While the focus group interview identified that the students saw the chat facility as a pragmatic solution to the educational need to meet to discuss their collaborative presentation, they did value the opportunity to talk, plan and debate online at a time convenient to them. The asynchronous discussion fora also played an important role in enabling the student groups to confer and discuss issues in ways that accommodated the unit’s learning objectives and their personal lives. Yet, there was evidence that they did not see this as fundamental to their success in the unit or their personal perception of how they learned and developed their skills in critique for investment decision-making.

Online Learning and Assessment

In a recent paper with Eley (Eley, Labjcyier, & Spratt, 2005), we investigated some common assumptions about group learning and group assessment practices. The two key assumptions investigated were whether indeed assessment tasks or project outcomes reflect some aggregate of the individual group members’ learning and that contribution to group functioning is sensitive to variation in that learning. In that study, we developed:

measures for individual students’ contributions to group processes, for individual students’ influence on the topic understanding of their group peers, and for the influence of the overall group experience on personal learning and understanding. (Eley, Lajbcyier, & Spratt, 2005, p. 1)

That study was positioned within the framework of the unit reported in this chapter but undertaken subsequently to the evaluation this

chapter reports. We were interested in that study in exploring whether the group-directed project work was a valid measure of an individual’s performance or learning. Typically, group work is encouraged in the tertiary environment. The same mark is given to all the group members, even if they have not all equally contributed to the group project. Eley, Lajbcyier and Spratt (2005) permitted groups to (anonymously) self assess and then tried to validate these marks by linking group performance with individual learning objective performance.

The “quality of group assignment outcome” seems *not* to relate to individual students’ attainment of the objectives associated with that group work. That is, the a priori “hunch” was that group outcomes would relate to individual learning. However, we found that group outcomes do not relate terribly well to individual “learning from the group experience” performances. How might we imagine a group operating in such a way that good group cohesion results in higher group assignment quality, yet has minimal influence on the learning attained by the individual group members? Put another way, if you were a member of a group, and the aim was simply to maximize the mark that the group attained for the group product outcome, with no account needing to be given to the learning of the “lesser abled” members, then how might you most efficiently coordinate and organize who does what? These findings open questions a bit more fundamental about the structuring of group activities than just the “how do we make group marks more valid” issue that was our entry into the area reported here and in Eley, Lajbcyier and Spratt (2005).

In that paper, we concluded that:

... in the final analysis, individual learning should be assessed individually. We caution that the present study is just one within a particular instructional context. But if the findings here prove generalizable, then maybe we should re-define group projects to be not assessment opportuni-

Using “Blended Learning” to Develop Tertiary Students’ Skills of Critique

ties, but a form of learning experience. (see Lejk, Wyvill, & Farrow, 1999)

Given the possible influence of contingencies discussed above, we might need to find ways to structure them to ensure that students commit and participate. This might mean not modeling group projects on workplace project teams, but rather deliberately designing them to encourage the student learning behaviors that we desire. But the simple conclusion here is that we cannot assume that individual assessments necessarily or directly derive from project outcomes. Perhaps this was an unfounded expectation in the first place. (Eley, Lajbcyier, & Spratt, 2005, p. 9)

The assessment strategy reported in this study was set in the pedagogical context of peer and group learning. Working in groups of about 10 students, all students were required to help decide on (virtual) investments across five market sectors, with the aim of maximizing their returns over the period of the project. The groups were constrained in their choice: They had to choose one company out of two for each of the five sectors (this was done to contrast the differing decisions made by different groups). Each group met at least once per week to review its portfolio and decide on any investment changes. The learning objectives associated with the project involved the use of various information sources in the making of investment decisions. These sources included company balance sheets, financial news media, technical price action reports and macroeconomic indices. The intent was for students to recognize that investment decisions are inherently ambiguous and are not uniquely determined by the range of information available.

The unit coordinator took pains to describe the assessment transparently and to make his expectations of the students unambiguous. The evaluation data revealed that students were very positive in their appreciation of the clarity and unambiguous nature of the assessment strategy.

They felt they knew what was expected of them. They valued the way each lecture clearly outlined its aims and the relationship to assessment. They valued the way the lecturer was able to refer to the assessment tasks at various times in more detail over the course of the semester. They believed this assisted their understanding of what was expected of them. In the context of the assessment strategy, students generally felt that the “group work allowed members to see how they were faring compared to other members and other groups and their members.” They believed this helped them learn and also contributed to developing their skills of analysis. The asynchronous discussion groups and the use of online chat enabled students to make their decisions about investments. They see these online strategies as complementing in a “supplementary way” the “negotiation that went on” in preparing investment decisions for the assessment tasks required. In conjunction with the assessment strategy, engaging in the online chat especially allowed them to be “task focused.”

We feel confident that the students’ perception of the success of the assessment strategy for them vindicates our attempts to be self-critical of our assessment practices. This critique reflects the recent growing interest in improving student learning through assessment and its place more strategically as a measure of institutional quality (Falchikov, 2001, 2005; James, McInnis, & Devlin, 2002; Knight, 2002). Given the mainstreaming of e-learning in higher education, then certainly assessment in e-learning environments will be similarly investigated (Gipps, 2005).

A cursory review of the assessment literature reveals that there is growing interest in using assessment to *lead* learning rather than simply *measure it* (James et al., 2002). We know that learners are ‘strategic,’ and our cohort in this study certainly presented themselves as such; they were generally employed in demanding professional positions in the field of financial computing and were studying to achieve their particular goals. The unit assessment, therefore, becomes

an important (some would argue the primary) indicator of curriculum expectations for students. Associated with the interest in using assessment to lead learning is the role that assessment feedback plays in learning, and this is also becoming more prominent in the literature (Hounsell, Hounsell, Litjens, & McCune, 2005; Carless, 2006). Indeed, Carless (2006) puts forward a strong argument for the idea of ‘feed forward’ rather than feedback in the context of what he calls ‘learning-oriented assessment’ (LOA).

In LOA as he describes it, “learning comes first, both in the way the term is literally constructed and as a matter of principle which seeks to emphasize the learning aspects of assessment” (Carless 2006, p. 4). In other words, learning, not measurement, is emphasized and reconceptualizing feedback as ‘feed forward’ can assist students in taking what they have learned and how they have understood it to progress forward to future work. These ideas sit well with the deeper pedagogical approach of the unit reported here and with the research that we undertook into the assessment strategy specifically reported in Eley, Lajbocyier and Spratt (2005).

Blended Learning and Variation Theory

Intellectually, we were convinced of the potential of peer learning and peer assessment as effective and legitimate pedagogical strategies. However, we were attempting this in a relatively new learning environment. If we called this environment ‘blended learning,’ then most readers would anticipate that we were discussing some form of combination of traditional (that is face-to-face) pedagogies with an online component. While this was so for us in this case (mixing online learning with face-to-face experiences), we must acknowledge the controversy surrounding the use of the term ‘blended learning’ in current debates about e-learning in tertiary education.

In the contemporary e-learning literature in both higher education and corporate training settings, ‘blended learning’ has become ‘amorphous’ (Oliver & Trigwell, 2005) in that there is considerable debate about ‘blended learning’ as a unifying descriptor for particular forms of technologically supported teaching. Oliver and Trigwell (2005, p. 17) identified three common definitions of the term that they go on to critique; these are:

1. The integrated combination of traditional with Web-based approaches
2. The combination of media and tools employed in an e-learning environment
3. The combination of a number of pedagogic approaches, irrespective of learning technology.

Oliver and Trigwell (2005) suggest that the first of these is the most common interpretation. They go on to present a comprehensive critical review of the literature and suggest that there are as many definitions of ‘blended learning’ as there have been of e-learning or online learning since the emergence of the Internet. They consider the array of definitions unhelpful and the remainder of their paper analyzes and critiques the three key definitions they identified. While we accept that clearly elucidated definitions are central to ensuring collective understandings among communities of scholars, be they teachers or researchers, we do concede that in the messy ‘low lands of practice’ (after Schön, 1995), clarity in definitions is often of less immediate interest to practitioners than scholars on the ‘high hard ground of theory’ (Schön, 1995). This is not meant to be flippant or to deny the importance of definition, *per se*, in research traditions. However, while Oliver and Trigwell’s (2005) arguments for a reinterpretation of the term blended learning may be honorable, practitioners continue to confront definitional quagmires regarding anything to do with flexible, online or e-learning as they busy themselves trying

to innovate and keep abreast of the rapidly changing learning environments created by advances in technology and research.

Martin and Oliver’s (2005) critique highlights a number of other important issues; one is that the majority of the definitions of ‘blended learning’ are “teacher centered” in that they are “all described from the perspective of the teacher, the instructor or the course designer” (p. 18). This, of course, is the key to their critique and one that may be helpful for those of us who see teaching more as the ‘context’ for learning (after Green, 1998) rather than an end in itself. If blended learning is conceived less as a ‘teaching methods approach,’ face-to-face with online tasks or integrated multi-media for example, and more as a learning approach that develops ‘variation’ for students in learning engagements, then Oliver and Trigwell (2005, p. 22) believe that blended learning could be a defensible term, and therefore “redeemed.”

The ‘variation’ they allude to here is a reference to variation theory, which suggests that for learning to occur, “variation must be experienced by the learner” (Oliver & Trigwell, 2005, p. 22). Variation theory has evolved from the early and highly influential work of Marton and Saljo (1976a, 1976b), which investigated qualitative differences in learning.

Variation theory is based on the idea that:

For learning to occur, variation must be experienced by the learner. Without variation there is no learning. Discernment is at the core of our ways of experiencing the world around us. (Oliver & Trigwell, 2005)

Where discernment is about the experience of ‘difference,’ variation becomes the context for discernment. The unit coordinator in our case was trying to find ways to create engaging learning opportunities so students would become active participants and collaborators on their own to develop their critical skills in investment decision

making. If we liken the learning design of peer learning and peer assessment within our blended learning environment as an attempt to promote ‘discernment’ in students, then the strategy begins to be unpinned by Marton and Trigwell’s (2000) variation theory.

The original impetus for the unit coordinator to reconsider and redevelop his pedagogical approach was his desire to promote particular cognitive skills; moreover, given his student cohort, he was also interested in progressing learning approaches that would be relevant for them and develop his students in their professional practice. Given the complex globalized world in which his students find themselves, this means that he was interested in preparing them to be able to function as professionals in settings of change. Marton and Trigwell (2000, p. 385) see variation theory as a means of explaining this; how “participation in one practice can prepare for participation in another practice.”

While they argue that learning theories have traditionally seen this intellectually as a question of similarity, it is in their view a question of difference. In other words, as they explain:

The experience of similarity between two situations is a function of the pattern of variation between all other situations. (Marton & Trigwell, 2000, p. 386)

In the context of blended learning environments and in keeping with the ideological basis of constructivism in learning, we can see that variation theory might help explain how and why students engaged in learning environments have variable experiences and learn differently. It may also assist in framing pedagogical research that will investigate longitudinally, the influence of blended learning environments in tertiary settings on change in professional practice from the learners’ perspective. In the context of the case discussed in this chapter, it may be that we now have grounds to reconsider the pedagogic of the

unit in light of this more contemporary research in blended learning and variation theory.

CONCLUSION AND IMPLICATIONS FOR RESEARCH AND PRACTICE

This chapter used a specific case report to illuminate the way in which assessment can be harnessed to foster deep learning of critical inquiry skills in tertiary students. It also provides evidence that students believe they benefit from use of an online learning environment constructed as a pedagogical support strategy, a form of blended learning.

There is an expansive and growing literature that explores many aspects of online learning environments in tertiary settings. It would be fair to say that in recent years this literature has begun to explore the importance of social presence and teaching presence as key determinants in improving the instructional effectiveness of online learning (Chih-Hsuig, 2001; Garrison, Anderson, & Archer, 2001; McConnell, 2005; Murphy, Smith, & Stacey, 2002; Stacey, 2002; Stacey & Rice, 2002). Social presence and teacher responsiveness, and the way in which sociality develops is important in developing the interaction that contributes to positive cognitive learning experiences. Indeed, it is these kinds of experiences that have been cited as predictors of successful e-learning groups generally and in cohorts similar to that reported in this case study, as the majority of the cohort was full-fee paying international students (Chih-Hsuig, 2001). The study results, despite some contradictions in conjunction with the experience teaching the unit, have led us to be confident that the social learning that can be engendered in peer learning groups online is potentially a powerful learning adjunct.

We have acknowledged that there was some contradiction between the survey findings and the focus group interview findings. Overall, students felt that the online environment in this

unit, including the discussion forum and chat forum, were not fundamental to the deep learning that was trying to be instilled. Students believed that this kind of approach to learning could have been achieved without the online learning site. Despite this, however, we can suggest that online environments can be used effectively as successful pedagogical support. Students are well aware of the importance of motivation and social presence (what they have characterized as “responsiveness” in this study) to successful learning in synchronous and asynchronous discussion fora and integrating online teaching environments with assessment tasks that are relevant and practical to support successful learning outcomes.

Students recognized the online experience as providing a complimentary or supporting role in attaining the deep learning objectives of the unit: not essential but somewhat helpful. The students recognized that the unit instilled collaborative discourse, debate and decision making in investment decisions, and that they understood how investment decision processes can “incorporate debate and discussion and how that can lead to better investment decisions.” However, they did not attribute the attainment of this knowledge purely to the online environment or the technology per se.

It is well recognized that “transforming a course by integrating new technologies is an increasingly common example of educational change and innovation” (Allen, Wedman, & Folk, 2001, p. 104). We acknowledge that assessing the efficacy of sustainable curriculum change brought about by technology innovation requires the application of longitudinal research approaches, such as that described by Allen, Wedman and Folk (2001). Moreover, our review of the more contemporary research in blended learning environments and learning theories—in particular, variation theory—as discussed by Marton and Trigwell (2000) and Oliver and Trigwell (2005) raises many new questions for research in the setting of e-learning environments.

Given this and based on the study reported here, as well as the issues raised by the literature in social and cognitive presence, blended learning, variation theory and peer assessment, new questions for research might include: If social presence and teaching presence are predictors of success in e-learning environments, how can they be modeled in academic practice? What kinds of research approaches in e-learning settings can help us explore the influence of social engagement on cognitive learning in groups? In what ways can synchronous and asynchronous e-learning environments be created to foster the development of skills of critique, analysis, debate and decision-making? How might variation theory support the development of blended learning environments? In what ways ought assessment to be structured to have a positive impact on students’ attitudes to learning so that it is conceived as integral to the teaching context for learning? How do students perceive differences in a peer group assessment as a learning experience and the assessment of the learning attained because of it? How do we make group marks more valid?

Chapter 2.48

Using a Blended Model to Improve Delivery of Teacher Education Curriculum in Global Settings

Vivian H. Wright

University of Alabama, USA

Ronnie Stanford

University of Alabama, USA

Jon Beedle

University of Southern Mississippi, USA

ABSTRACT

This chapter describes how teacher educators have used a blended approach, online and traditional delivery, to structure course content for its international master's program. The authors discuss challenges they had to overcome, lessons learned, and students' reflections on the blended approach.

INTRODUCTION

The delivery of teacher education courses and/or total programs at overseas sites is often compli-

cated and plagued with problems because of the distance between the home university and the location of the students. The Office of International Programs in the College of Education at The University of Alabama offers Master of Arts degree programs in elementary education and secondary education in five locations in Latin America: Asuncion, Paraguay; Bogota, Colombia; Lima, Peru; Mexico City, Mexico; and Quito, Ecuador. The students in these degree programs are teachers in private, United States (U.S.)-type, pre-K-12 schools. The delivery method used in the past has involved sending a professor to the foreign location for about 2 weeks to teach a 3-semester-hour graduate course. The course

schedule consists of approximately 3 hours of class Monday through Friday, and 3 to 6 hours of class on Saturday. Two weeks of this daily schedule creates a considerable amount of pressure and strain for the professor in attempting to deliver a quality course in a short period of time, and a large burden on the students who, while taking the course, are also engaged in full-time pre-K-12 classroom teaching. In addition, access to library research materials and other course materials has been complicated because of problems associated with transporting these materials to the country where the course was taught.

Educational technology allows organizations the ability to modify courses and curriculums and, at the same time, become more flexible in their delivery (Kvavik, 2002). Graves (2001) predicted that higher education is moving toward a more student-centric approach and away from the traditional instructor-focused environment. Electronic access to information allows students the opportunity to explore, discover, create and communicate more efficiently than in the past. Virtual classrooms can allow for more creative ways to collaborate and communicate without “the constraint of a physical classroom” (Lao & Gonzales, 2005, p. 471). With these new opportunities come new challenges to serve students at all levels and from locations around the world. The challenges include how to create a system that both works and is user-friendly. Creating an online component through a Web-enabled course has the potential to give instructors and students a greater opportunity for interaction and learning (Dabbagh & Schmitt, 1998) and can possibly provide opportunities for the students to become acquainted with the course assignments/materials and their peers in advance of the beginning of the course. In this chapter, we will describe how we have used computer-based instruction via the Internet and a course management system (WebCT) to create a blended model of course delivery for students that provides a good mixture

of technology-based instruction and traditional professor-led classes.

THE CHALLENGE

Electronic access of information allows students the opportunity to explore, discover, create and communicate more efficiently than in the past. With these new opportunities come new challenges to serve students at all levels and from locations around the world. Challenges include creating a system that works efficiently; is reasonably user-friendly; and offers opportunities for the students to become acquainted with the course materials, the instructor and their peers in advance of the instructor’s on-site arrival. An additional challenge is creating ways technology can extend the learning timeline of the course through activities, assignments and/or assessments that occur after the instructor has departed the overseas location. Lao and Gonzales (2005) noted that instructors who teach online should consider how to “capitalize on the different technological components to make learning meaningful for students” (p. 472).

Our format begins with about 2 weeks of technology-based learning activities prior to the arrival of the professor at the overseas site. The course design includes communication tools, such as e-mail, discussion boards and online chats. Educational hyperlinks are located on the home page so students can access additional course-related references and materials before the instructor arrives. Course content sections are posted on the course WebCT home page, listing assignments to be completed prior to the instructor arriving. These sections also include the syllabus, assignment summary, reading list, course links, course topics, library use instructions, examples of student work, glossary, calendar, and instructions for after the instructor leaves. Such a design provides students with extensive

learning activities that the professor extends and amplifies during the 2 weeks he or she is teaching the students in a “normal” face-to-face teaching format. When the professor returns to the U.S., WebCT technology and other online technologies make it possible for students to continue to complete assignments, receive feedback on those assignments and communicate with the instructor regarding questions, readings or discussions of course content. Thus, the technology has allowed us to extend the time frame of the course from the traditional 2 weeks of intensive professor-led instruction to a more relaxed blend of technology and traditional course delivery that lasts 6 weeks or beyond. Our pilot research with several courses and instructors has convinced us that this blend of technology and face-to-face teaching has many advantages for delivery of a teacher education curriculum overseas.

In the past few years, major universities have supplemented traditional library holdings with electronic databases of information that may be searched in a variety of ways. Given the correct set of circumstances (i.e., all of the technology works!), this information can be accessed from any location on the planet. It is now possible to locate, access, read, download and print articles from professional journals that are electronically housed in university library databases. In addition, computer technology and the Internet have made creating, editing and sending course information fast and inexpensive. The technology can include textual information and multimedia content. Similarly, computer technology has made it possible for students to create responses to class assignments and send these to the professor via e-mail or other electronic portals.

In our discussion, we describe how we have used technology to structure courses and course content. In addition, we discuss a variety of problems that had to be overcome to use the technology to maximum effect. We also present results of student evaluation and feedback. Although we describe how we have used technology to assist

with course delivery in Latin American, a point to be made is that the technology can be used anywhere the course instructor and the students are separated by distance and/or where limited instructor-student time together is a factor in student learning. We feel that this concept has important implications for how teacher education professors interact with students in all learning environments.

Initial Blended Delivery Experiences

The first course in which we used WebCT was *Modern Elementary/Secondary School Programs*, which was taught in Lima, Peru. The course is an examination of the K-12 school in terms of its overall programs and the trends, issues and problems that impact the school and student learning. In this course, WebCT was used to present a variety of course information to the students. Access to WebCT and the University’s computer system was made available to students 2 weeks prior to the professor’s arrival in Lima. The materials posted on the WebCT site included the course syllabus, directions for use of University of Alabama online library journal databases, pre-course reading assignments and the specific requirements of writing assignments, including grading rubrics and “good” examples of those assignments. Providing such guidelines and examples helps guide the students through an online experience and online discussions, providing advance organization and structure (Lim, 2004). The pre-course readings were accessed by students via the Internet through the use of electronic databases in the University of Alabama College of Education Library. The result was that students had accomplished significant work prior to the first day of class. Students had prior information and experiences in the course, which allowed the instructor to “hit the ground running” on the first day of the class.

The second pilot course using WebCT was an elective course entitled *Computer-Based In-*

structional Technology at the Quito, Ecuador site. The instructor began the class online via WebCT 2 weeks prior to arrival in Quito. Assignments and postings were due up to 2 weeks after the instructor's departure.

The course had 12 main links from the home page. These included sections for before the instructor arrives, syllabus, assignment summary, reading list, course links, course topics, library use instructions, examples of student work, glossary, calendar, discussion board, and instructions for after the instructor leaves. As Deubel (2003) suggested, we used various media throughout the Web site and included colorful graphics and animation useful in directing and keeping the students' attention and focus. Careful guidance by the instructor attempted to provide students with the necessary skills and tools to access the vast relevant resources on the Internet. Prior experience has indicated the necessity to consistently update and enhance the online courses, not only from semester to semester, but within the current semester as well. Palloff and Pratt (2001) suggested instructors typically will have a much more positive outlook on using Web-enhanced courses if they are given the freedom to make adjustments each time the course is taught. Additionally, it is essential that instructors understand how to upload content and other information to the Web site to make changes or add more materials. As in the research of others working with boundaries of locations (Ho & Burniske, 2005), we found that employing a teaching assistant and, in our case, an instructional technology graduate student, is helpful in working with faculty and students in troubleshooting problems that may occur in relation to technology.

For students, online discourse may be one of the most important characteristics of pedagogy used to benefit and facilitate effective communicative practice (Pittinsky, 2003). Some of the guidelines we followed are given by Palloff and Pratt (2001) and included collaborative assignments, posting of assignments so that peers can provide feedback,

online areas to communicate (discussion boards and e-mail) and requesting a certain number of posts per week to the course Web site.

Following the two initial courses with the blended delivery model, we have had experience with several other courses taught in the overseas sites. One use of technology that was explored was providing overseas students with sample papers written by previous students in the course being taught. In a prior semester, the course professor assigned research papers on a variety of topics. The student's task was to provide a definition of the topic and discussion of how the topic related to elementary and/or secondary school issues. Students were limited to a final product of three pages maximum, including a brief references list. When these papers were graded by the professor, the students made the suggested corrections and gave the professor the edited copy via e-mail attachment. Thus, a mini-library consisting of about 55 edited, electronic papers existed. The professor created a number of CDs that contained the full set of papers and took these to the Latin American location for distribution to students. In teaching a course with a relatively short timeline, the students were given "good" examples of student work, which was used as the basis to begin their assignment. Their assignment was to use the on-campus electronic journal databases to update each paper with the latest references from the literature. In addition, for each topic, class discussion was used to identify new ideas, concepts, points of significance and relationships to other topics.

Another technology-based technique that extended the learning timeline of the course was delaying the final examination until a week or more after the professor had completed the on-site teaching and had departed for the U.S. This simply involved securing a computer lab at the local school at the Latin America site, getting one of the local school administrators to give and proctor the examination, and having the students

send their examination answers to the professor via e-mail.

Delaying the final examination created multiple advantages. After 2 weeks of classes, the students were tired and in no mood to write a 2-plus hour discussion examination. The delay in the exam gave students additional time to read and study. The students were in favor of the delay and reported they felt much better prepared for the examination. The instructor graded the exams and sent each student an e-mail regarding the exam evaluation and final course grade.

Student Evaluations

There were 20 students in the Lima class. In this class, the majority of the use of technology was dealing with front loading of assignments. These included specific reading assignments, a first draft of one short research paper and initial research for a second short research paper. Thus, WebCT was used to make assignments, teach students how to use the library databases, show students examples of “good” work and present specific criteria for grading some assignments. Typical of student comments and feedback are the following items from the end of course assessment:

This was AWESOME!! It makes so much more sense to give the assignments (or readings) ahead of time so students can do thorough research and actually take in what is being read instead of rushing around once the course started. I would hope MORE instructors would use this method. Teacher and student satisfaction as well as student learning would increase!

It is very useful to have the info prior to the course. It allows for some preliminary work to be done, which is then reflected upon during the course. Additionally, the work is spread out over a longer period than the 2 weeks of class time.

Other students commented: “I loved this! I

appreciated the info ahead of time.” and, “I liked it. I felt prepared for the 1st class—it used my time better—I love having access to the database.”

Fourteen Quito students were enrolled in the Computer Applications course. The students received e-mail instructions on how to enroll in the WebCT course and how to locate and complete the first assignment. Once this first assignment was completed, students were then directed fully from the WebCT instructions for each topic associated with the class. Tutorials on how to complete the assignments and links to helpful Internet sites were all part of the WebCT course. Additionally, students were required to use the WebCT e-mail tool to communicate with the instructor and others enrolled in the class. Students also completed several assignments via the discussion board. After the instructor’s on-site teaching, and, on her return to campus, the instructor queried the students via the discussion board on their blended course delivery experience. Overall, the comments were positive and students enjoyed and appreciated the interactivity of the course. One student noted: “This is a good way to keep in touch with the teacher and also with the rest of the students. With this page we can read what the other classmates think about a certain topic, which is good.” Another student wrote: “Overall, the WebCT experience for me has been technologically enriching and challenging, but not beyond comprehension with some effort.”

Of the problems students noted in this discussion posting, most were associated with logging onto the course Web site with the first assignment, presented online in portable document files (PDFs) format. One student commented, “I don’t feel confident and sure about if I’m doing the correct job. I had problems with topic one, because my computer couldn’t open it.” Another wrote:

It took me a while to find the ‘Log in to WebCT’ button because it seems to be only “a title.” When I opened the page, all my attention was drawn to the different options listed for students,

faculty/staff and other. I just didn't realize that the button was in front of me, so I think that it could help others if you add a 'click here to ...' next to the login button.

A couple of the students noted that the calendar tool had not been updated promptly as assignment due dates were adjusted, with one student writing, "Another recommendation would be to allow students to have the original tentative calendar with the teacher's entries and to create a new one with the modifications that the teacher sends afterwards."

In addition to articulating the problems they experienced, several students noted positive attributes regarding the feedback, instructions and interactivity with other students. For example, one student wrote, "In terms of logging in to the program, I did not have any problems ... instructions sent via e-mail were clear." Another commented, "The system is user friendly, I have found clear instructions and tutorials. There are many helpful links, too." Another student wrote that he was surprised more instructors do not use an online component, writing, "I have been really surprised how little and how rarely this technology has been taken advantage of." Finally, a student noted, "It has the possibility to unite people over vast distances."

What We Learned

Potential problems that must be addressed before the class begins deal with issues relating to student enrollment in the WebCT course and the necessity of each student acquiring a university-wide login and password for use with all university-related technology systems. It was imperative that students be "officially" enrolled early to ensure they received their university-wide account information in order to access the Web site and the university's online library databases. A registration problem sometimes occurs with short-term courses offered during the middle of a semester.

Most university registration systems are set up to enter student enrollment data at the beginning of the semester. Adding student registration information into the university's student database at an odd time (i.e., other than the beginning of the term) can be a major challenge. Student information services can vary, and traditional identifiers, such as a social security numbers, student numbers or other "passwords" may not always apply. These details were addressed with the University's administrative structure prior to "registering" the class and with sufficient lead time to get all contact procedures working before students were informed that they could access the University's technology infrastructure. Additionally, a library tutorial was created and posted on the WebCT course home page in both PDF and Hyper Text Markup Files (HTML) formats. From past instructor experiences with online supplements, we were aware that some students' network connections at home, work or school were of limited bandwidth and the use of PDF files would result in longer download times, therefore requiring our use of html files in addition to PDF files. Network security, preferences and connectivity vary at each Latin American site. It is helpful to create a list of programs being used and any specific technological needs and questions prior to the course starting. Typically, each school has designated technical support personnel who can help troubleshoot and anticipate potential problems.

It was our goal to not give students too much technology in the beginning but to scaffold the technology into the course by allowing the students to become familiar with WebCT through the "Before Instructor Arrives" assignment on the home page. This process worked well with the pilot courses, with the exception of some students who did not have an Adobe Reader loaded on their machines and therefore could not read the PDF file. This problem created additional e-mails between the instructor and students prior to the instructor's arrival on-site. We noted this for

future revisions to the Web site. It is important to constantly note and work toward eliminating any problems that might occur with the technology. With the International Programs office located in one country and the students located in another, it is sometimes difficult to understand some of the problems students might encounter. The instructors for the pilot courses maintained field notes of all problems encountered throughout the weeks of instruction in an effort to better inform future instructors using the WebCT model. For example, some students had problems learning to access and manipulate the library databases, and other students had problems properly posting to the threaded discussions.

The Murphy's Law dictum "Anything that can go wrong will!" certainly applies to using technology through a platform such as WebCT, especially when it is accessed through the security maze of a university-based computer system. The debugging process can be lengthy and trying. Students get easily frustrated and short tempered when things don't work "as advertised." Professors need to be prepared to devote a large amount of time to trouble shooting and assisting students with a variety of problems. There are also networking issues related to accessing the university's WebCT server and the library's database server from Latin American countries. These issues of access and connection speed continue to present challenges.

CONCLUSION

The students involved in our blended delivery courses believed there were many advantages to using this approach. Our philosophy is that the blended teaching approach offers a number of advantages. Students gained supplementary content through the online instruction, while gaining additional skills and knowledge using Web-based materials and interacting with their peers and instructor. Student access to educational research through library electronic databases is a major

asset in increasing the quality of teacher education via distance education. The students must be able to e-mail the instructor with any problems or questions about the course before the instructor's arrival at the course site. Another important issue is the ability of the instructor to respond to student inquiries in a timely manner.

Planning is a key component in making the blended delivery methodology model work to its maximum potential. The instructor must carefully think through the entire course and plan the total learning experience well in advance of the first class. It has been helpful for the authors to think of the course in three components: (1) prior to the instructor's arrival; (2) while the instructor is on site; and (3) after the instructor departs. Each of these components may be elaborated as follows:

Prior to the instructor's arrival:

- Selection of the course delivery software and learning the limits of its use are essential. Many educational institutions are making a commitment to a course management system. Potential technology-based instructors are advised to determine if a particular platform is supported by their institution and to secure in-house staff development regarding its use.
- Planning the course should entail creation of assignments that the students will be asked to complete prior to, during and after the professor's time of face-to-face instruction. In addition to the assignments, methods of providing students with instructor feedback must be created.
- Instructions to students for using various aspects of the technology must be created and tested. Everything that students will be asked to do should be tested using technology infrastructure equivalent to what students will be able to access in their home location.

While the instructor is on-site:

- Instruction should include follow-up and feedback to students regarding assignments made prior to the instructor's arrival on-site.
- Instruction should be designed to take maximum advantage of student learning achieved prior to the instructor's arrival.
- Instruction can be slanted toward creating conditions and situations that will most effectively support learning assignments to be completed after the instructor departs.
- Student evaluation of the use of technology prior to and during the instructor's time on site should be secured. It is recommended that both formal and informal student feedback be solicited.

After the instructor departs:

- Methods of completing final course assignments and communicating these to the instructor must be in place.
- Opportunities for students to communicate with each other regarding assignments and learning activities should be considered. It is important for students to communicate with the instructor, but it is equally important for students to communicate with each other.
- Evaluation of student learning should be considered, especially how to effectively structure any examinations that may be needed.
- Methods should be created through which the instructor can provide students with feedback regarding their individual learning and the major elements of learning experienced by the entire class. Too often, students do "end of course" work and have no idea of its value or validity. The use of technology after instruction is formally concluded makes such feedback possible.

Success in implementing our past courses and future courses for the International Programs office will continue to rely on continuous evaluation and instructor/student reflections. Instructors should be trained on the use of WebCT tools (or the course management system of choice). Students should also receive advance instruction through the development of tutorials or extensive e-mail instruction prior to first use. Students in the pilot courses appreciated clear instructions in addition to the immediate feedback of the instructor and the interaction WebCT tools afforded them with the other students enrolled. Overall, our experience with the blended delivery approach of Web-based instruction coupled with traditional professor-led classes has encouraged us to continue to experiment with and refine the process.

Chapter 2.49

Developing Staff Training in Virtual High Schools

Chris Thompson

Elmbrook Schools, USA

Zane L. Berge

UMBC, USA

ABSTRACT

As virtual high schools grow in numbers across America more interest is generated in how to successfully plan and implementing them. Part of planning, implementing, and sustaining successful virtual schools includes delivering quality professional development that has a positive impact upon students' achievement. This article focuses on three virtual schools at different stages of maturity in order to describe such a model.

INTRODUCTION

Virtual schools are a rapidly growing phenomenon in American elementary and secondary (k-12) education (Berge & Clark, 2005). They are the latest and potentially the most controversial manifestation of the electronic learning (e-learning) revolution in schools. As Clark and Else noted in 1998, "For the foreseeable future, the World

Wide Web ... is likely to serve as an umbrella technology uniting distance education media for distributed learning ... Virtual schooling is the next wave" (Clark & Else, 2003, pp. 35-36).

Distance education in today's virtual schools describes not only the education of the students enrolled, but also the professional development programs used to train the faculty and support staff working for each online school. This article briefly profiles three virtual schools, each at a different stage of development, yet each dependent upon a successful and sustained distance education program for its professional staff, in order to remain viable long into the future. As virtual schools become more accepted by the public and the attention given to the online schools shifts from their sources of funding to their standardized test scores, a model for sustained distance training and education must be in place to deliver quality professional development that can positively impact students' achievement scores on standardized tests for each school's online student population.

There are three virtual schools used in this article to explore improvements to staff development. Electronic Classroom of Tomorrow is the largest k-12, electronic school in the United States, serving almost 7,000 students. The second school is the IQ Academies high school, which is just completing its inaugural year and proudly claims its 203 students a success. The third school is entirely virtual, and to date imaginary, but ideal in its delivery of distance training and education to its staff and faculty. The first two schools provide examples that collectively will serve as the foundation for a successful professional development program. The Virtual I.D.E.A.L. school will serve as a model for future management consideration. Taking into consideration what is known about barriers to online learning, best practices in virtual schools, and how to sustain virtual schools, success of schools that take into account the Virtual I.D.E.A.L. program will ultimately have a positive impact on the long-term status and its ability to service each of its students' needs.

The ECOT

The Electronic Classroom of Tomorrow (ECOT) was founded in 2000 and today serves as the largest online k-12 school provider in the United States, serving almost 7,000 students (ECOT, 2004). Based in Columbus, Ohio, this school enrolls only Ohio residents, drawing from a student and teacher population that is geographically spread across the state. Like most public, state-sponsored chartered schools, the ECOT high school provides a workstation and Internet access for each student and partners with course-content providers to offer curriculum through a course-management system. Each teacher begins with the provided course content and is able to adapt it to meet the needs of his or her class. Special education teachers are also available, modifying the course content and classroom activities for the students identified with special needs (B. Hartge, personal communication, June 23, 2005). Like traditional

classrooms, each special education student has an individualized education program (IEP), which is meant to guide and document specially designed instruction for each student with a disability, based on his or her unique academic, social, and behavioral needs (IEP, 1999). While serving the needs of a very diverse student population and growing at an incredibly rapid rate in its five years, ECOT approaches each school year as a work-in-progress, tweaking the system to better serve the changing needs of its online student population.

IQ Academies

The Waukesha IQ Academies (IQ) was the first virtual high school in the state of Wisconsin, opening its doors Sept. 1, 2004. Wisconsin's open enrollment laws require students wishing to attend a school district other than their home district to apply to those districts during a three-week window in February of each year. While a student has until Aug. 31 to decide if he/she will attend another district, if the student does not apply in February, the opportunity to enroll somewhere other than the home district is lost (Wisconsin Department of Public Instruction, 2005). Last year, the IQ, a public charter school affiliated with the 13,000-student Waukesha School District (Waukesha School District, 2004) located 20 miles west of Milwaukee, had nearly 500 students apply during the open enrollment process, with 220 enrolling by Sept. 1. In February 2005, IQ accepted more than 1,000 applications for open enrollment and anticipated its actual enrollment to be 600 students on Sept. 1, 2005 (K. Diener, personal communication, April 14, 2005).

IQ was created to better meet the needs of students that, for a variety of reasons, did not believe their needs were being adequately addressed. Students requiring an alternative education, traveling the United States, or who were traditionally homeschooled, did not have an educational system

Developing Staff Training in Virtual High Schools

that was working for them. The Waukesha School District recognized these needs, and in less than 10 months, energized its resources to put into place a complete online virtual high school.

Because of its affiliation with an existing school district and an agreement with the Waukesha Teachers Association Union, all IQ teachers are employees of the Waukesha School District and most continue to teach in the classroom in addition to their online work. In its first year, IQ had one full-time instructor and 27 part-time teachers, teaching as little as 1/12th of their instructional time in the online environment. Each instructor received a computer, but was not given Internet access, under the assumption that most instructors continued to teach in a district building with Internet access. It is hoped that with the increased enrollment projections, at least five to six teachers can be hired full-time for IQ, allowing the online teaching faculty to dedicate more of their time to their online responsibilities. As could probably be expected, in some cases, it was believed that in-person classroom needs consistently trumped online classroom needs, frustrating both student and staff. More full-time online staff will help address the challenge of trying to wear both hats as an online and in-person instructor.

Distance Training and Education Efforts for Faculty

Neither IQ nor ECOT fit cleanly into any one of Schreiber's (1998) stages of technological maturity that indicate an organization's readiness to successfully implement distance training and learning (see Appendix A). Due to the nature of their business, both schools met the stage two requirement, having the necessary infrastructure and technological capability to delivery online education and training. IQ may fall a little short because of the decision to not provide home Internet access to its staff. Nonetheless, all teachers still had access either at home or at school. Furthermore, IQ's full-time staff of two (principal

and secretary) simply cannot be expected to train, develop procedures, and evaluate the needs of its staff, which are also stage two expectations. Hopefully as it grows in size and resources, IQ can transition from a stage one school, providing separate and sporadic learning events, to an organization that is more established and consistent in its training efforts.

ECOT's size and experience allow it to meet more of the stage two requirements, including approaching distance education and training with a more interdisciplinary team and maintaining adaptability and flexibility in its course offerings. By establishing a mentoring program and its formation of a partnership with the University of North Florida to develop research-based, online faculty training solutions, ECOT approaches stage three but has yet to fully commit and embrace distance training of its staff as a core belief and philosophy.

Staff Development Efforts

Ironically, for staff development, both IQ and ECOT use on-the-ground instruction as their primary mode of delivery. The fact that both virtual high schools maintain in-person education and training for most, if not all, of their staff development may not be as much of a contradiction to their focus on online education as it first seems. Rather, a mixed-mode delivery of online and in-person professional development recognizes that each school must first build a learning community among its staff members, most of whom have been trained in a in-person environment, before engaging students in their respective online communities. While not taking advantage of some of the online efficiencies, it seems both institutions are most comfortable with a blended model of professional development delivery.

IQ offered one week of primary instruction to all faculty members before its inaugural school year, and, because all teachers currently or formerly taught in the district, it was not difficult

to arrange such in-person training. The training consisted of four parts:

- Exploring online teaching and how it compares with in-person teaching
- A mini-course simulation
- Technical skills training
- How to effectively communicate with the online student.

Because most of the course content is provided for the instructor, the training was focused on the supplemental, but very important, aspects of a course, such as classroom management, facilitating discussion, course expectations, and school policies. With more full-time staff projected for future school years, it is hoped that IQ can at least begin to have virtual faculty meetings as a first step in the distance training process.

ECOT has an established system of in-person training four times a year, lasting for two to three days, and held at various locations around the state. ECOT takes advantage of this opportunity to also hold parent-teacher conferences for students in that particular geographic section. ECOT's in-person sessions may include some technical skills training on new products or features but more often includes training on school initiatives, such as competencies and state test scores. Because state test scores are extremely public figures and are oftentimes the measure of a school's success (or failure) in the eye of John Q. Public, it is not uncommon for new charter schools and traditional brick-and-mortar schools alike to place great emphasis on achieving higher test scores. Because the state test is not yet online and must be proctored, the challenges presented in the coordination of a state standardized test at an online high school are incredible, doubling the need for all staff members' active participation at testing time.

Feedback for Staff Development

ECOT also has established an effective system for collecting feedback on training needs, incorporating suggested education and training opportunities into their quarterly meeting. This supports one of Rosenberg's (2001) five areas of transformation, when describing the new era of training and instruction, the ability to move training from cycle time to real time. Historically, training has taken some time to cycle from concept to delivery; but today, real-time turnaround is necessary and critical. ECOT's ability to turnaround its training needs from one quarter to the next demonstrates real-time training and instruction to its faculty members.

VIRTUAL I.D.E.A.L.

The Virtual I.D.E.A.L. (IDEAL) school does not exist. It serves here as a model to point toward considerations that need to be made when managing a virtual high school. IDEAL was established five years ago. It maintains manageable growth, its students test high on the required state exams, its staff is well-qualified, and its distance education and training program would be described by Schreiber (1998) as beyond stage four. The IDEAL school is just that, yet it somehow strives to be more. What makes its distance education and training program the best? Its practices are based on research, experience, self-reflection, and successful partnerships with industry experts.

A Strong Beginning

A well-trained staff is critical for sustaining IDEAL's programs and to meet the needs of students. Training staff at IDEAL begins with a structured program for beginning distance in-

structors, following many of the topics identified in IQ's training. The difference between the two is that IDEAL takes advantage of the particular strengths of in-person and online instruction. Rosenberg (2001) notes, "With all the potential of e-learning, it might be easy to dismiss traditional classroom training as completely antiquated—of no value down the road. Although e-learning has a great deal to contribute, it does not mean the end of a classroom learning" (p.120). Similar in concept to ECOT, the IDEAL school gives all incoming staff an assessment to determine the level of individual technical and instructional skills. Tobin (2004) cites ever-changing teacher competencies to justify the need for the development of competencies for online teachers as well as continuing professional preparation and training for online teachers. This assessment is based on the Educational Technology Standards and Performance Indicators established for all teachers by the International Society for Technology Education (ISTE, n.d.). ISTE identifies six areas of focus:

1. Technology operations and concepts
2. Planning and designing learning environments and experiences
3. Teaching, learning, and the curriculum
4. Assessment and evaluation
5. Productivity and professional practice
6. Social, ethical, legal, and human issues.

Because of its virtual nature, special emphasis is placed on needed technical skills, and any technical remediation is completed before the first week of distance training. In addition to the preweek assessment and technical training, new instructors also are required to complete online learning objects that introduces available administrative and support services, tutorials on copyright and policy issues, and an exploration unit on the components of a successful online course. IDEAL also uses its preweek session to have the instructors introduce themselves, de-

scribe their background, and share some of their personal interests. Completing these components online before the actual in-person session demands preparation, encourages camaraderie, and builds skill development, similar to what the instructors will soon be expecting from their students.

Finally, the week of training arrives and sessions are presented on the following items:

- Distance learning technology and its impact on learners
- How distance instruction ties in with the institutional mission
- Fundamentals of and assistance with course development and adaptation
- Techniques for encouraging interaction
- Development of back up and contingency plans
- An opportunity for addressing concerns (Clay, 1999).

Each session builds upon the previous and adequately connects the school's mission and vision with the online classroom teacher's responsibilities and expectations. One unique way that IDEAL uses to insure this connection is made by its new teachers is through formative and summative assessments. Instructors are quizzed and must complete practice exercises demonstrating formative, or short-term, learning. Instructors also must demonstrate summative learning, evaluated by how effectively they are able to implement training topics into their own virtual classroom, measured by a three-month, six-month, and nine-month classroom "visit and evaluation." To help insure their success, trainers teaching the introductory sessions to new teachers can earn financial incentives based on their students' ability to connect session training with students' classroom learning. Success in the classroom is evaluated by the administrators' ability to quantify interactivity, learning, and growing, something that remains quite a challenge in an online school. Sunal, Sunal, Odell, and Sundberg,

(2003) offer a Checklist for Online Interactive Learning (COIL), which centers on four main topics: student behavior, faculty-student interaction, technology support, and the completeness of the learning environment. Classroom teachers at IDEAL appreciate such an assessment because it is research based and can provide data to support both successes and future opportunities in their virtual classrooms.

The successful integration of online training and in-person training reinforces Rosenberg's (2001) other indicators necessary to transform distance training and instruction. Using online training both as a precursor to live instruction and as a follow up to classroom training deftly blends the strengths of the two modes of instruction. Holding the trainers accountable for their instruction and subsequently holding the instructors accountable for implementing what they have learned, encourages all participants to make the connection between training and performance. And, finally, by maintaining online materials, information can remain current and accessible when needed (e-Learning, pp.7-8).

Variety

As IDEAL's training program moves beyond the first weeks, variety becomes an integral part of its continued success. Just as teachers need to find ways to reach students of all learning styles, distance training programs need a variety of opportunities for learners with varying styles and preferences. Clay (1999) advocates for online programs that include mentoring, group sessions, one-on-one labs, printed materials, listservs, regular discussion sessions, and observation of others' courses. Not only does the variety address the needs of different learning style, but most of the learning options allow educators the opportunity to explore skills and technologies they could ultimately use in their classroom as part of their own instruction. Clay acknowledges the reinforcement of skills as valuable by noting

that "experience shows that training simply won't 'take hold' unless support is ongoing, with job-embedded opportunities for practice" (1999).

Knowledge Management

Rosenberg (2001) describes online training that is supported by expert modeling and stories, learning from others' mistakes, and having the opportunity to reuse information after learning. The reuse of information refers to knowledge management, and, once again, IDEAL is at the forefront of the virtual training field. Where as training and instruction is focused on specific learning outcomes, is sequenced for memory retention, and may contain presentation, practice, feedback, and assessment components, knowledge management focuses on the organization of content, is sequenced for optimum reference, and is centered primarily on effective presentation (Rosenberg, 2001). IDEAL's knowledge management archives contain many how-to's, alternative instruction and assessment strategies, and many tutorials on school and student policies and procedures. The database is easy to search and tracks hits on various information modules, to help identify future training and instruction opportunities.

Identifying and Assessing Needs

IDEAL's ability to use data from the knowledge management archives is vital to the proper identification of future training needs. While feedback and user input is another valuable collection tool, the data provides not only a basis from which to start, but also a means to measure progress over time to determine the success of training and instruction efforts. The power of data in sustaining distance training efforts cannot be overstated. Data can justify a major investment in new software or additional support expenses. In IDEAL's case, data can be used to demonstrate competency and achievement of individual or school goals,

and it also can be used to challenge both staff and students to raise the bar higher in all forms of instruction and learning. Identifying and assessing needs for distance training is an important aspect of Rosenberg's (2001) learning architecture and the IDEAL's continued success.

Variety of Teaching Methods

IDEAL's successful preweek assessments, remediation, and topical learning objects, combined with its week of in-person instruction, added to its extensive knowledge management database, and integrated into a system that stresses accountability, data-driven decisions, and constantly assessing learning and training needs, allows its well-trained staff to focus its distance education and training efforts on larger, school-wide initiatives. No longer are instructors learning how to make templates in Microsoft Word, but instead are using discussion board software to consider how to improve literacy, create common assessments, improve communication channels with parents and students, and how to align curriculum to state and national standards. In another chat room instructors are brainstorming at how to integrate more team-building exercises into the curriculum, while others are comparing classroom statistics to identify instructor strengths and areas for improvement. IDEAL is able to remain at the forefront of distance education and training through its continued creative use of online learning tools and its desire to tackle challenging issues facing most high schools today.

Barrier to Sustaining Distance Education

Cho and Berge (2002) identify 10 barrier clusters to establishing successful distance education and training programs:

1. Technical expertise
2. Administrative structure

3. Evaluation/effectiveness
4. Organizational change
5. Social interaction and quality
6. Student support services
7. Threatened by technology
8. Access
9. Faculty compensation and time
10. Legal issues

Ohio's ECOT seems to have already addressed many of these barriers. Through its preassessment, technical training, and quality internal support, its teachers are technically competent and can adapt to new technologies. It has provided a computer and high-speed Internet access for its staff members and pays its faculty well compared to brick-and-mortar institutions. ECOT's quarterly meetings encourage social interaction and community, and its willingness to accept feedback and evaluation helps include all staff in the development of the training process. ECOT's needs seem to revolve around an integrated learning architecture and a more substantial investment in online training opportunities for its staff. Like most schools, it struggles with implementing accountability and successfully managing the rapid growth of its student and teaching populations. While it has already started initiatives concerning competencies and state test scores, better use of its online resources will allow it to reach a new level of success when addressing organizational issues and goals.

Wisconsin's IQ has taken the first step towards sustaining distance education and training just by entering the virtual high school arena, yet there is certainly room for improvement. Faced with a small administrative staff, limited student support services, less provisions for faculty access, and no unique compensation packages, the challenges ahead of IQ are formidable but not impossible. As enrollment increases, more full-time teaching and administrative staff will generate increased opportunities for online collaboration and the development of a knowledge management sys-

tem. Two more years of experience will solidify its new instructor training initiative and perhaps lead to a preassessment to determine both teaching and technical skills. Increased administrative support may allow for more detailed assessment of classroom instruction and measurable student learning. The key to IQ's future success is continued growth and constant evaluation of the support services and offering instructional opportunities to its teaching faculty.

CONCLUSION

The IDEAL school focuses on the future. While it may be impossible for any one school or district to achieve the comprehensive success of the distance education and training efforts modeled by IDEAL, various components and strategies are attainable and can be matched in terms of quality and sustainability. The IDEAL school may best serve as a reminder that a school's commitment to its teaching staff is constant and unending, and consistent and determined effort is required year in and year out.

These three virtual schools are each at different stages of maturity. Successful and sustained distance education and training for all three schools revolves around continued growth, organizational commitment, quality resources and instruction, and measures of accountability. Not surprisingly, these factors are really not much different than the standards of success identified by brick and mortar institutions. By examining the current status of staff training that exists in a virtual high school and planning the direction a model program should have, school administrators can better plan to close the gap, while overcoming common barriers and identifying staff development needs.

Chapter 2.50

A Model for Effectively Integrating Technology Across the Curriculum: A Three-Step Staff Development Program for Transforming Practice

John Graham

Robert Morris University, USA

George W. Semich

Robert Morris University, USA

ABSTRACT

Technology training for college faculty has become an important part of the mission of colleges and universities today. Funding is allocated toward not only purchasing new technologies but also training faculty to use these technologies with their students in the classroom to better prepare them for the information workplace. Our interest at Robert Morris University was to develop a sequential staff development model that would not only help train faculty, but also help them apply and eventually integrate technology with their students across all of the academic disciplines. This model looks at three key phases of staff development: the training phase, the application or use phase,

and the final phase of integration that involves a transformation from the teacher-centered to the learner centered classroom.

INTRODUCTION

Today, nearly everyone at the university level, from chief information officers, deans, department heads, technology directors, and faculty, is committed to preparing students who can compete technologically in this fast-paced competitive work environment. Simultaneously, university budgets are bulging with technology requests, state and national standards are requiring higher levels of technology competence, and teaching

via technology is being heralded as a valuable instructional tool at all levels of the educational spectrum. Wiske (2004) advocates the use of a pedagogical framework that provides criteria for productively using technologies for deepening understanding, while the International Society for Technology Standards, through its National Educational Technology Standards (NETS) project (Thomas, 2004) is providing educational leaders with guidance in developing national standards for technology. Yes, effective use of technology is being considered a 21st century skill, just as important as communications, problem solving, and effective decision making.

One approach to meeting this demand is to simply teach for equipment and product usage, thus requiring courses focused on attainment of specific technology core standards of achievement. However, perhaps a more generalist and surely beneficial approach is to effectively integrate technology throughout the instructional process, thereby, exposing students to proper technology use while concurrently improving the learning process. Easier said than done! At Robert Morris University, although some courses have been developed to meet specialized technology course requirements, the primary goal is to effectively integrate technology across the curriculum. In order for successful technology integration to occur, however, there needs to be a strong link between content and delivery and that the use of technology will be most effective when technology use is based on sound instructional theory.

PROBLEM STATEMENT

With the aforementioned to set the stage, data was gathered about the use of technology by faculty and students before formulating a staff development model which faculty can use to effectively integrate technology across the curriculum. Given the importance of technology in teaching and learning, the primary question to be answered was:

How can this institution initiate a staff development program that can help faculty move from training, to use or application, and finally to the integration of technology to transform practice?

BACKGROUND

In recognizing the importance of technology, Robert Morris University (RMU) has provided state-of-the-art presentation classrooms. Teachers have access to an LCD projector, a computer, and a VCR for instructional purposes. Many of the classrooms, however, have additional resources including a smart cart, a touch screen, a document camera, cabling for a laptop, and a recording device. The RMU goal is to use technology to enhance the learning environment so that it is participative, customized, and student centered.

An academic technology committee is also in place and consists of representatives from both the administrative and support staff of the university as well as faculty from each of the six schools. A full-time faculty member, who is also on the committee, serves as the director of instructional technology. While the director works more closely with faculty on an individual basis, the committee, on the other hand, reviews concerns of the faculty/staff, initiates new directives, oversees the technology planning process, monitors the budget, and sets short- and long-range technology goals for the university.

THE TECHNOLOGY SURVEY

During the 2001-2002 academic years, RMU designed a survey instrument to measure the degree of technology usage at RMU for a wide array of pedagogical tools. Particularly, the instrument helped to determine the faculty and student usage across all programs at the university. Five basic categories of technology usage were surveyed: Internet/Web-based activities, PowerPoint, mul-

timedia classroom technology, electronic library searches, and technology integration. These categories were chosen as they were indicative of the variety of technologies and facilities that faculty and students can access at RMU. The survey results ultimately guided the university in planning for the ongoing integration of technology for instructional purposes.

Full-time faculty was asked to complete the surveys based on how technology is used in their courses; that is, both technology used by the faculty and required of the students. Furthermore, faculty was asked to forecast the types of technologies they would be using three years ahead to fall 2004. It was not surprising to learn that faculty anticipated using technologies in Internet/Web-based activities, PowerPoint, multimedia classroom technology, and electronic library searches in 70% or more of the sections taught. The results of the technology integration were not so positive. Table 1 shows the percentage of sections by department in which faculty expected to integrate technology by fall 2004.

Based on these findings and supported by our need to have faculty effectively integrate technology into their specialized curriculums, a three phase technology model was designed that would encourage faculty to work toward true integration of technology into the classroom by transforming

the classroom into a student-centered, technology supported learning environment.

DEVELOPMENT OF THE MODEL

Our first step, however, was to review the related literature on the subjects of technology training, technology use, and technology integration as they relate to staff development for faculty. It was important in the development of an applied model to emphasize three separate sequential phases critical to effective technology implementation and enhanced student learning. Combining these three phases into one generic staff program also seemed to us to be far more chaotic and probably much less residual in terms of successful classroom application since each phase requires a sequential level of competency to develop self confidence and fluidity with faculty. Thus, the suggested model of staff development included these three distinct phases: the training phase, the use or application phase, and the integration phase. However, as with many colleges and universities, the transition to the third phase of technology integration not only requires faculty to learn how to apply technology but also how to change the classroom into a learning center that promotes student application of technology. In short, this dramatic third phase presents the great-

Table 1. Technology integration

Department	Percentage of Sections
Communications	50%
Computer Information Systems	95%
Education and Social Sciences	47%
Marketing and Management	44%
Accounting	20%
Finance and Economics	13%
Science	43%
Mathematics	50%
Engineering	75%

A Model for Effectively Integrating Technology Across the Curriculum

est challenge since it embraces both philosophic and operational changes in teaching.

In a major study by the U.S. Congress' Office of Technology Assessment (1995), it was noted that a lack of teacher training is one of the greatest roadblocks to integrating technology into the curriculum. Thus, the first phase of the model was the training phase, which was a very basic approach to demonstrate to faculty how to operate the instructional technologies. The director of technology implemented small group training sessions in each academic school at the university. These sessions emphasized the step-by-step operations of the technology with numerous opportunities for individual faculty to experience direct hands on training. The sessions also highlighted the special features of the technology as a powerful teaching tool. To illustrate, most of the classrooms have a Crestron Controller Unit with a computer, projection system, recording and playback VCRs, tape recorder/player, document camera, and rear mount recording camera. Shifting through these various modes and demonstrating multiple and single operations of each piece of equipment gave faculty the heighten incentive to move to our second phase of using the new technologies. Since it was also suggested in the research (Shelton & Jones, 1996) that the training should occur outside the school day to remove additional responsibilities of teaching and/or advising students, the university provided training sessions later in the day. Finally, in this first phase the training sessions focused on the individual differences and specific strengths of participants, which help faculty to personalize the technology training. This aspect of teaching technology according to individual strengths and weaknesses is well supported by the research (Boe, 1989; Browne & Ritchie, 1991; Shelton & Jones, 1996). A lack of confidence and feeling uncomfortable with learning new technologies as suggested by Rosen and Wail (1995) might prevent the faculty from eventually using it.

In the second phase, the faculty actually used the new technology. This meant that much of their

technology use would be extensions or modifications of the teaching methods they presently practice. For example, those who were traditionally using the chalkboard or whiteboard would shift to using PowerPoint slides to deliver classroom notes. Essentially, state of the art equipment, including LCD projectors, computers, the Internet, VCRs, document cameras, and so on would replace older technology such as overhead projectors, flipcharts, paper handouts, and so on. This was the most logical transition since it supported using the new technologies from Phase I, and yet it allowed faculty to utilize familiar teaching methods. The primary goal in the model was to have faculty see the value of training and applying technologies to update and upgrade their present teaching approaches in the classroom. The added benefit of working with new technologies as a means of motivating students might renew their interest in delivering the course curriculum. Hardy (1998) reviewed existing studies on teacher attitudes to develop a profile of technology used by teachers and concluded that access to equipment, administrative support, and time did not have the impact that the teacher's own confidence level would have in really using technology. Thus, in this second phase, the faculty would apply the technology training they received to their own pedagogical teaching methods, and then move toward the goal of integrating technology and transforming the classroom from a teacher-centered to student-centered learning environment.

The third and final phase of the model, the integration phase, includes a systematic plan for staff development, as supported by Stager (1995), which places the teacher/student at the center of the learning experience and provides a meaningful background for learning. This phase is more of a transformation of traditional teaching since it requires a shift in roles placing primary emphasis on the learner. Honey and Spielvogel (1999), profess that this transformation changes the classroom in that it defines new teacher roles and heightens student interaction. The student

becomes the central focus in the classroom. The teacher assumes the role of coach or facilitator while students work in teams collaboratively (Jones, Valdez, Nowakowski, & Rasmussen, 1995; Kupperstein, Gentile, & Zwier, 1999). It is possible that this new role may even involve connecting with other schools perhaps in various locations around the world. It is as Bransford, Brown, and Cocking (1999) suggested that technology could support learning in five ways (p. 195):

- To bring exciting curricula into the classroom that is based on real-world problems and that involves students in finding their own problems, testing ideas, receiving feedback, and working collaboratively with other students or practitioners beyond the school classroom.
- To provide tools and scaffolds that enhance learning, support thinking and problems solving, model activities and guide practice, represent data in different ways, and are part of a coherent and systematic educational approach.
- To give students and teachers more opportunities for feedback, reflection, and revision, including those where students evaluate the quality of their own thinking and products, have opportunities to interact with working scientists, receive feedback from multiple sources which include their peers, and experience cognitive tutors and coaching in areas where improvement is needed.
- To build local and global communities that are inclusive of teachers, administrators, parents, students, practicing scientists, and other interested community people, expanding the learning environment beyond the school walls.
- To expand opportunities for teacher learning that includes helping teachers to think differently about learners and learning, to reduce the barriers between students and teachers as learners, to create new partner-

ships among students and parents, and to expand communities of learners that support ongoing communication and professional development of teachers.

Faculty must also begin modeling the technology themselves by implementing technologies like presentation software, online discussions, databases, spreadsheets, and smart boards (Duhaney, 2001; Schrum & Dehoney, 1998). This serves to motivate students to learn and use technologies and provides opportunities for both faculty and students to share new ideas relative to technology application within the learning process. Initially, faculty use of word processing programs and other software programs were sufficient, but they are no longer considered the only indicator of technology integration (Wetzel, Zambo, & Buss, 1996; Yidrim, 2000). In short, faculty needs to not only become adept at integrating technology in the classroom, they subsequently need to have students take control of using the new technologies to enhance learning.

THE MODEL AT RMU

The model consists of three stages or phases that are all inclusive of a comprehensive technology based staff development program.

Training → Using → Integrating (**TUI**)

As detailed in the preceding development section of this paper, the main goal was to move faculty quickly beyond the first two phases into the final, most critical, phase of technology integration in the classroom. Johnson and Liu (2000) noted, "Everybody is talking about technology integration, but few practicing teachers profess to know exactly how to proceed." They don't know how to proceed because the new technology presents a new challenge not only in how to use it, but also in how to work with students to truly

A Model for Effectively Integrating Technology Across the Curriculum

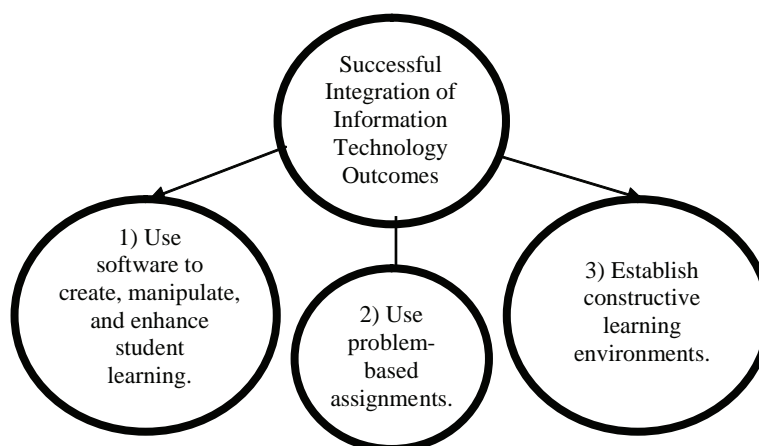

integrate technology into human learning. In this proposed model, the goal was to give the faculty in all the academic disciplines the opportunity to advance to this level.

The starting point for the integration phase was to shift from an instructional group and individualized mode to a learning/sharing model or learning community model. Faculty across the academic disciplines who were integrating technology and modeling learner-centered classroom scenarios would assist in working with other faculty who had worked through the first two phases of the model in their classrooms — the training and use phases. Duhaney (2001) emphasized that it is an important step for instructors to model technology applications such as software, online discussions, databases, spreadsheets, smart boards, and so on. This practice will encourage students to use the new technologies in their class work and in the construction of products for class assignments. Hence, “pedagogical design experts” and facilitators of learning were identified, whom Fullen (2000) argued are needed to change or transform existing teacher roles in the classroom. Faculty across the academic disciplines were integrating technology in ways that students were both learning and integrating technology. The current research (Bitner & Bitner, 2002; Guha, 2003;

Hruskocy, Cennamo, Ertmer, & Johnson, 2000; Mouza, 2002; Schmid, Fesmire, & Lisner, 2001; Walsh & Vannatta, 2001) also stresses support systems that involve technicians, administrators, and peers working together to assist in preparing faculty to successfully integrate technology into their academic disciplines. The task can be overwhelming for faculty since it requires learning new skills and transforming the traditional model of the teacher-centered classroom into a student or learner-centered classroom that promotes integrating technology to better enhance learning. One very useful technology integration model considered was John and Liu’s (2000) model of technology integration (see Figure 1). This model placed emphasis on student-centered learning in the classroom. The Johnson and Liu model was especially helpful since it was based on a National Educational Standards (NETS) program in the state of Florida and focused on how students used technology for productivity in the classroom. This was their critical first step toward successful transformation of teaching and learning.

The Johnson and Liu model, which exemplified the principles of constructivist education, defined integration for the third phase of the staff development model. Their study included student use of the National Educational Technology Standards

Figure 1. Johnson and Liu integration model

(NETS) and focused on how these students were productive by applying technology creatively to complete projects in the public school classroom. The goal was to apply this constructivist model at the university. Given the fact that many of the faculty had reached competency at the first two phases, it seemed logical to assume that they would embrace the idea of expanding their learning set and would consider applying new and innovative ways of applying technology, including placing special emphasis on student use of the technology in the classroom.

The starting point was to identify faculty who were presently functioning in the third phase and subsequently involve them in helping to work with their teaching colleagues. This faculty group would offer the support system that Zhao (2002) noted as a strong factor for innovative computer integration activities in the classroom. It was also important to have the technology director and technology savvy administrators be a part of this team, which is supported by much of the current research (Schmid et al., 2001). This team approach in the third phase offered faculty a cooperative learning model that fostered a learning community for technology integration. The following section includes examples that demonstrate this faculty driven, learning community approach.

LEARNING COMMUNITY APPROACH EXAMPLES

A faculty member from the CIS department demonstrated how to use Web Surveyor, a user-friendly, online survey research tool that facilitates the development of surveys, the collection of data, and the generation of reports. It was particularly useful for both faculty and students who are engaged in the research process. Since Robert Morris has recently placed added emphasis on scholarship, this should provide a valuable service to faculty who may in turn apply these software techniques in their classrooms.

A business faculty member demonstrated SPSS software for the applied use of statistical applications for both faculty scholarship and for use with student research work. This session also provided opportunities for extended software use and continued individualized support for interested faculty.

A communications faculty member demonstrated using online resources that could be used in the classroom. One of the featured sites was MERLOT, which provided a wide range of technology-applied topics designed primarily for faculty and students. These learning materials covered the arts, humanities, math/statistics, social sciences, education, and technology/science, which connected with all of the academic disciplines.

A business teacher education faculty member demonstrated MS Excel for grade book application. Many faculty members wanted to learn how to create a vertical lookup table for translating numerical grades into letter grades. This session had heightened benefit for all faculty interested in moving from the paper grade book to the electronic grade book.

STATUS OF THE INTEGRATION PHASE AT RMU

The integration phase of the model has, in effect, started to evolve over the past year. Presently, our newly hired dean of academic services is overseeing technology at the university and organizing separate technology committees for each of our six schools (business, communication and information systems, education, nursing, engineering, and adult continuing education). These committees will study ways the schools might better integrate technology within the respective disciplines. In turn, faculty and/or administrators from these committees will represent the schools at the university-wide technology committee, where all academic disciplines interact. The implementation

of these committees is sequential and collaborative in nature. Further, it is a cross-disciplinary approach that gives both variety to content and creativity in methods using modeling and mentoring to replace instruction and demonstration.

As previously noted, this third step of integration is in the infancy phase at Robert Morris University. It is a move toward making the technology meaningful in terms of both instructor delivery and student application. Further, it supports collaborative teaching and learning since faculty from across the disciplines share technology integration methods.

SUMMARY

The three steps to this model provide better opportunities for mastery at the various levels of learning. They are designed to establish competency at each phase of the process. Frankly, there are classrooms where teachers may have ideas about integrating technology but lack the technical training and pedagogical expertise to carry through with the lesson in an effective and efficient manner. By using a sequential staff development program, faculty will have the proper preparation and interest to pursue a more integrative approach of the technologies. Since each school and each academic discipline would have involvement, it would promote both intra and inter-departmental integration sharing sessions.

Ideally, this model might evolve into a type of specialized model such as writing across the academic disciplines where various methods, techniques, and approaches are shared across the disciplines. Furthermore, faculty could enter the staff development program at any of three phases depending on their level of competence. This is probably the most important aspect of this proposed staff training program since faculty have such varying levels of competence and interest in technology application. Integration of technology is the desired goal, but faculty needs to

move through the necessary steps to reach this level. Thus, it is believed that this model will significantly improve a faculty member's chances of successfully integrating technology across the curriculum in a way that will provide richer, more rewarding learning experiences for students.

Chapter 2.51

Putting Enterprise Systems in a Larger ICT Context: A Pedagogical Framework

Thomas Rienzo

Western Michigan University, USA

J. Michael Tarn

Western Michigan University, USA

James Danenburg

Western Michigan University, USA

ABSTRACT

Many business schools are attempting to integrate their curricula with enterprise software, particularly enterprise resource planning (ERP) software. Although the introduction of ERP into the undergraduate academic curriculum offers students a potentially deeper understanding of business processes, it cannot by itself provide for students a connection between the adoption of robust information systems and a paradigm shift in the way that business organizations operate in a global, information-centric environment. Connecting a new global economy with enterprise systems requires a course much broader than ERP that places enterprise systems in a much larger information-communication technology (ICT)

context. This chapter presents a teaching model that provides that context, emphasizing the critical role of systems components and relationships, the central function of information in problem solving, and business perspectives of information from infrastructure to applications.

INTRODUCTION

Technology has consistently been applied to the education process, with differing levels of success. In many areas, real-world technology applications are being used in teaching, including applications like CAD/CAM software, simulation languages, and enterprise resource planning (ERP) software packages. Industrial trends in IT have been moving

from traditional models with disconnected applications to complex integrated models involving enterprise systems (ES). Changes in industrial practice have prompted changes in business information technology education resulting in a potpourri of teaching and learning methods, but academic institutions are increasingly focusing on enterprise software as a means of integrating curricula (Hejazi, Halpin, & Biggs, 2003; Johnson, Lorents, Morgan, & Ozmun, 2004; Markulis, Howe, & Strang, 2005; Michaelsen, Hobbs, & Stead, 2000). Joseph and George (2002, p. 51) suggest that ERP software can bring about more effective pedagogy in higher education enabling deeper understanding of course materials and a clearer vision of interlinked aspects of business activity. Practical experience with ERP software may help students appreciate related business processes, but the effects of the global information infrastructure extends far beyond integrated business software. Training with ERP and customer relationship management (CRM) systems do not communicate the economic, political, and social revolutions spawned by world-wide telecommunications, robust wide area networks, prolific and effectual hardware and software, and the incredible power of the Internet to connect everything to everything. Students should appreciate the paradigm shifts occurring in the way people live and work, which are every bit as liberating and tumultuous as the shifts that were initiated by the invention of printing in the 15th century and the industrial revolution in the 18th century. In this chapter, a high-level framework is presented to incorporate enterprise systems in a larger picture of evolving and adaptive organizational structures, and the business processes that enable them. The authors present a pedagogical model that links enterprise systems to information and communication tools, an understanding of systems, and the role of information in problem solving.

CONNECTING BUSINESS PROCESSES

Businesses judge their performance by outcomes produced by entire business systems, not individual components. While control and optimization of integrated business processes have been goals of business managers since the Industrial Revolution, tools *capable* of complex control and optimization of diverse business functions developed only recently. Prior to about 1990, little attempt was made to integrate large scope business activities because:

- Computer processing capabilities were limited.
- Computer hardware and software were costly.
- Specialized business activities needed customized software code created from scratch.
- Robust computer networks did not exist.

The 1990s was a watershed decade. It produced:

- Robust computer networks
- Greatly enhanced computing power
- The World Wide Web
- Expanded multi-nationalism and globalization

Businesses first encountered software capable of connecting the enterprise during the 1990s, and many were compelled to move forward with enterprise computer systems because they did not trust the ability of the information islands created by their computer legacy systems to be able to cope with the year 2000. There is no doubt that enterprise software is changing the face of business. Manufacturing companies who have

been under siege from “the China Price” are using enterprise software to improve productivity an astounding 4% *per year* since 1994 (Frichol, 2004). The top 100 SCM vendors generated about \$4 billion in supply chain application revenue in 2002. The Yankee Group estimates that supply-chain integration reduced total cost of ownership of value-added networks by about 15%. Forrester Research expects U.S. firms will spend an average of \$4.8 billion a year through 2008 to tune their entire supply network processes. International Data Corp estimates that the U.S. market size for CRM applications was about \$5.6 billion in 2002 with projections of \$10 billion by 2006. Giga Information Group approximates sales of core ERP software at \$13 billion, and it predicts growth of 4.8% annually through 2006 (Targowski & Rienzo, 2004). American business schools must address enterprise software to stay relevant to current business practice.

Enterprise systems should be taught as a discipline because corporate emphasis is currently focused on the enterprise. This emphasis will remain because there is great potential for wealth creation. Enterprise focus is a formidable undertaking, and tools and techniques required to truly integrate the enterprise are still developing. When learning about enterprise systems, students should develop an appreciation of the way businesses create and employ information, regardless of its source. And they should also develop an appreciation of the relationships that system components have to the larger whole.

Systems are infinite in their expansion and regression, and business managers responsible for systems must draw system boundaries in an appropriate scale and scope that affords them prediction, control, and performance needed to achieve their objectives. Business systems are engineered to accomplish a goal, and significant resources are employed to get them to work together smoothly. Business corporations have evolved into economic dominance through coordination of nearly-decomposable hierarchical

divisions and organizational identification (Simon, 2001). Nearly-decomposable systems maximize component independence and minimize the cost and effort of coordination and communication. Companies have separate, and nearly independent, departments optimizing sales, production, and logistics. Near-decomposability allows a corporate department to independently change many of its processes and procedures without concern for effects on other departments. As systems become more complex, nearly-decomposable architecture with its hierarchical subdivisions has been shown to be much more effective than architecture with less departmentalized interconnections. Simulations with genetic algorithms, have confirmed the dominance of near-decomposability in complex biological ecosystems (Simon, 2001). Near-decomposability can apply to any business system of activities. Once coordination and communication demands are minimized, the responsibility for the system can be assigned to any group that can accomplish the activities effectively. The phenomena of outsourcing and offshoring are direct consequences of near-decomposability.

As effective as nearly-decomposable systems are in business, they minimize rather than eliminate the need for coordination, communication, and control of different departments, divisions, or activities in a business. As the quality focus of the 1970s and 1980s demonstrated, there is wealth to be created, and competitive advantage to be gained, from coordination and communication of business component systems. Successful businesses ensure that the products obtained by the purchasing department perform well in production, and that accounting and sales personnel know when raw materials are in transit, production is scheduled, shipments are made, deliveries can be expected, and invoices issued. As business systems expand from individual to multiple companies, the demands of coordination, communication, and control intensify. If sufficiently robust methods of coordination, communication, and control exist, then nearly-decomposable ac-

tivities can occur wherever they can be carried out most efficiently. Enterprise systems provide those robust methods.

CURRENT STATE OF ENTERPRISE INFORMATION INSTRUCTION

Implementing a curriculum focused on the connections of enterprise systems as opposed to the more traditional management information systems approach can be very challenging and expensive. Many universities have undertaken the process by introducing enterprise or ERP business software packages into the classroom, focusing on hands-on exercises with gradually escalating requirements for student understanding of process activities and implications. Many universities recognize that direct enterprise software experience can be helpful to students, but utilizing software to provide students with an opportunity to learn business processes experientially is a challenging effort. Antonucci, Corbitt, Stewart, and Harris (2004) observed that some universities flourish in their implementation of enterprise or ERP business software packages and others flounder. Academic champions of enterprise software must struggle through the same exasperating climb up the ERP tower as their industrial counterparts. Holland and Light describe an industrial ERP maturity model (as cited in Antonucci et al., 2004) with three stages:

- **Stage 1:** Planning and implementation.
 - Stage 1 has an operational focus, concentrating on tasks and tracking. Planning should include a long-term strategic vision, but the vast majority of time and energy in phase 1 involves operational tasks.
- **Stage 2:** Adoption and utilization.
 - Stage 2 expands operational thinking to tactical use of real-time data spread throughout the enterprise to improve quality and efficiency.

- **Stage 3:** Strategic use of ERP.
 - Stage 3 takes a broad strategic focus involving all elements of the business supply chain. The ERP system is used to coordinate the business value chain and is often linked to other enterprise systems including Supply Chain Management and Customer Relationship Management software packages.

Academic institutions can expect to experience a similar journey of maturity with ERP implementations, progressing from operational tasks to strategic thinking and learning. Most are still at stage 1. Some universities have made significant progress in integrating enterprise or ERP business software packages courses in their curricula. Fedorowicz, Gelinas, Usoff, and Hachey (2004) provide a dozen tips to guide institutions of higher learning to integrate enterprise systems in their curricula in order to illustrate current best practices of business processes and expose students to technology they can expect to use in their business careers. They can be summarized as follows:

- Develop infrastructure.
- Train the converted.
 - Spend training money on those who will incorporate material and share information with other faculty.
- Start with concrete and develop more sophisticated learning.
- Build networks.
 - Within faculty, industry practitioners, ERP trainers and support people.
- Share information through academic alliances.
- Give students support.

Even though universities implementing ERP systems in their coursework can expect to move from less sophisticated to more sophisticated uses of the software, core coursework must provide a

larger framework under which the connections of enterprise software can be appreciated, and the capabilities of these systems can be seen as drivers for organizational transformation. Enterprise systems are not just making traditional business processes more efficient. They are contributing to the design and engineering of new processes. The impact of enterprise systems cannot be appreciated without recognizing organizational changes underway in the corporate world.

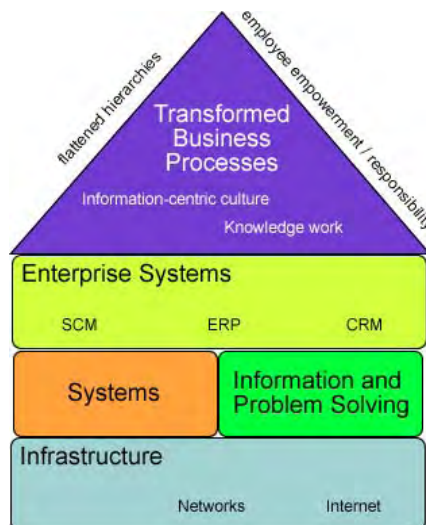

ENTERPRISE SYSTEM TEACHING MODEL

A model for enterprise teaching is shown in Figure 1. Infrastructure lays the foundation for enterprise system instruction. Students should receive a general overview of the components and tools of networks and the Internet, but a broad array of subjects can satisfy this requirement. Students cannot understand the connections of enterprise systems unless they recognize the technology systems that enable them. The unifying theme is *infrastructure*, lower level systems that allow

higher level ones to operate. Relating the familiar transportation infrastructure to components and relationships that form our modern information/communication infrastructure can be a useful analogy. Topics like telecommunications, LAN topology, network technologies, client-server systems, operating systems, programming languages, e-mail, electronic data interchange, and groupware prepare students to think about the roles of communication and information in modern businesses.

Following infrastructure, students should be introduced to generic business systems emphasizing the role components play in the larger business. General systems theory can be introduced to the students by explaining the characteristics of historic Cold War development of systems design and engineering. General systems understanding precedes the introduction of the systems life cycle and system development life cycle. Systems instruction is also an appropriate place to introduce organizational complexity and the increasing demands placed upon managers to balance the interests of shareholders and stakeholders in modern business. Information systems make it

Figure 1. Enterprise systems teaching model

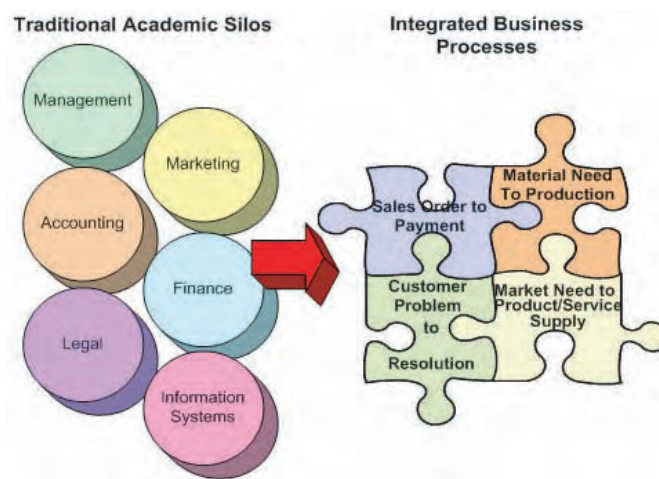

Putting Enterprise Systems in a Larger ICT Context

possible to cope with unprecedented demands to control and monitor many diverse aspects of business. An understanding of the role information plays in problem solving complements students' awareness of system components and relationships. Many business activities are problem solving activities. Students must understand that data can't solve problems but data is a critical starting point. Data must be analyzed, processed, and transformed into information, concepts, and knowledge in order to make prudent business decisions. Information systems play a critical role in process and analysis.

Infrastructure, systems, and problem solving prepare students for a discussion of enterprise systems that coordinate and integrate outputs from the many nearly-decomposable systems operating in business. By preceding the introduction of enterprise systems with the role of information and communication technology (ICT) in systems and problem solving, students can see enterprise software as part of business evolution. Enterprise systems can be seen as links in the business value chain. Supply chain management (SCM) links inbound logistics, operations, and outbound logistics. Customer relationship management (CRM) links outbound logistics, sales/marketing,

and service. Enterprise resource planning (ERP) links outputs of these systems as well as human resources, financial, and infrastructure support. Enterprise portals and electronic enterprises are included in enterprise systems discussions. The teaching focus involves moving from traditional business school discipline silos to integrated business processes as shown in Figure 2. Students should have an opportunity to work with enterprise software in class projects. Transformed business processes are the end result of enterprise systems. Paradigm shifts are occurring in business strategy, outsourcing, and substitution of technology for labor. Organization structures are experiencing flattened hierarchies, disintermediation, and networked alliances. Management is moving from task control to culture control with a pursuit of paradoxical goals. Knowledge is increasingly a source of wealth and knowledge workers are increasingly valued in the workplace. Information systems affect both our professional and personal lives with or without our knowledge or cooperation. The effects of the Information Age touch us all, and some of the changes in skill requirements, training, and attitudes occurring in modern workplaces are not comfortable.

Figure 2. Moving from academic silos to integrated business process

TEN LEARNING MODULES

Following the enterprise systems teaching model of Figure 1, a modern undergraduate business program can support the fundamental characteristics of presenting enterprise systems in a larger ICT context through the use of the following 10 learning modules:

Infrastructure

Network Infrastructure and Business Processes

An information infrastructure model is introduced with layers involving telecommunications, computer networks, the Internet, computer hardware/software, communication programs, and business application programs. Investments in telecommunications are described and different types of networks are discussed along with the role of servers and clients in those networks. Communication systems like e-mail, groupware, teleconferences, and electronic data interchange (EDI) are covered.

The Internet and its Business Applications

Internet technologies are introduced along with their history, governance, and protocols. Top-level domains of the World Wide Web are described. Languages of the Internet including HTTP, FTP, HTML, and XML are covered as are services like Internet search. Intranets and Extranets are introduced along with security concerns and network protection. Typical uses for each are presented. E-commerce and business models associated with e-commerce are described. Web services are described as heirs to e-commerce technologies pioneered by EDI. Architecture is modeled for e-commerce from a B2C and B2B perspective, and revenue associated with each is

discussed. Online payment systems are covered, as is public key infrastructure for secure on-line transactions. A short history of dot com companies is also provided. Students complete an Internet Services/E-Commerce project in which they compare service and commerce Web sites by specific criteria including ease of use, content/scope, privacy policies, customer service, and marketing techniques.

Systems

From Components to Business Process Integration

The systems perspective is introduced with general systems theory and a focus on components, relationships, and the role of components in a larger whole. A system definition is provided, expanded to information systems, and complexity of modern business systems is addressed. Information systems are presented as a means of coping with complexity. The system life cycle and system development life cycle are introduced with a brief history of system analysis and engineering. Quality management and project management are presented from a systems perspective. Students complete a systems project focusing on components and relationships of views relating to their majors. They create an input-process-output model of a company and examine critical perspectives for that particular business. Students calculate system complexity by calculating the number of pair-wise comparisons resulting from components they place in the views they believe are critical to their businesses.

Information and Problem Solving

From Data to Business Intelligence

The role of information in decision making is presented, exploring the way we move from data

to choices. Information richness and methods of problem solving are introduced. This module has a cognitive science focus and history. It looks at ways in which problem solving methods utilize traditional outputs of computer information systems, and more recent incorporation of artificial intelligence.

Transformed Business Processes

From Enterprise to Extended Corporation

Enterprise systems are introduced and connected to the business value chain introduced by Michael Porter (1985). Enterprise systems are presented as the glue of business activities from inbound logistics to customer service. They also impact Porter's support activities of procurement, technology, human resources, and infrastructure. Management information systems are introduced as well as their gradual evolution to knowledge management systems. Enterprise portals are presented as a gateway to the electronic enterprise controlled and optimized by supply chain management (SCM), customer relationship management (CRM), and enterprise resource planning (ERP) software systems. Enterprise software is also aligned with the Porter value chain.

Enterprise Systems Classification and Project

Characteristics of enterprise information systems are presented for accounting, human resources, marketing, legal, and operations. ERP components are categorized as business, operations, or management information systems and related to the Porter value chain. Students complete an exercise with ERP software working through an entire business process like purchase to payment or sales order to payment.

IT/Communication and Evolving Business Organizations

Shifts in business structure resulting from the control and optimization capabilities of integrated information systems are presented. Trends involving shifts in strategic resources, flattening hierarchies, network-centric work relationships, and virtual enterprises are addressed. Attendant changes in management responsibilities are described. The role of information in outsourcing and off-shoring is discussed, and knowledge workers are presented as a source of creating wealth.

IT for Business Transformation

The transformation of business from an industrial to an information mindset is explored. An industrial enterprise model is compared with an information enterprise model. The work system of the industrial model is focused on in-house standardization, hierarchical and task management, a disposable labor force, and separation of thinking and doing. The business organization is concerned with economies of scale and mass production. In contrast, the work system of the information model is focused on flexibility, immediacy, outsourcing, network and culture management, high trust relations, and the integration of thinking and doing. Its business organization involves economy of scope and mass customization.

Information: Past and Future

A historic look at information in society beginning with the invention of printing with movable type to the electronic global village of the 21st century is presented. This section deals with the movement from goods to services, increasing reliance on theoretical knowledge and creation of new "intellectual technology" based on computers and other smart machines. The "digital divide" which separates information "haves" from information "have nots" is discussed.

Social/Ethical Information Issues

The role of information in our culture is presented: values, life styles, security, privacy, cyber crime, and ethics. Global communication networks are both bringing the world together and driving it apart at the same time. Broadband and convergence are changing the way we work, shop, and entertain ourselves. Privacy and security are important issues in cyberspace with widespread information dissemination, protection of intellectual property rights, and identity theft. Ethics have new dimensions in the age of blogs and billions of pages on the World Wide Web. Information systems bring new problems from the standpoint of bioethics.

CONCLUSION

Enterprise systems provide an opportunity for students to experience the complexity of integrated business processes, but the complexity of business extends beyond the connections of enterprise systems. Technology provides new tools that permit businesses to re-engineer systems and relationships that offer new and exciting means of building wealth. Students must prepare to work in a global business environment that is continuously evolving, and they need a context to frame enterprise systems in new economic paradigms. As business students prepare to enter a connected world, they should do more than experience the technology that enables it. They should consider what technology means to their professional and personal lives. This chapter describes a course that is designed to position enterprise systems within the trends and challenges that are shaping the post-industrial age.

Chapter 2.52

An Embedded Collaborative Systems Model for Implementing ICT-Based Multimedia Cartography Teaching and Learning

Shivanand Balram

Simon Fraser University, Canada

Suzana Dragicevic

Simon Fraser University, Canada

ABSTRACT

Information and communication technologies (ICT) have created many new opportunities for teaching, learning and administration. This study elaborates a new embedded collaborative systems (ECS) model to structure and manage the implementation of ICT-based pedagogies in a blended learning environment. Constructivist learning, systems theory, and multimedia concepts are used in the model design and development. The model was applied to a third-year undergraduate multimedia cartography course. The findings show that regardless of student background, implementing effective ICT-based learning pedagogies can be managed using the ECS model.

INTRODUCTION

Integrating information and communication technologies (ICT)—specifically computers, networks, and the Internet—into higher education has created new opportunities for teaching, learning, and administration. Indeed, the role of ICT in the administration of the higher education process has been reflected in national initiatives such as the 1997 Dearing Committee of Inquiry into Higher Education in the United Kingdom (Dearing, 1997). One of the recommendations of the Dearing Committee was the adoption of national and local ICT strategies to improve the effective and efficient use of resources by U.K. education institutions. Canadian higher education

has echoed these strategies and has also increasingly used ICT in the improvement of the quality of distance-education models (Farrell, 1999). The diffusion of information and communication technology into higher education can be attributed to its potential to leverage education processes toward richer and more rewarding learning and management environments (Mitchell, 2002).

In teaching and learning, ICT is a platform on which key learning skills can be efficiently integrated into existing curriculum to boost learner motivation, deepen inquiry, accelerate learning, and widen participation among traditionally isolated groups (Hassell, 2000). Moreover, teaching core ICT skills such as computer operation and programming prepares students to function and succeed in an increasingly information-based society. However, some authors have pointed out that excessive optimism about the micro and mega benefits of ICT in education can develop into broken promises (Selwyn, 2002). These broken promises can adversely influence the adoption of ICT in educational contexts. While most educators agree that ICT has transformed the traditional education process and, hence, demands a new way of thinking, some have pointed out that achieving and verifying useful ICT educational benefits will require strong theoretical evidence, embedded analysis, and research to surmount the associated structural and cultural barriers (Kenway, 1996).

The utility of ICT in providing and retrieving information is of immense value to educators. Instructional designers are now better able to include a range of ICT-based pedagogy into curriculum design and delivery. Many accept that the technology itself does not ensure learning but acknowledge that it enhances traditional instructional systems to deal with modern-day literacy that is a key component of all education goals. Literacy is now generally considered as a multimedia construct (Abbott, 2001). Multimedia improves upon the traditional text and speech formats of interacting with knowledge by integrating other

forms of media, such as audio, video, and animations into the learning experience. This has made information more accessible and understandable. But the benefits of multimedia have also come with new challenges. Using multimedia in the classroom is a clear departure from traditional expectations and requires a new mindset and commitment from educators and administrators to ensure effective implementation. Challenges also arise due to the lack of consistent baseline experience to guide the integration of multiple media into the curriculum. Moreover, the wide range of multimedia tools available present a technical challenge to educators who must select instructional technologies to match pedagogical strategies and desired learning outcomes (Abbott, 2001). These challenges demand a flexible and systematic mechanism for managing multimedia tools in traditional learning. Systems theory provides a useful foundation to develop such a management mechanism. In systems theory, the key components of the process are identified and managed separately but as a part of an integrated and functional whole. The resulting systematic structuring ensures that valid models for pedagogy inform the learning process, and that the quality of education is maintained and improved through dynamic interactions between learners and educators.

The utility of ICT in promoting sharing and collaboration among learners is also highly desired. This is reflected in the many content management systems (CMS), such as WebCT (<http://www.webct.com>), that empower educators to implement synchronous and asynchronous collaborative environments in distance-learning models and in online support for face-to-face instruction or blended-learning models. Socially mediated constructivist learning theory, where learners explore and discover new knowledge, is the foundation for the collaborative learning paradigm. In face-to-face collaboration, individual and group interactions take place to varying degrees, and finding the appropriate balance is

one factor that influence teaching and learning effectiveness (Norman, 2002). Mediating these interactions with technology also presents challenges. Research has shown that non-technology learners in traditional learning settings who do not have access to desired levels of technology support are less willing to use and interact with the learning technology (Watson, Blakeley, & Abbott, 1998). This challenges educators to embed the ICT-based collaborative learning pedagogies into the curriculum structure and design.

The goal of this study is to elaborate on a new embedded collaborative systems (ECS) model for structuring and managing the implementation dynamics of ICT-based pedagogies in a blended learning environment. The specific questions addressed are as follows: How can we engage students in more meaningful learning activities to develop multiple skills of relevance? How can we achieve a useful balance between teacher-centered learning and student-centered learning? The literature on constructivist learning, systems theory, and multimedia education provides the theoretical basis for developing the model. The model was applied to a third-year undergraduate multimedia cartography course of 47 students with no prior knowledge of multimedia and with basic computing skills. The results show that regardless of student background, implementing effective ICT-based learning pedagogies can be managed using the ECS model.

PROMOTING MULTIPLE SKILLS OF RELEVANCE

The focus on the mastery of cognitive and technical skills in the modern-day classroom is a tendency inherited from traditional learning systems. There is now increasing evidence in the workplace to suggest that in the complex problem-solving environment of the real world, the ability to link classroom knowledge with soft skills is a requirement for success. The capabil-

ity to work in teams, being an enthusiastic and good communicator, infectious creativity, initiative, willingness to learn independently, critical thinking, analytical abilities, self-management, and ethical values are the main soft skills that are highly valued by employers. These new requirements place additional responsibilities on educators to impart knowledge or hard skills together with soft skills in teaching and learning activities so as to prepare learners to function beyond the classroom. This raises the question: How can we engage students in more meaningful learning activities to develop multiple skills of relevance? This question can be examined using a foundation of constructivist learning theory. In this theory, learning is characterized by shared goals and responsibilities, and knowledge is constructed in a discursive environment. Social networking and peer encouragement help motivation and aid individual learning experiences.

Collaborative and cooperative learning have their origins in constructivist learning theory. The goal of collaborative learning is to help learners display individuality and creativity in working with a group toward achieving targets. For collaborative tasks, rewards for achievements are allocated by comparative or normative evaluation systems. In cooperative learning, the focus is on efficiency and effectiveness in achieving a common goal in socially interactive settings (Piaget, 1926; Vygotsky, 1978). In this approach, rewards are allocated based on the quality or quantity of the group product measured against a predefined standard. Although collaborative and cooperative learning share similarities, they differ in their assumptions about competition. Collaborative learning assumes conflict as a part of learning, while cooperative learning tries to minimize this conflict (Bruffee, 1995). One way to resolve this contradiction is to implement the learning approaches in a way so as to extract the positive learning benefits from each.

BALANCING TEACHER-CENTERED AND STUDENT-CENTERED LEARNING

Implementing multiple learning skills activities requires a balance between teacher-centered and student-centered learning within the contact time limitations of the face-to-face classroom. Thus, efficient course management and structuring become important needs with which to keep track of the evolving course dynamics. Norman (2002) outlined a model that defines the interaction space among a set of agents and objects in the learning process. In the model, two sets of agents (instructors and students) and two sets of objects (course materials and course products) overlap to form a complex interaction space. This results in six intersecting areas that form regions where a combination of two or more agents or objects exists. The usefulness of this interaction model is that it shows the variety of interacting elements that require management during the learning process. But while the model provides a comprehensive description of the interactions, it does not deal explicitly with how to balance these dynamic interactions during the learning process. This raises the question: How can we achieve a useful balance between teacher-centered learning and student-centered learning? This question can be examined using a systems theory approach.

Systems theory can be used to manage the instructional tools used to facilitate teaching and learning among the agents. In this way, the theory guides the efforts in balancing the load between student-centered and teacher-centered learning. The theory considers the teaching and learning process to be composed of a set of tightly interrelated pedagogies that can be used to communicate and deliver educational content (Bertalanffy, 1969). Based on the systems approach, together with the constructivist paradigm, a wide range of possible pedagogies can be identified. Examples of these pedagogies include learning contracts, brainstorming, debate, observation,

simulation, case study, discussion, and forum. By integrating these approaches systematically, an equitable balance between teacher-centered learning that communicates knowledge and student-centered learning that integrates all levels of Blooms Taxonomy (knowledge, comprehension, application, analysis, synthesis, and evaluation) can be achieved.

MULTIMEDIA CARTOGRAPHY TEACHING AND LEARNING

The use of computer-based technologies in geography teaching and learning has a long and rich tradition (Gold et al., 1991). This stems from the influence of the quantitative revolution on many areas of the subject. Spatial information studies (encompassing geographic information systems and science, remote sensing, digital cartography, and spatial analysis) are a product of that quantitative influence. Over the last decade, ICT and specialized research software for geography, in general, and spatial information studies, in particular, has caused many changes to the community of research, learning, and teaching practices in these areas. Spatial information studies educators are now battling with how best to balance knowledge transmission with the necessary software practice in the learning process. The “cookbook” approach of traditional lectures and independent student learning of computer skills are two extremes in the learning spectrum of an increasingly computer-driven curriculum. Clearly, any solution must deal with establishing structures for an equitable distribution of the pedagogies across the curriculum and focus the pedagogies on skills students need for success in further studies and the workplace.

Cartography encompasses the art, science, and technology of making maps and requires diverse technical and creative skills for effective practice. The use of multimedia in cartography education serves two interrelated functions: as an

instructional tool and as a product development tool. Instructional frameworks to incorporate multimedia-based instruction into the curriculum must be consistent with existing theories of teaching and learning. This has been emphasized by a number of researchers (Alessi & Trollip, 2001; Benyon, Stone, & Woodroffe, 1997; Ellis, 2001; Najjar, 1996). The multiple representation (MR) framework allows the inclusion of knowledge domains within multimedia (Kinshuk & Patel, 2003). The MR approach involves the selection of multimedia objects, navigational objects, and the integration of multimedia objects in the representation of the knowledge domains. Teaching strategies and styles are also important factors in multimedia learning, as they impact learning. The benefits of multimedia education include improved learning retention, portability, modularity, enhanced visualizations, efficiency in instructional design, and learning consistency (Hede, 2002; Yildirim, Ozden, & Aksu, 2001).

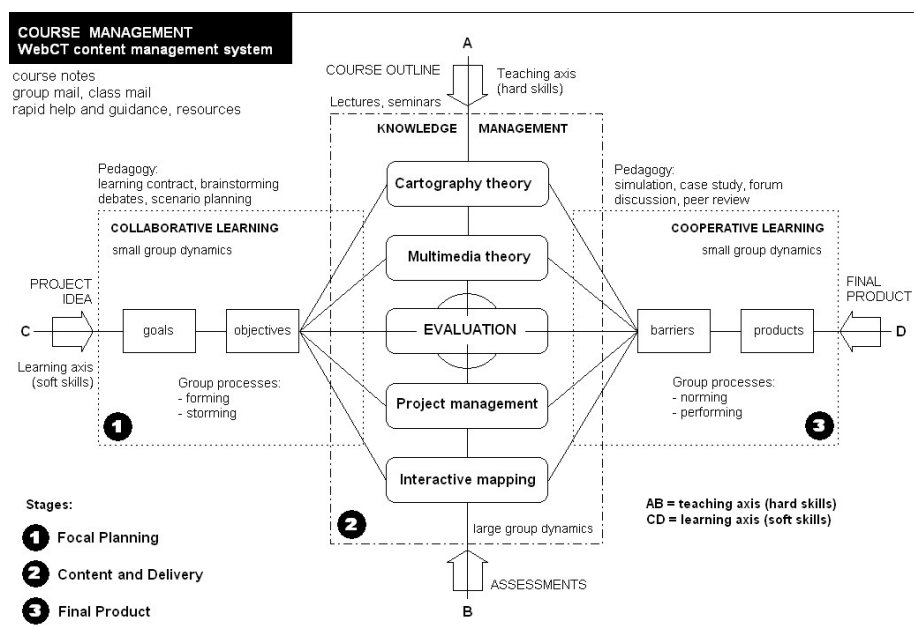

The use of multimedia authoring tools in designing course products enables learners to de-

velop and construct enhanced mapping products. This forms the basis of multimedia cartography, in which the paper map is transformed into an enhanced digital map that integrates multiple media to communicate visual and oral expressions of spatial information to the map reader (Cartwright, Peterson, & Gartner, 1999). These multimedia maps are accessed through CD-ROM, the Internet, or specially designed Web-mapping services. The benefits of multimedia maps include dynamic and multifaceted representation of space and time, superior map production and dissemination, improved information and knowledge transfer, and greater map accessibility.

EMBEDDED COLLABORATIVE SYSTEMS MODEL

The embedded collaborative systems (ECS) model is designed based on principles from constructivist learning theory and systems theory. The goal of the model is to improve the quality of student

Figure 1: The embedded collaborative systems (ECS) model

An Embedded Collaborative Systems Model

learning in the face-to-face classroom. This is achieved with a focus on the development of multiple learning skills and on independent learning. The model's structure is shown in Figure 1.

The collaborative, knowledge management, and cooperative working spaces are three distinct overlapping interaction spaces that are defined in the model. The overlapping structure strengthens the process and provides connectivity among the stages of focal planning of projects, delivery of course content, and preparation of final course products. The knowledge management workspace occurs in the classroom, where all students receive the same content through lectures and seminars. The collaborative and cooperative workspaces

occur during small group laboratory sessions or alternatively in informal meetings among students.

The teaching (AB) and learning (CD) axes serve as both workflow and information flow pathways in the model. These axes control the levels of hard and soft skills that are integrated in the learning experience. The hard skills or teaching axis deals with the substantive course content. This content is normally stipulated by institutional curriculum policies and is implemented using traditional pedagogical tools such as lectures, seminars, and panels. The knowledge management phase of the process is implemented in large groups to encourage critical thinking and

Table 1. Pedagogies and instructional media used in the ECS model

Pedagogy	Description of the Pedagogy	Instructional Media	Stage in the ECS Model	Targeted Skills
<i>Presentation</i>	Instructor-centered lecture notes and student-centered communication of project results	Multimedia, videotape, graphic visuals, text	1,2,3	Hard and soft skills
<i>Discussion</i>	Exchange of ideas and opinions among students–students and teacher–students; discussions are guided by reflective questions	Graphic visuals, text	1,2,3	Soft skills
<i>Demonstration</i>	Instructor-centered presentation of example of skills to be learned; use of expert to present case study	Software, the Internet, graphic visuals	2	Hard skills
<i>Drill and Practice</i>	Exercises such as assignments to reinforce skills	Software, text	2	Hard skills
<i>Tutorial</i>	Individual learning through practice and feedback	Software, text, the Internet	1,2,3	Hard and soft skills
<i>Group work</i>	Small group work on defining projects and allocating tasks	Software, graphic visuals, text, multimedia	1,3	Soft skills
<i>Simulation</i>	Experimentation with small version of reality that is to be described and understood	Software, graphic visuals, text, multimedia	1,3	Soft skills
<i>Gaming</i>	A user-friendly environment for testing specific rules and their effects on determined goals	Software, text	3	Soft skills
<i>Discovery</i>	Problem solving through trial and error	Software, graphic visuals, text, multimedia	1,3	Soft skills
<i>Problem solving</i>	Applying skills to find solutions to real problems	Software, videotape, graphic visuals, audio, text, multimedia	3	Hard and soft skills

discussions. Students develop individual and active learning habits during all stages of the hard skills implementation. The course outline and content together with the assessment requirements drive the nature of the interactions that occur along the teaching axis.

