned with each participant assuming personal responsibility for allotting time to be present in the task of writing and reading, that is, the Web conversation's two counterparts speaking and listening. This implies a degree of carefulness that differs from the impulses characterizing a great deal of computer communication—availing oneself of the possibility inherent in choosing for oneself, not only the point in time, but a period of time when Web talk takes place with peace and quiet for study. Just as the members (Dixon, 1994) of an organization (meaning, in everyday speech, associates/employees) have to shoulder their responsibility for the learning required for performance of the task in hand, so the members of the conversation have to assume personal responsibility for rigging up good preconditions for getting something out of the digital conversations that are a part of the course they are taking. This assumption of responsibility, however, is connected with the nature of the task that, as a participant, one sees ahead of one. Articulating this to oneself and to the others can help to prevent problems later on, for example, regarding work inputs and digital attendance, problems rooted in participants' differing perceptions of the task. For example, is it something you undertake because you are bursting to learn, or are you attending the course for some other purpose and aiming for it to take up as little of your time as possible?

BASICS ABOUT LEARNING

Dialogue for the purpose of learning is based on different people having different ways of looking at things because they have led different lives and acquired purely personal experience. In dialogue, the fact of us thinking and feeling more

or less differently is both a precondition and an obstacle. We shall now turn to consider learning processes of relevance in the sense of helping us to understand how a competent Web dialogue can be conducted.

Learning in Action

Experience-based learning takes place in concrete contexts, while the learning individual is occupied with quite different things from learning, namely the performance of tasks or duties, conversing, solving problems, and understanding things (Döös, in press; Kolb, 1984). Everyday learning, then, takes place within tasks; in other words, you busy yourself with something and you learn into the bargain. The individual person's learning proceeds by short steps, with the greater part of learning consisting, not of new things, but of confirmations and more of the same. One experience is added to another, and everyday knowledge is constructed and consolidated continuously. Differences and deviations also appear against this background. Only when one knows what something ought to be like, or usually is like, is it possible to be surprised by deviations (Döös, 1997). Learning through conversations with others can be described in similar terms (Bjerlöv, 1999).

When learning takes place via the Web, Fåhræus (2003) has identified three parallel learning processes: learning to communicate and converse electronically, learning to learn together (the collaborative aspect), and learning the matter with which the course is concerned (the content). These three learning processes proceed in parallel and, at best, support one another. As a teacher and course leader, one should bear all three processes in mind and remember that they need time and attention in order to come about and acquire quality.

Collective Learning

Reflection is a vital ingredient of learning, with the result that dialogue, conversation, communication and so forth have attracted a great deal of attention in recent decades, on research as well as practice. When people learn together, collaboratively (Fåhræus, 2003), in an interactive and communicative process, then in favorable circumstances we can also find collective learning taking place (Dixon, 1994; Ohlsson, Granberg, & Stedt, 2004). If so, we get synergistic effects, with 1+1 making more than two, that is, the participants change their conceptions in a different way from what each of them could do on his or her own. Instead of just each individual learning by belonging to a group, learning results in the participants' conceptions during the conversation becoming collective, that is, a great deal more similar, almost communal. In Swedish worklife education research, collective learning has been made theoretically comprehensible through studies of f2f meeting conversations of different kinds. It has been described as something that happens in teams or other clearly delimited, (most) often formalized and small groups in which it is established and known which people are included and what their functions are. Collective learning, however, has partly different principles and sequences in different specific environments, in different contexts (Döös & Wilhelmson, 2005). The engendering process results in changed understanding and similar preparedness for action. In more distributed contexts in working life, it has been possible to identify the importance of a common arena for action (op. cit.) in that product development in the telecommunications and data communication industry has led to collective learning through a host of paired contacts by telephone, Internet, e-mail, electronic subscription, and meeting points. The common arena for action consisted of coordination in the task, that

is, joint development of the technology. Accordingly, the results of one's own actions and other people's actions were also gathered together in technical artifacts.

WHAT IS DIALOGUE COMPETENCE?

Dialogue is something more and different than ordinary conversation. It differs from discussion by not being aimed at beating or convincing other participants in the conversation. Bohm (in Senge, 1990) describes discussion as a subject being tossed between the participants: the subject is analyzed and arguments for and against presented. Each participant's purpose "is normally 'to win' and in this case winning means to have one's views accepted by the group" (p. 240). The purpose of the dialogue, in contrast, is described as that of "going beyond any one individual's understanding ... individuals gain insight that simply could not be achieved individually" (p. 241). In a dialogue, one is not out to prevail over others; the purpose "is to reveal the incoherence in our thought" (p. 241).

Dialogue conversation is difficult and demands a competence that many people need to practice for. It contains (see Table 1) four different parts: speaking, listening, critical self-reflection, and critical review of other people's standpoints (Wilhelmson, 2002). In learning dialogues, people can meet by making different perspectives visible, conversing on a subject, and helping each other to relate it to a wider context, gaining an overview and seeing one's own part of the overall picture.

Group conversations can be powerful learning situations that change people's learning processes and the preconditions of those processes by providing an opportunity for the communal creation of meaning. This means creating conversation topics that make the conversation meaningful and necessary in relation to what is to be learned on this particular occasion. It is also recommended

that the topic of conversation be of such a kind that there are no right or wrong answers, and that if possible it should also concern something of which the participants have personal experience or knowledge. Dialogical quality of conversation (Wilhelmson, 2006) helps to make conversations in themselves instructive in a qualitatively good sense.

The point of departure for learning dialogues is for each individual taking part in the conversation to have specific experiences of his or her own that are different from other people's experiences. Wilhelmson (2006) likens the conversation topic to a statue, arguing that the statue is an imaginary picture of the conversation topic, which the participants in the conversation build up together when, from their various perspectives (each individual person's conceptions/experiences), they make different aspects of one and the same subject to reality visible. Together the people conversing walk around the statue and in their conversation highlight as many aspects as possible of the subject that they are together endeavoring to understand.

Speaking and listening are the core of dialogue competence, which is more complicated than it sounds at first. In order to learn from and with each other in the course of conversation and perhaps build new shared knowledge, every participant must be capable of pleading for his or her own standpoint in the conversation but must also be open to other people's arguments. One has to be prepared to query one's own standpoints and to critically review other people's.

A dialogical group conversation has both integrating and differentiating qualities. Contributing as a participant toward integration means building on what others say, gathering the threads of conversation into a fabric—not instantly dismissing other people's differing views, but instead trying to get inside their way of thinking. Contributing toward differentiation means problematizing and questioning on the basis of one's own experience and knowledge, contributing one's own view-

points and experiences, with personal integrity. The friction arising out of difference provides an opportunity for getting to the bottom of things and scrutinizing one's own and other people's conceptions.

DIFFERENT FORMS OF INSTRUCTIVE E-MEETINGS

There are many different kinds of e-meetings. Here, as has already been made clear, we are mainly concerned with electronic meetings conducted within the framework of a course in order for the participants to learn something. Meetings communicated electronically are primarily concerned with text communication, possibly supplemented by image or video transmission in which the participants can see each other. An e-meeting can be conducted in chat form, with all participants active simultaneously, but often an asynchronous (non-simultaneous) meeting is opted for and allowed to last longer. Even the relatively synchronous chat, however, is more asynchronous than f2f conversations, in which the speaker can be heard in mid-sentence, can read off the other participants' facial expressions, and can make the rest of what he or she says take a different course from what it was about to do just now.

Degrees of Liberty and Structure

Just as a dialogical f2f group conversation can be facilitated by adhering to a certain structure,

governing must be considered a natural part of the teaching context. Pedagogics is about processes of influence. Research has shown that computer-based training needs a certain amount of guidance in order to get a rewarding discussion started at a distance (Wännman, 2002). It is not the intention here to define a certain degree of suitable control, but rather to consider how it can be done. Basically, guidance can be exercised in two ways, firstly by intervening, through the medium of conversation, in the individual person's world of thoughts and ideas, directly in people's thoughts and contexts. Use is then made of the changed possibilities of the conversation itself, for example, through a direct question from the course leader to the participants. The other path to guidance involves conditioning surroundings and outward arrangements in such a way as to change the preconditions, for example, through the choice of subject or procedure.

There are ways of imposing a structure on the conversation without necessarily controlling it too closely. One can put out a vignette, which serves as a starting point and stimulus for thoughts and ideas that the participants want to share with each other, the plan being for this to arouse curiosity and trigger conversational activity. The conversation that then ensues can take quite a different turn from what the leader had envisaged, but if it is to be a free conversation, one should refrain from intervening and directing it. Another way of providing a common kick-off point is by asking the participants to see one and the same film or read an article, as in the introductory examples. They can also engage in brainstorming, role play, or a debate (Fåhræus, 2000).

Table 1. Ingredients of dialogue competence (Wilhelmson, 2002)

	Self	Others
Closeness	Speak	Listen
Distance	Critical self-reflection	Critical review of other people's standpoints

The next step toward more structure may be to indicate a certain sequence. All participants, for example, are to begin by describing personal experience of gender discrimination before embarking on more two-way conversation. To further structure the procedure, they may be required to read and summarize an article and then ask each other questions that have to be answered within a certain time. This structure can be made highly detailed, and computer support can be used for shaping it up. There can be different electronic conferences or folders in which the participants have to post their article summaries, or question boxes can be used with linking answers.

An extra clear structure is obtained if the system is made to verify that the participants complete all their assignments according to the procedure and remind them of what they have to do next. There are systems that create groups by pairing participants off when they have reached a certain stage in their studies. This can provide teachers and course management with support for the administration and monitoring of large groups. Systems can also direct students' questions in digital conferences, in such a way that they are first processed and thus potentially answered by the student group. This can have the effect of increasing communicative activity as well as lightening the teacher's workload and saving him or her from becoming a bottleneck.

Synchronous or Asynchronous?

The meeting assumes a completely different character if conducted with all participants present and active at their computers simultaneously, compared with the situation of its lasting for a fortnight and the participants deciding for themselves when to access, read, and post contributions. The synchronous meeting can get quite hectic: you have to be pretty nimble-fingered to get a word in edgeways. Without a predefined procedure for the meeting, things often seem pretty chaotic.

In f2f conversations, some moderators use the expedient of a talking stick or ball that has to be replaced in the middle before being picked up by the next speaker. Part of the purpose of this arrangement is to slow down the tempo. The time lag in the asynchronous conversation rules out the need for any such dodges. Basically it gives us more time to work out what we want to say, reread what we or other people have written previously, and amend what we write before sending it off. Each individual is enabled to say his or her piece, without being interrupted by those who have "the gift of the gab." Instead, another sort of time shortage is liable to occur, owing to competition from everyday commitments; reserving a bubble of time is not always easy.

An asynchronous meeting is sometimes found to be unenthusiastic and slow-moving. One variant that can pep things up and help to overcome the difficulty of reserving time is for the group to fix certain times when everyone will be online at once, an online seminar, or at least a day or two when everyone participates more frequently in a dialogue. This is something midway between the synchronous and the asynchronous, an attempt to combine the advantages of both.

Choosing Different Forms

It is natural, in a learning process during a course, to vary and utilize different forms at different stages. Perhaps you begin by getting a group to formulate their own questions in a subject on a brainstorming basis. What are the problems? What do we need to know? Or do? For arriving at a decision, for example, on a working plan, the synchronous meeting is the best alternative. Afterward, perhaps the participants will search individually for information on the Web, updating each other on important discoveries as they go along. Then a communal asynchronous dialogue ensues on the most interesting or controversial points, ending perhaps with a joint verbal debriefing to a larger audience.

On a course it may be a good idea to ask the participants to reflect on the form of dialogue in itself. One initial task could be to link up thoughts on one's notions and experiences of conducting a learning conversation and of doing so digitally. This is one way of getting the participants, right from the outset, to create their own understanding and insight concerning what is expected to take place, and what can take place, so long as they themselves make something of it. For example, the group could be issued with three pictures to begin with, for example, linking thoughts, Web talk, and alternation. Such digital starting conversations can be returned to, reread, and talked about again later on during the course, in order to reflect on their application in practice, what has been learned, what experiences have been gained, and what can be done differently for the remainder of the course.

THE DIALOGUE POTENTIAL OF THE MEDIATED CONVERSATION

Conversation at a distance *versus* f2f presents both similarities and dissimilarities. Among other differences, whereas communication in a group conversation on the Web is text-formulated, delayed, and enduring, f2f communication is oral, immediate, and evanescent. Dialogue, as already remarked, is a concept originally referring to a particular variant of oral f2f conversations.

Can one really speak, then, of conducting a dialogue when people cannot see each other, cannot read off the small but often distinct signs of the interlocutors being on the same wavelength or objecting to what one is saying? In the electronic meeting, a lot of the things people communicate to each other in the physical meeting through vision and hearing are lacking. To make up for this in the electronic meeting, extra care has to be taken not to offend each other and to verify that the person we are conversing with has understood us properly.

Habitual distance speakers often supplement the written word with emoticons¹, such as ☺, “laugh,” or <J> (for “joking”). Emoticons serve to clarify the participants' feelings and the meaning behind their words, which in turn can contribute toward involvement and help to underpin the dialogue. Emoticons can also have a disarming effect or provide a touch of humor.

The time lag is one characteristic of the asynchronous electronic meeting that can both impede and facilitate dialogue. Perhaps we are sitting at the computer, describing a harrowing experience we have been through or a new idea that has come to us. We would then prefer to know instantly what the others think of it. Instead, hours or days may pass before anyone picks up the thread of one's contribution. This can be frustrating, indeed frightening, and make us lose interest in the conversation. On the other hand a modicum of delay can be a good thing. There are advantages to allowing oneself time for reflection between the lines. One way of reducing the disadvantages of the time lag is for all participants to try to answer each other's contributions as promptly as possible, sometimes perhaps just to show that they have read what was posted and want to give it more thought before pitching in with their own viewpoints. That way I am spared the feeling of writing in a vacuum; someone out there can “hear” me (Fähræus, 2000).

Once the e-meeting conversation has gotten underway, the participants sometimes get very active, writing long contributions and many of them. This may complicate matters, with the participants finding it hard work and perhaps also tedious to read everything. There is a risk of one or two participants dominating the proceedings and crowding out others, just as in an f2f meeting. If the participants themselves do not notice this and propose a different speaking order, the course leader may have to intervene. Often just making everyone aware of what has happened and suggesting they keep it a bit shorter will help. Or again, one can identify different topics

of conversation and assign them to different communication spaces.

In an electronic conversation, whatever is said/written is perpetuated. Perhaps you happened to write something unusually silly, offensive, or ill-considered. Once sent away it cannot be retracted; it can be read and reread over and over again. What has been written can offend somebody seriously. That kind of damage is extra difficult to repair from a distance. But the permanence of the text also gives us instruments with which to proceed from other people's contributions, deepening the arguments. It all adds up to a different dialogue from the face-to-face variety, offering still greater opportunity for reflection, which may suit some people better than others.

In order for the thoughts about dialogue competence to be applicable to e-meetings, concepts like "speaking" and "listening" have to be reinterpreted. After all, we are not really talking but writing to each other. The speech component means presenting our viewpoints, arguments, and known facts in writing. We state who we are and what our background is. This applies not only to the content—the subject matter of the dialogue—but also to matters concerning the communication and learning process. Instead of just shaking our heads at a contrary opinion, we have to write about it. Not being ourselves visibly in purely physical terms, we have to be made visible by what we write.

The listening component in the dialogue competence matrix is concerned with reading what others have written, and showing that we wish to know more, are curious to see what others can contribute. In f2f meetings, just looking at a participant may be sufficient inducement for them to speak. Here we have to write a message and send it off, as a part of active listening.

Dialogue competence includes critical self-reflection. In an e-meeting this is achieved by writing in a way that shows we are open to changing our understanding. We should also tell the others when we have changed our minds and

tell them how we have received and understood other people's experiences and knowledge. Critically scrutinizing what other people say means that we describe how we interpret what others have written. We show what we agree with and suggest other ways of understanding and thinking, as the case may be. We can also query the other person's input data, requesting more facts and arguments.

CONCLUDING REMARKS

The electronic meeting can be regarded as an inferior variant of face-to-face conversation, but this is an oversimplification and an outmoded way of looking at things. Instead, possibilities are opening up for different forms of communication. These have their own advantages and disadvantages, knowledge of which increases with use. This article draws attention to what is new in relation to ordinary conversation, and, more specifically, it highlights group dialogues as learning conversations. Course leaders and teachers wanting to create opportunities for learning Web dialogues, as well as the interlocutors, need to wise up on the digital interchange of thoughts as a form. We hope that this article has contributed in this direction, even though the scope of it does not include clear-cut recommendations or considerations for developing a dialogue-based course.

An electronic meeting is here seen as an offer, an arena which I visit of my own volition. There I can find the thoughts contributed by my fellow-students and can decide for myself what to read and what to reply to. I can choose what to show of myself, but at the same time I should realize that my choice, my arena behavior, will affect the other participants and the group's interaction, and with them the benefit to myself from our coming together. It is hard to divest oneself entirely of the comparison with the f2f meeting and not to see the latter as the ideal worth pursuing, which makes it appropriate to recall the manifold disruptions

occurring in the course of ordinary conversation, the fact of some things being easier to talk about on the phone and the fact of many lessons and meetings being deadly dull and basically just a way of killing time. But the parallel to conversations in which people have, face-to-face, developed their capacity for engaging in a dialogue (Wilhelmson, 2006) is a useful one; knowledge from this field spurs each and every one to ponder the nature of its digital counterpart.

With technology present in the conversation space, we have access to tools that can create new meetings and a different kind of understanding. We can imagine an asynchronous conference system that projects the structure and flow of the conversation onto a screen that all the participants can see: who is talking, who is listening, and what is being critically appraised. Would this help the participants to reflect on their behavior and by doing so to succeed in deepening the argument? Or would it only be a source of confusion and disturbance? A system of this kind could resemble what are termed visualizing argumentation systems (Kirschner, Buckingham Shum, & Carr, 2003).

Returning to the example with which this article began, and considering what happened in the two groups, we may note that the participants in the first group showed little of themselves or where they stood. When, at the course moderator's request, they presented personal experiences, these did not meet with any critical appraisal. Assenting remarks can be encouraging to hear, but similarities alone will not deepen the conversation, and the dialogue fails to materialize. In the other group, both differentiating and integrating conversational qualities were present. The misunderstanding that occurred threatened to detract from confidence within the group, but the open dialogue that had already been treated enabled the misunderstanding to be cleared up. Arguments concerning the nature of gender discrimination and its causes gave the participants new perspectives on their own experiences. In

this instance the participants can be said to have demonstrated their dialogue competence in the electronic meeting.

Even if a computerized analytical system is not being used, it may help to pause every now and again during a course to reflect on meeting forms and the tone of conversation. The concepts presented in this article can be a good help. One cannot expect everyone to possess dialogue competence without having been given an opportunity for practice and reflection. It may, for example, be appropriate to have course tasks underpinning the participants' own awareness of what it takes for conversations to attain dialogical quality. This is a matter of understanding the basic ingredients of the f2f dialogue and of jointly considering, in the digital conversation, how it can be applied to e-meetings.

Talking in writing must be termed essentially alien to our human nature, and yet it is common enough. Digital exchange in the learning context involves changing one's thoughts, not just exchanging words. Verbal exchanges by computer are associated, not infrequently, with hasty action and impulsive responses, sudden statements, and brief questions. Pensiveness, exchange of thoughts, and individual learning are associated with paper, books, and armchairs. Perhaps technology today offers a digital context that can be likened to the common arena of action that is important for the occurrence of collective learning (Döös & Wilhelmson, 2005). Computer conferences have become a new way of meeting, and people now have the possibility of also being dialogue competent in digital conversations.

Chapter 5.13

Differential Impacts of Social Presence on the Behavior Modeling Approach

Charlie C. Chen

Albert Harris

Appalachian State University, USA

ABSTRACT

The continued and increasing use of online asynchronous learning (OAL) environments for training raises the question whether and to what extent behavior modeling, the most effective training method in live instruction, will prove to be effective in OAL environments. This article analyzes the effect of applying behavior modeling training in an OAL environment. Behavior modeling training can be delivered in three modes: face-to-face, videotaped, and scripted. Each behavior modeling mode expresses social presence to a different degree, which could impact both learning performance and the willingness of students to take online asynchronous training. This study reports on the effect of behavior

modeling mode on these variables in an OAL environment. Nine hypotheses were proposed. Four hypotheses were supported and five were not. This research found that the face-to-face environment is not significantly more effective than an OAL environment.

INTRODUCTION

The worldwide corporate e-learning market is expected to grow to \$24 billion (\$18 billion in the U.S.) by 2006, with a compound annual growth rate of 35.6% according to IDC (2003). The burgeoning online learning and training markets, and the increasing training budgets of businesses and

schools, have provided users of online training and marketing tools with practical reasons, as well as compelling research motives, to investigate the effectiveness of online asynchronous software training.

Behavior modeling is viewed as the most effective training method in live instruction (Simon, Grover, Teng, & Whitcomb, 1996; Compeau & Higgins, 1995). Three general modes of behavior modeling have been compared experimentally: (1) face-to-face (F2F) instruction, (2) videotaped instruction, and (3) scripted instruction. Since online asynchronous training does not use live instructors, it is possible that the F2F mode may be more effective than the other behavior modeling training modes. This article presents the results of a study to compare three modes of software training delivered in a Web-based format. It uses a "live instructor" behavior modeling format as a control.

The experiment was prompted by the need of 135 college undergraduate Business majors at the California State University, Northridge, and Loyola Marymount University, Los Angeles, to learn Access 2002 in an introductory computer course. The three general modes of behavior modeling training noted above were compared to see which produced the best performance, student satisfaction, and agreement with learning style.

LITERATURE REVIEW

Simon et al. (1996) categorize general training approaches into instruction-based, exploration-based, and behavior modeling. These three approaches are designed to improve learning outcomes for students with different learning styles in an F2F environment. Although not equivalent now, the online asynchronous learning (OAL) environment may eventually replace the F2F environment for practical training purposes. It is already the case that an online student can study lecturers' prepared slides, browse relevant

Web sites, and ask for solutions via discussion boards, among other means of assistance in solving problems. However, in the OAL environment, the immediacy of an instructor's F2F demonstration is hard to achieve. It is doubtful that behavior modeling methods have yet been adapted fully to the OAL environment.

Behavior modeling may be one of the better approaches for F2F instruction, but it may not be equally effective for online asynchronous instruction because it is based on instructor demonstration. For example, in a live training class, the instructor will demonstrate some software processes and ask the students to repeat the activity. However, in an OAL environment, where there is no live instructor, the demonstration may lose some of its benefits. The possibility exists that the behavior modeling approach is not the most effective training method in online training situations. Therefore, the effectiveness of behavior modeling in its different modes should be established in an OAL environment.

From the perspective of research design, "replication can and should mean testing empirical implications of theory — interpreting 'theory' broadly—in similar and dissimilar situations and experimentally and nonexperimentally" (Kerlinger & Lee, 2000, p. 570). The OAL environment provides a research opportunity to validate the assertions of Bostrom, Olfman, and Sein (1990) and Simon et al. (1996), and to extend their software training frameworks to the OAL environment.