The soft skills or learning axis characterizes the collective and social interaction experiences of students working to achieve targets in a group environment. Examples of pedagogies that can be used involve group projects, learning contracts, brainstorming, simulation, forum, discussions, and case studies embedded in real problem-solving contexts. The intersection of the learning and teaching axes provides an opportunity for formative evaluation. Formative evaluation is an important component of the process, as with it, we are able to establish how students are integrated into the learning experience and how satisfied they are with the learning environment. Formative evaluations include interviews and survey questionnaires, and corrective action is immediately implemented to control any identified imbalances. Evaluations take the traditional form of cognitive assessments using normative testing instruments.

The use of multiple pedagogies provides students with the opportunity to experience deeper learning as they master new concepts by manipulating and refining previous knowledge. The pedagogical tools and the instructional medium appropriate for each stage of the learning process are described and explained in Table 1. The flexibility of ECS model allows students to pursue topics of general interest during the group projects. This supports the assumption that learning is a lifelong process, and learners have a role in designing what they learn.

Achieving a balance between student-centered and teacher-centered learning is inherent in the ECS model. During the initial stages of the model implementation, teacher-centered cognitive learning is at a high level, whereas student-centered learning is at a low level (Figure 2). At the beginning of the collaborative stages, a progression is seen through a fuzzy period of mixed learning toward an equal partnership in learning between teacher and learner. Thereafter, students gradually become equipped with the skills and motivation to undertake active and independent learning. Eventually, instruction is replaced with independent learning, as the full spectrum of Blooms Taxonomy is covered. The

Figure 2. The dynamic phases of the group learning process

timing of the introduction of the collaborative and cooperative tasks coincides with the stages of the learning processes shown in Figure 2.

The ECS model is optimized for blended learning environments, where face-to-face instruction is supported and complemented by online instruction. Content management systems (CMS) such as WebCT (<http://www.webct.com>) offer comprehensive administration tools with which to deploy complex pedagogies that can emerge using the ECS model. The use of systems theory allows the educator to identify the major pedagogical components that will best achieve the desired learning outcomes. In addition, systems theory integrates the knowledge and pedagogy of the process through rigorous alternatives assessments. Each separate component of the process is analyzed for relevance and then integrated to consolidate and expand individual learning. This framework structures the learning environment, provides a mechanism for understanding interrelationships, and provides task balancing and process management benefits among others. The central aspect is that a systematic framework for group interactions is established that allows teams to define roles, define protocols for independent working, and devise strategies for individual accountability.

APPLICATION OF THE ECS MODEL

Cartography Course Background

The multimedia cartography course used to test the model was at the third-year undergraduate level and consisted of 47 students. The total contact duration was 13 weeks. Two hours of formal lectures and two hours of computer lab work were compulsory, guided sessions each week. The lectures were delivered to all students at the same time, while the computer labs were conducted in three sessions with not more than 20 students attending per session. The rationale for

multiple lab sessions was to ensure that students had access to computer resources and were able to receive individualized attention from the teaching assistant. The classroom and lab settings exposed students to both teacher-centered instructions and learner-centered instructions. Students initially had little knowledge of multimedia concepts, cartography theory, or relevant software tools. But this situation was ideal for investigating the ECS model for learning effectiveness among students and the management of the learning process.

Designing learning structures that stimulate and promote enhanced student motivation is perhaps the most crucial aspect of learning (Edstrom, 2002). Identifying motivations allows instructors to develop strategies for redirecting student goals toward more meaningful and rewarding learning experiences. A questionnaire survey was implemented at the beginning of the cartography course to determine student motivation and rationale. The open-ended anonymous question: *“What do you expect to achieve by attending this course?”* provided valuable responses (Table 2). Learning about Internet mapping and cartography principles was the most frequent statement given by students who responded. This indicated that student motivation was generally aligned with the course objectives, and hence, more time would be available for the instructor to focus on preparing engaging content. As is expected, some students were interested in software learning to improve their job prospects and others on obtaining the necessary credits toward graduation.

The open-ended anonymous question: *“What can the instructor and teaching assistant do during the lectures and labs to make you learn better?”* indicated that the most frequent expectation was for clearly explained example-based content (Table 3). The information obtained from the two questions guided the selection of pedagogical components in the ECS model, so that the learning process was balanced by student expectations and institutional curriculum policies.

Table 2. Motivation of students in the multimedia cartography course

What do you expect to achieve by attending this course?	Frequency of Statements (%) (Number of Statements = 47)
Better understanding of mapping on the Internet	13 (27.7)
Expand my knowledge of cartographic techniques	12 (25.5)
Greater familiarity with the software to be used	7 (14.9)
Academic credits and knowledge	5 (10.6)
Others	10 (21.3)

Table 3. Students' suggestions for a better learning environment

What can the instructor and teaching assistant do during the lectures and labs to make you learn better?	Frequency of Statements (%) (Number of Statements = 46)
Give clear and concise explanations	8 (17.4)
Provide many examples during teaching	7 (15.2)
Present the materials at a reasonable pace	4 (8.7)
Make the content relevant and interesting	3 (6.5)
Give well-organized lecture notes	3 (6.5)
Make notes available ahead of lectures	3 (6.5)
Others	18 (39.1)

Content Structuring and Knowledge Management

The first 4 weeks were dedicated to formal lectures and guided practice on the use of software tools. Moreover, cases were analyzed and best practices extracted such that students became familiar with general practices in the subject area. This forms the knowledge management phase of the model, in which learning proceeds through incremental steps, and individual learning is emphasized. The subsequent weeks were structured so that knowledge management at an individual level and collaborative project at a group level reinforced each other for an enhanced learning experience. Formal lectures included concepts related to cartography, multimedia, Web mapping and project management theory (Figure 1). The

focus of the lectures was on case studies, and students were exposed to analytical, application, creative, communication, social, and self-analysis skills (Easton, 1982). Moreover, students were able to discuss their views freely and to listen to the views of peers. The group work and peer support operated both as additional instructions for students and as a forum for wider discussions within the course framework.

Of significance in this stage is the concept of Web-based mapping, which involves some level of computer networking knowledge (Figure 3). In a Web-mapping multimedia application, a digital map, once created, becomes a dynamic index to multimedia content. The map is hosted on a Web server, and a map server provides a dynamic link to a database to allow end users to query and interact with the map in the browser

Figure 3: Levels of use of relevant software

window. Although the learning curve for this particular type of mapping technology is steep, it was surprising to find that students were extremely motivated and committed to learning the software. Informal interviews revealed that the general source of this motivation came from the structuring of the learning outcomes at each stage of the process and the out-of-class support and help provided by the teaching assistant. Students were more committed and motivated when they could control how and when they learned.

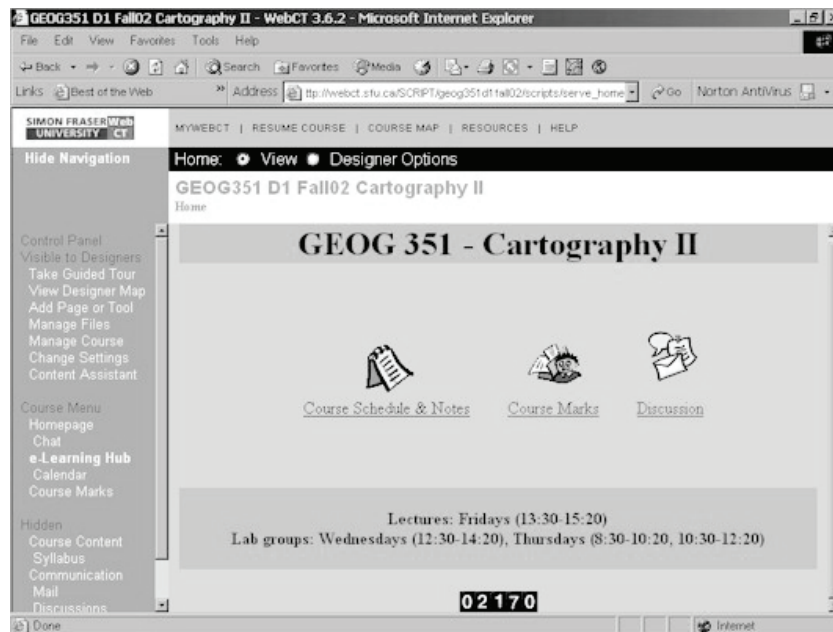

Accessing notes and supplementary materials before lectures ensures that students concentrate on synthesis and analysis rather than on note taking. The new electronic media make it easy to provide additional readings based on student needs, and the online environment provides a social space for continuous conversations and support among peers. Optimal learning occurs when students share knowledge among peers in a community of practice where ideas are evaluated and adapted. In order to manage the implementation of the model, the content management tool WebCT was used for managing mailing lists, discussions, and presentation of knowledge content (Figure 4).

The real-time facilities of the management tools were useful in fostering the “community spirit” outside of the classroom setting. The final multimedia cartography atlas products developed and implemented by students are documented on the Web (<http://www.sfu.ca/geog351fall02/>).

Collaborative and Cooperative Learning

In the collaborative learning exercise, learners were divided into nine groups (average of five students per group, some randomly and some based on individual preference), and step-by-step guidelines were given to each group on the final product to be achieved (designing and creating a professional multimedia atlas), and resources (books, journal papers, Internet Web sites) available for unraveling what is to be achieved. Tasks included mastering sets of specific learning objectives and finding ways to transfer that learning to the class as a whole. There was no briefing to students on group roles. Students reported that the first set of group discussions was difficult. This was expected, but students needed to learn

Figure 4: Model implementation using the WebCT content management system

how to cope in a new and unfamiliar social and learning environment. The leadership role was usually assigned to the student with much to say. That leader then assigns tasks, facilitates the discussions, and ensures that meaningful results emerge from the discussions. The weekly meetings provided time for critical reflections and perusal of new materials, ideas, perspectives, and further research. Each week, the instructor met with the group to evaluate problems and progress and to offer solutions strategies. Ideas were not imposed on the groups, and this was much appreciated by the learners. Moreover, learners agreed in principle to abide by “moral and ethical” conduct during the course.

Students were involved in the initiation and definition of a relevant project. Support was provided in the form of guidance about the format of the final products to be produced, potential areas for projects, course aims and expectations, time schedules, data resources, and project management information. In the design stage,

students were encouraged to develop a concept sketch of their product and to begin the process of tool selection and task allocation. There were many opportunities for students to consult with the course instructor and teaching assistant during this stage and, indeed, for the entire course. All members of the group were encouraged to participate in the creation, assembly, and layout of content so as to ensure a uniform individual learning experience. Internet resources and books were provided to help further the process. Each group identified a member to coordinate their activities and to maintain close liaison with the instructors. The final course products were presented to peers for review, and comments were gathered by the instructor and given to each group. This feedback was useful in improving the quality of the products and establishing a standardized level. This peer review also introduced critical and reflective practices into the process (Bazeli & Robinson, 2001).

The use of information technology together with communicating and working with peers was identified by students as contributing to the success of the project. There were instances in which some students were more focused on the technological tools and less on the content. The group-learning format ensured that group members provide focus and guidance to individuals. Evidence of this peer learning was reflected in the sophistication of the cartographic products and how these products quickly diffused and were adopted by other groups. The professionalism of the final products helped in motivating students toward greater learning and explorations.

Assessment and Evaluation

Evaluations have substantial gains for individual projects and progress in the field. Moreover, the use of new ICT technology has resulted in curriculum changes and may require new ways of evaluating students. In the collaborative modes of learning, the focus is on teamwork and communication skills, and appropriate measures of these are needed. An interim way of dealing with this is to use outside evaluators and student questionnaires. Also, multiple levels of evaluation can yield richer feedback from external, internal, and peer sources. Logging usage statistics and student interviews is another way to identify features of the course that are good and what improvements can be made so that future refinements of the process can be made.

Assessment materials were returned to students quickly, showing where improvements can be made. The exercise involved students preparing work individually and bringing it to the group. The small groups then integrated the materials using e-mail and face-to-face meetings. The small group work was then shown to the groups in a large-format presentation. The assessment also allows educators to learn about their work in a critical and reflective way so that rapid improvements can be instituted for the benefit of learners

(Gerber, 2002). The assessment for the cartography course was comprised of individual assignments, group mini-project presentations, individual participation, examination, and production of a final working group electronic atlas.

All students completed a questionnaire during the formal group presentations, and some students were randomly interviewed at the midway point in the course to obtain feedback toward formative evaluations. In the group presentations, each student was required to judge the presentations of the others on a 5-point verbal scale ranging from poor to excellent. Moreover, reasons for the judgments were also requested. The general trend of the responses was toward the favourable end of the judgment scale and was justified by the respondents on two main grounds—the sophistication of the tools and techniques used for creating the atlases and the non-duplication of these techniques across the groups. Students clearly indicated that these were attributed to the efficient small-group work and the collaborative settings in which they occurred. However, one shortcoming identified was the lack of time. While this was unavoidable given the constraints of the semester and curriculum, techniques and tools for time and project management were again reinforced such that facilities for handling this shortcoming were available to them beyond the course. Another shortcoming identified was the variation in skills within the groups. Although students recognized the difficult logistical problems that this can cause, they nevertheless felt that the group's experience would probably have been more rewarding with balanced skills. One way to deal with this is to make greater use of learning styles and skills inventory to categorize students into the small project groups. However, this will demand a trade-off between efficiency in the course logistics and effectiveness in implementing the ECS model. The two comments below characterize the general attitude of students:

“The projects and presentations overall were very impressive and obviously well thought out. The presentations give an overall view of the work-effort placed within each group.”

“In general I would like to say that all the atlas were very different concerning layout and information, but most of them were really very good.”

A summative evaluation in the later stages of the course elicited responses on the following questions using a 4-point scale (4 being most favourable):

- The assignments and lectures were [unrelated—well related]; mean score = 2.61 ($n = 36$)
- The exams and assignments were on the whole [unfair—fair]; mean score = 2.81 ($n = 36$)
- The marking scheme was on the whole [unfair—fair]; mean score = 2.92 ($n = 36$)

These results from the summative evaluations are inconclusive. While they indicate a general positive weight to the statements, the aggregations of different student backgrounds and experiences makes any interpretation uncertain. The issue of a learner capability to judge curriculum content and implementation is still unresolved in the literature. Nevertheless, the informal interviews and the level of accomplishment in the final atlas products provide strong indication that the collaborative learning process, as implemented using the ECS model, was indeed effective in managing and task balancing the components toward the intended products.

FUTURE TRENDS

The further development and integration of ICT into multimedia cartography education is dependent on three factors: access to ICT tools, instruc-

tors' knowledge of effective ICT use, and more studies on the benefits of ICT and multimedia in student learning. Access and instructor knowledge are issues best handled from the wider policies and practices of higher education administration. Systematic research is needed to further establish the role of ICT in learning.

The software and hardware needs for geography education are enormous. Centralized servers for demonstrating and hosting Web-mapping services, the multiplicity and constantly changing software tools, and the need to redesign current computer laboratories to accommodate collaborative group learning are some of the central considerations that will influence the wider adoption and diffusion of an ICT in the geography curriculum. A troubling issue for multimedia cartography teaching and learning is software licensing arrangements that can sometimes be a barrier to using certain software tools in the learning process. This, in some ways, dictates the eventual skills that students can achieve. Technology providers will need to seriously consider pricing mechanisms so that academic institutions are better able to afford and maintain basic technological infrastructures to implement core teaching and education programs. There has been some progress in this area, with mechanisms such as university campus licensing that enable widespread use of some software tools for teaching and research.

With the gradual expansion of the home as a center of learning, arrangements for students to use university resources at home promise to be a major issue, especially with respect to copyrights and off-campus licensing agreements. University libraries hold a key position in this regard. Already, electronic books, or e-books, are a common feature of many western university library catalogs, and there has been growing evidence to suggest that some of the more progressive university libraries have already begun to redefine their roles as information gateways to act as the intermediary between the user and information (Dowler, 1997).

Electronic data archives, multimedia reuseable learning object databases, subject portals, and continuing skills training for students are ways libraries have begun to accept their changing roles in university teaching and learning. A common thread in all the transformations has been the impact that ICT has brought to the university and classroom with respect to administration, teaching, and learning.

Existing models of multimedia cartography teaching and learning have been mostly descriptive. These models have been useful in understanding the mechanisms in operation and in enabling comparisons to be made across different learning contexts. The results from these studies have enabled educators to generally conclude that ICT and multimedia have positive benefits for learning. However, not much is known about the critical factors and how they influence learning. Systematic investigations of predictive models in diverse contexts provide the next steps for understanding the factors of ICT and multimedia that affect learning. Following along this line will be new learning tools, with which intelligent agents will guide learners through knowledge nodes and learning activities using hypermedia and multimedia in much the same way as the intelligent help assistant acts in the Microsoft Office software products.

CONCLUSION

The ECS model presented is based on a holistic perspective of learning as complex interactions between multiple agents, physical and social spaces, and instructional technologies. Although the model can be used in hypothesis testing, the main goal is to provide instructional designers and educators with a tool for managing the main factors that need to be considered when designing ICT-based pedagogies. This model provides the framework for good instructional and course-structuring design that takes into account the

diversity of learner styles and provides engaging interactions among students.

The use of ICT and multimedia pedagogy in cartographic education is still in the early stages of understanding and development. There are numerous possibilities and pitfalls. But given the early stages of diffusion of multimedia tools in education, the current focus among practitioners is on developing strategies and standardized protocols to produce effective multimedia components that blend engagement and entertainment into a single learning environment. Moreover, collaborative processes aid the pedagogical move toward student-centered learning.

The embedded collaborative systems model was developed to structure and understand the dynamics involved in the implementation of multiple learning skills activities. The implementation involved 47 students in a multimedia cartography course. The course was conducted in a blended learning environment, and discursive group learning was the foundation of the learning experience (Thorne, 2003). Each group defined project content, prepared a proposal, defended their proposal in front of their peers in a formal conference-type presentation, received feedback from peers, and used the feedback to improve their group's project. Also, the other groups judged each group on presentations. This forms the cooperative phase, where individuality and group opinions are merged for consensual learning.

In summary, the issues in this study, namely, how to implement effective (content and experience) multimedia cartography training and education to learners of diverse backgrounds, was addressed by the development and testing of a systems model for integrating the multiple facets involved in the education and training process. Within the systems model, the collaborative and cooperative learning strategies were integrated to promote individual and group development for effective multimedia cartography education and product development. The benefits of the ECS model include the following:

- Improves connectivity among the actors by embedded and continuous interaction
- Cultivates an attitude of independent learning through peer guidance and motivation
- Integrates multimedia information, thereby catering to a range of learning styles
- Provides ownership of the learning process through group and individual project management
- Develops individual social and learning skills and accountability

Chapter 2.53

Computing Curricula: A Comparison of Models

Anthony Scime

State University of New York College at Brockport, USA

Christine Wania

State University of New York College at Brockport, USA

ABSTRACT

An analysis of eight computing model curricula verifies that there are significant differences between computing disciplines. While there are many courses in the models with the same or similar names, the courses may be completely different. By reverse engineering model course descriptions, the courses are compared to determine the inclusiveness of each course in each of the others. Although expected, these results are significant for colleges and universities establishing or revising computing programs.

INTRODUCTION

The use of computers has become ubiquitous in society today. Yet, most of society does not understand computing as a field of study. Even the computing professionals and academics are only now coming to understand the variances in

the computing disciplines (Landry, Pardue, & Longenecker, 2003).

Education, engineering, and medicine are more clearly understood disciplines. Grade level and subject matter divide the education disciplines. Distinctions are made in work and education between civil and mechanical engineering. People seek out surgeons or internists for different medical conditions. Of course, these disciplines are older than computing and have developed these specializations overtime.

Much specialization occurs because a discipline expands to the extent that individuals lack the capacity to assimilate all the disciplines' knowledge. As a result, subsets of knowledge emerge as specialties (Stark & Lattuca, 1997). The computer disciplines are beginning to form into specialized fields. These fields, however, do not derive from a common reference discipline, as civil and mechanical engineering derived from military engineering. Rather, the different computing specializations came from different

reference disciplines, primarily management, mathematics, or engineering (Scime, 2002c).

As a result of these various origins, computing professionals have organized themselves into different professional organizations to share information and promote the profession. These professional organizations provide guidance concerning the particular knowledge necessary to be successful in the profession. This in turn influences the academic programs. The most direct method professional organizations have used to influence academics is the curriculum model. These models describe the topics to be covered in a program's curriculum. Typically these topics are organized as semester length (15-week) courses. Some of the models provide detailed knowledge units, comprising the discipline's body of knowledge which are then organized into courses. Other models take a more subjective approach, providing just a course title, leaving it to the program developer to interpret course content.

While it is unlikely that an electrical engineer would be hired to design a distillation column (a chemical engineering task), industry hires entry-level employees for computing positions, often without regard for the specific computing program. Entry-level jobs such as programmer, help desk worker, or network or database administrator will go to graduates of any of the computing disciplines. This may be because the courses in the disciplines appear the same. While it is recognized that it no longer holds that the traditional career path is from programmer to systems analyst to project manager and eventually to IS manager (Urquhart, Perez, Rhoden, & Lamp, 1996), the differences in computing programs are not always appreciated in industry.

This study is an analysis of computing curriculum models to understand their similarities and differences. It begins with outlining the work performed in the profession, followed by a discussion of the models, and then a topic analysis of model courses, comparing individual courses to

one another and the models as a whole to each other.

REVIEW OF THE LITERATURE

Computing as a Profession

The members of the computing profession have come together in various professional societies. These organizations provide an outlet for the exchange of information and provide a venue for discussion forums about computing. These groups may be primarily composed of practitioners or academics.

Table 1 outlines the type of members in professional organizations sponsoring or endorsing a model curriculum. Although most organizations may have academic and practitioner members, the purpose of an organization may be more oriented to one type of member than the other. Likewise, some of the larger organizations may accommodate both the academic and practitioner equally well.

The fields of computer science, information systems, information technology, software engineering, computer engineering, management information systems, and so forth suffer from a confusion of terms. Information technology (IT) is both an umbrella term for the professions and disciplines that maintain information and develop the tools to maintain information, as well as the term for a separate profession and discipline under that umbrella.

Some of the professional organizations consider information technology as a separate profession and discipline, while others view it as the umbrella for all computing-related activities. As a separate discipline it focuses on the operation of computer machinery (IEEE Computer Society, 2004), or as application of programming, computer networking and hardware, databases, and Web technologies to solve user problems (IT Curricu-

lum Proposal — Draft, 2002). The Information Resources Management Association considers IT a separate discipline for which they provide management expertise (Cohen, 2000).

As an umbrella term, IT is defined as a growth of computing beyond computer science (Denning, 1999). This includes involvement with the management of information resources or management of anyone working in information technology (Association of Information Technology Professionals, 2003). The Association for Computing Machinery considers information technology to be synonymous with the equally broad field of computing. It considers the major subdivisions of computing and information technology to be computer science, computer engineering, software engineering, and information systems (Association for Computing Machinery, 2001). To alleviate the confusion between IT the dis-

cipline and IT the umbrella, this article will use computing as the term for the umbrella over the entire range of computer-related disciplines and information technology as the term for the specific discipline.

Regardless of the professional society, computing involves the design, development, implementation, support, and management of software and hardware artifacts (ITAA, 1997). An artifact may be a chip, a device, a program or model, or a method to store and retrieve data. These artifacts are conceptualized, developed, modified, and supported by professionals who are knowledgeable in these activities (Freeman & Aspray, 1999). It is the job of academia to produce workers in all four categories. It is this last — the most abstract — definition that proves useful in establishing the roles of computing workers.

Computing Curricula

Conceptualizers are workers involved with the formation of ideas concerning the basic nature of a computer system artifact. They investigate new ways of processing, storing, transmitting, and representing information. These workers have job titles such as computer and information scientist, computer software engineer, and computer hardware engineer (Bureau of Labor Statistics, 2004b, 2004d, 2004e).

Developers are people who specify, design, construct, and test computing artifacts. They apply existing technology to new problems. Commonly the job titles are computer programmer, computer systems analyst, network systems and data communications analyst, computer software engineer, and computer hardware engineer (Bureau of Labor Statistics, 2004a, 2004b, 2004d, 2004e).

Computer workers who modify or extend a computing artifact work with existing hardware or software. Modifiers maintain systems by making improvements to increase the efficiency of information processing, storage, or communication. They may have job titles such as computer programmer, computer systems analyst, database administrator, network systems and data communications analyst, computer software engineer, and network and computer systems administra-

tor (Bureau of Labor Statistics, 2004a, 2004b, 2004c, 2004d).

Finally, there are those who support or tend the existing systems by delivering, installing, operating, maintaining, or repairing information artifacts. Supporters work at the interface between the computer system and the end user. These are the computer support specialists, and network and computer systems administrators (Bureau of Labor Statistics, 2004c).

The work categories students can expect to enter may be determined by their school's curriculum. Yet, all computing education consists of various technical, computer-oriented topics, ranging from a theoretical understanding of computing, through the design or support of practical applications for complex computer systems. In the development of the Information Systems 2002 (IS 2002) and Computing Curricula 2001 (CC 2001), curriculum models bodies of knowledge were developed (Gorgone et al., 2003a, 2003b; ACM, 2001). The courses in these models are organized into groups by general topic. These topics collectively represent the body of computing technical knowledge expected of graduates with a bachelor's degree (Table 2) (Scime, 2001a, 2002b). The depth of knowledge in each category varies with the program's intent for their graduates and the curricula model on which the program is based.

Curriculum Models

There are eight curriculum models (Table 3) designed to guide the undergraduate teaching of the computing disciplines of computer science, software engineering, information systems, management information systems, information technology, and computer engineering.

A Joint Task Force on Computing Curricula created by the Association for Computing Machinery and the IEEE Computer Society developed Computing Curricula 2001 (CC 2001). This model focuses on programs in theoretical and applied

computer science. It contains 47 introductory and intermediate courses, and 80 advanced courses. These courses are to be mixed and matched into specific models by a program implementer. This model provides for a total of 180 different combinations of courses (ACM, 2001).

The Information Resources Management Association/Data Administration Managers Association International (IRMA/DAMA) 2000 model takes a business approach to IS. It focuses particularly on the disciplines of information resource management and management information systems. It takes a management of data approach and includes the development of tools to main-

tain, communicate, and use data (Cohen, 2000). Taking a top-down approach to IS education, this model stresses learning general principles before specific implementation details. Central to the IRMA/DAMA curriculum is the recognition of information as a major organizational asset. This preparation for a computing profession revolves around the application of IT to business problems. Effective verbal and written communication, time management, leadership, and delegation of authority skills are stressed in this program.

The Model Curriculum for Information Systems (IS 2002) is sponsored by the Association

Computing Curricula

for Information Systems (AIS), the Association for Computing Machinery (ACM), and the Association of Information Technology Professionals (AITP). IS 2002 is endorsed by five other organizations. The IS 2002 model provides for the technical aspects in information systems, as well as a foundation in business processes. The model comes from a body of knowledge developed by surveying practitioners and academics (Gorgone et al., 2003a, 2003b).

The Information Systems Audit and Control Foundation (ISACF) is the research branch of the Information Systems Audit and Control Association (ISACA). ISACA recognizes that technology has a significant impact on business, and that technology must be properly constructed and managed to assure sound business practices. This assurance is maintained through accounting and auditing control processes (ISACF, 1998). ISACF developed for the ISACA a model curriculum that is designed to meet the needs of the IS auditing profession in developing the knowledge and skills of future IS auditors. This model provides the academic preparation necessary to achieve professional certification as a Certified Information Systems Auditor. This requires an in-depth education in accounting and auditing, as well as computing.

The ISCC'99 (Information Systems Centric Curriculum) model was developed by a National Science Foundation-sponsored task force that included members from academe and industry. This model is intended to fit between pure computer science and management information systems. The focus is on the construction of the tools necessary for information management (Lidtke, Stokes, Haines, & Mulder, 1999). This curriculum looks at information as an enterprise asset that must be managed. This management can be accomplished through large-scale, complex information systems. This is an engineering development approach to information systems. However, it does not exclude interpersonal skills,

which are necessary in the teamwork environment of information systems development.

There is an IT Curriculum Proposal in draft form. The Information Technology Education Special Interest Group of the ACM (SIGITE) is developing it. The curriculum is oriented toward the use of computing applications to solve business problems. The model's approach considers the outcomes desired for graduates, and the incoming knowledge and skills of students. The curriculum proposal currently consists of four IT core topic areas: programming, networking, database, and Web technology (IT Curriculum Proposal — Draft, 2002).

The OEIS (Organizational and End User Information Systems) model developed by the Organizational Systems Research Association (OSRA) is aimed at analyzing end-user needs in the development of information systems and supporting end-user operation of information systems (OSRA, 1996).

The SEI model from the Software Engineering Institute follows an engineering approach, in that analysis and design before implementation is stressed in the solution of practical problems. The model suggests specialization in a specific domain, such as operating systems, embedded systems, applications software development, or large-scale information systems (Bagert, 1999).

Of course, most of the models have database and programming courses. But the emphases in the database courses are quite different (Calero, Piattini, & Ruiz, 2003; Johnson, Wilkes, Ormond, & Figueuroa, 2002). With the curriculum models and professional organizations each taking a slightly different approach to computing, it is clear that computing is becoming specialized. It is important to determine model similarities because few colleges or universities have the resources to staff multiple departments. Decisions must be made concerning the desired direction for a school's computing programs.

RESEARCH DESIGN

With curriculum models developed by different professional organizations, questions arise about the differences between the models. For example, it is reasonable to assume that a database course in one model would be the same as a database course in other models. However, Johnson, Wilkes, Ormond, and Figueiroa (2002) found that by doing a keyword analysis of database courses, there was no similarity between database courses in the models. Extending such an analysis to all courses in the model curriculums will show the degree of similarity between models and between model courses.

This is significantly valuable in the design of computing programs of study. Universities will be able to tailor the program to graduate specific categories of workers and will be able to evaluate the transferability of courses from other schools.

While IS 2002 and CC 2001 were derived from bodies of knowledge, the common denominator running through all of the models is the semester course. A course is a collection of related topics that can be presented in a 15-week semester. By reverse engineering the course descriptions and titles, the particular topics composing each course can be determined. By comparing these

topics course by course, as well as across the curriculums, the similarities between the models can be determined.

In preparing for the analysis, each course was assigned a course number that included a prefix identifying the model (Figure 1). Where available, these numbers match the numbering system given in the model.

Each course in each model was reviewed. Topics covered in the course were manually extracted from the course description and title. The topics are represented by keywords. After all courses were reviewed, the union of the sets of keywords was extensive, and some topics were represented by similar keywords. The keywords were reviewed, and those representing the same topic mapped into a common keyword (Figure 2). This reassignment reduced the number of keywords and strengthens the comparison process (Hearst, 1999).

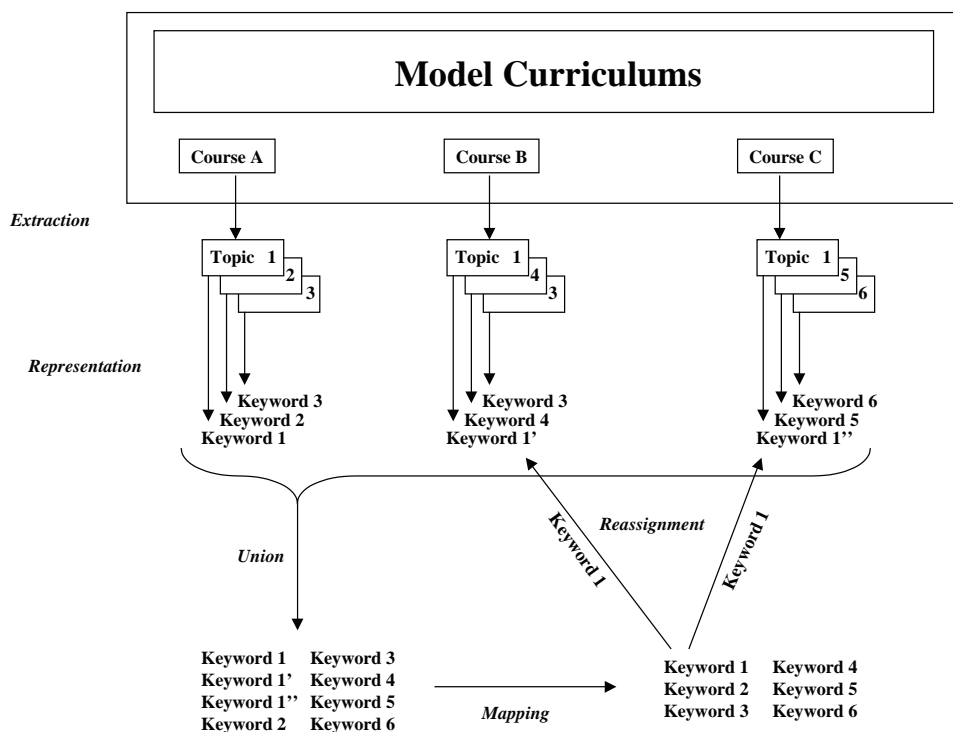

At a level above the course, computing curriculums all teach defined groups of topics (Table 2). These larger groups or categories are the super-topics that define computing. Courses were manually assigned to a specific category based on the majority of the topics in the course. One or more courses in a curriculum may be grouped together under these categories. It is the distribution of courses and topics between the categories that distinguish the computing disciplines (Scime, 2002c).

Comparisons were used to evaluate the similarity of the model curricula. Each model course was compared to all the other model courses by topic keywords. This tested the similarity of courses to each other. Each curriculum model as a whole was compared to each of the other models by topic keywords. In other words, all the keywords of all the courses in a model are compared to all the keywords of all the courses in the other models. This checked for the teaching of the same concepts in different configurations of courses.

OEIS	OEIS
ISACF	ISACF

Figure 2. Reverse engineering of courses

DATA ANALYSIS

Course-to-Course Comparison

A count of the number of common topics and calculation of the percent of common topics in a pair-wise manner was completed. The percentage of common topic keywords pair-wise comparison between all courses showed that the two courses with the most similarity, sharing the most topics, were Professionalism and Ethics (SE4) from the Guidelines for Software Engineering Education Version 1.0 and Social and Professional Issues (CS280T) from Computing Curricula 2001. Eighty-eight percent of the topics in SE4 are also in CS280T. Likewise, 78% of CS280T is part of SE4. The Professionalism and Ethics (SE4) course description states that it “covers material on the historical, social, and economic issues in software engineering. It includes study of profes-

sional responsibilities, risks and liabilities, and intellectual property relative to software engineering profession” (Bagert, 1999). The course description for Social and Professional Issues (CS280T) “introduces students to the social and professional issues that arise in the context of computing” (ACM, 2001).

Courses that have significant similarities of 80% or higher are primarily in the CC 2001 curriculum; this is to be expected from the number of introductory and intermediate courses from which to choose. The 180 courses are divided into introductory, intermediate, and advanced computing groups; implementers select a type of course from each group. Within the introductory group, courses cover many of the same topics, which is where the greatest similarity arose. For example, CS103B (Principles of Object-Oriented Design) shares 83% of its topics with CS102I (The Object-Oriented Paradigm) and CS112H (Object-

Oriented Programming Techniques). This means that what is taught in CS103B is 83% similar to what is taught in CS102I and CS112H. Note that these courses would not be implemented in the same program. CS103B is an introductory course in the breath-first implementation strategy, CS102I is part of the imperative-first strategy, and CS112H hardware-first.

For courses between models, significant similar results (see Table 4) occur in primarily three categories—ethics, system analysis and design,

and software development/programming. These results support findings of a survey of computing deans. Looking for common knowledge areas within existing computing programs, without regard to matching the programs to any model curricula, it was found that there is a cluster of knowledge in the systems analysis and design and software development process across computing programs (Landry et al., 2003).

There are also cross-category similarities. Courses that provide an overview of comput-

Table 4. Different model courses sharing at least 60% of keywords

ing are likely to cover material similar to more advanced courses, although in less detail. Also, systems analysis and design courses with a strong implementation emphasis cover topics that are also covered in software development/programming in another model. For example, 80% of the content of the CC 2001 course Algorithms and Data Structures (CS103O) is included in the SEI model's Introduction to Computer Science for Software Engineers 2 (SE2).

There are courses that contain parts of multiple courses. IS 2002's Physical Design and Implementation in Emerging Environments (IS2002.9) contains elements of three courses. It covers 71% of CS291S (Software Development and Systems Programming) and SE8 (Software Construction and Evolution), and 67% of CS341 (Programming Language Design). SE8 also contains 67% of CS341. The CC 2001 course Software Engineering and Formal Specifications (CS393) has 67% of its content in each of four SEI model courses: Introduction to Computer Science for Software Engineers 1 and 2 (SE1 and SE2), Introduction

to Software Engineering (SE3), and Software Design Project (SE9). ISCC'99 has two ethics half-courses (ISCC22 and ISCC52) in the model. These are half-courses because of a desire to teach ethics in stages as the students learn more complex material (Lidtke et al., 1999). These courses have 67% of their content covered in each of two CC 2001 courses, CS100B (Preview of Computer Science), an introductory overview course, and CS271S (Information Management), a database course at the intermediate level.

Model-to-Model Comparison

It is possible that the curriculum models spread the computing knowledge among the courses in a manner that produces the low similarity between courses. In other words, the topics are in each curriculum, but organized in courses in different ways. By aggregating the topics of a model into a single set, it is found that the number of distinct topics in a model varies from seven for ISACF to 180 for CC 2001. The ISACF model contains

Figure 3. Shared topics with IS 2002 (82 keywords)

Model	Number of Keywords	Shared Keyword Topics	Percent of Model in IS 2002
IRM	56	33	59%
OEIS	64	25	39%
ISCC 99	50	22	44%
SEI	50	23	46%
CC 2001	180	37	21%
ISACF	7	6	86%
IT	51	19	37%

very limited course descriptions, thus restricting the selection of keywords. Therefore ISACF has a high and misleading correlation with all the other models. The CC 2001 model is designed to allow implementations great flexibility in course selection, dependent on the program emphasis desired. This model can provide courses for programs ranging from hardware-first, Web-based net-centric computing to breath-first, imperative, topic-based information management.

As a result of the breath possible in CC 2001, five of the model curriculums (IS 2002, ISCC 99, SEI, ISACF, and IT) share the most topic keywords with CC 2001. Because of CC 2001's variability in implementation, it is difficult to draw the conclusion that it leads to the most inclusive programs.

The other models do not have CC 2001's flexibilities. If CC 2001 is not considered, then with one exception, all the models have the majority of their topic keywords included in the IS 2002 model (Figure 3). IS 2002 is a 10-course model (82 keywords) with no electives. The exception is the OEIS model, which slightly more closely matches the IRM model, sharing 27 topic keywords.

CONCLUSION

By reverse engineering the curriculum models, the similarity between model curricula and model courses was analyzed. Limited similarity was

found, at best an 88% inclusion of one course in another. Only 13 courses of a total of 196 courses had 60% of their content in another course.

At the model level, CC 2001 has the flexibility to cover the material in the majority of models, assuming the appropriate selection of courses on implementation. IS 2002 is a fixed-size model with no elective courses, yet it incorporates more topics than seven of eight of the other models. This is a clear indication that IS 2002 has the most general scope of the models. Although one model, with only seven total keywords, matched IS 2002 at 86%, the remaining models were all below 60% in matching.

Clearly, the limited similarity of topics at both the course and model levels supports the concept that computing is a diversifying discipline. Just as engineering schools have diversified into different specialties (civil, mechanical, electrical, chemical, etc.), and industry engineering projects need some of each specialty, computing schools will develop different programs. The professional organizations have already specialized. Likewise, employers will come to realize they need different skills, which come from different programs, to support their computing needs.

Students require different knowledge dependent upon the role they will perform within computing. The curriculum studied helps determine the graduate's role. To select or develop a curriculum, a school needs to assess their objec-

tives and capabilities in providing graduates to the computing workforce. A school with a strong liberal arts tradition has a different philosophy than a technically oriented school. A large university may have schools of Computing and Business; the focus of each may require following different curriculum models. Some schools prepare students for further study, while others are oriented to the job market. Schools with an international or national focus have different objectives than schools providing entry-level professionals locally. Whatever the focus, the correct curriculum model must be chosen.

Those schools that lack the resources to provide multiple programs should select one of the models to produce a graduate having the knowledge of a conceptualizer, developer, modifier, or supporter. Not covering the same topics of the common technical core of computing knowledge is what makes the computing disciplines differ from one another. Some areas of the core are emphasized in different model curricula, and provide an orientation of knowledge toward one or more of the professional roles. The relationship of the emphasis of technical topics with the computing disciplines and professional roles supported by the curriculum models is of value in selecting a model as a beginning to program development. Attempting to generalize computing may lead to generalist graduates unsuitable for any professional position.

RECOMMENDATIONS FOR FURTHER RESEARCH

This study looked at the model curricula and found limited similarities between all model courses, as did Johnson et al. (2002) in database courses. The question that remains is how the models are being implemented at colleges and universities. In future work it will be interesting to study the course descriptions of selected schools to see which model they most closely follow.

There are two major accreditation associations that evaluate computer science, information systems, and so forth. The Association to Advance Collegiate Schools of Business (AACSB) accredits schools that provide higher education in business administration and management. The Accreditation Board for Engineering and Technology (ABET) accredits programs that provide higher education in engineering, technology, applied science, and computing. It is possible that a school of business receives AACSB accreditation and its information systems program receives accreditation from ABET. If the information systems program is not in the school of business, it may be accredited by ABET. There are hundreds of schools and programs around the world that have received one or both of these accreditations. These schools have certifiably good programs in computing. Many of the models discussed may satisfy the program accreditation of ABET or help in satisfying the accreditation criteria of AACSB. “How closely do accredited schools and programs follow one or more of the model curricula?” is an interesting question.

Another thread of investigation is the association between the models and major categories of workers. Are some models more suited to produce conceptualizers, developers, modifiers, or supporters? Although holistic analysis of worker categories supported by the models has been done (Scime, 2002c), this can be refined by topic analysis. If topics can be identified with these professional areas, then an abundance of topics in an area could lead to a model supporting one area over the others.

Chapter 2.54

ICT-Enabled Education in Africa: A Sober Reflection on the Development Challenges

Shafika Isaacs

SchoolNet Africa, South Africa

ABSTRACT

This essay prompts critical thinking on the way ICT-enabled education programs in Africa have been conceptualized and implemented. It reflects mainly on the experiences of the African SchoolNet movement over the past decade. It highlights important lessons and demonstrates the beneficial effects of technology-enhanced learning programs on African learners and teachers who have had the privilege of being included in SchoolNet initiatives. However, it also shows that the accumulated interventions and programs to date remain insignificant in scale to catalyze a resounding shift toward resolving the crisis in Africa's education systems; it makes the case for integrated system-wide, locally led approaches that soberly takes account of the challenges imposed by globalization. The chapter traces the historical evolution of frameworks to promote African inclusion in the information society, and allusions are specifically made to the emergence of the NEPAD eSchools, and the Global eSchools and Communities Initiative of the UN ICT Task

Force, which hold the potential for advancing the frontiers of learning in Africa. Here, the author emphasizes, however, that these new initiatives need to draw on the accumulated learning and experience of the SchoolNet movement over the past 10 years in Africa to succeed. Finally, the chapter raises the dearth of evidence-based research made in Africa by Africans who would verify or refute the case for stronger investment in ICTs for education. It then proffers suggestions on areas for further research.

INTRODUCTION

Human resources are the essential infrastructure, without which technology means nothing. (Castells, 2001, p. 155)

The current practice of applying new information and communication technologies in the education systems in Africa is cause for concern. Much of the existing interventions have largely, although not exclusively, been informed by the discourse

on bridging the digital divide, ICT for development (ICT4D), and their concomitant supply-side approaches mainly suggested by international donors, and private-sector and development agencies. Often these engagements have not clarified Africa's vision for technology-enhanced learning beyond the setting of numerical targets for universal access and ICT literacy; neither have they been integrated within debates on achieving development goals beyond the narrow scope of digital-divide issues. Indeed, ICTs offer the potential for substantial improvement in education access and delivery, particularly in a developing-economy context. However, there remain obstacles of a systemic nature that militate against the realization of this potential. This systemic context is influenced by a parallel Northern-led discourse on bridging the digital divide on the one hand, and, in contradiction, an imposing framework of globalization that continues to foster social exclusion on the other hand.

This chapter critically discusses Africa's experiences with ICT for education (ICT4E) initiatives in current schooling systems. Because the author has been intimately involved in the African SchoolNet movement, there is a strong bias regarding this experience over the past 10 years. The chapter treats examples of the successful application of ICTs in African schools and their actual and potential developmental spin-offs with caution and warns of the disconnection with glaring social, infrastructural, economic, and political realities that militate against further system-wide success. The chapter further provides perspectives on future potential trends in ICT for education in African schools and concludes with proposals for Africa to proceed far more ambitiously in its drive to make the next century a truly African century.¹

CONTEXT

The global context within which ICTs enhance and support education systems in the developing

world is influenced by complex global, economic, political, and social forces that are intertwined with rapid technological innovation and diffusion. The emergence of globalization, shifts in learning and education paradigms, and shifts toward neoliberal economic-policy frameworks to support education delivery combine as powerful contextual influencing factors that affect the way in which ICTs have been adopted and diffused to support learning, teaching, and education systems in Africa.

Globalization and the Digital Divide

A general consensus prevails, albeit not unchallenged, that the world economy is in transition toward a global knowledge-based society that has been profoundly influenced by economic, social, political, and cultural globalization over the past three decades. It is widely believed that the rapid growth and impact of digital technologies have created the impetus for globalization and fueled exponential growth in society's ability to produce, consume, exchange, and distribute information and knowledge.

Castells (1999) asserts that new ICTs are at the root of new productivity sources, new organizational forms, and the construction of a global economy where brain power is seen as a prime resource and an increasingly dominant source of trade and global competitive advantage. Mansell and Wehn (1998) suggest that the term knowledge society has been coined to shift the emphasis from ICTs as determinants or drivers of change to technologies designed and implemented by people within their social, economic, and technological contexts. The rapid growth, innovation, and diffusion of ICTs takes place within existing uneven, embedded social relations, and a number of processes within the ICT sector contribute to continued disparities in the global distribution of wealth and economic power.

The digital divide is a broad allusion to the skewed distribution in the production, access, and

consumption of ICTs as mechanisms for social and economic development between and within countries. The concept also incorporates disparities in skill levels in the production and consumption of ICTs, literacy levels in the use of ICTs, varying constraints in enabling environments to promote ICT access and use, and the disparities in digital local content, particularly in countries with diverse multilingual communities. Hewitt de Alcantara (2001) correctly asserts that the digital divide is a function of existing development and socioeconomic divides, and within the digital divide itself, there are further manifestations of social imbalances biased against people in non-Latin language groups, rural communities, and girls and women. Hafkin and Taggart (2001) demonstrate how the digital divide is also a gender divide through extensive differential access, use, and production of digital technologies between girls and women in comparison with boys and men.

Shifts in Learning Paradigms

The transition toward a global knowledge-based economy has also coincided with a paradigm shift in learning and education systems. Information competencies and knowledge-society attributes are increasingly important requisites for participation in the knowledge economy, and education systems globally have begun to restructure to accommodate these requirements. The shift in learning and education systems is manifest in the growth of computer science as a school-based subject, the reform of curricula to suit the needs

of a developing knowledge-based economy, and the application and integration of ICTs in learning and teaching practice as well as the growing predominance of learner-centred, self-directed, social constructivist learning philosophies. The shift from traditional pedagogy premised on the transfer of knowledge by the teacher, didactic methods, and rote learning to outcomes-based, learner-centred, facilitative learning takes place both independently and under the influence of the growing application of ICTs. These changes are partly due to the development of ICTs and their specialized functionality in facilitating networking and collaborative learning, knowledge sharing, and interactive learning. ICTs are purported to support new ways of learning, provide lower costs for the delivery of education, facilitate flexibility in learning with diverse learner populations, and allow access to vast quantities of education resources. These are the much-vaunted advantages of e-learning or technology-enhanced learning that usher in new learning paradigms. Haddad and Draxler (2002) capture succinctly the way in which the paradigm shift would affect schooling in particular, illustrated in Table 1.

Neoliberalism and the Education Sector

There is also a widely held and contentious view that the predominance of macroeconomic policies premised on neoliberal economic principles have profoundly affected public-goods sectors like the education sector on a global scale. Neoliberalism is

Table 1. The new schooling paradigm (Source: Haddad & Draxler, 2002, p. 8)

From	To
A school building	A knowledge infrastructure (schools, labs, radio, television, Internet museums...)
Classrooms	Individual learners
A teacher (as provider of knowledge)	A teacher (as a tutor and facilitator)
A set of textbooks and some audiovisual aids	Multimedia materials (print, audio, video, digital ...)

an extension of the free-market economic framework propounded by Adam Smith with reference to the efficacy of market mechanisms to regulate economies. The framework promotes reduced state involvement in the economy, thereby allowing greater leeway for market regulation. Since the 1980s, there has been a notable shift away from Keynesian macroeconomic policy frameworks that promote state ownership of public-goods sectors and state welfare programs toward liberalized market economies that have also been a lynchpin of globalization. The effects on classical public-goods sectors like health, education, and indeed telecommunications cannot be ignored. Globally, governments have embarked on cuts in spending on education for programs to privatize public education and promote the increasing involvement of private companies in existent public-education institutions. The growth of private universities, schools, colleges, and even private preschools across the world as well as the availability of learning products and services by a growing number of private companies, particularly in the educational technology sector, are manifestations of this. Klein (2001) talks of the “branding of learning” with reference to the interventionist role of private corporations in education institutions in the USA and Canada, which are increasingly becoming manifest in the developing world and in Africa as well. In demonstrating the corporatization of education, she says that the corporations “are fighting for their brands to become, not the add-on but the subject of education, not the elective but the core curriculum” (p. 89). She explains that private corporations have been allowed to let their branding interventions in schools largely because schools are “starved of new sources of income” (p. 95), but that school governing bodies have also attempted to impose limits on corporate intervention, especially if they threaten to affect the educational activities in the school.

Additional features of the neoliberal economic paradigm include the progressive liberalization of trade since the 1980s and early 1990s as

expounded by the World Trade Organization’s General Agreement on Trade and Tariffs, which now includes the General Agreement on Trade in Services (GATS). GATS also includes trade in education services. Daniel, Kanwar, and Uvalic-Trumbic (2005) note the effect of the GATS on cross-border higher education, and they reference two of the four modes of trade in the GATS that allude to cross-border supply and commercial presence as the most contentious in view of their effects on developing countries. Daniel et al. provide three examples of experiences in India, Jamaica, and Sierra Leone in demonstrating how huge unsatisfied demand calls for the expansion of access, how for-profit cross-border providers are active, and how these providers are of low quality despite the high costs of their offerings.

The flexibility of the global labor market, including the global teaching profession that encourages greater mobility of teachers, particularly from the South to the North, is another salient feature of the global economic system. Analysts have written about the “brain drain” in Africa and the developing world with reference particularly to Africa losing numbers of qualified and skilled teachers. The decline in government expenditure on social services, privatization, and the sale of public goods, including in the education sector, are further manifestations of a trend toward a liberalized global markets. The social implications of these policies globally are profound. Fiscal constraints in education have influenced job losses among teachers, downward pressure on salaries of teachers, and a stratification of education access rendering formal education increasingly out of the reach of poorer communities. In Africa, these developments are pivotal in influencing the extent to which new learning paradigms via technology-enhanced learning can make significant inroads in improving education systems and reaching larger numbers of African youth and teachers.

DEFINING THE DEVELOPMENT CHALLENGE

Governments have globally been challenged with meeting the growing demand for the delivery of affordable education services to its populace. Compared to global trends, African education lags behind dramatically with weak physical and institutional bases, the effects of natural and human-made disasters and conflicts having placed extreme pressure on African education systems. Many countries in Africa have also been victims of austere structural-adjustment programs that led to cuts in educational expenditure. Together with increasing debt burdens, problems with governance and democracy, the challenges imposed by globalization, and the devastating impact of HIV/AIDS, the basic human right of access to education has been denied to many (Addo, Butcher, & Isaacs, 2002).

Current debates also point to the need to look beyond the achievement of universal primary education to address the need for increasing enrollment and retention in secondary education. The latter is considered important for the socialization of young people and for their preparation to participate in the labor market. However, the achievement of universal primary education alone is a mammoth task. It is estimated that approximately 50% of youth of school-going age in Africa are not in school. According to the United Nations Development Program (UNDP) Human Report Office (2005), there is an estimated 43 million youth not in the formal school system in sub-Saharan Africa, of which an estimated 50% are girls. These categories of youth not in school are mainly child ex-combatants, "street kids," nomadic children, and child laborers.

In 2002, in 19 out of 44 African countries, more than half of all children did not complete primary education (United Nations Educational, Scientific, and Cultural Organization [UNESCO], 2005). HIV/AIDS, disability, conflict, and child-labor practices put millions of children at an extreme

disadvantage. In sub-Saharan Africa, more than 11 million children under the age of 15 have lost at least one parent to HIV/AIDS. Their opportunities to learn are seriously obstructed by the need to care for sick family members or contribute to household income (UNESCO, 2004).

The African region has a gross enrollment ratio in secondary schools of less than 40%, which is the lowest in the world despite the fact that the number of pupils has grown by 5.3% in from 1998 to 2002 compared to 4.4% growth in from 1990 to 1995. This low rate can be explained by the fact that an estimated 58% of children live in countries in Africa where lower secondary education is not compulsory (UNESCO, 2005).

Moreover, the quality of education is seriously undermined by a shortage of teacher supply globally, which is more acute in Africa. Shortcomings in the teacher professional development system, poor wages for teachers, and the recruitment of African teachers by developed economies are contributing factors. Above all, the HIV/AIDS pandemic appears to be eroding the teacher population dramatically. Recent figures from a World Bank report indicate the "HIV/AIDS kills teachers faster than they can be trained, makes orphans of students, and threatens to derail efforts by highly-infected countries to get all boys and girls into primary school by 2015."² That women constitute the majority of the teacher population in most countries also points to the gender disparities within this debilitating crisis.

This report quotes figures that illustrate a disturbing trend. For example, in the Central African Republic, 85% of teachers who died between 1996 and 1998 were HIV positive. In Zambia, 1,300 teachers died in the first 10 months of 1998 compared with 680 teachers in 1996.

HIV/AIDS will rewrite the teacher supply and demand equations on current projections. The implications are as yet poorly understood but evidently very extensive. New systems of training and deployment are likely to be needed to meet this challenge. Whilst this issue is outside

the scope of this essay, the devastating effects of the HIV/AIDS pandemic on education systems in Africa is crucial in absolute terms when considering the facilitative role ICTs can play. Acevedo (2005) expands on various ways in which ICTs can be applied in the design of development programs including in health and education that can support strategies to combat the devastating effects of the HIV/AIDS pandemic. The Mindset Network³ in South Africa, with its dedicated multimedia HIV/AIDS channel, is one example of the effective use of ICTs in sensitization and awareness raising for issues of prevention and treatment of the disease.

The Digital Divide has an African Face

The digital divide has its most extreme expression in Africa. Jensen (2002) states that of Africa's total population of 816 million in 2001, it is estimated that:

- 1 in 4 had a radio (200 million)
- 1 in 13 had a TV (162 million)
- 1 in 35 had a mobile phone (24 million)
- 1 in 39 had a fixed line (21 million)
- 1 in 130 had a PC (personal computer; 5.9 million)
- 1 in 160 use the Internet (5 million)
- 1 in 400 have pay TV (2 million)

These figures, he emphasizes, do not take account of the widespread sharing of resources. For instance, a whole village may use a phone line. Jensen explains that the general low level of economic activity means that technology is often unaffordable. Many African countries still have irregular or nonexistent electricity supplies, which makes ICT use problematic. Rail, road, and air transport is limited, and this infrastructure is needed to implement and support ICT infrastructure, as well as the increased social and economic activity that this technology should stimulate.

Many tax regimes define computers and cellular phones as luxury items. This adds to the price of these goods, the vast majority of which must be imported, thus making the technology even more unaffordable for most people. In addition, as noted above, the lack of skills together with the problem of the brain drain also makes widespread adoption of new technology difficult. All of the above issues are further complicated by a business climate that does not always encourage investment in Africa in ways that benefit the continent (Addo et al., 2002).

The digital divide in primary and secondary education is evident from the disparities in PC penetration in schools. It is estimated that the PC-to-student ratio in OECD (Organization for Economic Cooperation and Development) countries averages about 1:10 at the lower end and 1:5 at the higher end of the spectrum, according to a recent survey (OECD, 2005). In contrast, a country like Mozambique has 7,000 schools, of which in 2006, 80 schools had PCs, making the average PC-to-student ratio 1:630. Table 2 gives a general picture of PC access in African schools based on fieldwork guesstimates of the author in the absence of readily available accurate data. Hopefully, in the coming period, more accurate data will become available as increasing numbers of government ministries adopt comprehensive education-management and information-system programs. For now, the guesstimates in Table 2 will have to suffice.

Of these countries, Egypt has the highest percentage of computers in schools at 100%. The Egyptian Ministry of Education reports that each primary school has at least one multimedia lab with one PC, and each preparatory and secondary school has a computer lab of at least 10 PCs. This contrasts with the more economically developed South Africa, where only 6,000 schools currently have access to computers out of a total of 28,000. Howell and Lundall (2000) note the following factors in the South African context (but relevant generally, too) that prevent schools from using computers for teaching and learning:

Table 2. Computer penetration ratios at schools in selected African countries (2006)

Country	Number of schools	Schools with computers	Percentage of schools with computers
Egypt	26,000	26,000	100%*
Ghana	32,000	800	2.5%
Mozambique	7,000	80	1.1%
Namibia	1,580	350	22.1%
South Africa	28,000	6,000	21.4%

- Insufficient funds
- Insufficient numbers of computers
- Lack of computer literacy among teachers
- Lack of subject teachers trained to integrate computers into learning areas
- The absence of a properly developed curriculum for teaching computer skills

While a number of inroads have been made since 2000 in South Africa, including dedicated rollout programs in various provinces and an e-education white paper, these factors remain as key obstacles in the achievement of universal access to ICTs in South African schools.

In addition, many of those schools that do have computers still do not have access to the Internet due to the exorbitant cost of bandwidth. The Internet can provide a wealth of learning resources that many African schools at present are not yet able to access because the costs of Internet access are prohibitive. In South Africa, of the estimated 6,000 schools that have access to PCs, only an estimated 2,500 have Internet access. The main obstacles faced by African schools with respect to Internet access specifically are the following:

- Lack of infrastructure generally and network infrastructure in particular
- High telephone and Internet costs
- Limited expertise and ICT skill levels
- Lack of enabling policy environment (Isaacs, 2002a)

The main barriers to ICT access in general relate to the small number of computers relative to the large numbers of teachers and students per school, the high cost of Internet access, and a dearth of technical skills to assist with troubleshooting and maintenance when computers break down. Notably, within this digital divide, greater gender disparities exist. Research of the experience in Africa shows that girls are further limited from school computer laboratories in some countries. A study commissioned by World Links for Development found that, in reality, it is harder for girls to access computer laboratories, particularly in Uganda and Ghana, especially after school hours (Gadio, 2001). These findings have been corroborated by Derbyshire (2003) and Isaacs (2002b).

The above is not a comprehensive overview, yet it succinctly captures the nature of the development challenge in African education.

AFRICAN FRAMEWORKS TO ACHIEVING QUALITY EDUCATION THROUGH ICTS

Already in 1948, education as a fundamental human right was proclaimed in the Universal Declaration of Human Rights. In an attempt to describe a vision for educational achievement in Africa, the international development community established the millennium development goals⁴

ICT-Enabled Education in Africa

(MDGs) in 2001. The goals related to education follow:

Goal 2: Achieve universal primary education

Target 3: Ensure that, by 2015, children everywhere, boys and girls alike, will be able to complete a full course of primary schooling

Goal 3: Promote gender equity and empower women

Target 4: Eliminate gender disparity in primary and secondary education, preferably by 2005, and to all levels of education no later than 2015.

(UN General Assembly Resolution A/56/326, September 6, 2001)

The details of the MDGs have their roots in the Dakar Framework of the World Education Forum. The Dakar Framework for Action set six “education for all” goals, which include the following:

- Expanding and improving comprehensive early childhood care and education, especially for the most vulnerable and disadvantaged children
- Ensuring that by 2015 all children, particularly girls, children in difficult circumstances and those belonging to ethnic minorities have access to and complete free and compulsory primary education of good quality
- Ensuring that the learning needs of all young people and adults are met through equitable access to appropriate learning and life skills programmes
- Achieving a 50% improvement in levels of adult literacy by 2015, especially for women, and equitable access to basic and continuing education for all adults
- Eliminating gender disparities in primary and secondary education by 2005, and achieving gender equality in education by 2015, with a focus on ensuring girls’ full and equal access to and achievement in basic education of good quality

- Improving all aspects of the quality of education and ensuring excellence of all so that recognized and measurable learning outcomes are achieved by all, especially in literacy, numeracy and essential life skills. (UNESCO, 2000)

However, educationists have criticized the MDGs and EFA for their lack of sufficient reference to education quality. Whilst it is an issue of much debate informed by varying philosophies and traditions of educational thought, it appears that a broad, standard definition as defined by UNESCO is for now generally accepted. Here, the definition of quality in education identifies the cognitive development of learners as the major explicit objective of all education systems. The role of education is to promote values and an attitude of responsible citizenship, and to nurture creative and emotional development (UNESCO, 2004). There is commonality in this definition with international legislation on quality such as the Convention on the Rights of the Child (1990) and the International Covenant on Economic, Social, and Cultural Rights.

From ISAD to NEPAD

However, the disconnection appears in clarifying the vision for technology-enhanced learning within a development context and linking such a vision to that espoused by the EFA, the MDGs, and related international conventions. Yet, in the many initiatives established to bridge the digital divide in Africa, almost all make reference to the importance of education in the context of developing an African response to the knowledge society. The historic Information Society and Development (ISAD) conference held in South Africa in 1996 officially introduced the African development community to the potential of ICTs. ISAD was a launching pad for the African Information Society Initiative (AISI), a framework that established the African mandate to use ICTs to

accelerate economic and social development. The AISI called for the creation of an African Learning Network that would comprise three pillars: the VarsityNet at the tertiary level, the OOSYNET for out-of-school youth, and the SchoolNet Africa.⁵ Since then, both the global and regional environment promoting ICT4D have grown. The New Partnership for Africa's Development (NEPAD), which represents a strategy for Africa's economic, social, and political renewal led by African heads of state, established an eSchools Program in 2002. One of its leading spokespersons announced that the vision of NEPAD eSchools is for every African secondary-school graduate to be ICT literate by 2014.⁶

Dearth of Evidence-Based Research

There is extensive literature on the experiences with the adoption and diffusion of ICTs in schools in both developed and developing economies in general. Usually, African economies are included in the general references to developing economies. However, it is widely known that many African economies are significantly poorer, with more than 40 referred to as the least developed countries and the highly indebted poor countries by the World Bank. The available literature on African experiences with ICTs in schools is limited mainly to desktop reviews with a dearth of evidence-based research that is premised on actual fieldwork reflective of the diversity of the continent. Within the limited research available, there is a substantial body of knowledge on the South African experience, and with this, the danger of extrapolating South African experiences as representative of the rest of the continent. There is also a very strong Anglophone bias in existing literature on ICTs in education in Africa with very little, if any, references to experiences in Francophone, Arabic, and Lusophone regions of Africa. A study of SchoolNets in nine African countries conducted by the IDRC (International Development Research Centre) in 1999, which also includes a French re-

port on the experiences in Senegal, represent one of the few field-based research works conducted by African researchers (James, 2004). Given the research limitations, perhaps this explains what appears to be a disconnection between general scholarly debates on development and education in Africa and policy and practitioner-based discussions at conferences on ICT for education. Hewitt de Alcantara (2001) correctly asserts that often the realities of the broader developmental challenges are not considered when addressing digital-divide issues, which are a function of the limitation with which notions of the digital divide have been conceptualized.

Debating the Benefits of ICTs for Education in Africa

Given the knowledge-production limitations with reference to Africa, the existing literature demonstrates increasing recognition of the developmental and educational benefits of introducing ICTs to schools (Alvarez et al., 1998; Byron & Gagliardi, 1998; Haddad & Draxler, 2002; World Bank, 2002). Some of these benefits include the following:

- ICTs can enhance education access and hence offer the potential for supporting the attainment of the Education for All goals. In places where books and qualified teachers are scarce, ICTs can provide access to vast quality educational resources and can facilitate the delivery of educational resources to large numbers of educators and learners relatively easily and cheaply. Importantly, though, access to educational resources should not be confused with automatic access to learning capability.
- ICTs enable access to networks of local and global learning and teaching communities, thereby facilitating collaborative learning.
- ICTs can enhance the quality of learning and teaching by offering new and different

learning opportunities through synchronous and asynchronous communication.

- ICTs support learner-centred, individualized, self-directed learning.

According to the African SchoolNet tool kit, ICTs also enable the development of knowledge-society attributes in students such as higher order thinking skills, lifelong learning habits, and the ability to think critically, communicate and collaborate, and access, evaluate, and synthesize information. They allow for the development of ICT skills and competencies in students as preparation for operating in an ICT-rich workplace and society, and they have the potential to address structural problems and deficits in education systems, such as using ICTs to enhance administrative and teaching efficiency; alleviate underresourcing in specific areas (e.g., a lack of textbooks or learning support materials); address equity issues through enabling equality of access to knowledge, resources, and expertise; or support teachers who may be underequipped to deal with new teaching challenges (SchoolNet Africa & the Commonwealth of Learning, 2005).

Some have challenged the approach to the application of ICTs in education in Africa. Enslin, Lelliot, and Pendlebury (2000) contend that globalization, the learning society, and their related interconnected ideas on productivity, change, lifelong learning, and the learning organization have been theorized and conceptualized based on experiences and development in developed economies. They suggest that these concepts have a very different purchase in Africa and the way in which these ideas are currently theorized tend to distort our understanding. For them, patterns of educational provision, styles of teaching and learning, patterns of inclusion and exclusion, and empowerment and disempowerment in Africa have differed from those of Europe and North America. They argue that access to ICT brings on new forms of exclusion and risks that make stern demands on distributive justice because they

represent an opportunity cost for money not spent on food, shelter, and basic education.

They refer to a gung ho approach to ICTs in education that offers simplistic truths in a populist fashion, and suggest that the promise held by ICTs for the benefit of education and social change are false and misleading. They do not provide a concrete demonstration of these “truths,” however. They also refer to the very notion of learning as being undertheorized in some of these pivotal concepts and suggest that those who espouse the advantages of ICTs for education and social change do so from the perspective of developed economies where basic levels of education have already been universally achieved.

In education, they say that in practice, the claims on ICTs are neither strong nor self-evident: They offer superficially simple solutions to complex economic, education, and political challenges.

For them, ICTs are overspecified in terms of their technological sophistication. ICT programs have not considered local knowledge production or the functionality of education institutions, and concerns about the way political, social, and individual interests are differently served by different patterns of deploying technology in schools and institutions have not been considered.

Whilst this essay may share some of these concerns, it also proposes that Enslin et al.’s (2002) observations are insufficiently substantiated and outdated, and they have not researched the successes within African education adequately to justify such a pessimistic view. Evidently, no reference is made to any of the experiences of African SchoolNets and related organizations in any of the African countries in Enslin et al.’s paper.

Indeed, with the limited experience and codified knowledge of African interventions on ICTs in primary and secondary education under conditions of severe educational deprivation, one has to treat the potential of ICTs with caution. This is important also in considering the vastness and

diversity of the African continent and the varying local education contexts and abilities for the adoption and diffusion of ICTs in their education systems. Moreover, whilst ICTs may have potential for educational inclusion of Africa's youth, they may create new forms of exclusion. Some still believe that ICTs represent an opportunity cost compared to spending on more basic requirements such as teacher salaries and school infrastructure.

The fundamental question with reference to the developmental potential of ICTs remains thus: How can ICTs contribute toward the achievement of the educational vision to attain universal quality education under conditions of extreme educational deprivation? In the absence of a coherent African vision and strategy on ICT-enabled education in general and in formal primary and secondary education in particular, this question can only be answered based on what has been tried.

SCHOOL NETWORKING IN AFRICA

A number of African governments who subscribe to the UN system have developed EFA plans and strategies to attain the MDGs. Where reports of these are available, including the Global Monitoring Reports of UNESCO, very little, if any, is mentioned of progress made in the use of ICTs. In spite of this, however, even though they are not clearly linked to the attainment of EFA and the MDGs, various initiatives to promote ICTs in African schools have emerged over the past decade; chief amongst these are SchoolNets.

The African SchoolNet tool kit describes SchoolNets as country-level programs that operate at the interface between education and ICTs. SchoolNets promote the development of knowledge societies by connecting schools to the Internet; building connections among learners, teachers, and schools; sharing information and resources; and supporting e-learning in online networked environments. In Africa, up to 33 countries

have some form of SchoolNet process under way, all of whom participate in an umbrella network called SchoolNet Africa⁷ and related regional and international education networks. They assume various organizational forms—from government agencies located in ministries of education to nongovernment organizations—and they vary in size and scope of intervention depending on resource availability and local conditions.

Foremost among the concerns of SchoolNets is the promotion of universal access to ICTs in schools as a crucial starting point for the involvement of learners and teachers in ICT-supported learning opportunities. Here, access to infrastructure including electricity, telecommunications, and PCs are important prerequisites. Because most SchoolNets in Africa are products of donor and development-agency funding support, their interventions to achieve system-wide networked access to ICTs in schools have been extremely limited. At most, the total number of schools reached in Africa is estimated at 27,000 mostly secondary schools out of a total estimate of 600,000 schools on the continent. The majority of these schools are located in South Africa and Egypt, leaving an estimated 2,000 schools reached for the rest of Africa. Here, schools reached refer mainly to the existence of at least one PC lab consisting of at least 10 PCs. The PC-to-student ratios referred to earlier on are very high as a result (Isaacs, 2005a). As stated above as well, these do not always refer to PCs networked to the Internet.

Over the years, the African SchoolNet movement has revealed the fact that physical access to ICTs alone does not translate into enhanced educational outcomes, and that a number of related activities need to be established in order for a technology-enhanced learning system to work effectively at both the micro and macro levels. These include the following:

- The development of extensive technical-support capacity

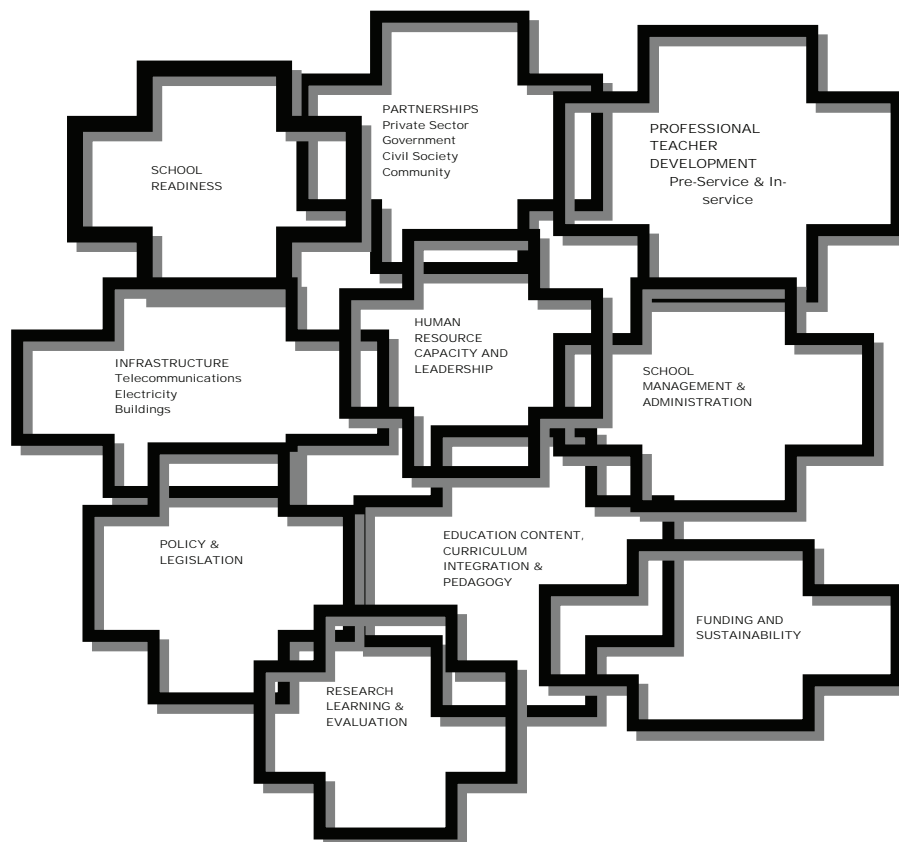

ICT-Enabled Education in Africa

- The professional development of teachers to be able to use ICTs as a learning-support tool
- The availability of appropriate digital education content and integration into school curriculum
- The availability of sustainable income streams to maintain the ICT infrastructure
- The establishment of monitoring and evaluation mechanisms for ongoing improvement
- The existence of an enabling policy environment that promotes access and use of ICTs in education

Given strong gender, rural-urban, and linguistic biases, conscious effort is also required to integrate these dimensions in a holistic approach to learning through the use of ICTs. These activities are depicted more clearly in a SchoolNet Value Chain, which was eventually established to encourage an integrated approach to the use of ICTs in African schools (SchoolNet Africa & the Commonwealth of Learning, 2005). The SchoolNet value chain is graphically depicted in Figure 1.

Importantly, too, the integration of ICTs in the learning process in the formal school system needs to be linked to their integration in the rest of the education pipeline to ensure continuity. This should include a strategy for ICT integration

Figure 1. The SchoolNet Value Chain

at the adult-basic, tertiary, and further education levels. Perhaps most importantly the connection of such a strategy to an overall macroeconomic plan geared toward the creation and development of a knowledge-based labor market to absorb and retain entrants flowing from the education sector is a crucial determinant of success. Few countries in Africa have adopted this holistic approach, albeit only at a policy level. These include Namibia, Botswana, Ghana, and South Africa. However, in practice, at the behest of the enormity of the development challenges, implementation has been very limited.

The current scale of intervention on ICTs in African schools is insignificant for any resounding widespread educational and developmental impact systemically. The scale varies from country to country, particularly when some countries like Namibia and Botswana have scales to their advantage given the lower school population relative to larger countries. However, within the confines of the limited scale of operations, considerable gains have been made in the promotion of online learning and the development of the knowledge-society attributes described above, which warrants serious consideration for further large-scale systemic interventions.

The main issues, successes, and challenges of some of the African SchoolNet organizations are documented elsewhere (Isaacs, 2004, 2005a, 2005b; James, 2004; SchoolNet Africa & the Commonwealth of Learning, 2005; SchoolNet South Africa, 2002).

Lessons Learned

One of the first lessons learned was that the attainment of universal access to ICTs needs to be part of an integrated strategy that considers the following:

- Subsidized rates for Internet access (called e-rates) to schools

- The use of both second-hand, refurbished PCs and new PCs
- The use of a range of ICTs not only confined to PCs, but that includes handheld devices such as cell phones, televisions, video, radio and print media
- The reduction of tariffs on imported ICTs designated for schools
- The use of free and open-source software and/or significantly subsidized proprietary software
- The establishment of effective technical support systems involving learners and teachers at a school level as well as technical service centres that provide education solutions to the school at least at the provincial and national levels
- The involvement of both school and non-school communities to support cost recovery
- Multistakeholder partnerships with the private sector, NGOs, community organizations, and government agencies at local and national levels

Almost all of these issues, with reference to sustainable ICT access alone, have been contentious and furiously debated within the network of practitioners and policymakers in Africa. On a small scale, various successful and sustainable models have been established such as that of the eSchools Network in South Africa, SchoolNet Namibia, SchoolNet Nigeria, and Computers for Schools Kenya (Isaacs, 2005a, 2005b).

It is argued that the SchoolNet movement (which includes those linked to the World Links program) has been technology-centred in its approach to ICT-enabled education in schools, and that less consideration has been given to the learning aspect of the technologies, and more importantly, their integration into improving the social systems at the school level. There is truth in this concern because the attempt at using ICTs

in the first place resulted in a preoccupation with issues of technology access, without which there can be no integration of any kind. Within this, the quest for workable technology solutions that were low cost and affordable, and which had the support of the major stakeholders, was an uphill battle that also required considerable learning over time. It would be myopic to suggest that these models can automatically be replicated and extended on a wide scale. However, within them lie ingredients of successful technology solutions for Africa that can be considered in the development and implementation of system-wide strategies.

The second major lesson is that teacher professional development, particularly in terms of ICT literacy and the use of ICTs to support learning, is central to their effective use in the learning process in schools. In practice, there have been many and varied teacher training programs (see research paper by SchoolNet Africa on teacher training, 2004) that focus both on ICT literacy as well as ICT use in learning and teaching. Again, the scale with which teacher training has taken place is extremely minimal. Here, African-owned models such as the Educator Development Network of SchoolNet South Africa, which is also available in French and Portuguese as well, and the pan-African and global teacher networks such as the African Teachers Network of SchoolNet Africa are examples of successful strides made in this arena. However, teacher training in many ways has also developed in a relative vacuum with limited consideration to the social and economic conditions of teachers. One example that stands out here is the dire lack of integration with the effects of the HIV/AIDS pandemic on the lives of teachers and learners and their professional development to use ICTs to enable learning (Isaacs, 2005d).

The third major lesson is that whilst content is king, more important are the learning strategies devised to ensure the educational use of the content. With reference to education content, however, there is a plethora of available cur-

riculum-based content, mainly in English, that have been produced in the developed economies. Notably too, a growing movement toward open education resources that make digital learning resources such as lesson plans, courseware, and so forth freely available on the Internet for use, reuse, sharing, and adaptation is a welcoming trend in e-learning globally. Indeed, it fosters an underlying principle of learning through sharing and highlights greater potential for access to learning resources for poor communities. Daniel (2005b) correctly highlights the accessibility, appropriateness, accreditation, and affordability of open education resources. An important lesson is that strategies that focus on the adaptation of content produced elsewhere together with strategies on the production and consumption of local curriculum content is an essential ingredient for the successful use in schools. Examples of content adaptation are the ways agencies in Kenya are adapting the curriculum content developed by Learnthings, which is based on the curriculum in the United Kingdom. The Thutong Portal, Mindset Learn in South Africa, and CurriculumNet in Uganda are examples of good practice in the development of local, digitized curriculum content on multimedia platforms coupled with strategies for learners and educators to use the resources. However, a few issues require considerable development and learning. These include a coherent approach on the use of local, indigenous languages in the development and use of education content and the need for policies on open education resource content and creative commons licensing. Given the critical discussion on education quality earlier on, it is also evident that processes of quality assurance and assessment in many existing content-related programs remain extremely limited.

What about the Learners?

Because much of the literature focuses more on the school and SchoolNets as units of analyses and less on the perspective of learners, one of

SchoolNet Africa's learner-based SchoolNet projects is discussed here: ThinkQuest Africa (TQA) typifies interventions that specifically aim to develop knowledge-society attributes among learners.

TQA (more recently called the Mtandao Afrika program)⁸ is a learner-centred educational contest based on an award system that promotes learning through the collaborative development of educational Web sites by teams of learners from different African countries, supported by teacher coaches. The process of involvement includes the selection of the team members, communicating with them over the Internet, the selection of the research topic, conducting research, and the technical development and design of the Web site. These activities require competencies in cross-cultural communication, planning, and Web design and Web-site development. One of the main objectives of the program is to encourage African learners to be producers of local knowledge through the production of African education content. A special award is presented to teams who also focus on the development of content in local, indigenous African languages. This Africanised approach to the ThinkQuest program was very important at the outset given that it was integrally linked to an international program, ThinkQuest Internet Challenge, which originated as a program in the USA in 1996, and which increasingly gained international recognition over the years. TQA as the African chapter of the contest was also designed to encourage more African participation in the program.

The program has been criticized for its focus as an Internet-based program that excludes the vast majority of African learners, thereby reinforcing the notion of new forms of exclusion espoused by Enslin et al. (2002). That it also assumes the form of a contest was cause for concern because it meant that some learners would be winners and others would be losers. Also, the program applied an elitist model of learning relative to a mass model that may be more relevant in an

African context. The program also laid claim to the production of education content although the quality-assurance process was reduced to the subjective considerations of the judges in the contest. With these criticisms in mind, SchoolNet Africa commissioned a study to determine the learning value of the program for African learners. The study conducted by Broekman (2002) asked the following important questions. What are African learners' experiences of participation in the ThinkQuest competition? What do they feel they have learned and what do learners believe they have contributed to online learning?

Broekman found that the learning that happened was extensive for the learners interviewed, and it included changes in attitudes and skill development. For most coaches and learners in the study, the social learning experiences were particularly significant, such as cultural sensitivity, new social understandings, tolerance, communication, creativity, and agency in a way that goes beyond the dynamics of the classroom, and which is developed primarily through working within a team as equals but with diverse backgrounds across race, gender, culture, geographical divides, resource divides, and histories. The program competition and its prizes, the opportunity to travel and meet participants, were major motivating factors for participation in the program. The participants also saw the program as more than a competition, but an opportunity for learning, "for changing thinking, outreach, and for an investment in national as well as personal development" (Broekman, 2002, p. 3). She found that the criteria for judging the sites produced by the learners included redress, inclusivity, and outreach. Furthermore, the competition was designed to motivate students to excellence, hence intrinsically limiting participation, but it also has broad educational goals, which imply mass participation. She noted a tension, however, between the notion of elitism used in this study as providing awards to a few, and mass participation, where many are recognized for their efforts. Here, she suggests

that mass participation would require considerable scaling up of the program at significantly increased costs. She proffers suggestions on ways to render the program more conducive to mass participation such as focusing on marginalized groups of learners working around connected centres in various African countries. That there has been a low number of African entries in the international contest historically, suggests that the program appeals more to an elite few, but also that African learners can produce excellent Web sites. She also found that in the competition, learning is learner driven, though in other models Web-site production is more coach or teacher driven.

Importantly, both learners and coaches in disadvantaged areas reported a sense of satisfaction with competing successfully against the more advantaged, for example, doing well by using older technology. An assessment of the sites produced suggested that they “put Africa on the map” through the production of local content. The production of quality Web sites are a resource for a wide range of target users as teaching and leaning resources, indicated by the comments of visitors to sites.

With the benefit of hindsight, the TQA program developed over the past 3 years to the extent that it involved larger numbers of African participants each progressive year. In 2004, the contest involved 1,034 learners and teachers compared to 709 during the previous year. The challenges faced by the TQA program are typical of all SchoolNet programs in Africa. The challenges of converting this extracurricular program into a mass program are linked to the challenge for universal access to ICTs in general. In the absence of mass access to ICTs, any SchoolNet program can be misconstrued as exclusive and elitist. The reality in Africa is that even primary education is a privilege.

If the alternative is to discourage SchoolNet-type initiatives in the face of severe poverty, then this means that the limited numbers of learners and teachers reached by SchoolNet programs

would be denied the learning possibilities, albeit limited, presented by these programs. This cannot be an alternative.

Instead, the limited strides made in Africa need to be encouraged as attempts at an extension to and in support of universal access to primary and secondary education. Herein lies the challenge.

Drawing on experiences from the World Links for Development Program, Hawkins (2002) details 10 lessons for ICT and education in the developing world:

- Computer labs take time and money but they work
- Technical support cannot be overlooked
- Noncompetitive telecommunications infrastructure, policies, and regulations impede connectivity and sustainability
- Wireless technologies are usually more effective
- Get the community involved
- Private-public partnerships are essential
- ICT initiatives should be linked to broader education reforms
- Training is fundamental
- Technology empowers girls
- Technology motivates students and energizes classrooms

Hawkins’ study corroborates the findings of Broekman (2002) and the research conducted by James (2004).

FUTURE TRENDS

The disconnections referred to extensively above will in all probability prolong for a while. The perspective for the next few years suggest that more and more African countries will in all likelihood develop national policies on ICTs in education in particular. There will be more debates on the value-added issues relating to open content and quality assurance in technology-enhanced learn-

ing, which opens the way for more research that would direct policy and practice in these areas.

There is hope for an expansion of ICT-enabled education programs in African schools, particularly with the prospect of growth of the NEPAD eSchools initiative given its more direct linkages with education decision makers at the highest level and its focus on reaching the remotest schools in rural areas. Furthermore, the emergence of the Global eSchools and Communities Initiative established by the UN ICT Task Force over the past year, with its bias toward Africa, holds the promise of increased qualitative intervention in the promotion of learning and teaching in schools and their surrounding communities.

Furthermore, a number of African countries are also taking bold steps both in collaboration with and independently of the NEPAD and Global eSchools initiatives. Countries like Namibia, Botswana, and Rwanda are cases in point. However, the success of all of these initiatives depend on the rigor of the conceptual framework and implementation strategies with which issues of ICTs in primary and secondary education are programmed in Africa. Here, the importance of drawing on the accumulated learning of 10 years of experience in the African SchoolNet movement is imperative.

In addition, in order for African ICT-enabled programs to yield developmental benefit and tackle the dire crises that they face, a combination of factors identified by Marcelle (2005) in her appraisal of the experience in the Caribbean would be worth considering. She suggests that ICT planning processes need to incorporate a combination of factors for success, which include the following:

- Strategic thinking
- Creative leadership
- Policies that are developmental in their objectives and that put people first

- Emphasis on impact evaluation and continuous monitoring
- Building on existing strengths and assets and facilitating continuous learning in planning and implementation
- Focus on sustainability and institution building
- Effective engagement with the global ICT community

Marcelle (2005) also suggests that it has been shown theoretically and practically that the market alone cannot ensure optimal provision or equitable distribution of public goods. Planning has to take account of market failure. However, Daniel (2005a) indicates that public goods like education need not only be supplied by the state. Governments alone do not have the resources to meet growing demand for education and are compelled to draw in stakeholders in the supply and sourcing of the education system. Daniel states this challenge pithily: "In an era of lifelong learning, there is simply no way that governments can provide at no cost, all the education that people will need throughout life. Governments will have to focus their contributions" (Daniel, 2005b, http://www.col.org/speeches/JD_0602IFCDinner.htm). Education has become both a public and a private good, but the onus still lies with the state to provide the leadership in the involvement of private firms in education in ways that foster greater access and affordability.

There still remains a need for more sober-minded reflection that can be supported by more evidence-based research that takes cognizance of Africa's rich cultural and linguistic diversity, where knowledge production is the domain of local African researchers. Here, more work on the connections between the developmental realities, the educational challenges of reach and quality, and the role of ICTs is important, particularly from the perspective of the so called end users, that is, the learners.

CONCLUSION

The approach to ICTs for education in Africa has strongly been influenced by supply-side, external interventions. Often, this assumes the form of global funding becoming available or global institutions promoting the setup of projects in African countries with a predominantly Northern perspective on the South. Often, too, these initiatives assume the form of a given sum of money available for delivery within a short period of 3 years with limited strategy toward longer term sustainability. This causes problems systemically, some of which have been highlighted by this essay.

Linked to this approach has also been a predominant preoccupation with process issues and product development, and less with implementation and product use, perhaps because within a short time frame, process-related and product-development deliverables are less challenging than implementation-based deliverables. Here, the convention of numerous multistakeholder conferences, which, at huge costs, have often lent themselves to aggrandizement, rhetoric, and posturing with a conspicuous absence of follow-up action plans, have been a salient feature of the ICT4E and ICT4D sectors. It has been cynically implied that this sector is perhaps the most “conferenced” of sectors. Indeed, engagement in conceptual and practical issues among a community of practice and building networks that these conferences also achieve is important. However, the convention of practitioners and policy makers in a manner that adds concrete value to local implementation is potentially a more constructive way to utilize available resources.

Also, a number of global institutions would develop models, tool kits, portals, and such products with the expectation that they will be utilized in Africa, but with no investment in the active involvement, awareness raising, and training that would encourage local ownership, which in turn would facilitate better use of the products

in question. Above all, it can also be argued that so much investment is going into products and processes, but very few programs are taking seriously the attainment on a mass scale of access to the technologies. Without a strategy to attain universal access to ICTs by the mass of African youth and teachers, there can be no use of portals, tool kits, or e-learning models.

It is absolutely imperative that this paradigm shifts toward long-term, demand-led, locally owned and locally led systemic application that responds directly to local conditions and that can be converged with global processes. The establishment of SchoolNet Africa and later the NEPAD eSchools initiative have been attempts to promote models that foster this shift in paradigm. For example, SchoolNet Africa’s campaign for 1 million PCs for African schools has been one attempt at highlighting the importance of adopting a mass model that focuses on implementation.

Within this context, African leadership is unquestionably the lynchpin of success. Leadership that encourages the shift of current global supply-side approaches toward engagement and support of demand-led programs, leadership that fosters convergence of the myriad of parallel in-country projects toward coordinated investments of local resources and programs, leadership that redirects global investment and partnerships more toward mass implementation—this is perhaps the single most important ingredient in taking us one step closer to making this century the truly African century espoused by President Thabo Mbeki.

Acevedo-Ruiz, pp. 210-234, copyright 2007 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).

Section 3

Information Communication Technologies Tools and Technologies

This section presents extensive coverage of various ICT-related tools and technologies that researchers, practitioners, and students alike can implement in their daily lives. These chapters educate readers about fundamental tools such as the Internet and mobile technology, while also providing insight into new and upcoming technologies and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with countless examples of the tools and technologies essential to the field of ICT. In addition, the impact of these various tools, as well as the current issue of ensuring equal access to them, is discussed within this collection of chapters.

Chapter 3.1

Internet: A Right to Use and Access Information, or a Utopia?

Inban Naicker

University of KwaZulu-Natal, South Africa

ABSTRACT

This study examines the impact of the Internet on a student society by investigating the effective use of the Internet at tertiary education. The main objectives of the studies were to determine whether the Internet is being optimally utilized at tertiary education, and to evaluate the level of utilization of the Internet. The study also identified problems experienced by students. A convenience sample of 95 undergraduate students was used at the University of KwaZulu Natal (Westville campus) (only information systems and technology (IS&T) students were included in the study because they had access to computers). The researcher compiled a questionnaire to collect the data. The study revealed that the activity that students mostly used was e-mail systems. The majority of the students (81%) have indicated there are insufficient computers for proper Internet usage. Fifty-eight percent of the students still use the library to access information. Seventy-four percent of the students have indicated that the Internet is easy to use.

INTRODUCTION

The Internet has been in a state of rapid evolution since its beginning in the late 1960s, and is currently evolving and growing faster than ever (Botha, Bothma, & Geldenhuys, 2004). Already the Internet has had an effect on the people who do business, study people who interact with each other, and how people live. However, one can expect to see more changes as society moves deeper into the 21st century. Cheung and Heung (1999) state that universities across the world are expanding their investment in Internet technologies and are promoting Internet usage in education. The study carried out by them showed that Internet usage was having a positive impact on students. The Internet can be a valuable tool at universities.

However, students are not optimally utilizing the Internet to its fullest advantage. They are not always using the Internet for academic use, and do not spend enough productive time on the Internet. An example of where students are misappropriating the Internet is the illegal downloading of

music and games.

This study will therefore briefly discuss the Internet and the impact it has on available information for tertiary students. It also explains the research methodology on how the data was collected and handled and it will discuss the results as well. Finally, some recommendations will be made.

LITERATURE REVIEW

This article discusses what the Internet is, how it is used, and its implications for tertiary usage. Much like the Concord leaving the competition in its jet stream at twice the speed of sound, nothing else has come close to the growth experienced by the Internet—not the industrial revolution, not the electronics revolution, and not even the computer revolution (Bothma, 2000). Berkeley (2004) defines the Internet as a network of networks.

According to Berkeley (2004), the Internet is the transport vehicle for the information stored in files or documents on another computer. The Internet itself does not contain information but is a mechanism for information dissemination and a medium for collaboration and interaction between individuals and their computers without regard for geographic location (Singh, 2002). Content created on the Internet ranges from simple e-mail messages to sophisticated sites incorporating sounds, images, and words. The Internet is therefore arguably one of the most significant technological developments of the late 20th century (Jagbora, 2003).

HISTORY OF THE INTERNET

Botha et al. (2004) note that the first baby steps, which eventually lead to the Internet as we know it today, were taken in the early 1960s at the height of the Cold War. The U.S. government

was looking for a way to maintain communications in the event of a nuclear attack. A team of engineers formed the Advanced Research Project Agency (ARPA), a part of the U.S. Department of Defense, teamed up with Rand Corporation to develop a network that could be used with confidence. Although the military did not decide to use this approach, it provided the basis of the Internet (Botha et al., 2004).

ARPAnet initially connected major computers at the University of California at Los Angeles, the University of California at Santa Barbara, Stanford Research Institute, and the University of Utah (Macura, 2004). According to Hughes (1994), ARPAnet was an experimental network designed to support military research. The idea was that every computer on the network could talk, as a peer, with any other computer. This early network proved so successful that soon other computer sites located within universities, government, and large organizations began linking to this network. Furthermore, this form of communication and the type of information that was shared over this network was very computer-orientated and user friendly (Bothma, 2000).

The Internet Working Group (INWG) was the first body to take up this role under the leadership of Vinton Cerf (known as the father of the Internet). ARPAnet's original standard for communication, developed by Cerf and Bob Kahn, became known as the network control protocol (NCP). As time went by, the NCP was superseded by a higher level and more sophisticated standard, known as the transmission control protocol/internet protocol or the TCP/IP. All networks joined together became known as the Internet (Botha et al., 2004).

GROWTH OF THE INTERNET

Clark (2003) notes that the Internet is the fastest growing technology in the world. Current estimates indicate that over half the estimated 200

million Internet users are in the United States. South Africa was ranked 25th in the world in terms of Internet connectivity (Clark, 2003). According to Singh (2002), it has taken 7 years to reach a 25% market share, as opposed to the telephone that took 35 years, and the television that took 26 years. A report states that 414 million people had Internet access at the end of 2000 and predicts that figure will almost triple to 1.17 billion by 2005. About 730 million of those will be using wireless devices such as Web-enabled cell phones to go online. In countries with low Internet penetration, most wireless Internet devices will be the primary or only Internet access device (eTForecasts ..., 2001).

According to a survey undertaken by a Canadian newspaper (General social survey ..., 2001), the survey found that people who use the Internet tend to be younger, have higher incomes, and more education than those who don't. About 70% of individuals aged 25 to 29 used the Internet, compared with 61% of those aged 35 to 39, and only 13% of seniors aged 65 and over. Individuals with university education were much more likely to use the Internet than those with less than a high school diploma. Among individuals 20 or older, 13% of those with less than a high school diploma used the Internet, compared with 79% with University education.

As far as South Africa is concerned, a recent study undertaken by Arthur Goldstuck and Cathy Stadler of Acuity Media Africa cited by Bothma (2000), revealed that the number of Internet users in South Africa, rated within the top 30 Internet user countries in the world, is estimated to be 1.2 million, expected to rise to 2 million by 2000.

SERVICES ON THE INTERNET

World Wide Web

The Web was created at CERN, Switzerland's nuclear research facility, by Tim Berners-Lee in

1989 (Bothma, 2000). He states that the term Web was coined by Berners-Lee in 1990 to describe information spanning the planet like a giant spider's Web, with threads linking knowledge and information from all over the globe, making it available to a worldwide audience. According to the article, the Web was originally conceived and developed to meet the demand for automatic information sharing between scientists working in different universities all over the world (What about CERN's ..., 2002). Hughes (1994) states that the initial project proposal outlined a simple system of using networked hypertext to transmit documents and communicate among members.

In 1991, an early WWW system was released to the high-energy physics community via the CERN program library. Early in 1993, the National Centre for Supercomputing Applications (NCSA) at the University of Illinois released a version of their browser. The world's First International World-Wide Web Conference was held at CERN in May. By the end of 1994, the Web had 10,000 servers, 2000 were commercial, and 10 million users (What about CERN's ..., 2002).

What is the World Wide Web?

According to Hughes (1994), the WWW is officially described as a wide-area hypermedia information retrieval initiative aiming to give universal access to a large universe of documents. It is basically a subset of the Internet and is a way of looking at and organizing the information on the Internet. The Web provides access to information on (Clark, 2003):

- Individuals, organizations, government (legal, commercial, and educational)
- Learning material
- Health services
- Journals and newspapers
- Virtual libraries, art galleries, and museums
- Virtual shopping malls

Internet

- Databases and archives
- Advertisements and promotional goods
- Pornography

The Web organizes information according to pages interlinked with each other using hypertext (Bothma, 2000). The current foundation on which the WWW functions is the programming language called hypertext mark-up language (HTML). Every document site, movies, sound file, or anything you find on the Web has a unique uniform resource locator (URL) that identifies what computer the thing is on, where it is within the computer, and its specific file name (Berkeley, 2004).

Web Browsers

The prerequisites for the WWW are a computer, a connection to the Internet, and a browser. The function of a Web browser is to interpret the programming language of the Web pages (HTML) and transform it into words and graphics. On each page, certain words, phrases, or even images are highlighted, and clicking on them causes the browser to go and find another page (What about CERN's ..., 2002). Berkeley (2004) describes a browser as a computer program that resides on your computer enabling the user to use the computer to view documents.

The first Web browser to become truly popular and capture the imagination of the public was NCSA Mosaic. Netscape is the browser that introduced most of all the remaining major features that define a Web browser as users know it. Boutell (2004), however, argues that Microsoft Internet Explorer is by far the most common Web browser in use. According to Bothma (2000), the most popular browser in use then was Microsoft's Internet Explorer with between 55-74% of the market share, followed by Netscape Navigator with between 26-35% of the market.

E-Mail

Lerner (2004) notes that e-mail is a message sent from one computer, known as a mail server, to travel over the Internet. Once it arrives at the destination mail server, it's stored in an electronic mailbox until the recipient receives it. To send e-mail, a connection to the Internet and access to a mail server, this forwards the mail. The standard protocol for sending e-mail is called simple mail transfer protocol (SMTP). The advantages of e-mail noted by Grant and McBride (2000) as: It's fast, cheap, and reliable.

File Transfer Protocol (FTP)

File transfer protocol (FTP) is the simplest and most secure way to exchange files over the Internet. The most common use for FTP is to download files from the Internet (Grant et al., 2000).

Internet Relay Chat (IRC)

Internet relay chat (IRC) is one of the most popular and most interactive services on the Internet. IRC lets people all over the world to participate in real-time conversations and was written by Oikarinen in 1988 (IRC, 2004).

Newsgroups

Newsgroups are a collection of messages pertaining to a particular subject. They are a combination of bulletin boards and newsletters, with each dedicated to a specific interest, hobby, profession, or obsession (Grant et al., 2000).

BARRIERS OF ENTRY TO INTERNET USAGE

According to Goble (2002), the barriers of entry to Internet usage are telecommunication costs, ISP costs, equipment costs, training and computer literacy, and language. These are discussed next

(Goble, 2002):

- **Telecommunication costs:** South Africa has only one authorized telecommunications company, Telkom. It has a monopoly and is the sole supplier of the country's telecommunication infrastructure.
- **Internet service provider (ISP) costs:** Internet access to users is provided by local ISPs. An ISP is a company that provides individuals or companies with access to the Internet, as well as other related services such as Web site development and/or the hosting of Web sites. It is usually a commercial organization that maintains a direct and permanent connection with the global Internet via the Telkom telecommunications infrastructure (Bothma, 2000). The initial cost is the purchase of a subscription and then a monthly charge for that subscription.
- **Equipment costs:** Access to the Internet implies that the correct equipment is available and configured. The majority of computer hardware is imported into South Africa from abroad. A&T cited by Goble (2002) recommends the following:
 - PC with a Pentium 90 processor or faster, Windows 95, 98, Me, NT 4.0 2000, or XP, Microsoft Internet Explorer 5.0 or higher
 - 128MB RAM
 - 40GB of unused hard disk space
 - A 32-bit colour display

This makes the cost of entry into this medium high for the average South African.

- **Training and computer literacy:** The Internet is a complex network of Web sites and Web pages developed independently and without any pattern. Users should be able to use the Internet, and tools such as e-mail, as effectively and efficiently as possible. Train-

ing in both the use of an Internet browser and the use of a PC is integral to being able to access the Internet (Goble, 2002). The average illiteracy rate in South Africa in 1999 was 15% of the total population. South Africa has a computer literacy percentage of 8% of the population (Goble, 2002).

- **Language:** The Internet was founded and based using the English language to send and receive information. Therefore, people who are unable to read, write, or speak English are excluded from communicating in this medium.

THE IMPACT OF THE INTERNET IN TERTIARY EDUCATION

In most universities, the Internet is already an important medium of communication, a way of enhancing access to educational resources and a means of creating interactive communities of learning (Pickering, 2000). Cheung et al. (1999) state that many universities across the world are expanding their investment in Internet technologies and are actively promoting Internet usage in university education. The study carried out by Cheung et al. (1999) showed that the Internet usage was found to have positive impacts on students learning. The potential role and use of the Internet in the provision of information services for both research and study in South Africa's tertiary institutions is no longer a highly debatable issue (Kaniki, 1999).

Fleck and McQueen (1999) argue that the Internet revolution arrived faster and with more complications than many institutions expected. They further state that the rapid development of search engines and the expanded use of the Web increased the demand for Internet-related services at universities. However, the Internet is unorganized and Web sites appear, disappear, move, or mutate on a daily basis. While the Internet is dif-

Internet

difficult to search, it is even more difficult to search it well. Moreover, the information found on the Internet has both useful and useless information co-existing (Jagbora, 2003). The rapid growth of some of the following places a real burden on institutions (Fleck et al., 1999):

- Pornography and hate sites, and downloading of useless information
- Interference with legitimate research and academic use
- Hacking, security
- Cost, growth
- Legal issues related to fair use, harassment, and so forth
- Chat rooms
- Access by non-students
- Competition with ISPs

There are thousands of Internet “home pages” which serve as information sources for institutions and organizations. Most Universities throughout the world have established their presence on the Internet, thereby making it possible for researchers to access past and current research publications. Prospective students can also access information on courses being offered by institutions as well as their admission requirements. Journals, magazines, newspapers, books, and archives provide another important avenue for the construction, publication, and circulation of texts (Jagbora, 2003).

Due to poor funding, university libraries ability to acquire new books and to subscribe to journals have been badly affected (Chifwepa, 2002). Academic libraries in South Africa are and will therefore increasingly come under pressure to provide Internet-based information services (Kaniki, 1999). While traditional library resources and services are suited for particular kinds of research and study information needs within the academia, the Internet is suitable for other needs and it can supplement traditional library services.

The question for academic libraries, should be not so much as to when will the Internet replace the library or how best will librarians counter the challenge but rather, as how best to incorporate the Internet into services offered by the library (Kaniki, 1999).