LEARNING STYLES AND ONLINE BEHAVIOR MODELING

Online asynchronous training differs from traditional training in its self-directed and self-paced learning approach (Belanger & Van Slyke, 2000). As a result, it is plausible that individual differences have more influence on learning outcomes in the OAL environment. Many researchers

(Davis & Davis, 1990; Palvia, Palvia, & Zigli, 1992; Vessey & Galletta, 1991) have investigated learning preference and its influence on learning outcomes. It is widely believed (even being a tenet of the Kentucky Education Reform Act of 1990) that students learn more effectively if they are taught via their preferred learning styles. Ramsden (1988) affirms that learning styles or orientations of students need to be taken into consideration when a teacher designs curriculum.

Different studies propose different learning styles (e.g., Myers-Briggs's Type Indicators and Kolb's Learning Style Inventory — LSI) to serve their needs (Mitchell, 2000). Most of them agree that learning styles are experiential or phenomenological in nature (Kolb, 1984; Lewin, 1951). Students change their learning styles based on their learning experiences (Harris & Schwahn, 1961). Students with different learning styles also show preferences for different teaching methods (Gregorc, 1982) and software training methods (Bostrom et al., 1990).

In the OAL environment, instructors should customize Web-based learning tools for students with different learning styles. For instance, online training tools may need to be tailored for students based on their LSI profiles (Ross & Schultz, 1999). The behavior modeling approach has been considered the most effective approach in the F2F environment. Learning style seems to be inconsequential with respect to behavior modeling. It is possible that the behavior modeling approach may still be the most valid method for training in the OAL environment, regardless of the students' learning style. It is not known which learning medium would be the most effective vehicle for the behavior modeling approach in the OAL environment.

OAL Environment

Built on his personal distance training and education experiences since 1971, Horton (2000) suggests that online synchronous and asynchronous

learning and training be designed for different purposes. Synchronous learning demands the control of schedule, time, people, class size, video and audio equipment, and place. These factors constrain the possibility of reaching large numbers of students at any given time and in any given place.

This study limits its focus exclusively to software training in an online asynchronous mode to avoid the influence of these factors embedded in synchronous online training. This choice reflects the reality that most online training delivered across continents is in the online asynchronous mode, and that use of that mode is destined to grow incrementally and exponentially. Therefore, this study is intended to develop a more versatile, compatible, and responsive online software training strategy for online asynchronous students in the IT field.

Online Asynchronous Mediums for Behavior Modeling

Simon et al. (1996) define the behavior modeling approach as “a combination of the exploration and instruction methods that concentrates on the idea of observing and doing while following a role model” (p. 44). The behavior modeling approach customizes the learning environment for all students, making it easier to understand learning materials. Its lecture formats include specific learning points and hands-on experimentation. Imitating the instructor in using a target system encourages the students to participate and experiment using the target system to follow their own paths. Online asynchronous training mediums empower the practice of behavior modeling because users can study lecture slides on one hand, rely on external resources to solve problems, and get feedback from teachers and students.

Without the presence of a live instructor, the scripted solution potentially narrows the difference of training approaches (yielding a smaller effect size) that may contribute to the difference

of training outcomes. Videotaped or videotaped-based behavior modeling may somewhat resemble the F2F learning environment. Since a live instructor is replaced with a scripted or videotaped demonstration, there is a necessity for students to play a more active role in an OAL environment. Nevertheless, the suitability of delivering behavior modeling in these different modes is unclear. Assessing the relevance and applicability of behavior modeling training method in different modes is the first important step toward discovering an optimal online asynchronous behavior modeling training method.

Social Presence and Information Richness of Online Asynchronous Mediums

Theories of social presence and information richness (SPIR) have strong implications to online learning. For instance, e-mail with social cues can deliver psychological presence, while asynchronous conferencing (e.g., whiteboard and net chatting) can deliver more rich information than downloaded files. Figure 1 shows a taxonomy illustrating the SPIR features of online asynchronous training mediums.

In the F2F environment, exploration-based, instruction-based, and behavior modeling approaches are three useful training methods to teach software use. In an OAL environment, different online mediums can support each traditional training approach. Lecture slides, indexing, FTP, and other accesses to workstation applications can be used in instruction-based mode for software training. Message systems, conferencing, and browser links to Internet sites, on the other hand, allow students to explore solutions for problems given by instructors.

The effectiveness of behavior modeling is a function of people and the environment (Lewin, 1951). Integrating mediums with differential SPIR degrees into the OAL environment may affect the usefulness of behavior modeling method.

Comparing behavior modeling method in F2F, scripted and videotaped modes allow students to investigate the impact of differential social presence on learning effectiveness.

Potential Difference of Training Approaches between F2F and OAL Environment

Numerous studies came to a similar conclusion, which is, there is no significant difference in end-user satisfaction (Russell, 1999) and learning outcomes (Smeaton & Keogh, 1999) between F2F and online modes of education. Swan (2002) recommended that social presence and interaction be incorporated into the design of online courses to improve student satisfaction and learning outcomes. Unlike online education, incorporating the three general software training approaches (instruction-based, exploration-based, and behavior modeling) that have long been successfully established in the traditional F2F environment into an OAL environment can be problematic. As a case in point, the success of the exploration-based training approach in the OAL environment is contingent upon: (1) the quality of the course materials, (2) the OAL environment (Web site) design, and (3) the available bandwidth. This differs from the training approach in the F2F environment where quality of course materials is the major determinant. Moreover, generic examples used in the course materials may be relevant to some online asynchronous users and irrelevant to the others. In the OAL environment, the student population is more diversified. An inability to customize course materials based on students' backgrounds may reduce the effectiveness of the exploration-based training approach. Lack of a live instructor is likely to make the situation worse. Students with lower motivation may direct their attention to other matters not relevant to the immediate learning task, without the presence of an instructor to provide the necessary discipline to redirect students' attention.

Differential Impacts of Social Presence on the Behavior Modeling Approach

Through the reiterative communication process, the exploration-based approach in the F2F environment can mitigate any misunderstanding between instructor and students about the goals of the training and course materials. In the OAL environment, an asynchronous communication pattern takes place. Misunderstanding is generally identified after a learning attempt takes place, that is, the instructor and students do not communicate with each other at the same time (asynchronous). This phenomenon may discourage some students with lower self-guidance abilities from keeping pace with the goals. The wealth of Internet information can even distract some students' attention away from the course objective. In the F2F environment, the live instructor can facilitate the process, give timely feedback, and quickly get a discussion back on track. This condition does not exist in the OAL environment. There is a need to make a trade-off between information richness and reach for students who do not have high-bandwidth connections at home or work. An instructor may need to give up some richness of

information to reach larger number of students. Without knowing the accessibility of students to the Internet, instructors will have trouble deciding the right trade-off. Class size adds another variable, complicating the situation. The greater the class size, the more time an instructor will need to respond to students' questions in both the F2F and OAL environments.

The behavior modeling method is an enhanced mode of instruction-based and exploration-based methods. As a result, the behavior modeling method naturally inherits potential flaws of the other two methods in the OAL environment. In addition, in the OAL environment students may have trouble with the lack of modeling behavior from a live instructor to assist their learning. One alternative that can address this issue is to substitute scripted or videotaped lectures for the instructor's lectures. The interactive presence of the instructor was the key determinant for the success of the behavior modeling approach in the F2F environment. The validity of the claim that using the video replacement for the instructor is

Figure 1. SPIR features of e-learning mediums (based on Fulk, 1993; Daft & Lengel, 1986; Zack, 1993)

the most effective training approach for students of all learning styles in the asynchronous environment may not be supported. Additionally, learning outcomes can be further degraded because the real-time reiterative communication process between instructor and students is lost.

Our literature review found that no effective online asynchronous training strategy has been formulated to date. Assessing the relevance and applicability of behavior modeling in an OAL environment is the first important step towards discovering more suitable strategy to deliver it in different modes.

RESEARCH DESIGN

This study applied Simon et al.'s (1996) well-constructed training theory to test experimentally three modes of the behavior modeling approach in an OAL environment. In doing so, we hoped to detect the effects of the independent variables (training method and learning style), as well as their combination, on training outcomes. The experiment was conducted in a field setting that enabled the study to garner greater external validity than would be the case with a laboratory experiment. A field experiment methodology has the merits of "testing theory" and "obtaining answers to practical questions" (Kerlinger & Lee, 2000, p. 583). The exploratory nature of the study requires that variables (e.g., learning style, training methods, and subject areas of study) under investigation be manipulated.

The setting for the field experiment comprised courses offered by two accredited universities: California State University at Northridge and Loyola Marymount University. The experiment was motivated by the need of 135 college undergraduate Business majors to learn Microsoft Access 2002.

Regardless of the teaching environment (online or off-line), computer training is intended to instill in users a level of competency in using the

system and to improve their satisfaction with the system. A user's competency in using a system is contingent upon his or her knowledge absorption capacity. Ramsden (1988) finds that effective teaching needs to align students with situations where they are encouraged to think deeper and more holistically. Kirkpatrick (1967) also suggests that learning effectiveness needs to be evaluated by students' reaction, learning, and knowledge transfer. The levels of knowledge absorbed by students, Bayman and Mayer (1988) suggest, may include syntactic, semantic, schematic, and strategic knowledge. Mennecke, Crossland, and Killingsworth (2000) believe that experts of one particular knowledge domain possess more strategic and semantic knowledge than novices. Knowledge levels, as Simon et al. (1996) suggest, can be categorized as near transfer, far transfer, or problem solving.

Near-transfer knowledge is necessary for being able to understand software commands and procedures. Procedural knowledge is important for a student to use software in a step-by-step fashion. Far-transfer knowledge is to ensure that a student has the ability to combine two or more near-transfer tasks to solve more complicated problems.

Both the use of software and the satisfaction levels of using them are useful surrogates to measuring the effectiveness of an information system (Ives, Olson, & Baroudi, 1983). End-user satisfaction levels have been widely adopted as an important factor contributing to the success of end-user software training. Since the study is to replicate Simon et al.'s research in a dissimilar environment, near-knowledge and far-knowledge transfer, and end-user satisfaction levels were adopted in this study to measure training outcomes.

Participants filled out a questionnaire regarding their experiences with Microsoft Access and other database applications. This survey was used to check subjects' computer literacy and experience.

To determine the effectiveness of the training treatments, subjects were evaluated immediately after training. Evaluation of retention and transfer of learning included 10 multiple-choice questions and one Microsoft Access database problem to solve. This study further links scientific investigation and solutions to real-world situations, while exploring the possibility of applying key determinants for the success of IT training strategy, found in the traditional training environment, to the online asynchronous training situation.

Hypotheses

The online behavior modeling approach replaces the live (face-to-face) instructor with the videotaped or scripted demonstration. Some key elements of the Face-to-face Behavioral Modeling (FBM) approach may be lost. Behavior modeling training in the F2F mode may be more effective at improving the learning outcome for a student than the behavior modeling approach in the online asynchronous mode. Researchers have demonstrated that behavior modeling is more effective than instruction-based or exploration-based approaches in the traditional environment. A similar relationship may still be identified in the OAL environment. Proving that the F2F behavior modeling is more or less effective than the online behavior modeling could justify the validity of replicating the same pattern in the OAL environment. Hence, it is only hypothesized that the FBM approach is more effective than online behavior modeling to improve learning outcomes for students of all learning styles. In the OAL environment, the videotaped-based training may retain more key elements of the online behavior modeling approach, such as the psychological presence of an instructor, than the scripted training approach. Therefore it is plausible that the videotape-based training is more effective than the scripted training approach. In all cases, we are hypothesizing that the FBM approach is more

effective than the Videotaped Behavioral Modeling approach, which is more effective than the Scripted Behavioral Modeling approach.

Perceived Usefulness (PU)

H1a: The Face-to-face Behavioral Modeling approach is more effective than the Videotaped Behavioral Modeling approach to improve perceived usefulness for students regardless of learning styles.

H1b: The Face-to-face Behavioral Modeling approach is more effective than the Scripted Behavioral Modeling approach to improve perceived usefulness for students regardless of learning styles.

H1c: The Videotaped Behavioral Modeling approach is more effective than the Scripted Behavioral Modeling approach to improve perceived usefulness for students regardless of learning styles.

Knowledge Near-Transfer (KNT)

H2a: The Face-to-face Behavioral Modeling approach is more effective than the Videotaped Behavioral Modeling approach to improve knowledge near-transfer for students regardless of learning styles.

H2b: The Face-to-face Behavioral Modeling approach is more effective than the Scripted Behavioral Modeling approach to improve knowledge near-transfer for students regardless of learning styles.

H2c: The Videotaped Behavioral Modeling approach is more effective than the Scripted Behavioral Modeling approach to improve knowledge near-transfer for students regardless of learning styles.

Knowledge Far-Transfer (KFT)

H3a: The Face-to-face Behavioral Modeling approach is more effective than the Videotaped Behavioral Modeling approach to improve knowledge far-transfer for students regardless of learning styles.

H3b: The Face-to-face Behavioral Modeling approach is more effective than the Scripted Behavioral Modeling approach to improve knowledge far-transfer for students regardless of learning styles.

H3c: The Videotaped Behavioral Modeling approach is more effective than the Scripted Behavioral Modeling approach to improve knowledge far-transfer for students regardless of learning styles.

Procedures

The experiment's procedure and timeline utilized in this study are outlined and described below.

Phase 1. Pilot Study

- Solicit opinions of 10 users using a prototype online asynchronous training Web site. These users are not participants in the actual experiment.
- Correct online training-related problems before executing the actual experiment.

Phase 2. Recruitment

- Students are college Business major undergraduates.
- Obtain a copy of students' registration records (names and student ID).
- Randomly assign students to different training methods on the class basis.

Phase 3. Pre-Training Activities (20 minutes)

- A five-minute analogical instruction to explain how the e-training system at <http://blackboard.csun.edu> and <http://www.lmu.edu/blackboard> could help students learn how to use the Access 2002 software.
- Provide students 10 minutes to fill out a pre-training questionnaire.

Phase 4. Training (20 minutes)

- Conduct the training session. The class instructor decided the timeline based on his ability to complete the teaching of five subjects covered in the experiment.
- Since the length of time can affect the learning outcomes, the timeline is standardized for online training approaches.

Phase 5. Post-Training Evaluation (30 minutes)

- Provide students five minutes to complete near-transfer knowledge testing.
- Provide students 30 minutes to complete far-transfer knowledge testing (solve a real problem).
- Provide students 10 minutes to fill out a post-training questionnaire.

Recruitment

Subjects were undergraduates who needed to learn Microsoft Access 2002. The subjects received no additional pay or monetary benefits for their participation in the experiment. Rather, students were notified in advance of their mandatory presence. Students also knew that an additional score of 5 (out of 100) would be credited to their total score of the semester. Subjects were not pre-screened

Figure 2. Allocation of participants

Training Approach	Behavior Modeling Modes			Number of Total Subjects
	FBM	VBM	SBM	
Number of Participants	45	35	35	115

for their participation because of the nature of the field experiment.

The students were randomly assigned to one of the three treatments on the class basis: (1) F2F behavior modeling (FBM), (2) scripted behavior modeling (SBM), and (3) videotaped behavior modeling (VBM). A total of 115 students registered to participate in the classes and all participants were expected to attend the mandatory class. Figure 2 shows the arrangement by which these students were to receive one of the three treatments.

Training

The topic to be taught included five main features and functions: (1) create tables, (2) create forms, (3) input records, (4) create queries, and (5) generate reports. All training sessions were conducted using a single instructor, providing continuity throughout all training sessions. This was to prevent the influences of teaching experiences and skills on learning effectiveness.

In the OAL environment, the instructor’s presence is often not an essential factor. The limitation of bandwidth also constrains the use of videotaped teaching materials. The study recognized the limitations of these constraints. Therefore, scripted and videotaped presentations were conducted in a computer lab where the 10/100 Mbps LAN infrastructure was established. The length of time for both online behavior modeling methods was controlled to be the same across all three treatments to avoid the outlier influence

of exposure time. Although the compromised solution might not fully capture all the key elements of each training approach, it adequately reflected the real situations of conducting online asynchronous training. Teaching materials were deliberately designed to reflect the key elements of the behavior modeling approach.

Scripted Behavior Modeling

SBM is an enhanced mode of exploration and instruction approaches. The behavior modeling approach includes both inductive and deductive approaches. The treatment was conducted in the same computer classroom as the other online training treatments. Both general concepts and procedural information sections were conducted utilizing Hyperionics’ Hypercam Version 1.70.06 software screen capturing application. The application allowed the researchers to record all the step-by-step cursor movements of instruction with voice annotation. More importantly, the Hypercam application substituted for the live instructor-based delivery. Each scripted demonstration focused on one particular function of the database management topic. At each learning point of a particular function, students were encouraged to experiment by practicing the related exercises.

Videotaped Behavior Modeling

Videotape is employed to deliver the image of a live instructor and his/her voice to students on the OAL environment. Like video-conferencing,

videotaped-based training permits psychological presence in addition to using both inductive and deductive approaches. Despite the benefit, the instant interaction between instructor and students are eliminated. Students may have a lower satisfaction level when taking the videotaped-based training rather than the F2F training. Videotaped-based training enlarges the difference between the instruction-based and exploration-based approaches. This increases the effect size that may have higher impact on the effectiveness of training.

F2F Behavior Modeling

Without the presence of a live instructor, the scripted solution had the potential of narrowing the differences between training approaches that may contribute to the difference of training outcomes (a small effect size). To properly control the potential problem, a group in which students received the traditional FBM training approach was introduced. The instructor followed the same script as the one designed for the behavior modeling class in the online asynchronous training mode. The length of time allotted to conduct the training was controlled to be the same as the other online training approaches. The traditional behavior modeling group took the same pre- and post-training tests as the three online groups to properly evaluate the contribution of training approaches and learning styles to training outcomes. The training literature recommends that a control group in a training experiment be included (Wexley & Latham, 1991).

Post-Training Evaluation

Treatment and control groups were administered two tests and satisfaction evaluations upon completion of the 20-minute training treatment. The two tests included 10 multiple-choice questions and one Access database problem to solve.

The multiple-choice questions were intended to evaluate students' procedural knowledge of the commands and features needed to manage a database using Access 2002. Solving a real problem allowed the researcher to evaluate the ability of the students to transfer that knowledge to another subject. There were a total of four sub-questions that required more than one command to solve. Five minutes were allocated for the multiple choice test, while 30 minutes were allocated for the problem-solving test. The two tests were graded on a 10-point scale. The multiple choice test result was based on the number of questions correctly answered. The Access database problem assigned a value based on the number of functions successfully completed.

Experimental Controls

Training Materials

Training materials were carefully crafted by adopting the non-anonymous Delphi method to reach a consensus of experts. Many rounds of discussion with experts insured that the customized content of training materials could properly capture the key elements of different training approaches. This was to ensure that the effect of size across training treatments was well addressed.

Training Packages

The training packages were designed to maximize the effect size or the difference of three training treatments. All training packages began with the illustration of four examples to manage a database using Access 2002. Two examples are prepared for each major. Subjects were encouraged to use one of the two examples relevant to their major to practice through the training session. Step-by-step instruction was adopted to illustrate each function.

Prior Computer Experience

All participants were classified as “novice” computer users or beginners because of their first exposure to the in-class training. Since it was a challenge to locate novice users or users with absolutely no computer experience, the recruitment of undergraduate Business majors from California State University at Northridge and Loyola Marymount University controlled the potential influence of varying prior computer experiences of participants. Most importantly, the majority of these students had not been exposed to Access 2002. Only six students (2.6% of the total number of subjects) self-reported their limited experiences (in the range of one to three hours) of using the software. This situation provided an objective baseline from which to assess the real effects of training approaches by managing the outliers of computer experiences.

Motivation

Controlling for motivation insured that all students had the same incentive to participate in the experimental study. Since the students were students who registered for the class, their participation was not voluntary. Upon completion of the training session, students took two exams, a 10-question multiple-choice test and an MS Access problem to solve. The total scores represented 5% of their aggregate semester grade.

Training Session Time Length

The length of training time is closely correlated with the learning performance of novice students (Wexley & Baldwin, 1986). To mitigate the influence of varying training time, the training time was fixed at 20 minutes based on the class instructor’s judgment as to the optimal time in which to complete teaching five features of the topic “Database Management” in the FBM class.

While 20 minutes may seem short for a training session, given the well-defined domain of the task, the 20-minute session was deemed appropriate and validated by external sources.

Dependent Variables

For reasons of internal validity, the study uses the same measurable indicators — near-knowledge and far-knowledge transfer — extensively used in training and learning experiments. Near-transfer knowledge is a student’s ability to understand syntactic and semantic concepts and procedures after taking an online asynchronous training. Multiple-choice questions are most widely used for this purpose in other studies. In addition, the study was particularly interested in understanding the problem-solving capabilities of students after taking online asynchronous training. Built upon prior studies, the study asked students to actually use the target system to solve a given real problem within a limited time. The MS Access project results were used to measure far-transfer knowledge.

The study also uses Davis and Olsen’s (1984) perceived usefulness and perceived ease of use instruments to measure end-user satisfaction levels.

DATA ANALYSIS AND RESULTS

Ninety-seven students completed the experiment; 18 did not complete the assignment due to missing data and class absence. Due to the possible interaction effects of attitudes and learning performance (near- and far-knowledge transfer), the assumptions of homoscedasticity ($p=0.023$) and normality were tested and supported. Mean and standard deviations of dependent variables are reported for three treatments in Table 1. Multivariate tests of significance are conducted to investigate the effects of personal factors on dependent

Differential Impacts of Social Presence on the Behavior Modeling Approach

Far Transfer	7.70	3.11	8.14	2.29	5.78	3.11

Table 2. Multivariate test of significance

Effect	Wilks' Lambda	F	df	p	Observed Power
BM Modes	0.736	5.081	2; 94	0.000*	0.993
Experience	0.656	1.631	8; 88	0.035*	0.965
Class Year	0.866	2.283	2; 94	0.038*	0.786
GPA	0.751	2.268	4; 92	0.010*	0.915

variables (see Table 2). Testing results indicate the existence of main effects of behavior modeling modes. Database application experiences, class year, and GPA are only three personal factors that have a statistically significant effect. These findings lend support to the proposition that different behavior modeling modes could have an impact on students' learning performance and attitudes due to their social presence attribute.

Univariate tests were further performed to understand the accountability of factors for the overall significant results (see Table 3). Significantly differential impacts of behavior modeling modes, frequency of using database applications, class year, and GPA were detected across dependent variables. For instance, behavior modeling modes of training and GPA have significant impact on the end-user satisfaction and knowledge far-transfer capability. In contrast, the frequency of

using database applications has little relationship with end-user satisfaction.

The post-hoc test (Wilcox, 1987) was assimilated in order to verify the formulated hypotheses (see Tables 4 and 5). The analysis results indicate that subjects taking FBM have higher perceived usefulness than the two online asynchronous treatments. The finding supports H1a and H1b. Contrary to these hypotheses, students receiving VBM did not express higher satisfaction levels than students receiving SBM. The existence of reversed relationship in the measure of far-knowledge transfer may be due to higher expectation of VBM than SBM. However, its statistical evidence on H1c is not clearly indicated. Technical barriers of retaining the same resolution level as SBM in VBM course materials may not properly meet the expectation of students.