According to Dos Santos (1998), technological advances and explosive growth of the Internet are rapidly eliminating the time and space constraints inherent in the existing model. Dos Santos gives an example of where one can easily have students view a video of an instructor’s lecture from anywhere and at their leisure, and students can chat (using text, audio, or video) without getting together physically (Dos Santos, 1998).

The Internet provides an educational discourse in which learners can interact widely with other members of a learning community. Their interaction for learning can be immediate, prompt, widely shared, and resource supportive, which may not be possible in a traditional mode of teaching, confined by the classrooms physical condition (De Villiers & Cronje, 2001). Irdus and Latch cited by Katz and Yablon (2002) state that through the Internet, learning has become significantly more flexible and content sources much more accessible.

Taylor and Cohen (2001) note that the primary institutional processes where the Internet can have an impact on tertiary education are communication, information and research, teaching and learning, and services and commerce.

- **Communication:** Communications solutions available via the Internet include e-mail, instant messaging, individualized Web portals, video conferencing, listservs, and group calendaring.
- **Information and research:** The Internet has revolutionized the process of accessing and retrieving information.
- **Teaching and learning:** How an institution employs the Internet to facilitate teaching

and learning depends heavily upon its mission, vision, competition, and positioning. Examples of teaching and learning tools include: software such as WebCT, Blackboard, and Prometheus); online class content; audio/video capabilities; instructional chat rooms; and distance education.

- **Services and commerce:** Many services and commercial transactions benefit in terms of timeliness, accuracy, cost, convenience, and customer satisfaction.

INFORMATION OVERLOAD

Since the advent of the printing press, there has been increasing pressure on individuals to keep abreast and in control of information. The Internet has compounded the situation by increasing the volume of available information and the speed at which new knowledge becomes accessible (Rochat, 2002). He defines information overload as large quantities of varied sources of information received on a regular basis at a rate that limits assimilation and increased by unsolicited information. Lyman and Varian (2000) notes that 2.1 billion unique, publicly accessible Web pages are on the Internet, while 7.3 million are added per day. The “deep” or “invisible “Web (information generally inaccessible to software spiders, for example databases) is 500 times larger than the visible Web. Butcher et al., cited by Rochat (2002), list the factors that contribute to information overload:

- Information is collected to illustrate a commitment to rationalize and competence while information is sought to verify the information collected.
- Vast amounts of unsolicited information is received.
- Managers require information to support decisions made.

- Information is collected in case it is useful.
- Managers play it safe and obtain all information possible.
- When the person does not understand available information he/she feels overwhelmed by the information.

In an attempt to deal with the quantity of information, people have developed the following adaptive mechanisms (Rochat, 2002):

- **Chunking:** Gathering information on the basis of generic terms
- **Omission:** Skipping of information
- **Queuing:** Deferment of processing at peak times
- **Filtering:** Neglect or irrelevant information
- **Capitulation:** Escape from the task

Information overload is a problem in an evolving society. Similarly, there is no solution to handle the vast quantities of information that are faced with on a daily basis. The solution is summarized by Lyman et al. (2000) as the challenge is to learn to swim in that sea (of information), rather than drown in it.

INTERNET ADDICTION

Since the advent of high quality, low-cost hardware, and software, the development of a graphically based, easy-to-use method of accessing remote computer sites (i.e., the WWW), use of the Internet by students has increased dramatically. Institutions find that students cultures are created via e-mail, Web surfing, multiple user dungeons (MUDS, which are interactive, role-playing games), spending time in chat rooms, and homepage production. Students provide e-mail addresses as the preferred code of contact rather than telephone numbers. Although the Internet can

Internet

be a powerful tool for academic study and personal communication, for some people, Internet access can prove to be a temptation that is hard to resist. Pathological or problematic use of the Internet, also called “Internet addiction,” is a behaviour pattern that appears to be affecting more and more people, including students (Kandell, 1998). Kandell describes Internet addiction as a psychological dependence on the Internet regardless of the type of activity once logged off.

In research conducted over the past four years, psychologists have theorized that it is possible to become addicted to the Internet. The addiction has been named Internet Addiction Disorder (IAD). To be diagnosed with IAD, an individual must meet some of the criteria. These criteria include developing a tolerance to the Internet and increasing Internet usage steadily, developing withdrawal symptoms, and surfing the Internet for longer than was intended and socially isolating oneself from friends or family members (Kovach, 2001). Research, according to Friedenber (2002), estimates that about 3% of those who go online may suffer from problematic usage.

Kandell (1998) argues that university students as a group appear more vulnerable to developing a dependence on the Internet than most segments of society. Use of the Internet in society and on institutions is growing at an exponential rate. Although the Internet is a tool for gathering information and for interpersonal communication, dangers exist for those who make it the central focus of their lives. Research in this area is just starting, but more is needed to understand the full scope of Internet addiction and the most effective modes of treatment (Kandell, 1998).

PLAGIARISM ON THE INTERNET

Although plagiarism has been around as long as students have, the Internet has dramatically increased the ease of and opportunities for pla-

giarism. “Cyber-plagiarism” is the term used to describe the process by which students either copy ideas found on the Internet without giving proper attribution, or the process by which students download research papers from the Web, in whole or in part, and submit it as original work (Guide to plagiarism ..., 2004).

Plagiarism has never been easier than it is today. The Internet now makes it easy to find thousands of relevant sources in seconds, and in the space of a short time, plagiarists can find, copy, and paste together a term paper, article, or even a book. Because the material online is produced by writers of varying levels of quality and professionalism, it is often difficult for educators and editors to identify plagiarism. Even when an educator does suspect plagiarism, the sheer size of the Internet seems to work in the plagiarists favour (Plagiarism.org, 2004). According to Harris (1996), the most often plagiarized works on the Web are “links” sites, such as “Yahoo.”

Reasons for Plagiarism

The reasons for plagiarism are (Why students plagiarize ..., 2004):

- **Lack of research skills:** Many undergraduate students do not know how to search the library catalogue, search databases for journal articles, or use other reference sources.
- **Problems evaluating Internet sources:** Many students do not know how to critically evaluate Internet sources and this can impact on the students writing.
- **Confusion between plagiarism and paraphrasing:** Studies indicate that up to 60% of students cannot distinguish between paraphrased and plagiarized text. The problem is magnified when students need to paraphrase unfamiliar vocabulary and technical terms.

- **Confusion about terminology:** Terminology is another problem that perplexes students and compounds their confusion and anxiety. Many students do not understand the difference between a report and an essay, between exposition and argumentation.
- **Confusion about how to properly cite sources:** The lack of consistency among the different style guides compounds the problems that students experience when citing sources.
- **Poor time management and organizational skills:** Undergraduate students often do not have the time management or organizational skills necessary to complete a large research paper.

Strategies to Avoid Plagiarism

In order to avoid plagiarism, students should (Harris, 1996):

- Give credit whenever you use another person's idea, opinion, or theory.
- Put in quotations everything that comes directly from the text.
- Paraphrase.
- Check your paraphrase against the original text.

Another option would be to use a plagiarism-detection service. Turnitin offers a plagiarism-detection service that addresses this growing problem of plagiarism. In an Australian study, Turnitin.com detected 166 of the essays, or 9% of the total, had more than a quarter of their material pilfered from electronic sources. Fourteen percent of the essays had 5% or more of the material plagiarized (Foster, 2002).

INTERNET ABUSE

Cyber-Crime

The Internet remains an open network that offers users no guarantee of security, privacy, or integrity (Schoeman, 2000). Botha et al. (2004) defines cyber-crime as the use of the Internet and its technologies to commit crime on individuals or organizations. Security on the other hand, is the means by which crime can be reduced or eliminated. The increase in Internet security breaches can be attributed to the following aspects (Botha et al., 2004) such as: The Internet is an open system, and the communication path is inherently unsecured.

Hacking

Conlin cited by Botha et al. (2004) describes hacking as the obsessive use of computers to gain unauthorized access into corporate systems. There are two types of attacks (i.e., passive attack and active attacks). In a passive attack, the perpetrator simply monitors the traffic to try and learn secrets. In an active attack, the perpetrator tries to break through the defences (Schoeman, 2000).

E-Mail Abuse

Watson (2003) defines spam as simply unsolicited and bulk mail. Unsolicited means that the recipient didn't give consent to receive the e-mail. The content could be commercial such as advertisement or company newsletter, or non-commercial such as joke e-mails or chain letters. Flame mail is hate mail that is transmitted over the Internet. Hate mail is used to incite employees against each other, or against the organization. For example, in 2002, a member of staff sent an e-mail around the then University of Durban-Westville campus purporting to be from another member of staff, making comments about colleagues and the management of the University (Botha et al., 2004).

Viruses

Viruses are programs that have the ability to destroy computer files, programme files, and sometimes computer hardware. Virus scanners are necessary as they have caused a lot of damage over the past few years. According to experts, viruses represent a much bigger problem than hackers (Schoeman, 2000).

Privacy

Customers are often expected to fill in detailed forms when accessing certain sites. Unsecured sites expose the customer to abuse from cyber attackers. The attacker can very easily obtain the personal information of the customer, such as residential addresses, account numbers, and passwords. These could be used to send the customer spam, flame mail, or even personal abuse such as stalking and assault (Botha et al., 2004).

Downloading Music Off the Internet

Over the past few years, there have been many technological developments granting people the ability to download music off the Internet. By law, downloading a digital song violates the intellectual property rights of the artist, or in most cases, of the record companies who contracted those rights from the artist (Choi, 2002).

Universities need to make every effort to educate students about what they are doing when they download music from the Internet. Institutions need to monitor student shares on computers and electronic storage systems that belong to the Universities. They must ensure that MP3s and other copyright-protected materials are not readily available for download to users either on or off campus (Powell, 2003).

Pornography

Pornography is defined as pictures, writing, or other material that is sexually explicit and sometimes equates sex with power and violence. Adult-orientated sites make up less than 2% of all content on the Web. While sexually explicit material comprises only a small fraction of online content, that fraction is highly visible, controversial and accounts for a significant amount of Web traffic (Wright, 2004).

SUMMARY

The literature has shown that problems exist on the Internet. The following research questions were not answered:

1. Is the Internet usage at tertiary education moving towards less learning efficiency and more time spent for non-study purposes?
2. Are students spending enough “productive” time on the Internet?
3. Does the university have enough computers for Internet usage?
4. Does the Internet help students with their studies?

This section has discussed the review of the Internet and issues that affect students and their application of Internet searches for information. The next section will discuss the various methods used to collect the data.

METHODOLOGY

The main aim of this study is to determine whether the Internet is being optimally utilized in tertiary education for information purposes, and to evaluate the level of utilization of the Internet using the University of KwaZulu-Natal (Westville).

Sampling

Convenience sampling is used in exploratory research where the researchers are interested in getting an inexpensive approximation of the truth. As the name implies, the sample is selected because they are convenient. This non-probability method is often used during preliminary research efforts to get a gross estimate of the results, without incurring the cost or time required to select a random sample.

The sampling method used was convenience sampling. A sample of 95 was drawn from the institution for the study. The 95 respondents were comprised of:

- 40-first year students
- 30-second year students
- 25-third year students

Only information systems and technology (IS&T) students were used for the study, as they were easily accessible. Furthermore, information systems and technology students have access to computers to use the Internet readily. Postgraduate students were not included in the study as they were not readily available.

The study was conducted at the University of KwaZulu Natal (Westville campus). Also, there is no known documentation of studies done at the University of KwaZulu Natal (Westville campus) after an extensive search was done at the library.

The Instrument

The researchers compiled a questionnaire to collect the data and were handed out to students during their self-study sessions. According to Walonick (1997), questionnaires are special purpose documents that allow the researchers to collect information and opinions from respondents. Questionnaires allow the researchers to collect

data from a large number of respondents while maintaining uniform responses.

The researchers decided to use a combination of both open format and closed-ended questions. The questionnaire comprised of dichotomous scale questions such as yes or no type of questions, tick the correct box, and one ordinal scale question, where respondents were required to use ranking. The researchers will use the questionnaire to collect the data and will do a correlation analysis using SPSS after collating the data on an EXCEL spreadsheet.

PRESENTATION OF RESULTS

This section deals with the presentation and analysis of data collected. The aim of this is to obtain a measure of association between each of the given variables. The majority of the respondents (59%) fell into the age group between 18 to 20, followed by the 20 to 22 age group, which made up 27% of the sample. Respondents aged 22 to 24 accounted for 8%, followed by 4% in the 24 to 26 age category. The smallest group was older than 26 years (one respondent). The reason why this age group is so small is because tertiary education students are young and the majority of them starts university at an early age and often completes their degrees/diplomas within three to four years. This is probably the reason why majority of the respondents fell into 18 to 20 category.

The first large group (64%) spends less than 3 hours on the Internet. The second largest group (24%) spends 3-6 hours on the Internet. Nearly 10% of the respondents indicated that they spend between 6-12 hours using the Internet. The smallest group comprising of only one respondent uses the Internet more than 12 hours per week. It is evident that students are not spending a lot of time on the Internet. The reason why 64.2% of students spend less than 3 hours on the Internet is probably because of lectures or other activities/commitments. Only one respondent shows

Figure 1. Age distribution

that if a student uses the Internet for more than 12 hours, he or she could have an addiction problem. This agrees with the statement made by Kovach (2001) that students develop a tolerance to the Internet, and has an inherent desire to surf the Internet for longer periods of time. Psychologists have theorized, according to Kovach (2001), that it is possible to become addicted to the Internet.

Nearly 50% of respondents have made the attempt to learn the Internet on their own, and it can be stated that they are Internet literate. This finding substantiates the statement by Katz and Yablon (2002) that through the Internet, learning will become more flexible, and will be a way of enhancing educational resources. This finding also shows that lecturers are not assisting students on how to use the Internet since they only constitute 21% of the respondents. Nearly 19% of the respondents indicated that they were taught by friend/s to use the Internet. Ten percent of respondents have indicated that they were exposed to the Internet by means such as computer magazines, newspapers, etc.

Ease of Internet Usage

Figure 2 depicts how long students took before they were comfortable using the Internet. The majority of respondents (63.2%) indicated that they took a week before they were comfortable using the Internet. Goble (2002) notes that for the

beginner, the process of “surfing the net” is both taunting and difficult. Training in both the use of an Internet browser and the use of a computer is an integral part of being able to use the Internet. It is important for students to quickly get accustomed to using the Internet.

Reasons for Using the Internet

Table 1 illustrates the various uses of the Internet by the students. Students were asked to select what activities they do online such as surfing the net, sending e-mails, SMS, chatting, etc. The activity that the students rated as the most constantly used was e-mail (mean of 1.6), followed closely by academic use (mean of 1.4). Many students according to Kandell (1998) provide e-mail addresses as the preferred contact rather than the telephone numbers. Since Internet access is free at university, students have access to free Web-based e-mail systems such as yahoo and Webmail.

Table 1. Rating of online activities

Description	Mean
E-mail	1.6
Academic use	1.4
Surfing	1.3
SMS	0.8
Chatting	0.6
Downloading	0.3
Online games	0.3

Figure 2. Period taken for ease of Internet usage

The Internet is a tool that can be used to encourage and help students with their studies. This is in agreement with De Villiers and Cronje (2001), who stated that the Internet is one of the most powerful tool for providing learners and lecturers with independent and interactive learning. They further state that the Internet provides an educational discourse in which learners can interact widely with similar members of a learning community.

According to Clark (2003), the WWW is a network of interlinked pages, displaying text, hyper-text, images, sound, video, and data. The Internet provides online presence and information such as learning materials, health services, journals and newspapers, virtual libraries, virtual shopping malls, music, game centres, advertisement and promotional goods, software, pornography, junk, and the list goes on. Therefore, students have a variety of sites to surf from. However, research according to Friedenber (2002) estimates that about 3% of those who go online may suffer from problematic usage, and these users fall into one or more of four categories. The first group has a lack of impulse control, showing difficulty in controlling their inherent desire to stay for long periods of time. The next group goes online when they are lonely or depressed. The third group seeks social comfort on the Web. The last category, the one that university students are most likely to fit in, goes online to avoid coping with stress.

Sending SMSs via SMS sites was rated as the fourth most used activity (mean of 0.8) when students go online, followed closely by chatting (mean of 0.6). Today, SMS is a fast and popular way to send text based messages, especially amongst the youth. There are many SMS sites that allow users to send SMSs free of charge. The activity that students rated as seldom used was downloading of music and playing online games (mean of 0.3). There are several Web sites students can use to download music for free. Choi (2002) is of the opinion that downloading a digital song violates the intellectual property rights of the artist. Kandell (1998) states that although the Internet is an excellent tool for gathering information and for interpersonal communication, dangers exist for those who make it the central focus of their lives.

Time Constraints

Nearly 90% of the students indicated that they are being restricted to use the Internet because of time. From analyzing the results, the researchers are of the opinion that the reasons for students having insufficient time to utilize the Internet is probably because of lecture time and due to computer laboratories closing early.

The questionnaire included a final question where respondents could express their opinions

Internet

on what problems they encounter when using the Internet. The question was phrased as follows: "List 3 problems that you encounter when using the Internet?" Fourteen respondents have indicated that they do not have sufficient time to spend on the Internet because the computer laboratories close early (at 4:30 pm). One of the questions that were posed to students was how much extra time they would recommend for Internet usage at University.

The majority of the respondents (39%) indicated that they require 2-4 hours, followed by 25% of the respondents who have indicated that they require 1-2 hours. Twenty percent of the respondents have indicated that they require more than 4 to 6 hours. The smallest group of respondents (15%) indicated that they require more than 6 hours. It is evident from that the University should allow students adequate time for using the Internet.

The majority of the respondents (97%) indicated that they access the Internet mostly at the university. This is quite a high percentage, and the reason for this is that because university provides the student free access to the Internet. This is in agreement with the statement by Cheung and Haung (1999) who argued that a high percentage of university has an Internet presence and these institutions provide students with the ability to access the Web as well as e-mail and other related Internet activities.

In other first world countries, students have 24 hours access to the Internet. This is in agreement with Cheung et al. (1999) who stated that the Internet is available 24 hours a day in most first world countries. Furthermore, students who pay their fees may feel that they have to take advantage of the free Internet usage offered by the university. Only one student indicated that they use the Internet at home. None of the respondents have indicated that they use the Internet at an Internet café. This is probably because of the cost factor involved.

From the correlation analysis of where the respondents mostly access the Internet and the overall hours spent on the Internet per week, the data showed significance at the 0.01 level. The correlation analysis demonstrates the strength of the association between the two variables (i.e., where students access the Internet and the number of hours spent on the Internet (.41)). This result proved that there is a strong relationship between these two variables and it is impacting positively on the outcome of the study. The researchers find it difficult to comprehend how 3 hours can be adequate for efficient use of the Internet to be achieved. When reviewing the group that spent more than 12 hours, it raises much concern because this group could lead to Internet addiction. To re-iterate and support the researchers viewpoint, the study done by Kovach (2001) also suggests that if students have an inherent desire to surf the net for longer periods of time, it could lead to Internet addiction.

Availability of Computers and Usage of the Library

More than 81% of the respondents have indicated that there are insufficient computers. Goble (2002) recommends the following computer equipment as a market entry requirement for effective Internet usage at tertiary education:

- Pentium 4
- Windows 98, ME, NT 4.0 2000, or XP
- Microsoft Internet Explorer 5.0 or higher
- 128 MB RAM
- 20 GB of unused hard disk space
- A 32-bit- colour display

Nearly 58% of the respondents have indicated that they still use the library to access information. Jagbora (2003) states that printed materials in libraries have a certain fixity and finitude and this is probably the reason why students still use

the library to access information.

The correlation analysis of whether there are adequate computers at the university and if respondents are still using the library for information showed a significance at the 0.01 level (.412). This result shows that because of the inadequate number of computers, students are using the libraries. There are not sufficient computers in the labs because of equipment costs. This is in agreement with the statement made by Goble (2002). According to him, one of the barriers of entry for proper Internet usage is equipment expenses such as hardware and software, network cables, etc, and ISP (Internet service provider) costs. Goble (2002) noted that access to the Internet implies that the correct equipment is necessary and must be available.

Another reason why there are not enough computers in the labs is probably because of telecommunication costs. South Africa has only one authorized telecommunication company, Telkom. According to Goble (2002), it has a monopoly and is the sole supplier of the country's telecommunication infrastructure. Goble further notes that since there is no competition, normal market effects prevalent in first world countries such as the USA and UK cannot play any role in bringing down the cost of telecommunication, and this fundamental flaw in government policy has a ripple effect on all goods and services produced in this country as consumers absorb the non-competitive costs. Telkom's pricing is also not competitive with the rest of the world.

A large percentage of students (58%) still use the library as their primary source of information. This implies that students are not fully utilizing the Internet for information. The students are turning to the library for information rather than the Internet. Today university libraries have suffered serious setbacks in terms of funding. Chifwepa (2002) supports this statement by noting that due to poor funding, the libraries ability to acquire new books and to subscribe to journals has been

badly affected. Jagbora (2003) states that libraries have become crammed with millions of printed materials. So, looking for any kind of material in the library can be time consuming. Kaniki (1999) states that academic libraries in South Africa are increasingly under pressure to provide Internet-based information services. He goes on further to state that while traditional library resources and services are best suited for meeting particular kinds of research and study information needs within the academia, the Internet is best suited for other academia information needs and in other cases, it can supplement traditional library services. In the near future, the Internet could replace libraries. Therefore, students need to be taught the necessary skills on how to use the Internet before this conversion can take place.

The correlation analysis demonstrates the strength of the association between the use of the library to access information and the restriction due to time constraints. The correlation analysis showed significance at the 0.01 level (.166-not high). This is an important observation as the researchers feels that the fact that there is inadequate number of computers would therefore impact on the fact that the majority of students are still using the library.

The correlation analysis demonstrates the strength of the association between the two variables i.e. the adequate number of computers and the time constraints (.402). From the results, eighty one percent of the students indicated that the computers were inadequate for proper Internet usage. The result is important as it shows a direct relationship between these two variables. The inadequate number of computers results in the students waiting their turn and thus becomes a time constraint. This can possibly have a negative impact by discouraging students to use the Internet.

Search Engines, Online Databases, Library Catalogues, and E-Journals

Eighty-four percent of the respondents have indicated that they know how to use search engines. A low percentage of the respondents (30%) indicated that they are familiar with online databases, library catalogues, and e-journals. Universities must therefore take the necessary measures to educate students, especially final and postgraduate students how to use online databases, library catalogues, and e-journals. Roachat (2002) notes that the Internet has revolutionized the process of accessing and retrieving information. One method of achieving this is through online databases, library catalogues, and e-journals.

The correlation analysis of whether the respondents know how to use search engines or online databases, library catalogues, and e-journals showed significance at the 0.01 level (.28). The correlation analysis demonstrates the strength of the association between the two variables (i.e., the use of search engines and online databases, library catalogues, and e-journals). From the analysis of the data in Table 4.9, it would appear that the majority of students (84%) know how to use search engines. Therefore, the researchers is of the opinion that the large percent (70%) not familiar with online databases, library catalogues, and e-journals is possibly due to the fact that they have to pay for this service.

Jagbora (2003) supports this statement by stating that information found on the Internet has both useful and useless co-existing. Therefore, it is good that a large portion of students (84%) know how to use search engines because knowledge of how to use search engines will eventually reduce the time that the student spends in finding the appropriate information that he or she is looking for. Kaniki (1999) states that a user must have the knowledge and skills necessary to conduct complex searches and sieve through the vast information to choose the most appropriate he or she needs.

Nearly 38% have indicated that they depend on the Internet. This shows that the students are not using the Internet mainly for academic purposes. This illustrates a correlation at the 0.01 (.268) level between the dependency on the Internet to assist students with their studies and how much more time students require to use the Internet. The association does not display any casualty. These results indicate that students need to start using the Internet to assist them with their studies. Digital classrooms, supplemented with telecommunications media according to De Villiers and Cronje (2001) are currently being used in tertiary institutions world wide in the form of Web-based courses. If these digital classrooms are implemented in the near future at South African tertiary institutes, it could have a major impact on students by encouraging and improving their learning efficiencies.

Nearly 74% of the respondents have indicated that the Internet is easy to use. The Internet is not easy to use for some students probably because they don't have a basic knowledge of computers. Therefore, to use the Internet properly, students need to be both computer and Internet literate. Eighty six of the respondents have indicated that information from the Internet is easy to read and understand with a correlation of .666.

From the correlation analysis of where the respondent felt that the Internet is easy to read and understand, the data showed a high significance at the 0.01 level. This is in agreement with the statement by Goble (2002) who stated that although modern applications use picture icons and multimedia applications, information is still primarily text based and communication, especially e-mail requires the user to read and write. Jagbora (2003) stated that hypertext publications, incorporating live or moving images and real sounds defy easy classification, and multiple links to other documents and sites encourage new patterns of reading activity.

The Internet was founded and based using English language to send and receive information. English dominates the world of computing and Information Technology today. It is the most widely used computer language, being used by both developers and end-users. Most Web pages are written in English (Goble, 2002). Therefore, students who are unable to read write or speak English will find difficulty in using the Internet. The correlation analysis demonstrates the strength of the association (.725) between the two variables (i.e., use of search engines and the ease of using the Internet). The researchers are of the opinion that a greater percentage of the respondents (74%) find the Internet easy to use and therefore they are encouraged to use search engines.

CONCLUSION AND SUMMARY OF THE RESULTS

The results that were obtained from the data and presented in tables and graphs were discussed. The study aimed to find out how effectively students are using the Internet at tertiary education. The study revealed that students are not using the Internet responsibly i.e. for educational purposes only. They are using the Internet for their own personal uses such as surfing the net, sending SMSs via SMS sites, chatting, etc. A number of problems were identified regarding adequate computer equipment availability in the computer labs; and students being restricted to use the Internet because of time constraints. The study has also revealed that students are not utilizing the Internet to assist with their studies.

RESEARCH QUESTIONS

The following questions were presented in the literature review:

1. *Is the Internet usage at tertiary education moving towards less learning efficiency and more time spent for non-study purposes?*

The study revealed that students are using the Internet for other purposes rather than for academic usages but there was no conclusive evidence from the study that indicates that Internet usage at tertiary education is moving towards less learning efficiency. The study has revealed that the majority of students use e-mail as the most used activity when going online. Therefore, the university should implement a monitoring policy, which is discussed thoroughly in the recommendations.

2. *Are students spending enough productive time on the Internet?*

The findings from the study revealed that students are not spending enough time utilizing the Internet because of time constraints. Nearly 90% of the students have indicated that they are being restricted to use the Internet and 10% have indicated that time is not a problem. The majority of the students have indicated that they require 2-4 hours more. Therefore, UKZN should allow students sufficient time for using the Internet.

3. *Does the university have enough computers for Internet usage?*

It is evident from the study that the university clearly has a shortage of computers for proper utilization of the Internet. The majority of the students (80%) have indicated there are insufficient computers for proper Internet usage. One of the reasons why UKZN has a shortage of computers is because of equipment costs, student's negligence, and not taking care of the equipment. The University can reduce this problem with the help of sponsorship programs.

Internet

4. Does the Internet help students with their studies?

The study has revealed that students are utilizing the library as a source of information more often than the Internet. The researchers strongly believe that the main reason for this result is that there is a lack of computers available to the students. This problem will need to be addressed if the university intends moving forward and keeping in line with international levels of other universities.

RECOMMENDATIONS

Responsibility of University and Students

The University provides access to various computer resources such as the Internet. These resources are available to enhance the learning process and to achieve quality learning outcomes for students. It is the responsibility of the university to encourage students to become familiar with the Internet. Students should be taught the proper way to use the Internet and not to abuse e-mail, the WWW, and so forth. Students, particularly first years should be made aware of Internet abuse. Students must also use the Internet and computers responsibly. They must comply with the rules and regulations of the computer facilities in the university labs. System administrators must also be responsible for the correct and reliable operation of the network and computers.

Monitoring

It was revealed from the study that students are wasting time on the Internet by surfing the net, sending SMSs, chatting, downloading music, playing games, and so forth. There is a large amount of offensive material from the Internet.

The most common type of offensive material is pornography and hate sites. Visiting or downloading of this offensive material is considered overuse, and Internet usage is therefore being wasted. Given that there is no guaranteed means of preventing student's exposure to this kind of material, strategies need to be adopted. University needs to adopt a monitoring strategy.

The university must monitor student's activities when going online. They can achieve this with the assistance of Web monitoring software, which records which sites the student has visited. According to Grant et al. (2000), companies are using Web monitoring software that records an employee's e-mail sent and received and the sites visited. Grant et al. further state that some of the software is capable of ringing "alarm like" bells to alert management when employees are visiting pornographic sites.

Computer Equipment

The study has revealed that the university has a shortage of computers, and some of them are not in proper working conditions. Every effort has to be made by the university to insure the stability, performance, and reliability of the equipment. University should repair the computers that are not working properly.

Technicians should be available when a PC or other equipment is damaged and must try and rectify the problem immediately. Therefore at least one technician needs to be placed in the various computer laboratories. Students should be responsible. They must take care of the equipment in the computer laboratories. They should adhere to the following rules and guidelines:

- Clean up after finishing using a laboratory computer.
- Do not bring food or beverages into the computer laboratories.
- Do not steal or remove any piece of equipment from the computer laboratories.

- Do not swap around any equipment such as changing of keyboards, mouse, or other equipment from one computer to another.
- Do not alter data, software, or directories.
- Report all equipment faults immediately.
- Students should properly shut down their workstations.
- Report suspected viruses to the systems administrator.

In order for the equipment to be functioning properly, both university and students must be responsible for the equipment.

Sponsorships

The university can promote Internet usage via sponsorships programs. They can either apply for funding or new equipment. In 2003, the university built the Govan Mbeki lab via a sponsorship, but this is only one facility. There should be about three to five computer laboratories in university. The only way this can be achieved is through sponsorships. There should be more available computers in the library since students use the library as their primary source for information. Funds coming from sponsorships could also be used to upgrade existing computers.

Computer Laboratories

Students are being restricted to use the Internet because of time. The computer laboratories should be opened at 8:00 am and close at 18:00 pm instead of 16:30 pm. The laboratories should also be opened on weekends. However, this privilege should only be granted to third year and postgraduate students. When a student enters a computer laboratory, university must ensure that each student has a computer available at his/her disposal. Only authorized users must be allowed into the computer laboratories.

E-Mail Usage

E-mail is a tool used for communications, in which users must have a responsibility to use in an efficient, ethical, and lawful manner. Students must adhere to the following guidelines when using e-mail systems at university:

- Do not send messages that are offensive, harassing, obscene, or threatening.
- Do not send, create, or forward advertisements, chain letters, and other unsolicited mail (spam).
- Do not send excessive e-mail messages to recipients, either on or off campus.
- Do not send e-mail containing warnings or virus alerts to other university users.
- Do not flood another system, network, or user account with e-mail.

Downloading of Music and Other Large Graphic Files

Sites such as IMESH, Kazaa, and other download sites needs to be restricted from students. Downloading music form the Internet is considered copyright infringements and is illegal. Therefore, university needs to ensure that students are aware of the consequences of downloading music off the Internet. Powell (2003) recommends that universities need to monitor student's shares on computer and electronic storage systems that belong to the universities. Limits should also be placed on file sizes and the types of files that are downloaded.

Web Filtering Software/Firewalls

Installed on a computers server, this Web filtering software is able to filter inappropriate Web sites (such as online chatting, SMS sites, etc.) while still allowing useful ones to be accessed. A firewall is an access control gateway and determines what type of acceptable traffic may flow through it.

Policies

The university needs to implement policies, which are designed to regulate day-to-day online activities. Policies give users guidelines of what constitutes appropriate and inappropriate use of university computer resources. Policies outline in very clear terms what kind of Internet usage is permitted, what kind is not, and the consequences for violating the rules. Having a clear designed policy will enable the university to protect against wrong doings such as engaging in behaviour that impedes normal use of the network, Internet, or other resources, overloading the network with excessive data, pornography, etc.

If students are in breach of these university policies, the user's account or computer access including access to the computer labs must be suspended and students will be subject to the normal disciplinary procedures of the university.

FUTURE RESEARCH

- Future research needs to be conducted concerning the reasons why students are misusing the Internet at UKZN (Westville campus). These findings could identify some important factors that can improve Internet usage among university students.
- A comparative study should be conducted between other South African universities and even the Technikons. The study would be able to identify which institutions have a better Internet usage.
- Further research must be conducted with regards to the reasons why students are turning to university libraries rather than the Internet.
- The activities of university staff when they utilize the Internet should also be researched to determine whether they are abusing Internet facilities.

CONCLUSION

The study proved to be beneficial to both the researchers and the students. The aim of the study was to assess the effective usage of the Internet at tertiary level. The study explored the various aspects and factors relating to efficient Internet usage in terms of how this was perceived by the students. It was evident that the Internet is not being utilized efficiently and effectively by the students. This has raised much concern with the researchers in terms of what steps need to be taken in order to improve on this result. The researchers recommends further research in this field in order to improve on higher standards of education through the Internet, which will be beneficial to future students.

Chapter 3.2

The Nearest Some of Us Will Ever Come to Information Heaven

Buyile Ngubane
TransNET, South Africa

ABSTRACT

This study addresses the needs for a community computer centre (telecentre) for the community of Emkhambathini. This study was part of the information systems research exercise that was conducted by students. The problem that the researcher experienced was that Emkhambathini has no access to information and a need exists to ensure that this community joins the 21st century. The telecentre will also serve as a community upliftment tool. The data was collected using a questionnaire, it was collated and analysed using SPSS. The conclusion was that gender or employment does not play a role when there is a real need to access information.

INTRODUCTION

Advancements in information technology (IT) throughout the world have had an impact on the way people live their lives, communicate, and even on the way they do business. These developments have become part of people's daily lives and it has become important for everyone to embrace technology and all that comes with it. Unfortunately for rural communities, the advantages of using technology have not been utilized to their best advantage. This has encouraged researchers (i.e., Campbell, 1995; Etta, 2004; Sayed, 2003) in many parts of the world to focus their attention in finding ways in which technology can be used in the development of rural areas.

THE PROBLEM STATEMENT

Although there has been some progress on the use of information and communication technologies (ICT) as previously mentioned, rural people are still falling behind in these developments. The lack of progress is due to the lack of infrastructure and finance that has led to a situation where there are not enough computers in rural areas. Rural people do not have computer skills and the cost of computer equipment is high for people in rural communities. Previous studies (e.g., Benjamin, 2000; Fuchs, 2000; Richardson, 1998) have focused on the use of computers neglecting the benefits that can be obtained in the use of other technologies. This caused the government and private sector to intervene by providing shared facilities such as telecentres. The study will uncover other services that can be offered to rural areas in addition to computing.

The spread of ICTs in the last few decades has had an impact on work, leisure, culture, and social interaction (Sayed, 2003). The modern world is undergoing a fundamental transformation as the industrial society of the 20th century rapidly gives way to the information society of the 21st century. This dynamic process promises a fundamental change in all aspects of people's lives, including knowledge dissemination, social interaction, business practices, political engagement, media, education, health, leisure, and entertainment. The speed of global technological and economic transformation demands urgent action to turn the present digital divide into digital opportunities for all (Ryan, 2004).

ICTs can be used as tools to provide access to information to the underprivileged people in the rural areas. Given the characteristics of rural women and men, such as having little or no schooling, speaking only the local language, among others, they are among the last to reap any benefits. This calls for more creative and innovative ways to enable the use of ICTs in rural environments (Epodoi, 2002).

There have been many examples in recent years of the applications of distance-shrinking effects of ICT. These technologies have been used in the United States and other parts of the world as an aid to economic or community development in rural areas (Campbell, 1995). The fact that more than 2.5 billion people (over 40% of the planet's population) live in rural and remote areas of developing countries has encouraged researchers to look into ways that telecommunications can help improve the lives of these communities (ITU, 2003). In Africa alone, over 70% of people live in rural areas, and there is limited access to telephony outside of cities. Telecentre projects have sprung up throughout Africa in an effort to provide access to telephony and other ICTs in the content with the lowest access to these systems (Castells, 1998). Telecentres offer a promising route for rural communities of the developing world to break out of their isolation (Fuchs, 2000).

Definitions

Benjamin (2000) defines a telecentre as an organization offering telecommunication and other information services to a disadvantaged community. Etta (2004) defines a telecentre as a place whose primary goal is the public provision of tools to enhance communication and the sharing of information.

Chapman and Slaymaker (2003) define ICTs as those technologies that can be used to interlink IT devices such as personal computers with communication technologies such as telephones and their telecommunication networks. Campbell (1995) defines a telecentre as a central location within a rural community or region equipped with computer and telecommunication equipment and services shared by users from a variety of sectors; the services are usually superior to those that the users often have themselves. It provides hardware, software, and support to a group of individuals and organizations that alone might

find them unavailable, difficult to understand, or more expensive.

This study will use the first definition because it also covers the issue of users and the kind of services available at telecentres. For the purpose of this study, a telecentre and a computer centre will have one meaning.

Telecentres as a Business Centre

In the work and debate around telecentres, some key themes have become clear, one is the business model. This can help answer the question of whether community centres should be economically self-sufficient, or rely on external funding of one kind or another (Benjamin, 2000).

A full telecentre costs around R20000. This buys around five phones, four computers, a photocopier, fax machine, printer, scanner, overhead projector, TV, video, and modem. The building is renovated with furniture and security being added. A mini-telecentre follows a model developed by the CSIR, a computer in a movable cabinet with a 3-in-1 (printer, copier, scanner) with phone lines and a modem, costing around R15,000. The turnover is usually around R8000 per month with a sizeable profit (Benjamin, 2000).

Fuchs (1998) argues for public funding of centres as a public facility similar to libraries and schools. However, Richardson (1998) notes that in developing countries, there is not enough money for such things and these projects should be run by self-sustaining entrepreneurs, anything else encourages incompetence and dependency. Benjamin (2000) further states that the rural telecommunications network must be operated as a commercial, entrepreneurial, profit-focused, and profitable enterprise as this will motivate the service provider to continually seek to maximize revenues and minimize costs. Their sustainability depends on them being run on business lines and charging enough money to users to keep the operation sustainable.

Fuchs (1998) argues that to create a tech boom in Africa will require African developers and entrepreneurs to join together in virtual, multinational companies to focus on developing African solutions to African problems. Balancing Act (2004) states that the central idea is that the public sector with donor support provides at a cost or low cost service for communities that are too poor to pay more. It is however important to ensure that the telecentre doesn't die when the donor moves on. And this can only be achieved because the local communities find that it serves their real needs and will continue supporting it (CINSA, 2004).

Policy

The advantages of rural communications and information technology collaboration may be becoming clearer to national policy makers (Campbell, 1995). Issues relating to policy about telecentres have generated interest in South Africa and the government is committed to addressing the inequalities of the past. This was seen in the reconstruction and development programme, which states that, "The aim of the telecommunications sector will be to provide universal, affordable access to all as rapidly as possible within a suitable and affordable telecoms system" (Benjamin, 2000). In South Africa, all telecentres are established in line with the Telecommunications Act of 1996, aimed at ensuring the supply of low-cost, local communication services to South Africa's townships and rural areas (Matsepe-Casaburi, 2003). She argues that guaranteeing the communications access rights are a state obligation as public security or education especially when market driven initiatives can't do it.

Sound and effective policy is the key to making sure that ICTs bring solutions that connect to real problems, otherwise it is likely that initiatives will be small scale and have little impact on the system (Sayed, 2003). According to Sayed

(2003), policy makers will also need to consider the following:

1. Who will pay for ICTs in schools and how?
2. What is the role the private sector should play?
3. What is the appropriate balance between investing in training and infrastructure, such as software and hardware?
4. What kind of software will be used?
5. How schools that obtain ICTs and infrastructure will cover recurrent costs (e.g., Internet access and maintenance)?

Festa (2003) further states that government involvement is a crucial point in the establishment of telecentres, for example if computers are to be installed in a certain area and there is no electricity, the government has to act fast to connect the area.

More policies concerning software and hardware have been adopted by governments. South Africa has adopted an official policy promoting the use of open-source software but stopped short of jettisoning proprietary applications (Festa, 2003). The new policy by Africa's wealthiest nation expresses a preference for open-source applications when proprietary alternatives don't offer a compelling advantage. The policy reads in part, "The primary criteria for selecting software solutions will remain the improvement of efficiency, effectiveness, and economy of service delivery by the government to its citizens," which was drafted and published in a final version. Open-source software (OSS) offers indirect advantages. Where the direct advantages and disadvantages of OSS and proprietary software are strong and where circumstances in the specific situation do not render it inappropriate, opting for OSS will be preferable. "Elsewhere in the policy, the government pledged to promote 'fair and impartial treatment' of open-source software in procure-

ment, create 'opportunities for trial use,' and take advantage of 'the opportunities presented by the OSS movement to promote access to information for citizens'" (Festa, 2003).

The State Information Technology Agency (SITA) has already helped the government save millions of rands by implementing open source in the public sector. According to Moseki (2003), the Northern Cape provincial government is the largest user of open source software, while the Western Cape government also uses an OSS-based document management solution and bases its portal on the system's platform. The department of land affairs uses Linux and is about to implement Oracle on Linux. Open source software is as good if not better than commercially available software. In many cases, it's more stable and more reliable. Unlike most proprietary software, OSS is available at little or no cost. Festa (2003) argues that South Africa and Africa will not be able to afford the investments in imported technology that are required to be a participant in the global information society if conventional approaches are followed. The government expects that OSS, by contrast, will provide flexibility (Festa, 2003).

Services

There is no magic formula for a successful local ICT's appropriation process. It depends on local specifications, and the designs should be relevant to local needs. There is no single successful model applicable to all; success depends on the capacity of adapting the model to best of local opportunities and synergies. No local plan or solution should be designed far away from the community. Top down solutions tend to be big failures.

Telecentres can also provide services in areas such as education, health care, local democracy, and small business support (Benjamin, 2000). The Mogalakwena Hewlett Packard project provides lessons daily for both adults and youngsters ranging from computer literacy to call centre training,

computer repairs, business, and science and technology training. In the past year, the i-Community has trained more than 1,000 people, including municipal councilors and staff, traditional healers, health officials, students, and members of the wider public (BuaNews, 2003).

Distance learning is also an area that can be enhanced by the use of telecentres, it is much easier for rural people to study through distance learning close to their homes than going to city universities, a privilege many of them can't afford (Eggers, 2000). The term telecentre has been used to describe a range of services that include call centres and facilities offering fax. Among the services offered will be videoconferencing and telehealth communications so that patients can avoid, for example, a helicopter ride to a hospital when a teleconference with a physician attended locally by a nurse might instead render the diagnosis and treatment plans (Romberg, 1999). According to Eggers (2000), ICTs can help improve the level of governance in rural areas by allowing the public to access government services like grant application, marriage applications, and business support.

Etta (2004) argues that in addition to all these points, services should be designed in accordance with public needs. Time and space should be allocated for different user types like women and younger users. Booths for privacy in addition to sensitivity to human functions and functioning e.g. availability of toilets, fans should also be cared for. Etta (2004) also argues that efforts should be made to develop subsidised services and group rates (e.g., for women, students, or members). Time banding where cheaper rates can be given for off peak periods and differential pricing must be implemented.

Training and Skills

Fuchs (2000) states that a first step in training is often to demonstrate how the equipment and

facilities available in a telecentre can work for the communities they are located in. Secondly, time must be spent helping locals, teachers, or entrepreneurs understand the value of information and the tools that can be used to access it.

According to CINSAs (2004), the processes that need to be redefined and implemented are:

1. Grow accurate awareness as to what is possible.
2. Establish a shared vision around measurable goals.
3. Establish a widespread skills development and citizen engagement strategy.
4. Establish a sustainable process for encouraging ongoing learning, skills sharing and innovation.

The need for basic literacy, computer skills, and training in the use of ICT applications remains a challenge for rural areas. Language barriers and the complexity of personal computer operation have been shown to hinder Internet diffusion (ITU, 2003). Matsepe-Casaburi (2003) agrees that in South Africa, there is limited capacity to operate affordable and sustainable ICT facilities, and there is also low utilization of ICT services due to limited training and skills.

Gaster (2003) adds that management and technical training and ongoing backup need to be built in because if the managers do not have the imagination or skills to search the internet, he or she won't be able to transmit them to others. Managers should also be able to handle money, organize, plan, mobilize, and teach. He states that centre managers are not only facility managers, they are trainers, facilitators, and motivators. It is essential that they receive special attention and training so they can develop a strategic vision of their role, raise community awareness, train for a productive ICT use, and facilitate the appropriation process.

Problems

Excitement about new ICTs is tempered by long-standing problems in development (Hafkin & Odame, 2002). Parkinson (2004) states that the reason is a combination of lack of resources and because a commitment does not generally exist at the policy level. A striking observation is the absence of old and disabled people at the telecentres. Fewer women than men use telecentre services in practically all of the countries and facilities (Etta, 2004).

The problems of gender inequality are, in most areas women are marginalized with respect to ICTs. Their needs are often different from those of males and this need to be addressed at planning phases of these centres. Etta argues that addressing the gender issue goes beyond promoting equal access and use of the facilities.

In other countries, an inferior level of service from the existing telephone system, the lack of organizational capacity to coordinate such projects, and the lack of leadership to make it happen (Campbell, 1995). Ryan (2004) found that the Kgautswane computer centre in the Northern Province, South Africa succeeded against all odds such as no power, telephones, funds, or trained personnel. They only had power from a generator. Etta (2004) states that examples of more sustainable community telecentres were found in Phalala (South Africa) and Guédiawaye (Senegal).

Benjamin (2000) argues that major telecentres are an overkill to provide basic telephony. They use too much capital for the services they deliver, have difficulty in recovering running costs, and can not be reproduced in the numbers required to provide widespread access. One problem is competition, which has reduced the turnover of the telecentre in Thembisa. Etta (2004) notes that most of the telecentres experienced management problems, ranging from poor attitudes, to weak management, and the absence of adequate technical skills, inadequate equipment and high cost of equipment maintenance and services

Parkinson (2004) adds that fragmented and isolated initiatives often lack knowledge, resources, and expertise. They may not know even about things like open source software, or depth of their understanding of its relative advantages and disadvantages compared to proprietary software may be limited. Staff at these centres often has fairly limited technical expertise, and they often do not know how to implement open source or have access to relevant technical support. Further, because so many of these centres are struggling to get by financially, they cannot afford the luxury of experimentation with solutions that may cost them in the short term but benefit them in the long term. If investment in ICTs for development is to be sustainable, it needs a proper long-term plan that considers these ongoing costs. Hafkin et al. (2002) states that as a result of all these problems in Africa, most of the population remains unable to afford access to computers and the Internet, and reliance on imported software and a closed IP regime slows local development of technology.

Rural areas are low dense and this means ground based telecommunications networks are costly per user (Campbell, 1995). Telecentres are therefore facing technical and infrastructure problems in all countries. These include power failures or interruptions, poor connectivity, computer failures, printer breakdowns, non-functioning software, obsolete or unusable equipment, complex management arrangements, security failure, and policy failures (e.g., import duties or taxes on equipment (Etta, 2004)).

The power problems in Malawi have made the implementation of ICTs impossible and as a result of this, a project that involves laying high voltage cables over a distance of 220 kilometres from the Matambo power station in Mozambique's north-western Tete province to Phalula, 60 kilometres north of Malawi's commercial capital, Blantyre has been started. The project is aimed at ending the frequent power failures in Malawi that are caused by prolonged environmental degradation

along the Shire river-site of the hydro-electric plants that form Malawi's main source of power (Etta, 2004).

Existing Infrastructure

Infrastructure has proven to be the first thing that demands attention before any project can be started. Matsepe-Casaburi (2003) proposes that the same cables that are being laid to bring electricity to rural areas should have the capacity to be used for ICT services. Benjamin (2000) agrees that existing institutions must be used where possible. BuaNews (2003) notes that the Mogalakwena Hewlett Packard project has succeeded by placing computers in libraries, schools, community centres, municipal offices, clinics, and traditional authority halls across the municipality

The Kgautswane Computer Centre has been used more than initially expected and as a result, there is pressure to add more computers (Ryan, 2004). According to Parkinson (2004), local schools can also play a role by introducing younger generations to computers, e-mail, and Internet. School computer labs are increasingly offering public use after-hours. But low Internet penetration rates and limited infrastructure outside of the major urban hubs indicate universal access is an ambitious goal. Etta (2004) argues that cheaper hardware and software should be developed (e.g., thin client solutions and telecentres should be used to pilot them).

Sayed (2003) argues that the debate over which technologies are appropriate and relevant in development has received little attention in the developing world context. One further cause for concern is the difficulty in obtaining good quality software at a reasonable price. Software is not only expensive initially but even if free in the first instance, as with Microsoft's recent promise to South Africa's public institutions, the cost of renewing the license prohibits many institutions from using it One target of private sector involvement should therefore be ensuring that developing

countries have access to sustainable software that is tailored to their needs (Sayed, 2003).

RESEARCH QUESTIONS

Although the literature attempted to solve all the problems as described, certain issues still need attention. These are:

1. Why does the South African government take such a long time to create computer centres?
2. How will the community benefit from such a computer centre?
3. What other benefits are there for the community?
4. Can this help in other terrains?

CONCLUSION OF THE LITERATURE

There is evidence that important support for the MDGs can be achieved with the use of ICTs. The Internet offers extensive development opportunities, particularly for people in rural areas and living in poverty. Wireless Internet technologies can allow developing countries to leapfrog generations of telecommunications. Connecting local communities in developing regions to the Internet will have a positive impact on education and their health system The Internet complements locally available information, improves and accelerates knowledge flows, and can be used to deliver innovative education models to remote areas (Eggers, 2000).

Support should therefore be given to start, maintain, and run telecentres because they perform a primary development function for information and education, which is considered a basic and important human right. telecentres are to information what schools are to education and health centres to health and bodily well being (Etta, 2004).

Telecentres still appear to be a good idea. Market-based mechanisms may be penetrating, but it is questionable that they are sufficient to address social inequities and maximize the potential of ICTs for rural development. While current research hasn't produced any easy-to-follow instructions on how telecentres are done, it has found broad support and validation for the idea amongst rural and other disadvantaged populations. Amongst these communities, access to communication tools is highly valued. However, implementing telecentres successfully in Africa remains a rare art mastered to-date only by a very few skilful social entrepreneurs. Creating access for all through telecentres remains a distant goal and the passage to reach it, a mystery (Balancing Act, 2004). The next section will discuss the research methodology.

RESEARCH METHODOLOGY

In this section, the researchers discuss the choice of methodology that was used in this study. It will also cover issues like sampling, questionnaire administering and data analysis.

How This Study Will Be Conducted

A quantitative research approach has been adopted for this study because the aim of the study is to come up with solutions relevant to the rural people in rural areas. This approach will help in the understanding of rural areas in their context (Ihde, 1977).

The motivation for doing quantitative research, as opposed to qualitative research, comes from the observation that, if there is one thing that distinguishes humans from the natural world, it is our ability to talk! Quantitative research methods are designed to help researchers understand people and the social and cultural contexts within which they live. Kaplan and Maxwell (1994) argue

that the goal of understanding a phenomenon from the point of view of the participants and its particular social and institutional context is an important feature of research. For this study, the need to collect quality data from different people and the fact that reliable results should be found before any telecentre project can be started has necessitated this choice of approach.

The Questionnaire

A questionnaire was designed to accomplish two main objectives: the first one was to maximise the proportion of subjects answering the questionnaire—that is, the response rate; and the second one was to obtain accurate relevant information for the survey. The questions were also divided into personal questions like age and gender, and knowledge questions like “How would you rate your level of computer competency?”

The researchers first explained to respondents that the questionnaire was anonymous and that the information they gave was intended for the research purposes only. A detailed explanation of the purpose of the study was given. The questionnaire was also made available in IsiZulu, as most rural people do not speak English fluently.

Sampling

The research was conducted from a sample of 125 randomly selected rural people residing in a rural area of Emkhambathini (Camperdown) outside Pietermaritzburg. This sample is taken from one district with the population of about 180 people according to municipal records. Respondents were chosen in no particular order to allow diversity in their responses. This was done by visiting them in their homes and in other public places such as the tribal authority offices and clinics. Random sampling was adopted for its ability to allow every member of the community to get an equal opportunity of being selected for participation.

After completion of this process, all questionnaires were analyzed using SPSS and graph plotters to derive possible conclusions from answers given by users. Graphs and charts were used for the purpose of presenting the findings in a user friendly and understandable format. The relationships between the different variables measured will be determined by computing correlations based on the Stockburger (1996) model.

This information and all data gathered from other sources such as popular press articles will lead to the finalization of the research results. The literature review also formed part of the data analysis process. Upon completion of the data analysis, the researchers derived answers to the research questions.

DISCUSSION OF RESULTS

The aim of this section is to provide a detailed explanation on all responses gathered by using questionnaires. The analysis also utilises other existing literature to support (validate) the findings of this research study. One hundred twenty-five questionnaires were distributed to the Emkhambathini community. Of the 125 questionnaires, 123 questionnaires were collected and two questionnaires were never returned to the researcher. Of the 123 questionnaires returned, one was considered unusable, as the respondent had ticked more than one response and in some cases left the response blank. The following analysis is therefore based on the 122 responses that the researcher considers usable. The return rate is therefore 98%.

Fifty-nine percent of the participants were females and this is attributed to the nature of rural life as women are still expected to remain at home and take care of the house and children while men go to the cities to find employment. This is supported by a study conducted by Ryan (2004) in African countries. He argues that old traditions have led men to believe that it is their

duty to be responsible for income generating while women look after children. Lack of employment opportunities in the rural areas is a problem.

Nearly all (97%) of the population studied is African, 2% is coloured, and only 1% is white. The Emkhambathini area is a deep rural area and the researcher could not find people of other races in the area except for those who came to work on government projects. Rural people still live in the ways their forefathers lived. Their need for farming has made them to occupy these rural areas. ITU (2003) states that agriculture is probably the mainstay of the economy in rural areas. It is further cheaper for them to survive outside the cities. They found that about 58% Africans are living in impoverished rural areas of South Africa.

Age of Respondents Who Participation in the Study

Table 1 reflects the age groups of the respondents. The biggest age group is 20 years to 29 years (30%), followed closely by the 0 years to 19 years group (29%). A further explanation of these figures would be the fact that older rural people are mostly uneducated and usually avoid participating in things they perceive to concern education (Etta, 2004). They referred the researchers to their children who attend school.

Table 1. Age distribution

	Respondents	Percentage
0-19	36	29
20-29	36	30
30-39	27	22
40-49	18	15
50+	5	4

The results show that of the 122 responses gathered, 60 went to secondary school and that 45 respondents had gone to tertiary institutions. The educational level measured was taken as the highest level of education reached which means that it also took into account the people who have dropped out of school. The pass rate at matric level in rural schools is low which has led to rural students not being able to go beyond secondary education. Another problem facing rural students is that tertiary education is expensive for them. Six respondents ignored this question possibly because they had no formal education to select.

Employment

Of the 122 responses, 57 (47%) respondents answered that they were employed. This consists mostly of teachers and people working as unskilled workers (like construction). Epodoi (2002) made a similar finding that more employed people in rural KwaZulu-Natal were engaged in the teaching profession than in any other type of paid employment. In bringing ICTs to this community, people will benefit, as this will provide them with tools to gather new knowledge. Also, the integration of services like youth portals and government information give them the opportunity to access services like internships and skills development initiatives. Telecentres also provide them with the opportunity to learn new skills that they could have not afforded to go to educational centres to learn. They access information to help them start businesses through government grants. All respondents answered this question showing interest in issues of employment.

Table 2. Employment

	Respondents	Percentage
Yes	57	47
No	65	53

Only 37% of the respondents have reached tertiary levels of education, which presently is the only level a rural student can learn computing, as rural schools do not offer these facilities. Due to the complexity of computers, most people in Africa will never own a computer (Ryan, 2004). Campbell (1995) states that by their very nature, rural communities do not produce economies of scale that make it less expensive to provide an advanced telecommunications infrastructure, powerful computers, and well developed networks. Etta (2004) agrees that the need for basic literacy, computer skills, and training in the use of ICT applications remains a challenge for rural areas. The low level of computer literacy presents a challenge in the implementation of telecentre projects as it requires that expertise be imported from urban areas, which might increase the cost of implementation. This was also supported by Sayed (2003) who states that because technicians were not obtainable locally many technology projects have failed to realize their goals.

Training to Use the Computer

Of the 25% of respondents who stated that they could use a computer 21% have received formal training at a university, technikon, or college. None of the respondents indicated that they have obtained an IT related Diploma or degree, but stated that they have learned the basics of computing as part of their studies. Others have taken computer courses at private colleges but these institutions are not available in rural areas. The results agree with the statement made by Campbell (1995) which states that in urban areas, single organizations such as large corporations, school systems, and city government can operate systems that are beyond the reach of any single entity in any rural community. Access remains an obstacle to rural participation in the ICT arena. Only three respondents had access to computers at school.

Table 3. Computer literacy level

	Respondents	Percentage
Beginner	35	21
Medium	12	10
Expert	3	2
None	66	54
No response	6	5

The Level of Computer Literacy

More than 50% of respondents indicated that they are completely illiterate and six respondents ignored this question. Only 41% of the respondents indicated that they have some knowledge of computers. Twenty-one percent specified they their knowledge is limited. Most of them only know word processing and are not able to use tools like the Internet effectively. Rural people have not been able to access these tools because of the disadvantaged background and due to the lack of infrastructure. Benjamin (2000) argues therefore that the legacy of apartheid is as strong in the telecommunications as other parts of life.

Money Available for Computer Training

It appears from Table 4 that rural people think it is important to get a certain level of computer training. Twenty-five percent of the respondents indicated they are prepared to up to R150.00 for their training. These people chose the minimum amount and there are several reasons for this. Firstly, most rural people don't know how much computer training is worth in practice. Adverts usually promise free training with participants required to pay around R75.00 for administrative costs. This has led these rural people to believe that computer training is cheap. Not having enough information on service fees is a concern in the deployment of ICT solutions and the need to grow awareness arises (CINSA, 2004). Secondly, they

Table 4. Money for training

	Respondents	Percentage
100.00-150.00	31	25
150.00-250.00	24	20
250.00-350.00	16	13
350.00+	20	16
Nothing	30	25
No response	1	10

might believe that computer training is for the rich and they don't have enough money to afford it or they do not see its importance in a rural setting. This is supported by Campbell (1995), who states that when payment is involved to access information, people at rural information centres are less likely to have disposable income to spend. They hesitate to use family food, education, and clothing money for information. Twenty percent might pay up to R250.00, which is enough money in many cases to cover essentials of basic computing like word processing, spreadsheets, e-mail, and Internet.

More than 15% of the respondents are prepared to pay more than R350.00 to receive computer training. This number probably consists of people who have already received basic training and feel they need advanced training like programming. They have been exposed to computer training and know it can be an expensive exercise. Telecentres can help them in areas such as education, health care, local democracy, and small business support (Benjamin, 2000). On the other side these people might be coming from the group that has never used a computer before and have always regarded computers as expensive equipment that are only available to the urban communities. This has made them believe it is more expensive to learn anything about computers. This is an area that must be addressed in the establishment of telecentres in rural areas. There is a need to develop subsidised services and group rates (e.g., for women, students, or members) (Etta, 2004).

The last group of respondents is not willing to pay anything for training. Their reasons can range from the fact that the unemployment rate in rural areas is very high and people do not have money to use on training. Others are old people who see no value in learning new tools like computing. There is also a belief that telecentres are for the elite educated (Etta, 2004).

The results confirm the fact that rural people are falling behind in the advances in technology. Only nine respondents own a computer at home indicating that rural people do not know about computers or cannot afford computers. Ryan (2004) agrees that most people in Africa will never own a computer in their lifetimes. Telecentres provide a solution to introduce them to the information society and bridge the digital divide and will enable the community to share resources and information. This will allow the people who already have a certain understanding of computers to help the community members who do not know how to use computers. Rural people and organizations must be organized to work together and pool resources and demand (Campbell, 1995). Telecentres also provide an alternative to buying a computer and refrain from spending maintenance costs allowing this to become the responsibility of the centre authorities. Ninety percent of the respondents would like to own a computer. This figure corresponds to the previous discussion of people who do not have a computer at home. People show an interest in owning their own computers and believe that having computers will improve their standard of life in terms of skills. It enables them to access the Internet. They want to use the Internet for job searching and learning about opportunities on the Internet. It shows they understand that ICT are a condition for freedom in the modern world (Eggers, 2000).

Amount of Money to Spend to Own a Computer

A number of respondents are prepared to pay amounts above R4000.00 to buy computers. This confirms that some rural people understand the value of computers and the contribution they have in development. More than 85% of the respondents are prepared to buy computers for their personal use. Computers have the potential to help leapfrog the development process and empower communities (Epodoi, 2002).

Lack of infrastructure has been the biggest threat to the implementation of telecentres in rural areas. Nearly 60% of the respondents do not have an alternative place to access computers. This number indicates that rural people are still living outside the information society. Telecommunications connectivity in developing countries is usually available only within the capital and in major centres. Yet the majority of the population lives outside these cities (Ryan, 2004).

To find out the kind of alternative places available to this community the researchers asked them to explain where they can alternatively access computers. Nearly 40% responded to the question.

Most respondents only use computers at work (Sayed, 2003). Second largest is that of users at a local school with 17 responses. The people who have access to a computer at the local school are

teachers and other people doing administrative work at these schools. If the schools can be used in the establishment of telecentres, more people will be able to access computers. This view was supported by Benjamin (2000) who proposes that existing institutions be used to establish telecentres. In the Northern Province, a secondary school has been used to establish a telecentre and they are control of this facility (Ryan, 2004). Matsepe-Casaburi (2003) made a similar proposal about the use of normal community institutions to speed ICT implementation in rural areas.

The majority of the people do not have an alternative place to access computers, which confirms that the alternative places previously mentioned are not available to the whole community. Sayed (2003) argues that there are two views in the public about telecentres and ICTs in general. In this community of Emkhambathini the optimistic view is that the establishment of a community computer centre will bring advantages to the community. It will bring development and open up opportunities that never existed before. This is particularly encouraging to the researchers as it indicates community readiness for ICT implementation. According to CINSAs (2004), establishing a shared vision around measurable goals is an important part of the implementation process. Fuchs (2000) agrees that the first step is often to demonstrate how the facilities in a telecentres can be made to work for community. In this community, this task looks simpler as most people support the establishment of a telecentre.

The responsibility of who will finance community initiatives like computer centres has been a key theme in the debate around telecentres (Benjamin, 2000). The majority of the people (84%) thought it is the government’s responsibility to build community computer centres. This was influenced by the background that rural people come from, which has made them dependent on the government for their needs. These people often think the government is the only institution that can afford these services. Their view is supported by Fuchs (1998) who argues for public funding of centres just like the funding given to schools and public libraries. About 10% of the respondents suggested that business people are the ones who should finance this initiative. Although there are no big businesses in the rural areas, the new movement of popular government officials to the business sector has made rural people to think these people are rich and can finance any project in the community. Benjamin (2000) also supports that telecentres must be run by profit-focused organizations to encourage quality service.

Use of the Computer Centre

Responses were collected into four categories. The first was community empowerment where 30% of the respondents indicated that they would use the computer centre to teach youth life-skills and starting community projects. The projects mentioned ranged from HIV/AIDS awareness, adult basic education, and youth empowerment. This can go a long way in improving lives and governance in the rural community (Eggers, 2000)

Table 7. Uses of telecentres

	Respondents	Percentage
Community empowerment	37	30
Computing business	9	7
Education	53	44
Internet and e-mail	13	11
No response	10	8

Only nine respondents wanted to start their own businesses in the computer centre (e.g., typing assignments and curriculum vitas). Some respondents already had businesses and believe the telecentre would give them added advantages. Also, access to government information like business registration records and tax records will be of benefit to small rural businesspeople. More than 40% of the respondents view the establishment of the computer centre as an opportunity for them to improve their education, learn skills like computer literacy skills, e-mailing, and also to take courses online. ICTs are known to bring about distance shrinking possibilities (Campbell, 1995). The computer centre is therefore seen as a tool to promote information literacy and provide access to information.

Correlation Between Gender and Employment

The correlation between gender and employment in the community was calculated and reflects that more males are employed than are females. Sixty percent of the males in the study are employed. In Table 8a and 8b, the correlation between gender and employment is presented. The correlation is -0.122 indicating a weak negative correlation. The researchers find that gender and employment are independent of each other. This means that whether a person is male or female that will not influence his or her chances of employment. Gender equality is an important issue in the establishment of telecentres as women have needs that are different from males (Campbell, 1995).

(b)

As a result, women find themselves marginalised in the implementation of ICTs.

Correlation Between Gender and the Ability to Use Computers

Table 9a shows that more males can use computers as compared to females. Table 9b reflects a correlation of -0.011 indicating a weak negative correlation between the variables. This correlation is very close to 0.00 and indicates that there is no linear dependence between a person's gender and the ability to use a computer. It implies anyone can learn to use a computer and gender plays no part in determining that. For this study this information is necessary as it tells the researchers that the services must be designed to the same standards for both males and females. It shows that women also have the potential to learn computers. In other countries, it has been discovered that fewer women use telecentres than men (Etta, 2004).

Correlation Between Gender and Educational Level

Table 10a indicates that females are more educated than males. This might be as a result of the fact that males are more likely to drop out of school and seek employment to support their families while females continue with their studies. Table

10b shows that the correlation between these variables is -0.03 which is a weak negative correlation. The variables are not dependent and an increase on one variable does not necessary imply a decrease on the other or vice-versa. Education plays an important role in the establishment of telecentres as the services must be developed to meet the educational level of the public. The fact that females are more educated as compared to males indicates that females will be more suitable to lead the development of a telecentre. It will also allow them to play a constructive role in the process leading to the establishment so that their needs are taken care of (Etta, 2004).

Correlation Between Education and Computer Literacy

In order to determine whether the level of education of respondents had any influence on whether they have learned a certain level of computing, a correlation was calculated between the two variables. Table 11a shows that people who have tertiary education are more computer literate followed by those who have secondary education. The study had found that most people have received formal training in computers and also the number of people who had access to a computer at work was larger.

	N	122	122
Pay For Training	Pearson Correlation	-.072	1
	Sig. (2-tailed)	.429	.
	N	122	122

(b)

Table 11b shows the correlation between the two variables to be -0.097. This weak negative correlation indicates the absence of a linear relationship between the two variables. This supports the researchers claim that people might have taken computer courses at institutions that do not require any level of prior learning like matric. This result is a reflection of the availability of people who can be trained to work as trainers and managers in the telecentre. Sayed (2003) notes that technology projects have failed because technicians were unobtainable locally and staff were not sufficiently trained to make the most of the technology.

Correlation Between Gender and the Willingness to Pay for Computer Training

Table 12a shows that females are more willing to pay for computer training. The reason for this can be that males are responsible for supporting the family and feel that the money they have must not be diverted to buying things like computers. The study also found that more males are employed as compared to females. Table 12b shows a weak negative correlation of -0.072, which implies that there is no significant correlation between the

measured variables. From this table it can be said that the gender of respondents has no influence on the decision to pay for computer training but factors like employment and level of income have an indirect influence on this decision.

Correlation Between Gender and Ownership of a Computer

The researchers wanted to know if there is any relationship between gender and the ownership of computers. Using Table 13a and 13b, it appears that only five females and four males have computers at home. Although more males do not own computers, the difference is too small to suggest that females have more access to computers than males. The correlation coefficient is -0.064, the result indicates that for both males and females the number of people owning computers in this rural area is very low. This further indicates that more training will be required in order to get the people used to computers. Fuchs (2000) agrees that the first step is training, to demonstrate how the equipment and facilities available in a telecentre can be made to work for the communities where they are located.

Correlation Between Gender and View on the Establishment of a Computer Centre

Table 14a shows that the majority of male and female respondents are in support of the establishment of a computer centre for their community. Table 14b shows that the relationship between the two variables has a correlation of only 0.001, a weak positive correlation. This coefficient is too close to 0.0 to suggest any linear dependence between the variables. This means that whether the respondent was a female or a male they all felt a computer centre would improve the conditions of life in the community. This is because all rural people suffer the same problems of underdevelopment regardless of their gender. The result means that the whole rural community will welcome the establishment of a computer centre which is very important in order for the project to be sustainable (Sayed, 2003).

Correlation Between Education and Employment

Table 15a is a reflection that more than 70% of the people with tertiary education are employed,

(b)

while 26% with secondary education are employed. Table 15b shows a significant correlation of -0.315. This means that the services offered at the telecentre must focus on improving the education level of the people, which will in turn improve their chances of getting employment or starting their businesses (Eggers, 2000).

Employment and Who Should Finance Computer Centre Projects

In this study, the researchers looked at a model for community computer centres. This is important in determining whether computer centres should be economically self-sufficient, or rely on external funding of one kind or another (Benjamin, 2000).

Table 16a shows the relationship between people's employment status and their view on

who should take responsibility to establish the computer centre. Among the people who indicated they were employed, 75% states that it is the government's responsibility to finance the establishment of a computer centre. These people take the government as the only source of finance for developmental projects like schools and clinics. They believe that this is part of government initiatives the RDP, GEAR and the Black Economic empowerment. Although these people are employed, they are not prepared to finance this project as the community. Nearly 90% of the unemployed people also see it as the government's responsibility to provide finance for the project. Their opinion is shared by Fuchs (1998) who argues for public funding of centres, as a public facility similar to libraries and schools. It is worth noting that the South African government passed the Telecommunications Act of 1996 to speed

Table 16. (a) Employment and views on who should finance the computer centre, (b) correlation between employment and views on who should finance the computer centre

Yes	2	12	43	
No	2	2	58	3

(a)

up the supply of ICTs to rural areas. More than 20% of the employed people stated that self-sustaining entrepreneurs must finance this project. The reason that can be given is that these people are working for big businesses and have been exposed to the way these projects are handled. A good example is that of the Mogalakwena HP i-Community (BuaNews, 2003)

Table 16b displays the correlations between the variables. A significant positive correlation coefficient of 0.236 was found. Although a positive correlation exists, it is not strong enough to suggest that there is linear dependency. There are obviously other factors that might have led to people's opinion on the issue. The past political system left rural areas out of the developments in the country and they now feel that because there is a new system, the government must correct past imbalances.

CONCLUSION

In this section, a discussion of the results collected from the respondents was presented by means of tables and charts. In examining the results of this study, it was found that the majority of the population of Emkhambathini is characterised by high illiteracy rate, high unemployment, high level of male absenteeism, and poverty. The results indi-

		Employed	Financier

(b)

cate a negative level of readiness in the community for ICT initiatives. More programmes aimed at the reduction of poverty and unemployment must be started to address the problems faced by rural people in accessing ICTs. Government and private sector programmes must also be focused in the provision of necessary infrastructure like electricity, water and roads as these might hinder the supply of ICTs to rural areas. Festa (2003) made similar remarks in his study.

CONCLUSION AND RECOMMENDATIONS

Information access in the lives of rural people around the world has become important and this study focused on their use for rural development. The advancements in technology must be used to help rural communities take advantage of the digital opportunities. The need to bridge the digital divide between the urban and rural communities has encouraged many researchers to investigate the implementation of ICTs in rural communities. This study makes a contribution by investigating the establishment of a computer centre for a rural community of Emkhambathini (Camperdown).

SUMMARY OF THE STUDY

The lack of proper infrastructure and finance in rural areas has prevented rural people from accessing the new opportunities that come with ICTs. The high costs of computers, low levels of education, unemployment, and poverty are some of the many things affecting rural development. This has made the government and the private sector start initiatives aimed at speeding rural development. The communities now have the task of ensuring that these initiatives contribute to their development by participating in their planning and implementation.

The study was carried out in the rural area of Emkhambathini to make a contribution in the resolving of these problems. The researchers randomly distributed 125 questionnaires to the community. The questionnaires were then collected and analysed using SPSS, which gave the results that were discussed. The findings are based on these results.

The Main Findings

The study wanted to investigate the feasibility of establishing a community telecentre for a rural community and the overall result of this study found to be that the centre can be established in this community. The area studied had access to electricity, which plays an important role in the implementation of ICTs in rural areas.

The study also wanted to establish if any rural people have computer knowledge and what they would best use the computers for. The finding was that the level of computer literacy in the community was very low in that only 31 respondents knew how to use computers. This indicates that the project must focus on the training of the community to use computers and other services that do not require computer knowledge must be offered. These projects include a government information centre where leaflets can be given to the community to read. This will improve gov-

ernment understanding in the community. The community was interested in using the telecentre for educational purposes. These include distance learning, adult basic education, and computer studies. The community computer centre must also address issues of community empowerment like life skills, youth development, and small business development. This can be achieved by the provision of information to the community and connecting them to government departments and other organisations offering help to small businesses.

Business Model

The study focused on the question of a business model that should be adopted for telecentres. The popular view on the business model for telecentres is that the government in partnership with the private sector must be responsible for establishing telecentres. For this study, the researchers find that the community of Emkhambathini would like the government to take responsibility for telecentres. Taking into account that this rural community is poor and cannot afford the costs of running a telecentre, the researcher agrees with this view. The fact that more than 80% of the community stated that the government must provide support similar to that given to public schools and libraries helped to make this conclusion.

Policy

Realising the importance of the role played by policy makers in the establishment of community computer centres, the researcher reviewed literature by other authors in the theory. This study has found that South Africa already has a policy on telecentres which is the Telecommunications Act of 1996 (this act specifies guidelines on the how to establish telecentres). The reconstruction and development programme also addressed the issue of telecentres but unfortunately, both of these policies still fail to achieve their goals because

of a lack of funds and information on the part of the local governments who are the ones to drive these initiatives. The researchers conclude that local councilors who are in daily contact with the people do not understand the different policy documents of the government.

Government involvement must also contribute to other projects like electricity, water, and sanitation, as these are important infrastructural requirements for telecentres. This means that the South African government must start drafting other policy documents to address the rural telecentre situation.

These policies must consider the following:

1. The role of the private sector.
2. What kind of software and hardware will be used.
3. How will the running costs be recovered?

Services

The research found that people would most use the telecentre for educational purposes. It was discovered that the level of education in the community was low and people wanted to improve their education and acquire more knowledge through the telecentre. Services that are aimed at improving the conditions of living for the community must be provided. These include Telehealth, distance education facilities, youth portals to house organisations like Umsobomvu Youth Fund, and the Youth Commission for the people to get information that can help address the high levels of unemployment and illiteracy. The telecentre should also be used to provide information for small businesses as this is an alternative to unemployment. For the success of these services, the Internet plays a crucial role to provide a platform for communication and information sharing. It must also be used to help schoolchildren in their assignments, as there is no local library in the community. This will improve the quality of assignments the students complete,

as they normally have limited information for this purpose.

Training and Skills

In any rural community, computer literacy levels are low because of limited resources to learn these skills. Training is therefore needed in this community, as 75% of the community cannot use computers. The study found that the rural community of Emkhambathini would need training before the telecentre project can succeed.

Infrastructure

The findings supported the fact that the infrastructure in this community is not as bad as in most other communities studied before. The community already has access to electricity, water, and tar roads. Although only a few individuals have access to their own telephone lines, the community has access to phone shops, which means providing Internet is possible.

Research Questions

Why Does the South African Government Take Such a Long Time to Create Computer Centres?

According to the findings of this study, the South African government does have a programme at the national level to create computer centres but slow delivery shows the lack of commitment by the provincial and local governments. This can be a result of a lack of information and funds for these projects. The rural communities are facing other problems such as limited electricity, clean water, health facilities, education facilities, and limited tar roads. The local governments prioritise these neglecting the telecentre projects, which are viewed as a luxury.

How Will the Community Benefit from Such a Computer Centre?

As discussed previously, the community will use the computer centre to improve their education and acquire new knowledge. Information about child nutrition, agriculture and tertiary institutions application procedures will be provided by use of leaflets or through the Internet. For a rural community this information is important as they do not have access to experts like the urban communities. For local business, the computer centre will enable them to obtain information on stock prices and free business training on the Internet. The government departments will find a place to make available information about grants, bursaries and other useful services.

Computer literacy in the community will be improved through the provision of computer classes at cheaper rates. This will also help in creating employment opportunities for the local trainers who have an understanding of computers.

What Other Benefits are There for the Community?

The telecentre can be used as an incubator for small business and youth will have a chance to form co-operatives and take advantage of the governments youth empowerment programme. For teachers and health workers in the community this centre will give them a chance to improve their knowledge, which will in turn ensure that the quality of service is kept in line with developments in their fields.

Can This Help in Other Terrains?

The study did not only focus on the use of computers in the telecentre but also looked at other fields that might benefit from the telecentre. Apart from the fields of education, business, and health,

which have been discussed in the previous pages, the telecentre can be used by government to train municipal councilors and staff on local government policies and update them on the policies being adopted at national level. This will help speed government service delivery and address the slow creation of computer centres as the information will easily get to the local government. Training on computer repairs, call centres, and science and technology are other terrains that will benefit.

RECOMMENDATIONS

Training

The researchers recommend that computer skills training be incorporated into the normal school curriculum to address the problem of high illiteracy in the community. The telecentre must, as its first priority, offer training to the community at low rates so that they are able to use the services offered effectively.

Infrastructure

As rural schools do not have modern facilities to house a computer centre, the telecentre must be built as a separate building that is reachable and accessible to the whole community. This involves taking into consideration disabled people, children, and female needs.

Government Involvement

The government must, in addition to drafting policy documents, set up a formal committee to lead the establishment of telecentres. The committee must be allocated a budget similar to that given to other departments for this purpose. The government must also embark on a fundraising programme to attract big businesses to sponsor telecentres. This has been achieved in the

Mogalakwena Hewlett i-Community project. Government supported companies like Telkom, Transnet, and others must also be encouraged to sponsor telecentres.

Staff Requirements

The researcher recommends that the governments SETA learnership project be used to recruit information technology graduates to work at the telecentres while they receive experiential training. This will decrease staff costs and help give unemployed graduates work experience, which will help them in applying for employment.

CONCLUSION

The advantages that come with the use of ICTs in the lives of ordinary people have started to show in South Africa. Although the South African government is determined to improve the lives of rural people, more support is still needed from the communities, the private sector, and international investors to address the imbalances of the past.

This research study has shown that the rural communities are disadvantaged in terms of accessing technology and information. The digital divide that exists between the urban and rural communities has played a contributory factor in deepening the crisis of poverty, malnutrition, high unemployment, high illiteracy, and other social ills in these communities. The lack of information can be easily addressed through the establishment of telecentres that will provide a single point of information and its sharing. It has been shown that information is an important part of a human's life and its unavailability isolates one from the progresses in real life. Telecentres are possibly a cheaper way of speeding rural development. It is the conclusion of this study that it is possible to establish a telecentre for the rural community of Emkhambathini.

Chapter 3.3

Establishing a “Knowledge Network” of Local and Regional Development Subjects

Olexandr Molodtsov

National Academy of Public Administration, Ukraine

INTRODUCTION

Efficiency of collective action, aimed at social development, in many ways depends on the level of being well-informed and the intensiveness of knowledge sharing between the social agents, which are the professional corporate communities in this domain. Modern information technologies allow influencing the social development by establishing of Internet networks for geographically separated social agents who collaborate on the basis of “horizontal” communications. From this point of view, the Internet can be considered a catalyst of inter-group communication and an instrument for decentralized projection of social development. There has been no sociological research conducted in Ukraine to find out the ef-

iciency level of cooperation between social agents using an Internet network to share information and knowledge concerning local and regional development. But even a general overview of the Ukrainian Internet shows an unsatisfactory state of such cooperation. Indirectly, this is proved by the data regarding the Internet content for 2002, which demonstrates that scientific research and educational organizations represented only 4.4% of the Internet content (Bryzhko, , Tsymbaliuk, Orekhov, & Galchenko, 2002, p. 101). We have all the grounds to state that computer databases existing in Ukraine do not meet the requirements of the local and regional development. Further, they do not contribute sufficiently to the professional growth and development of the professional communities’ ethical standards.

In the present situation, the environment for virtual information is one of the effective mechanisms enabling global changes on all levels of social modernization—international, national, regional, and local. As a result, this mechanism has to become an element of special public information policy and a key factor of strategy-building activity of social agents who act in the sphere of local and regional development. Thus it is suggested that the following elements of information processes need to be revisited:

- a. information (knowledge);
- b. type of communication, setting the modes of behavior in the information space; and
- c. type of social agents (participants) that form the value and goal structure of the information space.

These components in whole should give us an answer about the possibility of effective information interaction in the sphere of local and regional development in general but particularly relevant to the Ukraine.

As one of the resources, information is also an object of separation, and in this sense it is an object of information policy. In the purely administrative aspect, this last concept for the most part is interpreted as trends and methods of independent institutional objects—a state, its individual agencies, bodies of local self-governance, organizations, and institutions dealing with information collection, dissemination, and storage. The purely administrative context of information policy, in spite of wide variety of tasks that should be accomplished in the course of this activity, consists of the quantitative monitoring of information flow. Judgment about information openness and closeness of an information policy object are made on the basis of quantitative assessment of information flow index. In this perspective, information stands as an object of information policy. This orientation of the government authority’s

activity has achieved some success, which is demonstrated in particular by the establishment and functioning of the unified Government Web Portal and the setting into operation of the new communication trunk and zonal fiber-optical lines. The issue of information “electronic governance” systems and their implementation into public administration (E-Government) is also being developed (Klimenko & Litvinov, 2003), as well as variants aimed at broadening the possibilities of public access to the Internet. Further, the number of local self-governance bodies using the Internet for managerial purposes and for ensuring transparency of their work is gradually extending (Baiev, 2003). This gives us the ground to assert that the State of Ukraine, in the purely technical perspective, has the primary characteristics of an Information Society. The technological basis available allows a large information array of the activities of central, regional and local authorities, to become available for a wide circle of societal users.

However, the situation with regard to the control functions over the effectiveness of information is different. This task is a more difficult one for the subject of information policy. A useful information policy has to implement its policy in such a way that allows particular information to reach an appointed target group and results in an expected effect. In such circumstance, the task group (social agent) becomes an object of information activity, while information develops a meaning of an administration influence tool. From that standpoint, information should be viewed as a complex of information measures, which are aimed at changing behavior and attitude towards the knowledge of certain social groups. These measures create possibilities of extending the sphere of power of the state through methods of civil influence that, according to the Declaration of the World Summit on the Information Society, also include information methods (The World Summit on the Information Society, 10-12 December 2003, Ge-

neva, Switzerland, <http://www.e-ukraine.com.ua/viewnews/press/31>). The efficiency of such work can't be evaluated quantitatively, but only on the basis of the successful functioning of such social agents (corporate professional groups) on social development. This orientation (task) of information policy becomes especially significant when the matter concerns social agents, whose activity takes place outside the bounds of administrative subordination to the public authorities. In this case the concept of authority influence (Gavrilov, 2003) can be used, meaning that activity of government agencies is aimed at the dynamics of their relations with social agents, where the elements of public administration are absent.

CONFIGURATION OF INFORMATION AND COMMUNICATION SYSTEM OF LOCAL AND REGIONAL DEVELOPMENT

In every stage of social development, a state has to determine and regulate at a legislative level those societal elements and interrelations which serve its strategic goals (Atamanchuk, 2003). This state function becomes more important under conditions of market-driven economies in a pluralistic society. If social agents are not administratively subject to the state, only legislative and information tools through administrative influence can be used. Because of this, they (objects of information influence) will maintain their vital social activity, at the same time serving the purposes of social development. At the declarative level, the Ukraine government agency has already defined the subjects of local and regional development. Associations of local self-government bodies and their unions, as well as agencies of local and regional development are recognized as institutional subjects. The regulation of the legal status of associations and other voluntary unions of local self-government bodies is outlined in the

bill, “On local self-governance in Ukraine.” The government has also prepared a draft Law of Ukraine “On the principles of regional development stimulation,” which provides for creation of the Regional Development Agencies Network.

This conception of regional policy and the above-mentioned bills override any other structures, which one way or another are the agencies of local and regional development. Also included in this list are state regional training, retraining and excellence centers for managers of local government institutions and municipal companies, non-governmental training institutions¹, scientific institutions—academic institutes, universities, branch research institutes, state research organizations that execute the orders of budget and private organizations, “brain centers”—non-governmental research institutions specializing in the sphere of local self-governance; consulting firms and other similar institutions; information and analytical editions covering the matters of local and regional development. The potential of individual social agents should not be disregarded and these include—employees of local public institutions, working in the information and analytical divisions, subdivisions of local development; a certain part of state employees, who create information products concerning local and regional development². Some experts working in this field can act effectively expressing interests of larger elements of development infrastructure.

The groups listed above represent the configuration of an information and communication system of local and regional development, which is now spontaneously forming on the Internet without any external coordinating influence. This effort allows the observation of the processes of growth and self-organization of this system, which promotes engaging people and organizations into information bonds of various societal levels. Some of the agents of local and regional development are already involved on the Internet and in the analytical centers networks of Ukraine

in particular (Analytical Centers of Ukraine Network, <http://www.intellect.org>). This process lacks systematic character and coordination from the point of view of the creation of information resources. Most of the organizations involved function separately one from another. There is not enough information about their particular specializations and the market for consulting services. They don't have a clear idea of the experience and work results of each other, while institutions of local government receive scanty information about existence and consulting possibilities from many of them. Hence the unique experiences, document packages, knowledge, which are formed by every agent, remain untapped for the purposes of cohesive social development. Thus the conditions for synergetic effect as a result of combined activity of separate social agents of local and regional development have not been created.

It seems sensible to adopt an approach that makes use of ICT itself to solve this problem. The optimal way of addressing this can be found in creating information resources as a classified knowledge system, accessible for agents of local and regional development and other users regardless of their geographical location. Such networks to satisfy the needs of professional and special interest groups already exist in the developed countries. Many of these are known as “knowledge networks” because they meet the needs in information and knowledge exchange. Palmer and Richards (1999) are convinced that creation of new knowledge in the future will occur not in the frameworks of separate organizations, but in such knowledge networks. However, there is another point of view, asserting that significance of the Internet is exaggerated by commercial organizations for the sake of publicity. There is good reason to lean toward a positive estimation of network cooperation because it neither cancels nor changes the traditional forms of information and knowledge exchange. It reinforces the effect

of the creation of new ideas, accelerates the formation processes of the social idea, and provides transparency and accessibility.

There are some useful examples of successful international information networks, designed for professional and civic groups. The SIGMA Program (Support of Public Administration Improvement in the Countries of Central and Eastern Europe), which is a knowledge network has been created in 13 countries to support public administration reform. SIGMA provides network members with access to experienced specialists in the field of public administration, comparative information and technical knowledge related to the Public Administration Service. It provides material and the technical basis for establishment of a knowledge network between the subjects of state administration in Central and Eastern Europe, as well as between them and their colleagues in other countries (SIGMA Program, <http://www.oecd.org/puma/sigmaweb>). An information and knowledge base concerning local and regional development is located in the LOGIN (The Local Government information network) international network. This program which has functioned since 1999, is engaged in accumulating, processing and distribution of information and knowledge, designed for the needs of local self-governance (of local and regional development) through the Internet. Through a simple interface at the program's Web site, any user can learn about member organizations, to get in touch with them and receive current information on communication events, training programs, etc. (The Local Government information network, <http://www.logincee.org>.) The library fund, containing 2,000 documents on the different fields of action of local self-governance bodies, is a knowledge network of this program.

The availability of an international network doesn't remove the necessity of the need for the creation of similar national Ukrainian network. Especially because the access to the LOGIN li-

brary fund demands knowledge of one of three languages: English, French or German. The Cities and Communities Association of Ukraine, which has recently become a LOGIN Program partner and is creating its own library fund, doesn't provide for the needs of an expert. However addressing the problems of the Ukraine is not limited to the creation of a knowledge network. Mavko (2003), analyzing methodological principles of regional strategies in Ukraine, indicates that successful strategic planning for regional development in the Ukraine also requires the establishment of an institution of professional strategic planning consultants. The author of this article believes that it is necessary to form a municipal consulting institute with larger functions, which should be included into the wider context of system reforms covering administrative, administrative-territorial, municipal reforms, and the context of national regional policy. Together with other factors, creation of information network of local and regional development is an effective means of forming this socially important institution.

Information Stratification and Structure of Information Resources of a Local and Regional Development Network

The relevance of the content of information resources is determined by the field of their use. Therefore, it is considered useful to distinguish between scientific, social, economic, political, legal and other types of information. All of these in one way or another deal with local and regional development. However, generalised knowledge cannot be taken as an absolute truth in the information space. Knowledge is always subjective, because it depends upon the context of social agent activity and on its cognitive abilities. In this sense, information is a raw material transforming into knowledge as a result of its independent search and analysis. That knowledge, in turn, is

a foundation for autonomous decision making according to specific problems and activity of a social agent. For better understanding of such an approach to knowledge it is recognized that some information better resembles a real phenomenon having specific characteristics (Berger & Lukman, 1995). Indeed, any information has meaning of cognitive construction only if it is interpreted as reflection of a real existing phenomenon. Therefore formation of an interactive communication orientation in local and regional network will depend firstly, on the sense of one's presence in the information space as an equal communication partner, and secondly, on a creative and constructive attitude towards the information coupled with a high level of confidence in its author.

Every social agent, depending on his specialization, is using certain components of the information resources for creating the new knowledge. These are not new for a society in a general sense but are new for the developed knowledge. There should be information reflective of all agents' views on local and regional development in the network. The information resource related to a general destination should include knowledge determining the motivational dynamics of the social agents institutional behavior and constructions of their social roles in the context of particular local and regional development paradigms based upon their own decisions. The process of role distribution, which should be understood as an habitualization process, is of great importance for network cooperation, since it should result in connecting knowledge to specific activity types (typification). Playing roles and making decisions requires specific knowledge of specific situations, understanding of connections between goals and methods of their achievement. Thanks to typification and specification of knowledge of independent social agents, desegregation into components of local and regional development problems and goals then takes place. In that aspect we can question the necessity of social agents information stratification inside the network community.

Establishing a “Knowledge Network” of Local and Regional Development Subjects

Information stratification is a necessary component of network cooperation, since the creation of local and regional development information resources anticipates a lot of mental work and the elaboration of new knowledge in the form of models, algorithms, programs or projects of solving certain problems, etc. That can be achieved only by common efforts. A state has a particular role to play in the creation of information resources, presented on the Internet, as a social development coordination center. The Ukraine only has one Legislative Act determining the state position regarding the Internet use for the purpose of social development. This is the Decree of the President of Ukraine, formulating the basic tasks of development of the national constituency of the Internet and providing a wide access to it (<http://www.president.gov.ua/officdocuments/officdecrees/101228133.html>). However it doesn't include the legal requirements of Web-page content of any executive authority, or use of the Internet for organizing problem discussions and draft resolutions. But nevertheless, it guarantees the state support of the infrastructure development for delivering information services through the Internet. The creation of electronic resources of local and regional development on competitive basis could become a part of such state support. The strategy of carrying out competitive projects is already worked through in the context of Ukrainian-wide contests for local self-government development projects and programs, which were established in 2003. According to the Conception of National Electronic Information Resources Formation, created information resources should become available in this way (<http://www.kmu.gov.ua/z1/portal/search>).

From the point of view of a general approach to defining the structure of local and regional development information resources, the following basic positions can be distinguished. It consists of:

- a. Analytical analysis on national policy in the field of local and regional development, its primary problems and priority guidelines (constitutive and prediction knowledge);
- b. Information on informative and consultative abilities of local and regional development subjects, scale of their activity, specialization, experience, and personnel; and
- c. Innovation funding of local and regional development (best practices, methods of problem solving, etc.).

More detailed structuring requires further research. In conclusion, I would like to mention that the classification used in the context of information stratification for professional network entities implies distinguishing basic, advanced, and innovative knowledge. The above-mentioned classification is acceptable for knowledge networks of local and regional development, though it should be reinterpreted. This subject can be bounded by the establishing principles that should be followed in the course of network collaboration and creation of information resources, and which can be viewed as the conclusion to the above-stated material. These should include the principles of:

1. Partnership, to define interactive communication type in the virtual space;
2. Trust, to ensure implementation of the interactive communication type;
3. Information resource positioning, to ensure good user targeting;
4. Objectivity, to convert information into knowledge adequate to actual problems;
5. Integration, to build an integrated information resource on key problems of local and regional development; and
6. Optimal information volume.

KEY TERMS

Habitualization: The process of assimilation of certain social practices. Using the term "habitus" has long-standing traditions in the European socio-philosophical discourse. Berger and Lukman use the term because of its polysemy. "Habitus" can take on the meaning of habit, custom, inclination, development pattern (biol.), and so on.

Information and Communication System of Local and Regional Development: A system that combines all the subjects on the basis of common principles to realize information and communication interaction for local and regional development.

Information Process: The process of information products' creation, collection, processing, accumulating, storage, search, dissemination, and use.

Information Resources of Local and Regional Development: An organized entity of information products, which are created and

disseminated for local and regional development needs.

Information Space: The aggregate of all determined objects, subjects and information ties between them, which function and interact to provide for information needs of people, professional corporate communities, subject of local self-governance, region, society and state.

Information Stratification: The role distribution between the information interaction objects according to the amounts and types of information products, the creation of which is based on specialization in a specific activity sphere and on its scale.

Knowledge Network: The conventional name for an information and communication system, the framework of which includes information interaction and mutually beneficial collaboration of corporate professional groups for the purpose of information and knowledge exchange.

Municipal Consulting: The system (institution) and type of management consulting, the objects of which are the subjects of municipal scope of activity. A separate form of municipal consulting is giving consultations regarding issues of local and regional development. In the Ukraine, municipal consulting as a social institution is at the formation stage.

National Information Policy: The aggregate of basic trends and methods of the state activities, involving the information collection, storage, usage and dissemination.

Social agent of Local and Regional Development: The corporate professional structure working in the field of local and regional development. The meaning of the notion of "agent" indicates the fact of independent determination by this structure of the strategy of its activity.

ENDNOTES

- ¹ In the framework of the Community Partnership Program, five training centers operate in Donetsk, Lviv, Kharkiv, Kherson, and Cherkasy, which are financed by the "Ukraine–USA" Foundation. These centers provide consulting services to the bodies of local self-government, with the training itself being only one of the forms of consulting activity.
- ² Consultations and other information products concerning some issues of local self-government activities are provided by: the Department for Contacts with Local Authorities and Local Government Institutions of the Verkhovna Rada of Ukraine, Central Administration for the Public Service of Ukraine, Department of Regional Policy of the Ministry of Economy and the European Integration of Ukraine, Department on Contacts with Local Authorities of the Secretariat of the Cabinet of Ministers of Ukraine, Assistance to the Local Government in Ukraine Fund of the President of Ukraine.

Chapter 3.4

Sex Tourism and the Internet: Information, Amplification, and Moral Panics

Jerry Eades

Ritsumeikan Asian Pacific University, Japan

ABSTRACT

This chapter examines the relationship between the Internet and sex tourism. It argues that interest in sex tourism in the media erupted in the early 1990s, about the same time that the Internet itself was becoming popular. The relationship between the two was both positive and negative. On the one hand, the Internet has allowed members of sexual subcultures to contact each other and for new forms of sex tourism to be marketed. On the other hand, the Internet also provided a platform for those opposed to sex tourism to raise the profile of the issue, in the process conflating images of sex tourism with those of Internet pornography, pedophilia, and child abuse, particularly in relation to tourism destinations in the Southeast Asian region. It has therefore aided the amplification of moral

panics surrounding these issues. This sensational coverage has, however, tended to overshadow other forms of sex tourism, including those in which consenting adults meet together in resorts or clubs for recreational sex with each other. Thus, while the Internet has created moral panics and led to crackdowns in certain sections of the sex tourism market, it has allowed other alternative lifestyles to flourish on an unprecedented scale in an increasingly liberalized environment.

INTRODUCTION

Probably no sector of the tourist market has been more affected by the rise of the Internet than that of sex tourism. In fact, as will be shown below, until the advent of the Internet, “sex tourism”

as a concept was rarely discussed in the media, even though sex as a motivation for travel has a very long history. But the relationship between sex tourism and the Internet also is extremely complex and contested, as befits such a controversial subject.

In this chapter, I first argue that the emerging literature on sex tourism has, in general, tended to concentrate on the commercial provision of sex to the exclusion of other types of sex tourism, with the greatest attention being given to the relations between prostitutes and tourists in Southeast Asia.

Second, I argue that in relation to this particular type of tourism, the Internet has proved a double-edged sword. Even though it has provided greatly enhanced opportunities for members of a wide variety of sexual interests, orientations and subcultures to contact and interact with each other, it also has provided an environment in which certain types of sex tourism have been increasingly demonized by the media, civil society, and the politicians, resulting in the imposition of increasingly severe regulation and sanctions in a number of countries. The Internet has greatly assisted the stereotyping of the “sex tourist” as typically an overweight middle-aged Western male on the prowl for underage sex victims in the main Asian tourist resorts. This in turn has resulted new type of crime being brought onto the statute books in many countries, such as accessing and downloading child pornography. It also has made it possible for interest groups such as ECPAT (originally “End Child Prostitution in Asian Tourism”)¹ to get their message across more effectively, increasing the pressure on governments to take action. In the mid-1990s, a number of countries introduced new legislation controlling the extraterritorial sexual activities of their nationals, and a number of well-publicized prosecutions have taken place since. Media reporting and its dissemination on the Internet have generally contributed to the sense of moral

panic and indignation surrounding this issue, as well as conveying the comforting impression that something is being done about it, a questionable assumption given the small number of prosecutions and the large number of tourists.

My third argument, however, is that prostitution in Southeast Asia is only part of the story. Elsewhere, other forms of sex tourism involving consensual sex between tourists are flourishing, having been greatly facilitated and supported by the Internet. Far from experiencing increasing pressure from the law, these activities in some countries are enjoying an increasingly liberalized legal environment. The Internet acts both as an important source of information for the participants, as well as (to judge by the massive popularity of some of the sites where this information is disseminated) a significant source of entertainment for the casual *cybervoyeur*.

The chapter is therefore divided into five main parts. In the first, I discuss the definitions of sex tourism current in the literature, and the paradigms of its main variables offered by previous writers. The crucial variable, I will argue, is that of the power relations between participants in sexual activity. Where sex tourism involves the free participation of consenting adults with broadly equal power and rights in the relationship, there are clearly moral and legal problems than when some of the participants are coerced into sex because they are poor, vulnerable or under age.

Second, I look at the stages through which sex tourism typically develops in particular countries, in relation to other processes of economic growth and the development of a tourist market.

Third, I look at the growth of interest in sex tourism in the media, using online databases of press material that have developed into an important research tool in the last decade. Press databases are not only a good source of information on the topic, but also good indicators of the fluctuations of public interest in different countries concerning these issues over time. Here, I discuss

how specific issues turn into moral panics speeded by the Internet, attracting both media attention and official action.

Fourth, I look at those types of sex tourism that have not generated as much moral indignation as those involving prostitution or the exploitation of children, though clearly they are flourishing and even expanding, both in cyberspace and in the flesh.

In the final section, I consider the policy implications of all this, for social theory and the future of sex tourism.

DEFINING SEX TOURISM

In general terms, sex tourism is not difficult to define: tourism in which the primary object is sexual activity, either sexual contact with others (local sex workers, other tourists) or sexual stimulation and arousal, usually leading to orgasm either alone or in company. However, the forms and sites of sex tourism have evolved considerably over the years, particularly as sex has become a less tabooed subject of discussion in the developed countries, and as would-be entrepreneurs (including organized crime) have devised new forms of sexual activity and exploitation for the purposes of profit.

In their pioneering monograph on sex tourism, Ryan and Hall offer the following thoughts on defining their subject:

Sex tourism may be defined as tourism where the main purpose or motivation of at least part of the trip is to consummate sexual relations. It might be thought that these relationships are usually of a commercial nature. However, the apparent solidity of such a definition soon starts to fade as the marginalities and states of sexuality start to be explored in more depth. ... Although sex tourism exists throughout the world, it has come to be primarily associated with the travel of tour-

ists, usually male, in the developed world to less developed countries. One of the main attractions is the important cost differential that exists in the provision of both tourist and sexual services in the developing world compared to such provision in the industrialized world ... Therefore one of the key issues which these present work addresses is the relationship between visitor and prostitute ... (2001, p. x)

This initial definition points the way to much of their subsequent discussion. Although they state that the meaning of “sex tourism” is extremely wide, and need not necessarily involve a commercial transaction, they do nevertheless devote most of their time to male sex tourists buying sexual services in developing countries, particularly Thailand.

But despite this focus, they first offer three other sets of insights into the general nature of the field. The first concerns the range of activities and the variable degree of physical contact involved in sex tourism:

The sex tourism industry also takes different forms ranging from the production of videos, through to nude dancing in which no physical contact occurs and the tourist acts as voyeur, and tourism-related prostitution, of which there are several major forms. (Ryan & Hall, 2001, p. xi)

The key variable here is that of physical contact, though in practice dividing lines are fuzzy. For instance, exotic dancing is nowadays difficult to separate from lap dancing, and that can involve a considerable degree of physical contact, usually depending on how much the observer is prepared to pay (Lewis, 2002; Liepe-Levinson, 1998). It also can act as the curtain-raiser for other forms of sexual activity, to be negotiated separately.

Their second insight is a set of dichotomies through which different types of sex tourism can be differentiated from each other, according

to whether the sexual activity is (a) voluntary or exploitative; (b) commercial or non-commercial and (c) enhancing or degrading for self-identity (Ryan & Hall, 2001, p. 49). The third of these is problematic, as is quite possible given the transient nature of sexual excitement that clients find their self-identity enhanced during the transaction itself, only to feel degradation later. The other two variables yield a four-fold table, one cell of which (non-commercial exploitative sex) seems of limited importance, while the three others more likely to arise in the real world. Recent literature suggests that many sex workers rate their work positively and reject their stereotyping as “victims” (e.g., Kempadoo, 1998, p. 2 and later chapters in the same volume), but it is usually commercial. Child prostitution would fall into the category of commercial and exploitative, while consensual sex between fellow tourists could be classified as voluntary and non-commercial—though whether it is ultimately identity enhancing or degrading for the participants is more difficult to ascertain objectively. But what we are left with here is the broad distinction between commercial sex (whether involving exploitation, by definition as some feminists would argue, or voluntary action) and consensual non-commercial sex.

Other models are of course possible, and I would suggest four continua which would extend those of Ryan and Hall to cover a wide range of sex-tourism activities. The first is the extent to which these activities are purely local or regional in nature (such as locally based swinging) to those which become the object of tourism, for example, commercially developed clothing optional and other “adult” resorts and the various casual and institutional activities that go with them. A second continuum is the extent to which participation in sexual activity is the object of the exercise, rather than just viewing sex. This differentiates, for instance, the voyeur from the participant at dogging or swinging sites, and strip shows from prostitution, though lap dancing with

bodily contact (Lewis, 2002) or audience participation in sex shows (Liepe-Levinson, 1998) are intermediate cases. A third dimension is how far the participants are professional sex workers, as opposed to casual amateurs, similar to the commercial-noncommercial dichotomy of Ryan and Hall. Clearly where professional sex workers are involved, there are economic and legal implications which do not arise when consenting adults are meeting for the free exchange of sex. It also may relate to a fourth dimension, the power relations between the participants, and the extent to which the sex workers themselves are willing participants in these activities, in other words Ryan and Hall’s voluntary-exploitative dichotomy. Over the last two decades, as sex tourism has become an issue on the international radar, it has become clear that there are some extremely unpleasant forms of human trafficking involved, though in other cases participants may enter the sex industry on a more voluntary basis with a longer term goal in mind, as described for Dominica by Brennan (2004a, 2004b) or the Filipina hostesses and entertainers in Japan described by Garcia Dizon (2004, 2006). Finally, there is the question which most concerns this chapter, the extent to which the Internet has impinged on or amplified each of these types of activity.

THE DEVELOPMENT OF SEX TOURISM

A third group of insights into sex tourism provided by Ryan and Hall (2001, chapter 7, based on Hall 1992) arise out of a developmental model they present of its origins. The stages are those of (a) indigenous prostitution, (b) economic colonialism and militarization, (c) substitution of international tourists for occupation forces and rapid economic development (Hall, 1992) and (d) the internationalization of legal and political responses.

Their argument can be summarized as follows. In many of the countries of East and Southeast Asia, the sex industry has a long history, going back to indigenous institutions in precolonial times. Even though they discuss mainly the origins of prostitution in Southeast Asia, it could be argued that this applies especially to Japan and China. Historically, many cities have had zones of license, in which sex industries and other forms of entertainment have flourished. These date back to the ancient world, where many of them were paradoxically associated with temples, perhaps not surprising given a large influx of religious pilgrims interested not only in religion (for typical instances in the literature, see Flemming, 1999; Lerner, 1986; Rosner, 1998; Toorn 1989). In the early modern state, many cities developed entertainment zones, perhaps the best example being that of the Yoshiwara in Edo (Tokyo), also located near one of the largest temple complexes in the city (Bornoff, 1991; Longstreet & Longstreet, 1970; Seidensticker, 1983; Seigle, 1993).

The Yoshiwara brought together the worlds of *kabuki* theater, *sumo* wrestling and the sex industry, with both female and male (Leupp, 1995) sex workers. This was the floating world of the great Edo print artists, and *shunga* or erotic pictures formed a large part of their output, despite official disapproval and censorship. Yoshiwara survived as a zone of prostitution into the 20th century, when it was closed down by a government concerned with public morals and the spread of sexually transmitted disease. Ironically the area is now the site of a large number of “soapland establishments” where sex workers provide sexual services within the context of giving the clients a bath (Bornoff, 1991; Seidensticker, 1990). China had a similar tradition of courtesans, which in the 20th century also developed into a large-scale prostitution industry in major cities such as Shanghai, with close links with both gangsters and politicians (Hershatter, 1997; Lintner, 2002).

In the 20th century, therefore, the rise and transformation of the sex industry took place under the influence of colonialism and the presence of the military. As Ryan and Hall (2001, p. 140) put it:

In this stage the occupied culture's general acceptance of various forms of prostitution has been used as a justification for economic or military enforced prostitution or, as in the case of Japanese militarism in the 1930s and 1940s, was used as a means of exercising power on host populations. In addition, this stage commences the economic dependency of certain sections of host societies on the selling of sexual services as a means of economic growth and development. For example, in the case of Taiwan, hot spring resorts which provided for the spatial concentration of tourist-related prostitution activity were first developed under the Japanese colonial era between 1895 and 1945.

As Japanese colonialism and emigration expanded in the early 20th century, networks of Japanese brothels were set up around the world, into which Japanese women from poorer families were recruited to service a largely Japanese clientele (e.g., Yamazaki, 1990). As is well known, during the Pacific War, the Japanese forced large numbers of non-Japanese women into prostitution as “comfort women” to service the imperial army throughout the region (Hicks, 1995; Watanabe, 1995). Less well known but increasingly well documented were the American arrangements to provide “rest and recreation” or “R&R” facilities for their troops, in Korea, the Philippines and elsewhere. It has been estimated that since the Second World War, up to a million Korean women have been involved in one way or another servicing the sexual needs of American servicemen (Lie 1995; Matsu & Sharnoff, 1977; Moon, 1997, 1999; Soh, 1996). Similarly, there were an estimated 12,000 registered and 8,000 unregistered

hostesses in Olongapo City in the Philippines, serving the Subic Naval base and Clark Air Force Base (Law, 2000; Moselina, 1979; Philippine Women's Research Collective, 1985). Local city ordinances were changed to regulate the trade, and clear prostitutes off the streets and into clubs, a profitable source of income for local business (Claire & Cottingham, 1982). Similarly, the growth of the sex industry in Thailand stemmed partly from contracts to provide R&R services for the American troops fighting in Vietnam (Bishop & Robinson, 1998).

In the third of Ryan and Hall's stages, therefore, governments promoted sex work for the military, which later gave way to government-promoted sex work as a way of attracting foreign tourists. Prostitution and the commoditization of sex were presented as patriotic, promoting economic development, and creating jobs for the rest of the country. In Thailand, the process was helped by the image of the country promoted by popular culture, in the form of the *Emmanuelle* novels and films. Manderson (1997) suggests that Thailand was irrelevant to the plot of the original Sylvia Krystel film, which appeared in 1974: it was just a western soft-porn fantasy that could have been located anywhere. Nevertheless, it did help reinforce the image of Thailand as a sexual paradise in the Western tourist industry, and Patpong was soon firmly established in the guidebooks as a must-see site, the center of the burgeoning sex industry (Manderson, 1992). Thailand also established a reputation as a center for gay tourism, thanks to its comparative tolerance of homosexuality (Jackson, 1997, 2003; Sanders, 2002). Increasingly, sex tourism was becoming a literary theme, as shown by the success and notoriety of the work of Michel Houellebecq.

An important feature of the growth of sex tourism in post-war Asia was the emergence of Japan as the region's first economic superpower. After the Second World War, Japan had gone through its own occupation experience, and this continued

for many years in Okinawa, which remained under American administration until 1972. Relations between the population of Okinawa and their American neighbors have remained difficult, and there have often been sexual undertones to the relationship, as when American servicemen were involved in the rape of a young Okinawan girl in 1995 (Eldredge, 1997). But as the Japanese economy revived, Japan began to play an increasingly important part in the regional sex industry as consumers. The group solidarity of the Japanese salarymen was often reinforced by works outings to popular *onsen* (hot springs) and other resorts in Japan, and some of these outings involved having a good time with local sex workers (for examples, see Constantine, 1993). As the Japanese economy expanded, this Japanese tradition of company sex tourism increasingly moved offshore, and trips to Thailand, the Philippines and even China as described below, became common (Bornoff, 1991; Brown, 2000). The Japanese also began to receive adverse comment in the press, and Japan started to come under increasing international pressure to clean up its act.

The Japanese response was in part to import the sex workers into Japan itself. With the increasing level of education in Japan, the falloff in the birthrate, and the increasing prosperity of the nation as a whole, the traditional sex industry itself started to collapse and run out of recruits. The solution was to simply import girls from countries which Japanese tourists had long since been patronizing to fill the gap. As the bubble economy expanded in the late 1980s, so did the population of foreign migrants. Some of the women coming in were brought in by organized crime under highly exploitative conditions: pay was poor, passports were seized, and much of the money the girls earned went straight back to the brokers who had brought them as payment for transport, accommodation and loans incurred on the way (Brown, 2000). Others came in more independently, one of the incentives being the

chances of finding a husband in Japan. By the 1980s, there was a severe shortage of potential brides in some parts of the country, particularly in the rural areas, and in smaller towns and cities where the population was dropping rapidly. Foreign brides were an obvious solution to the problem. Even though there were problems with many of the marriages, they did at least legitimate the women's presence in Japan, and the birth of children with Japanese citizenship further strengthened their rights of residence (Garcia Dizon, 2004). Many Thai and Filipina women came in under special "entertainment" visas as a cover for their employment as hostesses or sex workers, and there were numerous complaints from women in the Philippines when the quota of visas was drastically reduced at the end of 2004 (Garcia Dizon, 2006).

The restructuring of the Asian sex tourism market from a military to civilian clientele leads into the fourth stage proposed by Ryan and Hall (2001), that of rapid economic development and international controls. Korea and Taiwan, like Japan, have gone through a period of high speed economic growth, and their birthrates also have fallen, the implication being that they too will probably follow the Japanese pattern of the collapse of the domestic sex industry, followed by the offshoring of sexual encounters and/or the importation of sex workers from elsewhere in the region. Meanwhile, sex tourism continues to flourish elsewhere in the region (Brown, 2000), including the Philippines (Law, 2000), Thailand (Bishop & Robinson, 1998; Seabrook, 2000; Truong, 1990), Vietnam (Marsh, 2006), Cambodia (Cater, 1995), and China (Jeffreys, 2004).

In the period from September to December, 2003, a particularly colorful scandal in China was widely reported by the international media. The affair, with its heady mixture of sex and nationalism, generated a considerable body of discussion and debate, much of which can be readily tracked down in the press databases.² It concerned a party

of Japanese tourists from Osaka who reportedly had stayed at a hotel in the Chinese resort city of Zhuhai from 16-18 September. They had been joined there by a large contingent of Chinese women, and the result was widespread and prolonged sexual activity. The authorities were alerted and raided the hotel: after investigations, 14 people were prosecuted in December 2003 for their part in arranging the event, and sentenced to varying periods of imprisonment. The two most serious offenders were given life sentences. The Japanese tourists returned to Japan, and attempts to extradite three of them back to China were refused. The company concerned denied any wrongdoing in the affair, though they received a large number of indignant telephone calls and emails from the outraged public. The hotel in Zhuhai, together with another one where similar events were said to have taken place, was closed for a time, but eventually allowed to reopen under stricter controls than before. A number of local security officials were dismissed, presumably for allowing all this to happen on their watch.

Several features of the affair are noteworthy. The first is the vagueness about the numbers of people involved, and the extent of what actually happened. The number of Japanese men involved is variously given as 185, 285, or 400. The number of sex workers involved ranges from about the same as the men in some accounts to as many as 500 in others. Presumably over the three days of the party, people came and went so figures are understandably hazy. In any case, clearly a large number of people were involved and the event required a considerable amount of planning.

Second, because the Japanese were involved, discussions in the media drew heavily on Sino-Japanese history, increasing the sense of outrage at what had happened. In fact, it appears from other sites on the Internet that the hotels in Zhuhai had a reputation for being good places to find sexual companionship, at more reasonable prices than other cities in the region (Zhuhai is close to Canton,

Macau, and Hong Kong). So what happened there was probably not unprecedented—apart perhaps from its sheer scale. Most of the participants were probably blissfully unaware that the date of their trip to China coincided with the anniversary of the “Manchurian Incident” of 1931, which marked the start of full-scale hostilities between the Chinese and Japanese. However, this fact was soon picked up by the Chinese and international media. Parallels were quickly drawn between the behavior of the Japanese invaders of the 1930s and the contemporary Japanese tourists, and the choice of date was presented as a deliberate attempt to humiliate the Chinese. It also happened that the date of the trial in December 2003 coincided with the anniversary of the Japanese entry to Nanjing in 1937. This also was quickly picked up by the media, allowing additional parallels to be drawn with the Japanese invasion.

Just to make matters even more complex, this was only one of a number of issues which affected Sino-Japanese relationships during the summer of 2003. Others included the location of an oil pipeline from Russia, the discovery of deposits of mustard gas left over from WWII, and disturbances between Japanese and Chinese students at Northwest University, Xian, China. Taken together, these various incidents provoked a sense of crisis in Sino-Japanese relations, reflecting not only Chinese hostility towards Japan, but also increasing nationalism in China. But what is clear is that the availability of the Internet exacerbated the crisis, through helping to popularize Zhuhai as a sex tourism destination, making the news of the scandal widely available, and allowing the Chinese public to coordinate their protests to the administration.

Generally since the early 1990s, however, several factors have produced an increasing outcry against sex tourism, and have led national governments to increase their efforts to try and exert greater control (Hall, 1998; Seabrook, 2000).

The first factor which lay behind these changes was the HIV/AIDS pandemic which spread quickly from the early 1980s, and increasingly came to affect countries with large sex tourism industries. As Ryan and Hall note, the Thai Public Health Ministry started to campaign against prostitution and sex tourism in 1989, because of their realization that AIDS could pose a problem for tourism as a whole, and for the wider economy. The Asia Development bank calculated that the costs to the economy could rise to \$3.5 billion a year by the end of the century (Ryan & Hall, 2001; see also Beyrer & Stachowiak, 2003).

A second factor was an increasingly vocal campaign against human trafficking, and in particular the trafficking and sexual exploitation of women and children. This had long been an issue in Asia (Brown, 2000), but with the collapse of communism in Eastern Europe, the problem soon began to appear there as well. By 1993, it was reported that in Amsterdam, “Young women are being lured out of Eastern Europe by offers of jobs in the West. But there their passports are taken away and they find they have been sold as prostitutes” (Henley, 1993, *Guardian Features* section, p. 12). Trafficking in both the former Soviet Union and China soon became highly organized (for a comparison between the two countries, see Shelley 2005.) Indeed, increasing numbers of East European women began to appear in the bars and nightclubs of East Asia. These issues also were attracting increasing attention from the media, as discussed in the next section.

SEX TOURISM AND THE MEDIA

By the mid-1990s, it became clear that the Internet had opened up not only immense possibilities for collecting information, but also for talking about sex online and accessing pornography. As with earlier new technologies, calls soon grew strident for the policing, censoring and regulation of the

Table 1. References to sex tourism in major world publications, 1990-2005 (Source: LexisNexis Total Research, Major World Publications)

Year	References	Year	References
1990	8	1998	145
1991	17	1999	130
1992	22	2000	134
1993	29	2001	156
1994	38	2002	146
1995	156	2003	175
1996	255	2004	290
1997	141	2005	267

Internet, but the way it was designed (with decentralized structure and control), and the desire of the courts, particularly in the U.S., not to limit freedom of speech means that it remained largely unregulated, apart from some states such as Singapore, China, or the Islamic countries which have made heroic efforts to filter out information which they find unacceptable.

An important strand in the debate over regulation of the Web has been that concerning sex tourism and, by implication, pedophilia and child pornography. Indeed, so strong emphasis on pedophilia and pornography in discussions of sex tourism, that other forms of sex tourism noted above and involving consenting adults have often been largely ignored.

The development of these issues as a “moral panic,” taken up by the media, pressure groups and politicians, can be documented in the major online press databases, many of which date back to the period before the rise of the Internet³. As a simple measure of the importance of these issues, the number of hits in each time period can easily be verified. Here I have used major publications included in the LexisNexis Total Research database, because of the ease with which large quantities of information can be downloaded from it. Using “sex tourism” as a search keyword, the database produced the following numbers of hits for each year from 1990 onwards.

As can be seen, in the early 1990s, sex tourism was hardly mentioned by the world’s media as a concept at all, though clearly sex was already of major importance in the tourist industry, as Truong’s pioneering study of Southeast Asia shows (Truong, 1990). Interest continued at a low level, until 1995-1996 when there was a massive jump. After a dip for a few years, media interest in the subject picked up again in 2003, and remains high until the present (the results for the first six months of 2006 are similar to those for 2005).

The sequences of events explaining this pattern seems to be as follows. By 1990, there was increasing concern about sex tourism in a number of quarters. First, national governments which were increasingly concerned with the international images of their country, particularly Thailand. During the 1980s, sex tourism slowly started to emerge as an issue, particularly in Thailand, as the number of tourists escalated, from less than 100,000 in the 1960s to five million a year by the late 1980s. In 1987, the Thai government launched a “Visit Thailand” campaign to promote the country as a tourist destination. Two thirds of the resulting visitors were men, and it was estimated that around 223,000 were there for the purposes of sex (Poole, 1991).

Second, medical authorities were increasingly concerned with the spread of AIDS which was

starting to take an increasing toll in the country's sex industry. Reported cases from 100 in 1989 to 14,000 in May 1990, and there were estimates that 25 percent of the nation's sex workers were HIV positive. By 1993, Thailand was said to have one of the world's highest infection rates (Brangin 1993).

Third, there was pressure from NGOs and activists concerned with the welfare of women and children, many of them with links to the churches. The most important of these was ECPAT, whose Web site became one of the best sources of material on the issue, and which issued a series of influential country profiles and reports.⁴

Fourth, there was a growing concern about human trafficking and illegal immigration worldwide, exacerbated by the collapse of communism in Eastern Europe, as noted above. Countries like Hungary also were beginning to use the sex industry as a way to draw the tourists. "The sex ship sets sail early but the sex castle stays open late. If you miss both there are nightclubs with nude go-go dancers and erotic 'live' shows. This may look like Bangkok but it is Lake Balaton, once Hungary's most popular resort now touted as the new playground of European sex tourism" (Beck, 1990, Overseas News section). AIDS was starting to spread in Eastern Europe as well.

Finally the increasing visibility of pornography on the Internet became linked with these other issues in the media and the public imagination, and discourses of sex tourism took on the form which has predominated in the academic literature ever since. As a reaction to this, politicians were spurred to rapid action, given that this was an issue on which they found it easy to reach consensus across the political spectrum. Governments began to consider action (Seabrook, 2000): in 1990, Thailand, the Philippines, Taiwan and Sri Lanka were holding talks Britain, Germany, Switzerland, the United States, France and the Netherlands on joint action against pedophiles, and by the autumn of 1991, Germany was starting

to take the lead in taking action against its nationals abusing children on holiday abroad (Ingham, 1991). Soon, calls for similar action were being heard in Australia and elsewhere (Skeggs, 1992). By late 1993, even French MPs were calling for curbs on sex tourism.⁵

The contribution of the Internet to the debate was therefore threefold: (a) to make available material which people found offensive on a massive scale and therefore force public discussion of the issue; (b) to give a voice to the various pressure groups campaigning for greater controls and (c) to disseminate media reports of these issues, the measures being taken, and their policy implications. The new legislation were touted as giving police a powerful tool in pursuing pedophiles, reinforcing the idea in the public imagination that the possession of images was synonymous with actual pedophilia. The British Home Office claimed that international collaboration had led to success: "Operation Starburst in 1995" led to 20 prosecutions in the UK and over 100 worldwide, and "Operation Cathedral" in 1998, which involved collaboration between 15 countries and seizures of 750,000 images.⁶ In 2000, the British Home Office announced that it was setting up a new unit to deal with pedophiles within the National Criminal Intelligence Service, putting it in the same league as sabotage, terrorism, and international money-laundering. Despite all this publicity, however, it is doubtful how effective these measures have actually been in deterring these kinds of activities, given that the number of prosecutions has been modest compared with the supposed numbers of sex tourists. Also, the people prosecuted have included a number of high-profile individuals whose activities only came to light accident. This is most obvious in the case of Paul Gadd, well known in the 1970s as rock star Gary Glitter, which received enormous publicity in the United Kingdom (e.g., Aglionby & Barnett, 2005; Bainbridge & Aglionby, 2005; Drummond, 2002, 2003; Drummond & Fresco 2005; England & Barnes, 2006; Mackay 2006).

In 1999, Gadd took his computer to the local branch of PC World for repair. The technician noticed that there were a large number of pornographic images on the hard drive, many of them of children, and reported the matter to the police. Gadd was charged with downloading child pornography and jailed for four months, though he was cleared of charges of actual sex with children. The case received immense publicity. On his release, Gadd flew to Cuba, but soon attracted attention there and was expelled. Cuba was increasingly being identified by the Western media as a haven for sex tourism, and apparently also wanted to clean up its act.⁷ Gadd then moved on to Phnom Penh in Cambodia in the late summer of 2001.

Unfortunately, he arrived at a time when both the British and Cambodian governments were attempting to take a hard line with alleged pedophiles and sex tourists. One Briton had already been jailed in Cambodia for sex offences, while another had been jailed in Britain for having sex with a 13-year old girl while in Cambodia. Early in 2002, the Cambodian Minister of Women's Affairs demanded Gadd's deportation from the country. Gadd spent the next two years moving between Cambodia, Thailand and Vietnam, with a series of court battles to resist attempts to remove him. By the summer of 2005, he had moved to Vietnam, but was arrested in November of that year on charges of having sex with a 12-year old girl in Vung Tau, a resort town popular with foreign oil workers, where prostitution was presumably not unknown. However, Gadd was difficult to ignore because of the media attention that followed him in his travels. Eventually, after charges of rape were dropped after payment of compensation, he was sentenced to three years in jail in March, 2005. In an interview with the BBC, he denied that he had slept knowingly with girls below the age of consent, and suggested that he might return to the UK after his release. As a reaction to this and similar cases, the British government put forward proposals to place overseas travel restrictions on registered sex offenders in future.⁸

Gadd's misfortunes were clearly made worse by his former fame and the tenacity with which the tabloid press followed the twists and turns of the story. He was not a sex tourist in the conventional sense, nor had he been convicted of actual pedophilia in his original trial. Before the new legislation of the mid-1990s, he might not have been convicted of any offence at all. However, the media coverage of his case persistently linked the issues of pedophilia, pornography and sex tourism, and articles in the popular press on sex tourism often referred to the Gadd case, just as accounts of the Japanese in Zhuhai tended to end with references to Nanjing.

COUPLES AND SEX TOURISM: SWINGING, DOGGING, AND ADULT RESORTS

As the history of the 19th and 20th century often shows, new communications technologies are often adapted to the sex industry with considerable speed. Earlier studies have shown that sex lay behind much of the popularity of the Minitel system in France during the 1980s (Castells, 1996), even though it was designed for more mundane uses such as looking up telephone numbers and paying bills.

Once the Internet itself was in place in the early 1990s, sex-related usage escalated. As with Minitel, sex became the most popular area of discussion in many of the bulletin boards and chat rooms that proliferated on the Internet, and dating and matchmaking sites took over from the agony columns of the magazines and newspapers (Merkle & Richardson, 2000). Dating sites had the added advantage that they could reach a much wider region, would be read by many more people, and provided facilities like e-mail and the instant exchange of photographs through ICT, the first of a new generation of instant messaging facilities. The matchmaking engines often had room for

information on sex, age group, sexual preferences, appearance, location, and personal statements, as well as email addresses that could be used for more general purposes. Clearly many people using these sites are hiding behind adopted personae and Internet pseudonyms, but much of the information is probably genuine, as shown by the large number of unflattering self-descriptions and the number of participants in older age groups to be found on these sites. Some commentators have seen the emergence of a new culture of “encounter” arising as a result (Holden & Tsuruki 2003).

What these chat sites and matchmaking services also allowed was the proliferation of groups with similar unorthodox sexual preferences. Perhaps the largest of these were the swingers, couples and singles meeting together either to exchange partners or for group sex. “The lifestyle” as it is often known became popular in the 1970s as part of the counter culture in America, and among the sexually more adventurous in Europe. It continued to spread, despite the onset of AIDS, thanks to the almost universal use of condoms. It tends to be found most often among middle class highly educated couples, including many who are middle aged, many of them churchgoers (Bergstrand & Blevins, 2000). It has even spawned its own associations (such as the International Lifestyle Association, NASCA International for the U.S., or the Sexual Freedom Coalition for the UK) and its own genre of guidebooks (e.g., Bellemeade, 2002; Thomas, 1997). The Internet has provided swingers with three important forms of information: the location and personal details of other singles and couples and their various interests, the location of clubs and other meeting places, and chat rooms and notice boards where people can interact online or post their fantasies, experiences, photographs and videos.⁹ The number of people using these sites appears to be enormous. At the time of writing, Swinging Heaven in the UK claimed to have over half a million members, with nearly a quarter of a million singles or couples including photos or

videos in their advertisements. There is at least one case in which a couple turned a Web site documenting their sex lives into a multi-million dollar business.

Many Web sites cater to gay men and women as well, though they also have their own specialized sites. As the popularity of the Internet spread, a variety of sexual subcultures soon appeared online as participants were able to describe themselves and their preferences to each other.¹⁰ The Web sites also began to provide information on travel to tourist centers with active sex service industries and sub cultures such as San Francisco, Berlin and Amsterdam (Brants, 1998; Wonders & Michalowski, 2001), and the kinds of attractions and activities available there.¹¹ This was part of a realization of the significance of the gay tourist market and the potential for businesses in catering to it (Clift, Luongo, & Callister, 2002). An online cruising culture is not confined to the West, but also has developed in Japan as well (McClelland, 2003). As with heterosexual couples, contacting partners online offers participants several advantages. It allows discretion, especially in countries where homosexuality is still either criminalized or discriminated against. Messages reach a much wider audience than they otherwise would, and potential partners are able to exchange photographs and discuss sexual preferences before actually meeting.

Making contact with potential partners does not necessarily overlap with tourism, but it often does. Many Web sites have information on a wide variety of “erotic vacations,” adults-only resorts (many of them “clothing optional,” and sex clubs located there which cater either the straight or the gay market.¹² There is probably a continuum between clubs which cater mainly for the local or regional crowd, as in the cities of northern England which are not major tourist centers, to those which cater almost entirely for tourists, such as those in the major tourist resorts aimed at a swinging clientele. The physical layout of

the clubs, whether straight or gay, appears fairly uniform. There is usually an area for meeting and preliminary socializing, often centered around a bar. There also is a shower area, communal “play” areas featuring around large beds or mattresses, and sometimes private rooms to which couples and groups that require more intimate surroundings can move. Other common features include rooms with mirrors, rooms with bondage equipment and/or swings, glory holes, saunas, steam rooms, hot tubs, pools or Jacuzzi, and TV screens showing pornographic movies. One club in the UK has even imported a camper van and gravel into one of its playrooms, to recreate the outdoor dogging experience without the risks (for dogging see below). The Web sites often have space for visitor’s comments, which can range from the enthusiastic to the highly critical.¹³ One of the main issues in straight clubs is whether or not to allow entry to single men. It seems to be a universal problem for the swinger community that there are more men wishing to participate than women. Opinions are divided about letting in single men. Some argue that more men are needed to keep the party going, given that they tire and give up more quickly than women. Others argue that too many single men get in the way, and spoil the fun. The result is a paradoxical fee structure in which often single men pay more than couples and women are often admitted free. Some times of the week in many establishments are restricted to couples and single women only, with themed gay, bisexual, fetish-wear, S-M, or “greedy girl” evenings.

Demographic and locational imbalance creates a market demand for more informal venues for the voyeur community, and another developing niche in the market for amateur sexual services is provided by isolated spots where singles or couples meet informally for sex, often in the evening or at night. In the UK, this is now known as “dogging” though its antecedents, such as gay men frequenting public toilets for sex (Humphreys,

1975) or casual exhibition and open-air sex on nude beaches (Douglas, 1977), have been around for a long time. The new element in dogging is that exhibitionism and group sex tend to take place in car parks or other places which are accessible to vehicles, and that information on sites and activities is mainly spread by the Internet. This is an ideal medium for listing such locations, given that there are frequent changes of venue in response to police surveillance. The police can find out where the action is as easily as the doggers, simply by surfing the net.

However, generally these activities are taking place in an increasingly liberal atmosphere in most countries in the West. Most of the EU countries have now adopted the liberal and relaxed attitudes to sex which have long been the norm in France, Holland and Scandinavia. Pornography (other than child pornography) is readily available, sex clubs are increasingly popular, and expressions of open sexuality, including gay sexuality are increasingly recognized. Clothing optional and gay-friendly resorts and hotels are multiplying, and couples post their experiences, fantasies, photographs and action videos on the Internet, as sources of information for each other, and free entertainment for other surfers.

CONCLUSION

As can be seen from the discussion above, the relationship between the Internet and sex, including sex tourism, has been extremely complex over the last decade. First, the relationship is not entirely one way: to judge from the preponderance of sex-related material in lists of the most popular Web sites, it was access to potential partners and the forbidden fruit of pornography that helped the Internet take off in the first place. In the late 1990s, the top sites on the Internet were nearly all concerned with sex or pornography. Now, the most popular sites are the search engines Google and Yahoo, technical sites such as Microsoft, or

news sites such as the BBC. The sex sites only start much lower down the list. Now that the Internet has been with us for a number of years, it is becoming possible to assess the impact of this relationship on the wider society, and here the three terms which feature in the subtitle of this chapter, information, amplification and moral panics, may be useful headings under which to summarize my findings.

Sex has historically always been an important motivation for tourism, and the sex industry has grown up alongside the travel industry from ancient times. However, "sex tourism" as an issue in the media and the popular consciousness is comparatively recent. The data from the online press databases suggests that there were very few references to it at all before 1995-96, when it first became the subject of widespread media attention and debate. This happened to coincide with the takeoff of the Internet, and the merging images of pornography, child abuse, prostitution in the popular imagination meant that sex tourism began to appear more regularly as an issue.

It is undeniable that, for better or worse, sites dealing with sex-related materials are incredibly popular, and presumably many people are using them as portals to free entertainment rather than active participation. However, the dating sites show hundreds of thousands of people registering their profiles and participating in email, and presumably a significant number of these are doing so in order to meet real people. The popularity of these activities is shown by the proliferation of adult vacations, erotic tourism, clothing optional resorts, and guidebooks catering to the people who use them. This is a niche market, but the Internet is significant because it can make available information on so many of them in a single search. It has taken over the role of the small personal ad in the newspapers or the contact magazines which started up in the 1970s, but performs it infinitely more efficiently. Meanwhile, of course, the drop in the cost of transport over the years has meant

that the possibility of actually meeting potential partners also has greatly increased.

It is difficult to know how many people are involved in alternative lifestyle options, but what evidence there is suggests that it is significant, particularly in the wealthier and more highly educated sectors of society. The AIDS epidemic precipitated a crisis in the 1980s, but the swinging fraternity has long since embraced the condom, and in any case there are plenty of other things to do which don't involve the exchange of bodily fluids. Meanwhile, governments in the West seem to have come to terms with the situation: the legal regime is increasingly liberal, policing is increasingly relaxed, and the impossibility of controlling and regulating what consenting adults choose to do with each other is recognized. When things get out of hand, there is discrete regulation. The amount of sex and exhibitionism behind the main beach in Cap d'Agde a few years back worried the authorities because many families used the beach. The solution was typically Gallic and pragmatic. During the holiday season, the area to the back of the beach was declared a "nature reserve," and the public was kept out by mounted police patrols. Daytime swingers moved elsewhere instead. Once the kids were back in school, controls were relaxed, the swingers returned to the beach, the police disappeared, and the *status quo ante* was restored.

If the Internet can inform, it also can amplify. It would be interesting to research the pattern of spread of information and associated activities, not only for sex, but for many other activities as well. As the popularity of a subject takes off, the increase in information on the Internet is exponential at first, reaching a plateau as virtually everyone who is interested is accessing information online. Interest might fall off later as new fads appear, though in the case of sex this has yet to happen. The power of the Internet may therefore mean that social trends are amplified and accelerated, reaching a plateau more rapidly than they otherwise might have done.

However, the Internet also can amplify indignation, dissent and protest, creating moral panics that led, in the case of sex tourism, to regulation with breathtaking speed. As images of child prostitution, pornography and sex tourism merged in the media and on the net, governments and politicians felt impelled to act, as being soft on sin was simply not an option for them. No matter that the legislation was badly framed, that it seemed to some to perpetuate images of colonial paternalism (Noh, 1997), or that it actually led to the arrest of very few individuals (Fraley, 2005), including some like Gadd whose activities were discovered more or less by accident.

As more dispassionate observers have noted, sex tourism involving prostitution is likely to continue for good economic reasons, the poverty of the families concerned, and the differential cost of sex between countries. The way forward, they argue, is improving the conditions of sex workers, given that policing and regulation are virtually impossible. The implication is not to try and stamp out sex tourism, or to keep it off the Internet, but to use the Internet to empower and educate the sex workers themselves (Law, 2000), on the assumption that an increasing number of them will gain access as costs continue to fall, for example through the merging of mobile phone and Internet technologies in the years to come.

ABSTRACT

This chapter examines the possibility of creating online creative production archives with which to make locally and internationally sourced high quality video, audio, graphics, and other broadband content available to grassroots producers in developing economies. In particular, the possibility of Cultural Knowledge Management Systems and the use of innovative Creative Commons copyright licenses are explored. It is argued that in

a global knowledge economy, cultural production is a major driver of economic growth. The creativity and culture needed for cultural production are plentiful in developing countries indicating that if technical and institutional conditions are right there is significant potential for developing economies to compete in the global economy. It is, therefore, desirable for local groups to be able to acquire, store, and distribute locally and internationally sourced content to stimulate local-level cultural production.

INTRODUCTION

In this chapter the authors argue that the recognized potential for social, cultural, and economic benefits that accrue from widespread participation in the production of cultural materials, as it has been discussed in developed countries such as Australia and the United Kingdom (Cutler, 2003; DEST, 2002; National Broadband Taskforce, 2004), and in the academic literature (Florida, 2002; Rooney & Graham, 2004), is equally applicable in developing countries. Recent discussions about cultural industries in the developed world show a concern for digital cultural production modes in the context of the Internet and broadband infrastructure. This chapter, therefore, discusses key aspects of capacity building for developing economies to take advantage of these new conditions. The kinds of capacities discussed are concerned with infrastructure, industry, creative expression, and cultural maintenance and renewal capacities. Furthermore, working on the assumption that culture is an expression or mode of enacting knowledge (Holden, 2002; McCarthy, 1996; Rooney & Schneider, 2005), the authors argue that such capacity building will be conducive to the emergence of developing countries as knowledge societies and economies.

In particular, this chapter is concerned with how cultural knowledge management in a digital broadband environment, and innovative copyright developments from Creative Commons (Creative Commons, 2003) have assisted in the creation of an “open” cultural content commons. This commons can develop into a global network of Internet accessible digital archives that collect, hold, and diffuse materials for use in creative production (for commercial or noncommercial purposes) in ways that increase the capacity for independent cultural production in developing countries.

Why Cultural Production?

Beyond the purely economic, there are important though less tangible benefits related to widespread participation in cultural life. Mumford (1934) identifies a civilizing aim that should reside at the centre of all economic endeavours:

The essential task of all sound economic activity is to produce a state in which creation will be a common fact in all experience: in which no group will be denied, by reasons of toil or deficient education, their share in the cultural life of the community, up to the limits of their personal capacity. (p. 430)

There are very practical reasons for taking such a stance in respect of economic goals. These include the health of democratic participation through sophisticated media practices; the economic and cultural benefits that flow from a vibrant, active, and innovative culture of creativity; the proven net economic benefits of a knowledgeable, educated, and intellectually active population; the decentralization of media power; diversification of sources and forms of media content; the maintenance and promotion of local, regional, and national identities; and the widespread personal fulfilment that comes from active and visible participation in the life of a culture. In more general terms, cultural participation assists in resisting the worst aspects of the Western tendency to instrumentalism and technocracy that impoverish culture, make authentic expressions of grassroots culture invisible and devalued, and make it difficult for non-Western countries to compete in the global creative or cultural economy.

One simplistic explanation for the disparity in cultural economic power of the U.S. is that its media corporations hold a global “monopoly” on distribution channels and key production enabling resources, and forcefully impose unfair

protectionist trade barriers in the form of oppressive IP rights frameworks (Drahos & Braithwaite 2002). While other factors are always at play, such monopolies are strong and recognizable forces in the historical distribution of economic and cultural power.

Broadband distribution networks and new copyright innovations challenge the mass media patterns that emerged in the twentieth century and as such have the potential to create new opportunities for developing countries. This technological change brings historically low and diminishing costs for global distribution of cultural content (Rooney, 1997). Simultaneously, rapid developments in digital production technologies have led to lower costs of production, thereby making it possible for a much broader range of people than ever before to work as multimedia content developers at a commercially viable level. There is unprecedented demand for digital media content. This demand has stimulated media organizations, telcos, and governments to position themselves to capitalize on broadband technologies and media convergence, and compete to attract consumers to online services. Just as cultural forms and artifacts from non-Western countries have found global metropolitan markets (e.g., Japanese *anime* and *manga*, Chinese martial arts films, and post-colonial literatures), distinctive media content from developing countries has the potential to appeal to mass and niche audiences across the world. As a result of these trends, significant new opportunities are emerging. In short, the rise of widely accessible global distribution networks, greatly lowered costs of production technologies, heightens potential rates of involvement in production activities, and increased demand for digital media content (particularly distinctive content with appeal to multicultural metropolitan audiences). Furthermore, a policy willingness to embrace the potentials indicated by the above mentioned developments means that people who in the past have worked on the periphery of global cultural

production may gain socially, culturally, and economically in the emerging online environments. While there are barriers in achieving this success in the form of poor infrastructure, the dominance of the English language on the Internet, lack of skills and training, low levels of investment, and so forth, the potential for mobilizing grassroots creativity that has direct economic and cultural benefits, in contributing to notions of civility and citizenry, in fostering artistic dialogue across cultures, and in exploring the democratizing potentials that a diversified media environment offers cannot be ignored.

Looking more closely, it can be observed that the mass media industry structures that developed throughout the twentieth century are premised on high-capital costs (e.g., large television, recording, and film studios); highly specialised divisions of labor (specialised divisions of labor in audio, music, cinematography, animation, pre and post-production, etc); long and expensive development times for content; heavy reliance on advertising revenues; highly integrated distribution networks; and highly restricted access to those networks through electromagnetic spectrum licensing regimes. As recently as a decade ago, the cost of plant and equipment required to create high-quality audio and video productions was a prohibitive barrier to entry for the majority of people regardless of their talents. Capital outlays required to finance the global distribution of multimedia works were even more prohibitive. As few as six companies have dominated global mass media broadcast networks (Bagdikian, 1997; McChesney, 2000; Schiller, 1999).

Today, however, the tools to create high-quality multimedia productions are widely and inexpensively available (Graham, 2005). In some cases, high-quality multimedia production tools can be legally downloaded by users at no cost. As a means of distributing creative content, broadband networks are becoming more common and efficient, with over 100 million people now

subscribing to broadband services (De Argaez, 2004). Data transfer rates are increasing, the cost of broadband access is falling almost daily, and in some cases access is provided at no cost (National Selection Committee, 2004).

Combined with the above trends, and facilitated by new digital production tools, a blurring of roles and functions in creative labor processes has begun to replace the fairly rigid historical divisions of labor characteristic of mass media industries. Using basic consumer technologies, it is possible for a person to film, edit, compose music, produce, and globally distribute their multimedia productions. Moreover, collaborative content creation programs and tools enable teams and networks of people to participate in co-creation online, and pooling of resources and skills. An aspect of these emerging production arrangements are new content “customizing” practices, such as the modification, personalization, “remixing” and “repurposing” of existing content. An interesting result of these changes is that the participants now involved in content creation include fans and hobbyists who might not identify themselves as content producers. Such grassroots practices exemplify the blurring of boundaries between production and consumption that is characteristic of new media environments and which open up opportunities for developing countries.

Consequently, a new, much larger group of people is now engaged in the production and global distribution of high quality multimedia productions. This presents as a benefit in relation to the creative development of culture because it enables societies to renew their knowledge of themselves, to have new insights about their own condition, and to have new things to communicate about themselves. Thus, it is important that cultural innovation comes from the bottom up; in other words from the grassroots. With this constant cultural renewal there are social and economic benefits.

As suggested above, aesthetic innovation emerging from the grassroots has significant social and economic benefits. The new means and forms of production, distribution and exhibition available to grassroots content creators facilitate experimentation and innovation. As the independent sectors in the cultural industries have demonstrated, low-budget productions often afford a higher level of creative control to artists than they have when involved in large commercial productions. The finished product is more likely to be innovative and diverge from established formats and genres.

Further, there are local, national and global markets for grassroots stories, local knowledge and cultures, and hybrid content forms produced in developing countries. Independent film and television production sectors in a range of countries (such as Nigeria, Taiwan, and France) illustrate the way that low budget productions, made from the margins (independent of the major media companies), can hold wide appeal, representing cultures and subcultures to local and global audiences, different to those usually seen in mainstream cinema. Public television networks such as the UK’s Channel 4, or Australia’s SBS, have tapped into their respective independent production sectors (which Leadbeater and Oakley [1999] call “the missing middle” in the creative industries) to generate diverse, innovative, high-quality content that has succeeded in reaching national and international audiences (Ferrier & Lawe-Davies, 2002). If one makes a distinction between the independent and the grassroots sectors, the potential and diversity of the independent production sector in developed economies can be seen as indicative of the value of grassroots digital content production in developing countries (Ferrier, Bruns, Rooney & Graham, 2004; Ferrier & Lawe Davies, 2002). What is identified here as the “grassroots” content production sector—emergent, rapidly growing, informal and dispersed—can be thought of as “the missing grassroots” (Bruns, Ferrier, Graham &

Rooney, 2005), and it is even less visible to many policy makers, governments and media corporations than the independent sector, yet is arguably a richer and more sustainable source of diverse media content. As the enormous success of discussion lists, online chat, Web site development, blogs, and wikis demonstrates, online grassroots or amateur content creation and consumption are thriving, emergent phenomena. At the very least, these conditions demonstrate that amateur media content regularly reaches large global audiences through the Internet. At best, it can be argued that when appropriate infrastructure for cultural production is available commercial producers will be able to access larger markets. However, significant penetration of those markets is not automatic and as will be shown later gaining access requires attention to content (storage, retrieval, and diffusion) management and copyright.

The “Grassroots” and the Economic Future of Genre

There are four main reasons why this chapter emphasizes grassroots production efforts. First, most approaches to developing broadband content have so far depended on principles and assumptions developed in older media environments. The most fundamental policy and regulatory frameworks designed to guide the development of broadband services are often developed and managed by national broadcasting authorities, applying “old media” logic to radically different converged new media environments (Young, 2004). Consequently, in developed countries there have been enormous losses associated with broadband content initiatives, as exemplified by the largest quarterly loss in U.S. corporate history by AOL-Time Warner in January 2003 (Keegan, 2003). The “dotcom bubble” notwithstanding, the impetus for the AOL-Time Warner merger, as well as the unparalleled losses the merged entity sustained in 2003, were in large part a function

of Time Warner executives wrongly believing that transferring their print, movie, and music offerings to the broadband environment would automatically result in new markets and increased profits (Rushkoff, 2002). The faulty working assumptions underpinning the above failures are analogous to the assumptions underpinning the many failed early attempts to develop television by transferring the production principles, or “genres,” used in radio (Twitchell, 1999).

Content types from older media, usually defined as “genres” of one sort or another, have been the main focus of attention in developed countries attempting to define and stimulate the broadband content agenda in the domains of policy, research, and industry (e.g., DCITA, 2003a, b). However, by definition the term “genre” refers to well established, relatively stable, and predictable media forms (Graham, 2001). A focus on genre is a focus on what has been successful in older media environments. However, entirely new types of content will flourish in broadband environments. These new types of content are unlikely to develop within the multinational mass media institutions for the reasons stated above. It is among grassroots producers that real innovation is likely to be found, precisely because of their distance from the centralized institutions of mass media. This situation suggests that by virtue of their distance from the core global production institutions the potential for developing countries to find competitive advantages in this new media environment is excellent.

Second, there is a vast difference between the “push” principle of broadcast mass media and the “pull” principle of Internet media. The “push” principle works on the assumption that relatively few people will participate in the production of mainstream mass culture while the majority of people will passively “consume” what the few produce. The “pull” principle operates on the assumption that people will, if given the opportunity, participate in the production of culture as well

as actively seek attractive content to “consume.” A recent Pew Internet survey found that 44% of Internet users in the US “have created content for the online world” sharing ideas, Web sites, photographs, video, and music (Lenhart, Horrigan & Fallows, 2004). Extrapolating from that figure, and given that broadband subscriptions have recently exceeded the 100 million mark globally, there are presently 44 million people with access to broadband infrastructure who are actively creating and sharing content. Even if these numbers were halved, this represents an enormous amount of creative energy with significant economic and cultural potential. These trends indicate a potential inversion of the economic model that underpins mass media—rather than a relatively small number of people and organizations controlling production and distribution networks for cultural content, many millions of people now have a potential audience of many millions. Again, the potential for developing countries to gain a foothold in the global production arena is clear.

By way of cautioning against over-optimism and of the need for concerted political and strategic effort, this is not to suggest all the content produced by broadband users will be successful or even of high quality, but if access to suitable infrastructure is provided in developing countries it is almost a statistical certainty that a sustainable proportion of people will learn to produce material that realizes economic, social, and cultural benefits, whether directly or indirectly. This can be seen as a similar process to that which resulted from the advent of cheap printing (following Gutenberg’s innovations) and growing literacy rates, which combined to assist the emergence of a sustainable publishing industry.

Third, there are significant social, cultural, and economic benefits for regional, remote, and community-based initiatives (National Selection Committee, 2004). According to the National Selection Committee, broadband can bring economic revival to remote and regional communities by

continuing the practice of leveraging “the high level of grassroots activism” evident in these communities (ITU 2003 in National Selection Committee, 2004). Remote regions are rich in cultural tradition and “broadband offers new possibilities for maintaining or reviving traditional cultures and languages as well as new opportunities for innovative cultural expression” by weaving the local—whether rural, remote, or urban—into the global (National Selection Committee, 2004, p. 7). It also “provides new ways for cultural industries, visual and performing arts groups, museums, and other cultural institutions to reach their audiences” (p. 7). As the Time-Warner-AOL debacle demonstrated, the broadband environment is not amenable to being merely another conduit for mass media industries. Rather, it is a platform for the unique, the exotic, and the unusual. Cultural materials with these characteristics cannot be mass produced: they require grassroots participation at the local level. In turn, “distant” communities and cultural producers can reap the economic benefits of a global audience regardless of where they are. UNESCO’s Creative Content e-Platform (<http://creativecontent.unesco.org>) is an example of an Internet-based attempt by producers from the fringes to reach out to a wider audience. This multicultural repository contains “challenging” productions by independent producers from Africa, the Asia-Pacific region, and South and Central America. While not focussed on creative content, the United Nations Development Program’s Asia-Pacific Development Information Program (APDIP) (www.apdip.net) and Malaysia’s United Nations Institute for Training and Research (UNITAR) (www.unitar.org) use online knowledge management systems to provide “open” access to such things as linguistic, cultural, health, educational, and software resources in ways that are designed to be responsive to their core users needs.

Fourth and finally, as Mumford (1934) has already pointed out above, closely linked to the

potential for economic benefit and cultural preservation is an ethical imperative underpinning economic development more generally. While Mumford's words may be interpreted by the hardened cynic as a value-laden "motherhood" statement, there are very practical reasons for taking such a stance regarding economic goals. Indeed, central to the Declaration of Principles governing the WSIS are these very ideas (WSIS, 2003). To reiterate, these include: the health of democratic participation through sophisticated media practices; the economic and cultural benefits that flow from a vibrant, active, and innovative culture of creativity; the proven net economic benefits of a knowledgeable, educated, and intellectually active population; the maintenance and promotion of local, regional, and national identities; and the personal fulfilment that comes from active and visible participation in the life of a culture.

At this point it is worth investigating a little deeper the economic value of broadband content in the global economy. The following quote is typical of emerging attitudes in policy circles in developed countries but they could be applied to policy imperatives in developing countries as well:

Broadband take-up and availability of compelling content are inextricably linked. The level of broadband take-up is likely to remain relatively low unless there is sufficient compelling content available. Since the majority of content is generated overseas it is essential to promote local content that reflects Australians' values, identity, and character. It is also important that distribution channels work effectively with Australia's content industries. (Alston, 2003)

This set of policy imperatives can be read from the perspective of the "knowledge consumption services" sector, which derives from the applied social and creative disciplines (business, education, leisure and entertainment, media and com-

munications) and represents 25% of economic activity in OECD economies (OECD, 1998). In fact all modern economies are consumption driven (e.g., 62% of U.S. GDP) and the social technologies that manage consumption all derive from the social and creative disciplines.

Worldwide, the creative industries sector has been among the fastest growing of the global economy. Several analysts point to the crucial role they play in the new economy, with growth rates better than twice those of advanced economies as a whole (Cunningham, 2005; Howkins, 2001; Jeffcutt, 2005). Creative production has become the model for new economy business practice (highly outsourced; producer model; project management within just-in-time teams, etc.). Rifkin (2000) claims that cultural production will ascend to the first tier of economic life, with information and services moving to the second tier, manufacturing to the third tier and agriculture to the fourth tier. This is a global economic structural change that developing countries should seek to participate in and benefit from.

DIGITAL PRODUCTION TECHNOLOGIES

The authors would like to discuss here, how digital production and postproduction technologies are able to change cultural production dynamics in favour of grassroots producers. Specifically, this section outlines the cultural knowledge management technologies that are central to being able to take advantage of recent changes and that will assist in reducing barriers to production of local content and the broadcast of cultural expression, the diffusion of knowledge, and assist in maintaining the cultural and epistemic integrity of content produced in, by, and for developing countries.

To understand how broadband can best be harnessed to increase economic, social, and cultural

benefit requires an appreciation of enabling infrastructures such as new and emerging production processes; archival technologies and multimedia databases; metadata practices for distributed production processes; and education and literacy strategies for new media environments. These environments are characterized by digital re-use and re-mixing of cultural expression, using cut and paste, and file sharing practices in a distributed, collaborative production processes. Therefore, the even more participatory and collectivist nature of grassroots production demands appropriate (enabling) knowledge management, technical, and organizational platforms. In particular, archival technologies and multimedia databases including middleware are essential. These include culturally dynamic metatagging systems, or metadata that can be relevant to members of multiple and diverse cultures; robust middleware initiatives that enable collaborative creation over different temporal and geographical spaces;¹ and, most importantly, flexible licensing and copyright regimes that simultaneously reflect creative design practices, national and international laws, and encourage openness while protecting ownership rights. Initiatives such as Creative Commons (Creative Commons, 2005) have helped create a legal environment that achieves these important criteria.

Open Source Content Licensing: A Legally Safe Open Sharing Environment

Perhaps the most critical aspect of open cultural production environments is the provision of intellectual property licensing arrangements designed specifically to stimulate creativity by accommodating open collaboration in a global “creative commons” (Creative Commons, 2005). This is a particular concern for open online repositories that mediate in the collection and diffusion of creative content, a process that is outside the value

system of multinational media businesses. Furthermore, because of the development concerns of this chapter, such open copyright arrangements should not only be open but must also be flexible enough to account for differences between Western and non-Western or indigenous cultural intellectual property. Therefore, the focus in this part of the discussion is on Creative Commons copyright licenses that are designed specifically to provide this kind of flexibility. To this end, it is important to note that Creative Commons licenses have been adapted in many different countries including Argentina, Australia, Austria, Belgium, Brazil, Bulgaria, Canada, Chile, China, Croatia, Finland, France, Germany, Ireland, Israel, Italy, Japan, Jordan, Mexico, Netherlands, Philippines, Poland, Slovenia, South Africa, South Korea, Spain, Sweden, Switzerland, Taiwan, England and Wales, and Scotland.

In developed countries like Australia that have indigenous communities suffering significant inequalities, it has already been argued that creatively oriented broadband infrastructure is a way to bring social, cultural, health, and economic benefits. *The Island Watch* and *Cape York Digital Network* infrastructure programs are examples of what is being done in this respect in Australia. The Australian experience also highlights how traditional Aboriginal laws, and cultural and spiritual practices are at odds with the inflexible all rights reserved structure of orthodox copyright. Australian Aboriginal experience highlights how copyright (and attitudes among creators to issues of ownership and rights that are ingrained through the dominant discourse on IP) struggle to deal with the products of cultural expression in ways other than as exclusive private property and economic commodities (Hunter, 2003; Johnson, 1996; Kleinert & Neal, 2000). Therefore, placing indigenous cultural intellectual property rights on a sound legal footing is not necessarily easy to do (Joseph & Ayres, 2005). Yet it is only the limits of imagination that prevent the develop-

ment of more flexible copyright licenses that will simultaneously respect indigenous cultural values and enable commercial activity on global markets. In respect of development, indigenous cultural production systems are key cultural innovation systems. In developing economies these innovation systems can be regarded as having particular importance for innovation and cultural policy. After all, indigenous systems of innovation are equal to Western systems of innovation even if they are different (Joseph & Ayres, 2005). Licenses already exist that acknowledge a range of rights (both economic and noneconomic); that go beyond the concept of exclusive private property and moral rights; that conceive of rights in ways that simultaneously enable the commercial and cultural handling of works of art while giving creators choices in how their works are accessed by different groups. Already at an advanced stage of responding to these issues, Gilberto Gil, Brazil's Minister of Culture and a practicing musician, has led a drive to provide freely available (online) locally produced cultural content using Creative Commons licenses (de Castro, 2004). However, before looking more closely at Creative Commons, it is possible to examine some larger questions related to copyright so as to frame Creative Commons licensing as a clear response to some important debates about the creative, social, cultural, and economic efficiency of copyright and IP law generally. Open content licensing is also an issue in education, software, health, linguistic and scientific archives, most notably in the UNITAR site.

Not only are there questions about the capacity of copyright to function effectively for economic reasons (Heller, 1998), there are persistent doubts about its effectiveness in facilitating what is often thought to be its central purpose: fostering creative and innovative work (Whale, 1971). As Bently and Sherman (2004) have observed:

Despite the prominent role that creative labour played in pre-modern intellectual property law, as the law took on its modern guise it shifted attention away from the labour that was embodied in the protected subject matter to concentrate more on the object in its own right. (p. 4)

Put another way, recognition of creativity as an activity or as a performance of value has been subverted to the extent that it is the economic value and communication of the finished work that modern copyright is primarily concerned with, while the activities, intentions, and values of the producer are now secondary considerations at best. The natural balance between equitably valuing the economic and social worth of creative work and creative workers has, therefore, been upset. Moreover, with this historical shift not only has there been a movement away from concern about protecting the rights and creative needs of the creative "laborer," there has been a shift in emphasis more towards protecting the financiers of creative work (Drahos & Braithwaite, 2002). This is a fundamental distortion of copyright, and one that is not helpful to creators—particularly those in developing countries. Most of the protected financiers controlling industrialized creative activities are organized into multinational media corporations. For this reason, the orthodox copyright framework favours developed countries rather than developing countries. Consequently, the copyright regimes of developed countries are a disincentive or barrier to cultural production, expression, and diffusion in developing countries. This is unhelpful because, while such cultures might be short of financial resources, two resources they have in plenty are culture and creativity. In other words, the raw materials for cultural development are present but the right institutional framework (particularly in terms of IP) may not be.

The open-source software licensing movement has shown that innovation can flourish outside

the traditional IP framework (Goldman & Gabriel, 2004), Linux is just one example of this. In particular, questions are now being asked about how efficacious overly restrictive (or strong) intellectual property regimes are as stimulants to the creative mind and worker (Drahos, 2005; Lessig, 2004; Mandeville, 1996). In this light, it is highly significant that Kretschmer (2005) found modern digital cultural production is now conducted in such a way that the reuse of copyright content in new productions is the norm. These work practices are an affront to the monopoly and exclusivity logic of orthodox copyright. Consequently, Kretschmer (2005) also notes that with those new practices (and attendant technologies), a more complex legal, work and business context has been created in which many independent producers either deliberately or through ignorance, routinely break the law or compromise the creative quality of their work. One of his conclusions, therefore, is that traditional copyright hinders rather than helps these producers.

As mentioned above, one attempt to modernize copyright and to give creative producers more flexibility and choice are the licenses devised by Creative Commons. Researchers at Stanford Law School's Creative Commons (CC) (Creative Commons 2003) have developed what they describe as "a spectrum of rights" that fall between the extremes of copyright and public domain (www.creativecommons.org). Creative Commons licenses are designed to promote the sharing of intellectual property and creative works to further stimulate creativity in the context of contemporary digital arts practices. In doing this the aim is to overcome the tendency of artists to "hoard" their work under an "all rights reserved" model, despite the advantages that a more open approach to sharing can bring to both the individual artist and the community as a whole. Creative Commons seeks to provide a flexible "some rights reserved" framework in which producers have more choices.

Importantly, the Creative Commons licenses are designed to accommodate both commercial and non-commercial uses of digital resources. They are based on the assumption that innovations and new ideas are fundamentally and necessarily extensions and elaborations of existing ones and that creative work should be possible in collaborative arrangements. This spectrum includes licenses in the form of:

- **By attribution:** a creator allows others to copy, distribute, display, and perform copyrighted work (and derivative works based on it) but only if they give the author credit.
- **Noncommercial:** creators allow others to copy, distribute, display, and perform their works (and derivative works based on it) but only for noncommercial purposes.
- **No derivative works:** creators allow others to copy, distribute, display, and perform only verbatim copies of their work and not derivatives based on it.
- **Share and share alike:** creators allow others to distribute derivative works only under a licence identical to the licence that governs the original work.

Once a licence has been assigned to a work by a creator it will take three forms: (1) a Commons Deed, written in plain language; (2) Legal Code, written in formal legal language that will be usable in court; and (3) Digital Code, written in machine readable form to help with archiving, searching and identifying creators' works. Authors are able to attach to their works the creative commons "some rights reserved" symbol (rather than the standard copyright symbol) (see Figure 1). The licenses can be used singly (e.g., By Attribution)

Figure 1. Creative Commons symbol

or combination (e.g., By Attribution and Noncommercial) and therefore offer an extremely flexible regime of copyright suited to modern digital broadband production environments.

As noted above, the licenses have been written according to local law in many countries and there is a need to write “purpose built” licenses for developing countries. It is not only the local differences in law that are significant here. The main point about Creative Commons is its potential flexibility for individual producers and groups. Choices could be made by different individual and groups of producers in response to, for example varying spiritual beliefs, cultural values related to individual and collective ownership, and assumptions about how to distribute wealth.

By providing a unique and diverse set of resources, and by encouraging derivative and open usage of those resources for the production of new creative works, open content repositories will help lay the foundations for new and alternative business and creative practices suited to broadband environments through which grassroots producers can benefit from. Equally important is that open content archives can be established to create a legally safe and culturally sensitive framework for individuals and organizations to work with multimedia resources in an open content environment.

Open Source Archive Model

Nigerian producer and director, Amaka Igwe, says; “Our dream is to sell Africa to the world. It’s going to be a display of our thoughts and an avenue to market ideas about Nigeria and products about Nigeria” (Balogun, 2005). She also points out that copyright, infrastructure, and distribution problems are holding the Nigerian industry back. The “open” provision of archives and their content, along with digital production and postproduction software will provide new opportunities to creative workers for whom such material would

be beyond usual budgetary constraints. In this environment, a country like Nigeria can begin to address issues such as those identified above. To begin addressing these constraints creative workers can “recycle” high-quality archival materials into new broadband content and commercial and noncommercial cultural materials using the kinds of technical infrastructures described earlier. This open framework will lower barriers to entry in the cultural production sector thereby providing incentives for employment and new business creation. Commercial cultural producers will no longer be geographically tied to the locations of major production houses.

The provision of relevant open resources has already begun. In particular, there is a growing collection of Internet accessible multimedia content and software resources, much of which is available under Creative Commons and similar licenses. For example, content is available from:

- **UNESCO Creative Content E-Platform:** <http://creativecontent.unesco.org> This is an online, multicultural catalogue of/for independent producers and broadcasters. It contains a variety of high quality recent video productions with a focus on Africa, the Asia-Pacific, and South America. This site uses standard copyright and is therefore restricted as a grassroots production resource.
- **ACRO:** www.acro.edu.au This is an archive of free content in the form of video, music, and photographs that use open source copyright licences.
- **Internet Archive:** www.archive.org This is a massive archive containing a historical record of the World Wide Web and other resources such as movies, music, computer games, cartoons, newsreels, and more.
- **Prelinger Archive:** www.archive.org/mov- ie/prelinger.php This is an archive within the Internet Archive containing over 4,000

movies, TV ads, educational films, and other interesting moving images.

- **BBC Motion Gallery:** <http://www.bbc-motiongallery.com/customer/index.jsp> The BBC Motion Gallery contains lots of old BBC footage from news, sports, natural history, wildlife, news, locations, art, music, celebrities, politics, culture, and the performing arts. Materials come from the BBC and CBS news archives.
- **The Freesound Project:** <http://freesound.iaa.upf.edu/whatIsFreesound.php> This is a searchable archive for downloadable sound files.
- **Creative Commons:** www.creativecommons.org There are a range of resources here including links to open content resources of all types and software to assist in searching for such content on the Internet.

In addition open (post) production software tools available include:

- Avid DV; Free <http://www.avid.com/freedv/>
- Audacity audio editor; <http://audacity.sourceforge.net/>
- Gimp photo editing software; <http://gimp-win.sourceforge.net/>
- PhotoPlus; <http://www.freeserifsoftware.com/serif/ph/ph5/index.asp>
- Zwei-Stein video editor; <http://www.thug-satbay.com/tab/?q=zweistein>
- STOIK Video Converter; <http://www.stoik.com/>
- AviSplit Classic video editor; <http://www.bobyte.com/>
- DubIt; <http://www.hitsquad.com/smm/programs/DubIt/>
- Soliton audio editor; <http://www.snapfiles.com/get/soliton.html>
- DeepBurner Free DVD burner; <http://www.deepburner.com/?r=download>

- Swarm DVD encoder/authoring tool; http://www.free-codecs.com/download/DVD_Swarm.htm

In addition, Google and Yahoo (see <http://creativecommons.org/find/>) search Internet engines are now able to conduct searches for Creative Commons licensed materials across the Internet.

To finish this chapter it is useful to discuss how the authors have attempted to provide an Internet-accessible creative production (rather than finished product) archive of mostly locally produced open content to provide ideas for others to consider. Australian Creative Resources Online (ACRO) is an online repository for a wide range of material and provides the opportunity to share content otherwise treated as waste or junk by mass media agencies. This “junk” is video footage and film; audio tracks and interviews; and still images. ACRO is designed to make this content available to producers with broadband access. ACRO, therefore, provides the capacity to support a new class of cultural producers who under the rigid framework of traditional commercial mass media and copyright structures would have only limited opportunities to produce content. Importantly, new producers can include teachers, students, and members of local communities. It is also important to note that there would be benefits in creating a network of such archives internationally. Each node would focus on developing local content for local and international producers.

A quick practical example of how production can be stimulated and efficiencies can be increased through open content infrastructure is when a documentary maker shoots 300 hours of nature footage to make eight one-hour documentaries for television. At the end of the series, the producer has precisely 292 hours of footage that will remain unused. Much of it will be of very high quality. Normally, this “waste” material would go into a personal archive, perhaps to be discarded unused years later. However, when the material

is digitised and made accessible on broadband networks, it can, for example, be used by teachers and students in multimedia courses, by budding documentary makers, by children learning how to make digital content in schools, or by cultural groups or communities to produce commercial and noncommercial works.

While much of ACRO is comprised of material originally intended for the traditional mass media, there is a new group of producers emerging. Producers who may come from outside the traditional commercial and educational structures can benefit from the provision of low cost, high quality content and production tools. Resource like ACRO will encourage a better understanding of the process of technology use and the role of ICT in economic and social development and in doing so will assist in building the skills necessary to develop new media production industries. In Brazil community telecenters using free software to enabling users to set up roaming accounts, and the use of wireless networking in Africa (APC, 2006) are examples of technological change in developing countries that can facilitate the construction of creative industries based around the benefits of digital multimedia technologies.

CONCLUSION

New work practices facilitated by new digital production tools and the blurring of roles and functions in creative labour processes have begun to replace the fairly rigid divisions of labour characteristic of traditional mass media industries. Using basic consumer technologies, a person or group of people can film, edit, compose music, produce, and globally distribute their multimedia productions. The new practices in interactive content production and consumption that have emerged in this environment challenge boundaries between production and consumption. Consequently a new, much larger group of people

can now be engaged in the production and global distribution of high quality multimedia works. Creative development of culture can enable societies to renew their knowledge of themselves, to remix or repurpose “received” content to suit their own needs, to have new insights about their own condition and to have new things to communicate about themselves. Cultural innovation in such networks must come from the bottom up; in other words from the grassroots. With this constant cultural renewal there are social and economic benefits for developing communities. Open content provisions should boost activities in cultural production that will lead to cultural and economic development. In the context of knowledge-based economies the importance of building this kind of capacity cannot be underestimated (Rooney, Hearn, et al., 2003; Rooney & Mandeville, 1998). If culture is knowledge (Holden, 2002; McCarthy, 1996), then, cultural production is an obvious way for developing countries to gain a foothold on a central pillar of the knowledge-based economy. It is important though that the combination of technology (archives and digital production tools), institutions (Creative Commons licenses) and creative workers (including their norms and work practices) are seen as a whole system in which none of the parts are neglected.

Chapter 3.6

The Right of Interpretation: Who Decides the Success of Picture Mail?

Michael Björn

Ericsson Consumer & Enterprise Lab, Sweden

ABSTRACT

This chapter is an empirical research report describing the diffusion of mobile camera phones and picture mail services in Japan between the years 1997 and 2005, based on annual consumer surveys conducted by Ericsson Consumer & Enterprise Lab. A general framework based on sociocultural values and attitudes to telecom for describing the telecom market from a consumer perspective is presented. This framework is then used to put different consumer life stage segments in relation to each other in respect to product diffusion. The change over time of attitudes and behavior is described, and the conclusion is drawn that the product terminology spontaneously created by consumers themselves in order to relate to the product is an important step for mass market diffusion. Furthermore, the group of people who develop this terminology becomes a crucial catalyst for diffusion—and in the Japanese case presented here consists of female students.

THE IPOD'S LIKE A CAN OF COCA-COLA...

Apple Computer has been very successful in the increasingly crowded MP3-player market. There are technical differences, the iPod can play AAC (also known as MPEG-2 Part 7; it was designed as an improved-performance codec relative to MP3) format songs and is tightly integrated with the iTunes store, but our studies at Ericsson's Consumer & Enterprise Lab (here referred to as ConsumerLab) indicate that very few people are even aware of technical differences, and that purchasing songs over iTunes is a minority activity. Instead softer issues come into play, such as design, image, and values connected to the product.

“At this point, the iPod's like a can of Coca-Cola—it's a given” says Beastie Boy Diamond in a *Wired* magazine interview (Steuer, 2004, p.187) and he is not alone in having made such statements. Instrumental in catapulting the iPod

into the ranks of the ultimate of “cool” seems to be the fact that musicians and other users themselves were early in taking a liking to the product; and, most importantly, were quite vocal in advocating its superiority. The fact that Apple had no control over this spontaneous endorsement campaign made a big difference. There is even an example of a full-featured but totally unendorsed ad film that in a matter of days had been watched 37,000 times (Kahney, 2004).

One might venture to say that although Apple undoubtedly designed and marketed the iPod, it was actually the consumers themselves who decided what was important with it. This is exactly what “right of interpretation” in this chapter’s heading is referring to.

In the current media landscape, it may well be that the meaning or significance of the product as perceived by the consumer is increasingly likely to have been imparted on it by other consumers. In other words, Apple still owns the iPod product—but the market (i.e., the sum total of potential buyers of the product) has decided what its benefits are.

To explore this point, this chapter presents a case study from Japan, based on research carried out by ConsumerLab in the years 1997-2005. The focus will be on mobile phones equipped with cameras and the picture mail service (sending pictures via mobile phones), and on how the meaning of this service was indeed decided by the market itself.

METHODOLOGY AND THE MARKETREALITY™ MONITOR

The basis of the research at ConsumerLab is annual quantitative studies (1000-2000 respondents per study, adding up to around 12,000 respondents globally per survey round) in a culturally heterogeneous sample of countries: Brazil, USA, France, Germany, Italy, UK, Sweden, Malaysia, China, and Japan. All studies are based on na-

tional representative samples in the age groups 15-69 years, except in China and Brazil, where we make urban samples because of large economic and social differences.

For Japan, specifically, the research is carried out as a mail-out questionnaire administered in late spring of each year by a well-known research institute with long-term operations in Japan.

The studies contain approximately 400 questions that are asked in the same way and same order across all countries. This questionnaire has been built up gradually since 1995 and tries to encompass a broad scope of technology-mediated information and communication, including radio, TV, computers, the Internet, and (fixed and mobile) phones (with more space given in the questionnaire to telephony). Approximately half of the questions are phrased as attitudes to telecom, from the general to the specific. The attitudes are measured using questions with seven-point Lichert scales (very important—not important; I agree completely—I do not agree at all; etc.)

The MarketReality™ Monitor

ConsumerLab has developed a conceptual MarketReality™ Monitor (hereafter referred to simply as the Monitor) based on consumers’ sociocultural values and attitudes to telecom. The Monitor is built in three steps: Identification of two-dimensional regional value maps, identification of a global two-dimensional telecom attitude map, and finally, a merging of the value and attitude dimensions based on standardized axes values with a 50/50 impact. Respondents are distributed in the model based on individual factor scores. This way we have been able to create a space where each individual is plotted and where it is also possible to plot different segments, behaviours, attitudes, and so forth—while still always describing the telecom market from a consumer perspective.

The Monitor consists of two dimensions: “Exploration ↔ Stability” and “Lasting Benefits ↔ Instant Gratification,” shown in Figure 1.

Figure 1. The monitor (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

Dimensions in the MarketReality™ Monitor

The first dimension, “Exploration ↔ Stability,” is the most important as it differentiates best between consumers on overall interest in telecom technology as well as on telecom product and service penetration. It also gives an indication as to the pace at which people need and require changes in their lives.

The higher a respondent is towards the *exploration* side, the higher her interest is in telecom technology and the more she is likely to have a large number of telecom products and services. On the *stability* side, we instead find a conservative attitude to telecom technology, and a low willingness to try telecom products or services that have not yet been tried and tested by others, and that have not received a social “seal of approval.”

Whereas the first dimension is usually present in some form in many models with a sociocultural heritage, we believe that the second dimension, “Lasting Benefits « Instant gratification” is unique to our own research. This dimension has to do with the relationship between oneself and others, but also with the reasons for using technology.

By lasting benefits we mean a tendency to take a more long-term view of the need for and

use of telecom technology. This indicates a more rational approach to the choice of telecom products and services, although it may well be that these explanations are made up “after the fact” and do not constitute truly rational behaviour.

By instant gratification, on the other hand, we mean a tendency to be more oriented towards satisfying one’s feelings and needs of the moment when considering telecom technologies. This indicates a shorter attention span when evaluating new telecom products and services, and less patience when expecting benefits from them.

A more in-depth description of the Monitor is given in the book *Situation Analysis* (Sekizawa, Washida, & Bjorn, 2002).

DIFFUSION OF PICTURE MAIL IN JAPAN 1997-2005: WHO DECIDES THE SUCCESS OF PICTURE MAIL?

Triggers for Diffusion of Services

If we apply our accumulated knowledge of triggers at ConsumerLab (i.e., something that makes people go from just showing an interest in a product or service to *act* on that interest) to diffusion (Rogers, 1995) of mobile services, we see

a pattern of differences in the Monitor.

At the explorative top of the Monitor, we find the earliest adopters (often referred to as *innovators* in marketing literature), who are triggered to use new mobile services because they are new and exciting.

In the first stage of diffusion, the explorative people towards the lasting benefits side are triggered by efficiency and the time saving they would get by using the new mobile services, whereas the explorative people at the instant gratification side are more triggered by the fun, speed, and spontaneity they get by using new mobile services. We might call this first diffusion stage early diffusion.

The second stage of diffusion is where the differences between those products (or services) that remain consigned to a niche market and those that go on to reach a broader market tend to appear—Moore (1991) coined the term *chasm* for this stage and it is used here in this sense. In our experience, the set of triggers in the chasm depend on which segment (i.e., which location in the Monitor) it is that adopts the service.

The segments towards the lasting benefits side are triggered by the convenience of the service. This convenience trigger is rationally oriented in the sense that it gets a task done in a dependable way, that is, the service fulfills an already existing need in a better way.

On the instant gratification side, triggers relate to the social enrichment offered by the new mobile service, that is, the need fulfillment is put in a social context rather than in a task-oriented context. Since the social context can change without active participation from the specific individual, chances are greater here that the need also arises implicitly in conjunction with the diffusion of the service.

Less explorative segments towards the instant gratification side are looking more for visual or (sub)cultural statements as an important ingredient to the identity they are building in relation to

their surroundings—the needs in this segment are more related to confirmation and status.

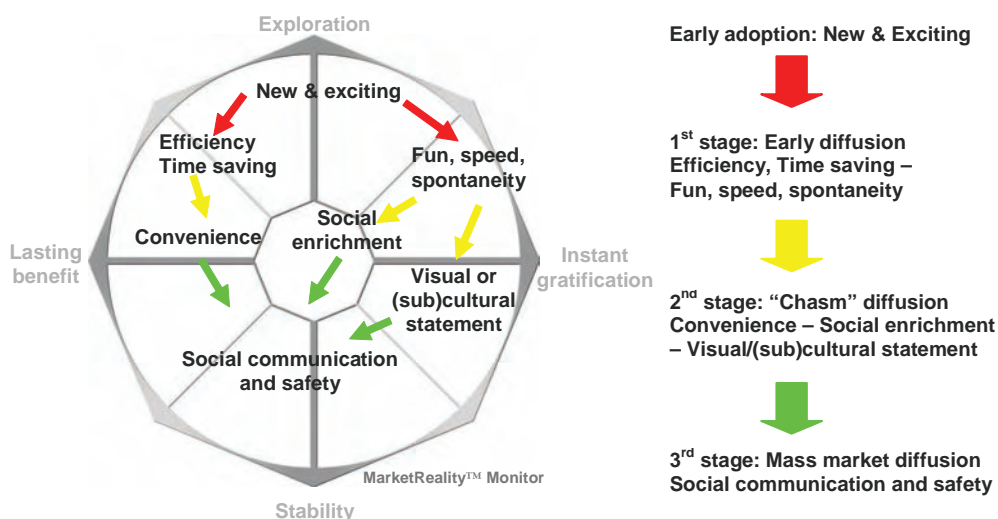

Provided that the new service does not flounder in the chasm stage, diffusion continues and reaches the mass-market diffusion stage. Here, the more stability-oriented people in the Monitor that are often the late adopters are mainly triggered by social communication and safety. It is however hard to trigger this group and many will only follow when the rest of the market is mature and everybody else is using the particular new service, which means that they have to use it in order not to be left out. Thus, we get the flow or diffusion pattern indicated in Figure 2.

We do not see this diffusion pattern in itself as anything controversial, and it could most likely be supported by evidence from adherents of linear schools of diffusion as well as by adherents of convergence diffusion models (although the naming of the various stages would certainly vary). Instead, the controversy lies in what process is needed to take place for any given product or service to move through the different stages. In order to explore this process, we will look at ConsumerLab survey data from Japan from the years 1997-2005 and follow the actual diffusion process of picture mail on the Japanese market. Interestingly, as you will see, the story is less of a diffusion story and rather more a story of how end users build a mass market!

At ConsumerLab we did our first quantitative survey in Japan in 1997 and the survey has continued on an annual basis since 1999, comprising in total over 10,000 respondents. For the sake of brevity, we only present data from the odd years (i.e., 1997, 1999, 2001, 2003, and 2005) here, but inclusion of the even years (i.e., 2000, 2002, and 2004) does not change the results in any way.

In order to look at the data, let us first establish what life stages (McDonald & Dunbar, 2004) are relevant for the different stages of diffusion, by plotting them in the Monitor.

Figure 2. Diffusion pattern in the monitor (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

Life Stages (Gravity Centres¹)

Figure 3 shows a plot in the Monitor of life stages in Japan 2001, the middle year in our series (the positions of the life stages vary very little over time). The major difference in comparison to life stages in our global (i.e., 10 countries) sample is that the group *men married no kids* is in the upper left side of the model (whereas it is in the upper right side of the model in the global sample).

Now let us look at the data year by year. Roll back your clock; imagine that you are back in year 1997 and visiting Japan.

Graphic Communication: Japan, 1997

Back in 1997, mobile phones were used for talking. Yes, it does seem like the Stone Age, but in fact it was not such a long time ago. New things were already happening that would change the way we view mobile phones for ever; SMS or

text messaging was already popular and the idea that the phone would become a multimedia communications device no longer seemed like science fiction. Specifically at Ericsson, we believed that inclusion of other media types in the communication process would provide powerful means to enrich phone conversations. Although there were no camera phones in the market, 1997 was the year when we started doing market surveys to understand the interest for camera phones (and Ericsson later became a driving force in the global standardization of picture messaging, MMS).

Figure 4 describes the starting point for diffusion of graphic communication services in the mobile phone in Japan. All the data for the years 1997, 1999, 2001, 2003, and 2005 will be presented in this manner. Indexes presented in the graphics are calculated so that the average for all twelve life stage groups is 100 (where, for example an index of 160 means 60% above the average). The picture shows the upper half of the Monitor and is focusing on two extreme life stage segments; the *men family university* group (i.e., men who

Figure 3. Life stage in the Monitor (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

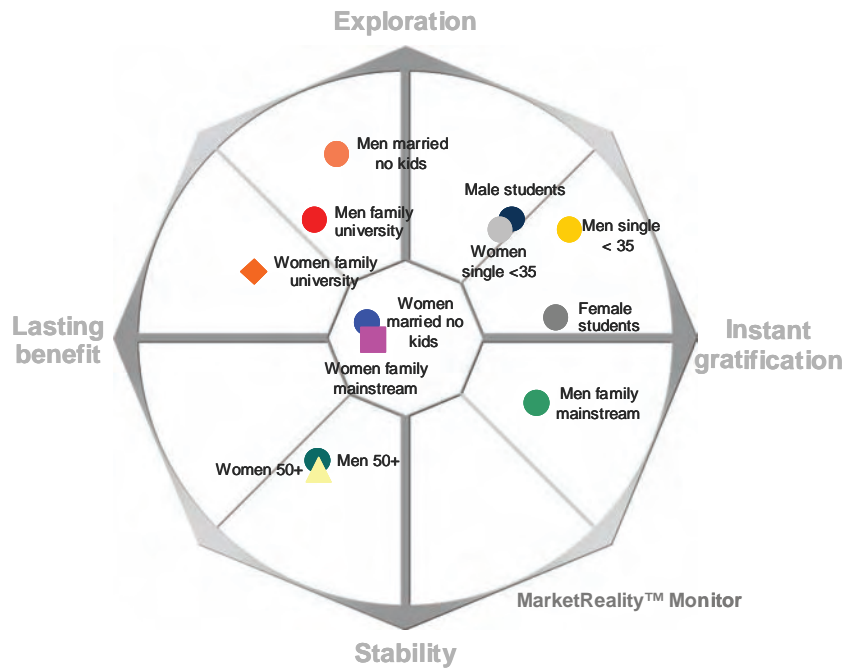

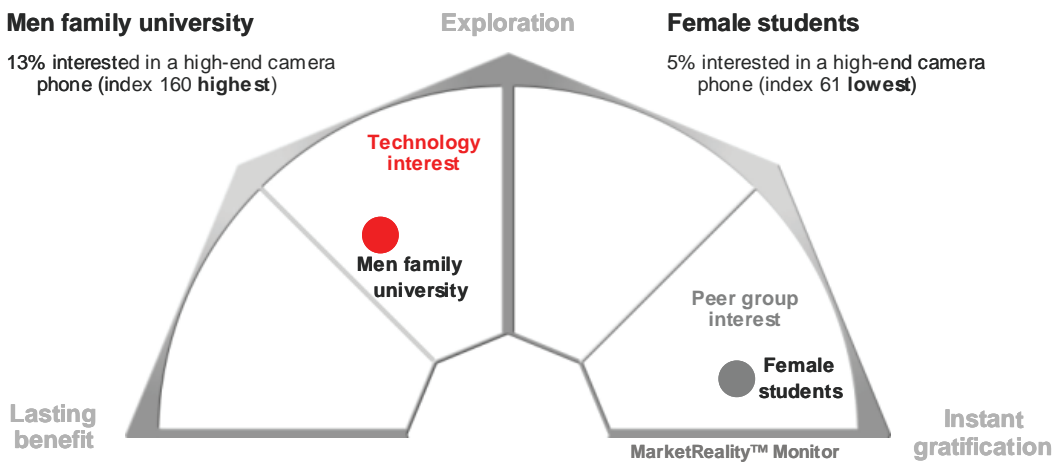

Figure 4. Starting point (1997) for diffusion of graphic communication services in Japanese mobile phone (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

The Right of Interpretation

have a university degree and also have a family) and the *female students* group. The left half of the graphic contains information pertaining to the *men family university* group and, correspondingly, the right half of the graphic contains information pertaining to the *female students* group (unless otherwise stated). We have selected these two life stage segments for a number of reasons:

- They are present in the early stages of the diffusion flow and are thus key segments for initial product uptake.
- They are the most consistently different segments and turn out to play unique roles in the diffusion process.
- They correspond reasonably well to the popular Japanese ideas of otaku² (for *men family university*) and kogal³ (for female students); whereas the *men family university* group are driven by an interest for technology (at least for the type of product/service category we are investigating), the *female students* group are driven more by an interest in what their friends are doing (their peer group).
- They are of sufficient size for statistical analysis.
- They are stable in comparison to the same groups in other countries (as is opposed to the *men married no kids* group that moves to the upper right side of the Monitor in other countries).

In 1997 the *men family university* group showed the strongest interest of all 12 life stages for a high-end camera phone (at a price level of around 375 euro) with picture mail capacity (i.e., the possibility to include photos or pictures in a message). On the other hand, the *female students* group had the lowest interest of all 12 groups.

Our interpretation of this is that the *men family university* group saw a range of possibilities with this type of a product and were also excited by the new digital photo technology as such. The *female*

students group on the other hand saw no relation between this product and their daily needs.

Graphic Communication: Japan, 1999

In 1999 we can see that it is not the camera phone that has been introduced on the market, but instead the digital camera. The *men family university* group have clearly followed up on their early interest in digital photo technology and are the early adopters as well as usage leaders of this product. However, they still see quality as an issue and are probably already upgrading to second-generation digital cameras. Having already been “burnt” by e-mail in the phone turning into nothing more than paging (or simple text messaging), they do not see the need anymore for having the digital camera integrated into the phone.

The female students, however, have a totally different approach to digital photos. Thanks to the interest shown by early adopters (i.e., the *men family university* group—possibly their fathers) already back in 1997, they have gotten used to the idea of digital photos, and they already find the quality good enough. They are in fact already using digital photos in the form of Print-Club pictures. Print-Club is a photo machine reminiscent of passport and identity card photo machines found in train stations and so forth in many countries—with the big difference that the photographs are in colour, can be decorated with frames, and are printed as stickers. At this point in time, Print-Club pictures were shared among friends and many youngsters carried around albums with pictures of all their friends to show other friends when meeting them.

As you can see in Figure 5, the female students were the group most interested in viewing Print-Club pictures (*photo-seals*). Although female students are also most satisfied with digital picture quality, it is important to point out that Print-Club pictures paradoxically at this point in time were of downright awful quality (when understood as pixel density and colour range); instead their

quality judgment was probably influenced by the usefulness of the pictures, namely in sharing with friends, where they also score higher than any of the other life stage segments. The indication is that for them, it would be almost as natural to move the Print-Club into the mobile phone, as it was to move the pager into the phone. This was also the gist of the message that ConsumerLab was giving our Japanese customers in this time frame.

The bottom line, however, is that digital photography in the form of a personal device, was not yet spreading from the early adopters, as the digital camera was not a device that the female students—or other groups with average or lower interest in technology—could fully relate to.

Graphic Communication: Japan, 2001

In 2001 we can see the gap widening between the two groups, indicated in Figure 6: The *men family university* group are more and more concentrating on the digital camera, and this product is becoming relatively harder to find a need for among the female students. The digital camera starts diffusing into the mass market, but as a direct replacement to the analogue camera with film (as we can see from analysis of other questions in the survey not presented here). The female students play no active role in this diffusion.

On the other hand, female students score highest on all counts relating to digital photography in the mobile phone. Their interest for Print-Club pictures is starting to migrate to an easier-to-use and more convenient platform, although the actual application is not changing and neither is their peer group interest: taking pictures of themselves together with friends in various situations and showing them to other friends in other situations. The platform they are moving to is Sha-Mail, a picture mail application that was introduced in the year 2000 by the Japanese mobile phone operator J-Phone (now Vodafone Japan K.K.). The other Japanese operators would eventually follow suit

and introduce similar picture mail platforms, but since this is not a description of the development of the competitive market situation in Japan, we will simply refer to Sha-Mail and the other competing applications as picture mail in this presentation. (However, it might be interesting to point out that the Print-Club machine vendors also responded to the new threat by starting to put their machines online—however, ultimately without great success.)

Graphic Communication: Japan, 2003

In 2003, shown in Figure 7, the definition of picture mail as a form of social communication has become firmly established on the market by the female students, and although they remain the most avid proponents for this type of usage, the service is now in the mass market (i.e., roughly 50% of mobile phone owners have camera phone and/or picture mail). However, usage rates are extremely much higher in the *female students* group than in other segments, with almost half of the group sending picture mail at least once a week.

The *men family university* group is reacting negatively to the apparent success of picture mail among youngsters in the market, and turns in the lowest score of the 10 life stage segments below age 50 measured on the interest in sending pictures directly with their mobile phones. One might say that their reaction is one of outright rejection of picture mail as an interesting technology.

Graphic Communication: Japan, 2005

In 2005, shown in Figure 8, the hype around picture mail is gone, but usage in the *female students* group remains reasonably high—the levels we see this year probably reflect lifestyle usage on a practical level and may be the type of usage we

The Right of Interpretation

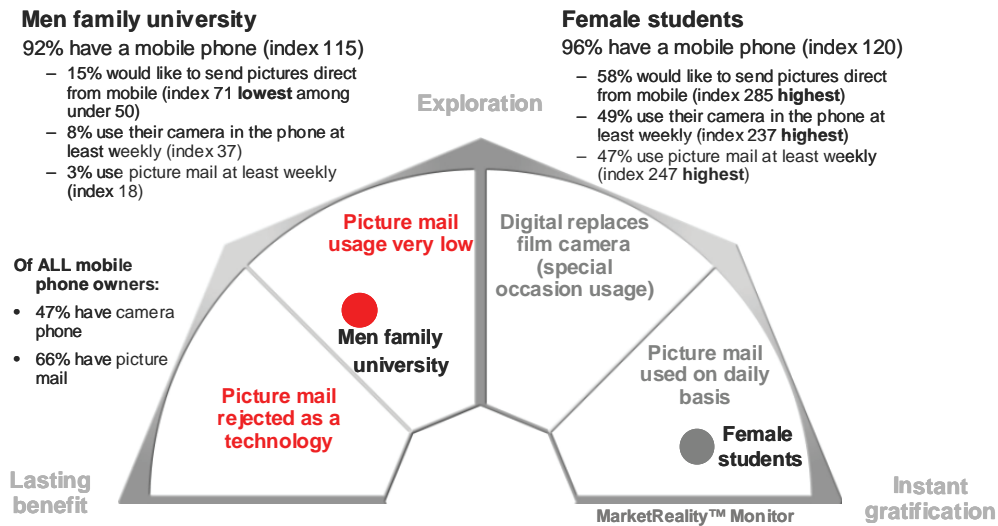

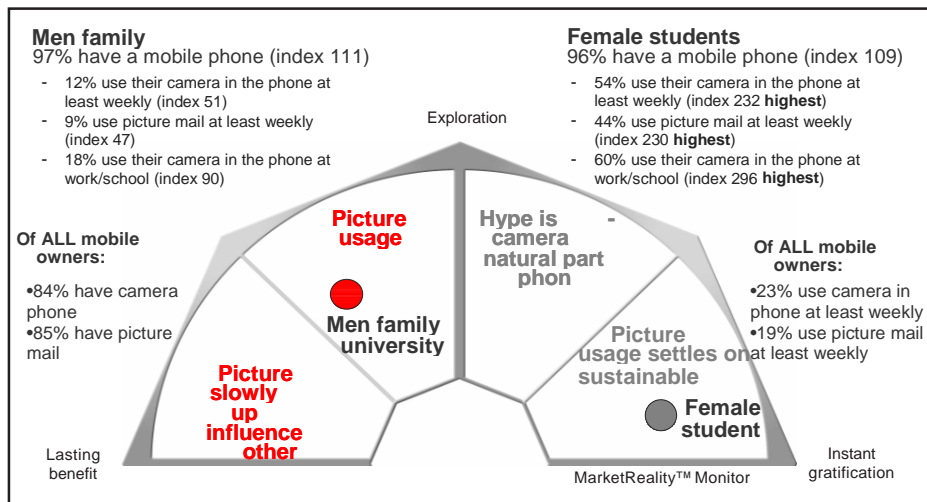

Figure 8. Diffusion in 2005 (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

can expect in the long run from this group now that the camera has become a naturally integrated part of the mobile phone.

Totally on the market a critical mass of users (i.e., roughly 30% of mobile phone owners use camera phone and/or picture mail at least weekly) has evolved, leading us to believe that picture mail will remain a mass market service in the 2006-2010 time frame.

Interestingly, the *men family university* group is still lagging far behind the general market uptake, both when it comes to using the camera in the phone and for sending picture mail. While they have rejected camera phones on the basis that stand-alone digital cameras represent better technology, they are still influenced by usage uptake in society surrounding them—their gradually increasing usage likely represents a need to communicate in a manner suitable to the receiver of the message rather than a need to express themselves in a richer way.

Who Decides That Picture Mail Will Become Successful?

What we have seen here is a total reversal of initial interest and actual behaviour. Although the *men family university* group showed the strongest initial interest in a mobile phone with built-in camera—and would have been the obvious recommended target group by market researchers (with a high-end phone model)—they end up nearly at the bottom of the ladder with very low usage rates even eight years later. Conversely, the *female students* group go from showing the lowest interest to being the group that drives usage and thus general adoption.

While this may seem paradoxical, the answer lies in the triggers for behaviour that we discussed earlier. The difference in triggers between these two life stage groups in the Japanese context—and the inherent opposition between them—has been observed by others, such as Fujimoto (2005), who

would most likely define the diffusion pattern described here as a third-stage (socializing) paradigm of adoption. And although we had labelled the different triggers with words, it turns out that the process behind that label is the crucial part.

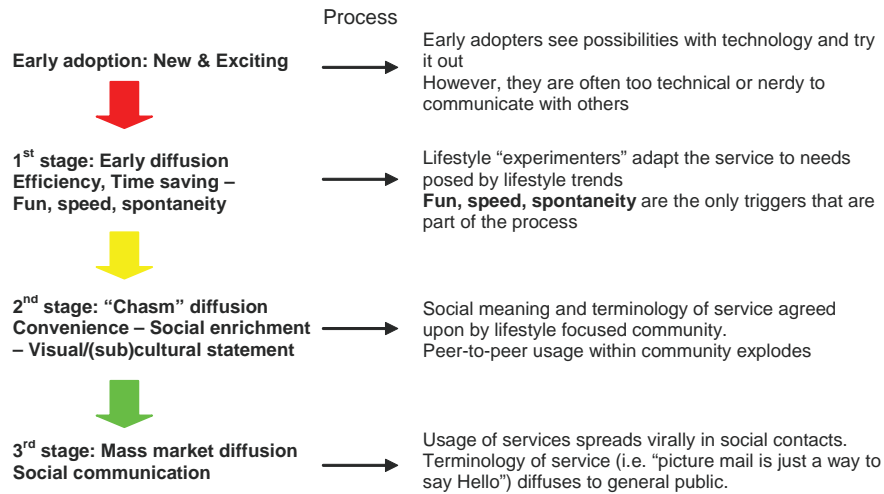

Early adopters in the top of the Monitor in Figure 9 are triggered to use new mobile services because they are new and exciting. They see the possibilities with the specific technology behind the service (product) and try it out. However, this group is often too technical or “nerdy” to communicate their vision or the benefits they see with the product to others. Others may call upon them as experts when problems arise, but this happens at a later stage when they already have started using the service for other reasons.

In the first stage of diffusion, the explorative people towards the instant gratification side are more triggered by the fun, speed, and spontaneity they get by using new mobile services. This group of people can be seen as lifestyle experimenters, in the sense that they are on the cutting edge of lifestyle-related trends such as fashion, food, music, and social behaviour. While not being interested in technology per se, this group takes high tech for granted and is thus willing to try out the service in order to see if it can be adapted to the lifestyles they are currently exploring.

In the second stage, the chasm diffusion stage, a process of redefinition of the need for and the social meaning of the specific service takes place. The social meaning of the service and terminology used to describe it is agreed upon inside of the lifestyle-focused community. By *social meaning* we here refer to the meaning of the service as it is actually interpreted by the users, it is social in the sense that the meaning is derived through interaction and exchange of opinions with others, and essentially a *conjunction* as described by Hebdige (1979).

In other words, it does not have to be the same meaning as the provider of the service intends the service to have—but it still needs to have a

Figure 9. Diffusion process (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

meaning, lest it will slip off the radar and be forgotten. The importance of meaning for retention is well documented by cognitive psychologists (Anderson, 1990).

Similarly, the terminology used to describe the service may be different in the user group from that used by the service provider. For branded services both users and service providers will probably use the brand name, albeit with different connotations. In this case, Sha-Mail would be used by end users to denote something pragmatic and useful like a “graphic hello”⁴ whereas, the service provider probably had a somewhat more technical association for the name.

Furthermore, usage within the community explodes. It seems that the explosion of usage is necessary in order to turn the service into a focus for behaviour in the peer-group community. There is a strong sense of a “we” in the peer group which stands in (implicit) opposition to a “them.” So the service becomes almost like a secret link between the members of the group, where a cultural behaviour basically unknown to the rest of society is developed. The Japanese term for this type of sudden and drastic increase in usage would be *my boom*⁵—and explosions

are indeed the cause of booms. This leads to the service becoming perceived both as some form of social enrichment and as a direct visual or otherwise (sub)cultural statement. The difference in perception depends on which market segment the observer belongs to.

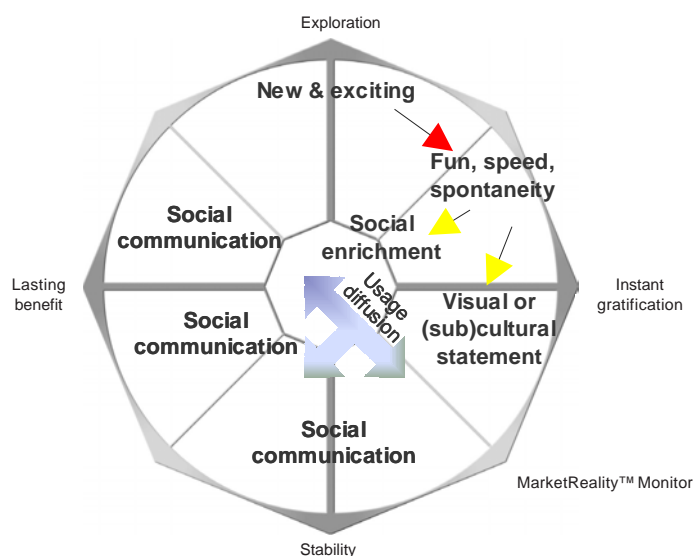

Provided that the social meaning of the service and the terminology used to describe it as defined in the *chasm* diffusion stage is relevant and makes sense to a broader part of the market, diffusion continues and reaches the mass-market diffusion stage. In the case of picture mail, the terminology comes from ordinary greetings: “picture mail is just a better way to say Hello,” the need of which is relevant to and easily understood by most people.

The later adopters of the service are mainly triggered by social communication. As diffusion progresses, it becomes increasingly harder to trigger users and they will only follow when the rest of the market is mature and everybody else is using the new service, which means that they have to use it in order not to be left out.

Putting back the triggers into the Monitor, we actually get a much simpler picture, shown in Figure 10, than what we started out with. The

The Right of Interpretation

Figure 10. Diffusion process in the Monitor (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

complexity lies not in the triggers but in the processes that actually make these triggers go off.

IMPLICATIONS FOR OTHER MARKETS AND/OR OTHER SERVICES

A relatively common point of view is that Japan is a very different country (in various senses, depending on whom you ask)—and that, consequently, results from the Japanese market are not applicable to any other market. When combining the different perspectives of politics, technology, value chains, marketing, and so forth, this may or may not be true. However, from a strictly individual-oriented perspective, our experience is rather the opposite. There are large differences between many countries in the world, but Japanese people are not more “different” than people in many other countries. This view is also corroborated for example in the Inglehart Values Map,⁶ which puts Japan very close to Protestant Europe,

especially on the Secular-Rational dimension, but also on the Self-Expression dimension. At ConsumerLab, we have also done measurements on the cultural effect of globalization on consumers, and the indication is that Japanese people to a quite high degree are affected by globalization (more so than Americans, for example).

The important insight is that the results presented here just may be the norm rather than the exception. In order to open the table for discussion, we will look at diffusion data for two other services, SMS (or text messaging) over the mobile phone and music download over the Internet. The first example points to a mechanism very similar to the picture mail case, but on a global scale; the second example is inconclusive.

Diffusion of SMS Over the Mobile Phone

It is safe to say that SMS (or text messaging) was the first successful nonvoice application for the mobile phone. However, since the industry probably was not aware of the large impact that SMS ultimately would have, it is difficult to find good

data from the early years of SMS usage. While not going back that far, we will here in Figure 11 look at SMS data for basically the same time period as we did for picture mail. In this case, then, the focus is consumers who send and/or receive SMS in the mobile phone at least once a week, but now covering all countries in the ConsumerLab survey sample.

First, however, some methodological points must be made: The countries in this sample are at various points of sociotechnological maturity and any interpretation of the results must bear this in mind. An age-gender division has been used instead of life stages for the reason of presentation brevity (8 groups instead of 12) and because of larger variation between countries in sizes of life stage groups. The usage levels have been indexed on a age-gender group per country and year basis, so that the usage level in a specific age-gender group in a certain country and year has been divided by the average usage level for that country in the same year—in effect giving us the relative importance of a specific age-gender group for SMS in that specific country and year. After that, all individual age-gender groups have been added for all countries in a specific year

and finally normalized so that all countries have equal weight—in effect giving us the relative global importance of any age-gender group for SMS in that specific year. Furthermore, the years 1996-1997, 1998-1999, and 2000-2001 have been combined, since ConsumerLab’s survey program was not fully annualized for all countries until the year 2002.

As shown in Figure 11, although the relative importance of the youth market is clearly seen, the result of the analysis also shows three distinct phases: The first phase is represented by 1996-1997, where there is a clear male dominance—with relatively higher incomes and a tech orientation similar to the *male family university group* mentioned elsewhere in this chapter. Usage levels of SMS are typically in the 15% range on a weekly basis. The second phase is represented by 1998-1999, where there is high growth but still some exclusivity in the user base. SMS usage levels are now typically in the 30% range on a weekly basis. In this phase we seem to be in the chasm and the overall equalling out of the age-gender groups; here it may be indicative of a reevaluation of the social meaning of SMS. Initially many possible meanings are present, including meanings related

Figure 11. Diffusion of SMS usage (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

The Right of Interpretation

to efficiency and time saving, but by the beginning of the third phase one meaning has taken hold over the other—and that is the real-time oriented conversational (or chat-like) meaning that is also dominant today. It is interesting to see that the 15-24 female age group is the largest group for the first time in 2000-2001, indicating a new phase, and that it remains as large as the 15-24 male age group for the rest of the data series. The third phase is then the mass-market diffusion scenario with weekly usage levels of up to 90% in the most recent data. For this reason the relative market importance of the 15-24 female (and male) age groups diminish over time as the behaviour and use pattern initiated by this group spreads to other segments in the market.

Diffusion of Music Download Over the Internet

Our second multi-country diffusion pattern example deals with downloading of music from the Internet (legally or illegally). The data set presented in Figure 12 is taken from our syndicated survey partner NOP World, as ConsumerLab's

own historical data are not as consistent in asking about specific services on the Internet, and for this reason the time period is slightly different. However the countries are the same as in ConsumerLab's own scope—except for the fact that Sweden has been omitted—and sample sizes are similar with around 1,000 respondents per country and year. Apart from this, the calculation methodology used is exactly the same as for the SMS over the previous mobile phone example.

In the data set in Figure 12, the male dominance throughout the whole series is the most striking feature—especially the 15-24 male age group. Moreover, there is no indication whatsoever that more than one diffusion phase is present in the series, even though there is a big downward movement in relative market importance for the 15-24 male age group from 1999-2000. Considering that music download music levels in 1999 were typically only in the 10% range of the population surveyed, the explanation rather seems to be a movement from the very earliest adopters to a larger but still early adopter-oriented type of user base. In the year 2000 typical usage levels are approaching the 20% range although there are still big variations between countries. From that

Figure 12. Diffusion of music download over the Internet (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

point usage levels gradually move up to the 30% range without any major movements in the market composition. This example has been added to show that cases that do not fit the Japanese picture mail pattern are readily available, although this is not the place to go further in analysing music download over the Internet. However, it should be pointed out that this example may well show influence of anti-downloading activities from the music industry—portraying music downloaders as “leeches” (Ebare 2004) and possibly forcing a peer-group-generated social meaning of music downloading back into the underground again.

Support for this idea also comes from the comparison of downloading of music from the Internet to downloading of music over the mobile phone using only 2004 data from the same data set indicated in Figure 13.

Although it is in the early days of downloading music over mobile phones, with typical usage levels in the 5% range and extreme youth orientation, it is interesting to see that the male domination is much weaker on the mobile phone than on the Internet. Because of earlier involvement from the music industry on mobile phone downloads, there is very little illegal downloading happening in this market, and it seems obvious that the music download market for mobile phones is poised to

take a different route from music downloading on the Internet.

Another obvious interpretation is that the diffusion mechanism for services over the mobile phone follows one pattern and that services on the Internet follow one or several different patterns. In other words, the Japanese picture mail example may be highly relevant for other mobile-phone-based services (in other countries) such as SMS and music download—but provide less insight on diffusion patterns on the Internet.

SUMMARY AND DISCUSSION

The point of this chapter is by now hopefully very clear to the reader: The Japanese female students were not the earliest adopters of the picture mail service, but they were the crucial group to capture in order to make the service successful on the mass market. This is true to the point where it actually becomes irrelevant who the early adopters were. For the picture mail service—or, we believe, for any service based on new technology—it is relatively easy to find a small group of explorative people who are willing to try the service out, but it is more difficult to find a group who can translate the ramifications of the inherently new

Figure 13. Music downloading in 2004: Comparing via mobile phone and over the Internet (Copyright Ericsson Consumer & Enterprise Lab. Used with permission)

technology that the service implies into something meaningful for the mass market.