Our findings did not support H2a, H2b, and H2c. First, VBM and SBM groups scored higher

Differential Impacts of Social Presence on the Behavior Modeling Approach

than FBM in the measure of knowledge near-transfer. Second, while students receiving VBM scored higher than those receiving SBM, the score differential was not statistically significant. The similar performance in the measure of knowledge near-transfer across three behavior modeling modes indicates that the element of social presence may have no effects on the dependent variable.

H3a is not supported because the VBM group scored higher than FBM, even though there is no significant difference between these two modes. This may indicate that both FBM and VBM modes present a similar degree of social presence to students. The effect size seems to be much larger between SBM and any other two behavior modeling modes. Both FBM and VBM groups outperformed the SBM group with statistical difference. H3b and H3c are supported. Our speculation that social presence has an impact on knowledge far-transfer effectiveness is partially supported.

Correlation tests showed that a positive correlation exists between end-user satisfaction and three elements of social presence attribute—control (0.621, $p=0.01$), sensory (0.559, $p=0.01$), and distraction (0.446, $p=0.01$). Realism (-0.086) is the only social element that is reported as having no correlation with the measure. These findings do confirm our speculation that the social presence would have impacts on the satisfaction levels of end-users who take online asynchronous training. That is, subjects taking FBM expressed a higher degree of control, realism, sensory, and distraction than VBM. And subjects taking VBM have higher degree of social presence than those taking SBM. The same pattern of evidence is also detected on the correlation tests between social presence elements and the other two dependent variables—knowledge near- and far-transfer effectiveness. These evidences further affirm the importance of integrating social presence elements into online asynchronous training.

DISCUSSION

Behavior modeling preserves not only the strength of induction and deduction pedagogy, but also allows students to imitate the behavior of instructors in the F2F environment. Facing technological discrepancy in their learning environment, online asynchronous students may not be receptive to behavior modeling course materials with high social presence. The reality has necessitated the trade-off among different training behavior modeling modes. Therefore, key challenges ahead of us are to understand whether the trade-off is necessary. There may exist no significant difference among three behavior modeling modes in terms of their social presence impact on end-user satisfaction and learning performance. If this is the case, lights may need to be shed on non-technological issues. Otherwise, technological barriers, particularly the bandwidth and course materials with a high social presence element, may still be an issue.

The results reported above indicate that students assimilating software knowledge through either VBM or SBM achieved comparable levels of satisfaction. However, most students still reported higher satisfaction by taking the FBM than the other two online asynchronous behavior modeling approaches. This result, somewhat consistent with the stated hypotheses, indicates the differential impacts of social presence appear to be much higher between the F2F and OAL environment. VBM and SBM deliver the same degree of social presence element that leads to a similar satisfaction level.

Social presence seems not to be a crucial factor contributing to the effectiveness of transferring near-knowledge. Three behavior modeling modes of training lead to no differential impact. The step-by-step element of the instruction approach seems to be more important than the social presence element. Three behavior modeling modes of training retain the induction element, thereby

allowing students to have the same mastery level of software command and functions.

Counter to the findings, social presence elements did lead to higher performance in knowledge far-transfer effectiveness. FBM and its counterpart VBM preserve a comparable degree of social presence that contributes to higher mean scores than SBM. These evidences clearly prove our viewpoints that behavior modeling modes with higher social presence would have a higher impact on knowledge far-transfer than behavior modeling modes with lower social presence.

LIMITATIONS

Course materials of VBM and SBM were delivered to students through a projector. Technical barriers to have students take advantage of higher levels of student control and flexibility available in the OAL environment seem to be an issue that leads to insignificant difference of end-user satisfaction between VBM and SBM. Most of answers towards the open-ended question, “What were missing from or needed to be added to the online training session?” centered on the control issue. One student commented that “sometimes there was confusion and the training went on further and caused some confusion.” Another participant stated that she needs “the ability to stop and go back, just in case you missed something.” Another way of expressing the lower control level of the course materials includes the control of audio quality and learning pace. Students with varying degrees of experiences and knowledge in database applications expressed dissatisfaction with the play speed of course materials and the frequency of repeating some basic commands. For instance, one student stated, “maybe the sound could be better and a little bit slower pace,” while other students suggested that “background noise should be omitted — [it was] distracting”; “long pauses should be omitted”; and “it may not have been necessary to instruct the users on how to

drag and drop when creating the queries (at least not more than once).”

Although the study was not designed to have replay/forward/backward functions, the degree of control seems to be an issue here to stay. Given no differential impact on the end-user satisfaction and knowledge near-transfer, we will not be able to determine whether the control or social presence is a more influential factor. Despite of the limitations, we can confidently conclude that the control factor is a less important issue than the social presence factor to the effectiveness of far-knowledge transfer. Subjects of the study taking VBM and SBM were given no control of the replay/forward/backward functions. Yet, we can clearly identify the differential impact of social presence on the measure of far-knowledge transfer. This evidence points out the possibility that the control factor may have an impact on the end-user satisfaction and knowledge near-transfer. The study could not testify and quantify the possibility because we could not overcome technical barriers of having the replay/forward/backward functions enabled for all students in the first place. That explains why we used the open-ended questions to measure participants’ opinions about the potential value of such functions. Additionally, the control element of social presence is also measured using a survey. Our findings indicate that three modes of behavior modeling training do provide a satisfactory level of control. In the future study, to measure end-user satisfaction and near-knowledge transfer, the degree of control may need to be manipulated to directly investigate its relative impacts.

A second limitation concerns the existence of potential flaws in recording quality and speed. Although we conducted a survey to measure the realism factor of VBM and SBM, no significant impact on three dependent variables can be identified. This may result from the varying perceptions of audio and video quality, pace, and so forth among all participants. A better instrument to measure these perceptions should be used next

time to serve as covariates for further analysis.

Failure to equalize cell size of three treatments demands that the assumptions of MANOVA and ANOVA be complied to improve the study's reliability. Most of their assumptions were met, except that the independent observations and equal variance-covariance were somewhat complied. Participants receiving FBM treatment are students from Loyola Marymount University, Los Angeles. Other participants are students from California State University, Northridge. They received VBM and SBM treatments. The former is a private university, while the latter is a state university. Students' demographical background may pose a potential threat to the assumption of the independent observations. Additionally, the assumption of equal variance-covariance may also be endangered. The correlation test indicates that students' self-reported GPA, class year, and frequency of using database application positively correlate with learning outcomes. Interpreting our findings may require the consideration of the correlation effect.

In addition to the potential threats of internal validity, the experimental study is also constrained with the generalizability of its findings to the assimilation of conceptual knowledge. However, we do believe that this would not be an issue because the study was principally rooted in the end-user computing field and had a clear objective of improving the learning effectiveness of IT skills, that is, primarily procedural knowledge. Still, researchers can make the generalizability of our findings a less debatable issue by replicating the study with different applications or with different research methodologies.

CONCLUSIONS AND IMPLICATIONS

While the importance of learning strategy and of degree of a student's control may continue to prevail, the design of course materials with a higher social presence element may need to be properly

incorporated in the OAL environment. Doing so allows students to improve their satisfaction level and knowledge far-transfer. There are two options to integrate our findings into the implementation of online asynchronous software training. In the scenario that students are unfamiliar with an OAL system or environment and face-to-face meetings can take place at the beginning of the session, a two-phased hybrid approach could be more effective than a pure online behavior modeling approach. Instructors may want to first conduct an FBM approach in the beginning of training sessions before students familiarize themselves with the training platform. Once the introduction phase is concluded, a VBM mode of training could be assimilated to accommodate the personal schedules of the instructor and students. Based on our findings, the hybrid approach may lead to the same degree of end-user satisfaction and learning performance, particularly in knowledge far-transfer.

In the second scenario, where most students have had experiences of taking online asynchronous training and are familiar with online asynchronous system, VBM could be as useful as FBM in terms of improving end-user satisfaction and knowledge far-transfer. Contingent upon what scenario an instructor is faced with, the two-phased hybrid of FBM and SBM, along with pure SBM may need to be used interchangeably.

A salient fact is that conducting online asynchronous software training is much more complex than the choice between hybrid and pure behavior modeling modes. When faced with a more complex learning environment (e.g., subjects with varying cultural and educational backgrounds, IT skills, cognitive ability, and learning platforms) (Piccoli, Ahmad, & Ives, 2001), control, interaction, and other factors may have more influential impact than social presence factors on the learning outcomes. Investigating those factors is not within the scope of the study and may need to be further probed.

These preliminary results suggest a number of avenues for future research. As we found, the degree of control may enhance or relegate the learning outcomes of students. Too much control by an instructor may risk devaluing the merits of personalized and flexible learning experiences. Without a certain degree of control by an instructor, students may risk over-exercising the merits of flexible learning experiences that may lead to distraction and degraded learning productivity. How to balance the degree of control relegated to students — and based on what factors — may need to be researched.

Our findings also indicate that personal attributes (e.g., experiences with targeted software and intelligence level) correlated with learning outcomes. Some students complained that learning materials were not customized for them. Their answers are either “too fast,” or “too slow” for certain commands, such as “how to drag and drop when creating the queries.” Future research direction may want to focus on the capability of an online asynchronous training session to present alternatives for students with varying personal backgrounds. For instance, an instructor may want to distribute to students a package of learning materials with differential control levels. The package may include three modes of the behavior modeling approach in VCD format (e.g., .avi file), or video stream formats for a few popular applications (Realplayer, Windows Media Player, and QuickTime). This technological design would allow us to closely examine the importance of control factor.

The human dimension is far more challenging to an instructor in a pure OAL environment where “in class” never takes place. A wide variety of individual characteristics may lead to the incapability of any instructor to individualize programs for all students. This leads to inefficiency of producing online course materials and ineffectiveness of satisfying end-users. The friction between users’ desire for learning flexibility and instruc-

tors’ scarce resources is “the biggest challenge in online learning” (Cameron, Beam, & Beam, 2000, p. 101). Nonetheless, future research may be able to cope with the challenges by examining the impact of cognitive styles on the effectiveness of different online asynchronous functions. For instance, researchers who are interested in the Discussion Forums function may want to investigate the usefulness of forming forums based on leadership, learning, or creativity styles.

Students with different creativity styles may be receptive to different tasks (Fellers & Bostrom, 1993). An online asynchronous platform could be a fertile “Press” or environment that can be used to support both explorative and generative tasks. Since the student-centered environment improves the accessibility and availability of information and domain experts (instructors and knowledgeable classmates), it is possible that the production of creativity could be more efficient than the traditional F2F environment (Csikszentmyhalyi, 1990). However, whether the OAL is suitable for any particular creativity style remains an open question.

In conclusion, the study attained its objectives by clearly illustrating the differential impacts of three behavior modeling modes of software training, namely FBM, VBM, and SBM, on end-user satisfaction and knowledge transfer effectiveness. On top of that, the study attests to the potential of presenting viable and effective alternatives to exercise different behavior modeling modes of training.

Chapter 5.14

Exploring the Behavioral Dimension of Client/Server Technology Implementation: An Empirical Investigation

Eitel J.M. Lauría
Marist College, USA

ABSTRACT

This paper explores the impact of human factor and organizational behavior on the outcome of information technology implementation projects. Client/server technology implementation is used as the leading case, given the fact that it is a good example of a major paradigm shift¹. The results draw attention to the importance of end-user interaction and the maturity level of organizations as significant factors in the success and benefits of the project. Client/server projects seem to be more successful, are executed in a more timely manner, and yield greater benefits when end users take an active participation in some of the stages, particularly during the implementation phase.

INTRODUCTION

Information has become one of the most important assets in today's business world. The threats, busi-

ness drivers and pressures on organizations in the information age were summarized by Hammer and Champy (1993) as the three Cs — *Customers*, *Competition*, and *Change*. Knowledgeable customers, increasing competition, and constant change have driven organizations to find new ways to respond in order to excel or even survive. At the center of the stage, information technology (IT) holds an ever-increasing role, steering innovation in products and services, enabling new business processes, and linking individuals and organizations.

It comes as no surprise that the impact of IT implementation in organizations has been one of the most important topics in both business and information systems research in the last 30 years. Organizations have increasingly relied on IT to maintain their competitiveness. However, the track record of IT implementation is not very good. In many cases, IT driven innovations have not fulfilled their potential to enhance efficiency and effectiveness within companies, due largely to human and organizational reasons. Benjamin

and Levinson (1993) suggest that the benefits of IT are not being realized because investment is heavily biased toward technology and not toward managing changes in process and organizational structure and culture. Among all factors that may undermine an IT project, behavioral issues are perhaps the less well understood. This perspective is the motivating force behind the current work.

The study has two primary objectives: 1) develop a causal model to assess the effect of human and organizational factors on the outcome of an IT implementation project; and 2) empirically validate the model on client-server implementation survey data, given the fact that client/server computing is a mature technology that introduced a major shift from legacy data processing systems.

The following section provides a short overview of IT implementation models and critical success factors, in particular those related to behavioral issues. Next the paper introduces the causal model, describing the hypotheses under consideration. Then the paper presents the client/server case study, depicting the survey data, the statistical methods applied for model validation, the outcome of the statistical analysis and a discussion of the results. Finally, the paper provides a summary, which includes future research opportunities.

IT IMPLEMENTATION MODELS AND CRITICAL SUCCESS FACTORS

There has been plenty of interest in identifying the critical drivers of IT implementation's success and to gauge their impact on how well projects perform. The reasons leading to mediocre and sometimes disastrous results can be viewed from multiple perspectives, including behavioral factors (people and organizational issues), planning, complexity, and technological issues. There is still no general agreement, though, as to the complete set of factors that lead to a successful

implementation, and their relationship or order of precedence. This fact suggests that considerable work remains to be done. We cite here some of the available research recognizing that we are just presenting an overview of the extant literature, and apologize for any notable omissions.

Researchers have developed a number of frameworks and models to better understand IT implementation success. Delone and MacLean (1992) propose a model based on six categories of IS success measures: System Quality, Information Quality, Organizational Impact, Individual Impact, User Satisfaction, and IS Use. Seddon (1997) considers three types of constructs: measures of information system quality, measures of net benefits regarding IS use (perceived usefulness, user satisfaction) and behavior with respect to IS Use. The Technology Acceptance Model (TAM) (Davis, Bagozzi, & Warshaw, 1989; Venkatesh, 2000; Venkatesh & Davis, 2000) regards perceived usefulness and perceived ease of use as critical factors that influence an individual's technology adoption decision. Somers, Nelson, and Karimi (2003) argue that user satisfaction is one of the most important determinants of IS success.

According to Griffith and Northcraft (1996), less than 10 percent of technology implementation failures stem from technical problems. Instead, most of these failures resulted from human or organizational difficulties. Technological change is always a big issue in any organizational context. It can mean loss of jobs, requires new skills and impels new working relationships and business decisions that were never made before. Focus is typically placed on tangible benefits and changes are usually applied without considering the human side of IT driven change. Some authors have gone even further in their criticism of the computerization phenomenon. In his book "The Squandered Computer", Peter Strassmann (1997) points at the lack of correlation between IT investments and financial returns, stressing the importance of the human dimension. In Strassmann's own words:

It is not computers that make the difference, but what people do with them. Elevating computerization to the level of a magic bullet of this civilization is a mistake that will find correction in due course. It leads to the diminishing of what matters the most in any enterprise: educated, committed, and imaginative individuals working for organizations that place greater emphasis on people than on technologies.

Researchers have focused on such issues as user involvement and management support, IT alignment with business objectives, and organizational maturity. Baroudi and Orlikowski (1986), and Baronas and Louis (1988) contend that user involvement results in more useful and accessible information systems. Kuk (2004) shows that, in the context of vendor-managed inventory (VIM) implementation, organizations with high levels of employee involvement are more likely to accrue the potential benefits of the new technology.

Ettlie, Bridges, and O'Keefe (1984), Cheney, Mann, and Amoroso (1986), and Brancheau, Schuster, and Mar (1989) suggest that senior management support is essential for effective IS planning and execution. Ravichandran and Rai (2000) identify top management leadership as an important element of a quality-oriented software development effort. Wixom and Watson (2001) via a Partial Least Squares (PLS) derived model, demonstrate that management support increases the likelihood that data warehousing projects will finish on-time, on-budget, and with the right functionality.

In a classical article on IT implementation and organizations, Markus (1983) explains that resistance to IT change is the product of the interaction of system design features and intra-organizational distribution of power. An empirical study conducted by the IBM Consulting Group (1994) indicates that organizational readiness is a critical implementation factor. Reich and Benbasat (2000) argue that congruence of IT vision (long-

term alignment) and shared domain knowledge among business and IT executives are contributing IT implementation success factors. According to Laudon and Laudon (2004), organizational culture is a powerful restraint on technological change. The ease with which change and innovation can be instrumented through the use of IT will vary according to organizational factors, the nature of its leadership and the way in which employees perceive these changes.

MODEL DEVELOPMENT

Client/Server computing technology represents a form of distributed cooperative processing in which a client, or requester, submits requests to the server, which in turn processes the requests and returns results to the client (Stallings & Van Slyke, 1998). Not since the evolution from batch processing systems have we witnessed such fundamental shift in systems architecture. The commercial Internet, the deployment of Web-based applications and the whole concept of electronic commerce can be considered as a side effect of the client/server craze that has swept organizations, at least from the perspective of IT change.

Based on findings from relevant prior research, an overview of which was presented in the previous section, we propose here a causal model for systematic analysis of behavioral issues of IT implementation, in the context of client/server technology projects. Specifically, the proposed model suggests that an IT implementation project success can be explained or predicted by behavioral issues. Behavioral issues in the proposed model revolve around two major themes: the human factor and organizational behavior.

Human Factor: We conceptualize human factor in two principal dimensions: end-user interaction and top management involvement. End users are people at work in the organization, including various levels of supervision and functional management that may be directly or indirectly affected

by the new technology put in place, and have the potential of being instrumental in its implementation. The most common reaction to IT implementation in organizations is resistance to change. New technology implies change, and change is threatening and disruptive if it portrays a future dissociated from past experience. McNurlin and Sprague (1998) explain that people resist change, especially technological change, when they view it as a crisis. If the employee does not feel as part of the overall transformation process, IT-driven change is likely to lead to job dissatisfaction. Greater participation by all those affected by the implementation of new technology contributes to a much more positive response.

Top management involvement adds another critical dimension to the human factor issue. This typically comprises the higher levels in the organizational hierarchy, including CEOs and CIOs. Since the early 1990s, there has been more awareness on the need for IT savvy executives. However, still few chief officers have the depth of background in IT that they have with their functions, such as marketing or finance. Most still do not understand the issues that drive technology and think primarily of the IT function as cost. This sketchy appreciation is augmented by the current hype and potential of new technologies such as the Internet and electronic commerce. IT is perceived as a technical issue and is often overlooked and left out of the scope of top management decisions.

Organizational Behavior: Organizational behavior is the other main theme. We focus on two dimensions when describing organizational behavior: shared vision and maturity. Shared vision synthesizes IT alignment with the organization's objectives and business goals. Maturity characterizes the organization's consistency and readiness to implement IT. McNurlin and Sprague (1998) define a technologically mature organization as one that realizes the business value of information and IT, and manages the assimilation of IT

into its business. New operating procedures and business policies are put in place to deal with IT implementation. Project details are approached in a systematic manner, as a part of a well laid out plan.

Project Success: We take the outcome of the project as the natural empirical indicator of IT implementation success, conceptualizing it in terms of four dimensions:

- **Benefits:** Benefits are usually a good objective measure of the outcome of a project, but they fail to capture other aspects of implementation success
- **Timeliness:** measures whether the project was delivered on time.
- **End-User Effects:** How were users affected by the project? Are they willing to use the new technology?
- **Overall Perception:** What is the general feeling of the organization with regards to the outcome of the project? Was it successful or was it a failure?

Additional Factors: Along with human factor and organizational behavior there are, of course, numerous other factors that could account for project success. Previous studies found that the result of a technology implementation project may be linked to the characteristics of the organization and of the project. For example, Duchessi and Chengalur-Smith (2000) found that the initiation and adoption process of client/server technology in organizations is affected by the market position of the firm and on certain characteristics of the application. Organizations that implement systems that are too complex for them or take too long to be implemented are likely to fail. Then again, applications that are too simple will not yield significant benefits. The inherent characteristics of the organization, (its culture, the level of centralization, the nature of its leadership, the distribution of power) may also have a major influence on the outcome of an IT project.

In order to control for the characteristics of the organization implementing technology and the nature of the client/server project, a group of measures have been included:

- Organization Characteristics
 - Private organization or government / public organization
 - Market position (dominant, major competitor, minor competitor)
- Project Characteristics
 - Length of the project
 - Project relevance (how critical the project is for the organization)
- Organizational Culture / Management Style
 - Degree of authoritativeness
 - Degree of decentralization

Causal Model and Research Questions

Figure 1 is a graphical representation of the causal model underlying this analysis. The goal is to explore the relationship between several measures of human factor and organizational behavior and several measures of project results, while controlling for background characteristics of the organizations, and the applications that they implemented.

Accordingly, we raise the following research questions:

- What is the effect of human and organizational issues on the result of the project?
- Are end-user interaction and top management involvement critical success factors?
- Are increases in organizational maturity and shared vision related to increases or decreases in project success?
- How are project benefits related to human and organizational issues?
- What is the influence of the organization and the project's characteristics on the outcome of the implementation.

RESEARCH DESIGN AND DATA COLLECTION PROCEDURES

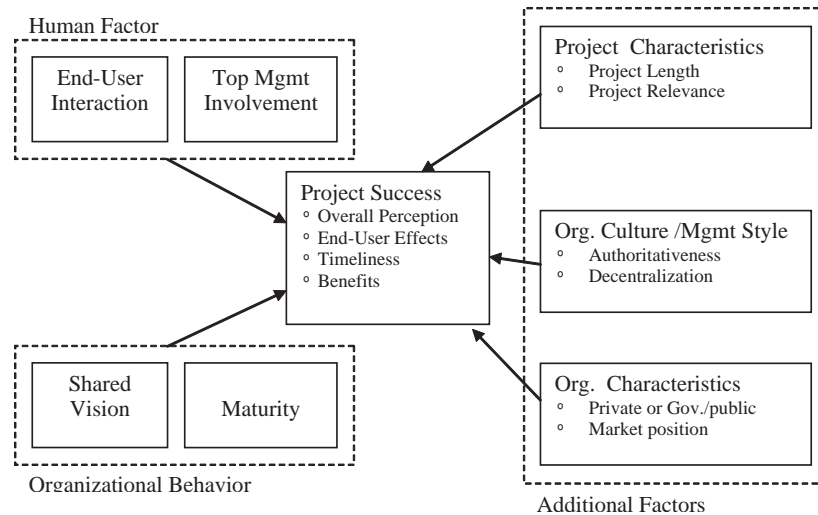

The objective of this study is to examine the effects of people issues (human factor) and organizational issues on the outcome of client/server projects and validate the behavioral model by statistically analyzing survey data of client/server implementations. At the time of the survey, client/server architecture had become the mainstream technology for development of distributed applications. Most organizations were either committed to actually implementing client/server applications or had shown considerable interest in the technology.

Data Source

The source of data for this analysis is a nation wide survey of companies implementing client-server systems (Duchessi & Chengalur-Smith, 2000).² The sampling list for the survey came from CMP Direct Marketing Services, which provided a database of about 400,000 organizations, either using client/server systems or interested in them. From this database a random sample of 5000 executives was selected. Questionnaires were mailed to 4593 executives (the other 407 entries had incomplete data) and 350 usable responses were received.