As shown in Figure 14, the life stage group *men family university* is the group originally interested in picture mail—but since the cameras in the mobile phones as well as the technical limitations in the messaging service do not live up to their expectations, they totally lose interest.

Female students start using digital images because they are delivered faster (e.g., in Print-Club machines) and fit better in a spontaneous lifestyle. Gradually they then focus this behaviour on picture mail in the mobile phone, creating a mass market in the process.

The answer to the question posed in the title of this chapter then becomes: The female students are the decision makers. It was they who decided that picture mail was bound for success; not the product managers, not the marketing people, and not even the early adopters. Obviously, they did not make a joint conscious decision at any point in time—instead many relatively unimportant individual decisions proved to have synergetic effect.

Compared to the *men family university* group (i.e., the early adopters in this case) they have lower social status, less individual power, and certainly lower income. But at least in the case of the picture mail service, it seems that their peer group networking nevertheless is a powerful vehicle for influence over other groups in society.

Moreover, the influence of the female students on other groups in society is at least twofold, since their adoption of picture mail has the effect of deciding the social meaning of picture mail (e.g., the usage style and code of conduct) and the terminology used to refer to the usage of picture mail (e.g., “a graphic hello”). The diffusion of social meaning of the service as defined by the female students, as well as the diffusion of their terminology was in essence what paved the way for the diffusion of the actual service itself.

This chapter has dealt mainly with communication services (and primarily with the Japanese picture mail service)—services that to some extent are all exposed to a network effect, as formulated with respect to individuals in Metcalfe’s Law⁷ (“the value of a network equals approximately the square of the number of users of the system”). As an idea for possible further exploration, it is interesting to note that when the terminology for picture mail fuses with ordinary language, a network effect is created in the sense that the more people that use this terminology the more natural it seems to become (and the greater its social value). In the same way, we may even attempt to describe the failure of the *men family university* group to have any impact on this market as a network externality effect (Liebowitz & Margolis, 1995)—since their terminology may be too difficult for others to internalize (i.e., adopt as part of their natural vocabulary).

The relevance of this story for other services in other markets could be argued, but from the data for other countries presented here, we have reason to believe that it may be quite relevant for mobile phone services such as SMS and music download—although it may provide less insight on diffusion patterns on the Internet. But even if the details of the diffusion patterns as such differ, the evidence is that it will be increasingly difficult to ignore the effects of how individual users themselves interpret product and service offerings and pass the word on to others. “At this point, the iPod’s like a can of Coca-Cola—it’s a given.” Indeed.

Chapter 3.7

The Role of Information and Communication Technology in Competitive Intelligence

Dirk Vriens

University of Nijmegen, The Netherlands

ABSTRACT

This chapter discusses the role of ICT for competitive intelligence activities. To this end, it starts with an introduction to competitive intelligence. Next, it discusses possible uses of ICT for intelligence activities. In this discussion attention is paid to the use of the Internet, to general purpose ICT tools, to ICT tools tailored to one or more of the intelligence stages, and to business intelligence tools (data warehouses and tools to retrieve and present data in them). Finally, the chapter describes how organizations may select ICT applications to support their intelligence activities.

INTRODUCTION

Competitive Intelligence (CI) can be described as producing and processing information about the environment of an organization for strategic purposes (cf., Kahaner, 1997). To (re-) formulate their strategy, organizations need to collect and process information about their environment—about, for instance, competitors, customers, suppliers, governments, technological trends or ecological developments. Collecting and processing environmental information for strategic purposes is by no means something new. It has always been important. Without knowing what is going on in

the environment, keeping the organization viable would be impossible. In fact, as Beer (1979) asserts, the “intelligence function” (scanning the environment in order to maintain the adaptability of a system) is a necessary function of *any* viable system. However, the issue of *explicitly* building and maintaining an intelligence function in an organization has only gained importance since the last few decades (cf., Hannon, 1997; Fleisher, 2001a). Due to the increasing complexity and dynamics of the environment the need to produce relevant “actionable” intelligence is increasing as well. Because of, for instance, increased global competition, (speed and impact of) political changes, and rapid technological developments (e.g., Kahaner, 1997; Cook & Cook, 2000; Fleisher & Blenkhorn, 2001) the need for information about the environment is more pressing than ever. As McDermott (in Hannon, 1997, p. 411) puts it, “Perhaps [CI] was inevitable, given the heightened competition that prevails now [...]” Or, putting it more directly: “If you are in business, you need competitor intelligence” (Fuld, 1995, p. 1). At the same time, organizations are facing a huge amount of available data about the environment. The Internet, although a very useful source of environmental data, is growing so large that finding relevant information is hard. As many authors point out (e.g., Cook & Cook, 2000; Chen et al., 2002), this leads to the problem of information overload.

Organizations are thus faced with an increased pressure to produce relevant information about the environment and, at the same time, with an extremely large, ever-increasing amount of data about the environment. To deal with this problem, many organizations are explicitly structuring their intelligence activities. Many have, for instance, implemented so-called “competitive intelligence units” (see Prescott & Fleisher, 1991; Kahaner, 1997; Fuld, 2002; or Gilad, 1996, for examples). To structure the process of competitive intelligence, several authors (cf., Kahaner, 1997; Gilad

& Gilad, 1988; Herring, 1991; Bernhardt, 1994; Fuld et al., 2002) propose an “intelligence cycle,” consisting of four stages:

1. **Direction.** In this stage the organization determines its “strategic information requirements.” It determines about what aspects in the environment data should be collected.
2. **Collection.** Here, it is determined what sources can be used for data collection and the data are actually collected.
3. **Analysis.** In the analysis stage collected data are analyzed to assess whether they are useful for strategic purposes. In this stage, the actual “production” of intelligence (data relevant for strategy) takes place.
4. **Dissemination.** The intelligence (produced in stage 3) is forwarded to the strategic decision-makers and used to formulate their strategic plans.

To make sure that these activities can be carried out properly, an organization should implement a so-called “intelligence infrastructure” (Vriens & Philips, 1999). This infrastructure consists of three parts: (1) a technological part, comprising the ICT applications and ICT infrastructure that can be used to support the (stages in the) intelligence cycle, (2) a structural part, referring to the definition and allocation of CI tasks and responsibilities (e.g., should CI activities be centralized or decentralized? Should CI-activities be carried out by CI professionals or can others be involved?), and (3) a human resources part, which has to do with selecting, training and motivating personnel that should perform the intelligence activities. The challenge for organizations is to find a balanced “mix” of technological, structural and human resource measures to build and maintain the infrastructure (cf., Fuld, 1995; Kahaner, 1997; Gilad & Gilad, 1988; Hannon, 1997).

In this book we focus on the technological part of the infrastructure. In particular, we focus on

the Information and Communication Technology (ICT) applications supporting the intelligence activities (see for instance Cook & Cook, 2000 for an overview). Examples of such ICT tools are the systematic use of the Internet for direction or collection activities (cf., McGonagle & Vella, 1999; McClurg, 2001), groupware applications for uncovering information requirements, specific applications for supporting the analysis of information (e.g., System Dynamics software), the use of an intranet for disseminating intelligence (cf., Cunningham, 2001; Teo & Choo, 2002), and data warehouses or data mining tools (cf., Zanasi, 1998; Cook & Cook, 2000; or Ringdahl, 2001).

Although many ICT tools to support intelligence activities are available, organizations face difficulties in using them. One particular difficulty is that there tends to be an overemphasis on the role of technology in obtaining intelligence. As a result, some organizations rely too much on the use of their ICT applications for intelligence. For instance, ICT for competitive intelligence often means ‘implementing’ a data warehouse with tools for (quantitative) analysis. The software industry even seems to equate the term “business intelligence” (a “former” synonym of competitive intelligence) with data warehouses and associated tools. In other cases, organizations implemented a “CI unit,” consisting of one person monitoring the results of an online database. In these cases, the technology is viewed as the only or most important means to produce intelligence. This can be problematic for several reasons. First, the data from data warehouses (or from ERP applications) mostly have an internal focus (cf., Fuld, 2002; Li, 1999) while competitive intelligence is about environmental data. Second, the use of ICT as the main source for intelligence may lead to an “unjustified sense of control” or even overconfidence in ICT for obtaining CI. This sense of control may emerge because of the vast amount of (electronic) sources one hopes to have at one’s disposal—e.g., by means of an online database, by means of clever search engines or

by means of a large data warehouse. However, the sense of control is unjustified, because one important source of intelligence—human intelligence (cf., Kahaner, 1997; Fleisher, 2001a; Fuld et al., 2002)—is not directly accessible via ICT [although the Internet may be used as a tool for tracking down and contacting primary sources (see Kassler, 1998)]. The sense of control is also unjustified because the number of electronic sources (e.g., websites) attached to the Internet is so large that no search engine covers all of them (see Chen et al., 2002). Moreover, their content is also (continuously) changing. Overconfidence in ICT for producing intelligence may also emerge because of the belief that intelligence activities can be automated. This is not true (yet) (see Fuld et al., 2002; Cook & Cook, 2000). As Cook and Cook (2000) remark: What you get from ICT-applications is data that still have to be put in a proper context to obtain intelligence. Direction and analysis remain the work of humans.

Another difficulty with using ICT in intelligence activities is that it can increase the information overload. If the collection stage is not properly directed, the Internet becomes “the intelligence-highway to hell”: without a clear focus one can go on searching and mining forever.

A last problem with employing ICT in intelligence activities we want to mention here is that ICT is sometimes implemented without paying attention to the human resource and structural parts of the infrastructure. For example, a persistent problem with the use of an intranet for intelligence gathering and dissemination is that some “refuse” to use it. The reasons are various: ranging from “lack of time,” “no part of my job-description,” to “I don’t see the point in using this system.” In such cases, the importance of additional human resource measures to motivate personnel to use the intranet application is not recognized (see e.g., Bukowitz & Williams, 1999, for a treatment of this motivation issue). A way to deal with such problems is to treat ICT as a part of the whole infrastructure.

Despite such problems, however, ICT is a valuable part of the intelligence infrastructure. ICT offers many opportunities to support (and sometimes carry out parts of) intelligence activities. However, to avoid problems, organizations should be careful in selecting and implementing ICT applications for CI purposes. They should know the possibilities of ICT to deliver internal and external data and its capacity for supporting (and carrying out) CI activities, and they should treat ICT as a part of the whole infrastructure. In short, to support organizations in using ICT properly for their intelligence activities, an understanding of the role of ICT in intelligence activities is needed—both in terms of the (im)possibilities of ICT for intelligence activities and of its being a part of the whole intelligence infrastructure. This chapter intends to address this need. Its main goals are (1) to give an overview of the use of ICT for the intelligence activities, and (2) to present criteria for selecting proper ICT applications. To reach this goal, the plan for the chapter is as follows. In the next section we discuss competitive intelligence more closely. Next, we present an overview of ICT applications for CI. And finally we discuss the issue of selecting ICT for CI.

WHAT IS COMPETITIVE INTELLIGENCE?

To determine the role of ICT in competitive intelligence, it is first necessary to define CI. Many authors use the term, but their definitions differ. Consider, for instance, the following two definitions:

1. “CI is the process of ethically collecting, analyzing and disseminating accurate, relevant, specific, timely, foresighted and actionable intelligence regarding the implications of the business environment, competitors and the organization itself” (Society of Competitive Intelligence).

2. “CI is the process of obtaining vital information on your markets and competitors, analyzing the data and using this knowledge to formulate strategies to gain competitive advantage” (Yuan & Huang, 2001).

At a first glance, these definitions seem to refer to the same thing. Both refer to a process of obtaining information, analyzing it and using (or disseminating) it. Some differences may also be noted. One definition speaks of intelligence, while the other refers to information, data and knowledge. The second definition explicitly states the goal of CI—while the first leaves it more implicit.

In this section, we examine competitive intelligence by means of the following four aspects:

1. the contribution of competitive intelligence
2. competitive intelligence as a product
3. competitive intelligence as a process
4. the nature of the obtained competitive intelligence

This enables us to define CI and, at the same time, understand the differences and similarities of different definitions in the literature.

The Contribution of Competitive Intelligence

Authors mostly refer to two reasons for obtaining competitive intelligence. The first reason is that it contributes to an “overall organizational goal” such as improving its competitiveness or maintaining the viability of the organization. The second reason refers to the contribution of CI to the organizational activities needed to reach the overall goal (e.g., decision-making or strategy formulation). For instance, the second of the above definitions of CI refers to both kinds of contributions. It states: “CI is (...) to formulate

strategies [second kind of contribution] to gain competitive advantage [first kind of contribution].” The first definition does not state either of the contributions. To our knowledge, most authors seem to agree about the overall contribution of CI. Some disagreement exists, however, about the organizational activities in which CI is used to reach this overall goal. Some hold the view that CI is used in decision-making at any level in the organization [e.g., the more ICT-oriented CI definitions (cf., Dresner, 1989)] while others maintain that it is mainly used in strategic decision-making (most authors seem to fall in this category: e.g., Fuld, 1995; Kahaner, 1996; Cook & Cook, 2000; Hannon, 1997). In defining CI, we will follow these authors and state that CI is tied to strategic decision-making.

Competitive Intelligence as a Product

In the literature, it is customary to make a distinction between (competitive) intelligence as a product and as a process (e.g., Gilad & Gilad, 1988; Fuld, 1995; Kahaner, 1996; Fleisher, 2001a). In treating intelligence as a product, authors refer to the “information” or “knowledge” obtained and used for strategic purposes. The process view stresses the process by means of which this information or knowledge is obtained and used. Both the above definitions stress the process aspect. The first definition also highlights intelligence as a product.

If competitive intelligence is seen as a product, it is usually compared with data, information and knowledge (cf., Fuld, 1995; Kahaner, 1997; Vriens & Philips, 1999). To define intelligence as a product (and to compare it with data, information and knowledge) we use a framework provided by Achterbergh and Vriens (2002) (see Figure 1).

For the survival of any individual, two processes are imperative: observation and the performance of actions. In the process of observation,

three steps can be distinguished. First, individuals perceive signals from the environment. These signals are referred to as data. The second step is that individuals make sense of these perceived data by putting them into a context or “frame of reference.” Once perceived and interpreted, individuals may evaluate whether the signal is informative (contains something new—i.e., something the individual did not know already) and whether action is required. Information is now defined as “perceived and interpreted data, containing something new to the observer.” Given this description, knowledge can be seen as the background for observation (cf., Achterbergh & Vriens, 2002). The process of performing actions consists of four steps: (1) selecting a desired effect (what does the individual want to achieve by acting?), (2) formulating options for obtaining the desired effect, (3) selecting an option, and (4) implementing the option. Figure 1 depicts these steps. Regarding the performance of actions, knowledge can be defined as that which serves as a background for these four steps.

In this view, knowledge has two main functions. It serves as a background for observing (or as Achterbergh & Vriens put it, the “assessment of signals”) and for “performing actions.” Note that knowledge is defined functionally. No attempt is made to sum up the content-elements of knowledge (see e.g., Davenport & Prusak, 1998). The reason for this is that the function of knowledge is easily pinned down, while its exact content is (still) “the subject of psychological research and philosophical debate” (Achterbergh & Vriens, 2002, p. 226).

Against the background of the definitions of data, information and knowledge, we can now define intelligence (see also Figure 2).

To do so, we transfer the above concepts from the realm of individual observing and acting to the organizational realm of strategic observing and acting. That is, we can define strategic observation as (1) “perceiving data from the environment,”

Figure 1. Individual observation and action—a model to clarify the distinction between data, information and knowledge

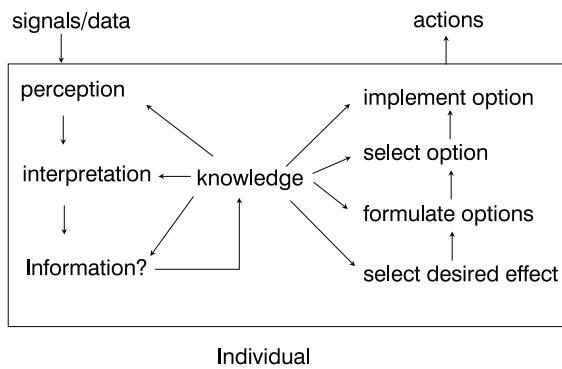

Figure 2. Organizational observation and action—a model to clarify the distinction between data, intelligence and knowledge

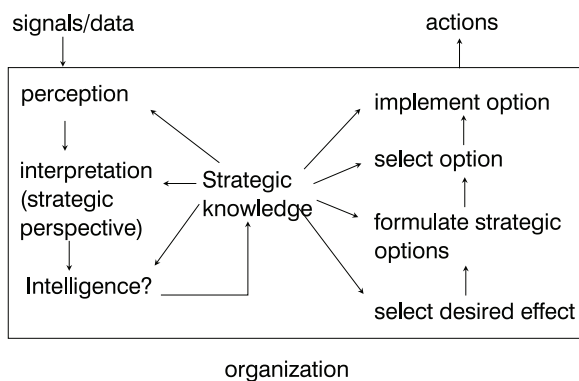

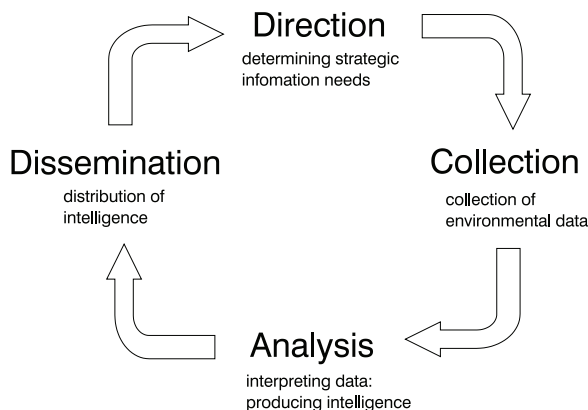

Figure 3. The four stages of the intelligence cycle

(2) making sense of these data—i.e., putting them in a strategic perspective, and (3) determining whether the data contain something of strategic importance (something new and relevant for strategic purposes) and assessing whether strategic action is needed. In this process of “strategic observation,” intelligence can be defined as the “strategic” counterpart of information. That is, if perceived and interpreted data contain something of strategic significance, and one did not already know this, the perceived and interpreted data can be defined as “intelligence.” Intelligence, in turn, is evaluated in order to decide whether strategic action is needed. The four processes of (individual) action, as described above, can also be translated to strategic action. Knowledge may then refer to the background against which these strategic observations and actions occur—the “strategic knowledge” in the organization.

This view on intelligence and knowledge also makes apparent that what counts as intelligence in an organization depends on the existing strategic knowledge in the organization. This seems self-evident—but as Gilad (1996) points out, it is anything but: Incomplete or incorrect strategic knowledge often leads to the phenomenon of business blind spots.

Competitive Intelligence as a Process

Next to defining “intelligence as a product” it can also be seen as a process delivering this product. As we already stated in the introduction, authors often divide the process of competitive intelligence into four stages: (1) direction, (2) collection, (3) analysis, and (4) dissemination. The whole process (comprising these four steps) is usually called the intelligence cycle (see Figure 3).

Below, we discuss these stages and illustrate them with findings from a study conducted by Lammers and Siegmund (2001). The object of this study was to give an overview of current CI practices in (large) organizations in The Neth-

erlands. Although we are aware of the fact that these findings only represent the “Dutch” situation, we are somewhat confident in generalizing them, because many participating organizations are large multinationals (e.g., Shell, Akzo-Nobel, or Philips).

In the direction stage, the “strategic information requirements” are stated. In this stage, one determines about what aspects of the environment data should be gathered in order to produce intelligence. A distinction can be made between a “rough” data profile (indicating certain data classes, e.g., “We need to know something about the logistic capacity of competitor X and Y”) and an exact data profile (indicating the exact data within a certain data class, e.g., “We need to know the amount of trucks and their capacity”). These topics (both in their exact or rough version) are also known as Competitive Intelligence Needs (Fleisher, 2001), Key Intelligence Topics (Kahaner, 1996) or Essential Information Elements (Sammon, 1984).

A particularly difficult aspect is determining the relevance of certain data classes before actual data about them are collected and before they can be interpreted, i.e., before intelligence can be produced. To accomplish this, some kind of model about the “organization in its environment” is needed. The challenge in the direction stage is to build and maintain such a model and to use it to define the strategically relevant data (classes) about the environment. In the literature, one often refers to the critical success factor method (or one of its variants; see for instance Sammon, 1986; Kahaner, 1997; Herring, 1999; or Cook & Cook, 2000) to build such a model and to derive environmental information needs from it.

In the second stage of the intelligence cycle, the required data are collected. To this end, two main activities are needed: (1) determining what sources are available and (2) accessing these sources and retrieving data from them. Many authors distinguish between several types of sources. For instance:

- open versus closed sources (open sources are accessible by everyone, closed sources are not);
- internal versus external sources (this distinction refers to the location where sources with data about the environment can be found: inside the organization (e.g., sales-representatives) or outside the organization);
- primary versus secondary sources [Primary sources are sources that hold the data in their original, unaltered form directly from the source from which the original data stems. Secondary sources offer altered data (cf., Kahaner, 1997)];
- sources that differ in data carrier—i.e., paper, electronic and human sources.

To collect data that may contain strategic relevant information, many possible sources can be identified. Several authors sum up lists of possible sources. Among these are: the Internet, online databases, trade shows, consultants, customers, universities, embassies, suppliers, journals, labor unions, etc. (see for instance Cook & Cook, 2000; Vriens & Philips, 1999; or Kahaner, 1997 for a more comprehensive overview). Most organizations tend to use more than one source. In a recent study, Lammers and Siegmund (2001) asked organizations in The Netherlands what data sources they employed in their intelligence gathering. Figure 4 presents the results. As can be seen in the figure, trade journals, the Internet and online databases were found to be the three most used sources.

Gilad and Gilad (1988) stress the importance of an “intelligence collection network”—a network of people involved in collection activities. Members of this network may be dispersed throughout the organization and have all kinds of functions (e.g., service, R&D, purchase, or marketing and sales). The idea behind such a network is that individuals may collect information about the part of the environment they are closely related to. To give an impression of the nature of such networks,

Figure 4. Sources used by large organizations in the netherlands for collection activities (scores range from 0 (never) to 5 (always); multiple answers are possible) (Source: Lammers & Siegmund, 2001)

Table 1 summarizes the findings of Lammers and Siegmund regarding their composition in large organizations in The Netherlands. As can be seen, the study reveals a high involvement of marketing and sales, R&D and management in the collection network

To collect certain data, knowledge about the available sources should be gathered and used. This entails knowing (1) what sources may contain the requested data, (2) whether these sources can be approached and accessed adequately (measured, for instance, by means of general criteria like timeliness, costs, relevance, accuracy, whether the data is up-to-date, accessibility, etc. (cf., Gilad & Gilad, 1988), and (3) who will be involved in

gathering data about the sources and in the actual collection activities. Managing the CI collection stage means ensuring that this knowledge is generated, stored and applied.

In the third stage of the intelligence cycle, the data is analyzed. In terms of the model we presented earlier (see Figure 1), the third stage focuses on interpreting the data from a “strategic point of view” to determine their strategic relevance (i.e., to determine whether the data contain intelligence). For this analysis, as with the direction stage, a model of what is relevant for the organization should be available. Many authors present both general and specific models for this purpose. Among the general models are

Table 1. Composition of the intelligence network members of organizations in the Lammers and Siegmund study (The percentage refers to the percentage of organizations indicating that their collection network consisted of a specific member.)

Members of the collection network	Percentage
Marketing and Sales	79
Service	14
Purchase	29
R&D	50
Finance	14
Human resources dept.	7
Lawyers	14
Production	7
Management	57
Other	36

SWOT analysis; the growth-share matrix of the Boston Consultancy Group; scenario-analysis; war-gaming; and competitor profiling (see Kahaner, 1997; Fuld, 1995; Powell & Allgaier, 1998; or Cook & Cook, 2000 for overviews of these models, and Fleisher, 2001b for a reflection on the analysis stage). More specific models are models about patent behavior (Kahaner, 1997; Poynder, 1998) or models tied to specific products. The goal of these models is to provide a context for interpreting data. For instance, an increase in R&D budget of a competitor may mean several things. A SWOT analysis may be used to put this “piece of data” in its proper context. If its R&D was analyzed to be a competitor weakness, the threat of a budget increase may be viewed as less serious than in the case where R&D was analyzed as state of the art.

In the same study we mentioned earlier, Lammers and Siegmund asked several Dutch organizations what models they used in the analysis stage. Table 2 presents the results. These results

Table 2. Models used in the analysis stage (Lammers & Siegmund, 2001) (The percentage refers to the percentage of organizations indicating that they used a certain model for analysis.)

Models used in the analysis stage	Percentage
Simulation	35
War gaming	15
Scenario analysis	40
BCG-matrix	45
SWOT analysis	80
Financial analysis	65
Competitor profiles	90
Other	40

confirm the popularity of the SWOT analysis. It also turned out that organizations used models they made themselves (in the “other” category).

In the last stage of the intelligence cycle, the intelligence should be made available for strategic decision-making. That is, the intelligence should be presented clearly and distributed to relevant decision makers, using it to evaluate current strategic options and to generate, compare, select and implement new ones. Relevant in this stage is to make sure that the intelligence is actually used in strategic decision-making. All kinds of measures may be helpful in accomplishing this. For instance:

- paying attention to the format and clarity of the presentation of intelligence to strategic decision-makers (e.g., Fuld et al., 2002);
- using electronic means to store and distribute the intelligence to the right people;
- designing CI tasks and responsibilities in such a way that strategic management is

involved in the intelligence activities (cf., Gilad & Gilad, 1988).

The Nature of the Obtained Competitive Intelligence

Some confusion exists about the difference between competitive intelligence and terms closely related or associated with competitive intelligence, e.g., competitor intelligence, market(ing) research or corporate espionage. One existing confusion is the difference between competitive intelligence and other kinds of intelligence. Data about many environmental aspects may be of strategic significance, e.g., data about competitors, about technological changes, about governments, about suppliers, etc. If the subject about which data is collected is not specified (if the scope is broad), one tends to speak about *competitive* intelligence. In this chapter, we will also refer to competitive intelligence in this broad sense. The common factor in data about these subjects is that they can all contain information of strategic importance. If, however, intelligence is produced and processed about a specific (environmental) subject, authors often use terms indicating this subject: e.g., *competitor* intelligence, *technological* intelligence, or *marketing* intelligence. Some authors even seem to equate competitive intelligence with competitor intelligence (e.g., Fuld, 1995). Of special interest is the term “business intelligence.” This term was previously used to refer to the same issues as competitive intelligence (cf., Gilad & Gilad, 1988; Pawar & Sharda, 1997 who use the term business intelligence instead of competitive intelligence). However, lately, the software industry took over the term “business intelligence” to refer to a specific constellation of ICT tools used for organizational decision-making in general (cf., Cook & Cook, 2000; Fuld et al., 2002). We will adhere to this development and refer to BI as a specific set of ICT tools.

In defining CI, authors (cf., Gilad & Gilad, 1988; Cook & Cook, 2000) also stress the difference between CI and marketing research. This difference is partly a matter of scope. As Gilad and Gilad (1988, p. 8) put it: “Although the information produced by a market research department is intelligence, it is only a small part of the total intelligence required for decision making.” Hannon, (1997, p. 411) states that marketing research is different because “it is usually undertaken within the marketing function and, obviously, is more limited in scope than the overall competitive intelligence process.” Gilad and Gilad (1988) also emphasize that CI tends to be a more continuous activity than marketing research.

A last related term is corporate espionage. Although one may obtain intelligence by means of corporate espionage, the difference is that corporate espionage includes collection activities that are usually viewed as illegal and/or unethical: such as “dumpster diving,” stealing information or illegal access to an intranet, to name a few. CI only employs legal activities to produce intelligence (cf., Hannon, 1997; Gilad & Gilad, 1988; Kahaner, 1997; Cook & Cook, 2000; Fleisher, 2001a).

Defining CI: A Summary

In our effort to define CI, we can now make the following statements about CI:

- As a product, CI is “environmental information relevant for strategic purposes.”
- As a process, CI can be described by the intelligence cycle consisting of four stages: direction, collection, analysis and dissemination.
- The CI process aims to deliver CI as a product for strategic decision-making.
- CI differs from corporate espionage, business intelligence and other kinds of intelligence and from market(ing) research.

With this understanding of the concept of CI we can now look at the role of ICT for CI in the next section.

ICT FOR COMPETITIVE INTELLIGENCE

In this section, we discuss ICT tools for CI, i.e., ICT tools for supporting the activities in the intelligence cycle. To this end, we first try to position ICT tools for CI in the traditional classification of ICT applications. Next, we discuss four classes of ICT tools for CI.

Traditionally, ICT applications for management in organizations are classified along two well-known dimensions: the type of structure of the organizational task or decision the application is supposed to support (divided in structured, semi-structured and unstructured tasks or decisions) and the organizational (management) level at which these tasks or decisions reside (usually the operational, tactical and strategic management level) (see for instance Laudon & Laudon, 2000). Typically, transaction processing systems (TPS) are operational level systems supporting structured tasks; management information systems (MIS) support tactical (middle level) management by summarizing and reporting output of all kinds of TPS's—still supporting structured tasks. Decision support systems (DSS) typically add analytical tools to MIS for performing “what-if analysis.” This analysis is said to be semi-structured. Executive support systems (EIS) refer to tools supporting high level management in their rather unstructured task of strategy making.

We acknowledge that this list of applications is incomplete and that it does not do justice to the research attempting to order ICT applications. The reason for the inclusion of this classification is to see where ICT for CI can be placed. ICT for CI aims at supporting strategic decision-making and thus supports—in the end—an unstructured

organizational task. However, CI activities differ in structure: some CI tasks are highly structured (e.g., find experts on subject X); while others are not (e.g., “define the strategic information needs” or “analyze what it means that competitor X closes plant Y”). Moreover, CI tools may be employed at all levels in the organization: at the operational level (e.g., aiding sales representatives in asking questions to customers and storing the answers), at the tactical level (e.g., in supporting the management of CI professionals or supporting the analysis of environmental information) and at the strategic level (e.g., in presenting overviews of trends and their effects on the current or projected strategy). Therefore, ICT for CI (or Competitive Intelligence Systems—CIS) seem to defy an exact classification according to these dimensions. Instead, the dimensions can be used to state that CIS is best seen as a collection of electronic tools (see also Rouibah & Ould-ali, 2002):

- ultimately meant to support strategic decision-making;
- dispersed over different management levels; and
- supporting structured and unstructured intelligence activities.

In this section we will elaborate on the nature of these electronic tools. For this elaboration, we classify them according to (1) their contribution to one or more stages of the intelligence cycle and (2) the specificity of the tool. The latter “dimension” has two positions: a tool can be a general ICT tool used for intelligence activities (like groupware, used for direction activities or the Internet, used for collection or dissemination activities) or a tool specifically tailored to one or more intelligence activities. We will use this classification in our discussion of the tools below. We first discuss the Internet as a “general” ICT tool for all CI activities. Next, we pay attention to other ICT tools—both general and specific.

And, finally, we discuss business intelligence applications as a specific set of ICT applications useful for CI activities.

The Internet as a Tool for CI

CI practitioners rely heavily on the use of the Internet for their intelligence activities. The Internet is sometimes seen as the most important information resource for competitive intelligence and, to our knowledge, the Internet as CI tool has received the most attention in the literature (e.g., Cronin et al., 1994; Graef, 1997; Teo & Choo, 2001; Chen et al., 2002; Cook & Cook, 2000; McCurgle, 2001). Chen et al. (2002, p. 1) state that a 1997 Futures group report identifies the Internet as one of the top five sources. Lammers and Sigmund (2001) found that, in organizations they approached, the Internet was the most preferred source for acquiring information.

The Internet can be used in numerous ways to produce intelligence. Examples are: searching certain information by using search engines (Graef, 1997; Chen et al., 2002; Cook & Cook, 2000); obtaining knowledge about costumers through interactive websites and agents (Teo & Choo, 2001); receiving feedback from costumers about competitors or one's own products and services (Teo & Choo, 2001); monitoring discussion groups on competitors (Cronin et al., 1994; Graef, 1997); conducting patent search (Poynder, 1998); improving stock decisions by monitoring online stock data available from retailers (Yuan & Huang, 2001); accessing the latest news through a wire service (Cook & Cook, 2000); learning about competitors and partners by visiting their websites (Cronin et al., 1994; Graef, 1997; Chen et al., 2002; Cook & Cook, 2000), searching and contacting experts (Kassler, 1998); accessing governmental files (Kahaner, 1997; Cook & Cook, 2000); monitoring the "e-behavior" of visitors to your website (Tan & Kumar, 2002); gaining easy access to expertise through discus-

sion groups (Teo & Choo, 2001; Cook & Cook); or "outsourcing" collection activities by using commercial online databases (Cronin et al., 1994; Graef, 1997; Gieskes, 2000; Cook & Cook, 2000; Kahaner, 1997).

To discuss the use of the Internet for one or more stages in the intelligence cycle, Teo and Choo (2001) propose to make a distinction between its internal use (Intranet), its external use (Extranet) and its use for "primary and secondary research." However, this seems to confuse two distinctions: one regarding a division of the Internet (into Intranet, Extranet and "beyond") and one regarding the stages in the intelligence cycle (of which Teo and Choo highlight the collection stage). To avoid this confusion, we would like to propose to use both distinctions. Below, we first discuss Internet tools for direction, analysis and dissemination and next devote a section to Internet tools for the collection stage.

Internet for Direction, Analysis and Dissemination

Few studies mention the use of the Internet for the direction, analysis and dissemination stages. To support the direction stage, an Intranet application may enhance communication of and collaboration regarding results of this stage [e.g., an internal discussion site may be used to define and monitor intelligence needs (see Vriens & Hendriks, 2000)]. The same sort of Internet applications may be used to support the analysis stage. Teo and Choo (2001) discuss the relevance of the Internet (Intranet and Extranet) for all CI activities: they hold the view that it (especially e-mail, Intranets, Extranets and databases) enhances internal and external collaboration in CI activities (e.g., multi-departmental analysis of intelligence and the exchange of intelligence between departments as well as the exchange of CI data with suppliers, external consultants and customers). The Internet can also be used to en-

hance internal and external dissemination of CI data (Teo & Choo, 2001, p. 70, 73; Graef, 1996; Cunningham, 2001). Furthermore, Teo and Choo expect an increase in external collaboration and dissemination (i.e., with relevant stakeholders for mutual benefit) through Extranets.

The Use of the Internet for Collection Activities

The Internet is mainly used for collection purposes and many different tools and uses are reported. A difference can be made between using the Internet for searching and accessing electronic data available on the Internet versus searching and accessing other sources by means of the Internet (like people, trade shows, conferences, etc.—cf., Cook & Cook, 2000; Kassler, 1997). In the first case, the Internet contains the requested data, while in the second case, the Internet is viewed as a means for referring to other sources (like a knowledge map—cf., Davenport & Prusak, 1998). To this end, Kassler (1997) explains that the Internet is invaluable as a means for locating people and contacting them. Cook and Cook (2000) give several sites where information about other sources (experts, trade shows, conferences, etc.) can be found and state their usefulness for CI.

Most attention, though, seems to be on searching and accessing directly available data. However, due to the extremely large number of sites, (and hence) the amount of information and due to the changes in this information, finding the right data is not easy. Chen et al. (2002) state that to deal with a possible information overload a number of tools are available that “analyze, categorize and visualize large collections of Web pages” and “assist in searching, monitoring and analyzing information on the Internet” (Chen et al., p. 3). Below, we discuss some of these tools.

Search Engines

Many CI authors discuss the usefulness of Web search engines for collecting data on the Internet. Typically, they refer to the difference between “common” search engines that can approach websites with some user defined information based on their own indexes (examples are Altavista.com or Yahoo.com) and “meta” search engines, using other (“common”) search engines to conduct the search and integrate the results (cf., Chen et al., 2002). Among the search engines a difference is made between general and specific engines (cf., Chen et al., 2002; Cook & Cook, 2000). The specific engines cover a part of the Internet (qua content) e.g., governmental information or patents. Chen et al. (2002) also distinguish between (commercial) engines available through a browser and engines residing on user machines.

Tools for “Outsourcing” Collection Activities

A part of the collection activities can be outsourced to some (automated) service or tool offered via the Web. One way of “outsourcing” collection activities is making use of commercial online databases such as Lexis-Nexis, Dow Jones or Dialog (see Gieskes, 2000; Kahaner, 1997; Cook & Cook, 2000). As Chen et al. (2002) assert and Lammers and Siegmund (2001) found, these online databases are among the main sources for CI professionals. Another way of “outsourcing” collection activities is to employ “Web robots or agents.” As Tan and Kumar (2002, p. 9) put it, “Web robots are software programs that automatically traverse the hyperlink structure of the WWW to locate and retrieve information.” Cook and Cook (2000, p. 112) add, that “there are many valuable types of bots that can speed up the information gathering process including stock bots, spider bots, shopping bots, news bots [...]”

Tools for Text-Analysis

To support the collection of valuable data in (large) text files, Chen et al. (2002) mention tools for text-analysis—i.e., “automatic indexing algorithms to extract key concepts from textual data.” Because of the time spent on reading textual material, these tools may greatly enhance the collection of relevant textual data.

Tools for Monitoring Changes on the Web

Another useful set of tools for collecting relevant data on the Internet are tools that help in monitoring changes in particular parts of the Internet. Among the tools monitoring the Internet are “alerting services” (see Kassler), an online service that alerts you whenever a change to a given topic in a relevant part of the Internet [like a collection of Web pages, bulletin boards, or mailing lists (cf., Kassler, 1997; Vriens & Hendriks, 2000; Chen et al., 2002)] occurs. The previously mentioned Web robots can be used for these alerting functions.

Tools for Collecting Data about the “Electronic” Behavior of Internet Users

One particular use of the Internet for analysis purposes also receiving little attention in the CI literature is monitoring the (electronic) behavior of users of the Internet [e.g., by identifying their navigational patterns or clickstreams (cf., Tan & Kumar, 2002)]. Of course, software is available to keep track of several statistics of visitors to websites, but tools to further analyze this behavior for CI purposes seem to be less available. Reid (in this volume) presents an example of such a tool.

Internet Tools for Collaboration in Search Activities

As has been put forward, the network of intelligence collectors plays an important role in collection activities (Gilad & Gilad, 1988). Internet applications can be used to facilitate the (self) management of and collaboration in these networks. As an example, one may consider an Intranet application through which a “competitor profile” is available to the members of the network, so that each member can fill in his or her part of that profile. Such applications enable monitoring the collection behavior of the members of the network and discussing and “correcting” each other’s contribution (see Chapter X, for such an application).

Moving Beyond the Internet: General and Specific ICT tools for CI

Above, we discussed how the Internet (or tools exploring or mining the Internet) can be used for CI activities. We thus discussed how a general set of Internet-oriented tools can be made available for CI purposes. In this section we discuss (1) other general ICT tools that can be used for supporting CI activities and (2) specific ICT applications designed for one or more CI activities (among them are “CI-software” packages as Fuld et al. (2002) call them, and CI applications developed in-house). ICT tools from both classes may or may not use specific Internet applications as discussed above.

General ICT Tools for CI

General tools for the direction stage should aid in formulating strategic information requirements and in storing and disseminating (sub) results of this process. Among these are tools:

- supporting specific methods for identifying, storing and disseminating strategic information needs; for instance, tools that visualize the variables and their causal relations relevant for specifying the information needs. Examples are software supporting system dynamics (e.g., Vensim or Powersim—see Vennix, 1996), or software supporting, identifying or visualizing CSF's or Key Intelligence Topics (e.g., Mindmap).
- supporting the process of identifying strategic information needs—such as different types of groupware (cf., Coleman, 1997) or software supporting group model building (e.g., Vennix, 1996). An example of a suitable groupware application is GroupSystems (Nunamaker et al., 1991). This application enables different users to anonymously discuss, brainstorm about, categorize, and vote on relevant intelligence topics. Rouwette and Vennix (this volume) discuss groupware for direction purposes.

General tools for the analysis stage are comparable to those in the direction stage. They should:

- support specific methods used in analysis—e.g., SD software that enables CI professionals to run “simulations” with certain data and thus helps to establish their relevance. Other examples are applications supporting war-gaming or scenario analysis.
- support (management of and collaboration in) the process of analysis. Again, specific groupware applications may serve this purpose. In this category one may also include applications supporting the storage and dissemination of the analysis results (for use during analysis). Many general databases with Intranet access can be used. Specific Intranet applications for dissemination and collaboration were discussed in the previous section.

For disseminating intelligence, one may identify all kinds of applications that support (1) the presentation of the intelligence in a suitable format and/or (2) transmitting reports throughout the organization. Many applications are available, including standard drawing packages or Microsoft Office, for sending and receiving documents.

Specific ICT Applications for CI

Fuld et al. (2002) produced several “intelligence software reports.” In these reports they analyzed a number of software packages said to be designed specifically for (supporting) one or more CI activities. For each stage in the intelligence cycle (Fuld et al. identify five stages: they split up collection into collection of primary and of secondary sources) they derived criteria to score the applications. For the most part, these criteria link up with what has been said in this chapter. For instance, for the direction stage, Fuld et al. (2002, pp. 12-13) state that the fulfillment of the following functions acts as criteria in judging CI applications:

- Providing a framework to input Key Intelligence Topics and Key Intelligence Questions
- Receiving CI requests
- Managing a CI work process and project flow that allows collaboration among members of the CI team as well as with the rest of the company

Criteria for other stages refer to the:

- Ability to search effectively and efficiently internal or external sources
- Ability to deal with qualitative information
- Ability to support ordering, visualizing and mining information
- Ability to support several methods for analyzing data
- Ability to report and deliver reports

(For the exact criteria, the reader is referred to Fuld et al., 2002.)

Based on their analysis, Fuld et al. (2002) arrive at several conclusions. Among these are:

1. The “CI-software cannot drive the CI-process” (p. 2), but it can help in collecting data, in reporting and communicating intelligence and in supporting the workflow and collaboration.
2. No application can deal with all the intelligence stages adequately.
3. No application can “truly conduct qualitative analysis” (p. 10)—but some tools seem promising in assisting CI analysts to see novel linkages (p. 2). This conclusion seems to fit comments of other authors about the possibility of ICT applications in replacing human intelligence activities. As Cook and Cook (2000) point out: “innovative applications for analyzing competitive factors and forecasting the outcomes of strategic decisions may seem like the unrealistic dreams of CEOs and CIOs alike” (p. 165). However, they expect changes in the future. It is our conjecture that CI activities remain the work of humans. ICT can facilitate them—but it can never replace them.

Fuld et al. (2002) analyzed commercially available CI applications and concluded that there exists no “one-size-fits-all” solution. They add that the technology needs of organizations differ depending on their specific CI requirements. This may be the reason for organizations to build and maintain CI applications themselves.

Business Intelligence Applications

For some time, the terms competitive intelligence and business intelligence have been used as synonyms (e.g., Gilad & Gilad, 1988; Vriens & Philips, 1999; Pawar & Sharda, to name a few authors). However, the software industry has taken over the term business intelligence (BI) to indicate a

specific set of ICT tools. These BI tools refer to ICT tools enabling (top) management to produce overviews of and analyze relevant organizational data needed for their (strategic) decision-making. As a BI vendor defines it: “Business intelligence (BI) takes the volume of data your organization collects and stores, and turns it into meaningful information that people can easily use. With this information in accessible reports, people can make better and timelier business decisions in their everyday activities” (www.cognos.com). As early as 1989 the Gartner group specified the nature of BI tools: “Today’s [BI] technology categories include EISs, DSSs, query and reporting tools and online analytical processing (OLAP).” These categories currently include data warehouses (cf., Mahony, 1998) and new tools for analysis (e.g., data mining, cf., Zanasi, 1998) and reporting.

Data warehouses seem to have gained a central position in BI. Moreover, most vendors seem to equate BI with the use of data warehouse and tools for access and analysis of the data in it. Inmon (1993) defines a data warehouse as “a subject oriented, integrated, nonvolatile, and time variant collection of data in support of management’s decisions.” In an organization, possible relevant data for strategic decision-making is scattered in many databases (e.g., transactional databases, financial databases, personnel databases, etc.). Long and Long (2002, p. 425) point out that such data, which are not integrated and may contain redundancies, are hard to access. To cope with these problems, these data are collected and copied to a data warehouse and ‘reorganized into a format that gives decision-makers ready access to valuable, time-sensitive information’ (ibid). To keep the data in the data warehouse up to date, data from the source databases should be copied to it on a regular (weekly or sometimes daily) basis.

To gain access to a data warehouse and analyze its data, three types of tools are usually identified: queries, OLAP and data mining. For queries, query languages (like SQL) can be used.

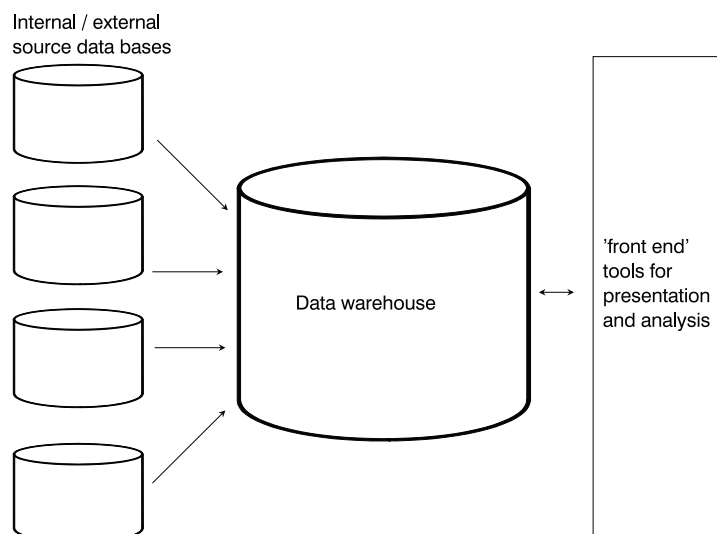

However, most of these are cumbersome for easy end-user access and not really suited for analysis. Online analytical processing (OLAP) is a tool for online analysis and manipulation of data. A user does not specify a query, but specifies so-called “dimensions” (like customer, product, region, time) and is able to relate these dimensions to each other in a very user-friendly way. The results can be shown directly in several formats (graphs, tables, numbers) and manipulated.

Data mining refers to a set of (statistical or artificial intelligence) tools to detect (new) relations in data (cf., Zanasi, 1998). Through data mining, for instance, elusive patterns in customer behavior may be detected. For example, a large retailer in The Netherlands discovered that buying a certain brand of diapers was positively correlated to buying a certain brand of beer. Such discoveries may be used for all kinds of purposes—ranging from identifying cross-selling opportunities or specifying marketing campaigns to improving shop layouts (cf., Long & Long, 2000). The basic architecture of a data warehouse (and tools for its use) is given in Figure 5.

The figure makes apparent that the source databases can be internal (transactional databases, financial databases, CRM data, or data from ERP systems, etc.) and external (e.g., databases from business partners, (commercially available) databases containing economic statistics, patent information, etc., or even online databases). However, most data warehouses only cover internal data—i.e., data generated in the transactions of the organization. As Fuld et al. (2002) put it: “BI software [...] typically deals with data warehouses and quantitative analysis, almost exclusively of a company’s internal data” (p. 7). This, of course, is a major drawback when treating BI tools as CI tools. However, we feel that once data warehouses are used for storing (and updating) relevant *external* data, they may become valuable CI tools as well.

Next to their internal focus, other drawbacks with BI software can be mentioned. In the previous quotation of Fuld, a second problem arises: BI software primarily deals with quantitative analysis, while CI relies heavily on qualitative data. Other problems have to do with costs and

Figure 5. Basic architecture of a data warehouse

implementation: data warehouses require large budgets and much implementation time and effort. Cook and Cook (2000, Chapter IX) also refer to the “high expectations” organizations have regarding BI software. In particular, one cannot expect BI software to produce intelligence. In their view, the results from analyzing data in a warehouse produce data that should “be analyzed and directly applied to a specific problem” to become intelligence. Therefore, “human intervention” is still needed.

HOW TO SELECT ICT FOR CI?

Now that an overview of ICT tools for CI has been presented, the question can be raised of what ICT tools are appropriate, given specific organizational CI needs. In this section we discuss three classes of criteria organizations can use to select ICT tools for CI. These classes are: (1) criteria regarding the contribution of ICT applications to one or more stages of the intelligence cycle, (2) criteria regarding the CI infrastructure and (3) criteria pertaining to costs. These three classes correspond roughly to the criteria used in the selection of ICT applications in general according to the information economics approach (cf., Parker, Benson & Trainor, 1988).

Criteria Regarding the Contribution to One or More Stages of the Intelligence Cycle

An (candidate) ICT application should contribute to one or more stages of the intelligence cycle. Criteria to judge the contribution of a particular ICT application to a certain stage (or to several stages) may refer to its appropriateness to deliver the desired *products* for the stage and to whether it fits the *process* leading to these products. For example, collection applications should be evaluated regarding their appropriateness to collect

the desired data (e.g., patent data). Applications should also match process aspects—for example, a particular application should support the particular methods (to be) used in the intelligence activities—e.g., a SWOT analysis or a system dynamics analysis. For more examples of such criteria, we refer to the criteria used by Fuld et al. (2002) to judge CI applications.

Criteria Regarding the Relation with the CI Infrastructure

The (CI) infrastructure may be decomposed into three sub-infrastructures: the ICT-infrastructure (this consists of the ‘technological infrastructure’ (ICT hardware, software and telecommunications technology) and the applications running on the technological infrastructure (cf., Earl, 1989), the human resources infrastructure and the organizational infrastructure; i.e., the structure of the organization qua CI-tasks and responsibilities. For each of these sub-infrastructures, specific sets of criteria can be given.

The criteria regarding the ICT infrastructure focus on the question of whether the application fits the current ICT infrastructure. This fit depends, among other things, on the current set of ICT tools used to support the CI activities. Does the application fit into this set? Does it deliver more functionalities than this set? Is an easy link between the applications in this set (if desirable) possible? Other questions for judging the fit to the ICT infrastructure have to do with the “technological” fit (does the current hard- and software permit the implementation of the application—or does it require large changes? Is the application reliable? Maintainable?). Yet another question for judging the fit to the ICT infrastructure has to do with the contribution of an application to the improvement of the infrastructure—e.g., through a particular application obsolete applications are replaced (or may be replaced more easily), or, through a particular application other state of the art applica-

tions can be implemented and used more easily. A data warehouse, for instance, can be seen as a contribution to the current infrastructure, because it enables all kinds of tools for visualizing and analyzing (internal) data.

The second set of criteria reflects the fit of the application to the human resources infrastructure—i.e., whether it fits existing skills, knowledge and attitudes of those who are carrying out CI activities. Important questions are, for instance, whether the required knowledge and skills (if any) are acquired easily, or whether the CI staff is motivated to integrate the ICT application into their routines. Criteria regarding the human infrastructure relate to the concept of “social acceptability” of an application [cf., Hendriks & Davis (this volume); Nielsen, 1999; Hartwick & Barki, 1994; Venkatesh & Speier, 1999]. This refers to standards or to the existence or absence of pressure to use an application. Authors on the subject of knowledge management have formulated criteria to diagnose and design solutions regarding problems with motivational aspects regarding the use of ICT for supporting knowledge processes (see e.g., Bukowitz & Williams, 1999).

The third set of infrastructural criteria reflects the fit of the application to the current definition and allocation of CI tasks and responsibilities (see Gilad & Gilad, 1988 for several ways of defining and allocating them). It does not make sense to install groupware for the direction stage if direction is not seen as a group process. The same holds for using ICT tools structuring collection and analysis activities if the whole CI process has a highly informal nature. In some cases, a task structure may be designed poorly and ICT for CI may act as a leverage to change the current task structure. An ICT tool can be valued because of its contribution to the improvement of the task infrastructure. A common example of a non-CI application said to improve the task-structure is workflow management systems (cf., Laudon & Laudon, 2000). In a similar vein, a groupware

application may be valued for contributing to implementing the direction stage as a group process. Philips (this volume) discusses an example of an organization using the implementation of a competitive intelligence system to analyze and change its whole CI infrastructure (including its human resources; technological and organizational structure).

Criteria Pertaining to Costs

These criteria refer to the costs of the application itself, its implementation (e.g., project costs, training, etc.) and its maintenance. These costs may be calculated by different methods (cf., Parker et al.).

Selecting ICT for CI Using the Three Types of Criteria

To judge the appropriateness of an application for CI in a particular organization, the application should be “scored” regarding all three classes of criteria. To this end, the individual criteria in a class should all be identified, valued, and integrated into an overall score for the class. We will not treat all these sub-steps in this section—rather, we show how these overall scores can be used to select ICT for CI.

The overall scores of each class express (1) the contribution of a particular application to one or more of the intelligence stages, (2) the fit of the contribution to the CI infrastructure, and (3) the costs related to an application. These scores can be plotted in a graph (see Figure 6) — the size of the circle indicates the costs of an application.

In this figure, the scores of several applications are depicted (the size of the circles reflects the costs related to the application). For instance, application 1 may be a data warehouse (with an internal focus). This application is very expensive and contributes only partly to the intelligence stages (it contributes to the collection stage, but

Figure 6. Classification of ICT Applications for CI Using Three Dimensions (See text)

due to its internal focus its contribution to the CI stages is low). The data warehouse may contribute to the general infrastructure, but, in our view, contributes only partly to the CI infrastructure. By contrast, a data warehouse with explicit external linkages would still be very expensive, but may score higher on both other dimensions. Application 2 may be a groupware application. These applications are moderately expensive, may contribute to the direction stage and fit the infrastructure in several ways.

An organization may treat several ICT tools for the support of its CI activities in this way and eventually select some of them.

CONCLUSION

To select and use proper ICT tools for supporting the CI process, organizations should know (1) what the CI process is, (2) what the role of ICT (tools) in this process can be, and (3) judge the role of ICT (tools) for their own CI process. In this chapter, we discussed these three aspects. We defined CI both as a product and as a process. We then discussed the role of ICT tools in the CI process. Here, we presented four types of ICT tools relevant for supporting (and sometimes even replacing) CI activities: the Internet, general applications to be used in CI activities, specific CI applications

and business intelligence applications. In the last part of this chapter we discussed three classes of criteria organizations can use in evaluating and selecting ICT tools for their CI process.

Although the definition of CI and the criteria for selecting ICT tools for CI seem to have stabilized, the possibilities of using ICT for CI increase rapidly. Some of the trends that may be acknowledged are:

- A convergence of BI and CI applications (e.g., data warehouses and associated software also tied to external and qualitative data) (cf., Li, 1999)
- Using ICT for qualitative data may increase (e.g., Chen et al., 2002)
- Using the Internet for more than just collection activities (e.g., for collaboration and dissemination purposes) (cf., Teo & Choo, 2001; Cunningham, 2001)
- Improvement of Internet applications for collection (more efficient and effective collection applications will continue to emerge)
- Implementing CI applications can be seen as a process by means of which the CI process and infrastructure can be re-analyzed
- Improvement of analysis applications (cf., Fuld et al., 2002)

Despite all the possibilities of ICT for CI, we would like to end this chapter with remarking that producing intelligence still remains the work of humans who are the only “machines” able to put the data from the applications in their proper strategic perspective. ICT tools, however, are invaluable in supporting this task.

Chapter 3.8

Information and Communication Technology Tools for Competitive Intelligence

Dirk Vriens

Radboud University of Nijmegen, The Netherlands

INTRODUCTION

Competitive intelligence (CI) can be described as collecting and processing information about the environment for strategic purposes (cf. Kahaner, 1997). To formulate a strategy, an organization needs to collect and process information about its environment—about, for instance, competitors, customers, suppliers, governments, technological trends, or ecological developments. Collecting and processing environmental information has, of course, always been important. However, because of the increasing complexity and dynamics of the environment, the pressure to produce relevant, timely, “actionable” intelligence increases as well. At the same time, the amount of available data about the environment also increases.

To deal with this problem, it is necessary to structure intelligence activities, and many organizations use information and communications technology (ICT) to this end. They use, for

instance, different types of Internet or intranet applications, so-called data warehouses, groupware applications, or applications specifically tailored to the organizations’ intelligence needs. The number of possible ICT tools for CI is large, and an important question for organizations is which tools they should select and implement for their CI activities. Organizations face difficulties in selecting, implementing, and using these tools. Many ICT tools, for instance, lead to an information overload—to large collections of irrelevant data—or are expensive applications that only marginally contribute to the production of intelligence.

To select proper ICT tools for CI, an organization needs to understand the role of ICT for CI. This paper intends to address this understanding. In particular, it will present a short overview of the available tools and it will discuss a procedure for selecting appropriate ICT tools.

BACKGROUND

To understand the role of ICT for CI and to select proper ICT tools, the CI process needs to be clarified. To describe this process, several authors (cf. Fuld & Company, 2002; Gilad & Gilad, 1988; Herring, 1999; Kahaner, 1997) propose to use the intelligence cycle, consisting of four stages.

1. **Direction.** In this stage organizations determine their strategic information requirements; that is, they determine about what environmental aspects data should be collected. These aspects are also known as competitive intelligence needs (Fleisher, 2001) or key intelligence topics (Kahaner, 1997).
2. **Collection.** In this stage, the required data are collected. To this end, one needs to (a) determine what sources are available, and (b) access these sources and retrieve data from them.
3. **Analysis.** This stage focuses on interpreting data from a strategic point of view to determine their strategic relevance (if a piece of data is strategically relevant, the term intelligence is used; cf. Kahaner, 1997; Vriens, 2004). For this analysis, a model of what is relevant for the organization should be available. Often, tools such as Strengths, Weaknesses, Opportunities and Threats (SWOT) analysis, scenario analysis, war gaming, or competitor profiling are used to arrive at such a model (cf. Cook & Cook, 2000).
4. **Dissemination.** Here, the intelligence is made available for strategic decision making. That is, the intelligence should be presented clearly and distributed to relevant decision makers who use it to evaluate current strategic options and to generate, compare, select, and implement new ones.

Using this cycle as a background, many authors acknowledge the possible and actual use of ICT applications for CI activities (see, for instance, Chen, Chau, & Zeng, 2002; Cook & Cook, 2000; Fleisher & Blenkhorn, 2001; Fuld & Company, 2002). It is also a background for discussing the shortcomings of ICT applications for CI (e.g., Cook & Cook; Fuld & Company). In line with these authors, we will use this cycle of intelligence activities as a framework for reviewing, classifying, and selecting ICT applications, as will become apparent in the next sections.

A CLASSIFICATION OF ICT TOOLS FOR CI

ICT tools for CI can be classified according to two “dimensions”: (a) their contribution to one or more stages of the intelligence cycle and (b) the specificity of the tool—that is, a tool can be either a general ICT tool used for intelligence activities (like a groupware application, used for direction activities) or a tool specifically tailored to one or more intelligence activities. Below, we first discuss the Internet as a “general” ICT tool for all CI activities. Next, we pay attention to other ICT tools, both general and specific. Finally, we discuss so-called business intelligence applications as a specific set of ICT applications.

The Internet as a Tool for CI

CI practitioners rely heavily on the use of the Internet for their intelligence activities. Some authors report the use of the Internet for supporting the direction, analysis, and dissemination stages, for example, Web Enabled Technology (WET) applications enhancing communication and collaboration regarding results of this stages (e.g., Teo & Choo, 2001). However, most attention has been paid to the use of the Internet for collection activities. Among the reported uses of

Internet applications for collection activities are the following.

- **Search engines**
The CI literature discusses many types of search engines and their application for CI (cf. Chen et al., 2002; Cook & Cook, 2000).
- **Tools for outsourcing collection activities**
A part of the collection activities can be outsourced to some (automated) service or tool offered via the Web. Particularly popular is the use of commercial online databases (Kahaner, 1997; Chen et al., 2002). Another example is the use of Web robots or agents that “automatically traverse the hyperlink structure of the WWW [World Wide Web] to locate and retrieve information” (Tan & Kumar, 2002, p. 9).
- **Tools for text analysis**
Tools supporting the collection of data in (large) Internet-based text files are used.
- **Tools for monitoring changes on the Web**
- **Tools for collecting data about the electronic behavior of Internet users.** These tools work, for instance, by identifying users’ navigational patterns (cf. Tan & Kumar, 2002).
- **Internet tools for collaboration in collection activities.** Internet applications can be used to facilitate the collaboration in collection networks (networks of people performing collection activities).

General and Specific ICT Tools for CI

Besides using general Internet applications for CI purposes, other general ICT applications can be used as well. Examples are tools supporting the following.

- **Supporting the process of identifying strategic information needs** such as different types of groupware or software supporting group model building (e.g., Vennix, 1996).
- **Supporting specific methods used in analysis**, for instance, system-dynamics software enabling CI professionals to run simulations with certain data, and thus helps to establish their relevance.
- **Supporting (management of and collaboration in) the process of analysis.** Specific groupware applications may serve this purpose.
- **Supporting the dissemination of intelligence**—for example, applications supporting (a) the presentation of the intelligence in a suitable format and/or (b) the transmission of reports throughout the organization

There is also a class of ICT applications specifically designed for one or more CI activities. Fuld & Company (2002) analyzed and evaluated a number of such dedicated CI software packages. They concluded with the following.

1. The “CI software cannot drive the CI process” (p. 2), but it can help in collecting data, in reporting and communicating intelligence, and in supporting the work flow and collaboration.
2. No application can deal with all the intelligence stages adequately.
3. No application can “truly conduct qualitative analysis” (p. 10), but some tools seem promising in assisting CI analysts to see novel linkages.

Business Intelligence Applications

For some time, the terms competitive intelligence and business intelligence (BI) were used as synonyms. Nowadays, however, the term business intelligence is often used to indicate a specific

set of ICT tools. These BI tools refer to ICT tools enabling (top) management to produce overviews of and analyze relevant organizational data needed for their (strategic) decision making. BI tools typically include data warehouses and tools for extracting and presenting information from them (cf. Cook & Cook, 2000; Zanasi, 1998). In essence, a data warehouse is a large database in which data from many different databases (e.g., transactional, financial, or personnel databases) are copied and stored in such a way that they are readily accessible. To access, view, and analyze these data, specific tools are developed (e.g., data-mining tools for finding relations between classes of data). Using data warehouses and their associated tools to produce intelligence is not unproblematic. Examples of reported problems are the following (cf. Cook & Cook; Fuld & Company, 2002).

1. Most data warehouses only cover internal data (generated in the transactions of the organization; Fuld & Company, 2002). This is a major drawback when treating BI tools as CI tools. However, once data warehouses incorporate relevant *external* data, they may become valuable CI tools as well.
2. The focus of BI software is primarily on quantitative analysis while CI relies heavily on qualitative data.
3. Data warehouses cause cost and implementation issues: They require large budgets and much implementation time and effort.
4. Cook and Cook (2000) assert that one cannot expect BI software to produce intelligence. Data resulting from analyzing data in a warehouse should still “be analyzed and directly applied to a specific problem to become intelligence” (p.165).

HOW TO SELECT ICT FOR CI

To select appropriate ICT tools for CI, given specific organizational CI needs, organizations can use three classes of criteria: (a) criteria regarding the contribution of ICT applications to one or more stages of the intelligence cycle, (b) criteria regarding the CI infrastructure, and (c) criteria pertaining to costs. These three classes correspond to the criteria used in the selection of ICT applications in general (cf. Parker, Benson, & Trainor, 1988).

Criteria Regarding the Contribution to One or More Stages of the Intelligence Cycle

A (candidate) ICT application should contribute to one or more stages of the intelligence cycle. Criteria to evaluate the contribution of an ICT application for one or more stages may refer to its appropriateness to deliver the desired products for the stage, and to whether it fits the process leading to these products (cf. Fuld & Company, 2002). For example, collection applications should be evaluated regarding their appropriateness to collect the desired data (e.g., patent data). Applications should also match process aspects. For example, if particular methods are used to analyze data, such as a SWOT analysis, candidate applications can be evaluated regarding their appropriateness in supporting these particular methods.

Criteria Regarding the Relation with the CI Infrastructure

The CI infrastructure consists of three parts: (a) the technology supporting the CI activities (ICT hardware, software, and telecommunications technology), (b) the human resources needed to carry out the CI activities, and (c) the organizational structure of these activities, that is, how CI tasks and responsibilities are divided and

allocated. Each possible ICT application should match all three parts—from these three parts, specific criteria can be derived.

The criteria regarding the technology part of the infrastructure focus on the question of whether the candidate application fits the current technology. This fit depends on the current set of ICT applications used to support the CI activities. Does the application fit into this set? Does it deliver more functionalities than this set? Is an easy link between the applications in this set (if desirable) possible? Other questions for judging the fit to the technology have to do with the implementation and maintenance of the application: Does the current hard- and software permit the implementation of the application, or does it require large changes? Is the application reliable? Yet another question for judging the fit to the technology has to do with the contribution of an application to the improvement of the infrastructure; for example, through a particular application, obsolete applications are replaced (or may be replaced more easily), or through a particular application, other state-of-the-art applications can be implemented and used more easily. A data warehouse, for instance, can be seen as a contribution to the current infrastructure because it enables all kinds of tools for visualizing and analyzing (internal) data.

The second set of criteria reflects the fit of the application to the human resources, that is, whether it fits the existing skills, knowledge, and attitudes of those who are carrying out CI activities. Important questions are, for instance, whether the required knowledge and skills are acquired easily, or whether the CI staff is motivated to integrate the ICT application into their daily routines.

The third set of infrastructural criteria reflects the fit of the application to the current definition and allocation of CI tasks and responsibilities (see Gilad & Gilad, 1988, for several ways of defining and allocating them). It does not make sense to

install groupware for the direction stage if direction is not seen as a group process. The same holds for using ICT tools structuring the collection and analysis activities if the whole CI process has a highly informal nature. In some cases, the CI task structure may be designed poorly and ICT can act as a leverage to change it. An ICT tool can be valued because of its contribution to the improvement of the task structure. For instance, a groupware application may be valued for its contribution to structure the direction stage as a group process.

Criteria Pertaining to Costs

These criteria refer to the costs of the application itself, its implementation (e.g., project costs, training, etc.), and its maintenance. These costs may be calculated by different methods (cf. Parker et al., 1988).

Selecting ICT for CI Using the Three Types of Criteria

To evaluate the appropriateness of an application for CI in a particular organization, the application should be “scored” regarding all three classes of criteria. To this end, the individual criterion in a class should each be identified, valued, and integrated into an overall score for the class. We will not treat all these substeps in this section; rather, we will indicate how these overall scores can be used to select of ICT for CI.

The overall scores of each class express (a) the contribution of a particular application to one or more of the intelligence stages, (b) the fit of the contribution to the CI infrastructure, and (c) the costs related to an application. These scores can be plotted in a graph (see Figure 1).

In this figure, the scores of several applications are depicted (the size of the circles reflects the costs related to the application). For instance, Application 1 may be a data warehouse (with an

Figure 1. Classification of ICT applications for CI using three dimensions (see text)

internal focus). This application may be very expensive, contributes only partly to the intelligence stages (it contributes to the collection stage, but due to its internal focus, its contribution to the CI stages is low). The data warehouse may contribute to the general infrastructure, but, in our view, contributes only partly to the CI infrastructure. In contrast, a data warehouse with explicit external linkages would still be very expensive, but may score higher on both other dimensions. Application 2 may be a groupware application. These applications are moderately expensive, may contribute to the direction stage, and fit the infrastructure in several ways.

An organization may treat several ICT tools to support their CI activities in this way and eventually select some.

FUTURE TRENDS

Many organizations recognize the importance of supporting CI activities by means of ICT. Although many ICT applications are already available, the possibilities of using ICT for CI will increase rapidly. Some of the trends that may be acknowledged are the following.

- A convergence of BI and CI applications (e.g., data warehouses and associated software

also tied to external and qualitative data; cf. Li, 1999)

- Using ICT for qualitative data may increase (e.g., Chen et al. 2002)
- Using the Internet for more than just collection activities (e.g., for collaboration and dissemination purposes; cf. Teo & Choo, 2001)
- Improvement of Internet applications for collection (More efficient and effective collection applications will continue to emerge.)
- Implementing CI applications can be seen as a process by means of which the CI process and infrastructure can be reanalyzed.
- Improvement of analysis applications (cf. Fuld & Company, 2002)

CONCLUSION

To select and use proper ICT tools for supporting the CI process, organizations should know (a) what the CI process is, (b) what the role of ICT (tools) in this process can be, and (c) how to evaluate the role of ICT (tools) for their own CI process. In this chapter, we discussed the role of ICT tools in the CI process. We classified several types of ICT tools relevant for supporting CI activities: the Internet, general and specific applications for supporting CI activities, and business intelligence applications. In the last part of this chapter, we discussed three classes of criteria organizations can use in evaluating and selecting ICT tools for their CI processes.

The possibilities of ICT to support CI activities will probably only increase. To make full use of its potential and to avoid many of the pitfalls associated with using ICT for CI, organizations should be careful in selecting and implementing ICT applications for CI purposes. They should know the possibilities of ICT to deliver internal and external data and its capacity for supporting

CI activities, and they should treat ICT as a part of the whole infrastructure.

KEY TERMS

Business Intelligence:The term business intelligence is used in two ways: (a) as a synonym for competitive intelligence and (b) to indicate a specific set of ICT tools to support managerial decision making. This set of tools often consists of a data warehouse and the tools to store, retrieve, and present the information it contains (e.g., data-mining software).

Competitive Intelligence: In the literature, two definitions are used: a product definition and a process definition. In the product definition, competitive intelligence is defined as information about the environment, relevant for strategic purposes. The process definition highlights

producing and processing this environmental information. Process definitions often refer to the intelligence cycle.

ICT (Information and communication technology): Can be used to indicate the organization's technological infrastructure (comprising of all hardware, software, and telecommunications technology) and to indicate one or more specific collections of hardware, software, and telecommunications technology (i.e., one or more ICT applications).

ICT Selection: The process of selecting proper parts of the technological infrastructure and/or specific applications. In the context of CI, specific criteria are used: criteria regarding costs, appropriateness in supporting intelligence activities, and their fit or contribution to the CI infrastructure.

Intelligence Cycle: This is a cycle of four stages (collections of intelligence activities). The stages are direction (determining the strategic [external] information requirements), collection (determining, locating, accessing, and retrieving sources to obtain data about the environment), analysis (determining the strategic significance of the environmental data), and dissemination (of the intelligence to strategic decision makers).

Intelligence Infrastructure (CI Infrastructure): The intelligence infrastructure comprises all technological, human-resources, and organizational means needed to manage, support, and perform the intelligence activities. It consists of three subinfrastructures: the technological, the human-resources infrastructure, and the organizational infrastructure.

Chapter 3.9

It's All in the Game: How to Use Simulation–Games for Competitive Intelligence and How to Support Them by ICT

Jan Achterbergh

University of Nijmegen, The Netherlands

Dirk Vriens

University of Nijmegen, The Netherlands

ABSTRACT

In this chapter, we explore the role of simulation games for intelligence activities. Although games have been used in intelligence activities, the contribution of building and using simulation games to Competitive Intelligence has, to our knowledge, not been examined thoroughly. In this chapter we fill this gap by explaining the building and using stages of simulation gaming and by discussing the contribution of these stages to directing, collecting, analyzing and disseminating Competitive Intelligence. Moreover, we discuss the role of ICT to enhance the contribution of simulation games to competitive intelligence.

INTRODUCTION

As many authors on competitive intelligence point out, organizations need to collect and process information about the environment to (re)formulate their strategy. Moreover, the pressure to produce timely, accurate, actionable and strategically relevant information is growing because the complexity and dynamics of the environment is increasing rapidly (cf., Kahaner, 1997; Fuld, 1995; Cook & Cook, 2000 for similar arguments). Hence, organizations are trying to structure their competitive intelligence process—the process by means of which strategically relevant information about the environment is delivered.

In the literature on Competitive Intelligence (CI), this process is usually broken up into four stages: direction, collection, analysis, and dissemination (cf. Sammon, 1986; Bernhardt, 1994; Fuld et al., 2002; Kahaner, 1997; Vriens & Philips, 1999). In the direction stage, CI professionals establish what data are relevant for the purpose of strategic decision-making. In the collection stage, relevant data sources are determined and data are collected from them. In the analysis stage, collected data are transformed into competitive intelligence that can be used by strategic decision-makers. In the dissemination stage, the competitive intelligence resulting from analysis is disseminated over strategic decision-makers so that they can incorporate it in the process of (re)formulating their strategies (for a more thorough treatment of the process of competitive intelligence, see Chapter I of this book).

If CI is to deliver its contribution to the process of strategy formulation, a pro-active mode of intelligence gathering seems most appropriate (cf., Ellis, 1993; Hannon, 1997; Tessun, 1997). In a pro-active mode, intelligence practitioners try to anticipate environmental developments that may have a strategic impact and assess their consequences. Pro-active intelligence requires, in our view, a deep insight into the “organization in its environment.” For instance, directing the search for information requires an insight into strategic problems the organization in focus has to cope with and environmental factors having an impact on these problems. To direct the search for data, CI professionals need to construct models of these strategic problems and environmental factors. Analyzing collected information and transforming it into intelligence builds on these constructed models and requires an insight into possible effects of a multitude of states of affairs and events in the environment of the organization, on both parties relevant to and the organization in focus itself.

Not only do CI practitioners need a model of the “organization in its environment,” it is also important that this model is shared among the different parties involved in the intelligence process. The model should be shared among CI professionals so that they have a common orientation towards performing their CI activities. Moreover, it should be shared among CI professionals and strategic decision-makers for several reasons. Among these are: (1) improving the understanding of CI professionals of strategic problems, (2) grounding the model in the strategic orientation of the organization, (3) facilitating the dissemination of the intelligence, (4) ensuring commitment of strategic decision makers to using the intelligence, and (5) improving the process of monitoring and maintaining the model itself.

Sharing the model among the relevant parties in the organization requires high quality communication (both regarding content and process) between these parties. In this chapter, we examine the potential of (ICT-enabled) simulation games to support this communication process. As Geurts et al. (2000) assert, simulation games may be a valuable tool contributing to improving the quality of the communication. The element of simulation requires participants to interactively model the organization in its environment, systematically analyzing relevant variables, parties, processes and their relations. The element of gaming allows participants to interactively experiment with the model in a relatively safe environment. Together, the simulation and the gaming elements can improve both the content and the process of communication required for pro-active competitive intelligence. Although the use of games in supporting intelligence activities has been reported (e.g., Allgaier & Powell, 1998; Clark, 1998; Fuld, 1998), the link between the different stages of simulation games to CI has not been treated thoroughly. In this chapter, we will examine this link.

To deliver its contribution to the intelligence process, simulation games may be supported by ICT in various ways (e.g., by groupware of various Web-based applications). The role of ICT to enable simulation games is also discussed in this chapter.

To explore the contribution of simulation games to improving the quality of the communication required for the CI process and the possibilities for enabling this contribution by ICT, we first discuss the process of competitive intelligence and its required communication. Simulation games at issue are then discussed. In particular, we define simulation games as practicing tools for improving communications about complex problems (e.g., problems related to competitive intelligence as a process). Moreover, we discuss the stages of building and using simulation games and list the particular functional contribution of these phases to the improvement of communication about complex problems. This is followed by linking previous chapter discussions and specifying a model describing the possible contribution of simulation games to improving the quality of communications required for the CI process. We then highlight the possible contribution of ICT to simulation games improving the quality of communications needed to carry out CI processes. Finally, we conclude the chapter with a summary of the findings.

COMPETITIVE INTELLIGENCE

By competitive intelligence as a product, we understand it to mean information about the environment of organizations required for strategic decision-making (see also Chapter I of this book for a full treatment of CI as a product). Competitive Intelligence is produced in a process consisting of four stages: directing, collecting, analysis, and dissemination. To be able to assess the possible contribution of simulation games to support the

required communication in the CI stages, we discuss these stages and their communicative requirements in this section.

In the direction stage, the environmental information needed for strategic decisions has to be identified. In other words, the strategic information requirements have to be specified. The result of this stage is a list of relevant data (classes) about which information has to be gathered to monitor and/or (re)formulate the strategy of the organization. A crucial issue in the direction stage is to determine the relevance of these data (classes). In order to determine this relevance, directing officers need to be aware of, have knowledge about, and insight into the decisions and underlying problems strategic decision-makers have to deal with. They have to build and maintain a model of the organization in its environment to be able to create the required awareness, knowledge and insight. Moreover, they should use this model to define which environmental factors have an impact on the organization and are, therefore, worth monitoring. Building and using these models places high demands on the communication and cooperation between CI direction officers and strategic decision-makers in the direction phase. During the direction stage, ideally, CI professionals (and strategic decision-makers) are engaged in a continuous process of communication in which they build and maintain a model of the organization in its environment and in which they use this model to derive relevant data classes about which environmental information should be gathered. This communication requires that CI directing officers and decision-makers have a shared language to conceptualize strategic problems and environmental factors relevant to make decisions dealing with these problems.

During the collection stage, sources are identified and data is retrieved from these sources. To this end, one needs to be aware of the availability of sources and of the suitability of the available sources for the efficient retrieval of

Table 1. CI-stages and required knowledge

	Description	Required knowledge
Directing	Determine strategic information requirements	Model of organization in its environment;
How to use the model to derive required information;		
Collecting	Identify sources and retrieve data from them	How to select sources;
How to approach sources;		
Analysis	Transform data into intelligence	Model of organization in its environment;
How to use the model to assess the impact of specific constellations of environmental variables;		
Dissemination	Forward intelligence to strategic decision-makers	Selection of presentation format and content of intelligence

data. Although a part of data collecting activities may be automated (e.g., by alerting services or online databases), knowledge about what the most appropriate sources are for a particular data class and how to approach them requires experience and the exchange of this experience. Hence, communication among those involved in search activities is important.

During analysis, CI professionals need to determine whether the collected data are significant for strategic purposes. In the analysis stage, the collected data are transformed into intelligence usable by strategic decision-makers. This presupposes that—just like in the directing phase—CI analysts are knowledgeable of the problems strategic decision-makers have to deal with. To this purpose, CI analysts need an underlying model of the organization in its environment—preferably the same model they produced during the direction stage. Moreover, they need continuous feedback about the intelligence they produce in the analysis stage.

In the dissemination stage, the intelligence produced in the analysis stage is forwarded to strategic decision-makers. This entails the selection of (content and format) of the way the intelligence

is presented and the actual communication of the intelligence. During this stage of intelligence, practitioners may also receive feedback on the presented intelligence. To disseminate the products of the analysis process, CI officers and strategic decision-makers, again, need a shared language to speak about the developments in the organization's environment in relation to the strategic decision-making process. Moreover, CI officers need to be aware of the formats of the intelligence that are convenient for the strategic decision-makers. If CI officers and strategic decision-makers are both involved in developing and using the model of the organization in its environment, they may have already created a shared language in which they can express strategic problems and the impact of certain environmental trends on the organization. Jointly building and maintaining such models, then, greatly enhances the understanding (and hence) dissemination of intelligence. Table 1 provides an overview of the four CI stages and their required knowledge.

In our view, the creation of the required knowledge in the stages is dependent on a high quality communication process involving CI professionals and strategic decision-makers. In

this communication process feedback is given about the required knowledge in the stages (e.g., about the quality of the model of the organization in its environment) and about the products of the stages (e.g., the information requirements in the first stage). For this communication process to succeed, all participants need to have a shared language to be able to articulate the specific requirements, problems and issues of a stage (e.g., a shared language to build and maintain a model of the organization in its environment, or a shared language to use this model for the assessment of the impact of environmental events).

SIMULATION GAMES

To define what a simulation game entails we turn to the work of Geurts, de Caluwé, and Stoppelenburg (2000). From an overview of the existing literature, these authors derive three perspectives relevant for defining a simulation game.

The first perspective is the *essence* of gaming that, according to Geurts et al. (2000, p. 27) consists of “people in models.” By this somewhat cryptic description they understand that simulation games involve: (1) models, i.e., representations to provide insight into complex wholes enabling the analysis of relationships between structure and behavior, and (2) people who from their own perspective interactively participate in and contribute to the simulation that is an organizational prototype.

The second perspective is the *function* of simulation games. This function consists of “practicing communication.” By means of simulation games participants learn from each other and from the model that provides a hybrid language for the complex problems the simulation game is about. Moreover, the game/simulation functions as an exercise providing a safe environment for communicating about problems by experimenting with and analyzing different interventions under varying circumstances.

The third perspective is the *form* of the simulation game that is described as “orchestrated complexity.” Simulation games are organized procedures consisting of particular building blocks (see Duke, 1974, for the “complete” set of 12 building blocks) allowing for the differentiation between the game package and its use, and the repeated, controlled, and documented application of the game.

Using these three perspectives, we define a simulation game as an organized procedure involving particular building blocks allowing participants to improve communication about complex problems by providing a safe and controlled environment to experiment with different interventions under varying circumstances by means of models representing these complex problems.

For the purpose of this chapter, it is relevant to distinguish between the *building* and *usage* stage of simulation games, for each of these phases may in its own way contribute to improving communication in the CI process.

Building a Simulation Game

Building a simulation game involves three interdependent stages, (1) building the model, (2) transforming the model into a simulation game, and (3) specifying relevant simulation game scenarios.

Model-Building

During the *model-building* stage, the simulation game constructors construct a simulation model of the problem they want to incorporate in the game. To this purpose, they start by defining the central problem they want to tackle by means of the simulation-game. This problem constitutes the core of the goal of the simulation game. For instance, the central problem the game should address is the improvement of communication

between CI officers and strategic decision-makers about CI required for selecting the organization's product market technology (PMT) portfolio. Given the definition of the central problem of the game, the game constructors translate this problem in terms of a simulation model.

To this purpose, they should proceed by identifying "real" systems, parties or actors involved in the problem that can become either players or exogenous forces influencing the course of the game (e.g., the organization in focus, its competitors, legislators, etc.).

Moreover, they should define variables relevant for modeling the problem in focus. Some of these variables count as "essential game variables." These are the variables used to establish game results (e.g., profit margin, market share). Other variables count as "playing variables" (e.g., number and type of products in the PMT portfolio). These variables both influence the essential game variables and may be influenced by the operations of the players of the game.

In addition to the variables, the game constructors should select "driving" parameters influencing the behavior of the selected essential game variables or playing variables. The values of these driving parameters influence the behavior of the selected parameters and the players of the game cannot influence them. Examples of such parameters are macro-economic parameters such as investment climate, inflation, or national spending on consumer goods.

Given the selection of the variables and parameters, the game constructors should define operations (interventions) admitted in the game. Operations change the value of playing variables. Given the change of the value of a playing variable and the values of the driving parameters, the value of other playing or essential game variables may also change. To be able to specify how an operation changes the value of essential game variables given the value of the driving parameters, the game constructors should define the relations between

operations on playing variables, the values of the parameters, and the value of the variables in terms of transformation tables or functions.

Finally, the model should be tested for consistency and realism. The result of model building is a tested simulation model of the problem the simulation game is about.

Transformation

In the transformation phase, the constructors *transform* the simulation model into a game/simulation. To transform the simulation model into a simulation game, the constructors should start by defining the goal of the simulation game in terms of objectives. It is useful to make a distinction here between out-game and in-game objectives. Out-game objectives are objectives the constructors want to realize by means of the game (for instance, improving communication about a particular complex problem). In-game objectives are objectives the players should realize while playing the game. These in-game objectives are measured in terms of the essential game variables (for instance, market share for a particular product).

Given the definition of the out- and in-game objectives, the game actors and their roles should be defined by selecting as actors "real" systems involved in the problem. Moreover, the in-game objectives should be defined in terms of "open" or "closed" targets for these actors. For instance, realize a larger market share for a particular product than your competitors is an example of an "open" target. Realize a market share of 80% is an example of a "closed" target. To make the game actors into real actors influencing the course of the play admitted operations should be allocated to them. If more than one individual player plays a game actor (e.g., four people play an organization that is an actor in the play), then individual playing roles should be defined.

It's All in the Game

Once game actors and roles are defined, the game constructors should define the game steps, specifying the sequence of operations in consecutive game turns. Moreover, rules and procedures for implementing these operations should be laid down. In addition, constructors should specify the physical appearance and paraphernalia (e.g., gaming documentation forms, meeting rooms, playing cards, etc.) of the game and the conditions for playing the game.

The result of the transformation stage is the untested simulation game. During the transformation stage, the constructors may be required to go back to the model building stage, for instance, because it may turn out that given the simulation model, the actual game becomes too complicated to play.

Scenario Building

To construct a playable game, the constructors should finally define scenarios for the simulation game. To this purpose, they should start by further specifying the out- and in-game objectives; for instance, improving communication about CI required for composing the PMT portfolio under different economic circumstances (growing or slacking economy) or improving communication about CI required for rolling out a relatively small PMT portfolio or rolling in a relatively large PMT portfolio.

Given this further specification, the constructors can define the “possible worlds” fitting these objectives by specifying the initial values of both the variables and the parameters and by defining “game events” (i.e., “unexpected” autonomous changes in values of either variables or parameters). For instance, in the scenario of rolling out a relatively small PMT portfolio, the essential game variables “number of product in the portfolio” and “market share per product” get a relatively small initial value. In the scenario of a growing economy, macro-economic parameters such as

“inflation” and “consumer spending” get values to simulate the growing economy.

Once the scenarios have been built according to the out- and in-game objectives, the game simulation can be tested for realism and playability. The result of the scenario-building stage is a set of tested relevant playable scenarios.

Using the Simulation Game

The use of a simulation game involves four stages: (1) preparation, (2) introduction, (3) gaming, and (4) analysis and feedback.

Preparation

To prepare playing the simulation game, the facilitators should start by specifying the out-game objectives of the simulation game session. Given these objectives, they can select the relevant scenario, the relevant participants/teams involved in the simulation game, the roles of these participants, and the physical requirements for playing the simulation game.

Introduction

In the introduction stage, the facilitator introduces the participants to the learning objectives, the goals, scenarios, roles, rules and setting of the simulation game session. The facilitator also takes actions to ensure the involvement and commitment of participants (anticipating uncertainty of the participants, difference in learning styles and possible resistance).

Gaming

During this stage, the actual game/simulation is played. Participants play their roles and try to reach the goals of the game/simulation according to the rules of the game. While playing the game, participants are taking actions that influence the

values of the relevant variables, given a certain scenario.

In addition, while participants are playing, the facilitator may intervene to increase the pressure, give feedback or motivate the participants to alter their behavior to improve the game.

Analysis and Feedback

Analysis and feedback can focus on several aspects of the game/simulation. First it may be directed at the results of the game—i.e., at the effect of (playing within) a certain scenario on the relevant variables. This analysis aims at the learning objectives of the game. Second, the analysis may be directed at the suitability of the game itself—i.e., whether it is properly built and used.

The analyses from simulation games may feed back into building them. In this way, building instructs simulation game usage, and simulation game usage instructs building. For instance, analysis of a simulation game may hint at problems with the model underpinning the simulation element of the game, may bring to light shortcomings in the gaming element of the simulation, or suggest additional scenarios for the simulation game. In this way, a simulation game can become an ongoing process of improving the simulation game and thereby improving the quality of the communication about the complex problem the simulation game is about.

Both the building and the usage phases of simulation games can contribute to improving communication about complex problems. To discuss this possible contribution in a more differentiated way, it is useful to identify the (desired) effects practicing communication by simulation game can serve and to analyze how building and using a simulation game may contribute to realizing these effects.

On the basis of their analysis of the existing literature, Geurts et al. (2000, p. 29ff) mention five organizationally relevant desired effects or

functions, as they call them, of simulation game: increasing awareness and motivation, training skills, improving knowledge and insight, improving communication and cooperation, and integration of learning experiences. Each of these desired effects, in its own way, contributes to improving the content and/or the process of communication about complex problems.

By increasing awareness and motivation, Geurts et al. mean that a simulation/game can help to gain a preliminary understanding of a problem, its consequences and the effects of particular ways of dealing with it. This understanding may also motivate participants to think about the problem and about particular ways to solve it.

A simulation game invokes certain new skills for dealing with a problem. As Geurts et al. put it: “participants are stimulated to find new lines of behavior and put these into practice” (p. 30).

By means of a simulation/game, participants can actively examine the specific consequences of certain lines of action regarding a certain problematic situation. It thus improves knowledge and insight into a certain problem and into the effects of certain ways of dealing with it.

In a simulation/game, participants work together on problematic situations—i.e., they need to communicate and cooperate to explore possible courses of actions. A simulation/game can therefore be seen as a means to diagnose and improve the communication and cooperation regarding dealing with complex problems.

A simulation/game can be used to integrate learning experiences of the participants regarding the complex problem at hand. A simulation/game provides a dynamic background against which knowledge and insights may be ordered.

In Table 2 we list possible contributions of simulation games to improving communication about complex problems.

Table 2. Contributions of gaming to improving the quality of communication

		Increasing awareness and motivation	Training skills	Increasing knowledge and insight	Improving communication and cooperation	Integration of learning experiences
Building the simulation-game	Model-building	Model-building may increase awareness of the importance of knowledge and communication	Training in structuring complex problems in terms of simulations	Increasing knowledge about the problem under consideration (what is the problem, why is it a problem)	If participative methods for model-building, transformation, and scenario definition are used, chances are created to improve communication and co-operation between parties dealing with the simulated problem	Participative building allows for pooling knowledge and creating a shared language, improving discussions between parties dealing with the simulated problem
	Transforming model into game	Motivating dealing with the problem	Training in making understandable complex models and making them transferable to other people	Increasing knowledge about relevant variables, parameters, events, and relations related to the problem		
	Scenario definition					
Using the simulation game	Preparation	Awareness of differences between points of departure, differences between events;	Quickly picking up relevant aspects of a complex problem situation	Knowledge and insight into (constellations of related) variables causing certain effects given certain starting conditions, events and interventions	Teams of players playing against or with each other need to co-operate and communicate and get feedback on communication, cooperation and the results	Shared understanding and awareness of the dynamics of the complex problem given different conditions, events and interactions
	Introduction	Differences between 'lines' of interventions and their effects	Operationally dealing with complex problems in different circumstances	Focus is on analysis and explicit knowledge	Improvements can be monitored by playing the game more than once	
	Playing the simulation-game	Motivation providing a sense of control and security needed to deal with problems	Dealing with unexpected events and interventions			
	Analysis and feedback	Focus is on habituation and tacit knowledge				

SIMULATION GAMES FOR COMPETITIVE INTELLIGENCE

To explore how simulation games can contribute to improving communication about the required knowledge related to stages in the CI process, we are now in a position to bring together the results from earlier sections. We had listed the required knowledge for the different stages of the CI process and we derived an overview of the particular contribution of building and using

simulation games to improving the quality of communication about complex problems.

In the present section, we first present an example of a simulation/game useful in the context of CI. Next to illustrating a CI game, the example also provides a background to explore how the contributions of building and using simulation games can contribute to improving communication about the required knowledge related to the stages of the CI process.

A Strategic/CI Simulation Game: The Product-Market-Technology Portfolio

Important strategic decisions focus on the composition of the “product market technology (PMT) portfolio” for a certain period. This portfolio consists of all the products (for certain markets, produced using a certain technology) of an organization at a given point in time. Strategic decision-makers should deal with questions regarding its composition in the future. Key questions are: do we need to change the current portfolio and if so—what is the nature of these changes? This decision-making requires strategic knowledge and information about the environment—particularly about the moves of competitors and environmental trends and developments. To focus the required intelligence activities, a game may be designed and used in which this process of decision-making regarding the PMT portfolio of an organization is in focus and a competitor is simulated.

The goal of such a game would be to formulate an adequate PMT portfolio for a certain period of time. Variables to determine the adequacy of this portfolio may be the impact of the portfolio (in terms of profitability, market share, brand-impact, etc.) and feasibility of the PMTs (in terms of costs and the effort to make them fit into the current organization, means of production, culture, etc.). These variables are the essential game variables.

Another set of variables consists of the parameters influencing the game. Among these may be internal parameters like available budget, available capacity (staff, competencies, machines, ICT, etc.), and the mission of the organization. External parameters may be the macro-economic circumstances, labor market, capital market, technological developments, moves of competitors, customer trends, etc. During the game, the players cannot change the value of these parameters. However, the game may be designed in such a way that developments in the external parameters may alter the

value of the internal parameters—and influence the course of the game. Such developments may be modeled by autonomous external events.

The game may simulate the discussion of two groups of strategic decision-makers: one group deciding about the PMT portfolio of the own organization and another group working on a PMT portfolio of the most important competitor. Both groups may consist of participants playing different roles in the discussion: marketing managers, production managers, financial experts, etc. During the game the groups may perform one or more of the following operations: (1) add a new item to the PMT portfolio, (2) remove an item from the portfolio, (3) acquire a piece of information about the environment and (4) share a piece of information with the environment.

The game may be designed in such a way that both groups may acquire environmental information by only “one piece of information” per time-unit (e.g., a statement about an environmental parameter) and that the total number of information elements that can be acquired is limited. In this way, the information-gathering behavior can be monitored.

The game can also provide one or more occasions where players from different groups meet each other (e.g., on a trade show, or on a golf-court). The goal of these occasions is to try to find out about the portfolio of the competitor—and, at the same time, hold back essential information as much as possible. Many more features may be added to the game—but a complete description is beyond the scope of this chapter.

Contribution of Simulation/Games to the CI stages

Simulation/games may contribute to the knowledge required in the intelligence stages. In general, building and using a simulation game may lead to an insight into (1) the definition of information requirements, (2) the definition and

use of information sources, (3) the analysis and use of information to strategic decision-making (for instance, in how it leads to a PMT portfolio), and (4) in the dissemination of the information and intelligence, given the different values of the parameters. In this section, we elaborate on these contributions.

Contribution of Gaming to the Direction Stage

During the building stage, a model of the organization in its environment in terms of relevant parties, variables, parameters, and variables relevant for strategic decision-making is built and tested. Such a model is relevant for the direction stage because it can guide identifying relevant environmental data classes. If, for example, CI professionals and game constructors work together to build a realistic game for generating a PMT portfolio, they should decide on the essential game variables, the playing variables and on the environmental parameters that may affect these variables. They should also decide on the initial values of these variables and parameters. A realistic choice (e.g., a relevant technological or customer trend, a relevant mission statement, relevant macro-economic circumstances) is impossible without a valid model of the organization in its environment. Building a game may be a trigger to improve current models for identifying relevant environmental (values of) variables and parameters.

In the building stage, a number of different scenarios (the specific initial values of the variables and parameters) are defined, each of which is the starting point of playing a game. During the game (for each scenario), knowledge is created about the impact of certain (initial) values of these variables and parameters in the context of making certain strategic decisions (e.g., formulating a PMT portfolio). For instance, it may turn out that certain initial parameter values have

a high impact on organizational or competitor behavior. This knowledge may again be used in directing the intelligence activities—specific environmental parameters or variables may be monitored closely because some of their values may have a high impact on the organization. Playing a certain scenario can also reveal that some data classes gain in importance to make a certain strategic decision, while others cease to be of value. This knowledge can also be used to direct intelligence activities when a certain scenario comes into being.

Contribution of Gaming to Collection

During the building stage of a game for competitive intelligence, the model of the organization in its environment should be consulted to identify possible sources for collecting information about the environment. These sources could be made available to the players during a game. While a game is played, participants may create knowledge about the usefulness of these specific sources. In particular, it may turn out that the use and perceived relevance of specific sources depends on the different scenarios.

Contribution of Gaming to Analysis

The building stage results in a tested model of the organization in its environment in terms of relevant parties, variables, parameters and their relations. It thus provides a model for analyzing collected information about the environment as well. If the model is a realistic one, it may serve as a background for interpreting changes in value of the variables and parameters in the “real world.” The value of this model increases when different scenarios are tested during playing the game. During a simulation game, one may find out that specific constellations of parameter values have a certain effect on the organization. This knowledge should be used to interpret the values of the actual parameters.

Contribution of Gaming to Dissemination

One of the purposes of simulation games is to provide an insight into and support for communication and cooperation practices. Communication and cooperation are important issues for disseminating and using the intelligence in strategic decision-making. It is often claimed that adequate communication and cooperation between intelligence professionals and strategic decision-makers is the key to ensure that intelligence is distributed correctly and used. Building a simulation game may provide several possible settings for the communication about intelligence and cooperation between CI professionals and strategic decision-makers (ranging from a “passive” mode, in which intelligence professionals give an update on their output once in a while, to a “collaborative” mode, in which both groups cooperate intensely and produce the intelligence together). During the building stage, one may thus gain insight into the different forms of communication and cooperation. While using the simulation game (in different scenarios) knowledge may be created about the adequacy of these settings (under different scenarios). This may help in designing an adequate setting for communication and cooperation.

Moreover, when both CI professionals and strategic decision-makers participate in (building or playing) the game, building or playing the game itself realizes cooperation and communication about relevant knowledge for competitive intelligence purposes (e.g., the models, possible scenarios, etc.). It helps to create a shared language to facilitate (current and future) intelligence matters.

Table 3 summarizes the different contributions of a simulation/game to the intelligence stages. Dependent on the design of the specific game, it may also lead to specific intelligence. The specific game of the previous section may, for instance, give valuable insights in how an organization sees the strengths and weaknesses of a relevant competitor (given different scenarios).

Simulation/gaming can be regarded as a means to support generating relevant knowledge for intelligence activities. In the next section, we discuss how ICT may support the building and using stages of gaming in order to create, store, share and apply required knowledge for the competitive intelligence stages.

Table 3. Simulation games contributing to the acquisition of knowledge for the CI stages

	Directing	Collecting	Analysis	Dissemination
Building the simulation-game	Building a model of the environment of the organization in focus in terms of parties, variables, and variables relevant for strategic decision-making that can guide identifying relevant knowledge domains and data classes	Identifying possible sources for collecting information about the environment	Providing a model for analyzing information about the environment. The model used in the direction stage can be used for analysis purposes as well.	Providing different settings for distributing environmental information and its use in strategic decisions
Using the simulation game	Identifying knowledge domains and data classes for making particular strategic decisions in different scenarios	Gaining knowledge about the usefulness of specific sources in different scenarios.	Gaining knowledge of the adequacy of the model for analysis purposes in different scenarios	Gaining knowledge about the adequacy of different settings for the distribution of the intelligence and its use (in different scenarios).

ENABLING SIMULATION GAMES FOR CI BY ICT

The role of ICT to support simulation games for competitive intelligence falls into two broad categories: (1) ICT for supporting building and using a simulation/game and (2) ICT for making the results of the game available for the 'real' intelligence activities.

In the building stage, ICT (e.g., the Internet) can be used to collect intelligence to construct a realistic game. In fact, the same ICT tools normally employed in intelligence activities may be used. Moreover, ICT can greatly enhance the communication and cooperation needed to construct and test a realistic model of the organization in its environment. For instance, Intranet applications and GroupWare can aid in online construction and testing of the model. ICT applications can also support the choice of parameters and relevant values of the parameters for the specific scenarios used in the game. For instance, system-dynamic software can help in building a model of the causal relations between the essential game variables and the parameters. It can also help in determining specific effects of parameter values on essential game variables.

ICT can support the stage of using the game as well. ICT can help the participants to monitor the environment, to store the results of the game and to support the communication and cooperation needed during the game. To store the results of the game, a "scenario database" can be made and updated. In this database, all the relevant outcomes of playing the game in different scenarios should be stored. This information is relevant for the participants playing the game as it provides a log of the results of the current scenario. An insight into the results of playing the different scenarios is also relevant for the "real" intelligence activities (see below). ICT can also serve to generate a virtual game setting—i.e., simulate a part of the environment participants use to play the game (e.g., a virtual stock market, or a virtual

trade show). In a similar vein, ICT can be used to generate autonomous environmental events and forward information about it to the participants. Another way of using ICT during the game is to provide a 'decision support system' participants may apply to calculate the consequences of their decisions.

Table 4 lists possible uses of ICT to support creating, sharing and storing knowledge for the CI stages.

The second function of ICT regarding simulation games for competitive intelligence is to store the resulting knowledge from the simulation game and make this knowledge available to intelligence professionals. To this end, the model that was built and tested and resulted in several playable scenarios should be stored and used in the intelligence activities. A model of the organization in its environment is the essential model for directing and analyzing activities. During the game it can be tested in a "safe environment"—and this may lead to valuable information about its use in real intelligence activities. Therefore, it is essential to store the model and provide easy access to it (and to the arguments leading to the choice of certain essential game variables, parameters and their initial values). Likewise, the information resulting from playing different scenarios should be stored (see the scenario database mentioned earlier) and made available for intelligence purposes.

CONCLUSION

The purpose of this chapter was to explore the relevance of simulation/gaming for competitive intelligence and to examine the role of ICT to support simulation/gaming for competitive intelligence. Simulation/gaming can be a valuable tool for arriving at knowledge required in intelligence activities. Its main contribution is to build and test different scenarios regarding the impact of the environment on the organization. During building and testing these scenarios, awareness, knowledge

and insight may be gained about the underlying model of the organization in its environment and about the impact of different values of environmental parameters on relevant organizational variables. Moreover, building and testing different scenarios may also enhance the communication and cooperation needed for intelligence activities. ICT can support delivering the contributions of simulation/games to competitive intelligence in various ways. In this chapter, we discussed some possibilities to support the building and using stages and to facilitate the dissemination and use of the knowledge resulting from the game to intelligence activities.

In our view, simulation/games can be an important tool to support intelligence activities. However, one should be aware of the effort it takes to build and use a simulation/game. At the same time, if a simulation/game is properly designed, the knowledge gained from it may well be *the* knowledge used in the direction stage (and for a great part in the analysis stage). In addition, if properly enhanced by ICT—simulation games may well be one of the most important tools to direct intelligence activities.

Chapter 3.10

Assessing Online Discussion Forum Participation

Matthew Shaul

Kennesaw State University, USA

ABSTRACT

As a socially constructive learning tool, discussion forums remain central to online education. They have continued to evolve in functionality, acquiring ever-increasing usability features. However, development has lagged in providing instructors the means to assess student work in forums. The author submits an overview of his software program that provides instructors with the means to evaluate forum work quickly, easily, and repeatedly. The software accomplishes this by accessing the forums' underlying database, searching for manifest and latent data, and calculating data associated with an array of metrics. This is a Web-based tool built on Open Source and standards-based languages, providing opportunities to port the program to numerous Learning Management Systems. It is the intention of this author to provide this tool, when completed, for such use as a free, Open Source tool. Interested parties may e-mail the author for progress updates. Currently, however, further work on the project must await the completion of another project, the author's dissertation.

INTRODUCTION

Learning Management Systems (LMS) continue receiving expanded toolsets and quickly assimilating new Web-technologies to provide users an increasingly interactive, richer experience. Chat, streaming media, "blogs," "video-casting," and "podcasting" found their way into online educational settings soon after being generally accepted on the Internet. Yet, discussion forums, an old (in Internet time) technology, seemingly remain the core from which many instructors build online classes. These technological descendants from long-ago bulletin boards and listservs, one of the earliest tools integrated into online education, remain central to the design and success of many distance education courses.

More so than the newer technologies, discussion forums approximate a replacement for the give-and-take of the brick-and-mortar experience, mimicking many-to-many discussions found in traditional classrooms. In addition, the recognizable conversational structure reflected visually in the tree-like output, simplicity and flexibility of the tool likely contribute to its continued success and

acceptance, granting users an immediate sense of familiarity. The importance of such comforting effects cannot be discounted, especially in a field still relatively new.

Discussion Questions

However, despite the history and wide, though not full, acceptance of the importance and use of forums, lack of awareness on how best to use them persists. Note that this unawareness does not pertain to the implementation of forums, or designing them to encourage adoption. In fact, Markel (2001) notes that forums have developed beyond simple, plain text message boxes, incorporating emoticons, HTML formatting, images, and hyperlinks to provide a more enticing tool to draw students into their use. Yet, while these features encourage participation, there is no clear way for instructors trying to devise effective forum evaluation schemes.

This article, therefore, examines forum technology assessment. Given the importance of assessment in learning, it is apparent that such a widely used distance leaning tool must provide instructors with sound options for evaluating student work. Moreover, effective assessment options, with associated feedback, provide the added benefit of encouraging an increase in student postings, thus adding to the forums' potency. Yeh (2005) notes that student participation increases as instructors place an importance on posting by assigning grades to forum use. This is unsurprising, as one would expect graded assignments to garner more attention from students than non-graded activities. Swan (2001) finds this true as students calculate reward versus effort when determining whether to participate in forums. Forums with a larger percentage of influence on grades receive more use. However, while most LMS do provide instructors some means of forum assessment, current tools remain either overly limited or too time consuming to use.

Forum Types

Note, different forum types exist, and not all contain posts needing assessment. The first might be termed "social" forums. These forums furnish students with an informal area to discuss class- or non-class-related matters. Often, instructors state they will not view these forums' contents, thus creating a space in which students are free to speak openly, criticizing or praising the instructor, course, curriculum, or school without concern the comments will influence grading. Instructors often refer to these forums as "water coolers" or "student lounges." While these forums may provide students social benefit, instructors almost never assess them (Nelson et al., 2005).

A second type of forum might be labeled "general discussion." Like the social forums, these tend toward a free flowing, less structured style. However, unlike the social forums, these pertain to the course material and are less informal. Instructors may select broad topics or simply ask students to post any course related questions or material. Whereas social forums resemble hallway discussions among students, general discussion forums mimic an open question discussion in the classroom. Like their classroom counterparts, online general discussion students might receive grades based upon participation, insight, argument, initiative, and other factors.

The last forum type considered here is the "topic driven" forum. These forums are the most structured in terms of content and correspond to classroom assignments in which the instructor picks topics and expects students to come prepared to debate and defend stances. Similar to general discussion forums, instructors may wish to assess topic driven forums as they would in the classroom—on participation, style, scholarship, argument, insight, and other subjective and objective factors.

Quantitative and Objective Forum Assessment

As stated previously, forums currently do possess methods to assess student work. The LMS and the instructor provide quantitative and objective means of evaluation. The concern, however, is whether these methods offer instructors the tools needed to accurately and meaningfully measure student work.

One of the most basic methods, in fact, exists in most LMS's, and is simply a count of each students' postings, allowing the instructor to assess based upon predetermined levels matched to grades. For instance, a minimum of five posts per week may warrant an "A," four a "B," and so on. The advantages of this method appear plentiful. For one, students easily understand the measurement and are clear on expectations, which Dennen (2005) notes may promote participation. In addition, assessing is easy for instructors, as the LMS likely provides reports listing a count total for each student. Instructors need do no more than run weekly reports and award grades accordingly.

Disadvantages, however, exist as well. Forum threads often contain a number of insignificant posts consisting of little more than "me too" or "well said." Since the LMS in this case only considers counts, these posts weigh equally with well-written, researched posts, a situation many students and instructors would find unfair.

Additionally, relying solely on counts encourages post submissions, but not necessarily forum participation, if the expectation is that students will also read their classmates' offerings. As a result, the forum may devolve into a writing exercise with each student posting detached, unrelated essays rather than interrelated posts, building an interconnected discourse (Dennen, 2005). Consequently, the forum in this case remains underused as an interactive, communicative learning tool (Dunlap, 2005) and becomes little more than a channel to submit electronic topical papers.

Instructors often address this shortcoming with a seemingly sensible solution: requiring students to comment or respond to a few of their peers' posts each week, in addition to submitting original posts. The requirements remain simple for the students to follow and easy for instructors tally. The new rule's intent, of course, is to forge threads from the posts, and subsequently, discussions from the threads, by mandating a level of interactivity. Although the idea seems reasonable and does produce at the least the instructor-assigned degree of interaction, the threads may consist of little more than this minimum. Students post to expectations (Dennen, 2005) and without more guidance than simple quantitative requirements will post the minimum type of reply necessary. Moreover, the response or comment posts can lack a depth matching the original post, and a repetitive pattern quickly ensues in which responders follow up initial posts with inconsequential replies, adding little to the aggregate knowledge (Ivankova & Stick, 2005). Thus, the forums attain some interaction, but the requirement change may not bring about the desired higher-level discourse or debate.

The next step, then, is to raise the degree of discussion while maintaining an easy means to measure student work. Some instructors attempt this by requiring all posts, including the response postings, to have citations from peer-reviewed publications. This seeks to infuse a degree of scholarship, thus raising the discussion level. At minimum, the hope is that the new rule forces students to research and form their responses around that research.

This remains a simple quantitative and objective measure. Instructors may alter the number of citations needed, or the sources allowed, but the measure remains merely a type of count. There is the beginning of significant change, however. Note, though in essence simple, such a measure is beyond the abilities of typical LMS because they lack the capability to differentiate a citation from

any other string of text. Thus, they cannot count or note citations, and the burden of tallying this assessment, then, moves for the first time from the LMS to the instructor.

Qualitative and Subjective Forum Assessment

Part of the allure of quantitative and objective assessment of forum work is the simplicity for the students and the instructors. For the instructors, this translates into speed and timesaving, as quickly accessed reports reveal each student's standing; grading is very straightforward. Yet, perhaps depending upon the student's age and grade level, relying solely upon quantitative measures may not offer the clearest evaluation of performance. In the case of tallying postings, the measure is ultimately an electronic attendance sheet, tracking whether students checked in and "participated." However, at the undergraduate level and higher, instructors likely prefer grading on criteria that are more substantial. Absent in most pure counting methods, subjective measures such as writing style, initiative, strength of argument, and originality offer a more robust grading rubric.

In fact, many such rubrics exist. For example, Edelstein and Edwards (2002) devised a forum assessment rubric called "Assessing Effectiveness of Student Participation in Online Discussions." This rubric consists of five categories: Promptness and Initiative; Delivery of Post; Relevance of Post; Expression within the Post; and Contribution to the Learning Community. The instructor is to consider each student's work as a whole, evaluating each post on a scale of one to four, with one the lowest, in each of these categories. Edelstein and Edwards provide explanations for each rating of each category to aid the assessor. For instance, a one rating in the "Relevance of Post" category translates to "Posts topics that do not relate to the discussion content; makes short or irrelevant remarks."

Such qualitative and subjective measures afford the instructor far more leeway in assessment than mere counts. Whereas a "me too" post is awarded standard points in a count assessment, such a post would draw the lowest score in the just mentioned Edelstein and Edwards category. These subjective ratings also provide the instructors the means to use their judgment, allowing them to weigh factors differently, perhaps for instance, heavily rewarding creativity in thinking or writing style, while affording less weight to the inclusion of citations.

Additionally, by moving to richer assessment rubrics, instructors lead students to submit richer messages, which elicit richer peer responses and lay the foundation of scholarly discussion. These subjective assessments attempt to measure higher-level learning, including analysis, synthesis, and evaluation and direct students to post accordingly. Bhagyavati, Kurkovsky, and Whitehead (2005) note that students adjust their posts to meet these expectations, and the forums' quality wholly moves upward. As stated earlier, students adjust their work to meet expectations.

Unfortunately, the instructor time expended is a considerable drawback of detailed rubric scoring and subjective qualitative assessment. Consider the time needed to work through a five-category rubric in a class of 20 students in which postings could easily total between 500 and 1000. Unsurprisingly, instructor fatigue becomes a concern as forum management evolves into a significant time- and effort-intensive activity (Dunlap, 2005).

Another drawback, often overlooked, is the return to manual effort for the assessor such rubrics require. This is unfortunate considering most LMS's run atop powerful computers very capable of intense calculations. Moreover, relational databases contain the actual forum data, availing a trove of information to SQL querying. Forgoing such computational resources is inefficient and counterintuitive considering online

courses exist only through the use of such advanced technologies.

Proposed Solution

The need for a forum assessment aid seems clear. The requirements are also apparent—develop a tool to assist instructors in assessing forums using measurements beyond the simple quantitative counts. The tool should incorporate some degree of qualitative or subjective measure and should utilize the power of the host computer. Certainly, the tool should provide a simple, usable interface to encourage adoption.

Current Packages

Ideally, forum software would offer an integrated tool to assist in assessing forum messages; unfortunately, this is presently not well advanced. However, Wu and Chen (2005) have developed software that attempts automating assessment of student forum work. Their software is similar to Qualrus, mentioned by Gilbert (2005), in that it parses written submissions and grades them based on the instructor's preprogrammed criteria. Whereas Qualrus and other similar essay-grading software purportedly evaluate style, grammar, structure, quality, and argument, Wu and Chen's software appears to measure fewer writing criteria. Instead, the software algorithmically determines knowledge density, or message quality, using instructor-specified keywords. The software then accesses the forum's database, and using the message field's length and participant-sorted message counts, assigns values for student effort and participation.

Wu and Chen's method attempts less to assess message content than essay grading software such as Qualrus, and examines the database for supplemental information; this may be preferable for forum evaluation. If the instructor uses forums for socially constructive learning, for instance,

much of the "construction" exists not individually in each message, but in the forum structure, in the interfaces between and among messages, captured latently in the database. Any assessment must consider the forum as a whole, messages inter-related in a web (Schellens & Valcke, 2004). To appraise each message separately and solely limits the instructor to an assessment of independent "mini essays," each presumably unaffected by others' postings.

Developing a Solution

Although Wu and Chen (2005) propose gleaning modest amounts of data from among the tables, this author believes the tables and the relations between the tables hold enormous amounts of valuable information. As an example, Dringus and Ellis (2005) believe mining the database has significant potential to reveal information hidden, for instance, in timestamps and sequence numbers. These numbers, referred to here as "manifest" information, lie in fields readily available to SQL queries. However, properly manipulating this manifest information potentially reveals additional "latent" information that is also useful in assessing the forums' contents.

For instance, message timestamps reveal relative temporal information that may show evidence of student initiative by indicating first postings or responses. Additionally, a post with many responses, evidenced by subsequent sequence numbers and parent-child pointers found in the database, may show a post's effectiveness. Certainly, for instance, it is arguable in a socially constructive environment that a student post, eliciting numerous responses and thus acting as the impetus for peer involvement, warrants a positive assessment to some degree. Yet, a methodology focused wholly on the individual message, and not tuned to consider the message "tree," misses this information entirely.

The solution, therefore, appears to require first the formation of meaningful measures, followed by a search of the database fields and relationships for latent and manifest data supporting the measures, and finally the development of the algorithm and SQL to pull the data from the database. The author has proceeded through these steps, designed such a program, and has developed a simple Web-based interface, allowing instructors to quickly and repeatedly use the tool. The hope is that the simplicity will compel instructors to use the tool often to provide students frequent feedback on forum performance.

Following is an overview of the measures used by this author, some insight as to the reason each is included, and a brief explanation of how the program attains the data:

- **Initiative:** Being first to provide an opinion is not easy, so the system rewards students in two situations: one if the student starts a thread, and two, if the student is the first to respond to an instructor post. The system captures this in the posts timestamps.
- **Effectiveness-Depth:** In a socially constructive environment, one measure of effectiveness is the amount of involvement elicited. Thus, the system calculates the number of responses and sub-forums spawned. Students are rewarded for being able to draw others into a discussion.
- **Effectiveness-Breadth:** This is similar to the previous measure in that it rewards students for educating classmate responses. However, a “deep” thread (many responses) may involve only two or three students, perhaps still valuable but less of an indication of the enthusiasm for thread than the number of responses indicate. On the other hand, this measure calculates and rewards effectiveness by tallying unique responders, thus revealing the scope of the enthusiasm.
- **Value:** In the current system, students can anonymously rate each other’s posts on a one-to-five scale representing “Not Valuable” to “Very Valuable.” The system then measures value by averaging the peer rating a student’s posts receive. This is a very important measure since each student defines value for each post differently. What may seem to many students a simple, low-value posting may clarify a point and offer high value to other students. This metric accounts for the possible variances.
- **Timeliness:** This measure is best used when the instructor does not impose a posting deadline on threads. Rather, students continue threads for as long as there is interest. In this way, students may revisit older threads as they learn more, or as they come upon new information. However, differences exist between legitimate, interesting late posts and messages submitted well after a thread is exhausted. The system recognizes this by calculating timeliness as the standard deviation of a thread’s posting time, and assumes interesting late posts will draw responses and move the standard deviation toward itself. Merely late posts will not alter the standard deviation and will not receive credit.
- **Participation:** Post count is not a good measure of participation. For instance, one student may log in and post several times a week over the extent of a course. Conversely, a peer may log in at the last minute and post an equal number of messages. Clearly, they participated at different levels. To reward consistent participation, this system determines whether each student’s Average Time Between Posts (ATBP) is within the standard deviation of the class’s ATBP. Students whose ATBP is outside do not receive credit.

Assessing Online Discussion Forum Participation

- **Scholarship:** Instructors may expect posts to contain certain keywords, phrases, or names. Additionally, they may require citations. The system searches each post for words from an instructor-determined list and scans for citations. Posts receive credit for containing either keywords or citations. The citation search is not flawless, as the system uses regular expression patterns to match what are likely citations.
- **Style:** Perhaps misnamed, the system does not examine the prose for writing style in this metric, but instead performs a word count. Students receive points for posts above a specified count but below another count. The attempt is not to reward short, unsubstantial posts, or long, rambling posts. Therefore, more precisely, the metric attempts to encourage succinct, concise writing.
- **Instructor Points:** While the previous metrics seek to cull needed data directly from the database, certainly some subjective measures cannot be calculated from the tables' fields. Thus, the system provides the instructor an opportunity to add or subtract points from each student's assessment. Therefore, for instance, the instructor may reward a student who has consistently put forth original arguments, or who has carried discussions to a higher level. Likewise, an instructor may subtract points from a student who has done well, but has consistently used poor grammar or spelling.

These metrics are varied enough to provide a flexible array of point opportunities to students. Some students may be comfortable, or in a fortunate position to attain points from the Initiative measure. Others may be better at writing concisely or with a style the instructor appreciates, and positioned to acquire Style points. Still others may have the time to post frequently and receive points for Participation. All can pursue Value or Scholarship points.

The author's system seeks to add further flexibility for the instructor as well. Rather than considering each measure equally, the tool allows instructors to weight each metric to their preference. For example, one instructor may find the Effectiveness-Breadth measure most compelling in assessing forum work. Therefore, the instructor may weight this as 40% of the overall assessment calculation. On the other hand, another instructor may weight this at 10%, and weight Instructor Points much higher. By allowing varying weights, the system incorporates another degree of instructor subjectivity into the assessment.

An instructor configures the desired weights on a simple Web page that lists each measurement with an accompanying explanation for the measure. Each is followed by a dropdown box listing numbers from zero to 100, and the instructor weights each measure so the total of all selected weights, added together, equals 100. This screen also has a textbox input for keywords, used in text searches, in the event the scholarship measure is chosen. Naturally, instructors weight measures they feel important for assessment highly and those they consider less important lower or zero.

If the instructor selects Instructor Points as a measure, the next screen displays a class roster with a dropdown box with numbers from negative 100 to positive 100 associated with each student name. Here, the instructor assigns positive or negative points to each student. Note, these are the actual points; the weight of these Instructor Points was configured on the first screen.

The final screen, whether or not Instructor Points is used, displays each student's calculated rating. It is important to note the system scores students as a percentile rank of all points awarded and not from a finite allotment of points. Thus, first the system determines total points awarded for everyone, and then ranks each student based upon the student's earned points. In this way, students are not aiming to amass a specific number of points for associated grades (i.e., 100 points

for a C, 200 for a B, 300 for an A), but instead realize they must maintain pace with classmates through participation by accumulating as many points as possible. As classmates participate, the pool of awarded points grows, compelling students to continue to post, less their awarded allotment shrinks as a percentage.

CONCLUSION

Assessing student work in discussion forums remains difficult for busy instructors, especially if one wishes to use measures beyond simple tallies. However, the author's software solution offers some hope by providing an easy to use, flexible solution. The tool is Web-based, written in Open Source and standards-based languages that should provide the basis for easy portability. Interested parties can e-mail the author for progress updates. Unfortunately, for the moment other project requirements demand a—hopefully brief—respite from the project. When finished, though, it will be freely available as Open Source.

Because of use of the LMS's underlying hardware and software, the tool performs its calculations quickly. Additionally, because of the simple interface, the tool encourages instructors to run assessment reports often, thus enabling the instructor to provide continual feedback to students. Consequently, the forums rise to higher levels of discussion and debate and become true socially constructive learning environments as students learn to post, read, and respond accordingly.

University of Queensland, Australia

ABSTRACT

This chapter describes the development of the E-News project which examined an interactive journalism approach in Rockhampton, Australia. This project provided an opportunity to examine how the introduction of this new technology into regional media and communication brings into question the traditional roles of the journalist, the editor, the graphic designer and the audience in the production and ‘consumption’ of written material. Such an approach provided the opportunity for grass-roots journalism to be examined for its capacity to provide a clearer insight into the nature of a community journalism-based approach such as the E-News system. It also allowed the examination of the resultant interaction that occurs between users and community. The experiences resulting from the E-News project

provide a framework for discussion regarding the potential of approaches such as E-News for community informatics in regional areas resulting from online news environment.

INTRODUCTION

Online development in the area of media and communication has taken many forms in the last decade. Information Communication Technologies (ICT) has enabled many areas which were traditionally physically orientated to emerge and explore a new dimension of online interaction. This chapter looks at the impact of community informatics on regional communities through exploration of collaborative issues in an educational context.

The nature of interaction between ICT and journalism is examined in the context of the issues that arose during the E-News project, and its implication for regional media and communication. This interaction occurred through collaboration between IT students at the University of Queensland's Ipswich campus and journalism students at the Central Queensland University's Rockhampton campus. It investigates the development and implementation of a real-life online journalism scenario.

The E-News project provided an opportunity to examine how the introduction of new technology into regional media and communication brings into question the traditional roles of the journalist, editor, graphic designer and audience in the production and 'consumption' of written material. The aims of the project were two-fold. First, it examined the development of an online environment for reliable information delivery for regional community-based journalism. The underlying assumption in this approach was that by enabling online collaboration, it is possible for a range of participants from varying backgrounds with non-technical levels of computer literacy to meaningfully interact in a news-based environment. The second aim was to examine how education could assist in addressing multi-disciplinary issues between all parties involved and the end consumers of the service: the community. The application of an educational framework to analyse a digital news perspective can reveal valuable lessons for community informatics.

The changing role of the traditional journalist because of ICT has been a rapid one. Despite this, the traditional definition of journalism has not changed, but has evolved along with the technology. Journalism still involves the collation and production of news and news articles for public consumption. What have changed are the process and the people able to conduct the preparation and publishing of news. Because of the increasing ability to post stories remotely or work online using ICT, community members

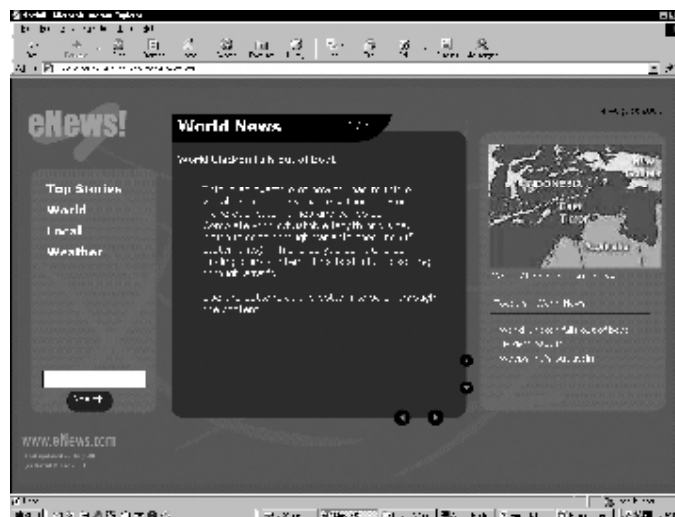

can now share concerns, and provide opinions and information into the news delivery systems. This has been termed 'grass-roots journalism'. In this chapter, the use of the word 'journalist' will include a non-professional, 'grass-roots' approach, describing an individual wishing to publish community information on a topic or event. This allows discussion regarding community involvement in topics of interest to consider professionals in the same sense as those who have a view on the topic in question. By adopting such an approach, the broader issues of community informatics in regional areas can be discussed, addressing all participants on equal terms.

The following section outlines the nature of the project and the participants. It explores project aims and the mechanisms by which the project was conducted and reviewed. Studio pedagogy and its role in providing a structural framework for project development is explored while examining the impact of the technology in this process. The chapter then moves to exploring a series of broader issues, particularly the interaction between users, which arose during the project. This approach lays the framework for discussion on the potential of E-News for community informatics.

BACKGROUND — THE E-NEWS PROJECT

The overall aim of the E-News project was to develop a Web site for the creation and modification of online news stories. The site was required to be highly usable and easily updateable. The nature of the project was collaborative, involving students from Information Environments (IE) at the Ipswich campus of the University of Queensland (UQ) and E-Journalism students at the Rockhampton campus of the Central Queensland University (CQU), and conducted in the second half of the year 2000. The IE students were required to function as a team of Web designers in order to develop a fully functioning database-

Figure 1. An Example of a Completed E-News Database Web Site

driven Web site for an external client (shown in Figure 1). The E-Journalism students acted as the client for this purpose, providing the requirements and the content for the site.

Communication between the Web designers and the clients occurred through many forms of the technology. Initial communication between the two parties occurred through video conferencing, followed by e-mail.

Another aspect of the project was to explore the impact that interactive technology can have on the presentation of news information that has traditionally been displayed in printed form. Throughout the course of the project, the nature of work practice in the creation, modification and utilisation of the system was observed through ethnographical approaches in order to gauge the comparative success of techniques applied by different groups. This was to be achieved through the re-representation of a real-life design environment in a Studio-teaching model. By teaching in such a manner, students were able to engage the client and gain experience in the nature of the design world. The nature of this pedagogy is effective not only in aiding the instruction and learning of students, but also in creating a realistic

environment for the testing of new methods and approaches in industry.

Pedagogy

The pedagogy underlying the Studio approach has its theoretical origins in social constructivism and is influenced by the work of Lebow (1993), Jonassen, Mayes and McAleese (1993) and Jonassen and Reeves (1996). The Studio approach places the learner at the core of the teaching and learning experience, and, like Simon (1960), emphasises the importance of learner activity and interaction as viable mechanisms to support learning. According to the Studio approach, 'what the student does is actually more important in determining what is learned than what the teacher does' (Shuell, 1986). In a break from the transmissive mode of delivery, characteristic of many lecturing situations and increasingly evident in the design of many content-driven online courses (Brown, 1997), the Studio approach creates both a learning environment in which students are actively engaged in the learning process, and a more fluid and responsive learning environment.

The project-based approach of the Studio provides an environment for learners to:

- Plan and develop their own learning projects,
- Apply the skills and knowledge learned in concurrent subjects to the specific real-life scenarios provided by the projects,
- Work collaboratively with other learners to develop knowledge and understanding,
- Work with mentors and coaches,
- Work as mentors and coaches.

Studio projects provide realistic and relevant contexts, which encourage ownership and a voice in the learning process. They also provide an opportunity for authentic assessment by assessing the learner's ability to use and apply the knowledge acquired in the learning process in the types of settings and situations where it is ultimately destined to be used. This is contrasted with approaches that use the number of facts or concepts that are memorised and reproduced under examination conditions. Transfer and application are also important outcomes of learning in the Studio-teaching approach.

The Role of Technology in the Pedagogy

Technology is used in the Studio approach, not to deliver content, but to move the classroom focus from the teacher to the learner, and to create a more active and engaging climate for the learners. Oliver (1998) argues that such a shift will encourage learners to develop their understanding and their capacity to think and act critically. Students are encouraged to use hardware and software to create new Information Environments, and the World Wide Web is used to support communicative, collaborative and cooperative activities among students and teachers.

The Studio approach aims to foster creativity, reflection, articulation and reasoning. All of these aspects are important lifelong learning skills and

valuable graduate attributes. The purposeful use of technology and of group work is central to these aims. This approach to Studio-teaching and real-life projects can be applied so that both the students and the client benefit from a rich, industry-orientated format. The nature of these outcomes is explained in the following section.

Final Product

In accordance with the nature of the Studio pedagogy, the IE students were initially briefed about the nature of the project, technical attributes and the context of the material to be displayed. Over the eight-week duration of the project, the clients informed the development process for the design of the project, the creation of the initial concept designs and the selection of several preferred designs, which were short-listed through an online presentation. From this point the IE students were formed into Web design production teams. The structure of these teams was similar to professional Web design production teams, consisting of graphic designers, project managers, interface designers, programmers, and other relevant members of the team (DiNucci, Giudice, & Stiles, 1998).

Communication with the clients was initially through video conferencing. This allowed personal initial introductions between students at the separate campuses, a more personal formation of conceptual ideas and increased project understanding between both parties. This level of discussion and the establishment of understanding were comparable to that which could be achieved through a physical meeting. By 'breaking the ice' through video feed, a familiarity between the clients and designers began to develop and continued through other less 'physically constraining' forms of communication. From this point, most communication and discussion occurred through e-mail and bulletin board discussion. During the group development process the client group reviewed the designs online through their Web sites. The

clients provided feedback to the individual Web site production teams through use of e-mail.

The evaluation of the process by the clients allowed prevalent issues about electronic news systems to be revealed. These were used to further the potential of the specific E-News project discussed here.

Application of the Product: Online newspapers allow much easier archiving than traditional printed newspapers. They also provide increased potential for forward chronological linking through post-hoc modification. In a traditional newspaper, cross-referencing between stories can occur, but unless the reader has direct edition access to the previous linked stories the link is of minimal practical benefit. However, digital linking provides the potential for easy back referencing which allows the context to be further understood by the reader. Electronically enabled news also allows for easier forward chronological linking as well; that is, to provide links to relevant articles written after the one being currently read. This process requires post-hoc editing, an issue that is addressed in further detail later in this chapter.

Multiple Layering: Multiple layering of digital information is a further advantage of E-News systems. Traditional news is subtly framed by story construction conventions deployed by mainstream journalists (Fuller, 1997). International news agency style, which was developed to send stories by telegraph, can be identified in newspapers, radio and television broadcasts across the world. This style usually demands a lead sentence, which summarises the key points followed by a second sentence, which provides context and a third, which consists of a direct quote (Cappon, 1982). Television reporting adds another dimension by layering on the perceived need for colourful moving pictures.

News agency style explicitly shapes story construction while implicitly ordering and informing content selection. This process is recognised by public relations practitioners who create events which serve these stylistic demands and are there-

fore advantaged in the news making process. For example, news releases are usually constructed in news style, so that they can be more easily integrated into material offered as news by journalists. According to Knight and Nakano (1998), events can be staged to satisfy news values linked to news style.

The Internet allows stories to be multi-layered. For instance, a story delivered on the Internet can include hyperlinks to other sites which provide background information. News stories presented in this way can carry colour photographs, audio grabs and short QuickTime movies. Since all of these additional layers can be created, edited and lodged on the Web from a laptop in the field, gatekeepers who might misinterpret or even seek to censor the material can be excluded from the process (Stevens, 2002). This enables a trade-off between the levels of physical discontinuity and increased digital continuity which not only can achieve actions and events, but also report on current actions or situations from remote locations.

Another important issue raised by an electronic news system is article ownership. In an ICT environment, initial ownership comes down to those who posted the article. However, a further issue of ownership revolves around the point about who should be able to edit the articles—the contributor only, or other associated parties. In an ICT-enabled process these issues relate to overall site management which can have an overall editor or have contributors as editors. Thus, the impacts of digital news delivery results in not only challenging the roles of journalism, but also in causing changes in the basic relationship between traditional news providers and the larger community.

Such discussion begins to expose the potential of E-News for collaboration, community-based discussion and issue awareness in regional areas. The specific approach taken in this project builds upon these initial concepts of usability and informance and examines the potential of expanding them to achieve greater community awareness.

Figure 2. Administration Login Page

Community Journalism in Action

The Web sites constructed by using the Studio approach went live at the end of eight weeks of consultative development. The end result was an online design presentation to the client groups which involved the client groups conducting user testing on the sites. The journalism students involved in the testing of the Web sites used them in a manner to reflect real life work. They achieved this by working in groups to upload an assortment of news stories which included images, video footage and sound files.

This level of analysis of usability allowed further understanding of not only existing capacity but also potential applications for the E-News Web site to be explored. With such prototyping, inherent in the nature of ICT, it was possible to examine the constraints of these Internet applications, in terms of social control, collaboration and technical approaches. This experimentation revealed the potential of E-News systems to act as tools for improving community informatics in regional settings. The final site structures developed in this manner clearly demonstrated the potential of E-News as a collaborative community tool.

The final sites developed through the processes outlined above consisted of two major sections: the public Web site that displayed the articles, and the administration section that enabled the uploading of articles and associated files by journalists. The administration section required a login access which provided some level of control (see Figure 2).

This administration section enabled the journalists to be able to upload, edit and delete their stories with relative ease, through an easily used Web-based system (as shown in Figure 3). Journalists only needed to enter a title and summary and cut-and-paste the story into the text field. Adding the local file name and location on the computer through a series of simple online operations uploaded all associated files. In some sites, the ability to choose the location of a file-based image was also provided.

When a story was uploaded, journalists were able to view the layout of the article and remove it if it was considered that the layout was unsuitable for public viewing. This provided a very useable means for editorial control. An extensive help section was created to guide less experienced users through the process of uploading stories.

Online collaborative communities are not a new concept. Particular issue Web sites, such as Rugby Online (www.rugbyonline.com.au), have been focusing and drawing together like-minded people interested in particular topics. There are also many Web sites such as Yahoo groups (groups.yahoo.com) dedicated to allowing individuals to start their own groups for discussion, and where people can moderate and manage their own lists. Using the Internet for connecting people who reside in the same spatial area or who have similar geo- and socio-economic circumstances is not yet quite as common as the more well-known global approaches. This style of Web site connects people of a spatial location and allows them to communicate about a range of issues that affect them as members of that community. Whilst some online newspapers such as the Sydney Morning Herald (www.smh.com.au) do provide a level of regional information, they do not provide the ability for readers to act as a content provider.

As an example of the type of Web site approach now making its appearance in communities all over the world, a recent initiative by a local government in Victoria, Australia, has begun to see online regional community collaboration increase in particular areas. For example, the Moreland Com-

munity Council trialled an E-Discussion forum and electronic newsletter for local residents. This E-Discussion forum worked through an e-mail list system to share information rather than a Web site which was viewable by the whole community (www.moreland.vic.gov.au/news/mr190802.htm). The E-News system has the ability to provide not only a supplementary online news service but also an asynchronous collaborative medium for sharing local content news in regional communities.

Advantages and Potential of E-News

The E-News system has a number of very clear advantages. It allows for not only increased flexibility, but also for greater media utilisation through processes easily accessible to regional communities. The major attributes which make the system beneficial as both a journalistic tool and a collaborative community medium are described below.

INFORMATION TECHNOLOGY

The key underlying aim of developing and examining this system was to enable users who only have

Figure 3. Adding News Articles

The screenshot shows the 'ROCK-E-NEWS' website interface. The header includes the site name 'ROCK-E-NEWS' and the tagline 'The Eye on Central Queensland'. Navigation links for 'Administration', 'Help', and 'Email' are visible. The main content area is titled 'Add News Article Page' and contains a form with the following fields:

- Title: [Text input field]
- Author: [Text input field]
- Date: [Text input field containing '20 September 2000']
- Category: [Dropdown menu showing 'Main News']
- Text: [Large text area for the article content]
- Media File: [Text input field]
- Summary: [Text input field]

 At the bottom of the form are 'Reset' and 'Submit' buttons. The background of the page features a repeating pattern of circular icons.

basic computer skills to be able to competently use the Web site, by providing usable layout, well-structured pages, simple upload mechanisms and clear instructions. As home adoption of Internet technology increases in developing and developed countries alike, the basic computer literacy is increasing. The system developed here only requires basic Web searching capacity.

Another aspect of access for E-News is access to basic computer equipment inside the regional community. Effective community use of an E-News facility does not require all community members to have Internet access. Rather, it requires that some of the key players (community figures, such as head of schools, mayors, community leaders and so on) have access, with others in the community being able to access the Internet. Whether this occurs through public or private resources is not relevant, just as long as large sections of the community can be involved in E-News with limited effort. It is in this sense that the community can be and is actually involved, which ultimately drives the usability of the E-News system.

Synchronous news delivery is made possible by such a system, by enabling users to contribute online and in real-time. A synergy is formed through this level of collaboration with the ICT facilitating the community interaction. Future directions for this E-News system are considered later in this chapter in terms of community interaction and involvement while considering the technical attributes and constraints.

The system employs a considerable level of flexibility involving such attributes as multiple file types and cut-and-paste which reduce the need for a content editor through real-time synchronicity. Further explanation of the role of editors continues in the discussion related to community below. As with normal practice of e-lists, E-News systems can be moderated or un-moderated. Moderated lists obviously require more effort from employed or voluntary resources. This can be in the form

of formal editors or subject specialist voluntary moderators.

The system described above may be seen to blur the lines between bulletin boards¹ and online newspapers. The expiry date of news articles for E-News is relatively short in the traditional sense.

The E-News online equivalent to 'letters-to-the-editor' may be implemented as a bulletin board. Essentially, readers may post comments related to articles that in turn may be replied to by other readers. Such an interactive discussion is called a 'thread'.² Through adding aspects of bulletin boards and online newspapers, a richer online environment for E-News can be created by merging these two systems. Such an approach allows the E-News service to not just disseminate news but to also encourage community involvement.

Community

E-News aims to bring journalism to the community. However, by developing such an online environment to aid journalism delivery, it may also contribute to bringing community to journalism. The system described above has added to existing mechanisms of traditional journalism, and in so doing, has expanded the scope of journalism to include informative members of the community. This has enabled the E-News service to adapt the potential nature of interaction between community members with traditional news services.

Such community involvement provides challenges to the traditional roles of journalists and editors. An initial step could involve the selection of community members that have trusted status to publish online. These community members would have the ability to write their own articles on local situations, events or public comments. Essentially this allows a set of 'grass roots' journalists to bring the mass media back to the community level. This is an extension of public journalism, which not only displays topical information but also

engages the community through readers' opinions and values. 'The public journalists newspaper is doing what the conscientious citizen would do given the time and resources to do it' (Rosen & Merritt, 1994). It opens an opportunity to engage in the user's stories through community discourse, which enforces a reader's sense of involvement and their perceptions of worthiness to state an opinion. This community interaction provides a potential catalyst for regional areas to regain a holistic feeling of belonging.

Interactivity: Traditional journalism has a distinct hierarchy of structure in its nature, with editorial control being applied across all stories and their headlines. The traditional role of the journalist is challenged by empowering untrained community members to make contributions of newsworthy items in a public place of mass dissemination. This challenges the traditional role of the editor in as much as the editorial role is thus devolved to the individual contributors. This can result in the contributors growing to be part of a trusted community who self-publish on a credible site which has regional community ownership in the same sense as a daily print newspaper. It is worth noting that this approach varies with the ability of contributors to post discussion and editorial comment adding to existing stories rather than the simple posting of articles. Figure 4 depicts the overlap in the roles of community, writers and key community members.

It is possible for a system to be structured in such a way that the approach of traditional journalism is encompassed in the new system. From a journalistic approach, this requires the editor to moderate stories, and from an ICT approach, a Web master to manage the structure of the site. However, these roles can be encapsulated into one, essentially combining the editor and the typesetter (i.e., Webmaster). For a community, this results in the hierarchy of information providers being diminished, allowing open discussion to occur, and encouraging greater community awareness.

Real-time synchronicity: Real-time synchron-

icity allows contributors to engage with E-News systems at several levels. This occurs directly, by encouraging interaction through discussion on community issues, but also indirectly by fostering community awareness. This occurs because users can interact (chat) in real-time, thus encouraging an approach that through its very nature, is community-orientated. In such a site, even with contributor moderation, a greater sense of local ownership can occur, and may lead to encouraging the community as a whole to interact and participate in the 'local' online newspaper.

Ownership: The issues of ownership essentially arise from adding and editing articles post-hoc completion. From an ICT perspective, the implications of ownership are almost non-existent. The ICT can be structured to deliver any ownership situation that is desired. The issue resides with the sense of ownership from a community viewpoint. If community control is achieved, as discussed in areas above, post-hoc altering can encourage:

- Forward chronological editing to articles,
- Additional information added to a story, thus enriching the reader's experience, and
- Information updates to correct errors.

Essentially, this approach adds to the community's body of knowledge.

So if the approach outlined here can be so beneficial to community journalism, there is the question of what can work against its implementation. Major issues are article ownership and authenticity. In cases where people are free to update, correct and change the article content, who owns the article and is it credible information? Thus, the potential to free journalism from the traditional constraints which restrain and centralise control of public knowledge through online collaboration raises questions about comment ownership and all of its legal implications, authenticity and community demand.

However, we suggest that like most other products of technology, community based E-

Figure 4. The Nature of Connections with E-News

Journalism should be seen as an adjunct rather than a substitute for traditional journalism offered online. Web sites such as the Sydney Morning Herald Online (<http://www.smh.com.au>) or the Washington Post Online (<http://www.washingtonpost.com>) continue to attract significant hits in part because they offer badged information, which is presented in recognisable and therefore more easily assessable packages. These packages are framed by the publishers' familiar political, cultural and social assumptions (news values) and contain stories created within journalistic conventions including notions of accuracy, fairness and writing styles. In light of this complimentary approach, the creators of local newspapers, which in the case of smaller circulations are run by those who have a community interest rather than just those who are professionally trained, can benefit. Developing a resource which encourages and allows the sharing of news, views and information in a continuous format, rather than on a weekly or fortnightly basis as is traditional in print formats increases community awareness and knowledge of local events and happenings.

While stories made available through this means can be seen as subjectively selected and assembled arguments, there is a qualitative

difference between journalism, which should contain identifiable reference points (quotes and undoctored photos), and unsubstantiated rumour or intentional misinformation. It follows that consumers might more easily judge a *Washington Post* report of President Bush's latest news conference than a Matt Drudge (Drudge, 1998) essay based on anonymous tip-offs from the Web.

While all community members who wish to contribute to the online formats outlined here should be considered equal, the information they produce should and could not be considered equally informed. One only has to log into any one of hundreds of Web sites, such as Yahoo's Washington Politics Arena, to see ignorance, arrogance, national chauvinism and unbridled racism paraded as the free exchange of ideas. In this sense, journalism's hierarchical gate-keepers (editors) can be seen to be responsibly serving communities by excluding vilification, defamation and intentional rumour mongering.

Freedom of speech demands responsible contributors as well as a discerning public, if it is to underpin democratic decision-making³. The Internet provides the public with greater choices but it does not necessarily validate the information it makes available.

The legality surrounding the publication of electronic material is an evolving area of law. As a rule of thumb, the common legislation of publishing printed material tends to apply in the virtual realm as well. This encompasses such issues such as defamation of character, slander, mis-representation, privacy, and intellectual property. While this is not an area of expertise for the authors of this chapter, there are still several general issues that require addressing in this discourse. From a legal standpoint, all users should be required to register before they can upload information to an E-News type of Web site. This essentially makes each user accountable for the material they upload, and also associates a user's name with an entry which results in an informal community moderation process. From an ICT perspective, the Web site administrator (responsible for technical issues) could potentially double as a secondary moderator. It is also possible with the use of smart coding to have the system scan all articles upon upload. The kind of technology is currently used on forum (chat) Web sites to either remove or replace offensive language with emoticons (icons, to imply the desired expression). Ultimately, by making users responsible for their own content and producing automatic safeguards on derogatory language, constructive community discussion can occur online. Further, it is possible to require individual computer registration before access is granted.

The potential of E-News as a tool for collaborative interaction at the regional community level is apparent. The ability of any community member to deliver information in a near synchronous format, to a wider audience, encourages a level of interactivity and a sense of belonging not limited by physical constraints. With such a system which enables grass-roots journalists to express views on events, E-News can work as a stimulant in community informatics for encouraging community practice (development, service and action) in regional areas.

Future Trends

The full potential of the E-News system has not yet been realised. The system described in this development shows the potential for online community journalism which at the same time could be applied to issues of issue-based collaboration inside a community. From an ICT perspective, E-News is flexible, interactive and adaptable, and can build upon the base of the traditional newspaper. From the community viewpoint, E-News can potentially be of great value by bringing journalism to the community, the community to journalism, increasing community awareness of local issues, providing new opportunities for community involvement in news, providing a basis for community action and increasing the sense of place which has been thus far threatened by all forms of new technology. However, issues of authenticity and the legal issues surrounding this are still problematical areas. This project has demonstrated the 'do-ability' of such an approach; however, there is great scope for research into application issues.

The future of such an approach described here lies in the ability to not only draw the community together, but for the system to be used as a vehicle for providing community standpoints to an external audience. The result is a potentially well-formed discussion catalyst and entity to encourage community cohesion.

Information Technology

From an information technology viewpoint the E-News approach has very few constraints. The real benefit of E-News lies in the flexibility of the system, providing information upon demand by the readers combined with delivery on demand by the contributors. The two exciting areas in which ICT enabled regional news can be further explored are in 'threads' and 'moderation'.

The concept of threads can be taken one step further than the majority of current use. Using threads, stories can be linked to other articles that contain relevant information, expanding the body

of supporting knowledge that both a contributor can rely upon and a reader can obtain. Viewing these ‘threads’ and previous discussions provides a further understanding and contextualisation of other articles posted.

Moving to more editorial control can deliver an ability to connect threads between discussions and link them to related articles. Through maintenance of editorial control, contributors need only have average computer skills — in particular the need for skills in linking articles or discussion through hypertext. This inverse relationship between level of moderation and skill level required can be shown in Figure 5.

Through the expansion of technological aspects, the usability of E-News is in turn increased. With the increasing access and uptake of Internet technologies, the nature of Web-based news systems such as that briefly described here, will result in increased possibilities for many communities in both developing and developed situations.

COMMUNITY

From a community viewpoint, the potential of the E-News approach needs to be dynamic and informative. The future trends need to incorporate the formation of virtual communities to support

the physically distinct locations, whilst enabling these groups to interact both as groups and as individuals with the greater virtual world.

The current E-News approach incorporates substantial community involvement through grass-roots journalism and an increased feeling of belonging as mentioned above. Because of its ability to be a catalyst for extending community interactivity and awareness, the future potential for E-News approaches are numerous. Some of the more easily achievable extensions are outlined below:

Forum: A relatively synchronous, two-way interactivity. This application will allow more direct discussion beyond the scope of merely posting comments to articles, thus encouraging continuous communication.

Interactive Newsletter: Such a newsletter could focus on a lower level of involvement through one-way asynchronous interactivity, thus encouraging engagement with people who are interested and want to be aware but who are passive consumers.

Empowerment: The technology and its applications briefly outlined above allow people to choose their own level of involvement. The relatively low threshold, both journalistically and technically, empowers people to become involved at whichever level they desire.

Figure 5. The Trade-Off of Skills to Centralised Editorial Control

Community Journalists: Community journalists can push information into the system, whilst allowing news consumers to discriminate what they draw from the E-News site. Future trends are towards an increasing percentage of the community having computer access, which allows an increase in push technology. The involvement of community journalists is shown in the following diagram (Figure 6).

The various levels of synergy between intra- and inter-community interaction are shown in Figure 6. The involvement of community journalists is depicted in Figure 6 and shows that the E-News system can be a catalyst for intra-community interaction. In a larger setting, the ability for communities to interact with each other as a whole can be motivated to a level of a co-ordinated local public approach. The holistic virtual community can also act to enable substantial interaction, through a critical mass, with society.

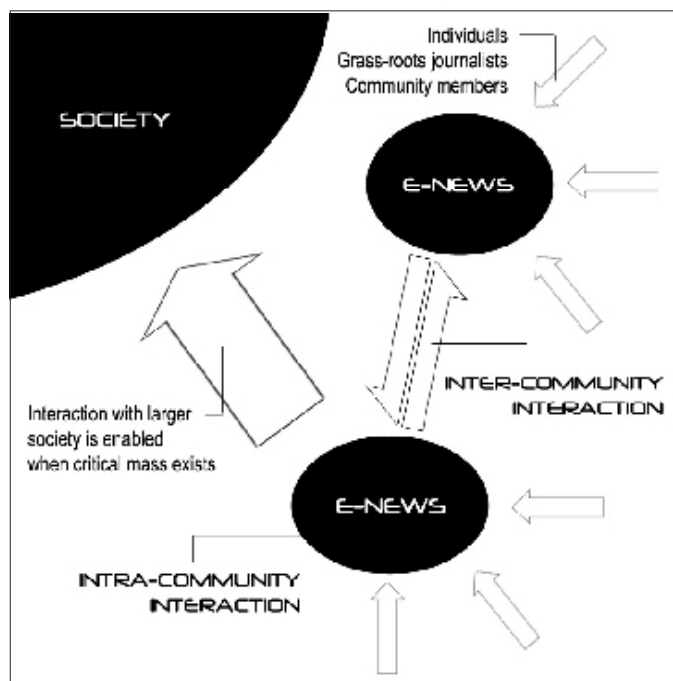

In this way individual members of particular communities can be engaged in discussion at

a societal level. This empowerment mediated through an E-News approach increases the value of community discourse at an intra-, inter- and societal level.

CONCLUSIONS

The experience described here, when coupled with similar experiences all around the world, demonstrates that the limiting factors of the E-News systems are in the bounds of community values and traditional organisational restraint, rather than in technology. By challenging the traditional roles of journalism through approaches similar to E-News, there is large potential for regional communities to make better use of Internet technologies in a social context through the resultant interaction that these approaches can deliver. This provides a framework to consider how regional community-based journalism may be reconceptualised.

Figure 6. The Levels of Community Interaction Surrounding E-News

This chapter has also demonstrated that there is value in using studio pedagogy to develop and test real life projects without affecting future success prospects through adverse experiences in undertaking pilot projects.

ENDNOTES

- ¹ A system that enables users to send or read electronic messages, files, and other data that is of general interest and addressed to no particular person.
- ² A thread is a set of posts on a newsgroup, composed of an initial post about a topic and all responses to it.
- ³ First Amendment, US Bill of Rights.

Chapter 3.12

Role of ICT in Establishing E-Government System for Disadvantaged Communities

Hakikur Rahman

Sustainable Development Networking Programme, Bangladesh

INTRODUCTION

Information and communications technologies (ICTs) are playing an increasingly vital role in the daily lives of all communities by revolutionizing their working procedures and rules of governance. ICTs offer a unique opportunity for governing elite to overcome the crisis of representative democracy, as ICT and the Internet empower civil society to play its role more effectively and facilitate the performance of governments' main function-serving the people who elect them (Misnikov, 2003). In the realm of government, ICT applications are promising to enhance the delivery of public goods and services to common people not only by improving the process and management of government, but also by redefining the age-old traditional concepts.

Community networking groups and local government authorities are well placed to campaign for greater inclusion for all members of the community in the information society. Possible

areas to target include the provision of technology at low or no cost to groups through community technology centres or out of hours school access. There are many possibilities and local government must take a significant role in these activities (Young, 2000).

Information society is based on the effective use and easy access of information and knowledge, while ICT for development (or ICTD) is not restricted to technology itself but focusing on manifold development and diverse manifestations for the people to improve their well-being. ICTD has deep roots in governance, is part of governance and has effects on governance patterns and practices at both central and local level.

By recognizing these facts, UNDP focuses on technologies to end poverty at WSIS Cyber Summit 2003, and emphasizes on ways that new technologies can help lift more than one billion people out of extreme poverty (UNDP, 2003). Apart from the four Asian IT giants (Korea, Rep., Hong Kong, China, Taiwan, China, and

Japan), most of the Asian countries have fallen under the “low access” category of the Digital Access Index. This has also been referred in the WSIS Cyber Summit 2003, until now, limited infrastructure has often been regarded as the main barrier to bridging the digital divide (ITU, 2003). Among the countries with ICT spending as share of their GDP, Sweden, UK, The Netherlands, Denmark, and France (8.63, 7.97, 7.39, 7.19, and 6.57% respectively during 1992-2001) remain at the top (Daveri, 2002, p. 9), while countries like Bangladesh, Greece, Mexico, Niger, and many more remain at the bottom (EC, 2001; ITU, 2003b; Miller, 2001; Piatkowski, 2002). In a similar research it has been found that in terms of average share of ICT spending GDP, New Zealand, Sweden, Australia, USA, and UK (9.3, 8.4, 8.1, 8.1, and 7.8% respectively during 1992-1999) were among the highest (Pohjola, 2002, p. 7), though most of the countries in the Asian and African regions remain below the average of 5%. The disadvantaged communities in the countries staying below average in ICT spending seem to be lagging in forming appropriate information-based economy and eventually fall behind in achieving proper e-government system.

The e-government system in those countries need to enhance access to and delivery of government services to benefit people, help strengthen government’s drive toward effective governance and increased transparency, and better management of the country’s social and economic resources for development. The key to e-government is the establishment of a long-term dynamic strategy to fulfill the citizen needs by transforming internal operations. E-government should result in the efficiency and swift delivery and services to citizens, business, government employees and agencies. For citizens and businesses, e-government seems the simplification of procedures and streamlining of different approval processes, while for government employees and agencies, it means the facilitation of cross-agency coordina-

tion and collaboration to ensure appropriate and timely decision-making.

Thus, e-government demands transformation of government procedures and redefining the process of working with people and activities relating to people. The outcome would be a societal, organizational, and technological change for the government and to its people, with IT as an enabling factor. E-government should concentrate on more efficient delivery of public services, better management of financial, human and public resources and goods at all levels of government, in particular at local level, under conditions of sustainability, participation, interoperability, increased effectiveness and transparency (EU, 2002).

ICT brings pertinent sides more closely by prioritizing partnerships between the state, business and civil society. A few East European countries have become economically liberal with the high level of foreign direct investment per capita and at the same time became ICT-advanced regional leaders in terms of economic reform. These countries also present the region’s most vivid examples of partnerships and collaboration. They have clearly manifested the importance of the public-private partnerships, transparent bottom-up strategies, involvement of all stakeholders, total governmental support, capturing economic opportunities, and enabling electronic mediated businesses, responding to the challenges of globalization.

BACKGROUND

Electronic government refers to public sector use of the Internet and other digital devices to deliver services and information. As the e-government industry expands worldwide, the complexity and specificity of online services continues to develop. Many nations have sites devoted specifically to e-government, on which they present new initiatives as well as offer listings of services available

online. For example, Taiwan, Singapore, and the United States have highly developed portals, which serve as gateways to a plethora of government services as well as directories to other specific government sites (West, 2004).

Definitions of e-government range from “the use of IT to free movement of information to overcome the physical bounds of traditional and physical-based systems” to “use of technology to enhance the access to and delivery of government services to benefit citizens, business partners and employees.” The common theme behind these definitions is that e-government involves the automation or computerization of existing paper-based procedures that will prompt new styles of leadership, new ways of debating and deciding strategies, new ways of transacting business, new ways of listening to citizens and communities, and new ways of organizing and delivering information (Pascual, 2003). E-government is a sub-set of the broader phenomenon of e-governance, and can be understood as the application of information technology’s tools and techniques to the workings of government for the benefit of its “customers”—citizens and businesses—as well as for itself (Scacco, 2003).

With the proliferation of easy-to-use Internet and Web technology, many federal, state and local governments now provide the necessary instructions and forms for specific services. This facilitates citizens with direct interaction with the desired government service. However, this first phase of digital government efforts has resulted in a fragmented conglomeration of services and information sources (Chun, Atluri, & Adam 2002).

In ways, governance systems are not always neutral to ICTs; they may sometime support or sometime obstruct the application of ICTs for development. The era of the global information society, as brought about by the technological advancement and globalization in trade and

economy may create challenges to the society, restrict the development of grass-roots communities; contests the business accomplishment and create barrier to the professional development if congenial policies have not been adopted by the government.

Governance, participation, and inclusion stand to benefit from the networking opportunities and access to relevant knowledge across distances. ICT can finally bridge local, regional and central governments, although it is difficult to separate the work of central government from overall governance practices. If a common platform of e-governance may be initiated, it does not matter much whether the central government provides nation-wide services or a grass-roots telecenter in a remote area services local villagers.

However, the central government need to review regularly its citizen services, retaining only those that are a clear public good, while outsourcing (whether fully or partially) to the civil society and private sector those that are too expensive or difficult for the government to administer or that would simply be better and faster delivered by non-governmental organizations.

Aims of E-Government

The aim of the e-government policy is to set the enabling framework for the government administration to effectively and efficiently utilize ICT opportunities and to guide the forward move in the right ICT direction along an accelerated path in contributing towards the economic and social upliftment of the nation. It will enable the citizen to be a beneficiary in the global information economy and would create the framework for an e-society to support their economic, learning, and personal needs (e-Sri Lanka, 2003).

E-government may be set to accomplish the following goals that move beyond mere efficiency of government processes to that of overall reform and development:

- Better business environment
 - Technology is a proven catalyst in increasing productivity and economic growth, especially in rural and under-served communities (Konrad, 2002) (remote and disadvantaged). The use of ICT in government and the establishment of e-government infrastructure assist to create a business-friendly environment at the grass root level. These can be achieved by streamlining the interactions and improving the interfaces between government and business focusing SMEs. By eliminating redundancies in procedures and emphasizing immediate and efficient delivery of services, e-government creates the atmosphere to attract the investors/investment
- Strengthened governance
 - Promoting transparency and accountability in government through the proliferation of ICT in management and operations opens opportunities for better mobilization of resources, efficient decision making and good governance
- Enhanced public participation
 - E-government facilitates swift delivery of information. Mass dissemination of information assists empowerment of citizens and facilitates informed decision-making. Eventually, citizens are made to be more actively involved in the policy and decision making processes of the government
- Improved productivity and efficiency of government agencies
 - Re-engineered management processes and procedures, efficient delivery of services, increased productivity of the bureaucracy, and increased savings are the inherent benefits of e-government system

With its emphasis on the use of information technology in the delivery of services, e-government presents a government agency with the opportunity to re-think how it delivers services. Specifically, e-government offers the agency the opportunity to: examine its current operations and procedures, identify business processes and practices that can be streamlined, implement those streamlined business processes, and implement new technologies that enhance those improvements. In the processes of streamlining business operations, a properly implemented e-government solution provides the agency with the opportunity to focus its resources on service delivery efforts that are most efficiently provided through direct contact versus other means (Pascual, 2003).

The success of efforts in achieving e-government lies in the way that technology is utilized and managed by the public sector. ICT as the enabling tool and with effective deployment it could facilitate the desired results in the long run. Systems, processes and procedures constitute the framework for the usage of ICT. However, the critical factor for the delivery of the desired results is the willingness of the public sector and the citizen to use and adapt to new technology-based environments (e-Sri Lanka, 2003). The government agencies should find innovative ways of working in fulfilling the needs of the people within the information society.

METHODOLOGY

Stripped down to its bare essentials, e-government is concerned with leveraging and distributing knowledge more effectively government to citizen (G2C), government to business (G2B), and inter-departmentally within government (G2G) (Smith, 2004), including government-to-employee (G2E) relationships.

A country needs to focus on the following areas from the unified perspective of national

governments, the telecom industry, and economic perspectives by:

- Making a connectivity breakthrough by expanding networks outside the urban areas
- Developing Web-based online services for the general public
- Providing large-scale Internet and capacity development training for the general public
- Identifying information and content needs and generating local content for social groups, entrepreneurs, farmers and communities
- Encouraging the development of need-based and bottom-up ICT strategies within a defined framework
- Making telecom sector a national priority
- Reforming telecommunications' legal and regulatory frameworks to facilitate nationwide network expansion, lower tariffs, affordable Internet access, higher teledensity, faster application of advanced technologies (broadband and wireless), increased openness and competitiveness in the markets
- Creating a regulatory environment in the telecom industry

The government should have clear concept on the formation of an information society with positive impact on the national economy. The transitional information society need to include the following strategies:

- Modernization of public administration and services
- Improvement in quality of life through the implementation of information technologies in the areas of education, health, environment and communication
- Development of an information technology sector and form a National Task Force to intensify congenial atmosphere for establishment of an information society

- Modify the educational system by including digital content (E-government Strategy, 2002)

E-government services focus on four aspects: citizens, the business community, government employees, and government agencies. E-government aims to make interaction with citizens, businesses, government employees, government agencies in more convenient, user friendly, transparent, inexpensive and effective way.

In e-government system individuals can request for a particular government service and then receive that service through the Internet or some computerized mechanism. The government service can be delivered through one government office, instead of many (as one-stop-service), a government transaction can be completed without direct in-person contact with the government employee.

The following sub-sections would like to constitute the main thrust of this chapter, describing a few parameters that may assist to enhance the e-government system in disadvantaged communities.

Improved Collaboration

Governments will have to explore new relationships among government agencies as well as partnerships with the private sector and NGOs to ensure quality and accessibility of e-government. Agencies may have to overcome traditional reluctance to work with each other to maximize benefits of scale in e-government projects. Collaboration among government entities, private enterprises and NGOs can assist policy-makers in crafting meaningful reforms and can expedite the implementation of e-government. Private sector experts, who deeply understand topics such as e-commerce, information technology, marketing and management, can advise government policy makers (Sakowicz, 2003).

In this context, four dimensions of e-government may be broadly categorized:

- **E-Services:** Electronic form of delivery for government information, programs, strategies, and services.
- **E-Management:** Information systems supporting the management and administrative functions of public institutions, including data and information management, electronic records maintenance and intra departmental information flow.
- **E-Democracy:** Assist to set agendas, establish priorities, make important policies and participate in their implementation in more deliberate ways (such as e-consultation or e-voting).
- **E-Commerce:** This concept is linked to the business side of government interaction (e-procurement—exchange of money for governmental goods and services conducted over the Internet/Intranet).

Extensive Participation of Common People

E-government is the use of ICT to transform government by making it more accessible, more effective and more accountable to the common people. By this definition e-government does not mean putting more computers on the desks of government officials. Rather, it concerns the relationship between government officials and people. The reformation may include:

- Providing greater access to government information by making laws, regulations, forms, data collected by the government to be made accessible online; promoting civic engagement by enabling the public to interact more conveniently and interactively with government officials
- Increasing government accountability by making its operations more transparent,

thereby reducing the delay in decision making and also reducing opportunities for corruption infiltration; supporting development goals by lessening the time and expense of small business entrepreneurs in their dealings with government, and by providing rural and disadvantaged communities with information and communications capabilities

- E-government is not any more a phenomenon limited only to the richer countries. Some of the most innovative uses of the Internet in governance are emerging from the developing world, as ICTs are increasingly being used to streamline government and connect it more closely with the people en masse it is intended to serve

Increased Economic and Societal Participation at the Grass Roots

Introducing e-government is a necessity in the contemporary economy. Its advantages are known, recognized, and incontestable. For this reason, the question is not if, but how, to implement and promote e-government in transitional economies by taking into account the significant discrepancies between the capacities of developing countries and those of more developed countries. These include both economic and social factors, not least of which is the relative absence of necessary specific habits and skills for the successful advance of technology.

The effectiveness of e-government solutions differs according to the stakeholders they address, whether common people of the community, business entrepreneurs or legal entities. The distinct challenge applies to reaching people in general. There are common thoughts of favoring business-oriented e-government applications over people-oriented ones.

However, implementation of an integrated e-government requires resolution of a few practical issues, like, breaking of monopoly on the fixed

telephone market; the capacity development for the Internet service providers; raising of computer illiteracy for the government staffs; easy availability of modern payment instruments in electronic form; and the application of electronic signature law.

In developing countries, access to information infrastructure remains always inadequate, and progress on telecommunications policy reforms are lagging behind. Yet there is an opportunity for leapfrogging the new technology can provide better, cheaper links to the grass root stakeholders, while competing global operators can provide low-cost long distance communications. Adopting new technologies, developing countries can deploy telecommunications at lower costs per capita than the industrial world and rapidify poverty alleviation processes (Rahman, 2003).

Enhanced Transformation

E-government is about transforming the way government interacts with the governed (government, business, people). The process can neither be easily accelerated nor simply can be manifested. It requires a coherent strategy, beginning with a thorough review of the nation's current regulatory environment and the ability of the population to make use of the planned technologies.

The primary motivation for e-government reforms should not be targeted to merely save money or reduce staff. While this can be a valuable output, the savings incurred from e-government initiatives should be the benefit the businesses and people utilizing the improved system are enjoying, rather than the government agencies have invested initially. In order to realize the long-term benefits of the transformation, governments should develop a citizen-centric model involving key stakeholders outside of government- businesses, trade associations, researchers, professionals, academics, CSOs, CBOs, and NGOs.

The success of e-government transformation is not just about the automation of existing pro-

cesses and inefficiencies. It is the creation of new processes and new relationships between governed and governor. The use of ICT should not be treated as just a cost- or labor-saving tool and simply allotting government officials with computers or automating manual records. E-government is a solution that can revolutionize the process of government within itself. Therefore, government leaders planning e-government projects should first examine the function or operations which they want to apply through ICT.

E-government requires strong political leadership within the government. In order to achieve successful e-government transformation, there must be officials at all levels of government who understand the technology and the associated policy goals with proper motivation to carry out reforms. Strong leadership can ensure the long-term commitment of resources and expertise as well as the cooperation of discrete factions within the system.

CASE STUDIES

A few case studies have been described in this section to illustrate cases in countries that have successfully adopted policies in their national ICT policies or taken approaches to implement the policies, focusing disadvantaged communities.

Bangladesh, being one of the developing country has integrated the societal participation at the grass root level. Relevant article from Bangladesh ICT Policy is added next for reference (ICT Policy, 2002):

- **3.10: Social Welfare.**
- **3.10.1:** Nation-wide ICT systems will be implemented for rural development activities, agricultural, horticulture, fisheries and livestock extinction for youth, technology guidance for rural enterprise, micro level planning, and so forth. Communicates and user groups or beneficiaries would be ac-

tively encouraged to participate in all such activities.

- **3.10.3:** Non-government organizations will be encouraged to establish centers at the village level for providing hardware/software or other support services. At the sometime the Government will use both the formal and nonformula channels to disseminate information about the application, advantages to communities of the use of ICT.

e-Sri Lanka takes a comprehensive approach to using ICT for overall development by promoting the growth of this promising sector, and more importantly by using ICT as an enabler for all the key sectors in the economy and society (World Bank, 2004a). The vision of e-Sri Lanka came about in response to the observed impact in India of the use of technology in development, and in transforming government. It is a concerted effort by the Sri Lankan government to design and implement a comprehensive, nationwide strategy to harness the potential of ICT for the achievement of broader socio-economic goals (Development Gateway, 2004).

Objective of the e-Sri Lanka Development Project is to promote: (i) use of ICT to enhance growth, employment, and equity through affordable access to means of information and communication; (ii) access to and use of public information and services on-line by citizens and businesses; and (iii) competitiveness of private sector, particularly of knowledge industries and Small & Medium Enterprises (SMEs). (World Bank, 2004b)

The Indian experience in e-government can be seen to be evolved in three phases. The first from the late 60s, or early 70s to the late 90s; second from late 90s to 2000; and the third 2000 onwards. The very recent trend of e-government systems in India achieved tremendous success in forming a homogeneous community across the country.

In the first phase, efforts to develop e-government were concentrated on the use of IT for in-house government applications with a principal focus on central government requirements as defense, economic monitoring and planning, and certain data intensive related to elections, conducting of national census, and tax administration (GOI, 1985). In the second phase, the implementation of the national IT Task Force and State Government IT policies symbolized a paradigm shift in e-governance policies towards using IT for a wider range of sectoral applications reaching out to a large number of people in rural as well as urban areas (Madon, 2003). The third phase has seen the ultimate development of e-government systems in India, reflecting visionary implementation of India Vision 2020 and e-India. Another example for India can be the Government of Kerala's recent policy focus on establishing front-end computerization to trigger the administrative reform, even before the automation of departmental records.

A statement made by Abraham Sotelo, the coordinator general of the E-Government Programme of Mexico has been quoted here, "E-Government is intended to strengthen the framework of professionalism in public service as well as lower government costs. It will help create a more deregulated government and eliminate a lot of paperwork and bureaucracy. The main objective is to create a high quality government service that is also honest and transparent" (World Report, n.d.).

Among many other successful e-government approaches implemented or adopted globally, IT2000 of Singapore, Digital 21 of Hong Kong, Malaysia Vision 2020 of Malaysia, and Mauritius Vision 2020 of Mauritius are to name a few.

FUTURE PROSPECTS

E-government offers the potential to bring citizens closer to their government. From 2001 to 2004,

e-mail interactions through government Web sites have increased from 73% to 88%. In e-government rating, North America scored 39.2, while Asia has only 31.6 in 2004. Despite this progress, there are still a diverse issues that hinder their ability to reach their full potential in terms of accessibility and effectiveness, especially in many developing countries (West, 2004).

E-government is an expensive tool requiring strong and enduring political will. Without the active commitment of government leaders, states are not assured the allocation of financial resources, the adoption of an appropriate legislative framework or even the most basic human investment in planning and implementing e-government. One strong indicator of political will is the degree of involvement of high level decision-makers in e-government implementation (Misnikov, 2003).

While the myth prevails that all e-government/e-governance initiatives are always costly, this is not true. The implementation cost of e-governance projects may seem expensive, but the cumulative social and economic outcome is much extended. However, there must be efforts and investment plan on the government side to create an effective e-government for providing direct value-added e-services for citizens.

Utilizing ICT to develop e-government will ultimately need to re-engineer government processes and transform governance. It is not enough to deliver services efficiently and effectively by following steps to accomplish certain procedural requirements. It has to simplify government processes altogether, change the concept of governance, and thereby transform the overall relationship between government and people. Increased information access and transparency in government processes leads to greater accountability and credibility, as online or computerized processes remove discretion from government officials and provide monitoring facilities.

Designing security systems for a digital government's multidomain environment requires balancing between providing convenient access

and monitoring permissions (Joshi et al., 2001). Developing an evolutionary architecture to integrate large heterogeneous systems poses another challenge. Although these systems support vertical applications, exporting their services requires reengineering their technological services and administrative processes. The goal is to establish an architecture that coordinates information exchange among government information systems while maintaining each organization's autonomy (Mecella & Batini, 2001).

CONCLUSION

The integration of ICT into development processes and delivery mechanisms of public and private services necessitates social mobility learning, vigorous planning, local level initiation and the sharing of local and international experience on best practice as pre-requisites. Effective monitoring and evaluation is also a must. It is a proven truth that no blueprint plan will sustain for long with the dynamic changes in ICTs and the degree of adaptation and innovation needed to exploit these technologies.

The strategies, standards, and guidelines on e-government schemes should form part and parcel of the policy and serve as the detailed blue print for the strategy development. The updated policy together with the set strategy is expected to increase productivity, competitiveness, cooperation, and foster innovation in the public sector to leapfrog in the knowledge economy. Successful implementation of the policy would assist the government to be more responsive and accountable to the citizen and achieve greater transparency by providing benefits of increased efficiency and fostering the trust of the citizen for greater cooperation towards the development efforts.

Good governance (including fighting against corruption and for greater transparency) has been identified as a "missing link" both in poverty alleviation efforts and equitable and inclusive eco-

conomic growth. Its basis lies in good governance: strengthening the diminishing the growing disparities among its members (Misnikov, 2003).

Developing countries cannot expect positive outcomes by following the strategies and building the institutions that served the developed countries in the industrial era. The development challenge in the 21st century will be entirely different to the development challenges of the past century. Indeed, all countries, whether developed or developing, will need to recognize the scale of changes currently underway and design new strategies for these realities (Clarke, 2003). Disparities in rural-urban infrastructure and in hierarchies of economic development are acute in most developing countries and tend to broaden with ICT development, due to high costs of ICT infrastructure deployment in rural areas and also due to limited profit potential of rural markets (Proenza, 2002).

Despite occasional setbacks, digital government projects now appear firmly on the road to fulfilling their promise of making civil and political processes more accessible than ever (Elmagarmid, & McIver 2001). However, it is estimated approximately 35% of e-government projects in developing countries are total failures and approximately 50% are partial failures (FairfaxDigital, 2004).

Ideally, the ICT tools offer an unprecedented opportunity for community to access information over any geographical distances and across any sovereign state borders. Opportunities for networking and knowledge sharing are also unlimited, regardless of its perseverance. Furthermore, ICTs position in governance systems and practices are becoming widely participatory and inclusive, with endless economic opportunities. Time has come to look backward, take a good view, breath a while, and re-think on strategies, policies, and planning on the developing countries acting locally, regionally and globally along this hopeful road to success and prosperity.

KEY TERMS

Community Networking: A form of network that brings together the practices of community development, community-based research, health, education, and insights from fields such as sociology, feminism, or library and information and management sciences.

Digital Divide: The digital divide is a social issue referring socio-economic gap between communities that have access to computers and the Internet and those who do not. The term also refers gaps that exist between groups regarding their ability to use ICT effectively, due to differing levels of literacy and technical skills, as well as the gap between those groups that have access to quality, useful digital content and those that do not.

E-Government: E-government refers to the use of information and communication technologies to improve the efficiency, effectiveness, transparency and accountability of government.

ICT: It is the convergence of information technology, telecommunications and data networking technologies into a single technology, and it is the electronic means of capturing, processing, storing and communicating information.

ICTD: It is a term for information and communications technologies for development, an initiative aimed at bridging the digital divide (the disparity between technological “have” and “have not” geographic locations or demographic groups) and aiding economic development by ensuring equitable access to up-to-date communications technologies.

Information Society: A society in which economic and cultural life is critically dependent on rapidly developed information and communications technologies and it is integrated by complex communication networks for exchange of information.

Information Systems: Also known as management information systems (MIS) is the formal study of the information systems within an organization, consisting of the network of all communication channels. An information system is comprised of all the components that collect, manipulate, and disseminate data or information.

Chapter 3.13

The Role of Place: Tasmanian Insights on ICT and Regional Development

Dean Steer

University of Tasmania, Australia

Paul Turner

University of Tasmania, Australia

ABSTRACT

Despite continued rhetoric that information and communication technologies (ICTs) make ‘place’ irrelevant in a global networked economy, insights from regional areas suggest a different and more complex experience. This chapter examines the issues surrounding the concepts of place in regional areas and ICT-based regional development, as a vehicle to dispel some prevalent ICT-related themes that permeate discussions in this sphere. These issues open up a broader debate on what is meant by ICT-supported development in a regional context, how it can best be achieved and what insights have been developed from past experiences in Tasmania, Australia.

INTRODUCTION

“Since the early days of the Internet, the death of distance and the associated devaluation of geolocation have continued to be popular themes. However, as technologies, and our understandings of cyberspace have grown and matured, it is becoming evident that geography continues to exert its influence.” (Ramasubramanian, 2002)

“It is no accident that there are so many successful semiconductor (companies) in California. It is not just that all the managers in California were smarter than the managers everywhere else.” (James, 2002)

The prevalence of technological determinism¹ and economic rationalism within academic and

business discussions on the role of technology in regional development is witnessed by the recent emergence in the literature of the 'king's new clothes' insight that 'place' still matters. For those living and working in regional Australia the reduction in basic services and lack of adequate or affordable telecommunications infrastructure has for some time been very much a part of their everyday experience of the 'information economy'.

From a research perspective, while information and communication technologies (ICTs) open the global economy up to a region they also expose it to global competition and its associated socio-economic uncertainties (Barling & Castleman, 2000; Coulthard, 2001; Wilde, Swatman, & Castleman, 2000). Clearly, glib statements promising regions unequivocal benefits from conducting business 'anytime, anyplace, anywhere' mask the more difficult processes of how to meaningfully evaluate the impacts of ICT on regional development. More significantly, there has been considerable confusion in the literature over what is meant by regional development, how it is to be achieved and what role ICT can play in reviving and sustaining regional communities.

Until recently, research in this field has focused almost exclusively on the role of ICT in urban economic development or on its impact on farming enterprises. The impact of ICT on the social fabric of the community has been given little attention, with an implicit underlying assumption being — what is good for the economy is good for the community. More recently there has been recognition of the need to examine and assess the social, cultural, and psychological impact of ICT. However, despite the emergence of research on ICT in developing countries and to a lesser extent regional areas, the majority of this work continues to be centred on urban economic development. Given that ICT impact on all aspects of society, marginalising fundamental questions about the role of ICT in social and community develop-

ment is highly problematic, particularly in less economically affluent regions.

This chapter aims to examine some key issues surrounding the concept of place in regional areas of Australia as a vehicle to dispel some prevalent ICT-related themes that permeate discussions on regional development. This analysis opens up a broader debate on what is meant by ICT-supported development in a regional context, how it may best be achieved and what insights have been developed from the Tasmanian (Australia) experience.

Defining Place

One major difficulty in approaching issues surrounding ICT-related regional development is the issue of how best to define what (or more appropriately where) is being identified by the often interchangeably used terms 'Regional', 'Rural' and 'Remote'. The Australian Bureau of Statistics (ABS)² has already acknowledged that while numerous users of statistical data have requested a standard classification for place/location, this is problematic because of the conflicting meanings of the terms used by different users (ABS, 2001a). These issues are further compounded by some users adopting a flexible approach to definition; e.g., the Australian Department of Finance and Administration (DFA) usually defines regional Australia as non-metropolitan Australia but for specialised proposals broadens its definition to include all metropolitan areas excluding Melbourne and Sydney (DFA, 2001). While adopting a broad based definition may appear to be a simple solution to these definitional dilemmas (Curtin, 2001) we must remain sensitive to how the different assumptions implicit within these different definitions may have consequences for regional development. As the US experience illustrates, the multiple definitions at play in policy-making have resulted in disparate policy impacts for different rural areas³ (RUPRI, 2001).

Given these issues, it is perhaps not surprising that many writers often avoid explicitly defining the place or the region under discussion. There are many reports and papers that do not attempt definition; for example, the NOIE (2000) report into 'E-Commerce Across Australia' uses the term region(s) in a generic sense without definition, and also does not define terms such as Metropolitan and Non-Metropolitan. Other well-known authors in this field such as Coulthard (2001) and Coulthard, Castleman, and Hewett (2000) use the abbreviation R-3 to represent rural, regional, and remote areas without any distinction between the component areas or between R-3 and non-R-3 areas.

As with any conceptual definition, there are numerous ways that the term can be delineated (Luloff, 1999) and many suggested that trying to provide a generic definition of regional Australia is likely to create as many problems as it resolves (Beer, Maude, & Bolam, 1994; Elvidge, 1999; Foster, 2000; MacLeod, 2001). However, the Commonwealth Department of Health and Aged Care (2001, p. 3) suggests: "In order to systematically tailor services to meet the needs of Australians living in regional Australia, 'remoteness'... needs to be identified." Furthermore, in the current climate of competition for funding, particularly in Australia, there is a need to unambiguously identify and contextualize the area(s) under investigation, and at the very least, facilitate the comparison of 'like for like' (MacLeod, 2001).

While this chapter is not proffering a solution, the lack of an official, consistent definition of 'regional' compounds the problem of consistent analysis when investigating the impact of ICT in these areas. This is particularly so for Tasmania where the state population (473,300) is of a similar size to the region⁴ of Newcastle, NSW, Australia, (487,843), where Hobart (194,388), Tasmania's state capital city, is smaller than Wollongong, NSW, Australia, (266,666) and where a significant non-metropolitan area such as Launceston, TAS, Australia, (98,437) is less than two-thirds

the size of Geelong, NSW, Australia (159,764) (ABS, 2001b).

Although there is little doubt that accurate definitions for regional development policy are of importance, the impact and challenges of issues such as the global networked economy and the role of ICT generate their significance.

Regional Development and Technology

According to the Institute for Sustainable Regional Development (ISRD) (2000) the most pressing challenge facing non-metropolitan Australia is "how to build an economically productive, socially viable and ecologically sustainable future" during a period of major structural change. While linking economy, society and environment together is an important step, it takes us no closer to identifying mechanisms to achieve it. Indeed, it can be argued that it may even distract us from the task. As Castleman (1998) states, "Sustainability has become a comforting word, a concept describing a future vision rather than a means of reaching it." What is however evident, even to the Australian Prime Minister, is that regional Australia "has suffered through cuts to basic services" (NineMSN, 2002). Indeed it is clear that the gap between urban and regional Australia (however it is defined) is widening. In regional Australia the general trends of slower industrial growth, increased urban migration and the depletion in the quality and availability of basic services are tangible to even the casual observer.

Unsurprisingly this context has provided fertile ground for the promises and hype associated with the Internet and the Information economy. There has also been a considerable amount of literature supporting the view that the widespread introduction of ICT will revitalise regional Australia. Governments at Federal and State levels have also been very active in funding programmes and initiatives aimed at ensuring regional Australia

can capitalise on these ICT-related developments (Coulthard et al., 2000).

In this context, there is therefore no question that ICT will impact on regional development. However, unfortunately it remains unclear whether this impact will, in the final analysis, be positive (Wilde et al., 2000; Coulthard, 2001). More seriously, within the current conceptualisation of the issues, there is no way of meaningfully assessing whether the introduction of ICT will mitigate, exacerbate or simply replicate the pre-existing urban/regional divide.

As a contribution to re-framing these issues and to conducting a detailed examination of ICT-related regional development, the next three sections explore three prevalent ICT-related themes that cloud current debates.

THEME 1: PLACE NO LONGER MATTERS

The first prevalent ICT-related theme to be explored in the context of this chapter is that through the effective use of ICT the concept of place no longer matters. The argument is that by investing in ICT, regional areas will be able to participate in the global economy on an equal footing with the rest of the world.

The quote below from the National Office for the Information Economy (NOIE) typifies the mantra that has been prevalent since the earliest days of the 'Information revolution'; ICT equates to the 'death of distance':

Australia is a land of great distances. We are a long way from most of the world's markets. Participation in the information economy allows us to overcome the isolation of Australia in remote and rural areas and the disadvantages of national isolation from world markets... online services can build stronger and more viable regional communities, with enhanced investment, employment and skills, by providing better access for businesses

to markets and market information, and enabling more efficient marketing and distribution of products and services (NOIE, 1998).

While it is hard to deny that ICTs have been instrumental in connecting disparate regions to the 'rest of the world', the impacts of doing so have been far from uniform, and not always beneficial (Coulthard, 2001; Dutfield, 2002). There also remains the paradox, (particularly in Australia where most of its land mass is uninhabited or very sparsely populated), that the geographical 'imperative of putting physical networks (optical fibres, mobile antennas and the like) in trenches, conduits and emplacements to drive market access' still exists (Graham, 2001, p. 405). The lack of uniformity of benefits may be a reflection of the fact there is no uniformity in the areas that are endeavouring to participate in the global economy. Therefore, it may be that the impact of ICT reflects the existing local regulatory, economic, and social environments, re-emphasizing the role of places and people.

Furthermore, ICT are primarily tools for moving data around the globe, and "while the power of distance has been eroded, it should not be confused with the diminished meaning of place" (Wilson, Corey, Mickens, & Mickens, 2001). Wilson et al. (2001) also identify the paradoxical relationship of place and technologies; "As ICT become more ubiquitous and permeating ... the actual importance of locality and spatial organization emerges." This paradox can be seen in Tasmania, an Australian State that has been the recipient of substantial funding through programmes such as the Telstra T2 sale Social Bonus, of which \$150 million was allocated for ICT-related development, infrastructure and service delivery (Tasmanian Govt., 2001).

In 2001, 30 Software Developers in Tasmania (an industry for whom it might be reasonable to assume location and/or place was not significant) were surveyed by one of the chapter's authors. Of those developers surveyed, approximately 20%

of the respondents indicated that if they were to expand their businesses to include interstate markets, they would need to seriously consider relocating to the mainland. The two primary reasons given for this were:

- a. A perceived need for face-to-face meetings with prospective clients and the associated high cost of transportation, accommodation, and 'wasted' travel time.
- b. Perception that 'made in Tasmania' was not associated within these markets with high quality.

The second point was identified as an issue for two of the respondents who were trying to sell to the Tasmanian Government. When trying to compete with interstate developers, the inference was if you were any good you would be in Melbourne or Sydney.

This cannot easily be dismissed as being peculiar to Tasmania. As a report prepared for the Rural Industries Research and Development Corporation (RIRDC) notes, most of the Internet activity in North America still revolves around particular places. The implication being that those outside of these areas continue to struggle to participate in, and to receive the promised benefits from, the global marketplace.

"As the majority of Internet activity is currently based in North America, and in particular the United States, it is interesting to note that this activity is concentrated in relatively small areas, most famously, Silicon Valley and Seattle (Microsoft's and Amazon.com's headquarters). This centralisation of the economic growth and resultant benefits has been of equal concern to the US Government as it has been to our own. Many regions in North America are struggling to capture the benefits of the Internet in the same ways as we are in Australia" (Simpson, 2001).

It appears that, despite the promises, "the death of distance ... is too simplistic a claim because it misses so many of the nuances of the structure and character of electronic interaction" (Wilson et al., 2001). Not only does place still matter and wield a significant influence, but it also appears to have an even stronger influence in regional areas.

THEME 2: CLUSTERING LEADS TO COMPETITIVE ADVANTAGE

The second prevalent ICT-related theme to be explored in the context of this chapter is that through clustering, regions will automatically gain a competitive advantage. The argument is that ICT allow regions to organise existing and new business enterprises into clusters. It is then argued that synergies will automatically flow, which will then lead to exploitable competitive advantages.

The quote below from Senator Nick Minchin, Australia's Minister for Finance and Administration, supports the accepted wisdom that clustering equates to an exploitable competitive advantage. "It is worth reinforcing that if Australian business is to compete successfully in the modern economy, it is critical to form and maintain networks and linkages to maximise our competitive advantage." (SABV2010, 2000)

It is understandable that regions such as California's Silicon Valley, which have experienced spectacular economic growth, have become attractive targets of emulation (DiGiovanna, 1996; MacLeod, 2001). However, MacLeod (2001, p. 809) offers a cautionary note by stating that "... policy prescriptions drafted for the purposes of renovating downbeat regions, but which are derived from theoretical investigations based on the selective experiences of ideal-typical hotspots, are misguided."

Further, Enright and Roberts (2001, p. 72) make the observation that "very little research

The Role of Place

has been published on industry clustering in Australia.” They also state, “Much of the investigation conducted to develop regional clusters in Australia has involved exploring and mapping the supply and distribution chains and networks of local industries and firms. Little research has been done to explore smart infrastructure and human capital requirements, core competencies, and marketing intelligence needed to support and sustain the development of local clusters” (Enright & Roberts, 2001, p. 73).

Despite the lack of research, governments around Australia, at national, state and local levels are attempting to use clustering (and ICT clustering in particular) to stimulate economic growth with varying degrees of success and failure. Indeed, the very nature of these attempts may be detrimental to the entire Australia economy, thereby actually reducing any potential competitive advantages that might be acquired. As Gartner senior vice-president Bob Hayward has stated, “I deal a lot with multinationals making investment decisions in the (Asia Pacific) region and they often tell me that their vision of Australia is of seven countries that compete against each other rather than a continent-country that gets its act together” (Janz, 2002). From a Tasmanian perspective this point resonates with the intra-state competition that exists between different regions within the state. Again, far from acquiring a competitive advantage all regions lose out due to their inability to plan strategically and act cooperatively.

In Tasmania, the City of Launceston is promoting itself as the “City of Learning and Innovation” and as an Information Precinct (iPrecinct) with many ICT-related programmes and activities occurring in parallel with each other (LCC, 2001). One such programme is the Launceston Digital Development Forum (LDDF), which was established by the Tasmanian Electronic Commerce Centre (TeCC) to bring together key players with the aim of helping the Launceston community seize the ‘new economy’ opportunities available to the Launceston region (TeCC, 2002).

However, simultaneously the City of Burnie, another regional city in Northern Tasmania, is also competing in the same space, recently declaring its Integrated Community Network (ICN) pilot programme (which saw the laying of fibre optic cable in the city), as “an exciting strategic initiative, which is in keeping with Burnie’s goal of becoming the information technology capital of Tasmania” (Arnold, 2001).

This raises the obvious question as to how much competitive advantage can be derived at inter- or intra- regional levels when ‘everybody’ employs the same strategy. Given that no two regions are identical, is it tenable that the same rules for acquiring a competitive advantage through clustering be applied in a generic manner? Porter says, “Many business people still don’t understand that a lot of their competitive position is based on their location . . . you must understand and use your local strengths. Location counts as much as ever” (James, 2002).

This emphasizes the point that any region is more than just the sum of its public infrastructure (sometimes referred to as hard infrastructure). Interaction and cooperation between the social, economic, and political (sometimes referred to as soft infrastructure) is what makes a region dynamic, and able to develop effective strategies. It is as much a product of the region’s capacity as any public infrastructure (MacLeod, 2001; Villeneuve & Gilbert, 1999). However, soft infrastructure is very difficult if not impossible to transfer or duplicate in different areas (MacLeod, 2001; Harris, 2002).

Of course, not everyone agrees with the current preoccupation with regional competitiveness. MacLeod (2001, p. 819) cites Krugman as saying that, “competitiveness can become a ‘dangerous obsession’: one that . . . conveniently safeguards us from considering a whole host of awkward questions relating to the uneven power networks that enframe the new regional world.” Indeed, for all the resources that have been expended in an effort to emulate places such as Silicon Valley,

it seems that we are no closer to understanding what makes a regional cluster succeed or fail (Garnsey, 1998).

There is considerable evidence to suggest that place still makes a difference to the success of regional clusters, and that blindly applying generic principles without calibrating for unique local issues may adversely impact on the success of any regional cluster development project.

If the benefits of clustering in regional development are not guaranteed, then perhaps there also needs to be a re-assessment of the promised benefits that have been made of ICT as being the catalyst of regional sustainability.

THEME 3: ICT CAN SUSTAIN REGIONAL AREAS

The last prevalent ICT-related theme to be explored in the context of this chapter is that the implementation of ICT in regional cities and towns can halt and even turn around economic decline. The argument is that through ICT regional areas can be seamlessly integrated into the global economy thus creating the required economic framework to ensure sustainability.

Again, the issue of definition emerges as a problem, because ‘sustainability’ has come to mean different things to different people (Carroll & Stanfield, 2001). Historically sustainability has been associated with environmental issues, but the term has been adapted widely and broadened to include many different issues including economic, social and business. However, Carroll and Stanfield (2001, p. 470) also highlight that the “regional development literature has generally ignored the issue” of sustainability. A working definition of sustainability in the context of development used by Robertson cited in Carroll and Stanfield (2001, p. 470) is: “Sustainable development is loosely defined as economic enhancement that meets the needs of the present generation without

compromising the ability of future generations to meet their needs.”

Clearly however, regional sustainability needs to move beyond purely economic growth to involve the unification of economic and social imperatives to produce an improvement in the quality of life for those of the region (Carroll & Stanfield, 2001; Rossi, Salieri, & Sartori, 2002; Villeneuve & Gilbert, 1999). Unfortunately, while the impact of ICT on regional sustainability is as complex as it is paradoxical, it has remained buried in largely unquestioned dichotomies, which makes its assessment, at best, problematical (Castells, 2001; Wilde et al., 2000). The technology that facilitates almost instant worldwide communication and helps to give the perception of a ‘shrinking global neighbourhood’ is the same technology that some see as creating a divide within the local neighbourhood (Symonds, 1999).

Despite regional sustainability exhibiting a complex nature (Gómez, Hunt, & Lamoureux, 1999), or perhaps because of it, the popular press, ICT advocates, politicians and much of the academic research has focused almost exclusively on economic indicators. Within this framework, given the widening regional divide, it would seem that ICT-related developments, with a few exceptions, are not fulfilling their promises. The use or misuse of a single measure to evaluate the impact of ICT can be observed in Telstra chief executive officer Dr. Ziggy Switkowski’s address to the World Congress on IT in Adelaide in 2002 when referring to a slower than anticipated uptake of ADSL in Launceston:

“... while you can build the field of dreams, will they come? Our experience from the Launceston project ... is that the availability of broadband, even when priced below cost, is absolutely no indication of people’s willingness to use it at this time.” (Switkowski, 2002)

Alternatively, if we broaden our conceptualisation of ICT-related development to incorporate

social, community and environment, a more complex and 'interesting' exercise can be revealed. From this perspective the success or failure of the ICT-related programmes in centres such as Launceston would be assessed in far broader terms than just economics. Even for the most optimistic, it would be hard to argue that the concentration of ICT funding in Launceston has elevated the city to a position of economic global significance. However, the focus on assessing economics indicators alone misconceptualises the problems and does a disservice to the analysis of complex positive and negative impacts arising from the introduction of ICT on regional communities, businesses and environments (Lovering, 1999). Luloff (1999, p. 314) supports this view, stating, "Rural community development is far too complex to be adequately captured by the use of only one variable or measure and/or by one method of gathering data." Further, Mansell, Steinmuller and When (1999) see similar problems when trying to compare the performances of different regions: "Current indicators or benchmarks for assessing how information society characteristics in local areas or regions compare with other regions are insufficient. ... Policy makers are often left in the dark about how their region is performing over time."

Fortunately some understanding of these types of issues is emerging in economic and political circles where aggregated indicators are gaining a measure of acceptance as alternatives to measuring progress using accounting measures alone, such as Gross Domestic Product (GDP). For example, the United Nations Development Programme's Human Development Index (HDI), and the Genuine Progress Indicator (GPI), are just two of the emerging measurement processes that recognise that economics alone does not accurately evaluate progress (ABS, 2002). Similarly, the regional development profession needs to develop empirically reliable methodologies and

tools that assess the overall impact of ICT on sustainable regional development. It is essential that these methodologies and tools recognise the inter-relational nature of economic, social and environmental policy, so that regional progress can be reliably and accurately demonstrated (Gómez et al., 1999; Haughton, 1998). More practically, it is obvious that the mere existence and availability of the technology to enhance regional development does not in and of itself guarantee use, nor does it assure the realization of the desired outcome (Gibbons, 2002; Hamelink, 1999; Mansell et al., 1999).

Therefore, employing economic measures in isolation cannot assess the full impact of ICT on regional areas. Successful measurement must include ICT's ability to enhance social integration, provide resilience to fluctuating global forces, develop the environment, strengthen the sense of community, improve lifestyle, and to provide easy and equitable access to services. Only then, when added to the economic measurements, can a complete assessment be made of the impact of ICT on regional areas.

CONCLUSIONS

Regional development is a complex process, perhaps more of an art than science. It has been seen from the above discussion that much has been promised of ICT for regional areas. The promises have included economic sustainability, competitive advantage and the opportunity for connection to the global community. However, difficulties with the measurement of ICT's impact and limited exploration of the problematical nature of the assumptions underlying these promises have clouded understanding and measurement of the experiences of regional Australia.

To ensure that the true worth of ICT for regional areas can be examined, this chapter has revealed

a need for a re-calibration from purely economic indicators to an aggregation of indicators including social, community, environment and economic. This exploratory chapter has examined issues surrounding the concept of place within discussions on ICT-related regional development. It has highlighted the prevalence of technological determinism in these discussions and contributed to a more meaningful conceptualisation of the role and impact of ICT-supported development in a regional context. Significantly, this chapter has promoted a more holistic view of ICT-related development that includes assessments specifically calibrated to capture the value of ICT.

ENDNOTES

- ¹ The term technological determinism is attributed to Marshall McLuhan, who suggested that, "We shape our tools and then our tools shape us" (Merkel, 2000).
- ² The ABS currently deploys two separate classifications of location/place: (i) Section of State (defining rural localities as populations 200-999, and rural balance areas as populations under 200); (ii) Accessibility/Remoteness Index of Australia (ARIA) measuring remoteness in terms of access along road networks to services centres defined as towns with more than 5000 population (ABS, 2001a).
- ³ "Public policies have different impacts across space. Rural and urban areas face different issues based on economic, demographic, and location issues, and therefore have different policy needs...The implications and ramifications of different definitions of rural areas on policy design, implementation, and impact must be taken into account to avoid unanticipated or unintended effects" (RUPRI, 2000).

Chapter 3.14

Radio for Social Development

Patrick Craddock

Multimedia and Distance Education, New Zealand

Peggy Duncan

Health and Social Research Consultant, New Zealand

INTRODUCTION

“*Tell me a story*” is an established educational technique. “*Tell me a story*” using radio is an application of this technique, but instead of having one or several listeners, it is possible to reach thousands or millions of people throughout both urban and rural areas. *The Archers*, was a British radio drama serial that started its life with educational objectives and has been broadcasting for decades to a large dedicated audience of millions (Gallagher, 1975). This article will describe how a radio drama education project expanded into small local communities, each with its own community radio station, and how the actors in the radio drama addressed specific health issues of a particular area through the use of live performances.

BACKGROUND

As far back as the 1970s, McAnany (1976) found in his Mexico study that in radio projects over two-

thirds of listeners preferred to listen to music and drama and that few tuned in to local educational programs or programs from the capital city.

Supporting radio drama for behavior change with other resources is a key part of any radio education project. In a presentation on behavior change, Brooke-White (1985) saw non-formal radio education for adults as being concerned with change. She said the role of the media educator is based on the principle of learning by choice, and that change came from within the individual listening to the programs. Her comments referred to writers, editors and producers who needed “skills in the communication of structured information geared to facilitate change” (p. 1).

Fossard (1996) has written extensively on the development of drama for radio, giving particular attention and emphasis on making the messages suitable and credible to the listening audience. With a particular focus on soap opera in bringing about social change, Nariman (1993) suggests that radio drama is very effective if it makes sense to the listener, and it addresses issues similar to those faced by the listening audience using characters

who are believable and who deal with the issues in a recognizable way.

In Africa, radio drama is regarded as being very effective in the education of rural people if it “encompasses cultural factors such as the oral tradition and social learning through performance” (Morrison, 2003, pp.1-4). Other factors that make drama an effective medium include the recognition that rural people tend to have lower literacy rates than urban people, they cannot be reached by other means of communication such as newspapers or television and that generally, there is homogeneity and social cohesion in small villages. The spoken word and traditional forms of drama incorporating cultural values and beliefs are the primary ways of educating the young and to sustaining cultural mores among adults in such situations.

An example that showed the impact of broadcasting radio drama programs took place in Tanzania during the period 1993 to 1997 (Ryerson, 2003). After four years of broadcasting, a Radio Tanzania drama serial had succeeded in attracting 58% of the population between the ages of 15-45 in the broadcast regions. Evaluation research of the radio drama conducted by The University of New Mexico and the Government of Tanzania showed that this radio serial stimulated behavioral changes. More than half of the population in the areas where the serial was transmitted identified themselves as listeners. HIV/AIDS is a huge problem in Africa and this story had, as one of the key characters, a truck driver with numerous girlfriends dotted along his truck journey route. He became HIV positive. Of the listeners surveyed, 82% said the program had caused them to change their own behavior to prevent HIV infection by using condoms and limiting their number of sexual partners. Independent data from the AIDS Control Program of the Tanzania government noted over a 150% increase in condom distribution in the broadcast areas during the first year of the soap opera.

Other data collected through Ministry of Health clinics indicated that the radio soap opera had influenced family planning methods in four out of ten new adopters. This included a quarter of the respondents who could cite the soap opera by name. Another 16% cited “something on the radio” and then identified the soap opera as their source when shown a list of programs being broadcast.

While radio serials obviously build up a regular listening audience and the potential for behavior change, it is also possible to use radio drama as a tool with campaign radio.

In Vanuatu, a small South Pacific nation, a radio drama project on health advice has strong links with the running of a local clinic. *Famili Blong Sarah (Sarah's Family)* is a weekly radio drama series aiming to increase knowledge of, and promote positive attitudes about, reproductive health issues. The soap opera also served as a teaching tool for nurses, teachers, and aid post workers. The first 20 episodes were dedicated to character development in the hope that the audience would bond with the radio characters before sensitive sexual health issues were introduced. Over 180 episodes have been produced to date. On their Web site, Wan Smol Bag notes “live performance and face-to-face training sessions are preferred, but radio drama can reach islanders nationwide on a consistent basis.”

LEPROSY EDUCATION USING LIVE RADIO BROADCASTS

An example of health education using a live radio broadcast performance at Alto Molocue, a town in the poorer part of the Zambezia province, Mozambique, took place at the beginning of 2003. A Danish NGO had funded a new FM community radio station in the town to broadcast items of interest and of educational and social value to the people of the area. Alto Molocue has the misfortune of having a high incidence of Leprosy, and

it was one of the few places where the Portuguese colonizers had built a treatment center. Although since Mozambique gained Independence, the center has had little maintenance. For 50 years, medical authorities have been doing their best to contain and cure the disease and have had some successes and some failures. Leprosy tends to be a “cunning” disease. Many young people who catch Leprosy do nothing about seeking medical help until the disease makes its first serious attack on their nervous system. A child will get a white mark on their skin. It does not itch or form an uncomfortable rash and often nothing is done. It is only when the disease has shown more serious manifestations that people will seek help and by that time it is too late to reverse the damage. Yet, leprosy can be cured if it is caught in its early stages.

In January 2003, a medical specialist in charge of Leprosy care in Alto Molocue obtained funds for the promotion of a small project “to celebrate fifty years of Leprosy care and treatment in this district.” He began preparing printed resource materials, coached a small theatre group to perform a play using traditional characters and showing how to detect the disease and to seek treatment, using methods and messages understood and familiar to the local people. He made contact with a radio drama coordinator who was producing a regular weekly radio drama series for rural people. Within a short time, the decision had been made to pool resources from the two projects. Thus, the small project began to expand into a larger multimedia educational event aimed at educating the people on early detection and treatment of leprosy, and making it possible to treat the disease before serious damage to the body occurred.

Using radio drama, entertainment, pre-recorded interviews, structured information and resource support from the radio education project, the local radio station manager suggested that the event take place over a whole weekend. Two experienced local radio announcers from Radio Mozambique (a six-hour drive away), who spoke

the local Elomwe language had visited the area to collect a number of interviews from Leprosy patients and medical staff. One producer made a point of collecting information from the local community. He said that “It was important to hear first men and then women make the same point. This way villagers and local people believe it. Always in our culture, you need different people repeating ideas—both sexes and people with respect in their lives, that is, the leaders” (Monteiro, 2003). Radio public service spots were prepared and the radio drama producer trained the theatre group to perform for a live audience and a simultaneous live radio broadcast. The Leprosy doctor talked with a local priest and organized the first ever live radio outdoor church service. The service was dedicated to the medical care of Leprosy. Extra copies of the printed resource material were prepared and printed.

To ensure non-stop live broadcasting, the professional Radio Mozambique broadcasters worked long hours over the weekend with the local radio staff who were inexperienced volunteers. People crowded into different venues in town to see the theatre group act, and they visited the radio station in large numbers. Competitions were held. Many adults and children won prizes. Around fifteen hundred people attended the special live broadcast of the church service. In terms of numbers and the apparent show of interest, the weekend was deemed a success.

While there was no formal research into the program impact, there was evidence that a large number of people had physically attended all the different events. Besides the live broadcasting, there were repeats of the pre-recorded interviews. After the event, the Radio Station Manager was approached and asked by various local groups to prepare and broadcast more radio programs on Leprosy and general health matters. She gave community groups airtime to develop their own radio programs on public health. Listeners and those people who attended the theatre performances and visited the radio station had been

made more aware of the help they could seek at medical clinics. This type of linkage is important. It shows community initiative and involvement that is independently stimulated by the programs. It also highlighted the strength of good communication between all the organizations working to produce the weekend event.

Within a very short space of time, other community radio stations wanted to be involved in educational community radio, thus reinforcing the view that local communities respond to educational messages involving drama. Various radio education campaign days were held throughout Zambezia in different towns. In each campaign, the actors who took part in the weekly radio dramas gave a live radio performance of a play. Within hours of their arrival at the town, word spread quickly that the radio actors were present. This knowledge acted like a magnet and people came to the performances because they “knew” the actors and they listened to the radio dramas. Local celebrities showed an interest in sharing in the campaign activities. Priests wanted to give church services, school teachers wanted to be interviewed, and the local council leaders offered to open the day’s activities with a formal speech and ceremony. The actors became instant heroes and heroines. One of the Radio Mozambique producers working with the campaigns said he had worked in media for several years, but he had never seen actors receive such popularity and accolades.

Why were the radio educational campaigns so successful and why did they attract such large local audiences? Part of the success can be attributed to the actors being known to their audiences through the regular broadcasts and to the characters having credibility with the listening audience. The characters face similar situations to those experienced by their listeners and they acted like people in real life with their own problems and their personal relationships. There was a measure of cultural acceptance by the audience, community involvement through

the involvement of local people and the pooling of material resources to maximize the impact of the campaign.

DISCUSSION

Van Zyl (2004) stresses that “Producers, writers and researchers in the field of development communication must sit down with funding providers and commissioners of programmes and convince them to move away from a blind faith in a single medium, the curse of media determinacy, to consider the entire social, economic, cultural and psychological context of the use of a medium in education and development programmes” (p. 2). Jallof (2003) has a similar point of view and notes that there are over 30 national languages in Mozambique that can be grouped into 14 different language groups. She says, “National solutions to Mozambique’s information and communication problems must take these factors into account...” (p. 116). Who can disagree? It is the old but so frequently forgotten point that you cannot teach effectively in a vacuum. You need to have an understanding of the culture and the ways in which people learn. Effective communication in radio requires people with skills, knowledge, cultural sensitivity and an intention to incorporate as many diverse elements into their programs as possible. Radio is only one medium. But with support from print, posters, community resources and support people from the community, communication begins and subsequent behavior change takes place over a period of time. Time for real change takes not months, but years of broadcasting. There is a need to increase the number of listeners and to then hold their attention week after week. Part of the task is scheduling programs at times suitable for your listening audience. Program credibility is essential and cultural values need to be present in all the radio programs. Care is required with the language level, amount of content presented and presentation styles.