The questionnaire is composed of a set of closed-ended (structured, fixed response questions) organized into five sections: 1) background (organization and application); 2) information planning; 3) project's analysis and design; 4) implementation; 5) systems support. The unit of analysis could be an entire company, a division, or a product group. Most of the questions, except those that require a specific input from the respondent, were based on a 5-category Likert scale, where 1 means "strongly disagree" and 5 means "strongly agree". The average number of missing values per field is 14, with a standard deviation of 13.

Figure 1. Causal model showing the effects of human factor and organizational behavior on project success and project benefits

Sample Profile

The majority of respondents to the survey were senior IT executives (41 percent); 24 percent senior corporate executives (presidents, CEOs, and chairpersons); senior managers, (9 percent), and the rest (26 percent) including primarily IS and functional managers (see Figure 2). Regarding implementation, 19 percent had completed at least one client/server implementation project, 56 percent were in the late stages of the project (most clients and servers implemented), and 26 percent were in early implementation (systems planning and analysis, network infrastructure). About 30 percent of the respondents classified their companies as dominant market leader, 47 percent regarded themselves as being a major competitor, and the remaining 23 percent classified as minor competitors.

The distribution of organizations' size, as measured by number of employees, was the following: 26 percent of organizations had less than 100 employees; 29 percent had between 100 and

1000 employees; 35 percent had between 1000 and 10000 employees; and only 11 percent had more than 10000 employees. This means that the sample is representative of small, medium, and large organizations.

Twelve percent of the respondents belonged to Government organizations; the other 88 percent were distributed in service (24 percent), industrial (18 percent) financial (18 percent) and retail and publishing (32 percent). Sixty percent of the applications spanned three or more functional areas, and 75 percent of the respondents described their applications as mission critical. Close to 50 percent of the respondents claimed their organizational structures are decentralized, and nearly 45 percent reported that their companies are highly authoritative.

Research Methodology

The research methodology followed a straightforward quantitative approach, through the application of multivariate regression analysis

Exploring the Behavioral Dimension of Client/Server Technology Implementation

The questionnaire asked respondents to report the way in which the client server application had been proposed, introduced, and deployed in the organization; the way in which the end users and the organization as a whole had faced the challenge; and the outcome and benefits of the project. The survey questions were used to operationalize each dimension associated with each variable in the model. Each dimension was measured as a combination (i.e. an average) of answers to survey questions.

Table 1, for example, shows the behavioral constructs (Human Factor and Organizational Behavior), their associated dimensions, and the survey questions that were used in each case to

formulate the measures. Note that in order to assess user participation at different stages of the project’s life cycle, “End-User Interaction” was subdivided into two stages: Planning, Analysis, and Design; and Implementation and Support. Appendix 1 presents detailed definitions of all the constructs, dimensions, and survey questions used in the study.

Data Analysis and Results

We used ordinary least squares regression analysis (OLS) to relate the behavioral factors to three measures of project result, and the remaining one was analyzed using logistic regression. We applied

Figure 2. Sample profile of respondents

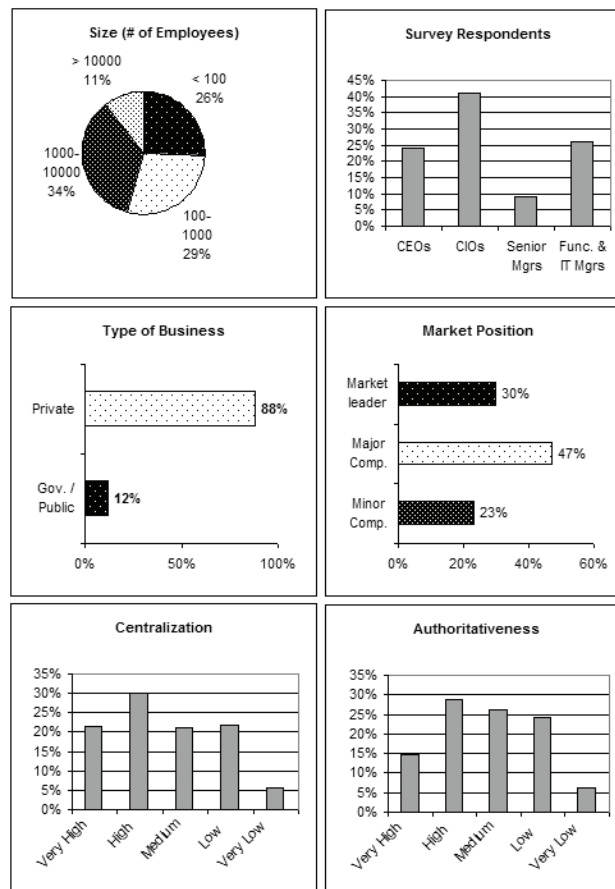

Table 1. Operationalization of behavioral constructs

Construct	Dimension	Survey Questions
Human Factor	End-User Interaction (Planning, Analysis, and Design)	<ul style="list-style-type: none"> ◦ functional managers are active in developing information strategy ◦ functional managers determine the requirements of c/s apps ◦ users had input in design of the c/s application ◦ proportion of end users in project team
	End User Interaction (Implementation and support)	<ul style="list-style-type: none"> ◦ users guided and directed testing activities ◦ users have been trained to use c/s app ◦ IS group works with users to ensure that c/s app continues to satisfy user requirements ◦ user consider IS group as partners
	Top Management Involvement	<ul style="list-style-type: none"> ◦ CEO is a technology champion ◦ CIO participates in strategic planning ◦ someone with full authority attended steering committee meetings ◦ steering committee met regularly
Organizational Behavior	Shared Vision	<ul style="list-style-type: none"> ◦ strategic fit of c/s app with IT strategy I ◦ IT strategy is part of SBU's strategic plan ◦ IS applications are aligned with SBU goals ◦ c/s app is an integral part of IT strategy ◦ business function requirements reflect business needs
	Maturity	<ul style="list-style-type: none"> ◦ cost/benefit analysis was used ◦ project team prepared detailed specs ◦ project team developed a migration plan ◦ new business policies and operating procedures were developed and promulgated ◦ project team had technically skilled people ◦ vendor products / services were tested

OLS in the case of *Overall Perception* (Regression 1), *End-User Effects* (Regression 2), and *Benefits* (Regression 3). Note that although *Overall Effects* is a discrete variable, it was approximated to a continuous variable. On the other hand, and due to its dichotomous nature, we applied logistic regression in the case of the dependent variable *Timeliness* (Regression 4).

We evaluated the reliability of the independent and dependent variables, specifically those composite measures generated by averaging groups of questions available in the survey (see Appendix 1). Reliability was assessed using Cronbach's alpha. Most of the investigated factors exhibited an alpha value greater than 0.70, suggesting a reliability exceeding the common acceptable level. End-User Interaction in Planning, Analysis, and Design showed an alpha value of 0.53, somewhat lower (but not by much) than the reliability threshold (0.60) considered adequate in exploratory studies.

Additional statistical tests were performed on the data to check for outliers, influential observations, and assess the degree of multicollinearity of the data. These tests as well as the details of the reliability analysis are depicted in Appendix 2.

The results of the multiple regression analysis are presented in Tables 2 and 3. Table 2 shows the coefficients for the independent variables from ordinary least-squares regression analyses predicting three different aspects of the outcome of the project: overall perception, end-user effects and benefits obtained. Table 3 displays the result of the logistic regression applied to predict the timeliness of the project.

The results of Regression 1 show that Human Factor (measured from the point of view of end-user interaction during the implementation stage of the project) and Organizational Behavior (measured in terms of the maturity of the organization to address technological change) are positive predictors of the project's success. A slope of 0.71 in

Exploring the Behavioral Dimension of Client/Server Technology Implementation

end-user interaction, implementation and support (HFEUIIS) means that, for each unitary increment in HFEUIIS index, the overall perception of success (OVERALL) increases 0.71 points, controlling for organizational behavior, organization's characteristics, culture and management style, and project's characteristics. In a similar manner, a slope of 0.50 in organization's maturity level (OBSMAT) means that, for each unitary increment in OBSMAT, the overall perception of success (OVERALL) increases 0.50 points, controlling for the rest of the independent variables. Mission critical projects tend to be more successful: for each unitary increase in MISSCRIT, the overall perception of success increases by 0.22 points. The results of Regression 1 also show that there are no significant differences in overall success between private and government organizations and among organizations with different market

shares (dominant, major competitor, minor competitor). Organization's culture and Management style are also not significant: project success is not affected by the degree of decentralization and authoritativeness in organizations.

Regression 2 and 3 confirm the findings of Regression 1. In Regression 2, Human Factor clearly predicts positive end-user effects, reinforced by the fact that in this case, end-user interaction during the planning, analysis, and design stage (HFEUIPAD) is also significant: a unitary increase in HFEUIPAD, raises end-user effects by 0.29 points. Organizational behavior, driven by maturity level, predicts an increase of 0.16 units in end-user effects for every unit of increase in maturity.

Project relevance (MISSCRIT) is not significant in Regression 2, and shorter projects seem to be slightly related to positive end-user effects

(an increase of 1 month in project length reduces overall perception of success by 0.01 points). As in the case of Regression 1 there are no significant differences among organizations with different characteristics (government/private, market position), different culture and management style (authoritative, decentralized). Regression 3 follows the pattern of Regression 1: unitary increases in Human Factor (end-user interaction during implementation) and Organizational Behavior (maturity level), increase benefits by 0.25 points and 0.30 points respectively. Mission critical projects are positively related to project's benefits and there are no significant differences in benefits among organizations with different characteristics, culture and management style.

Regression 4 describes the effect of Human Factor and Organizational Behavior on the timeliness of the project controlling for several project characteristics, organization characteristics, cultural issues and management style (see Table 3). We could verify that each unitary increase in end-user interaction during the planning, analysis, and design stage (HFEUIPAD) increases the log odds of timeliness by 0.67. This means that an increase of 1 point in HFEUIPAD raises the odds of meeting the target dates of the project by 96.4 percent. Major competitors have 0.76 less log odds of finishing the project on time than organizations with a dominant market position, controlling for Human Factor, Organizational Behavior, project characteristics and organization's characteristics,

^b The comparison category is Public Organization.

organization's culture, and management style. This means that the odds of a timely project decrease by 53.3 percent. Minor competitors seem to have no significant differences with dominant organizations regarding the timeliness of the project.

In the same manner, private organizations have 1.22 less log odds of finishing the project on time than government organizations, controlling for Human Factor, Organizational Behavior, project characteristics and organization's characteristics, organization's culture and management style. This means that the odds of committing to the target dates of the project decrease by 70.5 percent.

Discussion

The results of this analysis suggest that people and organizational issues influence the outcome and benefits derived from technology implementation projects. End-user interaction and organizational maturity were identified as two positive factors of project success. Projects seem to be more successful, are executed in a timelier manner, and yield greater benefits when end users take an active participation in the project, particularly during the implementation and support phase. This entails well trained end users that participate in testing and review procedures, and have established a fluid relationship with the IS group.

We would also have expected a significant positive influence of end-user interaction during the planning, analysis and design phase, as end users tend to feel a certain "ownership" of the project, which usually leads to higher levels of commitment and increased productivity. When end users are committed to the project from its early stages, the new technology is not perceived as a burden or a threat, but rather as a new component in the end user's set of skills. This is straightforward in the case of "end-user effects" and project timeliness.

But the results of the regression show no evidence of significant influence in the overall perception of success, and benefits of the project. This might mean that end users take a leading role at later stages of the project. It is during the implementation and support phase that their involvement can radically change the fate of a project. Activities such as testing, training and continuous review are critical to implementation success. It is possible that respondents' answers might have reinforced this view, reducing the relevance of end user's participation during the early stages of the project. Also, we must consider the possibility of some inconsistency in the composite measure (HFEUIPAD) given the fact that it has the lowest alpha value of all constructs.

Surprisingly, top management involvement does not seem to be a significant issue in the final outcome of the project. This result, which would otherwise contradict mainstream organizational theory, requires further investigation. A reliability error in the construct does not seem to be a plausible explanation: the alpha value for top management involvement is high enough (0.78). Neither could we find any correlation in the variables that would explain the lack of significance. We assume in principle that the outcome may be due to some bias in the way in which the respondents interpreted certain questions in the survey.

Regarding organizational behavior, maturity is a significant factor in the project's success, and subsequent benefits generated by the project. This is quite intuitive if we consider the attributes that define maturity: pragmatism to assess the cost-benefit equation of the project; methodic approach at defining and executing each phase, and aligning business procedures and policies with the implementation of new technology; and rigor to assemble the project's team and/or selecting the right vendors for the task. These are tangible qualities that easily reflect on the outcome of the project.

On the other hand, shared vision does not seem to significantly influence the project's results or its timeliness. This may be due to the fact that the survey questions used to operationalize such concept stand at a higher level of abstraction and may derive in positive effects only when measuring such effects in the long term. It is reasonable to assume that IT alignment with the organization's goals and strategies is a desirable feature. But in the short run, the effects may not be as visible as those coming from those related to maturity. It is precisely this set of attributes that are prevalent in defining short term results, which are basically those being measured by this study.

CONCLUSION

A contribution of this work is the extension of the IT implementation literature through the investigation of behavioral issues affecting client/server implementation projects. Both IT implementation research and client/server and distributed technologies research can benefit from these findings, stimulating future research and practice considerations.

We were also able to identify end-user interaction and the maturity level of organizations in addressing IT driven change as significant factors in the success and benefits of the project. Client/server projects seem to be more successful, and yield greater benefits when end users are actively involved in the implementation.

This work is based on a survey reflecting results of projects implementing "traditional" (2-tier / 3-tier) client/server architectures. While this approach is convenient, given the wealth of data available in the client/server survey, further research is required to broaden the definition of client/server architecture, in lieu of the fact that Web-based applications fall under this category. This opens up an avenue of research in confirming whether this study's findings are likely to hold true in a client/server Web-based environment.

APPENDIX 1. MEASURES USED IN MULTIPLE REGRESSION ANALYSIS

Organization characteristics

- Market Position (MKTPOS): categorical, dominant=1, major competitor=2, minor competitor=3 (Mean =1.94)
- Government or private: (ORGTTYPE, recoded from INDUST2): categorical, 0=Gov, 1=private (Mean = 1.88)

Organization's culture / management style

- Authoritative (AUTHORIT): 1=low to 5=high (Mean=2.79, SD=1.15)
- Decentralized (DECENTRAL): 1=low to 5=high (Mean=2.6, SD=1.2)

Client Server application characteristics

- Length of the project (MONTHS): measured in number of months (Mean=17.79, SD=13.14)

- Mission Critical (MISSCRIT): 1=low to 5=high (Mean=3.97, SD=1.07)

Human Factor

— End User Interaction

- **HFEUIPAD: Planning, Analysis and Design: Mean of 4 measures, 1=low to 5=high (Mean=3.51, SD=0.66)**
 - PFUNDEV: Functional Managers are active in developing information strategy
 - PFUNREQ: Functional Managers determine the requirements of c/s applications
 - ADUSERIN: Users had input into designing the c/s application
 - PCTENDUS: Proportion of end users in project team (normalized to meet the 1 – 5 scale)

- **HFEUIIS: Implementation and support: Mean of 4 measures, 1=low to 5=high (Mean=3.68, SD=0.6)**
 - UGUIDE: Users guided and directed testing activities
 - UTRAIN: Users have been trained to use c/s app
 - ISWORKS: IS group works with end users
 - UPARTNER: User consider IS group as partners

- **Top management involvement (HFTMI): Mean of 4 measures, 1=low to 5=high (Mean=3.74, SD=0.72)**
 - PCHAMP: CEO is a technology champion
 - PCIOPART: CIO participates in strategic planning
 - SAUTHOR: Someone with full authority attended steering committee meetings
 - SCOMMREG: Steering committee met regularly

Organizational behavior

- **OBSHV: Shared vision: Mean of 5 measures, 1=low to 5=high (Mean=3.91, SD=0.59)**
 - ADSTRAT: Strategic fit of c/s app with IT strategy was used as a basis for going forward with c/s application
 - PITSTRAT: Information technology strategy is part of SBU's strategic plan
 - PALIGN: IS applications are aligned with SBU objectives and strategies
 - PINTEGRT: Client Server Application is an integral part of IT strategy
 - ADFUNREQ: Business function requirements reflect business needs

- **OBMAT: Maturity: Mean of 6 measures, 1=low to 5=high (Mean=3.52, SD=0.61)**
 - ADCOSTB: Cost/benefit analysis was used as a basis for going forward with the c/s project
 - TDESPECS: Project team prepared detailed specs for all c/s modules
 - SPTDEV: Project team developed a migration plan for network systems, mgmt and org. change
 - TNEWPROC: New business policies and operating procedures were developed and promulgated
 - SPTSKILL: Project team had technically skilled people
 - VTESTING: Vendor products / services were tested to see if they functioned as advertised

Project Result

- **Overall Perception: 1=low to 10=high (Mean=6.7, SD=1.94)**
 - OVERALL: To date, overall, how successful has your client server implementation been
- **EUEFF: End User Effects: Mean of 5 measures, 1=low to 5=high (Mean=3.81, SD=0.6)**
 - UENHANCE: Users job performance is enhanced by client server application
 - UPREFER: Users prefer to use alternative systems whenever possible
(value reverted to convert into ascending scale)
 - UENABLE: C/S applications enables users to accomplish tasks that were not previously feasible
 - UTHREAT: User feel that this C/S pp threatens their employment
(value reverted to convert into ascending scale)
 - UFEELRES: Users feel responsible for success of this client server app
 - **Timeliness: categorical, Yes=1, No=0 (Mean=0.66)**
 - TIMELNSS: Target dates were met

BENEFITS: mean of 15 measures, 1=low to 5=high (Mean=3.16, SD=0.79)

- BINTEGRT: Integration of business information
- BORGPROD: Increased organizational productivity
- BCUSLINK: Improved linkages with customers
- BSUPLINK: Improved linkages with suppliers
- BFINPOST: Improved financial position
- BCOMPOST: Improved competitive posture
- BCUSERVC: Improved customer service
- BSYSRELY: Improved system reliability
- BSYSACCS: Improved decision making
- BDECMKG: Reduced decision making time
- BREDTIME: Reduced cycle time
- BREDCYCL: Reduced costs
- BREDCOST: Better control / mgmt of business

- BCONTMGT: Empowerment of employees
- BEMPOWER: Reengineered business processes

APPENDIX 2. STATISTICAL TESTS

Several statistical tests were performed to check the reliability of the constructs and to verify that OLS assumptions were satisfied by the data. The details of these analyses are described below:

Reliability Assessment

We ran Cronbach alpha tests for each set of survey questions that define a composite measure verifying that the reliability of the chosen constructs ranged between 0.53 and 0.89 (HFEUIPAD=0.53; HFEUIIS=0.74; HFTMI=0.78; OBMAT=0.78; OBSHV=0.70; BENEFITS=0.89; EUEFF=0.83). Note that although those tests correspond to additive composite indexes, we used the mean of the group of component variables as a summary statistic representative of the whole set. The reason is that the average provides a more robust measure, by allowing inclusion of cases missing responses.

Multicollinearity Assessment

To evaluate the degree of multicollinearity³ among the independent variables we calculated the variance inflation factor (VIF), which measures the proportion by which the variance of the slope is inflated by multicollinearity. A standard cutoff for VIF is 4, equivalent to $R^2_k=0.75$ (R^2_k is the coefficient of multiple determination in each auxiliary linear regression equation where the independent variable X_k is taken in turn as dependent variable). We verified that for each of the OLS regressions, VIF was below 1.8, which means that multicollinearity stayed below 0.45. For the four regressions (including logistic regression), we also checked the correlation matrix and verified that the Pearson coefficient was in all cases below 0.45.

Outliers and Influential Observations

For each of the three OLS regressions, we checked the studentized residuals, searching for outliers and influential observations.

We could verify that in all three regressions more than 93% of the observations were within 2 standard deviations of the regression hyperplane, which is a good approximation to normality. Extreme outliers (greater than 3 std. deviations) did not exceed 1.5%.

In the case of influential observations, less than 10 % of the leverage values in all three OLS regressions exceeded the cutoff value of twice the Mean Centered Leverage ($2 * \bar{h}$), which remained around 0.05. The residual scatterplots (Figure 3) show that data is rather evenly distributed with respect to the horizontal line drawn at 0; but regressions 2 and 3 exhibit a visible pattern in the deviations around the fitted regression hyperplane probably due to the fact that both dependent variables are quasi-discrete in nature.

ABSTRACT

There has been substantial interest in delivering ICT training options to rural and remote areas of Queensland, Australia, in order to bridge the rural-urban divide. But there is more than just education and training going on: Participants are being empowered to gain new skills and confidence, form new networks, become active in the community, and be proactive in addressing their own health and well-being needs.

THE RURAL AND REMOTE CONTEXT

Rural and remote populations often experience poor access to services (Simpson, Wood, Daws, & Seinen, 2001; Wagenfeld, Murray, Mohatt, & DeBruyn, 1997). This applies to essential health services, to services that enable individuals and communities to gain the skills necessary to participate in the social changes affecting the population, and to the peer-support services

needed by isolated professionals. In Australia, long-standing factors in service delivery to rural communities, such as sparse population, distance, and limited availability of public transport, are being exacerbated by the reduction in and withdrawal of existing face-to-face services. In terms of health services, access constitutes a significant issue for rural communities. At the same time, the traditional jobs base for these communities in primary production is shrinking, resulting in psychological pressures and the need for the re-skilling of many of those people formerly employed in such industries.

Health literacy, understood in its broadest sense, is a key issue for these communities. Parker (2000, p. 280) notes, "... for those with limited health literacy, as health care is becoming increasingly complex and health information is becoming more diffuse in the public domain, there is more reliance on written materials to educate and inform people about their health." As governments at all levels seek ways to simplify, and reduce the costs of, the task of meeting health-service needs, the attractions of e-government for service delivery to a receptive "wired" community are strong (and ICT vendors have encouraged that attraction). However, for those community members used to the supportive environment of face-to-face service delivery and unfamiliar with ICTs, the focus on service provision via the Internet creates new challenges. The incentive for computer literacy (Hamm as cited in Loader & Keeble, 2004) is strengthening.

The problems associated with negotiating the changed rural social and service environment impact particularly those people who have characteristics that may intensify their isolation and lack of access to information, including people of cultural and linguistic diversity (CALD), disabled people, and people with low literacy skills. A socially inclusive society requires informed communities that have the means, skills, and opportunities to communicate (IBM, 1997). For those unable

to meet these criteria because of age, ethnicity, disability, income, or circumstance, difficulties associated with the acquisition of everyday information via the Internet can potentially create considerable frustration and distress, increasing the degree to which these people are marginalized within their community, and impacting their health and well-being.

THE CASE-STUDY PROJECTS

The projects build on earlier work that identified the difficulty in accessing accurate current information and in obtaining appropriate health and well-being support for these populations. Interviewees in fieldwork for *Creating Rural Connections* (Simpson et al., 2001) reported a variety of information needs, including more timely access to a wider range of information, and the desire for specific information in response to an identified need (such as to address a health problem), to locate employment, or to improve the family business.

Community members identified two levels of specific need. First is the need for access to specialist services, including medical services and counseling; ongoing access to help, companionship, and mentoring; community-service databases to facilitate better networking and referral services; improved access to services for disability groups, particularly services that have the potential to overcome the effects of communication limitations and personal isolation; and opportunities to identify and reinforce existing support networks. They also identified the need for re-skilling regarding computing skills as a necessary tool in the changing work and social environment. The projects developed to help address these needs have provided an inclusive and supportive learning environment for individuals who had experienced marginalization in their communities. The focus in each project has been

on Bella and Bishop's (2004) "building on" community capacity: "helping people believe in their own skills" (p. 13).

HOW THE PROJECTS OPERATE

The projects are built on the recognition that social isolation and access to information are significant issues for marginalized people in far-north Queensland and, in particular, for people who speak little or no English, for indigenous peoples, and for disabled people. Drawing on research that has shown the Internet to be an effective, appropriate means of meeting such needs for a diverse range of people (Communication Centre, 2001; Simpson et al., 2001), the projects sought to:

- enhance the skills base in small communities;
- help create a more informed community and a more equitable society in part via access to information by marginalized groups;
- facilitate the sharing of skills through the development and creation of online and face-to-face social networks;
- develop an innovative and transferable process that will be relevant to other groups and other communities;
- increase awareness of the potential of online technologies for contributing to the social connectedness and overall well-being of potentially marginalized groups, particularly but not exclusively in rural and remote areas; and
- provide "train the trainer" instruction for volunteer community members from marginalized groups that will assist them in conducting training that is appropriate for their client base, taking into account the specific needs arising from age, gender, rurality, ethnicity, literacy, and/or disability.

While these aims focus on the technical and training needs of people in rural and remote communities, it is how these goals are enacted that creates the powerful social and health outcomes. Projects intended to deliver ICT training to marginalized groups have often failed. When asked what the problems were with computer training programs they had attempted, participants identified the following:

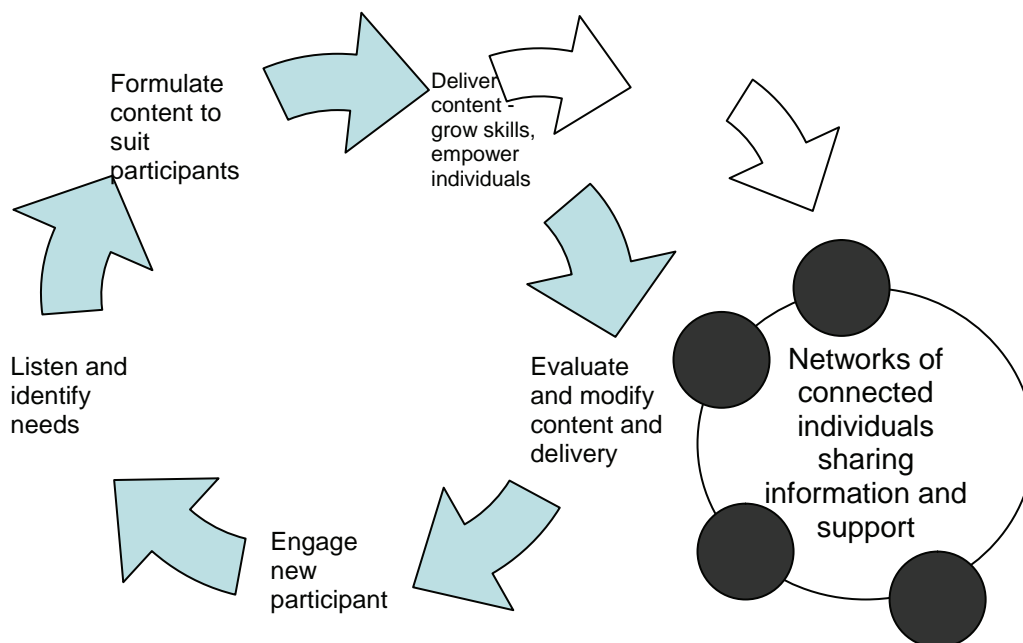

- Modules not relevant to their needs
- Training moved too quickly for them to keep up with the group
- Could not understand the trainer
- Class sizes too big
- Felt alienated from the other students
- Felt alienated from the teacher
- Too old
- Left it too late

As Feinstein, Hammond, Woods, Preston, and Bynner (2003) found, for those who have been away from learning for some time, there are particular qualities in the learning environment that enable the wider benefits to flow. Such programs need to "ensure engagement ... [C]lasses that are not sensitive to learners' needs are not necessarily going to generate the wider benefits. The provision of facilities and encouragement for interaction would also appear to be essential components" (p. 74). The projects described emphasize the need to surmount these issues, and the need for building a supporting and sustaining social infrastructure. The e-life cycle is the methodology common to all these projects,¹ revolving around a five-stage approach (illustrated in Figure 1): Engage the marginalized, listen to the learner, identify the need(s), formulate effective programs, and evaluate and modify.

Engage the Marginalized

Engaging the community and ascertaining their training needs is the crucial first step. Tu-

Figure 1. Inclusion, connectedness, and information sharing: Making connections face-to-face and online

tors publicize their programs through community places like hotels, community centers, and shops, as well as through recruiting clients via other community organizations, which refer people with literacy and/or numeracy needs to the program, and also offer services to learners taking part in the program.

Listen

Developing effective strategies for access and participation that take differences in community needs and the whole range of local social, economic, cultural, and technological factors into account can provide more equitable access to ICTs while increasing the overall success of community informatics initiatives (Rural Women and ICTs Research Team, 1999; Simpson, 2004;

Simpson et al., 2001). Providing an environment in which participants feel they are valued and are treated as capable equals is crucial to the e-life cycle's listening stage; participants here voice their needs explicitly, and those needs are addressed. Empowerment is also important for, as Feinstein (2002, p. 9) found, "Psychological well being, which encompasses a sense of personal control, and freedom from stress and hostility, in turn appears to lead to better health outcomes."

Identify

In this environment, specific training needs can be accurately identified since participants gain a sense that they are valued, that their needs are unlikely to be "way out" or in some way unacceptable, and that their contributions and concerns

will be treated with respect. Tutors encourage participants to use the technology to follow their own interests in the belief that something that has direct relevance to their own lives will be more enjoyable and more relevant, and will enhance the internalization of the learning process.

Formulate

Formulating effective programs, then, draws on the expressed interests of the participants. For example, participants might express a desire to be able to e-mail a friend or relative overseas, or to access a particular Web site or support group via the Internet. The learning is structured around this need while following a series of specified guidelines, and it is intended to provide all participants with skills in basic computing and connectivity.

There are both accredited and nonaccredited schemes in operation. In the nonaccredited training programs, material is taught in a flexible, self-paced delivery mode. Participants are encouraged to attend each session but are not penalized for not doing so. Emphasis is on meeting the learner's needs. Feinstein et al. (2003) found that the particular value of unaccredited courses is that they "may equip adults with the personal and social confidence as well as other necessary skills to progress to more challenging accredited courses, especially if appropriate guidance is available" (pp. 76-77).

Evaluate

In the projects in north Queensland, opportunities are provided for trying out new skills, sometimes in real-world situations, enabling the teacher to evaluate and modify the training. Is it working? Are participants moving toward confidence and facility? What adjustments can be made?

PRINCIPLES FOR COMMUNITY WORKERS

These projects have demonstrated a clear link between increased social cohesion and connectedness, health literacy, and health outcomes. Four crucial aspects of the e-life-cycle approach are the following.

Participation and Inclusion

The equitable and inclusive participation of people in planning, evaluation, and decision making is vital to sustainable community and economic development. The programs are specifically targeted at marginalized individuals, with the trainer taking a proactive approach to inclusion. The existing capacities and experiences of participants are overtly valued and celebrated, with trainers and other class members supporting and empowering one another in an encouraging, inclusive environment.

Content

It is crucial that content is individually tailored in a group setting to the needs and interests of the clients, is culturally sensitive and gender inclusive, and is made accessible by attention to the language and literacy needs of specific groups within the community. Hence, courses are designed around what participants want, using real-life learning needs or desires to shape learning delivery.

Delivery

Delivery must be flexible and responsive to learners' needs, incorporate design features that capitalise on the tools made available by evolving communication technologies, and support access by people with varying levels of ability, including

those with mobility, vision, hearing, and cognitive difficulties. In designing training-delivery projects, differences between people therefore need to be taken into account, including gender, age, ethnicity, occupation, and level of knowledge of new technologies.

Time

Allowing sufficient time for the development of the positive attitudes and skills necessary for the effective adoption and utilization of online technology is important. For example, the need for “hastening slowly” is evident in each of the human factors affecting the acceptance and value of Web-based services (Communication Centre, 2001). Taking this into consideration, some courses are self-paced, allowing participants to work through individual modules at their own pace and with the support of peers, tutors, family, or friends. This flexibility allows for work and family commitments, and allows participants to work around farm and seasonal commitments.

FUTURE TRENDS AND CONCLUSION

Advances in information technology and telecommunications may offer many potential benefits to Australia’s underserved communities by reducing the barriers of distance and space that disadvantage rural areas; this can only happen where projects enable the participation of all groups in the community. Improvements in the knowledge and use of such technologies have been identified as being beneficial in improving health literacy in rural communities, and they will continue to be an area of attention to reduce health inequities in Australia.

KEY TERMS

Capacity Building: The development of sustainable skills, organizational structures, re-

sources, and commitment to health improvement in health and other sectors.

Health Literacy: The capacity of an individual to obtain, interpret, and understand basic health information and services, and the competence to use such information and services in ways that are health enhancing.

Social Connectedness: The relationships people have with others and the benefits these bring to individuals and society.

ENDNOTE

- ¹ Workers delivering training refer to the process as “normal mode,” a label that downplays its exceptional and innovative qualities.

Chapter 5.16

Transforming Democracy through ICT

Andy Williamson

Wairua Consulting Limited, New Zealand

INTRODUCTION

This article explores the potential of ICT to be used to transform the processes of citizen engagement such that a citizen-centred approach to e-democracy becomes both viable and desirable. It will do so by exploring three tensions relating to democracy and civil society: first that participation in traditional democracy is falling, yet new technologies are mobilising citizens on a global and local scale (such as antiglobalisation protests and electoral protests in the Philippines and Spain); second, ICT increases the technocracy of government but also offers citizens a chance to become closer to it; and third, that macro strategies for ICT access are not enough to remove localised exclusion.

The transformation of government and democracy toward online models does not predetermine that our communities will be strengthened or that satisfaction in or engagement with civil society will increase. The potential success of technology in this field lies in its value as a tool or conduit, the ability of technology to remove barriers of

time and space and to provide access to information. To do this effectively, we need ICT solutions that transform the processes of civil society such that citizens are privileged at the centre of the discourse and so that systems and processes are citizen-centred. This article will attempt to resolve these tensions through the description of a simple evolutionary framework that privileges activities at the citizen-led end of the continuum. The model can be used to identify issues, maturity, and progress of ICT in a community or group of communities and act as input into the development of policy and localised models for community ICT that privilege citizens.

BACKGROUND

Observers such as Putnam (2000) note that engagement in traditional community activities has been declining since the 1960s. Although this decline is mirrored in the political realm, Coleman and Götze (2002) see a drift away from participation as having more to do with apathy brought about

by the increasing technocracy and perceived distance of governments, rather than apathy for democracy itself. ICT, they and others suggest, offers the potential to dramatically change the processes of government and the interactions between government and citizens (Coleman & Götze, 2002; Mälkiä, Anttiroiko, & Savolainen, 2004).

The potential for citizen-led agencies to successfully harness new and emerging technologies in order to subvert hegemonic discourses can be seen in the role that text messaging played during the 2001 Presidential Elections in the Philippines. SMS-enabled mobile devices are now considered ubiquitous in Manila, and a technology-savvy subculture is able to effectively utilise the Internet and new mobile technologies (Quintos de Jesus, 2002). On this occasion, the actions of over a million citizens were coordinated, and street demonstrations organised in what became known as the Manila “People Power II” demonstrations. These events led directly to the downfall of the regime of President Estrada. The 2004 terrorist attacks on Madrid’s rail system occurred days before a general election. While Spain prohibits political demonstrations during the 24-hour period before an election, Spanish citizens used text messaging to self-organize spontaneous demonstrations. Text traffic was 20% higher than normal on the day before the election and 40% higher on election day (Rheingold, 2002, 2004). On a local scale, Williamson (2003) discussed how community activists were able to subvert a political discourse through the use of a Web site and online publishing: A study of housing development in an environmentally contentious area commissioned by Waitakere City Council surprisingly came out against all but a very limited amount of further subdivision. The prodeveloper council attempted to hide the report, refusing to publish it, and, even when forced to by a Parliamentary Commissioner, the city council made access difficult. Obtaining a copy of the report, community activists then scanned

and published it on two local Web sites. E-mail networks were used to widely publicise links to the report. Those with access to the Internet were encouraged to print and distribute the report, thereby ensuring as wide a circulation as possible of this controversial public document.

MAIN THRUST OF THE ARTICLE

News media has long been considered a bridge between the public (and public opinion) and government, yet today it offers little more than “an uneasy compromise between quality and popular news discourses—that represents the worst of both worlds” (Atkinson, 2001, p. 317). This reduction in diversity has occurred alongside a dramatic increase in the management of news, leaving only limited opportunities for citizens to express their own views (Gustafson, 2001). Technology clearly offers citizens the potential to reclaim their voices at a time when there is ever-increasing decentralisation of decision making away from elected representatives toward “experts.” In this new technocracy, decisions are based on science and professional knowledge, not public opinion (Mälkiä et al., 2004). The Internet is a powerful tool for connecting people with information. ICT is valuable when harnessed (like other media) for communicating a message; however, it also extends the traditional concepts of media into an interactive experience, where the views of many can be expressed and potentially disseminated widely. It is this potential that sets ICT apart from traditional print and electronic media and that offers great potential for citizens to become more involved in the political and democratic processes.

Schuler (2000) observed that ICT provides tools for strong democracy, such as e-mail, forums, and online access to documents. Organisations such as Minnesota e-Democracy (www.e-democracy.org) and the Waitakere E-democracy Group (www.wedg.org.nz) demonstrate the

potential for citizen-led engagement. Examples of top-down, government-led initiatives include Brisbane City Council, Camden Council (UK), and Rutland County Council (UK) (online fora), the Queensland and Scottish Parliaments (e-Petitions), and Estonia, Queensland, and Camden Council (broadcasting of legislature and executive). In 2002, Ronneby (Sweden) created an e-democracy Web site and discussion forum with the intent of increasing interest in the upcoming municipal election. Council candidates were able to present their views, and the public could enter into online discussions. An evaluation of the project rated it as a successful pilot, and it was well received by citizens, however, it was not successful in increasing voter turnout (Ronneby Kommun, 2002). While many of these examples are aimed at engaging online with those already engaged in the democratic processes, Queensland has also gone further, creating a Web site for the State's youth to connect with government (www.generate.qld.vic.giv.au).

While the rhetoric of government values engaged citizens and governments feel the need to solicit "feedback in order to develop good policy and services at all levels" (Office of the e-Envoy, 2001, p. 1), citizen involvement should not be assumed. Ranerup (2000) observed that, while on-line fora can be initiated by governments, the community, or other active stakeholders (such as researchers), her own experience of Swedish local government was that citizens, while seen as participants in a forum, were not necessarily consulted over its establishment and design. This highlights a gap between the technocracy of public administration and the desire of those citizens interested in democratisation and the revival of representative bodies (Chadwick, 2003).

Although most developed countries have an e-government strategy, there is no clear articulation of the link between the often-stated efficiencies gained in the delivery of government services and strong democracy (Coleman & Götze, 2002). There is a discourse within governments that sees

e-government as a tool for the management and delivery of services from the centre out. While the New Zealand e-Government Unit observed that "new technologies will enable easier access to government information and processes. People will be better informed and better able to participate" (2003, p. 1), the strategy for achieving this identifies only three limited objectives:

- Make government information easier to find.
- Publish key government information online.
- Provide multiple channels for contact with government.

ADOPTION OF TECHNOLOGY

ICT is not ubiquitous, and clearly, a significant number of citizens remain excluded from the "information economy." Many more are yet to acquire the skills needed, first, to become effective users of ICT (Gurstein, 2003), and, second, to become producers of information, news, and knowledge.

The Australian Government noted that in June 2003, 62% of people in metropolitan areas and 53% of those in nonmetropolitan areas had accessed the Internet (a total of 59% of all Australians). They observed that 55% of the Australian households had Internet access in the home. Although these statistics show encouraging growth over previous surveys, they still point to 45% of Australian households having no Internet access. Only 7% of this group are able to access the Internet elsewhere, and the overwhelming majority cite the high cost (25%) or a lack of interest (25%) as the reason for no Internet access (National Office of the Information Economy, 2003).

Beyond statistics, Zhu, Taylor, Marshall, and Dekkers (2003) observed that, in considering the adoption of ICT, it is important to consider the microlevel motivators, both societal and personal.

They suggest that individuals need to first be aware of and then motivated to want to use ICT, and, subsequently, that it is important that individuals and groups are able to identify value in its ongoing use. As Moore (1999) suggested, adoption is based on an individual's perception of the value and attributes of technology, and the discontinuity of change caused by ICT adoption can itself act as a barrier to uptake and ubiquity.

FUTURE TRENDS

As new ways of communicating supported by ICT emerge, it is necessary to reconceptualise the way we communicate and engage in democracy. While technology can lead to the privileging of experts, it also offers the potential to transform democratic processes from government-led to citizen-led. E-democracy, Chadwick (2003) suggested, is about scale, rendering convenient access to participation beyond traditional constraints of space and time. ICT must become ubiquitous for e-democracy to be effective, and barriers to ubiquity can be technical, economic, cultural, social, or political. Where local communities can become effective users of ICT and active producers of their own content, it is demonstrably possible to affect change and influence local political decision making (Williamson, 2003). The challenge for policy makers and practitioners alike is that many communities do not have equitable access to ICT, not all citizens are ICT literate, and many communities and interest groups lack the knowledge and skills to be effective users.

The community ICT model described here draws on literature that includes Patterson's (1997) four interconnected nodes (design, access, critical mass, and impact) and O'Neil's (2002) meta-analysis of community ICT studies, which reveals five key areas of research: strong democracy, social capital, individual empowerment, sense of community, and economic development opportunities.

Day's (2004) three components of community informatics (policy, partnerships, and practice) are considered, which he underpins with a framework for the democratic design of community ICT initiatives. Day asserts that communities need to be empowered before they can campaign for their own interests and influence community policy, and they must create a "democratic community planning agenda" (Day, 2004, p. 33) by defining the critical criteria for successful and sustainable community ICT projects.

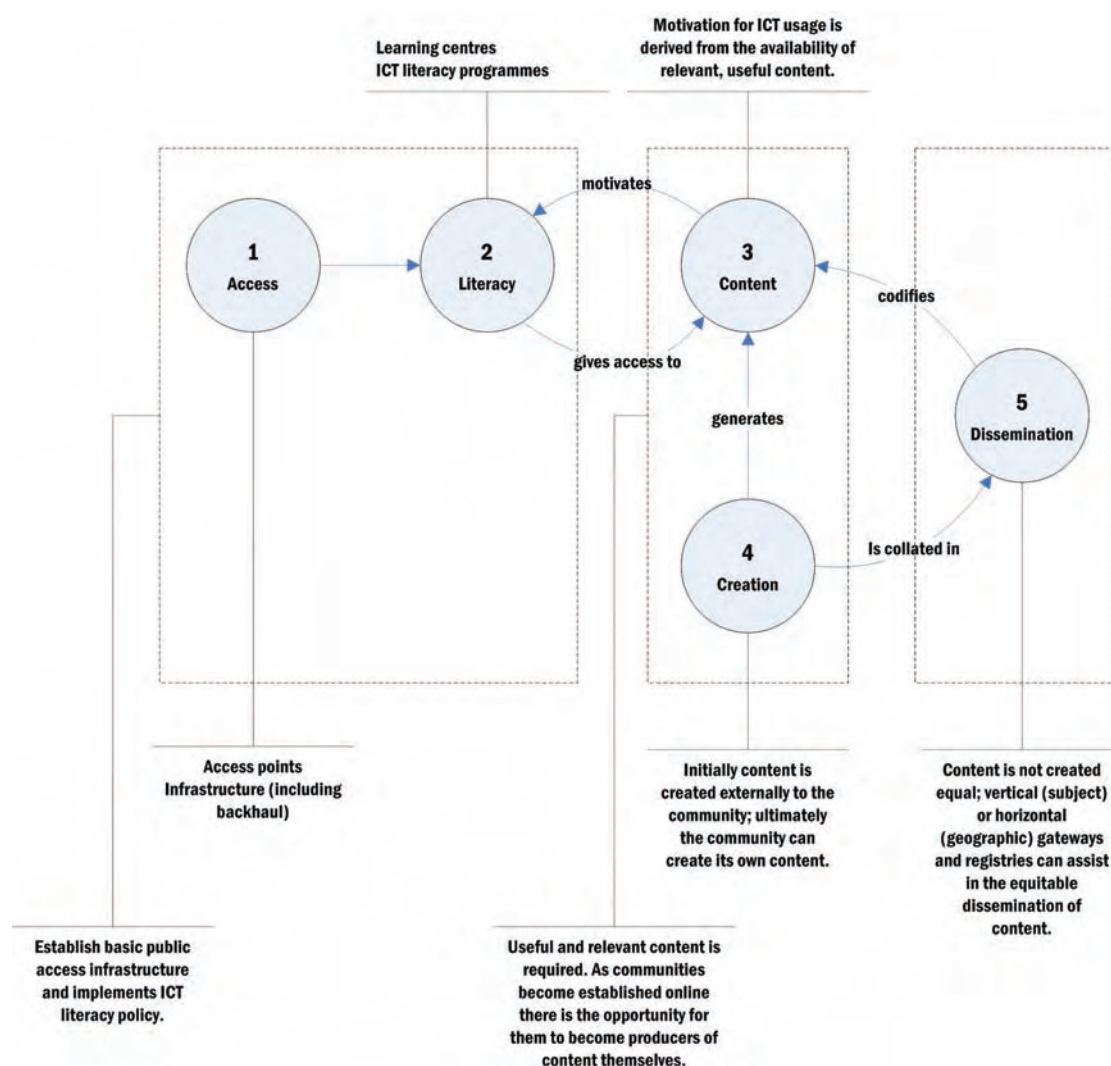

Practical experience informs the design of this model. In particular, discussions held on the Waitakere E-democracy Group Discussion list and within the Waitakere City Council EcoTech Working Party have strongly influenced its design. This draft model is strengthened by drawing on the evolving New Zealand National Information Strategy (Library and Information Association of New Zealand Aotearoa, 2002). Although the LIANZA model is developed locally, it is, in part, derived from UK models for library and information strategy. It has three core levels:

- Knowledge Access/Te kete tuātea (infrastructure)
- Knowledge Resources/Te kete aronui (content)
- Knowledge Equity/Te kete tuauri (empowered access to information) (Library and Information Association of New Zealand Aotearoa, 2002, p. 8)

This then extends to encompass issues of continuity and collaboration. The LIANZA model appears to be information centric, rather than community or people centric.