A study of 14 radio serials around the world by The Communication Initiative (2004, p.18) identified a number of replicable features including:

- a. Having an integral and ongoing audience research component;
- b. Incorporating audience feedback at every stage by reading letters on the air, adapting storylines in response to research, running competitions and so forth, will help to keep and increase audience;
- c. Paying constant attention to entertainment quality, realism and production values will keep audience, radio stations and donor funders happy;
- d. Giving strong attention to initial and in-service staff training is something that is sometimes overlooked, but pays off in the end;
- e. Collaborating closely with existing social/health/agriculture services is vital if the media intervention is advocating the use of specific services/technologies, and can be extremely damaging to the project, if overlooked;
- f. Paying strong attention to back-up materials in print and in person, and/or to accompanying factual/documentary/Q&A programs;
- g. Addressing both the supply and the demand side, that is, providing education and support for suppliers of health services as well as encouraging demand for health services from the general public;
- h. Promoting the show by running on-air spots/trailers and/or by advertisements in the local press seems to increase the audience; and
- i. Paying constant attention to the broadcast channel to be sure the show is on the air at or as near to prime time as possible.

A sustained time frame of broadcasting is a key ingredient of the media education package. In Mexico, Miguel Sabido developed five family planning soap operas: *Vamos Juntos* (“We

Go Together”), *Caminemos* (“Let’s Walk”), *Nosotros las Mujeres* (“We the Women”), *Por Amor* (“For Love”), and *Los Hijos de Nadie* (“Nobody’s Children”) that were broadcast from 1977 to 1986. During the time, these programs were transmitted there was a 34% decline in the population growth rate. In 1986, Mexico received the United Nations Population Prize for its role as the leader for the population success story in the world (Ryerson, 2003).

The University of Northumbria in Britain evaluated the impact of a two and half year radio education project in Zambia (Collins, 2002). This was the project that was also involved in the radio campaigns. The project designed a weekly educational radio drama and radio magazine for rural listeners. It was broadcast in two different local languages and repeated at times when there were a maximum number of listeners to the radio, for example, early morning and in the evening. After the program had been transmitting for one year, the university research team found that around half the population (53%) had become regular listeners to the radio drama serials. In one district, 47% of the listening audience said they had implemented something they had heard about in the programs. The same evaluation team also reported on the radio magazine program, which was transmitted in a similar time slot, with repeat broadcasts and with similar content messages to the radio drama. It had approximately half the number of regular radio listeners compared to the radio drama serial. In their comments on the radio magazine, listeners did not mention any details of the content. Yet, in the same district over 80% of the radio listeners correctly identified the names of the radio drama characters.

Why should there be a difference between the two programs, the radio drama and the radio magazine? Both programs were in similar languages, covered similar content, broadcast at similar times and were designed for the same audience by the same project team. Much of the material in the weekly magazine programs con-

sisted of interviews with experts and narration by the radio announcer. It must be assumed that it was the format of the programs, the language used and style of presentation that made the difference. A drama with an exciting story is more attractive than experts expounding on their field of expertise and sometimes talking in a voice that lacks the passion of a trained actor. Hence radio drama is a powerful tool.

In a final independent survey of the radio education project conducted in May 2003, it was noted that the message content needed refining. "The tone of some of the results from this survey also suggest that it may be time in some areas to increase the level of detail in the messages that go out through subject specific broadcasting" (Collins, 2003, p.7).

What can be implied from this observation is that the radio drama broadcasts have already built up a regular listening audience who find the programs credible and interesting and that they have absorbed some of the social messages. A report (Compton, Oliveira, & Spence, 2002, p. 20) on the same project came to the conclusion that "the 'radio soap' has just begun to gather a wide following, and its effectiveness will increase over time with increased listenership and increased experience of the local producers."

If the programs were continuously broadcast over several years, positive behavior change could be expected to take place. The same message echoes again and again through the research of radio drama for education. A radio serial creates awareness in listeners, transmits information effectively, but it needs ongoing human and material resource support and a long-term broadcasting commitment if the embedded social messages are to be absorbed and turned into positive behavior.

KEY TERMS

Drama Serial: An ongoing story told in dramatic form incorporating sound effects, music, dialogue and/or narration. It may be broadcast

once, twice, or several times in a week, and it is usually from 15 to 30 minutes in duration. Sometimes, it is referred to as a “soap opera”.

Drama Series: A story also told in dramatic form with a fixed number of episodes.

Radio Campaign: A project focused on a district or town with a radio station. It seeks to involve the whole community through, for example, radio, singing, dancing, competitions, displays, use of local officials, experts, schools and organizations. Its duration is variable.

Social Messages: These are created to both entertain and educate so that a listener will increase their knowledge on educational issues, develop favorable attitudes to the messages and change their behavior.

Chapter 3.15

Digital Bridges: Extending ICT to Rural Communities Using Space Technologies

Phillip Olla

Madonna University, Michigan

ABSTRACT

Space technology has advanced rapidly in recent years. Nevertheless, a number of countries still lack the human, technical, and financial resources required to conduct even the most basic space-related activities, such as meteorology, communications natural-resource management, and education. The need to make the benefits of space technology available to all countries has thus grown more urgent with each passing year. This chapter proposes a two-phased approach for using space technology to deliver information communication technologies (ICT) to underserved areas. The first phase involves the definition and implementation of the satellite global infrastructure to provide connectivity to underserved regions. The second phase introduces the concept of a coalition of space Internet providers (COSIP) model. The aim of this model is to encourage the diffusion of space technology delivered by the GBBS infrastructure to the grassroots level. The model defines how Internet capabilities should

be introduced to rural underprivileged societies to provide health and educational services in a sustainable manner. This model is a reincarnation of the local information utility (LIU) model that was successfully implemented over a decade ago to aid the diffusion of the Internet to rural American communities. This chapter explains the technology at the foundation of the COSIP model and describes the actors required along with their roles and responsibilities.

INTRODUCTION

Information communication technologies (ICT) are considered the driving force for economic, social, and technical development. In effect, high speed Internet delivers numerous imperative fundamental services such as education, health, telecommuting, electronic commerce, and e-government services, at unparalleled cost and performance conditions (Toumi, 2004).

There has been phenomenal growth in the increase in ICT over the globe; however, the digital divide still exists, posing major challenges to many of the developing countries, which are still grappling with a severe shortage of telephone lines, lack of electricity, and high levels of illiteracy. Although it is important to acknowledge the digital divide, it is more important to focus on the progress that has been made and dispel the myth about the digital divide. The most important document that highlighted the digital divide is the 20-year-old Maitland report. Some of statements that were accurate 20 years ago are now deeply established as global myth. Re-education will be needed to change opinions due to the constant e-mail chains and false reporting from journalists and researchers. An example is “There are more telephones in Tokyo or New York than in the whole of Africa.” As of the start of 2004, there were approximately 25 million fixed lines and more than 50 million mobile phones in Africa, which is several times more than the total population of Tokyo and New York. Another urban myth that you may recognize is “half of the world’s population have never made a telephone call.” Although considerable segments of the world’s population do not have access to a telephone, and probably could not afford to make a phone call if a phone was available, the international telecommunication union (ITU) estimates suggest the number is close to one-fifth of the world’s population that have no telephone access. Another myth relating to the availability of the Internet is that “there are more Internet users in Iceland than in Africa.” This statement originated in the 1999 report *Internet for Development*, and became obsolete in 2004. The Internet has become pervasive in society; however, rural and low-income urban areas are underserved in developing nations, and will probably remain so for the foreseeable future, for economic and structural reasons similar to those that limited expansion of Internet services in rural America over a decade ago (Clement, Holbrook, & Staman, 1996). The important

thing to note from these statements is that the rate of adoption of ICT technologies around the globe is accelerating and there is a need for new models, technologies, and networks to introduce new services and applications to those living in underserved areas around the globe.

In recent years the requirements for connectivity and information services has expanded throughout the developing world. However, connectivity is hampered by the time-consuming and costly process of building traditional fixed (i.e., wired) infrastructure. For example, only 3.6 % of the population of Africa has online access (Internet-World-Stats, 2006). The situation in Africa is indicative of the entire developing world: there is a substantial unmet demand for connectivity in developing countries. Further, humanitarian services such as telelearning and telemedicine could effectively and broadly be provided if connectivity costs were lower.

Satellite technology has great potential to reach people living in remote and underdeveloped parts of the globe, and in many instances, it is the only form of technology that can provide connectivity to remote or difficult-to-access regions. Satellite systems play an important role in enhancing the ICT landscape, extending necessary services to the hard-to-reach and bridging the digital divide. It is apparent that satellites, from their vantage points in low, medium, or geosynchronous orbit, dedicate a synoptic view and global coverage for either resources management or for global connectivity. Space technology, through communication and remote sensing satellites, contributes to both the conduit and the contents for the evolving Internet infrastructure. Communication satellites provide necessary interconnection to information sources, thus enabling access to “information services” themselves.

This chapter is structured as follows. The first section provides an overview of the digital divide; the next section discusses the vision of a world without a divide by the creation of a global broadband satellite system (GBSS). The following

section explores how a new wireless technology called WiMax can be converged with satellite technology to address the *digital divide*. Prior to the conclusion, this chapter explores the concept of a local partnership approach for digital inclusion called the COSIP model.

MEASURING THE DIGITAL DIVIDE

The use of the term “digital divide” became popular in the 1990s to portray the apparent emerging gap between those who have access to ICT technologies and skills and those who do not. The divide exists due to socio-economic or geographical reasons, and results in limited or no access to services such as the Internet, computers, and communication capabilities. There is a concern that ICT would exacerbate existing inequalities and allow people to be disadvantaged based on their country, geographic location, age, gender, culture, or economic status.

The view that restriction to information access closed doors to economic and social development opportunities is not new. In 1984, the *Missing Link Report* (Kelly, 2005) highlighted that the lack of telecommunication infrastructure in developing countries impeded economic growth. The *Missing Link Report's* scope was limited to access to telephones rather than the current ICT concept. In 1996, the ITU initiated a United Nations project *Right to Communicate*, that was aimed at providing access to basic ICTs for all, with the motivation to reduce information poverty for developing countries. This is a goal of many NGOs, and is also at the heart of plans of the world summit on the information society (WSIS).

Most reports looking at their evolution of ICT over the past decade in developed and developing countries express a view that an overall trend of growing ICT disparities exists between countries. Looking closer at the statistics as published by the different official bodies, such as ITU or the world bank, it is clear that the gap in ICT access

between developed and developing countries does exist and is still quite important. It is difficult to comment on the size of the gap, as recent measurement indicators are dependent on specific parameters such as:

- Internet host
- Internet users
- Fixed telephones
- Network speeds
- Costs

Despite these varied parameters that can be considered, one thing that is not in contention is that the availability and the quality of a robust telecommunication infrastructure is the key to a quick and reliable development of ICT in the developing countries.

Although the term digital divide was originally created to differentiate between those who have access to digital information technologies (computers and software) from those that do not, more recently, the meaning has changed to mean access to broadband Internet connections or ICT services. The important term is *connection*. In spite of the rapid evolution of telecommunications, there are still regions of the world that are isolated from major population centres and Internet connections. Over the next decade, the digital divide is expected to grow smaller due to innovative solutions that utilize satellite and wireless technology. To understand the extent of the digital divide, it is useful to identify services and hardware that focus on reducing the digital divide among the four key ICT (Kelly, 2005) domains listed below.

1. **Fixed line telephone networks:** These form the main telecommunication infrastructure. The digital gap fell from 14 times to 5 times greater, in the decade between 1992 and 2003, as economies such as China and Vietnam greatly expanded their fixed-line networks.

2. **Mobile telephones:** The reduction is even more dramatic here. Mobile phones took around 20 years to reach their first billion users; however, it only required 4 years (2002-2005) to surpass the two billion subscriber mark. During the decade, the digital gap was reduced from 30 times to 5 times. Since 2002, mobile phones have outnumbered fixed-lines.
3. **Personal Computers (PC):** Unfortunately, this area is not narrowing as quickly as the communications categories. Although the level of penetration in developing countries has risen from one PC for every 243 inhabitants in 1992 to one for every 29 in 2003, this is still a long way behind the rate of one PC for every 2.2 inhabitants in developed economies. The digital divide is wider in PC ownership than any of the other indicators tracked here. One reason for this is the high cost of acquisition and of ownership (e.g., upgrading memory, software, etc.) of a personal computer. The advent of low-cost computers such as the \$100 laptops, together with the widespread adoption of free and open-source software, may help to reduce the digital divide for PCs.
4. **Internet:** The Internet has had the most dramatic reduction in narrowing the digital divide. Between 1992 and 2003, the gap between developed and developing countries narrowed from 41 times more to 9 times more. Although there are fewer estimated Internet users than PCs in developed countries (44.8 and 44.9 per 100 inhabitants, respectively), in developing countries there are more Internet users than PCs (5.1 and 3.4 per 100 inhabitants). This suggests the significance of Internet access from cyber cafes, post-offices, schools, universities, and other public internet access centres (PIACs) in the developing world.

The evidence is clear that for the four ICT domains identified, the digital divide is narrowing as diffusion spreads, and in most cases at an accelerated pace. The concept of a narrowing digital divide is an oxymoron, as the technological changes are also accelerating, and ICT innovations are constantly being invented and deployed. This will lead to the impression that the digital divide is actually expanding faster. As more bandwidth becomes available, the Internet applications to use the bandwidth follow, and is eventually diffused to developing nations, and each succeeding ICT innovation starts the diffusion.

The Importance of Connectivity

The Internet and the World Wide Web symbolize the convergence of media infrastructure and services. Unlike any other medium, it has empowered the average user to become an originator of content and services, in addition to being a consumer. Used primarily in the early days for e-mail, file transfer, and remote login applications, the Internet has graduated to many innovative applications in areas as diverse as distance education, telemedicine, e-commerce, banking, and corporate communication, to name only a few. The browser programs that help the users access the Internet have sophisticated features, such as audio and video streaming and other multimedia applications. At present, the bandwidth constraints are the prime limitation which, once resolved, will allow more innovative, interactive broadband applications (UNESCAP-Report, 2002).

The Internet has had a profound impact on educational pedagogy, and innovative e-learning techniques are being implemented round the globe. However, the digital divide has a profound effect on how these techniques are implemented outside the Western world. Private individuals' homes in developed nations have more bandwidth than most African universities. Further, the type of access American and European households can receive for \$100 per month would cost African universi-

ties \$10,000 for the same time period (Partnership, 2002) African universities are significantly handicapped in their ability to provide modern educational opportunities to their students.

Bandwidth is central to the operation of university life, therefore improving access to a greater number and cheaper bandwidths. Managing it efficiently, and using it appropriately for teaching, learning, and research, has become a critical issue for African universities (Partnership, 2002)

In Africa, most institutions use dial-up, leased lines for connectivity and their average bandwidth is often significantly slower than residential service in the United States. The lines are generally used at 100% capacity, 60% of the time, and the average bandwidth cost is US\$5.46/kbps/month (Steiner, Tirivaya, Jensen, & Gakio, 2004). To compound the issues, universities often do not receive the bandwidth promised by their local service provider. Shared lines and lack of monitoring equipment mean African universities pay more for less.

Many end-user service providers already exist in most developing nations, and the major commercial ones, in particular, are expanding in both customer numbers and service offerings. However, rural and low-income markets are underserved and likely to remain so for the foreseeable future. The

reasons are similar to those that for a long time limited telephone access to rural and low-income communities in developed nations. Customers are scattered, it is expensive to reach, and often high-priced services are not affordable. Rural, isolated geographical areas offer slim pickings to large commercial service providers.

The challenge is to create models that begin by building on existing local resources, and can be scaled to expand as local markets grow. The community of regional and local service providers needs to come up with imaginative approaches to encourage this expansion. The groups most realistically able to step up to provide these services are the ones with experience in these markets. Local institutions who know their own communities with backing from local private investments are ideal. This approach is supported by the Organization for Economic Cooperation and Development (OECD). An OECD report concluded official donor assistance has *abandoned support* for communications infrastructure in developing countries (OECD, 2005). Focus has shifted to social investments to reduce poverty. The OECD states that assistance from private sector organizations is required to help cover the shortfall by building, delivering, and operating communications services. The approach discussed

Table 1. Bandwidth in African universities (Source: Bandwidth Task Force)

Current bandwidth utilization in selected universities	
Institution	Bandwidth Utilization: Kbps up/Kbps down
University of Dar es Salaam (Tanzania)	256/512
Makerere University (Uganda)	1,280/2,500
Eduardo Mondlane University (Mozambique)	384/1,000
Bayero University (Nigeria)	64/128
Obafemi Awolowo University (Nigeria)	128/256
University of Ibadan (Nigeria)	56/200
University of Jos (Nigeria)	64/128
University of Ghana	512/1,024

in the next section to create a global broadband satellite system is poised to lead the way in this type of initiative by building a communications infrastructure and ensuring a strong partnering between the humanitarian and learning organizations in the local community.

VISION OF A WORLD WITHOUT A DIVIDE: GLOBAL BROADBAND SATELLITE SYSTEM (GBSS)

In comparison to fixed cable solutions, satellite technology provides the advantage of universal coverage, point-to-multipoint transmission capabilities, seamless transmission, independence from terrestrial infrastructure, and rapid deployment. Satellite technology can deliver broadband Internet services to developing countries and to rural and remote areas in developed countries where terrestrial infrastructure is practically nonexistent or its rollout is prohibitive in an affordable and timely basis (ITSO, 2002).

Satellites are considered to be one of the keys to reducing the digital divide, especially in the more isolated areas, in much the same way as they brought telephone services. In fact, as far as Internet access is concerned, there are geographical areas where there is just no alternative to satellites. (EADS-Space, 2005). The ITU has a vision to address the communication infrastructure imbalance affecting underdeveloped countries by implementing a global, connected information and communication society. The initiative would be through an innovative public-private sector partnership that would lead to the establishment of a global broadband satellite system considering the deployment benefits over other communication support infrastructures. Cost permitting, a robust and affordable universal broadband infrastructure could be implemented within a reasonable timeframe. This initiative would lead to the development of a new market

for broadband equipment and services through the adoption of a universal technical standard for user terminals, effective access to the geostationary orbital and frequency spectrum resources, and a minimal procompetitive regulatory environment. The idea of GBSS can be traced back to a United Nations Resolution below:

Resolution 1721 (XVI) of the United Nations General Assembly sets forth the principle of the availability of satellite telecommunications to the nations of the world on a global and non-discriminatory basis.

In the 1960s, while trying to fulfil this resolution, the international community created the International Telecommunications Satellite Organization. The objective of this group was to operate a single global commercial telecommunications satellite system to provide expanded basic telecommunications services to all regions of the world on a nondiscriminatory basis. In theory, their task was to ensure that developed and developing countries would benefit equally from emerging satellite technologies. The same political will was behind the establishment of other government-operated international and regional systems, such as Intersputnik, Inmarsat, Eutelsat, and Arabsat, subsequently joined by dozens of successful private satellite systems.

When you consider the fact that there are over 200 commercial satellites in geostationary orbit that cover the entire planet, there should not be a digital divide, as there is no region on the planet without reasonable coverage. There are 69 countries, accounting for more than 60% of the world population, currently relying on satellites for their domestic and international telecommunication services. An investigation by the ITU into the reasons behind the mismatch of existing global satellite capacity and the need for communication and Internet services revealed the following (Toumi, 2004).

- a. User terminals are expensive and cumbersome. Traditionally based on proprietary standards, satellite systems are not interoperable. This is an obstacle to the economies of scale required for mass production of low-cost equipment.
- b. The technical and operational bases guiding allocation of frequency spectrum and geostationary orbital slots for fixed satellite services (FSS) are not optimized for use by inexpensive terminals accessing broadband services. In effect, these allocations were determined based on a small number of sufficiently large terminals (earth stations) coexisting with the terrestrial stations and taking up almost all frequency bands.
- c. The *passband* transmission capacity is costly. Satellite operators face tough administrative, technical, and regulatory hurdles to gain access to domestic markets. Restrictions on user terminals, including utilization taxes and fees, complex and costly type approval procedures, reluctance to use the so-called network, and *head-end* or *gateway* stations located outside the national territory, to mention just a few, are governed by agreements satisfactory to governments, operators, equipment manufacturers, and service providers.

Barriers to the Broadband ICT's Access Deployment

Broadband ICT access has been primarily deployed in developed countries in urban areas due to the economics and limitation of existing technologies. In the initial phases of the concept development stage, the service providers and the operators are always inclined to serve the most highly populated regions, which normally translate to rich suburbs and cities, where most of the potential customers reside.

There are two factors that affect the diffusion of ICT. These are called the demand and cost

factors. The first aspect driving adoption of ICT in developed countries and urban areas is the hunger for more bandwidth to support multimedia applications. Rural areas in developing countries prefer voice communication technologies and applications with a sluggish progression toward ICTs. Developed countries own telecommunication infrastructure and have the means to pool financial resources to invest and pay for new services, while developing countries lack any form of basic infrastructures such as telecommunication, electricity supply, and roads. The developing nations also experience great difficulty mobilizing the required financial resources. This concept can be described as the *demand factor*.

The next key factor driving ICT adoption is the available technologies. Existing wired or wireless technologies have intrinsic limitations either in performances or in capacity, for example, the 6 km maximum distance from the exchange for ADSL or the line of site (LOS) customer premise equipment (CPE) location from the base station for wireless access. If and when these limitations become eliminated using other complementary backbones or equipment such as WiMax, the additional expense for this new equipment, along with their deployment and operation, directly impacts the business model. This factor is referred to as the *cost factor*. To achieve a cost effective deployment of ICT in developing nations, both the demand and cost factors need to be addressed, as they are major barriers to broadband access. One approach used to address this problem is using an international partnership model.

An International Partnership Approach for Resolving the Global Digital Divide

The ITU recently released a statement that indicated the use of partnership as the key to connecting communities. The initiative is called *connect the world*. It is a global multistakeholder effort established and working within the remit

of the WSIS to encourage partnerships to bridge the digital divide. The main objective of this initiative is to provide ICT to people worldwide, of whom making a simple telephone call remains impossible.

Currently, the main driver behind the concept of a GBSS is the WSIS. This initiative definitely has political clout. It was attended by 50 heads of state/government and vice-presidents, 82 ministers, and 26 vice-ministers from 175 countries, as well as high-level representatives from international organizations, the private sector, and civil society who attended the Geneva Phase of WSIS and gave political support to the Geneva Declaration of Principles and Geneva Plan of Action (ITU, 2005) that were adopted on December 12, 2003. More than 11,000 participants from 175 countries attended the summit and related events. These types of initiatives are required because research suggests that over 800,000 villages, or 30% of all villages worldwide, do not have any form of connection. Research also reveals that 942 million people living in the developed nations have five times better access to fixed and mobile services, nine times better access to Internet services, and own 13 times more PCs than 85% of the world's population living in low and lower-middle income countries (Cayla, Cohen, & Guigon, 2005).

The trend for telecommunications' markets has been liberalization and privatization of the telecommunications market to free themselves of their public service obligations. This trend makes it almost impossible to visualize a global broadband service infrastructure owned and financed by the public sector or a solitary operator. Unfortunately, this means that any project aimed at providing universal broadband services must depend on global market forces and the voluntary participation of network and device operators.

Formation of the GBSS Association

The most sensible approach to attain a global broadband service infrastructure is to develop a

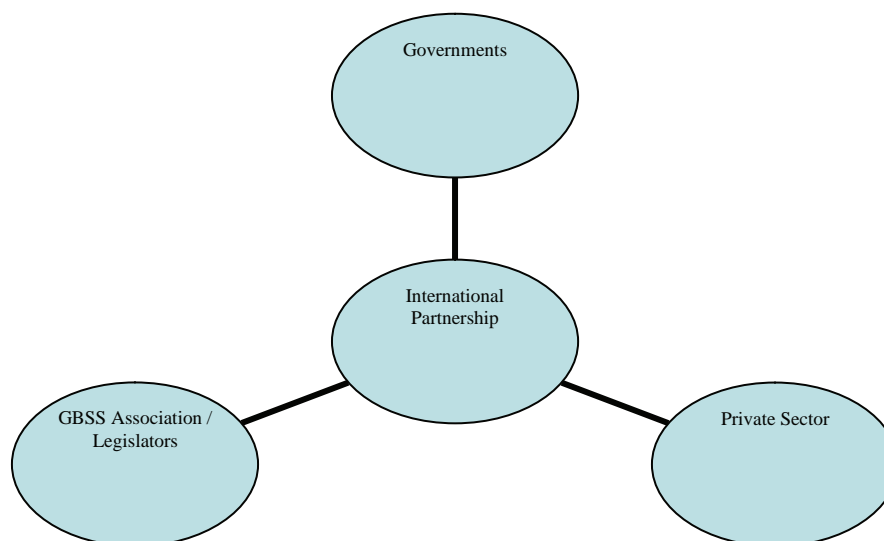

model similar to the digital mobile system GSM system. There are more than 1.7 billion people who use GSM networks and services. This equates to one quarter of the world's population. GSM is one of the greatest technological success stories of our age, on a par with the Internet. In fact, there are more people with GSM mobile phones than have Internet access. GSM networks are represented by the GSM Association (GSMA). This global trade association represents more than 690 GSM mobile phone operators across 213 territories and countries of the world. In addition, more than 160 manufacturers and suppliers support the association's initiatives as associate members. The primary goals of the GSMA are to ensure that mobile phones and wireless services work globally and are easily accessible, enhancing their value to individual customers and national economies, while creating new business opportunities for operators and their suppliers.

Role of the International Governments

Using the principles of the GSMA as a guiding model, there are fundamental issues that need to be addressed before we can even consider providing satellite high-speed Internet services through individual or community low-cost, small-dish platforms. This is a very elaborate project, and governments and private organizations, along with international bodies will have to develop an attractive technical and regulatory framework. Some of the components that fall under the responsibility of the governments would include:

- Identifying internationally harmonized radio-frequency bands and orbital locations that can assure global coverage, suitable for the provision of high-speed Internet services.
- In the likely situation that harmonized frequencies cannot be identified globally in "unplanned" bands, the allotment plans for the direct broadcasting satellite services

Figure 1. Actors for creation of global broadband satellite system

- The GBSS body would need to request that governments for member countries should make available part of their national allocation, without compromising their rights under the Plans.¹

One of the most important roles governments will also be responsible for is establishing a harmonized and minimal satellite telecommunications regulatory framework that promotes competition and broadband services. The regulatory framework would include the following four responsibilities:

1. Granting *landing rights* to all satellite operators participating in this initiative to provide high-speed Internet services
2. Licensing at least two service providers in each country to provide high-speed Internet services

3. Ensuring the principle of interoperability among all satellite systems providing high-speed services
4. Ensuring competition among operators providing high-speed services
5. Ensuring financial support where market conditions are such as to hinder access to high-speed Internet services

The Role of the Private Sector: Building Infrastructure and Markets

The primary role of the private sector is to develop innovative technical infrastructures and build strong markets for the products and services. The commitment from governments to create a global market for satellite broadband services will introduce new business opportunities for the private sector. It is imperative that the telecommunications industry, especially the satellite operators and device manufactures, should be actively involved in the design and development of a global infrastructure.

To ensure the creation of a harmonized global market, it will be important that GBSS operators have access to prime frequency bands and ideal orbital locations. This will allow them to deliver high-speed services via small-dish and low-cost user terminals. The role that needs to be undertaken by the private sector is described below:

- Harmonize universal technical standards for user terminals to access high-speed Internet service; the aim of this is to promote mass production of simple, low-cost terminals.
- Develop interoperability standards between broadband satellite networks to facilitate easy content exchange; the standards should also take account of ITU Resolution 101 on the development of the Internet protocol (IP) for public telecommunications networks.
- Use the orbital locations and RF spectrum resources identified for the global broadband satellite infrastructure, exclusively to provide broadband services in conformity with the universal technical standard specifications.

This initiative is more than just a system to resolve the digital divide. It also represents opportunities for the expansion of the telecommunications industry, an industry which is constantly investigating new prospects to ensure its survival and progress. Today's satellite telecommunication technologies are capable of providing universal access to high-speed Internet services within a reasonable timeframe at high cost. The GBBS approach will improve the access, provide more innovative features and content and become more affordable. This objective can only be attained by forging a new type of partnership between the public and private sectors. It is important to understand that providing a GBBS is merely providing the backbone network infrastructure. Ground networks will still be required to connect communities. One emerging technology that could be used to distribute the broadband signal over

a large area is called world interoperability for microwave access (WiMax).

CONVERGENCE OF SATELLITE-WIMAX TECHNOLOGY FOR ADDRESSING THE DIVIDE

WiMax is a standards-based wireless technology that provides high-throughput broadband connections over long distances. IEEE 802.16 provides Internet connectivity up to 50 km (31 miles) of linear service area range and allows connectivity between users without a direct line of sight. It is also anticipated that WiMax will allow interpenetration of broadband services such as VoIP, video, and Internet access, simultaneously.

The technology industry as a whole is committed to addressing the global digital divide, and there are numerous organizations and initiatives, such as WIMAX Forum, ITU, Intel, Microsoft, and GSMA, that are committed to reducing the technology disparity. The WiMax forum (Cayla et al., 2005) in particular is committed to delivering an innovative wireless technology standard to address the new millennium development goals aiming at a *global partnership for development* (Goal 8), and more specifically through Target 18:

In cooperation with the private sector, make available the benefits of new technologies, especially Information and Communications. And the objective that: everyone can create, access, utilize and share the information and knowledge, enabling individuals, communities and people to achieve their full potential and improve their quality of life in a sustainable manner.

The new WiMax wireless technology will adequately address the following WSIS goals for 2015:

- **Target 1:** To connect villages with ICT and establish Community Access Points, knowing that it is estimated that 1.5 million villages in developing nations remain unconnected to telephone networks
- **Target 10:** To ensure that more than half the world's inhabitants have access to ICT, knowing that the total number of estimated Internet users in 2002 was around 600 million, or just under 10% of the world's population

In areas without preexisting physical cable or telephone networks, WiMax could allow access between anyone within range of each other. Home units the size of a paperback that can provide both phone and network connection points are already available and easy to install. Intel is already working on creating processors that support WiMax. PanAmSat, the satellite communications company recently called satellite-delivered WiMax “the future for handheld devices.” At the WiMax Forum Plenary in Vancouver 2006, PanAmSat used WiMax to deliver the first-ever live video sent by satellite to a handheld device. PanAmSat anticipates that mobile phone, PDA, and laptop users will begin to access the Internet over satellite-based WiMax connections, and also foresees the technology as a way to deliver IP-TV throughout.

WiMax is considered to be a cost-effective solution for remote deployment; however, it is definitely not limited to such applications, and may also be an answer to expensive urban deployments. Due to the lack of wired infrastructure in most developing countries, the costs to install a WiMax station in conjunction with an satellite hub will be minuscule in comparison to developing a wired solution. The wide, flat expanses, rugged terrain, and low population density is ideal for WiMax deployment, and its current diametrical range of 30 miles. For countries that have skipped wired infrastructure because of inhibitive costs and unsympathetic geography, WiMax can en-

hance wireless infrastructure in an inexpensive, decentralized, deployment-friendly, and effective manner (Cayla et al., 2005).

Satellite broadband converged with WiMax technology provides a very strong technological offering, with the potential to cover the globe. Unfortunately, having good technology does not ensure that the people who need it the most can afford the technology or understand the full potential. It is important to have viable and sustainable access models. The model proposed in the next section involves the formation of an alliance called coalition of space internet providers (COSIP) and is based on a proven methodology.

LOCAL PARTNERSHIP APPROACH FOR DIGITAL INCLUSION: OVERVIEW OF COSIP MODEL

This section proposes the concept of using local initiatives to increase demand for new ICT services. The solution proposed involves the formation of an alliance called coalition of space internet providers (COSIP). This model exploits ideas developed over a decade ago to successfully aid the diffusion of Internet connectivity to communities in rural North America. The solution involves identifying a local institution and creating infrastructures that build on existing local resources and expertise. This model can be scaled so as to expand as local markets needs expansion. The COSIP model is based on the Local information utility (LIU) proposed in 1994 (Clement et al., 1996). The idea of a LIU was created by CICNet Rural. The LIU was built around one or more local organizations, such as a school district, a community college, or a public library.

The coalition will provide a means to access health and educational resources to a rural community using one of the described space technology configurations. The technological configuration will be dependant on the technical requirement,

size of community, and the purpose of the connection (education, telemedicine, community engagement, etc.). There will also be the opportunity for Internet connectivity to be extended to other groups in the community or to a telecenter which could serve the ICT needs of the local community. The resulting system must provide access to local and community information resources. As experience in localities grows, project stakeholders will need to broaden their information holdings and come to integrate educational, business, cultural, and governmental purposes and information within their structures.

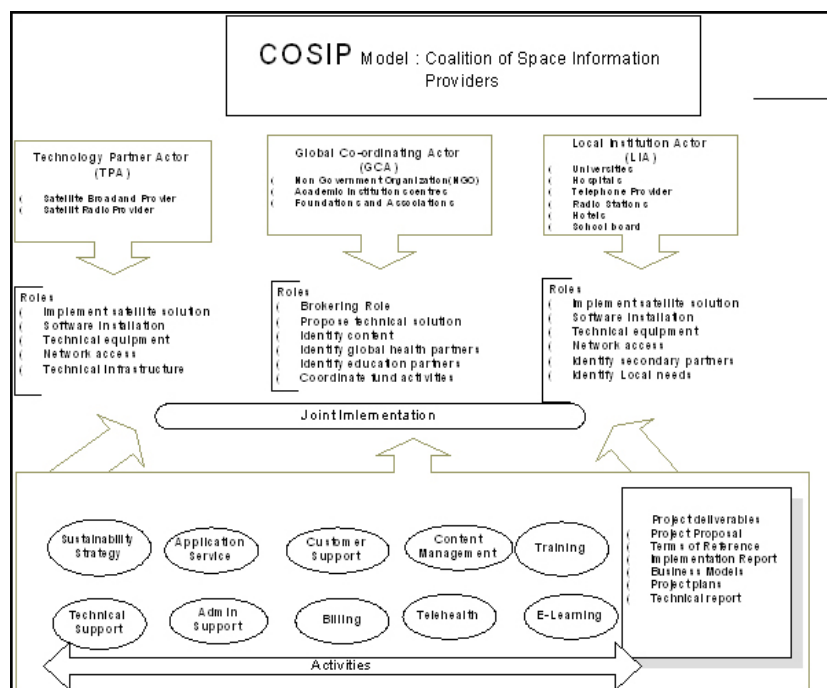

All initiatives similar to COSIP, which aim to implement ICT services to bridge the digital divide, must aim to address the following issues (Gurstein, 2000):

- Provide support for a multiplicity of usage roles involving the creation, dissemination, and retrieval of information

- Address the full range of possible users and the diversity of their life situations
- Recognize the interplay of social and technical dimensions in infrastructure development
- Encompass both conventional and new media
- Highlight *access gaps* and social forces likely to be left out by market forces
- Help to identify essential services

The growth of the Internet as a means of providing communication, education, or health services offers an opportunity for new, agile groups of people to come together and work from widely dispersed geographical locations around the globe. Education is a very important aspect. The perceived potential of computer-based networking to transform primary, secondary, and basic health education will eventually lead to widespread networking for schools. Higher

Figure 2. Coalition of Space Information Providers (COSIP) model

educational institutions are realizing opportunities to extend their campuses by using radio, computer networking, and video technologies to impart educational content, in effect moving the universities closer to the community for the purpose of continuing lifelong education.

Successful implementation of the COSIP Model will certainly contribute to the achievements in the field of ICT, as well as in other priority areas, such as poverty alleviation, managing globalization, and addressing emerging social issues. Using the COSIP model, each interested local community will have to find their own motivations for investing in community networking. The opportunity to improve the economic prospects of many localities, coupled with educational institutions' drive to improve educational services and the ability of local health care providers to form telemedical partnerships with international health care organizations, can serve as overall motivating forces.

This type of initiative will require the creation of a partnership consisting of three focal actors; technology partner actor (TPA), local institutional actor (LIA), and global coordinating actors (GCA). These roles will be explained in more detail in the next section.

COSIP Actors' Roles and Components

To successfully implement the COSIP model, there are three important groups of actors. The local institutional actor, the satellite technology partner, and the global coordinating actor.

Local Institutional Actor (LIA)

The LIA are normally the primary actor. The primary actor is the focal point of the relationship. The primary actor can be any local institution or group, such as a school district, university, community college, public library, business group, community coalition, or even a local communica-

tion service provider such as a telephone, radio station, or television company. The plan should be implemented so as to adapt to local conditions and growth patterns.

Satellite Technology Partner Actor (STP)

The STP will use its considerable technical assets and knowledge to build in the air what does not exist on the ground in developing countries. Satellite and broadband wireless technologies will be blended to provide low cost, secure, and easy to use connectivity to locations not readily accessible by wired, land-based systems.

Traditionally, satellites are used to link a facility in a developed country to a particular location in a developing country. From that location, a wired network is built to provide connectivity to computer users. Often, connectivity is limited to a single location such as a university, hospital, or cyber café. The solution being proposed by the COSIP model builds on this concept to extend the coverage to sites in the vicinity of that community. The coverage can be extended depending on the requirements of the COSIP group members. Satellite and wireless technologies can be combined to provide fast, reliable, and secure connectivity by establishing "hotspots" that are independent of location and wired networks. See Figures 3 and 4 for example configurations.

Global Coordinating Actors (GCA)

The GCA takes on the role of a broker, responsible for validating the LIA's claim for resources and matching it with the capabilities of one of the STPs. They will also be responsible for coordinating the local organizations along with regional service providers providing guidance and advice. Any applications for funds will be via this group, and initial payments to the TPA for equipment, training, and support will be handled by the GCA. To achieve the goal and support

Figure 3. Primary location=university secondary location=school (nonprofit making)

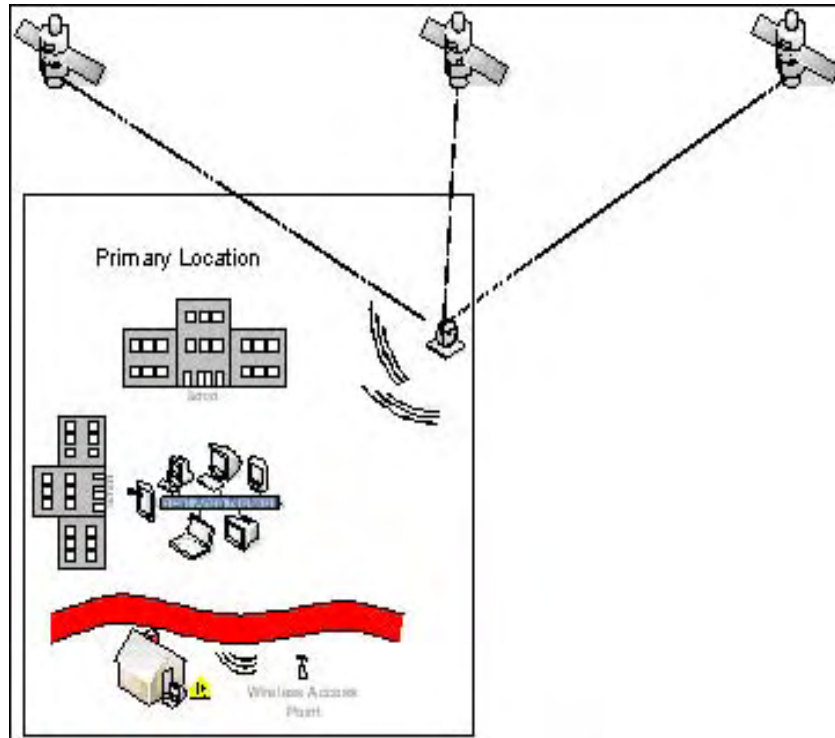

Figure 4. Primary location=university secondary location=school (nonprofit making)

the alliance objectives, the GCA, in conjunction with service providers, needs to play a brokering role, developing technical, human, and capital resources to help local groups plan and implement realistically.

Components of COSIP

The local institutional actor LIAs may, if they so choose, resell services to other users or user groups in the community. This approach is encouraged to aid sustainability of the project. The LIA also has the potential to create private information exchanges (PIX), purpose-driven connections between local groups to support more efficient means of local resource access. Providing the connectivity is not enough. The core components that must be considered include customer support, user training, the right mix of services, the proper information infrastructure, and content.

Support and Training

Support is critical to the success of the project in the community, and the agreement between regional service providers and local customers should place special emphasis on the customer's likely needs to provide a robust service package. The models implemented must define locally appropriate user training, both entry-level and advanced. Regional service providers should work with the LIA to identify training sources for local trainers or broker referrals to knowledgeable resources, often at postsecondary educational institutions in the region. The LIA should also define a help desk capability to answer service questions from users, and should provide a centralized referral capability for networking consultants, trainers, and other experts.

Application Services

The range of services an LIA will provide can include electronic mail, news, Web and Gopher

servers, internetrelay chat (IRC), video conferencing, voice over IP (VoIP), mailing list management, and caching applications for Web client and server response speedup. Other services can be provided on the basis of an appropriate bandwidth infrastructure (i.e., higher bandwidth may permit video applications).

Technical Infrastructure

The TPA will need to supply the LIA with a basic package of middleware and services, and should be responsible for their coordination and for conducting ongoing, standards-based research and development. The capabilities should include:

- Authentication services (i.e., verification that a given user is allowed access)
- Authorization services (i.e., verification that a user can invoke a given application)
- Call detail and settlement services (for access from remote LIAs)
- Domain name service
- Accounting and financial support services

If the components above are considered, the chances of success are increased. It is important to consider models such as the COSIP model due to the fact that these initiatives are being implemented in developing nations with limited resources, knowledge, and technical competencies. It is also likely that government and local official are corrupt, which would mandate that the concept of a GCA is utilized to avoid fund mismanagement.

CONCLUSION

The availability of ICT services and applications are considered to be the driving force for economic, social, and technical development. The convenience of a good infrastructure facilitates the delivery of high speed Internet, which transports

important services such as education, communication, health, telecommuting, electronic commerce, and e-government services. The development of ICT applications promises a ray of hope to the developing countries; however, the prospect of accelerated growth still seems to be far away. It is imperative to facilitate the emergence of a global broadband satellite system capable of providing high speed Internet access on a global and nondiscriminatory basis, in accordance with the provisions of United Nations General Assembly Resolution 1721 (XVI), as well as the International Telecommunication Union Resolution 64, which mandates nondiscriminatory access to modern telecommunications facilities and services. Once a global system is in place, the next challenge would be to encourage deployment in the local vicinities using models such as the coalition of space Internet providers. This type of approach is necessary to ensure that a sustainable model is implemented at the grass root facilitating the use of appropriate equipment, devices, services, and business models.

Chapter 3.16

Voice Over IP for Rural Telecommunication Provision

Thomas Wilsdon

University of South Australia, Australia

Jill Slay

University of South Australia, Australia

INTRODUCTION

With the continual convergence of analogue technologies with those either simulated or implemented in digital based equivalents, future benefits usually involve better reliability and lower costs. As current technical limitations are removed, the literature does not show any large scale assessment of the legal and security implications of the removal of cables in this digital world or the effect of a move toward wireless transmission in this context. Neither Voice Over Internet Protocol (VoIP) nor IEEE 802.11b is new technology, but the combination of these services to provide a primary telephone network for small regional centres is an innovative solution to rural telecommunication problems.

There are many companies, especially in the context in rural Australia, currently developing satellite communication networks for regional communities to access broadband equivalent

internet access, generally where this type of bandwidth is usually unavailable. Reasons for insufficient access primarily are due to lack of infrastructure and this can be directly attributed to either the remoteness, or to the effect of a low level of population some areas which generally equates to the lack of potential return on investment for telecommunication companies wishing to establish infrastructure out to these regions.

The cost of implementing a traditional wired infrastructure to reach these lowly populated regions offers no great reward to the companies providing the service and therefore they usually discount such an expansion or explore other means to provide the minimum service required by the Australian legislation to every household.

Australia's primary telecommunications company, Telstra, who has a majority owner in the Australian government, is required to meet service supply standards to all Australian households—no matter the geographical location. Service levels

to regional and remote regions of Australia are similar in quality to that of highly populated metropolitan areas but traditionally limited in the services they are required to provide. While current telephone coverage is of an acceptable level, the growth of internet access, among other forecasted future technologies requiring data like infrastructure (IP), has caused great bottlenecks within current solutions and network providers such as Telstra are exploring ways to overcome this. Simply stated, the infrastructure available was implemented with limited foresight and will not scale to accommodate these new and emerging services.

Satellite usage, among other networking technologies, is now being tested and implemented to allow for the delivery of large volumes of IP traffic to regions which are not covered within the major telecommunications network infrastructure. Most of these technologies being explored take the form of wireless. Included benefits of wireless such as the substantial cost reduction achieved with the avoidance of installing long distances of cable and infrastructure. Satellite, particularly with the use of KA band services, allows for clients to connect in a bidirectional fashion with very small aperture terminals (VSAT), transmitting via satellite hub locations to apertures in similar trip times to that of wired infrastructure.

The principle of satellite, and other technologies, is packet switched based usually on the underlying infrastructure of digital transfer as compared to analogue transfer used within the current circuit switched networks. While this provides significant increases in the amount and types of traffic which can be transferred simultaneously, it requires the translation of current analogue technologies, such as telephone and fax, to digital equivalence and back again to analogue to simulate current models. As with most of the services proposed to be offered, and in VoIP in particular, the timing and delivery model are of the utmost importance to ensure the quality of

service for all users. Substantial fluctuations in the time for the delivery of digital packets can confuse the protocols and participants, making the phone call seem unnatural in comparison to current phone usage.

VoIP, as a standard, attempts to simulate the current analogue telephone call but utilises the advantages of digital networks with its ability to generate, route and receive phone calls. Of major concern is the efficiency of the network, along with quality of service (QoS), integration with plain old telephone systems (POTS) and last mile connections. Small companies hope to address some of these issues by offering clients access to metropolitan like services in regional Australia using the benefits of wireless communications not only for the major distance (satellite) but also at the last mile with wireless local loops in the form of 802.11b to connect to this service.

WHAT IS VoIP (VOICE OVER INTERNET PROTOCOL)?

This suggests traditional telephony, which is a circuit-switched technology, can be adapted or interact with an IP network (Marjalaakso, 2003). One may pose the question of why the traditional phone systems must be updated or complemented while it appears to be satisfying current requirements?

BENEFITS OF VoIP

Not only are the merging of voice and data traffic down an individual stream financially beneficial to users, but possible services provided are greatly increased with the ability for scalable updates over time, a characteristic not associated with the traditional analogue telephone network.

Financial Benefit

McPherson reports the financial benefits alone are not enough to entice a large scale of take up of VoIP (McPherson, 2003). Although it is known the cost of a packet switched network for VoIP is approximately half the cost than that of a circuit switched network, an end user will not be aware of these costs other than the monthly subscriber bill. Thus, the financial benefit will be the greatest selling point of the technology to customers and it must be highlighted and marketed openly.

How these vast financial benefits are achieved is due to the architecture of IP networks, and the ability for intelligent navigation (routing) to occur. This gives the appearance that the VoIP solution determines the cheapest method to place the call, when in fact it is predetermined by routing tables within the network. The private network is intelligent and directs the phone call to enter the PSTN where a local call charge will be incurred rather than that of a long distance call. The financial benefit is appealing but IP networks are not always reliable—particularly with time sensitive information.

Other benefits can include no external bills generated by internal calls, even if geographically separated. If a phone call is routed the entire distance via the IP network and never enters the PSTN, no third party bill will charge for that call, as compared to a leased line solution. An example of this is a company with many offices interconnected via broadband links into the internet using VPN connections to secure communications.

Service Benefit

The integration of two networks into one provides maintenance benefits, but is the convergence of voice and data a good relationship? Marjalaakso (2003) predicts the VoIP will compliment the already existing Internet based services such as

web, email and newer technologies like net meeting and instant messaging.

SECURITY VULNERABILITIES OF VoIP

As with all technologies it is essential to examine whether customers confidentiality, integrity and availability to their conversations, data and service are preserved. Marjalaakso (2003) discusses the inbuilt security of standards such as SIP, but summarises that these are not valid as they are flawed and knowledge is widespread about such vulnerabilities. While this is true and valid, the level of encryption and secrecy on telephone services for domestic users and the current level of secrecy on circuit based networks must be determined.

Other risks associated with VoIP implementations are categorised below, using the traditional security goals of confidentiality, integrity and availability.

Confidentiality

Confidentiality concerns one's ability to remain anonymous to outsiders while being able to disclose information for authorisation and billing. Issues in confidentiality include eaves dropping and tapped. The Australian Telecommunications Act allows for a call entering a public network to be "tapped". In 2001-2002, 2,500 authorised phone tapping warrants were issued to authorities, with prosecutions from the information gathered from authorised tapping rising 48% proving this to be a valuable weapon for law enforcement. Thus it is an essential requirement for VoIP to be able to provide a similar or better attribute than current networks.

While current telephone networks offer no encryption on transport it is an attribute that is required for VoIP as it merges into accessible networks and makes the task of unauthorised access

much easier with the use of freely available tools such as traffic sniffers etc (Marjalaakso, 2003).

Integrity

Integrity is essential in a communication technology and by its very nature it is difficult to actually modify traffic in real time with VoIP as delay will cease the call. The integrity of the telephone call is rarely ever jeopardised when operating in real time. The public will need reassurance of this, along with their other fears of VoIP, when it comes VoIP is implemented in rural communities.

Authentication is important for receiving correct calls but also for network protection. It must be determined whether existing authentication techniques are going to be adopted for network access or if VoIP-specific means are to be implemented. Typically authentication within an internal network is not applied, but for gateway passthrough this generally requires an authentication of some type. Other issues of authentication relate back to the Telecommunications Act and its requirements in regards to call logging, tracing and tapping. By using strong authentication techniques, identification of unique persons is available during the authorisation stage.

Billing is one of the core features in a public network and must be reliable, accurate and non repudiable to ensure financial recovery of cost. Analogue telephony has suffered from phreaking and avoiding tolls to make calls and billing procedures disputable; VoIP must address these as high priorities when working in an external network. Different methods of billing can be implemented by service providers and authentication servers such as RADIUS or IAS (Microsoft's RADIUS equivalent product) can be used with appropriate software to enforce these plans.

With the experience from traditional telephony the practice of removing all service commands out of the user's accessible band can minimise the threat of phreaking. Traditionally the practice of playing various tones through a handset can

override the accounting and billing mechanisms (Mitnick & Simon, 2001).

Call logging is a requirement of the Australian Telecommunication Act. While this is not so important within internal networks, it is a feature usually undertaken by VoIP hardware such as gateways. The Australian Telecommunication Act requires the ability to back track a call from destination to origin, this is established when connecting initial handshake between the two nodes with and is addressed in H.323 Annex D (Nichols & Lekkas, 2002).

Availability

Availability refers to the ability to access and use the service being provided. In this context this means to either make or receive phone calls. Current telephone networks offer a high rate of availability and stability—this sets the benchmark for any technology which may supersede the current network.

The costs for a non functional phone can be not only in terms of the company's reputation but a phone service has now become an expected service which at its worst can be life threatening.

Availability may be enhanced through redundancy. Traditional VoIP implementations have a gateway to interconnect two or more IP networks. In the case of this network becoming inefficient or ineffective there must be some form of an alternative; this may be in the form of many gateways performing some load balancing function. An alternative could be the PSTN gateway located at every branch, allowing not only for redundancy but also the routing of phone calls from other geographical locations to be charged at local call access fees. Companies using a VoIP solution could then be more resilient to a Denial Of Service (DOS) attack which attempts to remove the functionality of the IP network but with intelligent devices this can be overcome to route through an available resource such as an alternative gateway.

Availability is also increased by use of peering networks—the concept of networks providing connection to each other. Generally this is done to improve performance, reduce costs and create better market dominance. Peering is not merging of companies but rather a merge of networks owned by companies. The benefits are matched with some of the following less beneficial properties such as attack from one to the other by diversion, spoofing, DOS, overload etc.

A trust relationship must be established between companies to allocate resources to the other's connected network which satisfy requirements to carry the traffic and generally will not be static. As load increases when demand is greater, it can be assumed the load would be higher during business hours in local time when compared to the middle of the night—therefore it is required that either a well researched usage plan is provided or a real time analysis and network control tool be implemented.

VoIP Orientated Denial of Service (DOS) Attacks

Convergence of voice onto data networks has merged the vulnerability of traditional data network attack methods to affect VoIP as a system. One such attack method is DOS and essentially is the abundance of traffic aimed overwhelmingly a single network device, interface or service. The vulnerabilities of computer networks are well publicised and continually exploited and one must question its ability to provide the infrastructure to voice networks. However VoIP DOS are not prevalent to this date.

Environmentally Orientated VoIP Attacks

Attacks on the environment where VoIP is existent are a greater concern. DOS attacks and even peak traffic can serious degradation of network QoS and may render VoIP not available. Network manage-

ment tools exist for both security and performance but this is a consequence from merging the two services on to the one network.

Many concerns have been highlighted with the convergence of data and voice traffic into one sole network. These fundamentally relate to the theory of “placing all your eggs in one basket” which ensures greater loss if the network becomes unavailable.

Counter argument is also valid in terms of the cost reduction in the form of less development, construction, maintenance and management of separate networks. Generally voice has a greater priority during network transmission and this may have adverse results if not configured correctly for both data and voice—generally, with the correct management tools, if sufficient resources are available then the relationship can work gracefully.

EXAMPLE OF VoIP IMPLEMENTATION

Our research examined the marriage of two independent technologies to provide a last mile solution to users. Utilising the 802.11b architecture to form a network of connected clients to allow for VoIP to be accessible in remote communities where cable infrastructure is either non existent or not capable of scaling to new technologies such as broadband equivalent internet access. The primary purpose of the project was to build a conceptual model and determine whether this would work at a carrier grade equivalent. The project aimed at remote centres, i.e. less than 20 dwellings, and therefore focused on clients in a determined radius from one central access point.

Network Model

The model this system proposes is described as Bridged Mode between wireless points. This allows for static connections to exist with little

Figure 1. Proposed client structure

network management requirement for the connection, and securing of connections, in a dynamic period. As phone calls are bi-directional it requires that a connection is not only in the pull model (client generated), but if a call is to be received and the SIP model is used it requires the device to be active on the network to have a call routed to it.

Protocol Usage

The protocol to be used is SIP, since it has been seen to be a better performing solution in the wireless solution than H.323—as this solution only documents within the set bounds the interface to the WAN may transform into another protocol with the appropriate gateway. No security or authentication services will be provided from the SIP implementation; rather these will be developed on the network infrastructure. In case of a WAN outage it is expected a PSTN connection

will exist with multiple connection lines to act as a form of redundancy.

Security

Encryption must be applied to this service as the ability to eavesdrop and gain unauthorized access in 802.11b is well documented. The security model chosen is that of a Virtual Private Network (VPN) with the server residing at the remote centre, this may be located at another location if an implementer wishes to secure the entire transit for inter-network transmissions, but this would increase round trip time upon establishment of connection.

The network model discussed above documents that the clients exist in a static position with a connection via antennas and bridged devices. For this reason it is proposed that the VPN client exist within this device to allow for encryption between the connection point for the client and the central access point. By making the VPN client exist in this device it allows for unencrypted traffic flow within the client's local area network meaning management is less intense. Other benefits include security by abstraction, the VPN service cannot be shutdown as it is part of the boot up and connection to the network and the user would not know of its existence.

Concurrent Connections

The number of simultaneous connections is dependant on the access point, the network performance, and WAN interface among other elements such as codec used. A standard access point can support up to 50 connections, realistically the load bear can handle 25 at reasonable quality. This is based on our research using an Asus WL-300b using an omni external antenna with 31 clients, after this the service degraded substantially. This research did not include any security measures and therefore would suggest fewer connections due to overheads.

It is hard to determine the exact number of connections as is based upon many factors and variables. Realistically for high quality of service if offering both VoIP and internet access (256kbps/64kbps equivalent) using the security measures listed above no more than 20 connections should be made.

As this solution is based on remote town, less than 25 dwellings, and therefore one access point should service this if industrial hardware is utilised. The Asus WL-300b is a mid range access point aimed at small business with the external antenna connections.

DISCUSSION AND CONCLUSION

While 802.11b and Voice over IP may be utilised in the situation described, this is an unreliable and not a true carrier grade solution. The provision of VoIP over the wireless network does pose some issues in terms of performance and quality, but generally these can be rectified with the usage of proprietary solutions. The greatest threat is that of the infrastructure which 802.11b provides.

Placing this system in a remote centre would require constant monitoring which is not available. Cable infrastructure has a higher reliability, but this study has not assessed other wireless mediums. Some of the greatest shortcomings of utilising 802.11b are the use of unlicensed spectrum which allows other devices to readily use this same frequency and degrade service. Moving into a licensed spectrum increases the network capacity, performance, reliability and cost but may be a solution that will be reviewed with technologies such as GSM, 3G, and GPRS.

It is also noted that such a network may not be viable with the progression of satellite technology. Optus, in Australia, has revealed plans to deploy two new satellites and the possibility of using these to service individual households is not unrealistic with the low cost of hardware, smaller dishes and increasing bandwidth.

However VoIP is continuing to blossom and the marriage with 802.11 infrastructure is continuing. Dominant usage of the two technologies together are for office environments, but we predict within two years mobile phones with 802.11 access will exist within current handsets (GSM, 3G) which determine the cheapest method of call when 802.11 networks are available.

KEY TERMS

Call Logging: A requirement of the Australian Telecommunication Act in regards to the ability to generate call lists made to or from a particular node on a network with public access.

Eavesdropping: The ability for one to access a call and either in real time or after reconstruct the conversation.

IEEE 802.11b: An established protocol or standard for wireless networking.

Phreaking: The ability to use a phone service without being billed.

Voice Over IP for Rural Telecommunication Provision

Quality of Service (QoS): An indicator of availability and specifies the transmission rates, error rates, and other network performance metrics which can be measured, improved, and, to some extent, guaranteed in advance.

Voice Over Internet Protocol (VoIP): The use of IP networks rather than circuit-switched ones for the transmission of phone calls.

Chapter 3.17

ICTs as Tools for Poverty Reduction: The Tanzanian Experience

Zaipuna O. Yonah

Tanzania Telecommunications Company Ltd., Tanzania

Baanda A. Salim

Sokoine University of Agriculture, Tanzania

ABSTRACT

This chapter attempts to enhance the understanding and knowledge of Information and Communication Technologies (ICTs) in relation to the Tanzania National ICT Policy as a case study. The authors extensively explore these pervading technologies as they impact on the education, commerce, social, cultural, and economic life of the poor Tanzanian people. The chapter looks at how Tanzania is coping with the issue of poverty eradication as one of the eight UN Millennium Development Goals (MDGs). It addresses the issue of digital divide and the role that ICTs can play in poverty reduction. Tanzania's efforts in embracing ICTs and the challenges facing the country in its efforts are also addressed. Overall, the chapter demonstrates that ICTs are a set of tools for knowledge sharing, which is a powerful means for poverty reduction. Furthermore, it is

advisable to focus on information literacy rather than just focusing on computer literacy.

INTRODUCTION

In this chapter, an attempt has been made to enhance the understanding and knowledge of Information and Communication Technologies (ICTs) in relation to the Tanzania National ICT Policy as a case study. The authors extensively explore the evolving frontiers of these pervading technologies as they impact on education, commerce, social, cultural and economic life of the poor Tanzanian people. The chapter also attempts to show case examples of ICT national projects in Tanzania to demonstrate how the government of Tanzania, entrepreneurs, and some of the rural communities are appropriating ICTs to fit into their needs. The chapter reflects on perspectives,

trends, and potential of using ICTs to develop innovative approaches and methods for poverty reduction in Tanzania.

The chapter is organized into six sections. The Background section looks at the general issues, putting Tanzania into perspective and how it is coping with the issue of poverty eradication as one of the eight U.N. Millennium Development Goals (MDGs). Targets for achieving poverty eradication are articulated in the National Poverty Eradication Strategy. The Development Vision 2025 aims at guiding Tanzania to achieve five goals by year 2025, namely, (1) high quality livelihood, (2) peace, stability, and unity, (3) good governance, (4) a well educated and learning society, and (5) a strong and competitive economy. This section further puts into perspective Tanzania's position on the role of ICTs in meeting the goals of the Vision 2025 as well as the MDGs. The framework for appropriating these ICTs for national development and poverty reduction is articulated in the National ICT Policy.

The second section attempts to answer the question: what is poverty and what causes it? It is noted that ICTs are now acknowledged to be a set of powerful tools for building the capacity for knowledge management and hence for building the capacity for poverty reduction. It also addresses the issue of digital divide. The third section addresses the role that ICTs can play in poverty reduction. It outlines the desirable characteristics and attributes of the modern ICTs useful for poverty reduction. This section further addresses issues of connectivity, affordability, and capability. The fourth section details efforts that Tanzania has made in embracing ICTs. It narrates on various projects being undertaken in Tanzania such as projects on increasing capacities and opportunities; projects on reducing vulnerabilities; projects on enhancing government capacity, efficiency, and accountability; and projects on participation, empowerment, and the strengthening of civil society.

The fifth section looks at the challenges fac-

ing the country in its efforts to embrace ICTs. It also looks at the prospects and try to project the trend of adoption of ICTs in the country in the next five or so years. In the last section of the chapter, some recommendations are drawn on "an entry point" into dissemination of ICTs to the rural areas of Tanzania. In this section, the authors try to lay out priority areas in harnessing the power of ICTs in bringing about development to the rural people of Tanzania.

BACKGROUND

Tanzania is one of the 191 United Nations member states that have pledged to meet the eight UN Millennium Development Goals (MDGs) by year 2015 (URT, n.d.). These goals are: (a) Eradicate extreme poverty and hunger, (b) achieve universal primary education, (c) promote gender equality and empower women, (d) reduce child mortality, (e) improve maternal health, (f) combat HIV/AIDs, malaria and other diseases, (g) ensure environmental sustainability and (h) develop a global partnership for development. In response to this pledge, Tanzania restated the UN-MDGs and came out with its own nine (9) development goals, herein to be referred to as TZ-MDGs, namely (URT, n.d.):

- a. **Extreme poverty:** Halve the proportion of people living below the national poverty line by 2015.
- b. **HIV/AIDS:** Halt and reverse the spread by 2015.
- c. **Hunger:** Halve the proportion of underweight, under five year olds by 2015.
- d. **Basic amenities:** Halve the proportion of people without access to safe drinking water by 2015.
- e. **Primary education:** Achieve universal primary education by 2015.
- f. **Gender equity:** Achieve equal access for boys and girls to primary and secondary schooling by 2015.

- g. **Reproductive health:** Reduce maternal mortality ratio by three-quarters by 2015.
- h. **Under-five mortality:** Reduce under five mortality by two-thirds by 2015.
- i. **Environmental sustainability:** Reverse loss of environmental resources by 2015.

The focus of this chapter is on the first TZ-MDG, which is on eradication of extreme poverty. As is in many developing countries, poverty in Tanzania is characterized by low income and expenditure, high mortality and morbidity, poor nutritional status, low educational attainment, vulnerability to external shocks like natural disasters (e.g. drought, pests, diseases and floods), and exclusion from economic, social and political processes. Generally, poverty is particularly widespread in the rural areas, but is not insignificant in urban areas. There are also important regional and district differences in the levels and specific dimensions of poverty. Those most at risk of being trapped to live under poverty are young children and youths, the elderly, women, those in large households and those involved in subsistence agriculture, livestock production and small-scale fishing.

The primary targets for achieving the first TZ-MDG on poverty eradication are articulated in the National Poverty Eradication Strategy (NPES) (URT, 1997). The set timeline for this TZ-MDG, which is more ambitious than the international one (2015), is to halve extreme poverty (measured by income and expenditure) by 2010 and eradicate it by 2025, which corresponds to the articulation of the goals of the Tanzania Development Vision 2025 (URT, n.d.). The Development Vision 2025 aims at guiding Tanzania to achieve five goals by year 2025, namely: (1) high quality livelihood, (2) peace, stability and unity, (3) good governance, (4) a well-educated and learning society, and (5) a strong and competitive economy capable of producing sustainable growth and shared benefits. Overall, the Vision foresees that by the year 2025:

Tanzania should have created a strong, diversified, resilient and competitive economy, which can effectively cope with the challenges of development and, which can also easily and confidently adapt to the changing market and technological conditions in the regional and global economy.

The challenge is, therefore, to mobilize massive resources towards the realization of the Vision 2025 goals.

It is worth noting that the Government of Tanzania has already acknowledged that ICTs can be harnessed to meet the goals of the Vision 2025, as well as that of the TZ-MDG on poverty reduction. In broad terms, ICTs refer to any technique or knowledge used to create, store, manage, and disseminate information. They include simple information centres with notice boards, books, brochures, posters, and newspapers, simple content systems running on cheap (safely disposable) hardware, for example, audio and video cassettes, disconnected mailing systems, to locally browse-able content accessible through a range of electronic technologies such as telephone, fax, television, and radio. Modern ICTs include the Internet, e-mail, computers, mobile phones, digital cameras, online databases and portals.

In a sense, ICTs enable communication, a process that links individuals and communities, governments and citizens, in participation and shared decision making. This is done through use of a variety of ICTs to engage, motivate, and educate citizens of opportunities for development and poverty reduction, in this way promoting changes in peoples attitudes and behaviours and thus increasing their participation in the development or poverty reduction processes (Gillman, 2003).

The framework for appropriating these ICTs for national development and poverty reduction is articulated in the National ICT Policy (United Republic of Tanzania, 2003). In the policy framework, it is clearly shown that ICTs are crosscutting in nature, an attribute well shared with poverty. As

such, therefore, ICTs can indeed be appropriated as tools for realizing effective communication processes to achieve, among others, distribution and sharing of knowledge and information for supporting poverty reduction initiatives.

In this chapter, an attempt is made to enhance the understanding and knowledge of ICTs and the evolving frontiers of these pervading technologies are explored as they impact on education, commerce, social, cultural and economic life of the poor Tanzanian people. It also attempts to show case examples of ICT national projects that demonstrate how the government of Tanzania, entrepreneurs, and some of the rural communities are appropriating ICTs as tools to fit into their needs and empower themselves to fight poverty. Further, an attempt is made to stimulate debate to reflect on perspectives, trends, and potential of using ICTs to develop innovative approaches and methods for poverty reduction.

WHAT IS POVERTY AND WHAT REALLY CAUSES IT?

Widespread and persistent poverty in Tanzania is the main development challenge since the 1990s. Currently, about 40% of the population lives below the basic needs national poverty line (World Bank, 2004), that is, a population surviving on less than US\$2 per day. A debatable issue arises here: *what does poverty really entail?* Poverty is often viewed from an income-based perspective as lack of income and measured in terms of income and expenditure. In recent years, however, the concept has been enlarged. Poverty is now seen as a multidimensional concept that is the opposite of well-being, which includes more than income. Therefore, apart from the inability of poor people to meet basic needs (such as nutrition, clothing, and shelter), poverty also refers to disadvantages in access to land, credit, and services (e.g., health and education), vulnerability to violence, external economic shocks, natural disasters, powerless-

ness, and social exclusion (Shaffer, 2001; Williams, Sawyer & Hutchinson, 1999).

According to the Government Poverty Reduction Strategy Paper (PSRP) (URT, 2000) and the Poverty Monitoring Master Plan (PMMP) (URT, 2001), people living in poverty in our society are reidentified to include: illiterate people; unskilled labourers; self-employed micro-entrepreneurs; subsistence farmers; women; children; and population living in remote (rural) areas. Those in the group that are extremely vulnerable include children, persons with disabilities, youths, elderly, people living with HIV/AIDS, women, drug addicts, and alcoholics.

Poverty, the simplest indicator of alienation (Allen, 2002), causes a citizen to feel devalued, resentful, frustrated, and angry. Despite the vast advances that are being made in the spheres of science and technology, medicine, capital mobility, and so forth, income disparities are ever widening, both within countries and between nations. This imbalance in equity is characteristic of alienation—alienation between developed and developing nations; alienation between civilizations or cultures; alienations within our nation (regions, districts, etc.) and even alienation within families. Therefore, overcoming poverty, a consequence of alienation, will require the full participation of every member of the Tanzanian society. It is worthwhile to note that ICTs are now acknowledged to be a set of powerful tools for building our capacity to care, knowledge management, and hence for building the capacity for poverty reduction. In the literature, alienation based on modern ICTs is also popularly known as the digital divide (Weigel & Waldburger, 2004).

POVERTY REDUCTION

The poverty reduction challenge is about how to empower the poor with knowledge and skills, thus availing to them new opportunities to improve their livelihood (Weigel & Waldburger, 2004).

In terms of income and expenditure this would mean an increase in income, and hence capacity to afford food, health services, and other basic needs.

The strategic approach is to use ICTs in a creative manner to level the playing field in economic, social, cultural, and political terms by reducing the rapidly growing gap caused by a very asymmetric architecture of opportunities between the rich and the poor. As a matter of emphasis, the role of ICTs in poverty reduction is not limited to reducing income poverty, but also includes non-economic dimensions, in particular, empowerment (Gerster & Zimmerman, 2003). This can be accomplished through a variety of strategies ranging from the *sustainable livelihoods approach*—by putting people first; *production-oriented growth strategy*—which focuses on pro-poor corrective measures; a *distribution-oriented strategy*—which emphasizes the redistribution of wealth within the nation; and a *rights and empowerment strategy*—which promotes knowledge about basic rights and empowerment (Gerster & Zimmerman, 2003; Weigel & Waldburger, 2004).

It was stated earlier that modern ICTs facilitate the creation, storage, management, and dissemination of information by electronic means much more easily, efficiently, and conveniently. Some of the desirable characteristics and attributes of these modern ICTs useful for poverty reduction include:

- a. **Interactivity:** ICTs are effective two-way communication technologies, which have drastically changed the way individuals, organizations, and enterprises interact. This is made possible by the fact that modern ICTs embody broad communication and processes of economics, social, political activity, and organization to empower citizens. At the same time ICTs increases transparency within and among societies, fostering empowerment and accountability (Sharma, n.d.; Spence, 2003).
- b. **Permanent availability:** The new ICTs are available 24 hours a day, seven days a week. For this reason they can be mainstreamed into our daily activities.
- c. **Global reach:** When ICTs are embraced in any socioeconomic activity, geographic distances hardly matter anymore. This has changed the shape of the socioeconomic activities. One of the impacts is in conditioning and changing the structure of markets, hence pushing the world towards globalization. This is true for the case of the Internet, which enables individuals in any country to participate in markets or activities beyond the immigration constraints determined by geographic locations (Sharma, n.d.).
- d. **Reduced per unit transaction costs:** Relative costs of communication have shrunk to a fraction of previous values and this effect has impacted on the cost of business transactions. Transaction costs have tended to rise with time, distance, and correlated variables, especially as the global economy has expanded and become more integrated. With modern ICTs, time and distance essentially do not matter. Therefore, the reduction in transaction costs can be larger in absolute and percentage terms than the rising trend. A good example is on long distance or international telephone calls vis voice over IP (VoIP) calls.
- e. **Creates increased productivity and wealth or value:** ICTs are value adders and amplifiers in products and services. In addition to lowering transaction costs, modern ICTs can be very liberating by enabling wholly new possibilities of creating wealth/value. For example, by making services previously difficult to trade or non-traded at all to become easily tradable—within countries and internationally. ICTs also are capable of untrapping the value of human resources or human capital (e.g., with local skills) by

marketing such capital globally than just locally, for example, in the case of outsourced jobs and offshore opportunities (Proenza, n.d.; Yonah, 1999).

- f. **Multiple sources of information and knowledge:** Modern ICTs embody a lot of knowledge, particularly if such ICTs include electronic networks. These embody and convey knowledge and in this sense provide important intermediate products and services and content in education, human, and social capital formation activities. In this context, it is a fact that the creation of knowledge and access to information is the basis of new prosperity. Access by the poor to high-tech opportunities empowers them with valuable knowledge and equips them with productivity skills, which is essential in any poverty reduction process. In this respect, poor people do not have a simpler set of living needs and aspirations, as may be assumed (Gates, 1999; Kao, 1996).

Despite these powerful attributes of ICTs, access to information using ICTs is determined by (a) *connectivity*—are the services available? (b) *affordability*—can the targeted poor users afford the access, and (c) *capability*—do the targeted users have skills required to support and utilise profitably the access? The user's skills relate to technical abilities, language, and literacy. Therefore, for ICTs for poverty reduction to succeed they need to be integrated and mainstreamed in the national development priorities and projects.

SHOWCASE EXPERIENCES

It is worthwhile to note that ICTs are impacting on all dimensions of life: education, health, quality of family, culture, leisure and arts, scientific and technological world. The way people do business globally is changing beyond imagination. ICTs are helping economies expand at an unprec-

edented rate and competitiveness has become the motto of the way. However, for ICTs, as tools of empowerment, to contribute to the poverty reduction initiatives, certain conditions have to be met. These relate to ownership, local content, language, culture and appropriate technology enabled by adequate functional basic amenities and connectedness, e.g. roads, electrical power, telephone, water, etc. Access becomes important only once these conditions have been met. Due to this requirement of connectedness most of the ICTs have an urban bias and discriminate against rural areas.

Since the 1990s, years of economic liberalization in Tanzania, there has been a large wave of investment in ICTs for development and some significant part of this has been aimed at poor people—both in terms of bringing ICT access to poor communities, and in using ICTs in many other ways which support poverty reduction. These investments have produced *many* documented successes, lessons learned, and experiences. Most of the documented materials on ICT projects are mostly sector and application specific covering multipurpose community access; access technologies amenable to poverty reduction; gender equality; education and human resource development; science, high-tech, and ICT-sector growth; business and livelihoods development and support; public sector, services, and poverty management; environmental and natural resource management; and transparency, accountability, and empowerment.

The many experiences that are discussed in the subsequent sections offer a lot of insight and value, though it is difficult to consistently maintain focus on poverty, and separate poverty reduction from broader economic development insights. However, it has to be noted that growth and development are necessary but not sufficient for poverty reduction; and also that pro-poor strategies and investments are as important for ICTs and knowledge-economy strategy as for other connected areas of social and economic development. This section uses some

of the material from publicly available websites carrying content about Tanzania.

Projects on Increasing Capacities and Opportunities

One of the many deprivations that compound the misery of the poor and prevent them from rising out of poverty is their lack of access to adequate education, training, skills development, broader information, and knowledge resources that could help them improve their lives and livelihoods. One of the show case projects on information sharing is the *Sharing with Other People Network* (SWOPNet) managed by the Tanzania Commission for Science and Technology (COSTECH). It may be found at www.swopnet.or.tz. The SWOPNet portal electronically brings together all owners of ICTs projects under one roof. The site is essentially very useful for publishing outputs from different research and development projects in the field of ICTs conducted within Tanzania.

It has been envisioned that education and knowledge helps the poor to improve their current livelihoods, address impediments and vulnerabilities that prevent them from seeking opportunities to improve their lives, and participate in new sectors of the economy that require advanced skills and, therefore, offer higher incomes. ICTs can help make educational institutions more efficient and responsive, both by improving communication flows within them and between them and their various constituencies; and by increasing their access to global knowledge and good practice in education. One of the most promising areas where ICTs can help improve education quality and outcomes is in teacher training. The Tanzania educational system is, in general, plagued by inadequate resources for teacher training and curriculum development leading to low quality of education. Creative combinations of the Internet (for content access and interactivity) and digitally stored training materials (including CD-ROMs) can dramatically increase both the *reach* and

the *yield* per unit cost of teacher training efforts. The government of Tanzania is making efforts to build strategy to integrate ICTs in the Tanzanian secondary schools (Menda, 2005b). There is also a showcase ICT project owned by the Ministry of Education and Vocational Training (MEVT) geared at integrating ICTs in Secondary Education and Teachers Training colleges (TTCs). These are the preferred entry points for integrating ICTs into the secondary education in Tanzania (more at www.pambazuka.org/index.php?id=26807).

Projects on Reducing Vulnerabilities

Poverty and illness go hand in hand and feed upon each other. Poor people are particularly prone to disease and illness.

There are several ways that ICTs can help to address the health challenges facing developing countries. First, the capacity to monitor, respond to, and thus hopefully control disease outbreaks and address their causes, can be significantly enhanced by improving communication flows and the information-management capabilities of health care professionals at community, district, regional, and national levels. In many cases, time is of the essence in responding to disease outbreaks, and faster communication and information gathering can often make a dramatic difference in how well an outbreak is contained. More generally, the ability of health care providers to assemble and share timely information about health trends and needs enables a country's health care system to adapt more quickly and allocate resources more effectively.

The government of Tanzania is ready to adopt ICTs in the provision of health services (International Institute for Communication and Development, 2004; Menda, 2005a), a commitment made recently by the Permanent Secretary in the Ministry of Health and Social Welfare, Hilda Gondwe, when officiating at a national roundtable workshop on the application of ICTs in the country's health sector. The workshop was organized by Chris-

tian Social Services Commission (CSSC) and financed by the Catholic Organization for Relief and Development (CORDAID) and International Institute for Communication and Development (IICD) (The Guardian, 2006).

Several show case projects that show how ICTs are being appropriated to realise health information system, to collect health data at village levels, and on child vaccination programs are reported at http://www.swopnet.or.tz/ws_projs.html.

Projects on Enhancing Government Capacity, Efficiency and Accountability

Government officials, and the institutions in which they work, are hampered in many ways by poor information and knowledge flows. They often have weak access to even basic current data about the issues and trends in the country. Information flows poorly within most government departments because of a combination of weak communications infrastructure, hierarchical structures, and rigid bureaucratic cultures.

In addition, government officials have limited information on global good practice, and few opportunities for consultation and collaborative problem solving with colleagues elsewhere. At the same time, citizens, entrepreneurs, and particularly the poor, often have limited information about their rights and the services available to them, about the structure and functioning of government agencies, and about procedures for requesting services.

ICTs can help in a variety of ways to address these problems. ICTs can be used to reorganize and speed up administrative procedures, to increase the volume and speed of information both within government institutions and between them and the larger society, to train government officials in global best practices, and to allow greater collaboration and sharing of experience among government officials both within a country and across borders. The government of Tanzania is

exemplarily active in appropriating ICTs to improve its e-readiness and the delivery of public services. The official online gateway of the United Republic of Tanzania is accessible at <http://www.tanzania.go.tz>. Information accessible from this site includes fully analysed population census data, and most of the government policies and presidential speeches are hosted at this site.

There are several other information gateway projects in the country, for example, the Tanzania Online Information Gateway at www.tzonline.org and the Tanzania Country Gateway project at www.tanzaniagateway.org. Collectively these Internet-based gateways give Tanzania a global presence. The gateways provide links to ideas and good practice, information about development activities and industry trends, funding and commercial opportunities. These portals provide and promote exchange and dissemination of information on development matters.

Another project is the Tanzania National Assembly (Parliament or “Bunge”) portal at www.parliament.go.tz. Acts, bills, and useful Bunge documents are readily available from this site through its Parliamentary Online Information System (POLIS). This Internet-based global presence clearly demonstrates that the Tanzania Parliament is appropriating modern ICTs to transform the Bunge from an old-fashioned institution to a new, modern, paperless electronic parliament. Furthermore, the Tanzania Investment Center website at www.tic.co.tz acts as the official investor’s guide to Tanzania.

ICTs can also play an important role in combating corruption and making government institutions more transparent, by reducing the opportunities and incentives for, and increasing the costs of, corruption. The most obvious role for ICTs is to “disintermediate” between the citizen and the services, procedures, and documents by automating and making widely accessible, many of the simpler procedures which have traditionally depended on the involvement of a local government officer. If a citizen can directly access a

needed form, acquire required documents, permits and certifications, or register a new small business, using automated procedures, the opportunities for corruption are reduced. ICTs can also empower individual citizens and groups to hold government officials publicly accountable. These efforts are evident from the TIC Web site www.tic.co.tz especially links to the Business Registration and Licensing Agency (BRELA); www.necta.go.tz for the National Examination Council of Tanzania; and www.isd.co.tz for the insurance supervisory department.

Projects on Participation, Empowerment, and the Strengthening of Civil Society

ICTs can play an important role in informing and empowering citizens and strengthening the capacities of a wide range of civil society organizations and institutions. This is important not only in increasing the demand for good governance and strengthening the voice of citizens in government policy, but also for promoting both the stability and responsiveness of the political system and for the economy and society as a whole.

By facilitating new forms of many-to-many communication, collaboration, and information-sharing, both within a given country and among groups with similar interests and concerns across borders, ICTs can add to the vibrancy of civil society institutions and networks as a check on government. They can also act as a source of ideas and innovations, and an outlet for the interests, concerns, and desires for solidarity on the part of individuals and groups. This will reduce the alienation of the poor from feeling isolated, powerless, and neglected. A contrast can be found between a physical rally meeting to the famous eThinkTank user group at www.eThinkTank.org focused on issues concerning ICTs. Another portal is at www.hakikazi.org, a civil society meeting place for sharing ideas promoting the rights of all people to fully participate on social, technical,

economic, environmental, and political (STEEP) issues. The portal carries a cartoon-based guide to popularize the PRSP (URT, 2000).

By definition, however, the poor have scarce resources, and the burdens of their daily lives often leave them little discretionary time to engage in activities designed to protect their interests and articulate their needs. Their limited education, and in many cases illiteracy, puts them at a disadvantage when faced with sophisticated ICTs that are not adapted to their most pressing needs, their modes of communication (including a frequent preference for oral communication), their cultural norms, and the social contexts in which they typically interact and pursue joint action. In such cases, community radio and video conferencing facilities (like that at the Tanzania Global Development Learning Center (TGDL—www.tgdlc.go.tz) become very appropriate.

Projects/Challenges on Appropriating ICTs for Income Generation

Economic programs implemented by the Tanzania Government have been based on the philosophy that Tanzania is committed to a market economy whereby the private sector will take the lead in creating incomes, employment, and growth. On the other hand, the State will be a producer of public goods, play a regulatory role to level the playing field, and create conducive environment for the private sector to take the lead in driving economic growth. The private sector has started playing an ever increasing role in creating incomes and employment. Small and Medium Enterprises (SMEs) account for a large share of the enterprises active in Tanzania. In fact, SMEs are the emerging private sector and do form the base for private sector led growth (Hakikazi Catalyst, 2001; URT, 2002, 2003a).

According to Drucker, there are eight key areas that constitute any business (Drucker, 2001), namely: *marketing, innovation, human*

resources, financial resources, physical resources, productivity, social responsibility, and profit requirements. Let us recall Gandhi's test for technology appropriateness: to "*find out how the last man would be affected by it*" (Gates, 1999). The authors, therefore, propose to apply Gandhi's test for the effectiveness of ICTs in each selected income generating activity by examining the impact of mainstreaming ICTs into the eight key business areas.

THE ULTIMATE CHALLENGE: TO FOCUS ON INFORMATION LITERACY AND NOT ONLY ON COMPUTER LITERACY?

The Tanzania Vision 2025 (URT, n.d.) would like to see Tanzania be a well educated and a learning society. What does this mean in relation to ICTs as tools for poverty reduction? It has been said earlier that ICTs are embedded in networks and services that affect the local and global accumulation and flows of public and private knowledge.

The authors hold the view that the government of Tanzania needs to focus more on information literacy rather than mere computer literacy. Information literacy is the ability to access, evaluate, and use information from multiple formats—books, newspapers, videos, CD-ROMs, or the Web. Information literacy is a set of competencies, skills that will grow with the people as the society evolves towards a knowledge society, even when current computer operating systems, search engines, or computing platforms and devices are obsolete.

To date, however, it has been observed that, in promoting the information society agenda, citizens and the government are still focused on technology. However, they must focus on increasing awareness of the potential applications; on improving the availability of and access to modern digital communications; and on encouraging people and organizations to use technology more

efficiently and effectively. It also has to advocate for policies that encourage and allocate funding towards the development of skills to use technology and improve computer literacy. This focus has been, and is still, invaluable. To really move into the information age and get benefit from the potential of a knowledge based society, it needs a new focus, that is, on the content that flows through the ICTs, a focus on information and knowledge, and focus on how to create it, manage it, and use it. To do this a new focus on information literacy is needed. An information literate person is one who (American Library Association, 2000):

1. Recognizes the need for information and determines the extent of the information needed;
2. Identifies potential sources of information, accesses the needed information effectively and efficiently from sources of information including computer-based and other technologies;
3. Evaluates information and its sources critically and incorporates selected information into his or her knowledge base and value system;
4. Recognizes that accurate and complete information is the basis for intelligent decision making, develops successful search strategies, then organizes information for practical applications and uses information effectively in critical thinking to accomplish a specific purpose;
5. Identifies potential sources of information and understands the economic, legal, and social issues surrounding the use of information and accesses and uses information ethically and legally.

Therefore, there is a challenge: how to ensure that the Tanzanian society becomes information-literate? It is the ultimate challenge to the government, public sector, private sector, development partners, and the whole Tanzanian community

though all of the society, that especially the poor people are flooded with information options on day-to-day basis.

CONCLUSION

Tanzania, like other developing countries, is confronted with the challenge of eradicating extreme poverty and hunger. It is acknowledged that the new opportunities which ICTs are opening up can be harnessed in Tanzania's efforts to eradicate poverty. The framework for appropriating ICTs for national development and poverty reduction is articulated in the National ICT Policy.

This chapter has attempted to enhance the understanding and knowledge of ICTs in relation to the National ICT Policy and has extensively explored the evolving frontiers of this pervading technology as it impacts on education, commerce, social, cultural, and economic life of the poor Tanzanian people. The chapter has also presented several show case examples of projects in Tanzania that demonstrate how the government of Tanzania, entrepreneurs, and some of the rural communities are appropriating ICT tools to fit into their needs. Some challenges have been identified and presented with the aim of stimulating debate to reflect on perspectives, trends, and potential of using ICTs to develop innovative approaches and methods for poverty reduction. It is emphasised that, since these ICTs are not solutions to social problems by themselves, they must be carefully chosen and implemented for each appropriate purpose. Overall, the chapter demonstrates that ICTs are a set of tools for knowledge sharing, which is a powerful means for poverty reduction. Further, it is shown that ICTs could only be tools of empowerment for those who have access to them. And that "I" (Information) and the "C" (Communication) are far more important than the various technologies which are just means to an end. Therefore, ICTs cannot turn bad development into good development; they can make good

development better. It all has to do with focusing on information literacy as opposed to just focusing on computer literacy.

Chapter 3.18

Information Technology Standards in China

Michelle Rowe

Edith Cowan University, Australia

INTRODUCTION

“If you want to access my market, you have to use my standards.” This seems to be the approach adopted by some in China and certainly is the line promoted by the Director of the Ministry of Information Industry’s research institute, Chen Yuping (Chen, 2004, p. B.1). Standards have been seen to be the cards available to China in its negotiations, given the desire of many multinationals to locate or outsource their businesses and operations in the Chinese market.

BACKGROUND

Many multinational firms have located in developing countries such as China to develop their overseas and industrial markets and to take advantage of low cost environments. Multinationals find it profitable to contract IT software and services in developing countries and many have done so in China.

China’s reform and opening up in the late 1970s gave the impetus to rapid economic growth. This reflects such outsourcing as well as its source of cheap labour, highly skilled workers, and modern factories. Increasingly domestic demand and the size of the Chinese market provide a growth mechanism for the economy and outsourcing enables access to this growing world market.

China’s entry into the World Trade Organisation no doubt will have an impact on accessibility of investors into the market and demonstrates the realisation of the globalisation of markets. This is especially the case in terms of IT, which has been a major player underpinning rapid growth occurring in the Chinese economy.

The Chinese computer industry has been a main player in the growth of electronic and IT industries in China. From January to October 2003 the Chinese computer sector achieved sales of 453.7 billion yuan (U.S. \$54.6 billion) (Info-Prod Research, 2003, p.1). This represented an increase of 64.7% and can be equated to a contribution by IT of 15% to a 34.6% growth in industrial sales in

the country for that period (Info-Prod Research, 2003, p. 1).

Gartner, Inc. anticipates Chinese demand for IT services to be an estimated U.S. \$25 billion and U.S. \$30 billion by the year 2007, a growth of eight times the present level of demand (Jen Lin-Liu & Singh, 2004, p. 26). No doubt the Beijing 2008 Olympics also will contribute to this growth and will lead to a greater presence of multinationals and increased investment in IT in the country (Xie Jia, 2004).

Advocates of globalisation focus on removing barriers to trade. However, where their interests potentially could be affected by global competition, they often seek to protect their interests. Nationalism takes over from globalism (Datt, 2004, p. 1). This seems to be the case in terms of IT standards in China.

STANDARDS

One of the ways China is striving to shift their position from assemblers to innovative firms that are able to compete internationally is to use its market size to create competing standards rather than allowing multinationals to create the technology, set the standards and control industry.

One such example of this is the attempts by Government and industry to establish critical technology standards regarding 3G wireless standards called TD-SCDMA, rather than adopting worldwide CDMA2000 or WCDMA standards.

This strategy sought to solidify China in the telecom-equipment industry. TD-SCDMA was hoped to guarantee Chinese manufacturers some role in the Chinese market as foreign corporations such as Nortel Networks Ltd, Royal Philips Electronics N.V. and Siemens AG were willing to form partnerships with Chinese firms-Datang Mobile and Huawei Technologies Co. Ltd.-to manufacture TD-SCDMA equipment.

However, China recently agreed to put on hold its wireless encryption standard that differed

from IEEE802.11 standard adopted world wide. This encryption technology was to be provided free to 11 Chinese national firms ranging from large players such as Huawei to smaller emerging players. What this meant was that after June 1, 2004 companies selling Wi-Fi equipment to China would have had to licence technology from one of these national firms and incorporate it into their equipment.

Why is multiple standards a problem? Technical standards ensure that, say, a CD bought in one country can be played on a CD player made in another. Standards typically are set by groups of manufacturers or, increasingly, by international organisations. If China enforces its own standards, companies would need to make special versions of products to sell in the Chinese market, adding cost and complexity (Chen, 2004, p. B.1). Compliance with multiple standards would have been onerous, hence the reaction from other players in the market.

China, in promoting its interests and in endeavouring to reduce reliance on foreign technology and multinationals, has attempted to “shake up the global standards game” (Chen, 2004, p. B.1). In setting its own standards China was seeking to strengthen its position in negotiating royalties or technology transfers which it has had to pay to use components and software developed by others (Chen, 2004, p. B1).

China, in attempting to enforce its own standard, was striving to use its “clout” as the factory floor of the world and as an emerging market, potentially being one of the largest wireless markets. It assumed that this encryption standard would be supported. The shelving of this standard was in the face of growing pressure from other players, including Intel Corp. and the U.S. Government.

Some observers see the need for the Chinese to emerge as leaders in setting standards through “inducement” rather than dictating terms (see Stevenson-Yang in Chen, 2004, p. B1). Failure to do so could lead to being “cut-off from export markets, international customers and collabora-

tion in technology” (see Stevenson-Yang in Chen, 2004, p. B.1). Some in the Chinese bureaucracy are taking a more flexible approach to the standards issue, underscoring the need to work in partnership with the international community.

China’s domestic market and its role as a major player in IT manufacturing has lead it to consider setting other standards, especially those that are compatible with standards already established. Examples of this are in the areas of RFID and video-compression technology. Partnerships with foreign companies to set standards potentially could benefit China to enable it to access new markets, and vice versa. It is understood Nokia is working with Chinese manufacturers to develop a standards for the next-generation Internet (Chen, 2004, p. B1).

Despite this decision it is likely that China will continue to promote its wireless encryption standards. Further work is being undertaken to draft additional standards regarding routers and other Internet hardware and software that deal with security issues (Chen, 2004, p. B1).

Nevertheless the issue remains one of “why should we follow established standards when we could design our own?”

KEY TERMS

3G: Third generation technologies. 3G is the generic term used for advanced multimedia wireless communication.

IT Standards: International standards that ensure compatibility of technologies produced throughout the world.

Multinational Corporations: A company that owns or controls production or service facilities in more than one country and so conducts business globally.

RFID: Radio Frequency Identification is a technology used to uniquely identify objects, often in transit.

Chapter 3.19

ICT and Distance Learning for Agricultural Extension in Low Income Countries

Colin R. Latchem

Open Learning Consultant, Australia

Ajit Maru

Agricultural Informatics Consultant, India

INTRODUCTION

About 2 billion people in low-income countries are dependent upon smallholding farming for their livelihoods. These are among the world's poorest people. Most of them lack land tenure and farm in regions with limited land and water resources. Many must cope with drought, desertification, and environmental damage caused by failed land reforms, large-scale monocropping, overgrazing, logging, destroyed watersheds, and the encroachment of new pests and diseases. They use only the most primitive of tools and they lack the knowledge and skills to improve their farming methods, value-add their produce, and compete in national and global markets. Many of these smallholder communities have been devastated by HIV/AIDS. In some regions of sub-Saharan Africa, food production has dropped by 40%, and

it is estimated that over the next 20 years, 26% of the agricultural labour force will be lost to this pandemic. And demographic and economic changes in the low-income nations are increasingly leaving farming in the hands of women, who lack the knowledge and resources to farm efficiently.

The Food and Agricultural Organization of the United Nations (FAO, 2000) stresses the importance of information and knowledge in achieving a food-secure world for present and future generations. There is a massive need for agricultural extension to maintain the natural resource base, for example, to help smallholders increase cropping intensities, diversify into higher-value commodities, and adopt new methods of natural resource management and integrated pest management (Swanson, Bentz, & Sofranko, 2003).

In its traditional forms, agricultural extension has aimed at transferring research findings to farmers through face-to-face training and farm visits. It has been top-down, limited in scope, and slow to change ideas and practices. The more recent approaches to extension are farmer-demand-driven (Lightfoot, 2001). They empower the smallholders to form themselves into learning communities, identify needs, trial proposed methods, and adopt, modify, or discard practices according to their findings. They do not depend solely upon information, ideas, and practices provided by agricultural researchers and extension workers. The farming communities are encouraged to share their knowledge and experience.

The major challenge lies in finding how to fast-track such extension programmes more widely and equitably. Because of their locations or other personal circumstances, many smallholders cannot currently access extension programmes. To make matters worse, many extension services are now being downsized, decentralized, privatized, or only made available on a fee-for-service basis, which puts them even further out of reach of the smallholders. There is, therefore, enormous need and potential for ICT and distance learning to be applied to expanding and strengthening agricultural extension in low-income countries.

TECHNOLOGIES AND METHODOLOGIES

ICT and distance learning allow training and information to be delivered far beyond the traditional catchments of the providers. They allow for interaction, negotiation and exchange as well as the transmission of content. By allowing rural communities to be contributors and communicators and not merely passive consumers, they have the power to really help to change hearts and minds (Richardson & Paisley, 1999; Mundy & Sultan, 2001).

A number of agricultural research and extension agencies are now adopting these newer approaches. Some focus on using technology to overcome the physical and communications barriers between researchers and extension workers, while others are concerned with developing the tools to provide the smallholders with access to databases, decision support tools, online discussion groups, advice, news items, etc.

It should not be assumed that computer, Internet, and satellite technologies invariably provide all the answers for this work. Connectivity, cost, and a lack of technical know-how and support are still major constraints within many farming communities. This is why the CTA (2001, 2003) concluded that what is needed is a mix of new and conventional technologies adapted to the specific needs, skills, and resources of the local communities.

Table 1 summarizes the nature, strengths, and weaknesses of the various technologies and applications that can be used in extension, and gives examples of their use.

FUTURE TRENDS

Combining the technologies and methodologies described above with demand-driven, participative, community-focused distance learning offers an exciting new paradigm for agricultural extension. Networks, programmes, and services can be developed to provide farmers with just-in-time education, information, and advice from multiple sources, regardless of where the providers or end users are located.

The overriding challenge is to achieve strong commitment and partnership by governments and public and private donors and service providers and ensure that their actions match the rate of technological change. If this can be achieved, there never need be any lack of access to training in farming and agribusiness, or too many communities to serve.

competencies (Lightfoot, 2001). Experts in agriculture need to adopt learner-centred approaches. Experts in ICT need to understand the particular requirements of extension. Rural organizations need to help find ICT-based solutions (CTA, 2003). Regional and local service providers need to help in translating programmes, materials, and support services into local languages, cultures, and agro-ecological zones. And, systems are needed to ensure that the education and information provided is timely, user-friendly, relevant, and available at the click of a button to farming communities, local radio stations, newspapers, NGOs, etc.

Some of these services will need government or donor funding. Others may have to be paid for by the communities themselves. The circumstances will determine the means (van der Stichele & Bie, 1997).

Like the CTA, the FAO (1997) cautions against depending upon the Internet as the panacea for development. The CTA (2003) stresses that the technical tools and solutions must be country- and location-specific, and Maru (2003) observes that technology-based approaches can only succeed where there is appropriate and localizable content and interaction and indigenous capacity to generate them.

Perraton (2000) observes that distance learning has met with failure as well as success in the developing world, and McLean et al. (2002) stress that no single model of distance learning is appropriate for all target groups. A distance-learning provision must therefore be carefully adapted to the social, cultural, economic, and political circumstances of the communities and their environments. Far more is needed than merely placing lecture notes, handouts, research findings, or PowerPoint presentations in English and using technical jargon on the Web or CD-ROM. The programmes need instructional design. They need to be:

- Developed in conjunction with, and disseminated to, multiple stakeholders (farm-

ing communities, extension workers, rural businesses, NGOs, schools, etc.)

- Interactive, multimodal, and multimedia
- Collaborative, with extension workers or local facilitators helping the smallholders to become motivated, master the technology and new learning, and apply and test the new or improved methods in the field
- Up-to-date, authoritative, and appropriate to the circumstances, expectations, culture, language, prior learning, literacy, and comprehension levels of the smallholders
- Designed for self-paced individual and group learning
- Dialogic, offering the smallholders opportunities to collaborate and share ideas and experiences with others who understand their circumstances and whose views they respect
- Simple to understand, easy to work through, and practically oriented
- Based upon both local indigenous and global knowledge and practice
- Appropriate to the technology, budgets, and time available to the providers and users
- Faster, cheaper, better, and more equitable than any of the alternatives

KEY TERMS

Global Positioning System (GPS): World-wide radio-navigation system formed from a constellation of 24 satellites and their ground stations that provide reference points to calculate positions accurate to a matter of metres, and with advanced forms, to less than a centimeter. GPS receivers are so miniaturized that they are becoming accessible to virtually everyone. Used in cars, boats, aircraft, construction equipment, farm machinery, and even laptop computers, they are predicted to become almost as basic as the telephone.

SMS (Short Message Service): Facility that allows short text messages to be sent to GSM (Global Systems for Mobile Communications) mobile phones.

Wireless Application Protocol (WAP): Advanced intelligent messaging service for digital mobile phones and other mobile terminals that allows Internet content to be viewed in text format on special WAP-enabled GSM mobile phones.

Chapter 3.20

ICT for Knowledge and Intellectual Capital Management in Organizations

Jacques Bulchand

University of Las Palmas de Gran Canaria, Spain

Jorge Rodríguez

University of Las Palmas de Gran Canaria, Spain

ABSTRACT

This chapter describes which information and communication technologies (ICT) can help in the process of managing knowledge and intellectual capital in organizations. We start the chapter examining the risks we face when we use technologies for knowledge management (KM) and for intellectual capital management (ICM). Once we have done this, we review the literature to see which technologies different authors mention; choosing then the most frequently cited ones. We classify these technologies in base technologies and technological applications, getting to a final number of 17. Each of them is then summarily described and its possibilities in helping KM and ICM are stated. The chapter ends by classifying all of them according to their utility in helping

in KM and ICM and in which of the processes needed in organizations for managing knowledge and intellectual capital they can be used.

INTRODUCTION

Since the 1960s, information and communication technologies (ICT) have been present in organizations. After some years in which organizations just used ICT to automate repetitive processes, an era begun in which ICT started to be used to process data in order to get information out of it: organizations that were able to carry out this process obtained a sustained competitive advantage over their competitors. But, obviously, and as it usually happens, after some time, all companies in one sector where obtaining the same kind of information using the same data as input and the

same ICT as tools, arriving to a state in which good use of ICT stopped providing a competitive advantage.

But in the last few years, a new opportunity has arisen in this area: the use of ICT to process knowledge and intellectual capital. This is a huge challenge for organizations. In fact, organizations that get to use ICT for these mentioned processes will once again obtain sustained competitive advantage over their competitors. In this chapter we examine which of all the technologies that belong to the vast amount named under ICT can be used for knowledge and intellectual capital management and in which of the processes needed to process these two items in organizations they can be used.

BACKGROUND

We start the chapter describing and analyzing technologies that serve as KM facilitators. In this section we review the literature on those technologies.

The first contribution that we cite is that of Bollinger & Smith (2001), who classify the tools that they believe facilitate KM processes into four types: hardware, software, collaborative work and intelligent tools, as shown in Table 1.

We can see that one of the groups, intelligent tools, comprises the tools that permit user needs to be anticipated and new knowledge to be extracted from existing knowledge. Therefore, the tools in this group are more interesting for KM although, as we shall see later, they unfortunately have the problem of a low present level of development, which is the reason why their diffusion is still in its infancy.

Table 1. Computer information technology tools for knowledge management

Tool category	Tool
Hardware	<ul style="list-style-type: none"> • Investment in IT • Networks • Intranet
Software and data-base tools	<ul style="list-style-type: none"> • Knowledge-based systems (KBS) • Collaborative hypermedia for documentation of discussions • Learned lessons databases • Data warehouses • Databases for classification, codification, and categorization of information • Storage of e-mail threads to create a repository of best practices • Corporate memory databases, also known as knowledge archives • Corporate yellow pages • Employee home pages on an Intranet
Collaboration tools	<ul style="list-style-type: none"> • Electronic meeting systems • Video-conferencing • GroupWare • Electronic bulletin boards
Intelligent tools	<ul style="list-style-type: none"> • Decision support tools using neural networks • Virtual reality • Genetic algorithms • Intelligent agents • Internet search engines • Knowledge mapping

Source: Bollinger and Smith (2001, p. 12)

Ruggles (1998) cites four technologies as being the most used in KM nowadays: Intranets and Extranets, knowledge repositories, tools to support decision making-and workgroup tools to support collaborative work

Wen Chong, Holden, Wilhemij, and Schmidt (2000) indicate that the most frequently used technologies are Intranets, knowledge repositories, search engines, workflow management tools, data warehouses, workgroup tools, document management systems and decision support systems.