The temporal model shown in Figure 1 identifies five stages of maturity for the use of ICT within communities and can be used as both an assessment tool (for current maturity) and as a planning or policy development tool. Each of the five stages recognises an increasing maturity and

Figure 1. Five-stage model (Williamson, 2004)

sophistication in ICT usage, however, the model should not be seen as linear; the target is not to reach stage five, rather to ensure that technology is being applied in a way that is seen as appropriate to the community in question at a point in time (either present or future).

Stages one through four occur within communities. They are not necessarily formal and are not entirely dependent on each other. The requirements and relative importance (or even existence) of a stage are related to the maturity of

ICT usage. In other words, each of the four stages, while to some degree reliant on its predecessor, does not require that prior stages are or were formalised or even articulated. (There is likely to be a continuum between a laissez-faire approach and formal strategy or policy initiatives.)

Stage 1: Access

It is not lack of access that causes the digital divide but the consequences of that lack of connection

(Castells, 2001); hence, strategies are required to ensure equity of access and opportunity. Citizens must have basic access to ICT. This could be through private ownership, community ownership, or privately owned access points. Stage 1 can be subclassified in terms of the nature, cost, and availability of access.

Stage 2: Literacy

It is not enough that we simply provide community-based ICT resources. It is imperative that those in the community whom the technology is intended to benefit are trained to make effective use of it. As the generation of knowledge supersedes physical production in the postindustrial age, literacy can be judged at two levels: basic literacy and literacy in ICT.

Stages 1 and 2 are not necessarily formal; if access and literacy are already present or if no policy/strategy addresses them, they could be ad hoc, however, this requires individual motivation. Formal strategies are more likely to be needed where other socioeconomic factors restrict opportunities for access.

Stage 3: Content

For ICT to be useful and for communities to be motivated to use it, material and services must be available online that are of a perceived value to the community. Communities must be aware of such information and services and have access to them.

Stage 4: Creation

Communities have the knowledge, skills, and facilities necessary to produce and publish information themselves and to repackage or highlight information that is directly pertinent to them. Logically, Stage 4 must have occurred elsewhere to provide usable and useful material for communities entering Stage 3.

Stage 5: Dissemination

The final stage, Stage 5, is a meta-stage, occurring beyond individual community boundaries. As communities become publishers of new knowledge, society risks becoming overwhelmed with information. At present, there is also a reality that some information is more readily available and accessible than others (because the producer is more widely known or because of search engine bias). In a truly participative model for community ICT, processes need to exist to ensure the fair and equitable dissemination of information (that is being received at Stage 3 and created at Stage 4). Examples of such models might be portals or more likely would involve meta-data, meta-indexes, and registries.

Stage 5 becomes viable and appropriate once critical mass has been reached at Stage 4. Dissemination can then take place via fora that are geographical (by city, region, country, etc.) or topical (democracy, environment, social services, etc.). At this level, a clearly defined taxonomy is vital, and the use of agreed upon standards for metadata becomes important (Surman, 2002).

The five stages (access, literacy, content, creation, and dissemination) are temporal and nonstatic. Community A can be a newcomer to ICT, getting up to speed with computers in a new learning centre. However, they require content to make the technology useful. This is potentially delivered by others locally or elsewhere who are already creating content. At some point, some members of Community A become both literate and motivated enough to publish their own information: stories, histories, and news. Once enough vertical or horizontal communities have become publishers, it becomes viable to offer a collated dissemination service, by way of a portal or gateway or through online registries. The potential of this model is that it empowers communities by creating a transferable road map that acts as a good to assess where a community

is currently situated and provides direction for future strategic development.

CONCLUSION

This article has explored the tensions that exist in the use of ICT to support engagement in the democratic process: falling participation vs. ICT as a tool for citizen-led engagement; technocracy vs. closeness of the citizen to government; and centralised models of access leaving some citizens behind. It proposes a model based on localised solutions that privilege the position of the citizen at the centre of democratic discourse. Inherent in this is the recognition of ICT value in supporting localised solutions to transform the processes of citizen engagement.

The relative low cost and increasing ubiquity of ICT means that communities can now realistically expect to be able to publish their own stories and create citizen-led initiatives to influence and interface with governments. However, this does not become truly democratic until the barriers to ICT ubiquity have been overcome. Policy is required to promote ICT literacy as a life skill and ensure that access is available to all who want it. However, localised solutions are vital; no two communities are alike, and the model presented in this article is designed to act as a broad road map, assisting communities in identifying their own paths to becoming effective users of ICT and for measuring the effectiveness of community ICT projects. Equally, this model can inform policy makers in terms of recognizing the critical phases of ICT maturity within a community.

KEY TERMS

Access: Citizens have access to the technology they need. Access is both physical (ICT is located

at a physically appropriate place, such as in the home, community centre, library, or school) and economic (it is affordable).

Citizen-Led E-Democracy: Bottom-up, transformative process. Citizens create and sustain ICT applications, including e-mail lists, discussion boards, chat, and Web sites, etc., that accurately capture and reflect the discourse of citizen. Such fora can be vertical (subject) or horizontal (geographic). Such an entity must be able to influence government actions either directly (through shared involvement) or indirectly (through public, media, or political influence). Citizen-led e-democracy involves governments “working with,” rather than “delivering to” citizens.

Content: Online material or services that are relevant, useful, and timely for the community and that are made available in appropriate and affordable ways.

Creation: The ability and opportunity for communities to create and publish their own online content that actively reflects their own position and that is inherently counterhegemonic.

Dissemination: Because information is not created equally, it must be codified and aggregated such that one producer of knowledge is not privileged over another. For example, a city portal where all community information is collated or republished.

E-Democracy: The electronic process through which citizens engage with government and its agents (and vice versa), including consultation and voting. E-democracy is a two-way process that can be driven by either government or citizens.

E-Government: The provision of information, transactions, and services between government agencies and from government to citizens and businesses. E-government encapsulates the electronic delivery of government “business” from the centre out (governments “doing to” citizens).

Government-Led E-Democracy: Top-down, change process. Governments create points of electronic interface in order to consult or capture opinion from citizens. This is most often a change process—a new way of recreating existing communication and consultation models, for example, consultation on policy issues or planning processes and clinics with politicians.

Literacy: Citizens have the skills to use ICT effectively to meet their needs. In policy terms, ICT literacy should be considered a basic skill alongside traditional literacy. Strategies are required to achieve equity in this area and ensure that existing educational, geographical, cultural, or socioeconomic barriers do not exacerbate the digital divide.

Chapter 5.17

ICTs, Empowerment, and Development: Articulating Grassroots Analysis Through Participatory Approaches

Hannah Beardon
ActionAid, UK

ABSTRACT

The digital divide has its roots in the political and power dynamics that underlie all inequality. It follows, therefore, that the response from the development sector should be rooted in learning from the long experience of tackling inequality and unequal power relations in many other fields. This chapter draws on the example of the Reflect ICTs Project to show how participatory theories, tools, and processes can be applied to ensure that ICT initiatives fundamentally address power and empowerment issues rather than ignoring or, worse, exacerbating them. The project methodology is described and some findings shown, in an attempt to show how attention to the human communication dimension of ICTs can make applied technology more sustainable and appropriate for poor communities in their struggle to access their rights.

INTRODUCTION

Information and communication technologies (ICTs) can be an empowering force, providing access to rapid communication and timely information. According to a recent study of ICT for Development (ICT4D) projects in Africa, access to communications technologies can improve people's livelihoods, access to services, agricultural practices, participation in government (and government's accountability and transparency), incomes, voice, security, social relationships, and health.

Where people are struggling to access even their most basic needs, such as clean water or school for their children, information and communication technologies may not appear to be a priority. However, within a rights- or empowerment-based approach to development, there are many types and levels of work: whether to enable

people to access their rights; to influence policy makers; to enhance communication between actors; or to develop new methodologies, tools, and resources. Information and communication are at the heart of all these. As such ICT4D can be an important part of the empowerment process, if (and only if) explicitly placed within a wider movement to achieve equity and social change through access to and realisation of human rights.

Learning from the Past

The so-called digital divide is a term which, although of relatively recent coinage, deals with concepts and problems of long-standing in the development world. For the divide between those who can avail themselves of ICTs for rapid and efficient communication and those who suffer from lack of timely and reliable information has at its root the same dynamic as any other gap between rich and poor, have and have-not, exploiter and exploited. As such, the same theories and practices which have evolved in the development sector in the past 50 years also have great significance for the field of ICTs for development or empowerment.

This chapter draws on the example of the Reflect ICTs Project to show how participatory theories, tools, and processes can be applied to ensure that ICT initiatives fundamentally address such gaps rather than ignoring or, worse, exacerbating them.

The project, which has been running pilots in Burundi, India, and Uganda since 2003, highlights in its methods and findings the importance of recognising politics and power relations at all levels, and of forming transparent and effective partnerships between different actors in the field. Here, some of the methods are shared and their applicability to different contexts discussed, based on a review of some of the perspectives and theories underlying the work.

BACKGROUND

Participatory theories, such as Participatory Rural Appraisal (PRA) and Participatory Learning in Action (PLA), have evolved over the last two decades to enable and encourage a shift in relationships within the development sector. This means away from a traditional paternalistic donor/beneficiary paradigm towards a situation where the traditional targets of development — the poor, women, older people, refugees, and so forth — could become the drivers of change in their own environment. Values such as equality, empowerment, solidarity with the poor and marginalised, and gender-equity are explicitly held at the heart of such approaches.

Participation is the vital ingredient in the PLA process (Ruland, 2003). Participation is understood as a process, not an event, whereby local people undertake their own analysis, reflection, and action. Theories, tools, and methods have been developed to understand and deal with the dynamics of power, confidence, and culture that create elites, amplify some voices, and drown out others. It acknowledges the ways that built pedagogies constrain some learning practices and enable others, and the works to create dimensions that catalyse empowerment through participation (Monahan, 2000). The most famous include visual and oral methods for facilitating appraisal, analysis, and planning. Examples of such tools and reviews are available in a number of literatures (Wilcox, 1994; UNDP, 1997; Belgeonne & Brookes, 1999; Allen & Kilvington, 2001; Allen, Kilvington & Horn, 2002; Bates, Bruce, Doig, & Gitonga, 2002), including Communication and Power (CIRAC, 2003), on which this project is partly based.

The focus on group dynamics and power relations is not simply an objective one, but involves a transformation of our own roles as researchers and practitioners as well. This relationship is transformed from one of doing, directing, or

transferring technology, to one of facilitating, sharing, enabling, catalysing, as well as learning and reflecting ourselves.

The early theories and methods have been used, adapted, rejected, and reinvented for innumerable contexts and thematic focuses so we now have what Robert Chambers describes as:

A growing family of approaches, methods, attitudes, and behaviours to enable and empower people to share, analyse, and enhance their knowledge of life and conditions, and to plan, act, monitor, evaluate, and reflect. (Chambers, 2004)

ICTs in Participatory Theory

In light of this shifting relationship and empowerment focus, information and communication technologies have an interesting (potential) significance, for information and communication are at the very heart of the appraisal, analysis, and action which make up this approach to development. Good choices are well-informed choices. People can make more appropriate decisions or plans if their local analysis is rooted in an understanding of the larger-scale processes which influence them. Technologies, including video, radio, and the Internet, can be put to use to ensure both that information flows adequately and that voices are heard more fairly. As the Rockefeller Foundation states on its Web site (www.rockfound.org):

Communication can enable poor people to move from being passive recipients of externally generated development interventions to being effective advocates for the enrichment of their own lives and, finally, generators of their own development.

The Reflect ICTs Project was designed as a participatory approach to ICTs for Development. In essence, the aim is to test the assumption that ICTs chosen by communities based on a thorough

and participatory analysis of their communication and information needs (and practices) will be more useful, more empowering, more sustainable, and ultimately have more impact. The project builds on the existing work of Reflect practitioners in the pilot locations and around the world.

The Reflect Approach

Reflect is an approach to adult learning (see Figure 1) and social change, which is used by over 350 organisations in 60 countries (CIRAC, 2002). It began as a fusion of the pedagogical theories of Paulo Freire, who argued that education is not a neutral process and therefore must be deliberately designed to liberate (Freire 1968, 1994), with participatory methodologies such as PRA (Chambers, 1994). The result was an approach to adult learning which focuses on power relations and works through systematising and deepening people's existing knowledge to enable them to base their choices and actions on thorough analysis (Archer & Cottingham, 1994; Phnuyal, Archer, & Cottingham, 1998).

Although Reflect originated as an approach to adult literacy, it has in recent years evolved to link empowerment with communication practices more broadly, including access to information and influence over decision makers. People need to articulate their views through any available or appropriate means of communication — oral, written, visual, or audio — to strengthen their participation in decisions that affect their lives.

Some of the principles and methods behind this are collected in the recent Reflect publication *Communication and Power* (CIRAC, 2003). With this, local groups and community organisations are able to own and adapt the resources and techniques of PRA to strengthen their voices and sharpen their struggle for change. In different contexts this means different things, whether communication for peace and reconciliation in Burundi, holding local institutions accountable

Figure 1. Women from Babel reflect circle, Orissa, India

through budget tracking or school management in El Salvador and Mali, challenging racism in the UK, or accessing land rights in South Africa. More examples are available on the Reflect Web site (www.reflect-action.org).

With this changing focus of Reflect, and the emergence of the digital face of the resource gap, the Reflect ICTs Project was born. The project, funded for three years by the UK Department for International Development (DFID), aims to build on the emerging understanding of the relationship between communication and power, not only to provide a critical analysis of existing ICT for Development work, but also to provide resources and models for applying participatory principles and theories to future ICT projects.

ISSUES AND PERSPECTIVES

Though ICT for Development is a relatively new field, it has taken a well-trodden path. A technology which the market has made cheaply and easily available to the more advantaged and wealthy, then becomes considered important or necessary

to those the market does not reach — the poor and marginalised. Various powerful individuals, international and local non-governmental organisations (NGOs), governments, and their departments and agencies develop policies and plans in order to make these technologies and their valuable impact more widely available. Meetings, conferences, and summits are convened; articles, papers, and books published, trying to understand why technology is not being taken up, reaching the poorest, or making a difference.

From a participatory or empowerment perspective, it is possible to see a link between the involvement of people in decisions made for and about their lives, and the sustainability and impact of development interventions. Too many failed or questionable development projects suffer from a surplus of good ideas and intentions from the top and a deficit of real involvement and understanding at the grassroots. So what looks good on paper does not translate directly into reality. Plenty of evidence, anecdotal or otherwise, exists of such failures: of fully equipped telecentres in Argentina remaining unused, or complex computer systems aimed at decentralising land registration in India

ending up in the hands of the same corrupt elites who routinely use their power to deny poor people their constitutional rights (Sanjoy, 2003).

Participatory theory has emerged from an understanding that development must not be done on behalf of others, but must be based in locally generated processes. The field of ICT for development or empowerment also needs to follow such logic to avoid such failures and be fair to those in whose name the work is done. The value of a computer or a video lies not in its existence, but in its use. Empowerment is not an easy process, and requires taking sides and making waves. It is a political process, whereby the voices of poor and marginalised people are strengthened and broadcast to challenge the status quo that exploits them. Information and communication can transform, if the aim is to expand meaningful participation in decision making. But for this to be possible, attention needs to be paid not only to the technologies applied, but also (and more importantly) to the relationships and processes that underlie interventions and policies.

This places at the centre of project planning the question: How can the voices and knowledge of poor people be sufficiently represented in policies, technology design, and implementation? This is a question which the Reflect ICT project aims to highlight, but also to tackle through example and by developing transferable methodologies and tools.

A Critical View of ICTs

It is common to find evangelistic attitudes towards ICT for development, and this project and learning is based very much in a critical analysis of the tools and approaches in the field. ICTs may have a lot of potential for empowerment, but they also have potential to be tools for exploitation and cultural imperialism. In fact, there is probably a lot more evidence of the latter than the former in existence.

As is argued in the publication *ICTs for Development: Empowerment or Exploitation* (Beardon, 2004), modern ICTs are generally the product of powerful western and commercial cultures, and both are designed to meet the needs of that community first and also to fit in with their existing logic and communications culture. If such technologies are promoted blindly throughout the world, it could in effect consolidate existing power relations between cultures and communities in the world. It could also have the practical effect on the ground of relegating traditional forms of knowledge and its expression to second-best or lower value.

Other negative effects of the introduction of ICTs can be the brain-drain effect of equipping people with skills and education without the accompanying opportunities, meaning that they leave the local community to find opportunities elsewhere. Even where this may be a positive impact for the individual involved and their family, it should still be recognised that any change in their individual circumstances does not constitute empowerment as such. While these people cannot determine the terms of their employment, or appropriate the technology to meet the needs of their own communities, they remain vulnerable to exploitation.

This means that ICT projects and initiatives which are aimed to empower and strengthen local cultures and strategies need to be explicitly designed for this. If technology is merely introduced with no awareness of these issues, then the exact opposite may end up taking place, weakening local traditions and structures which are the basis for survival strategies. ICT projects that are not explicitly aimed at empowerment of the poorest and most vulnerable — that is, real structural change — are also likely to end up replicating and consolidating the status quo.

Whether at household or community level, those who already have the best opportunities and advantages will be the first to avail of the new

technologies provided. In all three of the Reflect ICT pilots, the groups noted that women have little access to, or control over, existing information technologies such as radio and newspapers. A gender analysis, as part of a wider power analysis, should form the basis of any empowerment-focused ICT project.

LEARNING AND RECOMMENDATIONS

The Reflect ICTs Project was developed in order to combine the experience and techniques of participatory theory with the potential of ICTs for empowerment and development. This potential is great, and not to be ignored, since access to timely and reliable information is the heart of a rights or empowerment-based approach to development. Only with strong communication capacity can people really influence the decisions — or access the rights and benefits — that affect them. Reflect participants across the world have shown how they can use a collective analysis of their situation to bring about real and significant changes.

The basis for the Reflect ICT project is a set of resource sheets for facilitators to use in order to encourage analysis of the value of information, the strengths and weaknesses of existing and traditional communication practices, and potential means of improving access to information and communication capacity. Existing Reflect groups in the three pilot locations of Ruyigi (Burundi), Bukuuku (Uganda), and Balangir (India) used the sheets to build a comprehensive picture of the context into which any new technologies would be applied. This includes analysis of the appropriateness of different technology to different sections of the community including women, youth, social classes, and so on. From this analysis was developed a plan for a community communications system, which combined new technology resources with clearly defined and accountable roles and relationships.

In the case of these three pilots, limited funding for the new system was pre-assured. However, it is hoped that the resource sheets will go on to be used either for community groups to develop clear proposals for funding and resourcing from outside, and/or for donor groups and implementing agencies to strengthen the participatory needs assessment element in their own programmes.

The Facilitated Process

The process was structured around five Reflect ICT resource sheets (Beardon, 2004), which set out some key issues for communication and provide simple exercises to encourage discussion and contextual analysis. The first of these looks at the value of information, and how it can make a difference to people's lives and livelihoods. Participants are encouraged to think of examples from their own experience and develop them into analysis of general factors and trends.

The second sheet explores the different factors which make a piece of information useful or meaningful, which can include the source, format, media, relevance of the information, or capacity or confidence of the person receiving it. It is this analysis which feeds into the design process of a communication system that really fits the needs and culture of a community. In many cases people may not use information unless it comes from an already known and trusted source. So new technologies and media must be introduced carefully and only to strengthen existing networks and information sources.

Another sheet helps groups to think through the value and purpose of documenting their own knowledge, then how best this can be done. Exercises and facilitated discussions help them to think through who might wish to share their knowledge, what the implications might be, and what media could be used to store and transmit it. In the first place, it encourages people to recognise the knowledge they have, as often people take their own knowledge for granted. This is

also an important step in building people’s own confidence to communicate.

The other sheets help groups to identify specific information gaps and evaluate different strategies and resources for overcoming these. Visualisation techniques such as matrices can be used for groups to list and rank the different communications media and technologies in terms of their availability, appropriateness, or affordability. Finally there is a sheet to help with planning, highlighting areas to be considered in a funding proposal or work plan.

The Diverse Pilot Contexts

The three pilot locations emerged through a process of communication and consultation with active Reflect implementing organisations. When the project was in conceptualisation, Reflect practitioners and organisers were encouraged to get involved, share ideas, and participate through the

Reflect network. Where there was clear convergence between the aims and ideas of the Reflect ICT project concept and the existing work and direction of Reflect implementing organisations or networks, strong links were made, and from there the three pilot locations were chosen. Although all three pilot locations are poor, rural areas, they each have marked differences in terms of size, terrain, infrastructure, social and economic realities, and as a result, in pertinent issues.

Burundi

In this society dealing with and emerging from conflict, Reflect is oriented towards promoting peace and strengthening the role of women in building peace and reconstruction. Communication is key to this, as mistrust and misinformation have been key factors in perpetuating the conflict at local and national levels.

Table 1. Access to communications media: Burundi

Schools	X	X	X		X			X

There are currently 91 circles operating in Ruyigi province, offering a space for Hutu and Tutsi neighbours to meet and talk, share accurate information, and rebuild confidence and collaboration. Participation is around 60% male and 40% female, and in total approximately 1,000 people participate regularly in groups involved in the pilot. A newsletter called Ejo is compiled by ActionAid of contributions from Reflect participants, and is distributed in villages and in refugee camps to promote accurate and trusted information on conflict, development, gender, health, and other relevant issues. Cultural activities are also promoted and organised to bring communities together.

As Table 1 shows, women and older people are specifically disadvantaged in access to communications media, relying mostly on face-to-face contact. This type of analysis, deepened through the Reflect ICT process, enabled the team and participants to devise a communications system which caters for these excluded groups. New equipment, including Internet-connected computers, are being used to strengthen the scope and quality of Ejo, while both content and receivers for video and radio are integrated into the Reflect process. The analysis shown in Table 1 also highlighted for Reflect facilitators the role of access to information as an indicator of vulnerability to conflict — a key for future programme work.

India

This pilot is located in Balangir in the state of Orissa, near the Bay of Bengal. The majority of the population live below the poverty level and literacy is under 40% (among women only 21%). Reflect is used by 19 local organisations in 344 villages to support popular planning and mobilisation processes. The organisations form a network known as Collective Action for Drought Mitigation in Balangir (CADMB) and supported by ActionAid India; 112 of these villages are involved directly in the Reflect ICT pilot, with the others

indirectly involved through facilitators forums, public meetings, and collective planning.

In total, nearly 5,000 people participate directly in Reflect groups in Balangir, of whom 42% are women. Sixty-six percent are from scheduled castes and tribes, meaning the lowest social status, as opposed to only 37% of the general population.

The focus of the project in this area is transparent and accountable governance. A drought-prone area, many of the poorest people are forced to sell their land or migrate seasonally to nearby cities and industrial areas. Food security, land rights, and labour protection are all key issues, and at the heart of them all is good information about rights and entitlements available in the constitution and state laws. In many cases in the pilot area, information is withheld by the local elites, and the poorest people are kept in the dark about funds or entitlements which are their rights. In this situation it is clear that information is not neutral, and access to it needs (see Figure 2) to be carefully targeted and monitored.

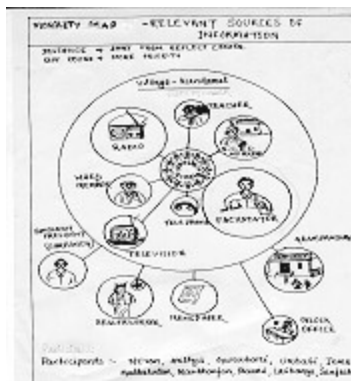

The initial analysis carried out in Reflect circles showed that poor people depend on other people, such as facilitators, health workers, or elected representatives, for information (see Figure 3). Televisions, telephones, and even radios are out of reach of the majority of people, and literacy levels are so low as to make printed information require interpretation.

As a result of such analysis, the emerging communication system relies heavily on oral communication and accountable, informative relationships. There is great emphasis on not only the articulation of information needs at the village level, but the communication of these needs to the appropriate authorities and advocacy at different administrative levels to ensure that the needs are both heard and met. Equipment, including video and radio, as well as cultural troupes, leaflets, and public meetings, have been funded in order to increase information flow among and between village communities.

Uganda

Bukuuku sub-county is in Eastern Uganda, bordering the Democratic Republic of Congo. The area has 25 villages and a total population of slightly more than 25,000 people. Most households live in absolute poverty (less than \$4 per day) despite fertile soils and good agricultural conditions. In large part this poverty is due to poor market information, leaving local farmers vulnerable to exploitation. Another key development issue is health, in particular HIV/AIDS, and with family sizes averaging 8 to 10, access to education is also a major problem.

Figure 4. Reflect participant listening to a radio set provided by project

There are 12 Reflect groups in the area, each with an average of 30 members, most of whom are women (see Figure 4). In addition there are seven school knowledge groups, which are Reflect groups based in the local primary (5), secondary

(1), and tertiary (1) educational institutions to address issues relating to local youth. Since the introduction of the Reflect ICTs project, new circles have been introduced and the demand is increasing. Literacy and Empowerment, a lo-

cal community-based organisation, implements Reflect, training and supporting facilitators and circles, and manages the ICT project with support from ActionAid Uganda.

The Uganda pilot has the best access to telecommunications infrastructure and conducive ICT government policy, and both mobile and fixed-line telephones are widespread. However, the Reflect circles' analysis showed that poor people still rely on trusted, well-informed individuals and organisations to access required social and economic information (see Table 2). Meetings, cultural events, and social gatherings were ranked as the most widely used and useful media of communication, while radio, video, and telephone were desirable but less accessible. Internet awareness was quite low, especially among adults.

Due to the smaller scale of the pilot, the groups were able to plan for a centralised resource centre with Internet access and training, bolstered by radio sets for each circle. Databases have been established to catalogue local knowledge of herbs which can be used to treat opportunistic diseases related to HIV, and another to list and monitor all orphans living in the area. Training is tailored to the needs of the groups, and additional funding and sponsorship is being sought to meet capacity needs. Women in particular are targeted for training on ICT use.

Some Interesting Insights

The actual findings of the pilot communities are part of the planning process and not to be taken as stand-alone facts and figures. However, they provide an interesting opportunity for researchers and policy makers to compare the outcomes of grassroots-level analysis with their own assumptions in applying new ICTs to poverty reduction.

In all three pilot areas, oral communication was the primary and most trusted source of information. This may be through local health or child

care workers, leaders or facilitators, or through mutual exchange at meetings and gatherings such as church or market. Beyond this, media such as radio, cultural performances, posters, and leaflets or newspapers were considered useful and accessible. Due to high levels of illiteracy in all areas, textual information is only accessible to many through an interpreter and is therefore not directly effective.

Thus, literacy can be treated as one important factor in determining existing access to and control over ICTs. Other factors include social class, education, income, and gender. In Orissa, for example, the cost of a black-and-white television set is more than the value of the land of most villagers. In Uganda, where households do own radio sets, they are usually controlled and operated by the male head of household, who chooses what to listen to. In Burundi, Reflect facilitators noted that vulnerable groups, such as the very poor, widows, elderly, and displaced people, were less able to access reliable information about security threats which make them still more vulnerable to the effects of conflict.

The types of information that people wanted to access also differed between groups. For example, in Uganda, while everyone wanted market and credit information, men and boys were more interested in job opportunities while women and girls in health and women's rights. The youth were more interested in HIV prevention and reproductive health than their parents.

In each pilot the funds for ICTs were spent differently, but in all three places the resulting plan was a combination of technologies and people to transmit information and queries. In this way, the community communications systems continue to build on people's preference for face-to-face communication. The resulting systems were influenced heavily by the size and level of infrastructure in each area.

- Uganda, being a smaller-scale pilot, has been able to create a central information/

resource centre, backed up by training and advice sessions, equipment, and continued activities of Reflect circles.

- In India, where the scale is much larger (over 100 villages), the groups have developed a complex network of local organisations, committees, and individuals to support the flow of existing information to Reflect participants and their communities, as well as advocating to different levels of government for better information provision. At different levels this network is using the Internet, video and radio programmes, travelling cultural troupes, and printed information.
- In Burundi insecurity has created a problem of mobility, and the main technologies being adopted are radio and video, and the Internet will be used to support and strengthen an existing community newsletter as well as linking Diaspora communities.

FUTURE TRENDS FOR ACTION AND RESEARCH

The Reflect ICT Process aims to enable groups to develop and define their own knowledge—about their context, needs, and existing patterns and prejudices. Theirs is not the only knowledge needed to ensure a good, effective ICT project or programme. However, it is necessary to ensure that their perspective is heard and informs the decisions of other players in the process, including technology experts, policy makers, and donors. It appears that effective and equal working relationships between these different actors, built on mutual respect and transparency, is the key to a sustainable intervention. More research is needed to understand the nature of such relationships and how existing modes of working in development need to adapt in order to allow them to flourish.

As such, the Reflect ICTs model is useful for strengthening the grassroots analysis element of any ICT for Development project. The model can

be made more effective in combination with other perspectives, expertise, and resources.

Policy advocacy is also important in order to strengthen the impact and reach of the Reflect ICT Project, and approach this in two areas. Firstly there is the question of directly influencing ICT policy. Grassroots analysis of information needs and the applicability of different ICTs should be heard and considered by those making policy decisions at local, national, and international levels. It is up to projects, organisations, and research institutions to help to establish this link.

There is also the question of what happens to the types of information and analysis that participants in projects such as this are creating and documenting. As documentation of analysis improves through participation in such projects, there is scope for forging greater linkages between the issues arising from such grassroots-level analysis and the development, advocacy, and aid agendas of NGOs and donors at national and international levels.

CONCLUSION

This chapter argues that in order to unlock the full potential of ICTs for empowerment and rights-based development, the knowledge and resources of the full range of stakeholders need to be combined. It is not only donors, technicians, and large implementing organisations who hold the key to successful project planning and implementation. A large and essential chunk of the knowledge and expertise needed rests with the people and communities who are the intended beneficiaries.

The Reflect ICT Project has been created to build on and complement existing participatory theories, approaches, and techniques, and make sense of ICTs and the digital divide in this context. The aim is to provide a model for developing this grassroots analysis of communication needs and appropriate technologies. However, finding ways

to effectively bring this perspective together with all the other essential elements of good ICT for development policy and practice is a challenge still very much ahead of us.

TERMS AND DEFINITIONS

Digital Divide: The condition of one group (the dominant group) having an advantage over another group (the marginalised group) concerning computer or technological skills. It can also refer to the general lack of access to computers and the Internet, which affects women, children, various ethnic groups, and older citizens.

Empowerment: Involves a process which pays attention to power relations and their impact on the opportunities individuals and communities have to create changes in their lives. Empowerment is about structural changes. More than simple service delivery, it is about building capacity of people to make demands and influence decision making.

Empowerment Processes: The processes of empowerment can be at individual, group, or community level, and include capacity building and participatory approaches.

ICT for Development (ICT4D): When ICTs assist to meet development objectives, in particular global development goals for poverty reduction, education, health, and environment as a tool for economic growth.

Participatory Approaches: Techniques to promote participation in development through a focus on Participatory Learning and Action (PLA) information exchange. In particular, participatory

approaches allow a community to express and analyse the realities of their lives, plan themselves what action needs to be taken to change the situation, and monitor and evaluate the results by themselves. Participatory approaches have been used in many settings in development both in rural and urban aspects.

Participatory Learning in Action (PLA): An umbrella term of methodologies in participation of people in the processes of learning about their needs and opportunities, and in the action required to address them. PLA techniques are being used to encourage community members to express their ideas and needs.

Participatory Rural Appraisal (PRA): A label given to a growing family of participatory approaches and methods that emphasise local knowledge and enable local people to make their own appraisal, analysis, and plans. It evolved from rapid rural appraisal — a set of informal techniques used by development practitioners in rural areas to collect and analyse data.

Chapter 5.18

Enacting and Interpreting Technology—From Usage to Well-Being: Experiences of Indigenous Peoples with ICTs

Bjöm-Sören Gigler

London School of Economics and Political Science, UK

ABSTRACT

Under which conditions can information and communications technologies (ICTs) enhance the well-being of indigenous communities? This chapter investigates this question, focusing on the role of information and communications technology in promoting indigenous peoples' development. First, the chapter analyzes key factors under which information and knowledge can be instrumental and substantive for the empowerment of marginalized groups. Hereby, it will be argued that improved informational capabilities, similar to the enhancement of a person's writing and reading skills, can enhance poor people's capabilities to make strategic life choices and to achieve the lifestyle they value. The chapter develops an alternative evaluation framework for ICT interventions based on Sen's capability approach.

This framework places, in contrast to the current discourse around the digital divide, the human development of the poor and not technology at the center of the analysis. The chapter concludes that a direct and causal relationship between ICTs and enhanced well-being does not exist, but that in fact this relationship is being shaped by a dynamic, multi-dimensional interrelationship between technology and the social context.

INTRODUCTION

What is the impact of information and communication technologies (ICTs) on indigenous peoples¹? Can the introduction of ICTs enhance their human and social capabilities and thus improve their well-being²? The starting point of the following chapter is to investigate the impact

of ICTs on development from the vantage point of marginalized communities themselves. This approach centers on people and their well-being rather than on technologies. It underscores the notion that communities are not mere beneficiaries of development, but have the capacity and creativity to define their own development priorities, goals, and vision for the future (Chambers, 1983; Cernea, 1991; Eade, 2003; Max-Neef, 1991; Korten & Klaus, 1984). Using this concept, an alternative evaluation framework of ICT programs has been developed that places their human development rather than technology at the core of its analysis (Madon, 2003) and which operationalizes Amartya Sen's capability approach.

The chapter addresses the two key questions, whether and under which conditions the improved access to information and knowledge facilitated by ICTs can enhance the capabilities of marginalized groups to better achieve the lifestyles they value. At the outset, it will be argued that information and knowledge can play an important role to improve the well-being of marginalized groups, as long as they are fully integrated into the broader socio-political realities of the communities (Castells, 1997, 1998; Madon, 2000; ITDG, 2001; O'Farrell, Norrish, & Scott, 1999). This approach places communities' assets and capabilities in the center, and examines the catalytic role of information and knowledge flows in expanding the capabilities of marginalized groups. Within this framework the chapter investigates key factors that enable marginalized groups to gain real and meaningful access to ICTs and allow them to appropriate these technologies as an instrument for their own development.

On the basis of two case studies, the chapter will provide a set of conclusions, which point out that it is in fact not possible to identify a direct and causal relationship between ICTs and the improved well-being of marginalized groups, stressing the complex and dynamic interdependency between people, social institutions, and technology.

BACKGROUND: INDIGENOUS PEOPLES AND ICTS FOR DEVELOPMENT

Indigenous peoples have historically been the poorest and most excluded in Latin America. They have not only faced serious discrimination in terms of their basic rights to ancestral property, languages, cultures, and forms of governance, but also in terms of access to basic social services (education, health and nutrition, water and sanitation, housing, etc.) and the essential material conditions for a satisfying life. These conditions of extreme poverty and material deprivation — what might be best described as a denial of the fundamental social citizenship rights of indigenous peoples — are widespread in many parts of the world (Davis, 2002; Partridge & Uquillas with Johns, 1998).

In recent years, the potential of information and communications technologies³ for development has gained a lot of attention in the development discourse (Braga, 1998; Heeks & Kenny, 2002; Panos, 1998; UNDP 2001; Wade, 2002; World Bank, 1995, 2000). Within this debate, critics highlight that the emphasis is frequently being placed on providing access to ICTs to the poor before analyzing the value information and knowledge exchanges play for development at the local level (Black, 1999; Mansell, 1998; Menou, 1993, 1999; Norris, 2001). But an unanswered question remains — what is in fact the impact of ICTs on the lives of indigenous peoples?

The analysis will draw on the contextual approach to ICTs, emphasizing the importance of the socio-economic and cultural milieu, considered crucial for a better understanding of the potential effects of ICTs on development (Avgerou, 2001; Kling, 2000; Walsham, 1993, 1995). This approach stresses that technology only receives meaning once it is enacted by users, and thus people can exert control over its use by interpreting and appropriating it to their specific realities (Orlikowski, 2000). In essence, it places human action rather

than technology at the center, and emphasizes the interdependencies between technology and the social context (Orlikowski, 2000; Avgerrou, 2001). The chapter focuses on this very interrelationship between technological and social change, in effect, seeking to broaden the focus from simply studying the immediate and measurable effects of ICT diffusion and usage to a wider scope encompassing the analysis of social, economic, and cultural aspects of the local context in which ICTs are placed. This approach follows earlier empirical works (e.g., Harris, Bala, Songan, & Khoo, 2001; Madon, 2001; Miller & Slater, 2000; Nelson, 1996) which have demonstrated that the researcher has been able to discern the specific factors (i.e., local culture and social structures) influencing whether or not technologies have a positive impact on the daily lives of poor communities (Avgerou & Madon, 2003).

KEY FACTORS FOR ICTS AND INDIGENOUS PEOPLES' DEVELOPMENT

The chapter highlights the following main factors that influence whether and to what extent the access to and use of ICTs can enhance the capability of indigenous peoples, ultimately resulting in their improved well-being. These include the following:

1. The role of existing indigenous information systems,
2. The role of intermediary organizations,
3. The appropriation process of technology, and
4. The broader socio-political context.

The Role of Existing Indigenous Information Systems

In contrast to more conventional approaches to ICTs, this chapter highlights the key role indig-

enous information systems — which are based on indigenous knowledge and communication practices — play for securing the well-being of indigenous peoples (Agrawal, 1995; Chambers, Pacey, & Thrupp, 1989; Brokensha, Warren, & Wern, 1980; Harris et al., 2001; Wang et al., 1994). This approach emphasizes that the existing information and knowledge gaps are rather mutual in nature, whereby not only poor communities lack access to information and knowledge, but at the same time policy makers in capital cities lack knowledge about the local and cultural context of the poor and marginalized groups (Scoones & Thompson, 1994; Long & Villareal, 1994). It is thus crucial to first analyze the existing information ecology and traditional information systems and communications channels before exploring the impact of the introduction of ICTs (Madon, 2003; ITDG, 2001; O'Farrell et al., 1999; Slater, 2002).

These traditional information systems are embedded into the existing social and organizational structures at the community level. A common reason for the failure of ICT programs is that key community members (e.g., elders and other information brokers) perceive the new technologies as a mechanism to undermine the existing information systems embedded in the social and organizational structures of the community (Robinson, 1998; Long & Villareal, 1994).

The Role of Intermediary Organizations

The literature points to the critical role intermediary organizations are playing in the process of introducing ICTs to local communities (Madon, 2000; Heeks, 2002; McConnell, 2000). For instance, Heeks argues that intermediaries play a critical role in supporting rural communities to overcome some of the previously-mentioned barriers while providing ICT services (Heeks, 2002). However, the literature has neglected to specify the exact role that intermediaries play in

the process. Instead it takes a more institutional perspective and analyzes the effects of ICTs within organizations (Avgerou, 2001; Powell, 1999; Meyer, 1997).

Based on this gap in the literature, the chapter suggests investigation in greater detail of the different types and levels of intermediation in ICT programs, hereby distinguishing between the following two types: (1) ICT or technical and (2) social intermediaries. The main role of ICT intermediaries is defined as an organization providing effective support to local communities in the use and adaptation of technology. Most commonly an ICT intermediary will be a specialized organization from outside the community, such as a non-governmental organization, local government, or international donor. On the other hand, a social intermediary is defined as a local institution from within the community, such as a community-based organization. This classification will be used to analyze the two main aspects of the intermediary process: (1) the manner in which ICTs are being introduced and which technical support services (i.e., training, content development) are being provided to the community, and (2) the extent to which the ICT program is embedded into existing social and organizational structures (i.e., the relationship between existing informal information systems and the ICT intervention).

The Process of Technology Appropriation

Based on this contextualized approach to ICTs (Avgerou, 2001; Madon, 2001; Walsham, 1998, 1993), the chapter emphasizes that the local appropriation of technologies by local communities and the contextualization of information provided through ICTs is a key factor that determines whether indigenous communities are able to derive real benefits out of the use of ICTs. Pure access to ICTs by the poor does not translate into improved well-being (O'Farrell, 2001). In fact, a tool such

as the Internet is a very 'western' medium and needs to be appropriated by poor communities before real benefits can be derived. For instance, the content on the Internet often does not reflect the realities of local communities (Ballantyn, 2002). Also, language many times represents a prohibitive barrier for communities in their use of information, as most of the Internet's content is written in a rather academic or business style, and thus is not directly applicable at the grassroots level. Another factor which acts as a barrier to access, stems from the fact that the majority of the content available on the Internet is in English — limiting access in poor communities across most developing countries (Gurstein, 2000).

The Broader Socio-Political Context

Several authors have argued that existing barriers to the use of ICTs are not simply about the lack of access to technology or inadequate access to relevant and timely information, but that these are in fact much more deeply rooted in underlying social and institutional structures which continue to perpetuate existing socio-economic inequalities between the elites and marginalized groups of society, ultimately reproducing themselves also in the uneven benefits accrued from ICTs (Castells, 1997, 1998; Hamelink, 1994; Hewitt de Alcántara, 2001; Mansell, 2004; Skuse, 2000). Thus, rather than the lack of knowledge of marginalized groups, the existing political, socio-economic, and cultural barriers between the urban elites and the poor inhibit them from making their information and knowledge known and disseminated, blocking their participation in the dominant society's political and economic system.

THE CAPABILITY APPROACH

Amartya Sen argues that human development should be viewed first and foremost as a process of expanding people's capabilities. What matters,

according to Sen, is what people are capable of being, or doing, with the goods to which they have access. A person's capability therefore refers "to the alternative combinations of functionings that are feasible to achieve. Capability is thus a kind of freedom: the substantive freedom to achieve alternative functioning combinations (or, less formally put, the freedom to achieve various lifestyles)" (Sen, 1999, p. 75). Capabilities include things that a person actually has done, as well as things people can possibly do. In other words capabilities refer to the extent of one's positive freedoms (Gasper, 2002, p. 5).

The concept of functioning "reflects the various things a person may value doing or being" (Sen, 1999, p. 75). They represent "various components or aspects of how a person lives" (Gasper, 2002, p. 4). A person's ability to realize her or his desired and valued functionings very much depends on her or his capabilities as well as entitlements or assets.

Operationalizing Sen's Capability Approach

In the last couple of years, there has been significant debate in the literature on ways to operationalize Sen's capability approach and to apply it in a more practical way to empirical research (Alkire, 2002; Comin, 2001; Corbridge 2001; Gasper, 1997, 2002; Stewart & Deneulin, 2002). On the one hand, as Comim has suggested, the capability framework is well suited for "evaluating and assessing social arrangements, standard of living, inequality, poverty, justice, quality of life or well-being" (Comim, 2001, p. 4).

On the other hand, however, several scholars have highlighted the difficulties to operationalizing the approach. Comin points out that these difficulties derive from the capabilities approach's "theoretical underspecification and inclusive view of operationalization which contest not only the evaluative but also the practical foundations of utilitarianism" (Comim, 2001, p. 2). Furthermore,

a key challenge has been to define a-priori a set of basic capabilities, in order to have a baseline from which to start specific evaluations (Nussbaum, 2000; Alkire, 2002).

Another difficulty related to operationalizing the capability approach is that some capabilities are harder to measure than others. For instance, it is much more difficult to assess a person's ability to have self-esteem than their ability to write and read. This represents particular challenges for gathering data on the non-material aspects of people's well-being.

Comim highlights that the capability approach is particularly suited for micro-level studies, since to a large extent it focuses on non-income variables (Comim, 2001). Such an approach, he argues will reveal more interesting findings at the micro-level than at the macro-level, as research at this level can better analyze people's ability to choose what to do or be.

TOWARD AN ALTERNATIVE EVALUATION FRAMEWORK OF ICT PROGRAMS

Based on the theoretical background discussed earlier, the chapter develops an alternative evaluation framework (AEF) of ICT interventions based on Sen's capability approach (Garnham, 2000). The center of the analysis focuses on whether or not and under which conditions the improved access to information and knowledge facilitated by ICTs can enhance the individual and collective capabilities of marginalized groups to better achieve the lifestyles they value.

This approach stands in contrast to the majority of existing ICT evaluations that have focused primarily on the issue of access and usage, and assume that the improved access to ICTs will have a direct positive impact on the lives of the poor (Daly, 1999; Hudson, 1995; McConnell, 1995, 2000; Wilson, Daly, & Griffiths, 1998; White, 2000). These evaluations focus on measuring more

immediate and quantifiable output indicators, such as the increase in total numbers of Internet hosts and computers per capita.

In an earlier analysis Richard Heeks (1999) has argued that information instead of technologies needs to be in the center of the analysis. The proposed approach, however, goes even one step further and places individual and collective capabilities in the center, with information and ICTs being placed at the outermost circle of the model. The aim is to underscore that ICTs are not a means to an end by themselves and that in fact only under certain conditions can they act to expand the capabilities of the poor and realize improved economic, social, political, and cultural opportunities. Although it is argued that the right to information and knowledge is an important entitlement and its absence can be a contributing factor to poverty, this notion needs to be balanced against the broader context of existing social and economic inequalities, which may reinforce themselves through the technology (Hewitt de Alcántara, 2001; Castells, 1997). Consequently, the sustainable livelihoods framework⁴ will be integrated to attempt a more holistic socio-economic analysis of the possible effects of ICTs through its breadth and scope.

As a starting point, it is being argued that it is important to introduce information as an additional asset or capital into the sustainable livelihoods framework. The analysis of the role that information and knowledge can play for development and the view that the right to information represents an important entitlement of the poor serve as the rationale for including the concept of informational capital into the livelihoods approach. This concept is defined through the following four components:

1. The extent to which the poor have access to information from the formal institutions of the market, state, and civil society;
2. The ability of the poor to process and evaluate information;
3. The extent to which the poor do not only consume, but produce and share information within their community and networks; and
4. The extent to which indigenous knowledge is used.

As Table 1 shows, the informational capital has been added as an additional dimension to the set of livelihood resources of the poor. Thus the framework aims to underscore that the interlinkages between informational capital and all the other capitals are crucial for evaluating the role information and ICTs play in the livelihoods of the poor. At the same time, it is being argued that information in its own right is an important asset for the poor to improve or secure their livelihoods.

This approach contends that the capability of individuals and social groups to transform valued functionings into realized functionings depends to a large extent on their livelihood resources or capitals (Bebbington, 1999). The expansion of capabilities is hereby understood as the strengthening of people's capitals. However, questions remain such as: what is the role that information plays in this context, and what justifies broadening the livelihood approach by the additional dimension of the informational capital? The main argument for including this dimension into the framework is that information and ICTs can play an important role not only in their own right, but can act as a catalytic agent for the strengthening of the poor's capital in multiple areas. As the literature has demonstrated, only the combination of strengthened resources and agency can lead to enhancing individual and collective capabilities (Kabeer, 1999; Bebbington, 1999). Based on these findings, the AEF analyzes under which conditions the expansion of the informational capability can have a positive multiplier effect on the other capabilities. In other words, does the expansion of the poor's capability to make meaningful use of ICTs strengthen their capabilities to achieve valued

Table 1. Empowerment through ICTs framework

functionings in multiple areas? This notion stems from Sen's concept on the role that human capital plays not only in enhancing a person's ability to generate income, but also in expanding her or his capabilities to lead a freer and more fulfilled life, and to reach her or his valued functionings (Sen, 1997, p. 1960). In this sense the focus is on the agency role of human capabilities for bringing about social change. The AEF applies this concept to the field of ICTs, arguing that better access to information and improved ICT skills similar to the enhancement of a person's writing and reading skills can increase people's capabilities to make choices in their lives in various areas, including the economic, social, and political spheres. Thus, as a result of expanded informational capabilities, individuals will be able to increase their control over important life choices — in this sense information and ICTs can contribute towards the empowerment of the poor.

It is, however, important to emphasize that in this scenario the improved access to ICTs has indirect rather than direct effects on the well-being of the poor. In fact the relationship between these variables is multi-dimensional and needs to be seen within the broader socio-political context of a country.

Moreover, the framework requires that at the outset of ICT programs, an assessment of existing indigenous information and knowledge systems be carried out (Brown, 1991). A common reason for the failure of ICT programs is that key community members perceive the new technologies as a mechanism to undermine existing information systems and as a challenge to the role of traditional knowledge brokers (Robinson, 1998; Long & Villareal, 1994). Thus, it is decisive to carry out an information needs assessment prior to introducing ICTs, and to use this tool in identifying the key stakeholders and their interests in the information system. Such an assessment will make explicit the role that information plays for the community, and which information and communications channels

(i.e., oral tradition, community-radios) have been used traditionally.

Furthermore, the evaluation framework underscores the importance of understanding the institutional structures and processes that mediate the transformation process from livelihood resources into the expansion of capabilities, thus contributing to the attainment of positive livelihood outcomes. Hereby, it is important to analyze the interrelationship between existing social structures and ICT inter-mediation. The framework contends that a successful mediation process by an effective and local intermediary is required before ICTs can have a positive contribution towards expanding the livelihoods of the poor. In addition, intermediaries play a decisive role in: (1) identifying and providing access to ICT products and services that suit the local communities' information needs; (2) supporting the generation of local and relevant content; and (3) providing ongoing support in the areas of training and capacity-building (Delgadillo, Gomez, & Stoll, 2003; Gurstein, 2003). Based on this contextualized approach to ICTs (Avgerou, 2001; Madon, 2001; Walsham, 1993, 1995), the AEF emphasizes that the local appropriation of technologies by local communities and the contextualization of information provided through ICTs is a key factor that determines whether indigenous communities are able to derive real benefits out of the use of ICTs.

AN OVERVIEW OF EXPERIENCES IN USING ICTS FOR INDIGENOUS PEOPLES' DEVELOPMENT

In spite of tremendous challenges associated with the use of ICTs, indigenous peoples have been proactive in embracing the opportunities provided by the use of new ICTs. In particular, the indigenous leadership has used these new technologies to establish or strengthen existing

national, regional, and international networks. Hereby indigenous peoples frequently stress the need to foster horizontal exchange of information, knowledge, and experiences among each other. Furthermore, many indigenous peoples have used the Internet as an instrument to strengthen their alliances with international NGOs, academic institutions, and international donor agencies, as well as to raise the awareness of the international community about their needs and concerns.

In order to analyze the specific effects of new ICTs on indigenous peoples, it is necessary to clearly distinguish the different levels at which indigenous peoples are making use of ICTs. In the analysis, the chapter will distinguish between the following five levels: (1) international indigenous leaders, (2) regional leaders (i.e., in Latin America), (3) national leaders, (4) community leaders, and (5) indigenous communities⁵.

At the international level, indigenous peoples are increasingly gaining spaces at the international fora, such as through the United Nations Permanent Forum of Indigenous Issues established by the U.N. Economic and Social Council, the U.N. Working Group on Indigenous Issues of the High Commissioner of Human Rights, or various global summits, such as the World Summit on Sustainable Development. As a consequence of this renewed international interest in indigenous peoples' concern, a new international indigenous leadership has been formed. This new indigenous leadership makes intensive use of the Internet mainly as a communication tool in order to coordinate their actions, to lobby for indigenous rights, and to maintain close contact to international organizations, governments, and international NGOs. A good example of this proactive use of ICTs by international indigenous leaders is the Indigenous Media Network (<http://www.indigenousmedia.org>). This network was established in May 2002 with the support of the U.N. High Commissioner for Human Rights and the Advocacy Project to bring together indigenous journalists from all

parts of the world to "promote indigenous identity, language, culture, and human rights" (Indigenous Media Network Website, www.indigenousmedia.org). The initiative was conceived as a reaction to concerns by indigenous peoples that the traditional mass media is solely based on the values of mainstream society, and thus can lead to the erosion of indigenous peoples' culture or be misused as an instrument to stereotype against them. The indigenous leaders see their own initiative as a key vehicle for reporting more accurate and culturally appropriate news coverage from indigenous perspectives to a broad international audience, including indigenous communities, international NGOs, governments, and international agencies.

An experience that demonstrates the new opportunities ICTs can provide indigenous peoples to influence international policy dialogues is the program of Indigenous Dialogues jointly organized by the Rigoberta Menchú Tum Foundation (<http://www.frmt.org>), the University of the Autonomous Regions of the Nicaraguan Coast — URACCAN (<http://www.uraccan.edu.ni>), and the Development Gateway⁶ (<http://www.developmentgateway.org>). In a series of seven videoconferences, the program connected indigenous leaders from up to 17 countries — primarily from Latin America and to some extent from Africa, Asia, Europe, and North America — to exchange their views and make their voices heard on such global issues as sustainable development, human rights and discrimination, cultural diversity, women and development, and free trade. The program enhanced the participation of indigenous peoples in international policy dialogues. For instance in October 2001, more than 300 indigenous leaders participated in a dialogue to evaluate the results of the World Conference Against Racism, Racial Discrimination, and Xenophobia. Through the use of videoconferencing, hundreds of indigenous leaders, who were not been able to travel to this international conference, were enabled to par-

ticipate in the debate and in the development of a joint indigenous peoples' position. This experience highlights that the new international indigenous leadership has proactively engaged with new ICTs and appreciates the value it can bring towards furthering their causes. Dr. Myrna Cunningham, the director of URACCAN, expressed this view by stressing:

We, the indigenous leaders have to take full advantage of this wonderful technology to continue discussing key issues of our concern and to prepare ourselves for international summits, as for instance the World Summit on Sustainable Development. (Gigler with Simmons, 2002, p. 1)

At the regional level, increasingly indigenous peoples are using new ICTs to better coordinate their activities and to develop joint regional programs. A good example of the use of ICTs at this level is the experience by the Fondo Indígena para el Desarrollo de los Pueblos Indígenas en America Latina y el Caribe (<http://www.fondoindigena.org>). This regional international organization, representing indigenous peoples of 16 countries in Latin America, has developed since mid-2000 a strategy to use new ICTs as an instrument to: (1) enhance the organization's transparency, (2) improve the information flow between its indigenous and government representatives, (3) promote indigenous peoples' issues at a regional and global level, and (4) enhance the capacity of indigenous leaders to make use of the new ICTs. In order to implement its strategy, the Fondo Indígena established a small communications team, which developed an institutional Web site as one of its first activities, containing information about the institution, specific programs, news, a calendar of events, and contact information. In addition, the organization started a quarterly newsletter, which provides its members and the general public with regular updates about its main activities.

A second main challenge of the institutions represented the need to improve the information

flow between its member governments and indigenous representatives. As an important step the organization organized jointly with the Development Gateway in September 2001 the first of a series of capacity-building workshops in the use of ICTs for indigenous leaders. The core objectives of these workshops were: (1) to train national and regional indigenous leaders in the practical use of the Internet (i.e., use of e-mail, Web-searches); (2) to provide indigenous leaders with specific online tools and resources (i.e., through the hosting of Web sites and the provision of free e-mail accounts); and (3) to promote a culture of information sharing and enhanced information flows between indigenous peoples.

Third, the Fondo Indígena became the main partner of the Development Gateway in developing an international Indigenous Peoples Community Portal (<http://www.developmentgateway.org/indigenous>). The main objectives of this portal is to develop an interactive Web-based platform, where indigenous organizations, international NGOs, governments, and international donors can freely share information about development projects, best practices and lessons learned, research reports, contact information, current events, and related information on such issues as indigenous rights, cultural diversity, sustainable development, and indigenous health. The portal offers a broad range of information on indigenous issues; provides indigenous peoples with the opportunity to access information about the activities of international donors, NGOs, and governments; and disseminates its own information and content to a broad international audience. Moreover, the portal serves as a major source of information about the current situation of indigenous people for the international community.

Finally, one of the key objectives of this ICT program, aiming to strengthen indigenous peoples' capacity to design and develop their own community sites, has however encountered a series of important difficulties. Due to the lack of access to computers, Internet connectivity, and

technical skills, many indigenous peoples remain de facto excluded from the services provided by the program. Even national indigenous leaders and organizations frequently lack the resources and capacity to make meaningful use of the portal and other online services. Furthermore, a key lesson of the project is that there exists an abundance of content on indigenous issues, which is more academic or theoretical in nature. However, it is very challenging to develop content that meets the local needs of indigenous leaders or local communities. Finally, due to the previously-described important differences within the indigenous leadership, the portal is confronted with the challenge of serving the information needs of a very diverse audience. For instance, the information needs of international leaders are entirely different from the needs of a community leader.

At the national level, there exists an abundance of experience of the use of ICTs by indigenous organizations which provide useful information about existing national policies, laws, and government policies; the current situation of indigenous peoples; and other issues relevant to indigenous peoples. In Ecuador, for instance, the national confederation of indigenous peoples, CONAIE — with the support of an international NGO and volunteers — is providing a broad range of information of the situation of indigenous peoples in Ecuador through its Web site (<http://www.conaie.nativeweb.org>). Furthermore, the organization has been quite effective in using its Web site and e-mail listservs in coordinating its joint actions between the different indigenous groups, as well as to influence the national and international policy dialogue on such issues as land rights or the structural adjustment programs.

In Canada, the main indigenous organizations have formed an alliance with the government in the development of a national Aboriginal portal (<http://www.aboriginalcanada.gc.ca>). The main objective of the portal is to provide a single, national Aboriginal window on federal, provincial, and local Aboriginal information and services.

Many indigenous peoples however continue to perceive this program as a government-led initiative, since the content and the design of the portal has been coordinated by a technical group within the Ministry of Indian and Northern Affairs. In order to minimize this type of criticism and to allow the full participation of the main national aboriginal organizations, the government has created a Working Group for the project, where all the main aboriginal groups of Canada are represented. The main function of this Working Group is to define the strategic priorities of the portal's future development.

Another example of how the Internet can facilitate indigenous peoples' access to the political arena and can raise awareness about indigenous peoples' issues at the national level is the Mirror Art Group from Thailand. Since 1991, this small NGO composed of young professionals committed to social change has supported the Akbar hill tribe in the highlands of Thailand. The Group's Web site (<http://www.bannok.com>) has obtained on average 300,000 hits a month, making it one of the country's most popular Web sites. Through its Web site the organization has successfully promoted indigenous peoples' rights, and carried out many campaigns to support the Akbar people through the recruitment of volunteers and solicitation of financial resources and in-kind donations. Furthermore, the Akbar people have had some success in trading their arts and crafts through the site (Gigler, 2001).

These examples, however, illustrate in themselves a key challenge — that the large majority of information found on the Internet is produced by outsiders (i.e., international NGOs or academic institutions), rather than developed by indigenous organizations themselves. An evaluation of 200 Web sites from Latin America carried out by the author in 2002 demonstrates that approximately 75% of these sites are being produced and maintained by international volunteers, NGOs, and academic institutions, rather than by indigenous peoples themselves. An interesting case high-

lighting this issue represents the AymaraNet (<http://www.aymaranet.org>), which provides some of the most comprehensive coverage about the Andean Aymara culture on the Web. Although the site provides information in English, Spanish, and Aymara, it is significant that the site has been developed and maintained by an Aymara activist living and working in Washington, DC, instead of being locally developed and owned by indigenous leaders of the region.

At the community level, there seems to exist a discrepancy between the use of ICTs by community leaders and community members. Frequently, community leaders have started to use new ICTs by using cell phones and Internet services (mainly in the form of e-mail), particularly when they are traveling to the nearby urban centers. For instance in Peru currently exist approximately 1400 public telecenters exclusively in urban centers, which enable community leaders and certain more privileged indigenous subgroups (i.e., indigenous professionals) to access ICT services. At the same time, the large majority of indigenous peoples living in their communities remain completely excluded from the access to new ICTs.

Furthermore, local indigenous leaders play a key role in deciding whether or not communities should engage with the new forms of ICTs. In the Ecuadorian community of Sumbagua in the Cotopaxi province, for instance, a proactive local community leadership cooperated with Chasquinet (<http://www.chasquinet.org>) — a local NGO dedicated to promoting the use of new ICTs for social change and sustainable development by developing a telecenter in the community. The center directly supported the livelihoods of the local community, when community members were able to find a solution to an insect plague that was threatening the local potato harvest via the Internet. This came about after connecting themselves with indigenous communities that had faced similar problems in Bolivia, Brazil, and Peru. The community leaders were able to use the provided information in order to launch

an awareness campaign on how to combat the plague, and through a consolidated effort the community was able to control the plague (Gigler with Daly, 2003). On the other hand, in Mexico one of the main reasons for the failure of several community-based telecenter pilot projects located at the edge of Mexico City and in the State of Michoacán has been the opposition to the project encountered by local indigenous leaders, who felt that the introduction of new ICTs would undermine their position of power as the main holders of information (Robinson, 2000).

Based on this brief overview, it seems key to analyze the impact of ICTs on indigenous peoples in more detail through specific case studies. In the following section, the chapter will provide a more in-depth analysis of two cases studies, whereby ICTs have been introduced to indigenous peoples at the community level. The main reason for limiting the analysis to the community level is that it seems that ICTs have the potential to most directly impact the well-being of indigenous peoples at the community level. As the previous analysis has shown, many of the ICT programs at the international, regional, and national levels seem to reach only a relatively small number of indigenous leaders, as well as having rather indirect effects on the well-being of indigenous peoples. It is thus the aim of the following section to apply the previously-developed Alternative Evaluation Framework (AEF) to the analysis of the impact of ICTs on the well-being of indigenous peoples at the community level.

UNUMA: BILINGUAL AND INTERCULTURAL EDUCATION PROJECT FROM VENEZUELA

Since 2000, UNUMA — Sociedad Civil de Apoyo al Indígena (<http://www.unuma.org>) — a local NGO working for the promotion of indigenous peoples' development and rights in Venezuela, has focused on the innovative use of ICTs to support

a bilingual and intercultural education project of indigenous peoples.

The key objectives of the program are to strengthen the capacity of indigenous teachers from the Wayuu (Guajira peninsula), Kari'ña (El Tigre, Anzoategui), Uwo'tuja, Hiwi (Amazonas), and Pemón communities (Estado Bolívar) by providing training in linguistics; production of books in indigenous languages, mathematics, and psychology; and the use of ICTs (see Appendix 1). The role of the ICT capacity program was catalytic in nature and sought to reinforce the other training modules, rather than focusing exclusively on the field of ICTs themselves. Early findings demonstrate the high value of integrating an ICT intervention into a bilingual and intercultural education program. Most indigenous teachers had never used a computer before the training and were enthusiastic about the ICT program. During a field visit in December 2000, an indigenous leader showed the author his computer artworks — all of which were based on traditional Kari'ña cultural and spiritual motifs. He explained to me that this activity was also an important source of income, as he took his digital artworks (see Figure 1) and reproduced them on t-shirts and other prints, selling them in the local marketplace.

Based on the success of this pilot experience and the strong demand from indigenous peoples

to continue the program, UNUMA was able to finance a second phase of the program in 2002 through a \$50,000 grant from the Development Marketplace of the World Bank. As a first step, a series of consultation workshops with indigenous communities was organized, where it was decided that several computers needed to be purchased in order to expand the ICT program and provide the training to more indigenous teachers, in addition to organizing a series of capacity-building workshops at the community level. Due to the strong interest from many communities, the indigenous communities in all three regions developed a system of sharing the computers, whereby indigenous youth themselves were trained to maintain the equipment and organize the distribution of computers among the different communities. This model is based on collective identity and the strong organizational tradition of indigenous communities, drawing on their cultural value of reciprocity, which provided the basis for the sharing of computers among different communities.

Impact of the Project on the Well-Being of Indigenous Peoples

These first findings from the field clearly illustrate that ICTs can play an important role in strengthening the human and social capabilities of marginalized groups. It is, however, important to take a closer look at the program and to analyze the following questions:

1. What is the overall socio-political context in which the project is taking place?
2. What were some of the ingredients of this successful application of ICTs?
3. What role did the local NGO play in enhancing the individual and collective capabilities of indigenous peoples?
4. In what manner did the project build on and strengthen existing community structures?

Figure 1. Artwork: Graphic designed by an indigenous leader of the Pemón community

5. What are the effects of the project on the cultural identity of indigenous communities?
6. What are some of the key challenges the project is facing?

Firstly, the overall socio-political context of the program is characterized through a permanent struggle of the cultural survival of indigenous peoples in Venezuela. With a population numbering between 2 to 3% of the overall population, indigenous peoples represent a very small minority within the Venezuelan society. For instance, the Kari'ña live in the surroundings of El Tigre, a city that has been for the past 70 years a major area of oil exploration in Venezuela. As a consequence of the oil boom in this region, the cultural identity and social institutions of the Kari'ña communities have come under significant pressure. Many Kari'ña communities are today facing a situation of severe poverty, struggling to make their ends to meet and attempting to preserve their cultural identity.

In spite of this challenging socio-economic and political context, the project is demonstrating that the meaningful use of ICTs by indigenous peoples can significantly enhance their human and social capabilities. One of the key success factors of the project is the fact that the ICT project was fully integrated into the bilingual and intercultural education program. The main role of the ICT program is to enhance the other program components such as increasing literacy capacity, rather than to support the capacity-building of indigenous peoples in the use of computers and the Internet on a stand-alone basis. It is important to highlight that the overall program responds to a key priority of indigenous communities — the strengthening of their cultural identity by recuperating their own languages and improving the quality of the existing bilingual education programs.

This case study illustrates how ICTs can form part of a holistic approach towards promoting

indigenous peoples' development, and they can act in a catalytic manner enhancing the human capabilities of indigenous peoples, thus ultimately contributing to improving their well-being. In the project, the instrumental value of ICTs are being well integrated into the more substantive aspects of the education program, thus contributing in a significant manner to its overall objectives. In this sense, the objectives of the ICT capacity-building activities are to enhance indigenous peoples' informational capabilities not for their own sake, but in order to enhance their skills and further their human capabilities in the cultural, social, and economic spheres of their lives.

A very positive aspect of the ICT program is the enthusiasm the project has created for the overall program, particularly among indigenous youth (see Figure 2). For instance, several youth were able to find employment as a result of their newly acquired computer skills. Furthermore, for the first time, six students from the Kari'ña community have been accepted to pursue a career in computer science in several universities in Caracas. A more intangible effect of the program

Figure 2. Training workshop with indigenous youth in a Kari'ña community of Venezuela (photo by Haydée Seijas, Executive Secretary, UNUMA)

was that the increase in self-esteem of most of the indigenous youth who participated in the training workshops. An important ingredient of the program's success has been the key role that the local NGO has played in acting as a facilitator in promoting the process of individual and collective empowerment of indigenous peoples. It is important that UNUMA has continuously been working with the same indigenous communities since 1992 and thus has gradually gained the respect and trust of many indigenous peoples. Furthermore, the executive director of the NGO has been a longtime ally of indigenous peoples in their struggle to maintain their cultural identity and affirmation of their rights.

Finally, an important aspect of the program has been the emphasis on building all project activities on the existing traditional social structures. Hereby, indigenous leaders have played a key role in facilitating an open participatory approach that includes all community members, including the most marginalized groups (e.g., women and youth). A key aspect of this process encompassed a detailed needs assessment carried out in 2000 with indigenous teachers in order to better understand their attitudes, needs, and perceptions towards the role of information and ICT for development.

In spite of the overall positive outcomes of the program, several important challenges remain. Firstly, due to the overall difficult political situation in Venezuela, the execution of the program was seriously delayed. Furthermore, the indigenous organizations, particularly among the Uwojtuja, Hiwi, and Kari'ña communities, remain relatively weak, and thus the entire financing as well as a large portion of the program management responsibilities remain with UNUMA. Finally, the program very much relies on the personal commitment of the executive director of UNUMA, and it was not yet possible to transfer its management to the indigenous communities themselves.

INTERNET ACCESS IN THE PERUVIAN AMAZON

The following case study illustrates the significant challenges involved in promoting the use of ICT for indigenous peoples' development. In the year 2000, the Ashaninka community Marakiri Bajo (see Figure 3), with the support of IDRC Canada and the Red Científica Peruana, initiated the first telecenter project located in a remote indigenous community in the Peruvian Amazon.

The Ashaninka represent the largest indigenous group of the central Peruvian Amazon region. They live in severe poverty, while their cultural identity and subsistence economy are under severe pressure due the exploitation of natural resources and invasion of indigenous lands since the early 1900s (Garcia Hierro, Hvalkof, & Gray, 1998). Moreover, their access to such basic social services remains very limited. Within this overall political and socio-economic context, many indigenous peoples had very high expectations about the potential benefits of the project, while others remained skeptical about the usefulness of ICTs from the beginning. This early enthusiasm about ICTs is best reflected in the words of Mino Eusebio

Figure 3. Ashaninka leaders of Mari Kiri Bajo using the Internet

Castro, the Asháninka leader, who spearheaded the project from inception. In an interview with the author in early 2001, he emphasized that “through the help of the Internet[,] indigenous peoples have the opportunity to overcome their exclusion and to have improved access to education, markets, and political participation. The Internet also enables us for the first time to directly contact international donors, to present our opinions in policy debates, and to directly negotiate funding proposals without any intermediaries.”

In the first phase, the project focused on finding a technical solution to provide telephone and Internet connectivity to the remote village of Marakiri Bajo, a community without access to electricity and running water. Furthermore, since it was one of the key objectives of the program to provide distance education to indigenous youth, the program installed in the community a state-of-the-art videoconference facility (via a generator-operated satellite system).

What was the impact of such a high-level investment in technology at the community-level? How did the community react to the newly introduced telecenter? What were the reactions of the Ashaninka in the surrounding communities? Was it possible to maintain the interest of the community into the project? Were people really empowered and did they derive real value out of its use?