Another author who cites ICT for knowledge management is Binney (2001), who defines a KM spectrum and classifies the applications and technologies according to their usefulness to the

management of each type of knowledge. That spectrum is shown in Table 2.

As we can see in Table 2, Binney (2001) believes that there are six types of KM, ranging from transactional KM to KM in the areas of innovation and creation of knowledge, via analytical KM, knowledge resource management, KM of the processes and development of an organization's knowledge capabilities. The order in *Table 2* is relevant since, from left to right, the theories move from the most technological theories to the most organizational, and the knowledge moves from explicit to tacit.

Junnarkar and Brown (1997) also examine the use of technologies for KM and, in the spiral that describes the knowledge management process

Table 2. Enabling technologies mapped to the KM spectrum

	Transactional	Analytical	Asset Management
Definition	The use of knowledge is embedded in the application of technology.	Interpretations of, or creates new knowledge from, vast amounts or disparate sources of material.	Management of explicit knowledge and intellectual property assets
KM Applications	<ul style="list-style-type: none"> • Case-Based Reasoning (CBR) Applications • Customer Service Applications • Order Entry Applications • Service Agent Support Applications 	<ul style="list-style-type: none"> • Data warehouse • Data mining • Business Intelligence Management Information Systems • Decision Support Systems • Customer Relationship Management (CRM) • Competitive Intelligence 	<ul style="list-style-type: none"> • Intellectual Property • Document Management • Knowledge Valuation • Knowledge Repositories • Content Management
Enabling Technologies	<ul style="list-style-type: none"> • Expert Systems • Cognitive Technologies • Semantic Networks • Rule-Based Expert Systems • Probability Networks • Rule Induction, Decision Trees • Geospatial Information Systems 	<ul style="list-style-type: none"> • Intelligent Agents • Web Crawlers • Relations Object DBMS • Neural Computing • Push Technologies • Data Analysis and Reporting Tools 	<ul style="list-style-type: none"> • Document Management Tools • Search Engines • Knowledge Maps • Library Systems
Portals, Intranet, Extranet and Internet			

Table 2. continued

in organizations (Nonaka, 1994), they identify a series of enabling technologies in each type of interaction. In *socialization*, they identify videoconferences and virtual and asynchronous conference systems; in *externalization*, electronic mail and distribution lists. In the case of *combination*, they name workgroup tools, IS, distribution of documents in electronic formats, Intranets and push technologies. Finally, in *internalization*, they identify data mining tools based on neuronal networks, simulations and visualization technology based applications, such as geographical information systems.

Another interesting point of view is that of Mentzas, Apostolou, Young, and Abecker (2001), who classify KM software according to whether the knowledge is considered a process

or a product (Figure 1). In the first case, KM is considered to be a social communication process, since the knowledge is possessed by the person that generates it and is shared through the interaction. Therefore, the ICT are used to transfer the knowledge and not to store it. In the second case, greater attention is paid to the documents containing the knowledge, and to the creation, storage and reuse of the knowledge.

Other authors who explicitly use the term knowledge technologies in their mention of technologies for KM are Meso and Smith (2000), who identify technologies frequently used in those systems and group them according to their function in KM. Thus, for the use of knowledge they cite workgroup tools, messenger tools, videoconference, push technologies, and technologies

to support group decision-making. In the case of searching for knowledge, they cite navigators and Web technologies, data mining tools, search and locate technologies and intelligent agents. For knowledge creation, they only consider intelligent agents suitable and, finally, in the case of packaging knowledge, they identify document management systems and intelligent agents. Of

all those technologies, the authors themselves consider that workgroup and Web navigators are the most prominent nowadays.

That ends our review of the principal works citing technologies for KM, in which it is clear that certain technologies are repeated on various occasions. The next two sections give more detailed descriptions of which of those technolo-

gies we consider the most important for KM, and classify them into two blocks: base technologies and technological applications (Table 3). The first group includes those technologies that are available in the market for any type of use and that can be employed in KM processes, although they were not conceived solely for that purpose. The other group comprises those packets formed by the combination of a group of basic technologies and those specifically configured for KM, although they may also have uses in other organizational areas.

Apart from the technologies and technological applications shown in Table 3, we have seen that the literature mentions many others that are not habitually used in KM, although we should not discount the possibility of their future applicability. Among those, we can refer to data analysis and report tools, trees of deduction and induction by rules, process modeling, probability networks, semantic networks, library systems, simulation technologies and cognitive technologies.

Dangers and Potential Problems when Using ICT for KM and ICM

We dedicate this section to analyze the dangers and potential problems that can arise from the use of technologies in knowledge and intellectual capital management. First of all, we examine some of the dangers cited by various authors. For example, from their experience in two practical cases, Swan, Newell, Scarbrough, and Hislop (1999) draw the conclusion that focusing the KM project on technical and infrastructural elements blinds those in charge to the social and cultural aspects. These authors state that these last two aspects are necessary to change the management of organizations in order to enable the development of a true and complete network of shared knowledge.

Chase (1997) agrees with that approach when he indicates that, in spite of the investments that organizations make in ICT and in training em-

ployees in its use, the best knowledge existing in the organization is not normally available in the right place, time or format.

Junnarkar and Brown (1997) consider that, although ICT constitute a key enabler of knowledge creation, they are insufficient by themselves to increase an organization's collective intellectual capital. In other words, ICT are necessary but insufficient for KM and therefore, Baker, Baker, Thorne, and Dutnell (1997) and Tiwana and Bush (2001) indicate that, for ICT to function as facilitators of communication among an organization's members, they require a structured framework that permits that communication to take place efficiently.

Sveiby (2001) indicates that a climate of internal competitiveness should not be created since, in this case, the knowledge to be shared is only that which adds no value, while Junnarkar and Brown (1997) consider that there are three key elements that would facilitate the use of ICT for KM. Firstly, standards of hardware, software and communications should be developed for the entire organization in order to facilitate the sharing of information and knowledge. Secondly, investments in ICT must be made according to the organization's overall KM strategy. Thirdly, multidiscipline workgroups of the organization's experts in the areas of organizational design, organizational development and technologies should be formed with the aim of developing a joint strategy.

Finally, we should cite Lueg (2000) and Lang (2001), who state that the area of application of ICT for information management, and especially for KM, is very limited since, if information is considered to be the result of man's interpretation of the data, the complexity of getting computers to perform that task can easily be appreciated. They also indicate that the problems lie in the present ICT and believe it necessary to redefine them and create new languages, categories and metaphors. For their part, Baker et al. (1997) consider that the technologies are especially valid to access explicit

knowledge since, for technology to permit access to tacit knowledge; it must be capable of solving problems related to the non-structure of this type of knowledge, to the impossibility of writing it and to the numerous interactions between the individuals involved.

Our opinion is in line with those contributions. We agree that the limitations of current ICT for KM may be overcome, on the one hand, by improving their capability to work with tacit knowledge, and attempting to improve significantly both the way in which they are used and the corporate approach to them, and, on the other, by selecting those ICT that really are relevant to the area and creating a bundle labeled knowledge technologies and applying them selectively.

BASE TECHNOLOGIES FOR KNOWLEDGE AND INTELLECTUAL CAPITAL MANAGEMENT

In this section we give a detailed description of the previously outlined technologies that are especially significant to KM. We first describe each of them and then define their specific contribution to KM.

Web Technologies

There are numerous technologies created around Web services and based on the use of HTML, its extensions and XML. Web technologies serve to access knowledge resources available on Internet or Intranets by using a Web navigator (Meso & Smith, 2000). These technologies are widespread for a variety of reasons, from which we can highlight their allowing simple development of KM systems, their flexibility in scalability terms, their simple use and their imitation of the way humans interrelate, by making the knowledge of others available irrespective of hierarchies, formal barriers and other aspects. We can include

the following technologies in this group of Web technologies:

- **Intelligent Agents.** Laudon and Laudon (2000) define these as programs that perform specific, repetitive and predictable tasks for a particular user for a business process or a software application. They are programmed to seek and find information relevant to the user based on his/her preferences. Some examples of these tasks are the deletion of junk mail, making appointments or searching for the cheapest travel tickets of interest to the user. The agents are not endowed with great intelligence but they do hold a significant amount of information about their owner. Search Engines. Search engines comprise a series of programs that permit the location of documents that meet certain of a wide range of criteria. The searches can vary from the very simple to the highly complex.
- **Push technology.** This technology consists of providing the user with the information required, thus avoiding the need to search for it on the Web. The user indicates the type of information required (sports, weather, etc.) and the software warns the user when it locates something interesting that is available to the user (Laudon & Laudon, 2000). In that respect, the syndication technologies and reception of feeds in RSS format are currently enjoying great success. To be specific, that is a shift from a proactive user to a system of proactive sources that provides the user with the requested information. In the case of KM, the main use of *push* technologies is in their ability to make a selective diffusion of knowledge.

Databases, Data Warehouses and Mining Tools

A *database* is a set of data organized to service a series of applications efficiently by centralizing

the data and minimizing their redundancy. When databases contain a large amount of static data, in other words, data that is not frequently modified, for example, historical data, they are called *data warehouses*. *Mining tools* serve to analyze a great quantity of data normally contained in a database, searching for patterns that can be used to guide decision-making and to predict future behaviors (Laudon & Laudon, 2000). The three described elements are initially thought of for data management but may also be used in information and knowledge management, providing that the latter is explicit. That is why some authors speak of *knowledge repositories* instead of using the term data warehouses.

From the point of view of KM, databases and knowledge repositories capture the explicit codified knowledge present in different organizational levels. In other words, they are used to store and make available what we know of the organization. That task is supported by mining tools, which are able to collaborate in the knowledge generation process (Bhatt, 2001).

The main problem of those repositories is that they usually lack contextualization, meaning that the users have to make a significant interpretation; in other words, the repository contains information and not knowledge (Bhatt, 2001). Some repositories aim to integrate the maximum possible content when information is captured, thus permitting the storage of resources complementary to text, such as images, audio and video. In any case, it is clear that there is the limitation of their only being able to capture and represent a fraction of the knowledge and intellectual capital, namely, the explicit knowledge (Quintas, Lefrere, & Jones, 1997). In spite of those problems, repositories facilitate the maintenance of the organization's shared intelligence and historical memory (Ruggles, 1998).

These technologies have a highly promising future in KM processes since they will participate in the vast majority of associated processes, namely, the creation, codification, application, validation, protection and distribution of knowledge.

REAL WORLD IMITATION TECHNOLOGIES

In recent times we have witnessed the appearance of a series of technologies whose objective is the development of systems that simulate the behavior of entities in the real world, be they human humans, cell groups or social systems. In this section we examine some of them.

Expert Systems. Expert systems are systems dedicated to the capture and codification of the knowledge and wisdom of a human expert in specific domains (Laudon & Laudon, 2000). They belong to the area of artificial intelligence and their functioning comprises three distinct phases. In the first phase, they convert the experts' tacit knowledge into explicit knowledge in the form of IF...THEN... rules until a rule base is created. In the second, faced with a determined situation, they are able to arrive at a valid result by using a minimum number of context-relevant questions for the user to answer, thus advancing in the search for the result. In the final phase, they are able to explain how they arrived at a solution, thus enabling new, apprentice experts to absorb that tacit knowledge by transforming it into tacit knowledge.

Their area of application is limited to situations where we have one or several experts to help us in the creation of the expert systems. However, those experts are not sufficient in number to be present wherever and whenever decisions are made. The expert system helps users who are not experts but who have a certain basic knowledge of the issue to be resolved. According to Hornik and Ruf (1997) expert systems allow training costs to be reduced, albeit in exchange for high initial investment in their development. Those authors also show that knowledge is transferred to a greater extent with expert systems than without the aid of this type of tool. In any case, the ideal way of using this type of system is in combination with analogue techniques (principally contrasts and reflection)

so that, on the basis of the problem posed by the expert system itself, it is the learner who thinks and not always the expert system that answers the questions.

Two areas where they have been successfully applied are health and finance. In the health area, their use is based on codifying the diagnoses of diseases and their treatments in a system that is later used by a doctor to aid him/her in relations with the patient. In the financial field, the most common application has been as an aid in granting loans and in conducting audits (Hornik & Ruf, 1997).

Genetic Algorithms. Genetic algorithms, also called adaptive computing, refer to a set of techniques that use the conceptual model of the adaptation of living beings to their environment as a method of survival (Laudon & Laudon, 2000). One of the principal advantages of these algorithms is that they are able to solve problems in which individuals are unable of understanding its structure (Holland, 1975).

Genetic algorithms are particularly indicated for product optimization and the design and monitoring of industrial systems. For example, in business environments the need for optimization (minimization of costs, maximization of profits, efficient allocation and use of resources, etc.) is usual in complex and turbulent environments (Laudon & Laudon, 2000), which is precisely where they are seen to be more useful.

Since this is such an incipient technology and is in a phase that we could call embryonic, its use in KM is still rare, although it is foreseeable that, in the not too distant future, genetic algorithms will become increasingly important in the same areas as expert systems and even in some areas where the latter display little utility.

Neuronal Networks. A neuronal network is a set of software and hardware that attempts to imitate the process patterns of the human brain. These networks have been attracting great at-

tention recently since, as Laudon and Laudon (2000) indicate, we are witnessing a resurgence of interest in approximations of artificial intelligence that are based on an approach in which machines are designed to imitate the biological process of thought.

The neuronal network approach differs from that of expert systems in that neuronal networks are able to understand, but not to explain, how they came to a specific conclusion while the expert systems, being based on rules, are always able to explain their method of working.

Their use is centered on the resolution of problems related to the classification of patterns, predictions, financial analyses, control and optimization, all of which are applications in which the importance of the knowledge is very high. Normally, their aim is to help a human, not to replace him/her.

Computer-Based Learning

Learning is fundamental to an organization's ability to execute KM processes. As we have seen in the previous sections, the two concepts are intrinsically linked since, to be able to manage knowledge, it is essential to have suitable conditions for learning to take place (Mellander, 2001).

Computer-based learning is that set of technologies designed for the worker to access organizational knowledge about ways of doing things from his/her computer whenever he/she wishes or needs, instead of attending training courses planned by the organization itself or by the organization charged with providing the information.

There are two principal advantages to using this type of system (Trodsen & Vickery, 1998). On the one hand, concepts are retained better when they are applied directly and immediately. On the other, it improves knowledge transfer since it has been shown that students learn faster in a risk-free environment, with no fear of being seen to make

mistakes or of teachers or colleagues discovering their ignorance.

Work and Document Flow Management

Work and document flow management consists of analyzing the sequence of tasks and documents involved in executing a business process and creating the necessary mechanisms for the transfer of documents and information to take place in the most automated way possible under some procedural norms (Laudon & Laudon, 2000). Sometimes, workflow management is also called document flow management.

When these systems are used to automate the transfer of documents, with pre-established rules and no value to the firm, between administrative assistants, their contribution to KM is quite limited. However, when the analysis achieves the definition of the set of business rules, and even permits its management, we are performing tasks of knowledge codification, validation, creation and distribution. As in most of the described KM cases, for this process to be executed correctly, there must be a series of standards and classifications referring to the basic concepts of the business (Sveiby, 2001).

Geographical Information Systems

Geographical information systems (GIS) are tools designed to analyze and display data on maps of a geographical or other nature (Laudon & Laudon, 2000). Their capabilities include those of combining, storing, manipulating and representing information with geographical references (georeferenced information).

From the KM perspective, the main use of geographical information systems is the creation of knowledge by locating patterns of behavior in the data by spatially visualizing it. Just as data mining tools look for patterns by means of numerical analysis of data, these tools enable humans

to be the ones that look for patterns by means of spatial analysis.

The future development of this technology will be to create geographical data mining tools that are able to contextualize the data geographically and then look for significant patterns in those data. However, we believe that the development of this type of tool will take quite a time: that is, until numerical data mining reaches a point of maturity that permits its application in other contexts.

Knowledge Maps

A knowledge map is a diagram that shows the knowledge available in an organization. It allows fast and efficient location of information relevant to decision-making and problem-solving. Moreover, it is a directory that describes a series of categories of specialized information and indicates where it can be found, and its state, value and utility.

According to Ruggles (1998), it is evident that a great part of organizational knowledge can not be codified; it remains in the minds of experts. Therefore, it is important to be able to locate those experts through these maps and to know what knowledge they possess. Ruggles states that there are several reasons for the complexity of constructing the maps. On the one hand, someone must determine who in the organization knows the most about a topic. That task is complicated; not only in terms of locating the subject who meets that requirement, but also because of the possible problems among other workers who may feel undervalued. On the other hand, true experts are not normally interested in being easily located by anyone in the organization, especially if there is not a system that rewards them for the additional workload involved.

We find the use of these maps in the distribution and creation phases of KM. They permit concepts to interrelate, thus easily defining a common language by observing the different maps and checking the meanings of a particular term in each of them.

Workgroup Tools

Workgroup software, or groupware, refers to software that includes functions and services that facilitate the collaborative activities of geographically disperse workgroups by permitting the users to interact and share structured and non-structured information (Shani, Sena, & Stebbins, 2000), thus facilitating the creation of systems to aid decision-making (Meso & Smith, 2000).

Many workgroup software options are available on the market. These packages usually include a series of applications aimed at managing the following aspects:

- *Meetings of physically disperse groups* (Bollinger & Smith, 2001), either through visual systems such as videoconference, or through textual tools such as chat.
- *Information sharing*, which is achieved through the exchange of electronic messages between members of a group, with the messages stored by topic, making it possible for every member to access everything that has been said about any topic. Similarly, it is possible for several group members to work on a document because it enables all members to access the document and make modifications that are clearly displayed.
- *Electronic agenda* of group members and the resources they have available. Those resources include the management of common resources such as meeting rooms or equipment, while also permitting meetings between group members to be arranged according to their availability.
- *Electronic mail*, a tool that has previously been described, the only difference being that, in this case, the application is included in an overall system.

As in the case of Web technologies, and since workgroup technologies are available to every organization, we cannot consider them to be pro-

viders of strategic resources although they could become so depending on the use made of them and the contents inserted into them.

TECHNOLOGICAL APPLICATIONS FOR KNOWLEDGE AND INTELLECTUAL CAPITAL MANAGEMENT

Having analyzed the principal technologies used in KM, either as direct contributors to the processes, or simply as supports in their development, we now describe the most common KM technological applications that use the technologies described in the previous section.

Data Warehouses

The term data warehouse is used to refer to the combination of a database management system, a series of mining tools and a set of current and historical data of potential interest to an organization's managers (Laudon & Laudon, 2000). Those data are standardized and consolidated for the firm as a whole so that the joint analysis of the data of the different areas is possible. The data are available to everyone with access to the warehouse, with no modification to the data permitted.

The main utility of these data warehouses lies in their enabling quality information for decision-making to be obtained (Boar, 2001) by facilitating the extraction of knowledge from operational level databases by manipulating them until what was being sought is found. That extraction is conducted with data mining tools.

From the point of view of KM, data warehouses are also interesting because, to a great extent, they facilitate the distribution of knowledge, permitting all the organization's components to have access to the strategic data that they need for their work.

Help Desk Tools

Help desk services are those which users of a product or service can contact (normally by telephone) when they have a query regarding the installation, set up, use or functioning (e.g., technical assistance in ICT related issues). The objective is to combine a series of resources in such a way that incidents are resolved by optimizing the resources, and customer satisfaction is achieved (Wen Chong et al., 2000). The term help desk can be used both for services provided internally in organizations and for services provided to external customers.

Since these are services whose objective is to assist and satisfy the customer, in many cases they include such diverse concepts as business resource management, customer relationship management (CRM), call centers, sales force automation (SFA) and front and back office solutions.

The knowledge used in those applications is complex since it has to be vast and at the same time deep in order to meet all requests. Therefore, the use of KM in technical assistance services leads to a series of advantages (Davenport & Klahr, 1998), such as higher quality solutions given to customers, consistency in the responses, a higher proportion of problems resolved on the first call without having to escalate the problem to a higher level, lower cost per call, fewer calls to the support service and lower total costs, the possibility of having less technical, more user-oriented, staff, speedier learning and improved staff satisfaction.

Decision Support Systems

The term *decision support systems* (DSS) was first coined by Peter G. W. Keen and his collaborators at Massachusetts Institute of Technology in the mid-1970s. According to Keen and Scott-Morton (1978), DSS are based on four basic characteristics:

- The point of attention is not the operational level, but the resolution of the managers' specific problems, whether in their repetitive tasks or one-off tasks.
- The objective of the system is to support decision-making and not to replace the decider.
- The system comprises the person responsible for management and the technological mechanisms that permit a conversational interactive functioning.
- It is a support system that must be conceptualized more as a service that grows and evolves as the user learns and adapts, than as a finished product.

In practice, DSS are the result of the combination of ICT with operational research and business science, giving rise to generalized or specifically designed interactive models that are frequently of the "what if" type and intended to support decisions that are not completely structured in any level of the organization.

DSS are very useful in organizations wishing to improve their workers' capacity to make decisions, by making available the wealth of knowledge existing in the organization. Wisdom is collected from those who know about different subjects, transformed into rules and guides and made available, usually by means of ICT, to the organization as a whole (Ruggles, 1998). The possibility of making better decisions is one of the main reasons behind setting KM projects in motion (Wen Chong et al., 2000).

Discussion Forums

The term discussion forum is used generically to refer to any type of system of online bulletins where it is possible to post questions or messages in general, and find answers from others who read the forum. They usually include the option of accessing the forum with the sole purpose of reading the contents without actively participating.

Various organizations have attempted to implement the approach of creating a space for these forums on the firm's Intranet, with the idea that the workers use them as a place to exchange their ideas and experiences and to resolve their most common queries. Unfortunately, that type of approach is not usually successful (Shani et al., 2000), since the workers are normally reluctant to air their queries in public and in writing, on the one hand, and to answer their colleagues' queries, on the other.

Intranets and Extranets

An intranet is a private network in which Web technologies are used for communication between members of an organization, and which is protected from outside access by the use of passwords and firewalls (Laudon & Laudon, 2000). An Extranet is an Intranet to which access is granted to a limited group of external users and organizations, such as partners, customers, suppliers and collaborators in the distribution channel (Cothrel & Williams, 1999). In what follows, we only use the concept of Intranet although all the statements could equally be applied to extranets.

Not every intranet project should be thought of as a KM project; however intranets are frequently used to permit access to knowledge and to exchange it within the organization (Ruggles, 1998). Despite the apparent evidence about the utility of an Intranet, the reality seems to be quite different. Thus, authors like Cornellá (2001) indicate that it is common to find organizations shocked by the little use made of their Intranet and the low impact of Intranet on the generation of outcomes despite the significant investment that it represents. That situation is especially serious if it is considered that the objective of the intranet is precisely the exchange of knowledge between members of the firm.

According to that author, the answer lies in the fact that every *digital space* (a set of information and technological exchange tools) invariably needs

a *social space* (a series of motivation, incentive and recognition mechanisms that stimulate people to make use of the digital space) and that this need has a multiplicative format, so that, if either of the two is absent, the result is zero, irrespective of the strength of the other.

Yellow Pages

Corporate yellow pages are databases on experts: a place in which the specialty areas of all the organization's members figure. One of its simplest applications is to locate experts in a determined field. The function mechanism of yellow pages is very simple: the management defines the areas of interest to the organization's functioning and the relevant workers declare themselves experts in the different areas.

As in the case of previously mentioned technologies, it is necessary to have reward systems linked to the use of this tool otherwise workers will not register as experts in any aspect because it would entail an additional workload. From the point of view of KM, the main interest in yellow pages is their contribution to the application and distribution of knowledge in organizations.

Knowledge Portals

A knowledge portal is a Web page containing a series of intelligent agents necessary to locate on the Internet information that is important to us.

Knowledge portals were conceived with the idea of them becoming the brain of the organization and providing its workers with the vital information needed for success in the hypercompetitive markets (Kotorov & Hsu, 2001), thus guaranteeing the survival of the organization.

Those authors believe that one of the problems is that, with the cost of publication practically nil, there has been an avalanche of content that has caused the cost of finding valid information for decision-making to soar. Knowledge portals

represent a possible solution to that problem since they locate on the Web what the user needs.

However, for information to be valuable, it must not only be relevant, it must also be timely, exact, verified and suitably presented. We have already seen that intelligent agents are ideal for locating timely and relevant information but they are unable to participate in its verification and presentation. The problem of verifying information is especially serious when the source is Internet, where any rumor can become reality in a very short time, regardless of whether it is true or not.

In short, knowledge portals are applications of special interest in KM, since they permit access to knowledge in a simple, automated way, even when faced with high levels of uncertainty and an avalanche of information. However, they do have their limitations, one of the most significant being their inability to verify the information.

CASE-BASED REASONING

Expert systems capture and codify the knowledge of expert individuals, but organizations also possess collective knowledge that has been accumulated over the years. *Case-based reasoning* (CBR) systems are useful to capture and store that type of knowledge.

Their working mechanism is based on storing descriptions of the experiences of human specialists in the form of cases in databases, to be retrieved when a situation that is identical or similar to a stored experience occurs. Once the most similar case is located, new parameters are applied and, if possible, the solution to the old case is adapted to the new case. If the outcome is successful, the new case is also stored in the repository (Laudon & Laudon, 2000). In other words, adapting the solutions of previous problems solves new problems.

While the functioning of expert systems is based on a set of IF-THEN, IF NOT-THEN rules, case-based reasoning represents knowledge as a

constantly expanding combination of cases. These systems comprise four elements: a dictionary of resources used, a cases base, the resources to find similarities, and the resources to adapt the solutions (Richter, 1995). As previously mentioned, their contribution to KM is based on their capturing and applying organizational knowledge. Therefore, we can say that they participate in the codification and application phases.

DOCUMENT REPOSITORIES

The objective of document repositories is to capture knowledge and pass it to documents that the entire organization can use later (Davenport & Völpe, 2001). According to those authors, repositories are the most common type of KM and usually contain different types of knowledge: about the best practices carried out, sales management, lessons learnt during the development of projects or products, putting IS into motion, intelligence for the strategic and planning functions, and so forth.

Repositories may be official (edited, vetted and approved by management) or not. A portal is usually created to permit simultaneous access to several repositories. Many of them contain pointers to the experts in each document, thus creating yellow pages of knowledge at the same time.

Davenport and Klahr (1998) point out that one area in which repositories are normally used is technical assistance for users. However, they also state that, although the knowledge is stored on electronic documents, performing a search in all of them is not a valid option because it takes too long while the user is on the other end of the line. In seeking a solution to that problem, Tiwana and Bush (2001) propose a system of star-rating the documents according to the perceived usefulness of each of them, so that the most useful documents appear in the search results before those that are less useful.

CLASSIFICATIONS

After the review of the principal technologies and technological applications currently used in KM, this section classifies them according to their utility and the KM processes in which they play a part.

Utility

In Figure 2, we show the relationship between the current utility of the mentioned technologies for KM and the actual use that organizations are making of them. It should be borne in mind that the use being made of them is measured as a whole and not only for their use in KM.

Dividing that figure into four quadrants, we examine each quadrant in turn, starting at the top-right and moving in an anti-clockwise direction. The first group contains the high-utility, high-use technologies comprising Web technologies, work-

group tools, databases, repositories and mining tools, and work and document flow management tools. These are the elements available to organizations wishing to conduct KM processes. The only aspect that needs developing in this group is a more intensive application of the technologies in KM, especially in the cases of databases and workflow management tools, which are currently used in the resolution of operational and routine tasks that do not really contribute much to KM.

The second group contains the lower-utility, high-use technologies; comprising computer-based learning and geographical information systems. Given the lower utility of the technologies in this group, the actions to be taken should be on the lines of discovering whether it is possible to use these technologies to a greater extent for KM. The third group, the low-utility, low-use technologies, is empty because no elements meeting those two conditions were included in the technologies under consideration.

Figure 2. Utility and current use of the different technologies in KM

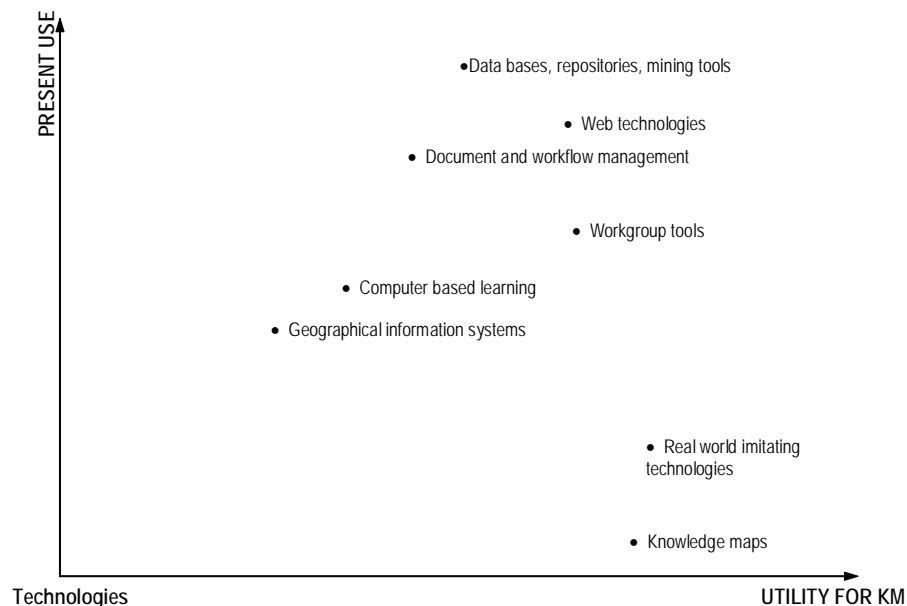

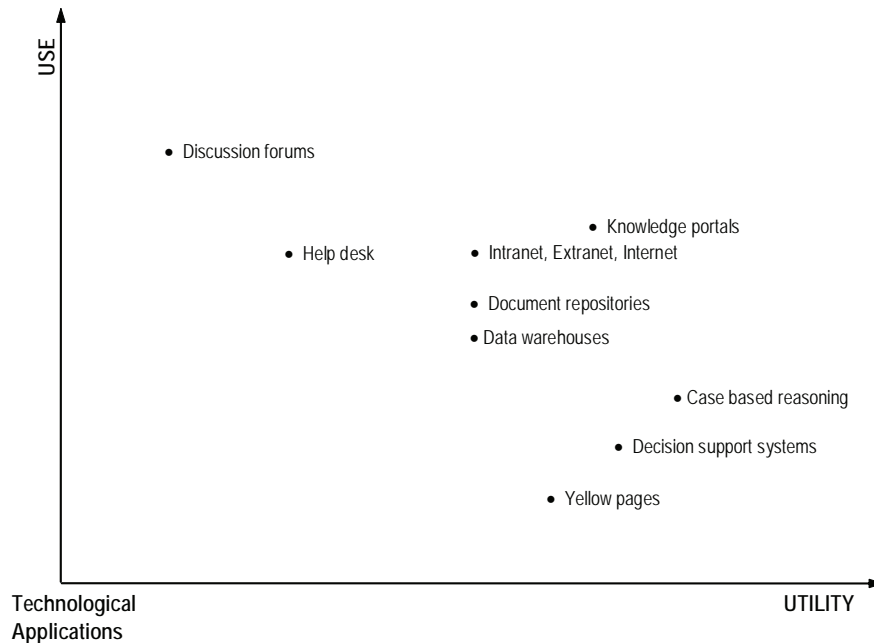

Figure 3. Utility and use of the different technological applications in KM

Finally, we come to the group with the highest potential for development: the high-utility, low-use technologies. This group comprises the real-world imitation technologies and knowledge maps. It has been confirmed that experiences of these technologies in the field of KM have been positive; therefore, we consider it advisable to intensify research into these areas, both in the technologies themselves and in their applicability to KM.

Figure 3 is similar to the previous one, but for the technological applications. Once again, we analyze the quadrants in an anti-clockwise direction. The first quadrant contains a series of high-utility, high-use applications comprising data warehouses, document repositories, Intranets and Extranets and knowledge portals.

The second quadrant refers to low-utility, high-use applications, in which we include discussion forums and help desk systems. The former have been in use since the early days of Internet in

the 1970s, although rarely for KM-related tasks. The latter are generally proposed with the aim of managing knowledge, although that has been accomplished on only a few occasions. Their diffusion is relatively widespread, but we believe that by themselves they can not properly support KM processes, and that applications such as case-based reasoning are required.

As in Figure 2, the third quadrant, high-utility, low-use, is empty. The fourth quadrant contains the group of applications with the greatest potential: those that we consider to have high-utility for KM processes, but whose actual use in those processes is low, either because they are still in the development phase, or because the results of tests that have been conducted were not as positive as expected. These applications are case-based reasoning, decision support systems and yellow pages. Therefore, we propose that future research focus on those three applications and the two previously mentioned technologies,

namely, real-world imitation technologies and knowledge maps.

Knowledge Management Processes

We also consider it interesting to classify the contribution of the different technologies and technological applications to the various basic processes related to the knowledge existing within an organization. To that end, we use a chart containing seven processes: creation, codification, validation, distribution, protection, updating and application.

Table 4 shows that the technologies contribute most in the codification and distribution processes, which was logical to predict, since they are the two areas where technologies display significant advantages over other means. However, they also have the ability to collaborate in each of the other five processes, albeit to a lesser extent.

In the previous section, we also indicated the contribution of each technological application to the seven processes necessary for KM. We use that information to produce Table 5.

The results shown in Table 5 are similar to those in Table 4, but with differences in the support given by technological applications to the knowledge application processes, on the one hand, and the near absence of applications that aid the creation and updating phases. That situation is normal since it is precisely those two processes that depend most on the human component.

FUTURE TRENDS

It is logical that the study proposed here should be, and is, in a state of constant evolution. Since what is being proposed is the possibility of defining a group of knowledge technologies, the evolution

of participation of these and other technologies in KM and ICM in organizations will have to be seen.

CONCLUSION

The principal conclusion that we can draw from this work is that the participation of ICT in the KM and ICM processes can be significant, especially in the management of explicit knowledge and under determined organizational circumstances. We should not fall into the error of thinking that two components of the organization as complex as its knowledge and intellectual capital can be properly managed with ICT alone. However, we can be sure that, with ICT, those processes can be facilitated and greatly improved. Moreover, it is foreseeable

that, in the near future, other technologies based on those mentioned in this work will appear, and they will be technologies that enable further development of this applicability since they will be conceived more specifically for that purpose.

Chapter 3.21

Digital Business Portfolios: Categories, Content, and Production

Eleanor J. Flanigan

Montclair State University, USA

Susan Amirian

East Stroudsburg University, USA

ABSTRACT

Developing an innovative and original professional digital business portfolio and keeping it updated is one of the most effective tools that can be used either by the business professional or by the student emerging into the business world. It constitutes a lasting comprehensive experience for both groups. Continual reflection upon their work arms students and business people alike with more confidence in their own competence and worth as they embark on their professional careers or justify their desires for advancement. This article will confine itself to the types of portfolios used most frequently in the business world or in preparation for entering a career, showing that content in each can be cumulative or separate. It will describe ideas for the types of artifacts to compile along with how to format them effectively and digitize them creatively. It will give answers to why to create a portfolio,

who should have one, what should be in it, and how portfolios are created.

INTRODUCTION

Many people are oblivious to the structured paths that lead them from one level of knowledge or one career path to another. Unless they are unusually reflective and deliberately trace their intellectual growth, most people move along and go with the flow of daily living and daily work needs. Whereas professionals keep pace with new requirements placed upon them, students move ahead according to a required college curriculum, taking the prescribed courses as directed. Both groups, however, accumulate valuable experiences along their paths.

Students find that as graduation approaches, preparing comprehensive resumes requires them to sum up their achievements and experiences.

This is usually an onerous task. Rather than waiting until the end of the program, it may increase the students' abilities to comprehend the path of learning if they have to collect and preserve their work in a creative accumulative project, reflecting and assessing during the process.

Business people are certainly aware of keeping their resumes up to date, although they may not do this until some employment crisis forces them to reflect and to report on their accomplishments. Annual job assessment reviews often prompt scrambling through papers or memories of the prior year to compile a report for the desired salary raise or promotion.

Developing a creative portfolio also can help to guide writing a creative resume. Overall, declarations in resumes are strengthened by providing concrete examples of competencies and skills attained. Statements on the resume can be linked to the portfolio artifacts to show specific examples of projects or supporting documents for claims made by the interviewee. This is "show and tell" brought to life by the creator of a digital portfolio who not only proclaims that he or she knows about technological advances but can put them into practice, using them for creative enhancement of the traditionally static resume.

PORTFOLIO OVERVIEW

Although comparatively innovative in business settings, structured portfolios are not new to many other disciplines. Their uses vary, depending on their purposes and their intended audiences. Whereas self-reflective portfolios serve as journals or organizers of activities and experiences, academic portfolios show student learning and progress or the development of skills. Professional portfolios are used in career determination or assessment of accomplishments as well as serving as demonstrations to validate claims of professional development.

Some portfolios consist of one's own work, while others, such as teachers' portfolios, incorporate the tasks they developed for their students along with evaluations, exemplary projects, or external and internal assessments.

Another definition of portfolios is common in the financial world. There, a portfolio is a collection of monetary assets reflected in stocks, bonds, real estate, and personal possessions. Reallocating and shifting these assets for optimal return is the task of financial analysis. Borrowing from this description of an asset portfolio, another way of summing up one's assets is by evaluating a collection of one's personal achievements. These assets are perhaps more precious than mere monetary accumulations. It takes a lifetime of work to acquire educational, professional, and personal assets. Enhancing this theme of portfolios as a collection of assets, Poore (2001) considers a person's business career as a portfolio of well-chosen investments.

DIGITAL PORTFOLIOS

Digital business portfolios basically are collections of artifacts used to validate claims made by the creator. These artifacts are in a creative variety of formats: text documents, Web pages, presentations, research papers, assessment instruments, original projects, academic or external teamwork, internships, performance videos, certificates of achievement, spreadsheets, databases, digital images, and multimedia demonstrations. These digital portfolios serve the business student population as well as business professionals, encouraging them to look critically at their work and to analyze it objectively. Using concrete examples of their achievements and growth, portfolio developers create technologically creative resumes with the portfolio artifacts to support statements of proficiency in their chosen fields.

In short, a portfolio is a demonstration of skills and abilities containing evidence of growth and competence. Portfolios can be learning tools, job search tools, and career growth tools. The purpose of the portfolio to some degree dictates the artifacts collected as well as the format of the design.

TYPES OF DIGITAL PORTFOLIOS FOR ASSESSMENT, JOB SEARCHES, AND INTERVIEWS

Learning and Assessment Portfolio

Students create portfolios as part of classwork for assessment or for tracking their growth during their academic careers. While collecting the artifacts of learning, students realize that they have concrete evidence to support their perceptions of their own development. Their belief in their own growth is given support by looking objectively at the increasing complexity of their projects. Their self-assessment is substantiated by recognizing how their knowledge base changed, comparing the artifacts from the beginning of their studies with the more sophisticated projects done toward the end of their academic years.

This reflection on one's work prompts another important area: developing the ability to be objective when assessing both the quality and/or quantity of materials used in the portfolio. Nicholson (2004) considers self-reflection as "the first step in knowledge construction" (p. 322). With encouragement from a teacher/mentor, the students have a chance to reflect upon their progress, do remedial work, and plan their paths for continued growth.

Students also find portfolios invaluable when pursuing internships or employment at the conclusion of their program. Learning portfolios preserve artifacts that later can become part of career portfolios. Thus, the initial portfolio is done as a student provides a base or example for any future

portfolio development. At many points in a work career, the employee frequently pursues further skills or education in a full degree program, a certification, or even a workshop. It is important that these achievements be documented to demonstrate growth or achievement to the employer. So, the portfolio is the constant base ready to receive and preserve new artifacts.

Initial Job Inquiry Portfolio

In advertisements for employment, the candidate is often directed to send documents such as resumes or supporting material electronically. If the initial inquiry is made online, a small portfolio of work examples could be submitted, along with an electronic resume as an e-mail attachment. The content of the portfolio would consist primarily of text documents including a resume and several work examples or a few highly compressed images. The portfolio creator must be aware that sending this type of portfolio has restrictions in that there are a variety of e-mail systems on the receiving end. Any portfolio sent electronically should be in the neighborhood of one megabyte of memory.

An alternative to actually sending the resume, text documents, or supporting images would be to compose a resume and cover letter with internal hyperlinks directing the reader to a Web-based portfolio. This type of portfolio also can take the form of an expanded Web resume or be an extensive multimedia Web-based presentation. This different strategy means that the original portfolio does not need to be restricted in size. In these cases, the portfolio is Web-based and simply linked from the job application materials.

The introductory portfolio differs in structure from a comprehensive portfolio in the amount of material available. The introductory portfolio also might be an electronic document tailored for each job application or initial inquiry, showing just the type of experience, skill, or education that best pertains to each company or position being

sought. Thus, the creator would pick and choose among the various artifacts in order to focus on the needs expressed by the employer or interviewer. This more personal, focused approach would show depth of preparation as well as forcing the prospective employee to focus on addressing the specific requirements of the job proposed.

Interview Presentation Portfolio

This portfolio also should be tailored to the particular needs of the company or the position sought, perhaps using the mission statement of the specific company as the base for comparison with the job seeker's competencies. Since the purpose of this portfolio is to add to the smaller introductory portfolio, it should include more materials, since size is not as great a limitation. Graphically, this portfolio should follow the rules of good visual communication for presentations, being aware of appropriate colors or formatting. This type of portfolio lends itself to including slide presentations or multimedia projects.

This portfolio should fit on a CD with several copies available. When taken to a job interview, the applicant can present the portfolio during the interview session. A copy then can be left with the interviewer to accompany the application materials following the interview.

Career Growth Portfolio

Once hired, the employee should continue to collect artifacts and include them into portfolios to demonstrate the work performed and growth achieved in skills and responsibilities. This type of portfolio is very helpful in yearly performance reviews and for applications for promotion. As Williams et al. (2004) state, "The portfolio should be designed to transition" with the employee (p. 2). Quality artifacts should increase as years on the job increase.

As an example of this concept of transition during one's career, the field of teacher educa-

tion has been in the forefront for the past decade, encouraging portfolio development. Wilcox and Tomei (1999) address developing portfolios to fit three growth phases of a professional career in education: teacher as learner, teacher as expert, and teacher as scholar. These phases are direct reflections of the portfolios of many professional educators.

This type of portfolio could fit on a CD or, if it includes video or other multimedia, could be distributed on a DVD. If there is a yearly review, the parameters of the review should dictate the main content of this type of portfolio. The employee would choose artifacts focusing on more recent achievements and would not include irrelevant material.

PORTFOLIO ARTIFACTS

A simple rule of thumb is to save everything that relates to work, professional growth, and achievement. It is vital to organize storage methods and to digitize artifacts as soon as possible. Artifacts may be digitized by scanning or photographing them with a digital camera. Once the materials are digitized, it becomes less important to store artifacts in paper form. It is important to create at least one backup of the original digital materials.

The purpose of the portfolio will determine which of the artifacts is placed into the digital document when it is time to create the digital portfolio. For example, a career portfolio would contain the documentation found in Table 1.

Students may find the documentation presented in Table 2 helpful in preparing their portfolios for the interview presentation portfolio.

The sample of careers presented in Table 3 may find the suggested portfolio content topics helpful when preparing for new job interviews, annual reviews, or promotion requests.

Table 1.

Personal Information	Evidence of personal interests, mentors, role models, personality inventory, assessments
Educational Credentials	Evidence of education history, thesis or other major papers or research, examples of coursework products
Career Achievements	Evidence of work history, career plan, references, inventory of career accomplishments
Communication Competencies	Evidence of communication skills, technical skills, certifications, speaking, diversity skills, teamwork
Professional Activities	Examples of publication, presentations
Recognition	Evidence of academic honors, workplace achievement or recognition, promotions

Table 2.

Statement of Career Goals	Statement of how their skills and competencies will enhance the mission of the company
Academic Achievements	Transcripts, relevant courses taken, honors, awards, internships
Evidence of Competencies	Skill-based projects, reports, papers, relevant team activities, original computer-based cases
Exterior Assessment	References, academic commendations, club or group affiliations, leadership roles, community service, volunteer work

PORTFOLIO PRODUCTION TIPS

Digitizing documents and objects for archiving is different than scanning or photographing for presentation. For archiving, the largest file possible should be created. It should be the highest resolution in RGB color mode at the largest scale that the hard drive, digital camera, or scanner can handle.

If the original document becomes lost or disintegrates through aging, this technique of using the maximum settings creates the best possible digital representation of the document. Using the highest settings allows for creating additional smaller files, optimized for portfolio presentation.

Creative Digitizing

Digital documents that are originals should be copied and stored at least twice. Full-size original digital files should be kept on CDs or DVDs. When it is time to prepare them for a portfolio, the original files should be copied from the discs. The archivist should be alert to several situations relating to present and future technologies. Digital files should be in standard formats. Proprietary or native application formats may not stand the test of time. These also should be saved in a standard format such as TIFF for images or RTF for text documents with formatting. This does not mean resizing or compressing the files. The original

Table 3.

Graphic Artists	Professional graphics, artwork, commercial projects, freelance work, gallery showing, private commissions
Sales and Marketing Personnel	Presentations, reports on client success, service awards, promotion paths, recognitions
Office Personnel	Creative documents, relevant projects, recommendations, management reviews
Information Systems Workers	Multimedia or sophisticated technical projects, proof of certifications, images of systems projects, commendations
Help Desk Personnel	Commendations from clients, technical manuals, performance reviews

files are best saved uncompressed. Once the files are sized and prepared for a portfolio, then they can be compressed.

Dimensional objects also should be saved. Good, high-resolution digital pictures of the objects should be taken and at least two copies of these images on CD or DVD should be stored. It is worth the time and cost to get a professional to create quality images as artifacts. If a non-professional chooses to take digital pictures, the photos should be shot in a large format with the highest resolution the camera allows. Natural or bright artificial lighting is necessary to illuminate the object in order to separate it from the background. Tools such as tripods help to steady the camera for crisp, sharply focused images.

Tape or digital audio and video media may be used in portfolios. Since analog tape media degrades in the duplication process, the tape that is closest to the original edit should be kept and backed up digitally to CD or DVD discs. When preparing files for a portfolio, the file size may be reduced or compressed, but the best quality digital copy of the original serves as a backup to which to return.

Digital Portfolio Formats

Portfolios can be constructed using a variety of media, including popular office application programs as well as portfolio software and Web-based platforms.

Text-Based Portfolio Formats

Microsoft Word, PowerPoint, and Adobe Acrobat provide a ready source for text-based digital portfolios. These popular software programs are very efficient to use, especially for the novice creating a portfolio.

Adobe Acrobat, for example, requires a free plug-in but is rarely a limitation since Acrobat Reader is a business standard and can be installed virtually on all computers. This program particularly makes the collection of creative artifacts possible, as it allows for a combination of text, graphics, video, Web projects, and interactive displays to be integrated into an easily accessible electronic format. Since portable document files (PDF) are transportable across all platforms, they are readable by both sender and receiver.

Another key criterion for software selection, according to Barrett (2002), should be its capability to allow hypertext links between stated goals and outcomes as related to the artifacts. Each of these programs has sophisticated hypertext features that provide flexibility in portfolio design while still maintaining coherence when relating one section to another.

Portfolio Software

There are several software programs that specialize in areas crucial to portfolio creation. Among these are Extensis Portfolio, Cumulus Canto, and Epsilon Portfolios. The underlying goal of each of these programs is digital asset management (DAM), which is the underpinning of portfolios. DAM is an enabling technology and solution to creating, archiving, managing, and finally using the collected artifacts or assets.

There are several benefits to using professionally created programs. They provide the structure needed to create portfolios efficiently. They catalog the digitized assets or artifacts using metadata, which is data about the data describing the artifact. This description standardizes the naming and filing of each artifact, thus enabling the portfolio creator to find appropriate material when creating different portfolios needed during various levels of a professional career.

Web-Based Portfolio Formats

The three software programs — Extensis Portfolio, Cumulus Canto, and Epsilon Portfolios — are also Web-based. Their features vary, but secure server storage is common to all three. Along with storage, the most desirable features in Web-based software should include the structure needed to create and archive artifacts, create personal Web pages, provide suggestions for Web design, and offer well-designed templates. Helpful features also should guide the user through the steps needed for distribution of the portfolio, burning

to CDs or DVDs, creating QuickTime movies, developing slide shows, and e-mailing.

Another Web-based portfolio collection and storage area is available through a feature in Blackboard, a widely used educational course management system. The Blackboard Content System includes the ability not only to store artifacts but also to manage the portfolio by allowing the creator to control its availability to external users and to check that the links to items within the portfolio maintain their validity.

Successfully constructing and implementing Web-based portfolios involves more than just collecting artifacts and distributing an attractive and useful portfolio for career purposes. Academic use during a student's development may aid in greater reflection on the student's scholastic path. Counselors can enhance their interaction with students by tapping into students' portfolios for advisement. Coursework and assignments can be checked and commented on by instructors with further suggestions for improvement. Due to the ability to store securely on institutional servers, students and teachers could develop a more collaborative association.

A Webfolio, according to Gathercoal, Love, Bryde, and McKean (2002), is more than simply digitizing a traditional portfolio. Since the portfolio could be made available to external viewers, it could be made an integral part of a curriculum. Serving several purposes, it could be used by students as a "working portfolio generating artifacts only they can view, a developmental portfolio they share with faculty, and a showcase portfolio they share with the world" (p. 31).

Using the Web as a storage medium and then manipulating artifacts to fit appropriately into a variety of portfolios, as the need arises, permits portfolio creators to be more adaptive and flexible. The base portfolio, perhaps created during student years and stored on the Web, could become a lifelong touchstone for professional and career advancement.

Multimedia Use — Pros and Cons

Some career documentation is most effectively delivered via multimedia or motion media, such as audio, video, or animation. This type of documentation is usually not appropriate for inclusion in an e-mail attachment, as the file size likely will exceed the one-megabyte recommendation.

Multimedia can be effective when delivered on CD or sometimes through a hyperlink to the Web. Whatever delivery method is chosen, the important consideration is the software or plug-ins that are required on the user's computer in order to view the multimedia files in the sender's portfolio. If the end-user computer lacks the programs needed, then the multimedia portfolio files cannot be viewed. If users get an error, they may stop viewing the portfolio altogether. Therefore, including multimedia can be risky.

To avoid problems, preview the portfolio on the broadest possible range of computers, operating systems, and installations. Multimedia is safest used in presentations made directly from a laptop or computer during an interview, guaranteeing that there will be no problems with plug-ins or missing software.

CONCLUSION

Compiling a digital portfolio is a strong asset to the student's learning path as well as means of collecting and preserving valuable projects for the business professional. It serves not only as an archive for precious material that otherwise may be lost over the years but also as an organizing principle, according to Campbell (2004). Learning theory reminds us that people remember what they do and what they produce instead of what others have done for them. So, portfolios provide a memory jog with a record of quantitative and qualitative growth over time. Portfolios capture a moment in time when students were acquiring the skills and competencies needed for their careers.

However, having had the experience of creating a portfolio, the student-turned-professional can build upon it and add to it during their business careers.

The reflections made when collecting and archiving projects allow students to make cohesive connections between concepts learned in various courses. Business personnel also capture significant documents, projects, images, reports, recommendations, and programs. Prior to developing a formal portfolio, these artifacts often are misplaced physically as well as forgotten at just the time when the employee needs all of the support possible to shore up a request for a promotion or to keep a job.

The portfolio provides concrete evidence of learning, improvement, and successes. It serves as a snapshot of knowledge growth and experiences attained. Overall, it serves as a proof to claims of skills and competencies for potential employers and provides students with concrete evidence of some of their achievements.

Chapter 3.22

A Socio–Technical Analysis of Factors Affecting the Integration of ICT in Primary and Secondary Education

Charoula Angeli

University of Cyprus, Cyprus

Nicos Valanides

University of Cyprus, Cyprus

ABSTRACT

We live in a world that is constantly impacted by information and communication technology (ICT). ICT is considered an important catalyst and tool for inducing educational reforms and progressively extending and modifying the concept of literacy. With the extensive use of ICT in schools and everyday life, the term computer literate has already been established. Schools are open systems that interact with their environment, and the effective use and integration of technology is directly associated with the role of various socio-technical factors that may impact the integration of ICT in schools. In this chapter, we report on an exploratory study undertaken in Cyprus schools to examine the status of using ICT from the perspective of socio-technical systems. Specifically,

teachers' knowledge of ICT, frequency of using ICT for personal purposes, frequency of using ICT for instructional purposes in different subject matters, attitudes toward ICT, self-confidence in using ICT in teaching and learning, and school climate were examined. The findings provide useful guidance to policymakers for planning, implementing, managing, and evaluating the integration of ICT in schools. Implications for the concept of computer literacy are discussed.

INTRODUCTION

Due to rapid technological advancements, we live in a world that is constantly impacted by information and communication technologies (UNESCO, 1999). Some key-markers that charac-

terize differences between 19th-century societies (i.e., industrial-age societies) and 20th-century¹ societies (i.e., information age societies) are: (a) standardization vs. customization, (b) bureaucratic organizations vs. team-based organizations, (c) adversarial relationships vs. cooperative relationships, (d) parts oriented vs. process oriented, (e) compliance vs. initiative, and (f) conformity vs. diversity (Reigeluth & Garfinkle, 1994). By virtue of these differences, we are obliged to evaluate once more the worth of our existing educational systems. Are our current educational systems, with their emphasis on content coverage and teacher-centered classroom practices, conducive to preparing students to survive in a changing world that is steadily shaped by developments in information technologies? How do we prepare our future citizens to become computer or technology literate? Do new computer technologies herald the beginning of an era of broader literacy, and if we are educating children to be active citizens in an information society, what forms of literacy are required? What does it mean to be literate, an active reader, a writer, and a communicator of meaning in the information society?

Countries in North America, South America, Europe, Asia, and Africa have all identified a significant role for information and communication technology (ICT²) in improving education and reforming curricula for the purpose of preparing future citizens to be productive and actively involved in an information society (Kozma & Anderson, 2002; Pelgrum, 2001). ICT is considered by many not only to be the “backbone of the Information Society, but also to be an important catalyst and tool for inducing educational reforms that change our students into productive knowledge workers” (Pelgrum, 2001, p. 165). For these reasons, schools have made major investments and continue to invest heavily in increasing the number of computers in schools and the networking of classrooms.

ICT is thus steadily becoming part of classroom life, and it progressively changes the concept of

literacy (Brindley, 2000; Watt, 1980). The traditional concept of literacy as the ability to read and write (Crystal, 1987x) is changing, and ICT opens up a further definition of literacy—one that goes beyond the acquisition of basic skills. Brindley (2000) argues that “schooling literacy, which traditionally sees the acquisition of the ability to construct and interpret text as largely an individual activity, bounded by the concept of text as linear and fixed, is no longer adequate” (p. 13). With the enduring introduction of computers in schools and the extensive use of ICT in our everyday life, the term computer literate has been established and flourished.

For many, being computer literate simply means acquiring technical expertise to be able to competently use computer software and hardware. In this chapter, we consider a much more complex and exciting concept of computer literacy—one that is directly associated with the affordances of ICT and the concept of visual literacy. “Visual literacy refers to the use of visuals for the purposes of communication, thinking, learning, constructing meaning, creative expression, [and] aesthetic enjoyment” (Baca, 1990, p. 65). Thus, the extensive use of multimedia in schools and everyday life opens up the way to an extended concept of literacy. For example, ICT reinvents the text and leads us to a new form of literacy, which encompasses a range of media by which students learn and communicate, such as graphics, video, and sound (Papert, 1993). Similarly, McFarlane (2000) argues that multimedia allow students to record and present their own meaning using multiple media. Thus, the technology of multimedia does not restrict reading and writing to the mere coding and decoding of text. Using a computer, children can represent their creativity with text, graphics, speech, video, animation, and more. Technology offers us new forms of representation and expression that extend the traditional and limited concept of literacy. In the information society one has to be able to “read the text and the image and the moving image and the

ability to secure understanding through reading the pictures as well as text in a rich and organic way” (Kempster, 2000, p. 25). For these reasons, Papert (1993) argues for an emerging model of literacy, which encompasses a range of media by which students learn to express themselves and communicate. In the emerging model of literacy, the ability to read and write are enhanced and sometimes replaced by images, graphics, and sound. These new forms of expression and communication can be used by students to construct meaning and represent their understandings after selecting the most appropriate form from multiple alternatives.

McFarlane (1997) also argues that with computers, literacy extends beyond simple manual encoding and decoding of text. “It involves the habit of viewing writing as a way of developing and communicating a child’s thoughts. The use of word processors, for example, helps to present text as something to be experimented with, redrafted and developed as ideas develop, or the demands of purpose or audience change. It liberates the writer from the heavy burden of manual editing and presentation” (McFarlane, 1997, p. 119). Word processors are not only great productivity tools to write faster, or to make fewer mistakes, but also tools that fundamentally change the authoring process children are engaged in (Hep- pell, 2000).

Moreover, a literate person in the 21st century makes judgments about the quality and value of information. The Internet presents new challenges in the way text is presented, and requires a new set of reading skills that go beyond linear book print to screen print. The inclusion of graphics, hyperlinks, and bookmarks also requires an understanding of how text in a Web page is structured in a non-linear way. Thus, a computer-literate person should be able to access this non-linear text with speed and accuracy and construct understanding. Similarly, the National Grid for Learning in the United Kingdom (DfEE, 1998) refers to the new form of literacy as information

or network literacy that is defined as the capacity to use electronic networks to access resources, create resources, and communicate with others. The use of e-mail, for example, to electronically communicate with others dramatically extends and alters students’ written language in many ways. E-mail can rapidly expand the audience that children write for, and secondly, it can engage children in a different type of writing than the traditional one (Easingwood, 2000). It can also be used to support students’ collaborative work with other students in different schools. The notion of children working collaboratively using the new technologies enables them to develop skills that are needed in the workplace and modern society. Thus, it is clear that computers have the potential to make new things possible in new ways, creating new forms of literacy that are critical to our present and future society.

It therefore becomes important to examine whether schools offer the education needed so that students develop the new forms of literacy that are so important for surviving in the information age. Several researchers (Eraut & Hoyles, 1989; Snyder, 1994) argue that teachers need to be trained in order to utilize ICT appropriately in teaching and learning, and that computers by themselves cannot develop the new form of literacy. Pelgrum (2001) also suggests that ICT in education is an area that is in turmoil and in which many participants play a role. For example, forces operating in schools and in classrooms may be influential in bringing about changes or inhibiting them. Hence, it is important to regularly monitor the status of ICT in education in order to not only account for the financial investments, but also to inform policymakers regarding the content and direction of future policies.

Apple (1986) states that technology in the schools has usually been seen as an autonomous process. “It is set apart and viewed as if it had a life of its own, independent of social intentions, power, and privilege” (p. 105). Along the same line of reasoning, Street (1987) also argues that

computer literacy erroneously rests on the assumption that ICT is a neutral tool that can be detached from other specific and social contexts. According to Kling (2000), the integration of ICT in the school system should be examined within a socio-technical framework, where people need to sufficiently interact with the technological tools within the system for the change to be effective. The term “socio-technical systems” was coined in the 1950s (e.g., Trist & Bamforth, 1951; Trist, 1982) to capture the interdependencies between the social and technical aspects of a system. Put simply, a socio-technical system is a mixture of people and technology, hence the concept of “socio-technical system” was established to stress the reciprocal interrelationship between humans and machines. More importantly, the socio-technical systems approach provides us with a comprehensive and systemic methodology for holistically examining factors that may impact the integration of ICT in elementary and secondary education.

In this chapter, we present an exploratory study undertaken in Cyprus schools to examine the current status of using ICT in primary and secondary education, and discuss implications for the development of the new form of literacy given the current status of ICT in Cyprus schools.

THEORETICAL FRAMEWORK

Schools, like other organizations, are open systems that continuously interact with their environment (Getzels & Cuba, 1957; Hanna, 1997; Hoy & Miskel, 2001). The interaction of a system with its external environment is vitally important, because as a result of this interaction, the system receives feedback and appropriately adapts to new demands and circumstances. A system that does not adapt to the needs of its external environment will gradually become extinct (Hoy & Miskel, 2001).

Thus, the introduction of ICT in the school

system has created a need for extending the theory of social systems into a theory of socio-technical systems such that the interaction between teachers and technology can be examined and understood. Social informatics is an area of research, which systematically examines the design, uses, and consequences of technology, taking into consideration the context of the organization, the people who work within the organization, and the interactions between people and technology (Denning, 2001; Friedman, 1998; Kling, 2000). One key idea of social informatics is that ICT, in practice, is socially shaped and the uses of technology in an organization are contingent upon several social and technical dependencies. The concept of socio-technical networks or systems is used to describe the interdependencies between technology and people, and to explain that the culture of an organization and people’s beliefs, attitudes, and feelings play an important role in shaping the organization’s mood and determining the effectiveness of the integration of technology in the organization (Kling & Lamb, 2000; Kling, 2000; Markus & Benjamin, 1987). Thus, the effective use of technology in different organizational settings is directly associated with the intertwining of technical and social elements (Friedman, 1998; Heracleous & Barrett, 2001; Kling, 2000).

Trach and Woodman (1994) support that the socio-technical model constitutes a flexible model for successfully implementing systemic changes in an organization. Thus, technology should be viewed as a catalyst for pursuing systemic as opposed to piecemeal changes across the different subsystems of an educational system (Angeli, 2003; Valanides & Angeli, 2002). Teachers, for example, constitute an important subsystem of every educational system. According to Fullan (1991), every reform effort should take into consideration the knowledge, skills, beliefs, and attitudes of the people who will implement the changes. In general, a precondition for a successful implementation of any change effort is adaptation,

which includes all adjustments an organization makes in order to realize the changes (Hoy & Ferguson, 1985). Adaptation is a broad term and may include multiple criteria. In this chapter, six areas of adaptation are examined: (1) teachers' knowledge of ICT, (2) teachers' frequency of using ICT for personal purposes, (3) teachers' frequency of using ICT for instructional purposes in different subject matters, (4) teachers' attitudes toward ICT, (5) teachers' self-confidence in using ICT in teaching and learning, and (6) school climate.

According to Huberman and Miles (1984), many educational reform efforts died out because teachers were not supported in their change efforts and thus never accepted or understood the changes they had to implement. Therefore, the adoption of changes requires educating teachers to understand and accept the nature of the restructuring effort, and develop the knowledge, skills, and attitudes that are required for bringing about the change in their classrooms (Fullan, 1991; Louis & Miles, 1990). As Barth (1990) characteristically stated, nothing influences students more than their teachers' own professional and personal development. The process of integrating ICT in teaching and learning is demanding and requires teachers' continuous professional development (Picciano, 2002). In addition, Picciano (2002) believes that school principals and inspectors also need to participate in ICT training so that they understand how ICT integration affects the classroom (micro level) and the school (macro level). Fullan (1991) explains that educational change efforts often create feelings of uncertainty that are not only related to lack of knowledge and skills, but also confidence, as teachers often feel inadequate and uncertain about their new roles (Fullan & Hargreaves, 1992). For these reasons, teachers' ICT professional development is important not only for the development of ICT knowledge and skills, but also for the development of positive attitudes and confidence in using ICT in teaching and learning. Hoy and Miskel (2001) point out that the style of leadership in an organization is

also an important factor. For example, a principal who encourages the use of ICT in teaching and allows teachers to create collaborations within the school and between schools for the exchange of ideas will play an important role in successfully institutionalizing the change effort. Thus, as Hoy and Miskel (2001) state, what is needed is transformational leadership. Transformational leaders are those who foresee the need for change, create new visions for education, and encourage teachers to take responsibility for their professional and personal development in order to successfully fulfill their new obligations and roles.

METHODOLOGY

The Context of the Study

The public educational system in Cyprus consists of the primary and secondary levels, while just recently new attempts have been made to also include pre-primary (3-5½-year-old children) education. Grades 1 to 6 constitute the primary level, and grades 7 to 12 the secondary level. Education is free for all grade levels and mandatory until grade 9 or the age of 16, but an overwhelming 95% of students complete all grade levels. The majority of students attend public schools, and there are only a small number of private schools mainly at the secondary level. Fifty teachers were randomly selected from each one of the 12-grade levels in primary and secondary public education. During the spring semester of 2004, a questionnaire and a pre-stamped self-addressed envelope were delivered to each individual teacher with the help of research assistants. Each teacher was asked to individually complete the questionnaire and return it to the researchers. The majority of the teachers (520) returned their completed questionnaires within a week, and only 22 teachers did not return their questionnaires at all, even after a second reminder by telephone two weeks after the questionnaires were delivered to them. Thus,

the data from 578 questionnaires were used in the study.

Data Collection

The questionnaire consisted of seven parts. The first part collected demographic data related to teachers' age, number of computer labs in each school, number of computers in each lab and teachers' classrooms, teachers' ownership of a personal computer, and teachers' participation in an ICT professional development training program. The other six parts collected data related to: (1) teachers' knowledge of computer software, (2) teachers' frequency of software use for personal purposes, (3) teachers' attitudes towards integrating ICT in teaching and learning, (4) teachers' self-confidence in integrating ICT, (5) teachers' frequency of using ICT for instructional purposes in the classroom, and (6) school climate and support.

Specifically, the second part of the questionnaire used a Likert-type scale from 1 to 5 (I do not know how to use it, I somewhat know how to use it, I know how to use it satisfactorily, I know how to use it well, I know how to use it very well) to measure teachers' knowledge of various software, and the third part used a Likert-type scale from 1 to 5 (never, once or twice every three months, once or twice a month, once or twice a week, almost every day) to measure frequency of software use for personal purposes. Similarly, the fourth part measured teachers' attitudes with a Likert-type scale from 1 to 5 (absolutely disagree, disagree, neither disagree nor agree, agree, absolutely agree), and the fifth part used the same Likert-type scale that was used in the fourth part to measure teachers' self-confidence. For the sixth part, which measured teachers' frequency of using various computer programs in classroom practices, teachers had to write how many times a week they were using different software in their teaching. Finally, the seventh part of the questionnaire measured school

climate and support. A Likert-type scale from 1 to 5 (absolutely disagree, disagree, neither disagree nor agree, agree, absolutely agree) was also used. Thus, the questionnaire collected demographic data and data related to the six areas of adaptation from the perspective of the socio-technical systems perspective.

RESULTS

Demographic Data

Among the 578 teachers, 446 (77.14%) of them were females and 132 (22.86%) were males. The average age of the participating teachers was 31.98 ($SD=8.107$), but the average age was significantly smaller ($t = -5.501, p = .000$) for female teachers ($Mean = 30.94$ years) than for male teachers ($Mean = 35.24$ years). All teachers owned their own personal home computer ($Mean = 1.05, SD = 1.05$), and in some cases, there were teachers who owned two computers at home. Also, 67.5% of teachers recently participated in an ICT teacher professional training program where they learned how to use several computer programs, such as Word, Excel, PowerPoint, and the Internet. Teachers taught in schools where there was a computer lab with an average of 5.55 computers in each lab and at most one computer in each classroom. The computer-student ratio differed for each school, but in all schools computer access was not prolific.

These data signify the tremendous effort that has been undertaken for successfully integrating ICT in the teaching-learning environment, considering the fact that not too long ago there were no computers in the classrooms and no computer labs in most of the schools in Cyprus. It is however more important to investigate how and to what extent ICT is used in Cyprus schools in relation to teachers' ICT knowledge, frequency of software use for personal purposes, attitudes, self-confidence, frequency of using ICT for in-

structional purposes in the classroom, and various factors pertaining to the socio-technical character of the school system.

Teachers' Knowledge of Computer Software and Frequency of Use for Personal Purposes

Descriptive statistics related to teachers' knowledge of computer software and teachers' frequency of using software for personal purposes are presented in Tables 1 and 2, respectively.

The results in Table 1 indicate that teachers' knowledge of software varied according to the type of software. Specifically, teachers appeared

to be more familiar with Word than with any of the other software such as PowerPoint, the Internet, e-mail, Excel, graphics, authoring software, and databases. More analytically, the results in Table 1 indicate that teachers knew how to use well only Word, while their knowledge about PowerPoint, the Internet, and e-mail was rated just above the level of satisfactory use. Teachers' knowledge regarding the rest of the software was rather poor and below the level of satisfactory use. It is also important to mention that these data refer to teachers' self-reported estimates of their knowledge and do not necessarily represent their actual knowledge.

The results in Table 2 indicate that teach-

ers used Word most frequently and rarely used databases. The Internet, e-mail, educational CD-ROMs, and PowerPoint were less frequently used than Word, but more frequently used than graphics, spreadsheets, authoring software, and databases. For example, teachers used Word once or twice a week, while they almost never used databases or authoring software. Thus, the collective results from Tables 1 and 2 clearly indicate that teachers' knowledge of computer software was dependent upon the type of software, and that their frequency of software use followed almost the same order, in terms of magnitude, as their knowledge of computer software. The means of the variables related to knowledge of software and frequency of software use were found to be highly and significantly correlated ($r = .905, p = .01$). Correlation, of course, does not mean a direct causal relation, and it cannot explain whether better knowledge of a computer program causes its frequent use, or whether the need to frequently use a computer program causes better knowledge of it. The only valid conclusion is that the participants reported better knowledge for some kinds of software and higher frequency of use for the same kinds of software.

Teachers' Attitudes

Dealing effectively with ICT relates not only to knowledge of ICT tools, but also to individuals' attitudes and perceptions regarding ICT tools. Attitudes and perceptions act as a filter through which all learning occurs (Marzano, 1992), and are considered as a constituent part of learners' "self-esteem" that oversees all other systems (Markus & Ruvulo, 1992). Thus, learners continually filter their behaviors through their self-belief system to the extent that they even attempt to modify the "outside world" and make it more consistent with the "inside world" (Glaser, 1981). The limited teachers' knowledge or skills about

the use of several software and computer applications seem to have an impact on their attitudes and concerns.

For these reasons, teachers' attitudes towards ICT were also examined in this study. Table 3 shows descriptive statistics related to the 19 items measuring teachers' attitudes towards the use of ICT in education. The results in Table 3 indicate that the majority of teachers expressed rather positive attitudes towards the use of ICT tools in education. Teachers felt rather comfortable in using ICT for instructional purposes, and expressed positive attitudes towards applying ICT in teaching and learning, because ICT could make learning easier, meaningful, and useful. However, there were a lot of teachers who expressed skepticism or even fear, because they felt incompetent to resolve potential technical problems with the computer. In general, teachers expressed a somewhat overall positive attitude towards the use of computers in education, although some of them also expressed concerns pertaining to technical problems that might hinder their work and students' learning. Of course, even though ICT-related attitudes seem to play an important role in how ICT is used in teaching and learning (Levine & Donitsa-Schmidt, 1998), research indicates that positive attitudes alone are not always good indicators of teachers' eventual use of ICT in the classroom (Wild, 1996). This is due to the fact that teachers often times have positive attitudes about ICT integration without realizing how difficult the task is, or how much effort they need to invest to successfully complete the task. Thus, despite teachers' rather positive disposition towards ICT integration, they may still find the task of integrating computers in the classroom difficult, once they realize what it really entails. This also seems to be a reasonable conclusion from the current results, taking into consideration that the participants of the present study had limited knowledge of the full range of affordances of

Table 3. Descriptive statistics of teachers' attitudes

Item	M	SD	n
I feel comfortable with the computer as a tool in teaching and learning.	3.78	1.07	577
The use of computers makes me stressful.	3.84	1.06	575
If something goes wrong with the computer, I will not know what to do.	2.63	1.12	576
The use of computers in teaching and learning makes me skeptical.	2.70	1.13	576
The use of computers in teaching and learning makes me enthused.	3.78	.83	574
The use of computers in teaching and learning interests me.	3.99	.93	575
The use of computers in teaching and learning scares me.	2.28	1.14	572
I believe the computer is a useful tool for my profession.	4.33	.81	575
The use of computers in teaching and learning will mean more work for me.	3.61	1.00	574
Computers will change the way I teach.	3.77	.83	575
Computers will change the way my students learn.	3.74	.88	571
Whatever the computer can do, I can do it equally well in another way.	2.50	.90	572
Computers make learning harder because they are not easy in their use.	2.16	1.71	575
Computers make learning harder because often times there are technical problems associated with them that students cannot resolve.	2.67	1.07	574

The computer makes learning more meaningful.	3.86	.75	576
The computer helps students represent their thinking better.	3.85	.74	577
The computer is a meaningful tool for the teacher because it can help him/her teach a topic more effectively.	3.92	.79	575
The computer hinders teaching because of the technical problems it may cause.	3.62	.92	576
ICT Attitudes	3.36	.26	545

several ICT tools and their applications in the teaching-learning environment.

Teachers' Confidence

Table 4 shows descriptive statistics related to teachers' confidence. The results indicate that teachers felt somewhat confident in selecting appropriate software to be used in their teach-

ing, and felt about the same with designing and implementing classroom activities with ICT tools. Several factors seem to play an important role in affecting how individuals use ICT (Fullan, 1991). These factors include not only ICT knowledge and the amount and nature of prior ICT experience, but also ICT-related attitudes and learners' beliefs in their ability to work successfully with ICT tools (self-confidence or self-efficacy) (Levine & Donitsa-Schmidt, 1998; Liaw, 2002;

Table 4. Descriptive statistics of teachers' confidence

Item	M	SD	n
I feel confident in selecting appropriate software to use in my teaching.	3.51	1.12	572
I feel confident in preparing classroom activities with ICT for my students.	3.30	1.20	569
Confidence	3.40	1.04	568

Table 5. Descriptive statistics of teachers' frequency of using ICT in the classroom

Software	M	SD	n
Internet	1.233	2.46	578
Word Processing (i.e., Word)	1.606	2.78	578
Spreadsheets (i.e., Excel)	.309	.97	578
Databases (i.e., Access)	.031	.21	578
Presentation (i.e., PowerPoint)	.711	1.45	578
Educational CD-ROMs (e.g., drill and practice, tutorials, etc.)	1.524	2.75	578
Frequency of Instructional Use	5.413	8.22	576

Murphy, Coover, & Owen, 1989). Attitudes and beliefs are considered as predictors of behaviors and behavioral intentions that are linked to self-confidence. Beliefs about an object usually lead to attitudes towards it, and in turn, attitudes lead to behavioral intentions regarding the object, which affect actual behaviors towards the object. Finally, there is a feedback loop where behavioral experience modifies preexisting beliefs about the object. In terms of ICT use, attitudes toward ICT affect users' intentions or desire to use ICT. Intentions in turn affect actual ICT usage or experience, which modifies beliefs and consequent behaviors or behavioral intentions (future desire), and self-confidence or self-efficacy in employing ICT in learning. Thus, teachers' actual ICT usage in the classroom is directly associated with their knowledge, attitudes, and self-confidence, although attitudes and confidence are directly dependent on knowledge and improve with success and frequent use. It seems that teachers' self-confidence was

delimited by teachers' knowledge of software and frequency of software use.

Teachers' Frequency of Using ICT in the Classroom for Instructional Uses

Table 5 shows descriptive statistics of teachers' frequency of using ICT for instructional purposes in the classroom. The results in Table 5 draw a rather pessimistic picture in terms of actual instructional use of ICT in the classroom. First, none of the teachers reported any use of electronic communication (i.e., E-mail), authoring software (i.e., Hyperstudio), or graphics (i.e., Paint) in their teaching. Second, computer applications such as spreadsheets, databases, and PowerPoint were minimally used, and teachers' reported mean frequencies of use for these software were .309, .031, and .711, respectively. Third, only the mean frequencies of use for the Internet, Word, and

educational CD-ROMs had values higher than one indicating that they were used infrequently and only by very few teachers. Finally, in comparison with the results in Table 2, teachers were using the same software much less frequently for instructional purposes than for personal purposes. This seems to suggest that teachers' knowledge, attitudes, and self-confidence had probably less impact on teachers' instructional use of the software or that there were some other reasons inhibiting the instructional uses of ICT in teaching and learning. For example, the existing socio-technical character of a school could substantially constitute a significant factor in supporting or inhibiting both use and frequency of use of certain software, despite teachers' technical expertise, attitudes, and self-confidence in employing ICT in teaching and learning.

Socio-Technical Environment

Table 6 shows descriptive statistics of various factors related to the socio-technical character of a school. Based on the results, there were

participants who felt that their superiors, the computer coordinator, and other colleagues tended to encourage them to use ICT in the classroom, but there were also other participants who did not share the same point of view. Also, teachers in general neither agreed nor disagreed about the availability of technical or instructional support in their school, or whether there was adequate computer equipment or software available. Lastly, teachers expressed mixed views on whether the subject of ICT integration was sufficiently discussed in faculty meetings. The only valid conclusion from the results in Table 6 is that at least teachers did not feel discouraged for their attempts to integrate ICT tools in their classrooms. They perceived a rather neutral socio-technical environment in their schools. It is also possible that teachers did not have a clear understanding of the situation in their school, and thus were unsure about it. Obviously, there was not a strong momentum, nor systematic plan of action for effectively integrating ICT in the participants' schools. Teachers' somewhat positive attitudes and perceived self-confidence were rather compatible with the existing socio-

Table 6. Descriptive statistics of socio-technical factors

Item	M	SD	n
There are teachers in my school who help me integrate ICT in my teaching.	3.12	1.120	564
The computer coordinator encourages me to use ICT in my classroom.	3.38	1.171	565
The principal encourages me to use ICT in my classroom.	3.15	1.083	566
The inspector encourages me to use ICT in my classroom.	3.43	1.087	565
We often talk about ICT integration during our faculty meetings.	2.92	1.109	567
There are many software available in my school.	3.04	1.072	566
There is technical support readily available in my school.	3.09	1.086	565

There is adequate computer equipment in my school.	3.04	1.223	566

technical environment, which, as the results indicated, was not overwhelmingly supportive, but rather neutral.

Personal Computer Use and Instructional Computer Use

The fact that teachers reported rather infrequent instructional use or no instructional use for most of the software is contradictory to teachers' frequency of using computer software for personal purposes, as well as contradictory to their subjective self-confidence, attitudes, reported knowledge of several software, and the socio-technical environment.

In order to better examine the existing discrepancy between the frequency of ICT use for personal purposes and frequency of ICT use for instructional purposes, five composite variables were created, namely, teachers' knowledge (KNOW), frequency of personal computer use (PCU), attitudes (ATT), self-confidence (SCF), and frequency of instructional computer use (ICU). These five variables represented the mean value of the single items in Tables 1, 2, 3, and 4, respectively, with the exception of ICU, which represented the sum of the individual items in Table 5. Two regression analyses were consequently conducted with the frequencies of PCU and ICU as the dependent variables for the first and the second analyses, respectively. The independent variables for both analyses were the other three composite variables (KNOW, ATT, and SCF), teachers' age, participation in an ICT professional development training program, and the nine individual items shown in Table 6 measuring aspects of the socio-technical environment (STE₁ to STE₉). Other variables from the first part of the questionnaire were excluded from the analyses, because they were found not to be discriminating nor redundant, as they were highly and significantly correlated with other variables. For example, *years of teaching experience* was considered to be a redundant variable, because

it was highly and significantly correlated with age ($r = .960, p = .01$). *Ownership of a personal computer* was also not a discriminating variable, because all teachers owned a personal computer, with the exception of some of them who reported that they owned two personal computers. Table 7 shows the correlations between all possible variables (dependent and independent) that were used in the two regression analyses and some additional variables from the first part of the questionnaire.

Regarding the items in the first part of the questionnaire (demographic information), it was considered more appropriate to use them as individual variables, since they could not be considered dimensions of the same construct, as it was, for example, the case with teachers' self-confidence or attitudes. Regarding the items in the last part of the questionnaire, although they were measuring aspects of the socio-technical environment, we used them as individual variables, because we were interested in identifying which dimensions of the socio-technical environment seemed to play an important role in ICT integration. In most cases, the guiding principle for including or excluding a variable in the regression analyses was their overlapping meaning and high significant (positive or negative) correlation with other variables. Table 7 shows the correlations between all possible pairs of dependent and independent variables, as well as some additional variables that were considered important to further clarify and interpret the results of the regression analyses.

Table 8 displays the results of the first stepwise multiple regression analysis with the frequency of PCU as the dependent variable and the independent variables that were determined as significant predictors of the dependent variable. The independent variables that contributed significantly to the prediction of frequency of PCU were teachers' knowledge, self-confidence, and gender, and from the socio-technical factors those related to inspector support and computer equipment in the

Note: SCF = teachers' self-confidence, KNOW = teachers' knowledge, ATT = teachers' attitudes, STE1 to STE9 = individual items of the socio-technical environment corresponding to the items in Table 6, TE = years of teaching experience, ICT inservice = participation in ICT professional training, Gender = 1 for females and 2 for males.

school. Teachers' knowledge was found to be the best predictor of teachers' frequency of PCU and alone explained 59% of the variance.

Teachers' self-confidence was found to be the second best predictor that contributed to a significant increment in R^2 , from .590 to .617.

There were three other variables, namely gender, inspector support, and computer equipment that also contributed significantly to the prediction of teachers' frequency of PCU, but the amount of variance in frequency of PCU attributable to each one of them was much smaller, namely,

A Socio-Technical Analysis of Factors Affecting the Integration of ICT

Table 8. Multiple regression analysis of factors predicting teachers' frequency of personal computer use

Model	Variables	R	R ²	Adjusted R ²	Adjusted ΔR ²	F Change	Significance
1	Knowledge .	.768	.590	.590	.590	693.205	.000

5	Knowledge	.404	.163	.154	.008	6.125	.014
6	Self-Confidence (removed)	.400	.160	.153	.003	.761	.185
7	Age	.410	.168	.160	.008	.743	.030

.9%, .4%, and .6%, respectively. Although the correlations between teachers' frequency of PCU and some other variables (i.e., age, ICT inservice, and the remaining socio-technical factors) were significant, these variables were not found to be significant predictors of PCU.

For the purpose of further clarifying and interpreting the results of the first regression analysis, a careful examination of the pair-wise relationships between teachers' age, gender, knowledge, and ICT inservice training in Table 7 indicates that these variables were highly and significantly correlated, but only teachers' knowledge and gender proved to be significant predictors of the frequency of PCU. This can be explained by the fact that the younger teachers tended to have more knowledge than the older ones ($r = -.274, p = .01$), female teachers were in general younger than male teachers ($r = .225, p = .01$), and younger teachers were more inclined

to participate in inservice ICT training ($r = -.190, p = .01$). Similarly, as shown in Table 7, all items corresponding to the socio-technical factors were highly and significantly correlated among each other, but not all of them were found to be significant predictors, as the unique contribution of many of them was not found to be significant. In multiple regression:

It is possible for a variable to appear unimportant in the solution when it actually is highly correlated with the dependent variable. If the area of that correlation is whittled away by other independent variables, the unique contribution of the independent variable is often very small despite a substantial correlation with the dependent variable. (Tabachnick & Fidell, 1989, p. 143)

Thus, from the list of the socio-technical factors, only inspector support and availability of

computer equipment in the school were found to be significant predictors of the frequency of PCU. Interestingly, computer equipment was found to be an important predictor of PCU, although there was not a significant positive correlation between the two variables. This outcome is really difficult to explain, because computer equipment in the schools does not seem to be directly related to teachers' frequency of PCU outside the classroom. One possible explanation is that teachers began to use computers for personal purposes after the introduction of computers in the schools, which possibly served as the impetus for teachers to learn how to use computers.

Table 9 displays the results of the second stepwise multiple regression analysis between frequency of ICU as the dependent variable and the significant independent variables. The independent variables that contributed significantly to the prediction of the frequency of ICU were teachers' self-confidence, instructional support in the school, teachers' attitudes, support from colleagues, and knowledge. Teachers' self-confidence was the best predictor of the frequency of ICU, but it could explain only 9.1% of the variance. The variables of instructional support, teachers' attitudes, support from other colleagues, and teachers' knowledge also contributed to a significant increment in R^2 . These variables could explain 2.4%, 2.5%, 0.8%, and 0.8% of the variance in the frequency of ICU, respectively. The total amount of variance attributable to these variables was only 16.8%.

Interestingly enough, the significant predictor of self-confidence was removed from the regression equation in step six, as its unique contribution was no longer significant. When, in step 7, age was introduced, there was a significant increase of ΔR^2 that made the total amount of variance, after partialling out the contribution of teachers' self-confidence, significantly higher. In stepwise regression, "independent variables are added one at a time if they meet statistical criteria, but they also may be deleted at any step where they

no longer contribute significantly to prediction" (Tabachnick & Fidell, 1989, p. 147). Thus, the total amount of variance attributable to instructional support, teachers' attitudes, and support from colleagues, knowledge, and age, was found to be 16.8%. Teachers' self-confidence that was initially found to be the best predictor of ICU was in the end excluded from the list of significant predictors for two reasons. First, teachers' self-confidence, after the inclusion of four other variables (instructional support, attitudes, support from colleagues, and knowledge), did not contribute significantly to the prediction of the frequency of ICU and could be excluded without any significant decrease in R^2 . Second, the combination of teachers' knowledge and age was a better predictor of the frequency of ICU than teachers' self-confidence.

DISCUSSION AND IMPLICATIONS

The socio-technical systems model provides us with a framework to systematically identify factors that could possibly affect the integration of ICT in education. From this perspective, a questionnaire was used in this study to collect demographic data and information related to teachers' knowledge of ICT, frequency of using ICT for personal and instructional purposes, attitudes toward ICT, self-confidence in using ICT in teaching and learning, and school climate. The findings tend to support that female teachers were more inclined to participate in ICT inservice training; had better knowledge, attitudes and self-confidence related to ICT; and used ICT tools more frequently both for personal and instructional uses than male teachers. Teachers' knowledge of computer software and frequency of use for personal and instructional purposes were dependent on the type of software. For example, teachers' knowledge and frequency of use for personal purposes was mainly restricted to word processing, and to a much smaller extent to the Internet, e-mail, and educational CD-ROMs, while other software were almost unknown

and rarely used. Teachers expressed somewhat positive attitudes towards the use of computers in education, but they also expressed concerns pertaining to technical computer problems that might hinder their work and students' learning. They also felt, to some extent, self-confident in selecting appropriate software to be used in their teaching, and somewhat confident in designing and implementing classroom activities with ICT tools. Teachers' attitudes and self-confidence seem to be delimited by their restricted knowledge of software and frequency of software use for personal and instructional purposes.

Teachers also reported infrequent instructional use or no instructional use even for software that they frequently used for personal purposes outside the classroom. This discrepancy seems to be attributable to the rather neutral socio-technical environment that existed in their schools, but also to other factors. Specifically, a stepwise regression analysis indicated that 63.5% of the variance in teachers' frequency of personal computer use could be predicted by teachers' knowledge, self-confidence, gender, inspector support, and computer equipment. However, according to a second stepwise regression analysis, only 16.8% of teachers' frequency of instructional computer use could be predicted by instructional support from officials, teachers' attitudes, support from the other teachers in the school, knowledge, and age.

The findings indicate that teachers in Cyprus are not illiterate in terms of having ICT skills and in terms of using ICT for personal purposes. What the findings clearly show is that teachers do not feel empowered to actively use ICT in authentic teaching and learning activities. Teachers need to develop confidence in their own professional activities and realize that what they are doing is right and important for their students' education. As Gable and Easingwood (2000) state, it will take time to train teachers to fully appreciate the power of ICT, but it is crucial to invest in such efforts, so that teachers fully appreciate the

philosophical aspects of what they are doing, rather than just learning how to use the computer. These results indicate that policymakers in Cyprus have to seriously consider the lack of learning opportunities for the development of new literacy in Cyprus schools, and make coordinated efforts for providing a different and better kind of training to teachers. This training should pay attention not only to teachers' technical expertise, but also their attitudes, self-confidence, and in-depth understanding of ICT's affordances and added value in teaching and learning targeting an extended concept of literacy. Teacher professional development about the instructional uses of ICT in the classroom and about computers as learning tools for providing us with new forms of media that can enrich learner communication and expression is absolutely in great need.

Along the same line of reasoning, teacher education departments must also consider the quality of their curricula and adapt them appropriately, so that they adequately prepare teachers to integrate ICT in teaching and learning. We argue that teacher preparation, inservice or preservice, should focus on new interactive computer-based technologies, such as electronic communication systems, visualization and dynamic systems modeling tools, simulations, and networked multimedia environments, for scaffolding and amplifying students' thinking (Bransford, Brown, & Cocking, 2001). These tools are known as cognitive tools or mindtools (Jonassen, 2000), because they engage learners in meaningful thinking to analyze, critically think about the content they are studying, and organize and represent what they know. Jonassen, Carr, and Yueh (1998) state that "learning with mindtools depends on the mindful engagement of learners in the tasks afforded by these tools and that there is the possibility of qualitatively upgrading the performance of the joint system of learner plus technology" (p. 40). Therefore, mindtools require learners to think harder about the content being studied, and engage them in thinking that would be impossible

without the tools. Finally, the tools we use and the way we use them shape our experiences and our thinking (Vygotsky, 1978) and impact our literacy. Thus, “if technology is to be viewed as an add-on in the learning environment that is pursued for the sake of technology alone, then it will not change education” (Valanides, 2003, p. 45), because technology, in and of itself, cannot influence learning, no matter how powerful it might be. On the other hand, if technology is utilized as a cognitive tool that has added value in certain instructional situations, then it will become a driving force for systemic educational change to help teachers and students to experience deep learning and acquire an extended concept of literacy that is compatible with the needs of our society.

The overall findings of the study indicate that ICT is not systematically integrated in Cyprus schools and is not an important part of everyday classroom practices. This seems to be related to several reasons, such as teachers’ limited knowledge of a variety of software, limited instructional support provided to teachers by the Ministry of Education, teachers’ somewhat positive attitudes, lack of a true community of practice in the schools where teachers help each other to integrate ICT in teaching and learning, and teachers’ age. It seems that a supportive school environment could play an important role in effectively and successfully integrating ICT in teaching and learning. Teacher support can be provided in each school by the more experienced teachers in the school or even by more experienced teachers in different schools, by inspectors who visit the school in order to assist teachers in their ICT integration efforts, or by an Instructional Support Service in the Ministry of Education that is responsible for providing instructional guidance to practicing teachers. Moreover, a supportive school environment can eliminate teachers’ feelings of isolation in the school, and can encourage effective communication and collaboration among teachers for achieving common goals and literacy in education.

In addition, when ICT is integrated into the classroom environment, the learning environment becomes more learner centered than before, and new assessment strategies are needed in order to capture the essence of learning that takes place in these environments. Traditionally, assessment has been used to sort out students, as well as distinguish the good students from the weak students and, as the end-point of instruction, to assess students’ understandings after the instruction ended (Graue, 1993). Hence, the focus of evaluating student learning has been on the products or outcomes of learning, such as facts and information, and not the processes of learning. In ICT-enhanced classrooms, learning objectives vary from achieving deep understanding of concepts to developing critical thinking, decision making, and problem-solving skills, to cultivating positive attitudes towards learning. Therefore, as Shepard argues (2000), the form and content of assessment must change to “capture important learning goals and processes and to more directly connect assessment to ongoing instruction” (p. 5). If the focus of assessment does not change and if new assessment strategies are not developed and accepted as valid methods for assessing student performance, then, as we strongly believe, teachers will hesitate to generously use ICT in their teaching.

Another factor that we consider important, even though it was not found to be a significant predictor in this study, is the lack of adequate computer access in Cyprus schools. For example, given the current situation in Cyprus schools, a teacher who wants to use ICT in a lesson must first make special arrangements to reserve the computer lab in the school in order to be allowed to use it. It seems, however, that because at this point teachers do not use ICT regularly in their classroom practices, they feel that the one computer lab in the school provides them with sufficient computer access. McFarlane (2000) also argues that computer access is a key factor in inhibiting teaching with ICT and states that “until children

come to school with a powerful portable computer of their own, access will remain a key brake on the use of digital media in school” (p. 22).

In conclusion, the schools in Cyprus do not seem to be adequately preparing students to develop the new forms of literacy skills that are needed in the information society, and have not been affected to a great extent by new modes of communication, new tools for expression, and new ways of the representation of knowledge. Given the current situation, it is hard to see how new forms of literacy can be satisfactorily developed in Cyprus schools. These findings have implications for Cyprus’ international competitiveness. If the educational system in Cyprus will not invest in learning with ICT, then the students in Cyprus will not develop the competencies and the literacy skills that are needed to fairly compete with the students of other countries, which have a better status of ICT in education. Technological illiteracy “could lead to becoming a member of an underclass with a similar status to those who, in previous generations, could not read and write” (Easingwood, 2000, p. 97).

The development of an extended concept of literacy is not an easy matter and many factors seem to affect its development. The implications of this study for the development of an extended concept of literacy are important and need to be seriously taken into consideration by policymakers. It seems that policymakers and government officials have to systemically approach the issue of ICT integration in primary and secondary education, so that ICT is infused in a system that is ready to accept the new educational change. The results imply that a systemic effort for the development of an extended concept of literacy should include a focus on creating a supportive school environment, and a revised focus on teaching and teacher training.

Another implication for the development of an extended concept of literacy is that plans of

action have to be developed to identify areas in the curriculum that can be enhanced with the use of ICT. Currently, the curriculum in Cyprus does not include a focus on ICT, and does not appear to have a direction and urgency in systematically integrating ICT. Specifically, the official curriculum in primary and secondary education does not currently include the use of ICT in the teaching of the subject domains despite the fact that ICT integration has been proclaimed as a top priority in the agenda of policymakers. Thus, in the present system, the teacher has to decide how and when to integrate ICT in teaching and learning. Curriculum restructuring efforts need to be undertaken so that teachers receive better guidance about how ICT can be integrated in different subject matters and how ICT can extend the traditional concept of literacy.

CONCLUSION

The purpose of this chapter was to examine factors that may affect teaching with ICT in primary and secondary education, and thus ultimately hinder or delay the development of new literacy skills that are important for citizens to survive in a rapidly changing world. Based on the findings of the study, the development of an extended concept of literacy is not easy and many factors seem to affect its growth, such as teachers’ knowledge of ICT, attitudes, self-confidence, age, and instructional support from colleagues and superiors. We argued in this chapter that policymakers need to carefully plan the development of the new forms of literacy in Cyprus schools by systemically integrating ICT in the schools so teachers and students together can develop an extended concept of literacy that is critical for surviving in the information society.

Chapter 3.23

Satellite Technology in Schools

Annalene Cosemans

Audiovisual Technologies, Informatics and Telecommunications, Belgium

INTRODUCTION

SchoolSat1 was an initiative to utilise advances in satellite technology to improve access to the Internet for Irish schools. It was partially funded by the European Space Agency under the ARTES 3 Multimedia Programme and ran from December 2001 until January 2003. The purpose of SchoolSat was to set up, manage and evaluate a pre-operational, satellite-based service for compulsory schools in Ireland. It had as a clear objective and expected outcome: the establishment of a business and deployment plan for a fully operational and sustainable service for the Irish compulsory school sector based on a strategic mix of uni-cast and multi-cast services.

BACKGROUND

In most countries, the Internet is seen as a central component of an educational ICT strategy. It is seen as important for a variety of reasons. In part, the Web can be seen as a vast library of resources, some of which can be used by both teachers and students to enrich teaching and learning. There is also an equality dimension to the resource view of

the Web, as the smallest and most isolated schools with no library can access exactly the same online material as the biggest urban schools.

The Internet may also be a conduit for a new generation of educational software. For decades specialist software aimed at schools has been produced however, despite the success of the educational software sector in the home and training markets, little of it is in use in schools. The use of software in schools may have been constrained by logistical difficulties including licensing, installing the software, etc. Many of these difficulties can be avoided if educational material is available online, providing an easier solution in school, one that students can continue at home, and teachers can explore in advance with ease.²

The need for Internet access in school also goes beyond the content of the World Wide Web. In part, “the medium is the message,” as it becomes important for learners to develop information literacy. Negroponte, in his seminal book *Being Digital*, describes a “post information age,” where individuals have much greater control of the information they receive and send, where they can communicate with agencies in a “place without space,” and where they can control more of the information they receive.³ This vision of a society

with empowered individuals finding information as they need it and managing their own learning and information needs is an attractive one, but it is dependent on learners having the skills to deal with the vast amounts of material available to them.

THE SCHOOLSAT PROJECT

The SchoolSat Pre-operational Pilot project used Internet via DVB (Digital Video Broadcasting) satellite technology with the KU band return channel for the establishment of the interactive channel. The aim of the trial was to investigate how far this technology could offer a solution to connect schools to the Internet, to build school networks and to transmit large files of information, be it data, video, audio, or graphics.

The planned service was based on the Digital Video Broadcasting (DVB) standard which is deployed Europe-wide (and is becoming accepted as a worldwide standard) for digital television. It allows the user to receive Internet services with a relatively small antenna (less than 1 metre diameter) and a PC (personal computer) equipped with a satellite modem anywhere within the footprint of the Eutelsat W3 satellite (used by the technology provider, Web-Sat4). This PC can be used as a gateway to connect multiple PCs to the Internet.

The 14-month project included the following phases:

- Phase 1: Set-up and orientation of end-users: December 2001-February 2002
- Phase 2: Pre-operational pilot phase: March 2002-December 2002
- Phase 3: Evaluation: March 2002-January 2003
- Phase 4: Business planning and deployment: September 2002-January 2003

The following schools took part:

- Gairmscoil Mhic Diarmada, a vocational school on the Irish speaking Arrain Mor island
- Gairm Scoil Chu Uladh, Bellanamore Secondary School
- Carrick Vocational School
- Loreto Community School, Milford
- Scoil Mhuire, Buncrana
- Abbey Vocational School, Donegal Town
- Loreto Secondary School, Letterkenny
- Carndonagh Community School
- Donegal Education Centre

SchoolSat was a direct response to the relatively poor level of connectivity to the Internet experienced by primary and secondary schools, despite the Irish Government's stated intention to provide every Irish classroom with a broadband connection to the Internet. Although it is true that throughout the developed world most schools have Internet access—(recent EU figures suggest that 90% of EU schools have Internet access, and this figure is growing all the time⁵), increasingly narrowband access is seen as insufficient for real educational use, and provision of broadband access is seen as a major objective for educational ICT policy. That is why in Northern Ireland, the current ICT strategy provided broadband access for all second-level schools. But although city schools are offered more and more choice according as ADSL services roll-out and competition drives costs down, the rural schools and schools in towns have too small populations to attract a competitive broadband offer. Despite the best efforts of all concerned, broadband access to the Internet in Irish schools remains considerably below European norms and there is a danger that Irish pupils will find themselves on the wrong side of a digital divide in terms of their access to and use of resources and opportunities afforded by fast access to the World Wide Web. Nolan Bowie notes, for example, that in the US there is

a geographical dimension to the digital divide, with rural families less likely to have access to the Internet than urban families.⁶

From the service provider point of view, SchoolSat proved that putting a service like Web-Sat in a school environment was viable and provided a great deal of evidence as to the service requirements of a schools community. On average, each school transferred about 1GB maximum of data each month with a usage ratio of approximately 1:20, where each school downloaded about 20 times more content than they transmitted. Technical problems were minimal and to a large extent such a service can be expected to run trouble-free with the minimum of maintenance. Problems, where they occurred, had far more to do with connectivity into the schools LAN and local maintenance issues that they had to do with any difficulty to do with the satellite service.

Having said that, it is clear that in order for a satellite supported service to be viable, it has to be to a community of school users and is not a service that can be offered on an individual basis. In rather simple economical terms, it is just not viable to offer a service such as SchoolSat to individual schools as installation, maintenance, and service provision all require specific levels of buy-in to make such a service sustainable. Significant economies of scale can be called upon in order to build a reasonable business case, but without these, satellite service providers will struggle to offer a reasonable and long-term solution for Irish schools regardless of brash marketing campaigns.

This requirement for some form of centralised service provision is not all bad news, however, and another significant outcome from SchoolSat was that given schools' tendency towards predictable and pre-defined content, they are in a good position to benefit from the added value of satellite multicasting services. During the 12-month pilot in Donegal, it was evident that a great deal of Internet traffic was to a small number of Web sites. School communities tend to be conservative and inclined to visit the same sites, where

quality, suitability of content and safety can be guaranteed. This means that a satellite-supported service that delivers a set of pre-described content to the local server is eminently suitable and one which can deliver significant economies of scale. To this end, Web-Sat and ATiT are now building a school multicasting offer within another ESA project which can offer end-to-end multicasting and caching services to schools aimed at maximising their use of the Internet and delivering safe and reliable content to the classroom using state-of-the-art technology. The objective behind the project, called SchoolCast⁷, is to plan, design, implement and bring to pilot utilisation a content delivery system, whereby a variety of multimedia files (Internet, video, audio, image) can be multicast to 10 or more Irish schools using a two-way satellite infrastructure, and cache the files at the school server for fast local access. The pilot will also validate the service on high bandwidth terrestrial multicast networks through the collaboration of HEAnet.

The intention is to pilot test SchoolCast in schools in Ireland with a view to its take-up as a sustainable commercial service. Through the pilot the business case for such a service will be refined and elaborated. Key target clients include satellite service providers, educational stakeholder communities including national and regional school portals, ministries of education and government agencies, schools and educational content providers.

FUTURE OF THE PROJECT

In June 2003 the final report⁸ was submitted to ESA, which includes the report on the pedagogical value of such a service as carried out by Dr. Aidan Mulkeen from the National University of Ireland, Maynooth. This report describes the main activities and outcomes from the project and broadly concludes that the service is of great benefit to schools, particularly those in rural communities

where opportunities for broadband access via means other than satellite are scarce. It also shows that putting in place a satellite service for schools is manageable and describes a service which ran relatively fault-free for more than one year. Although attempts were made to correlate the level of service with both size of school and pupil/PC ratio, it is apparent that the use of the Internet in schools is generally far more a function of teacher motivation, experience and expectation.

Meanwhile, SchoolSat has continued in Donegal despite the fact that the funding from ESA ended in February 2003. The service to the schools taking part continues due in part to the direct support of NCTE and more recently with the partial support of Údarás na Gaeltachta. This support has guaranteed the continuation of the Web-Sat service to the schools taking part until June 2004.

It is important to note, that since the end of the SchoolSat trial in Ireland in January 2003, the Irish Department of Education and Science has launched a significant initiative to provide over 4,000 schools in Ireland with a broadband connection. Given the advantages and feasibility of satellite technology as proven in SchoolSat to meet the connectivity needs of rural and remote schools, it is estimated that more than 60% of these schools will require satellite connectivity of a similar type to that provided during SchoolSat. Roll-out is planned to begin in January 2005.

CONCLUSION

One thing remains clear, given the geographical spread of Irish schools with more than half located in rural communities or towns of less than 10,000 people and that is that satellite services remain the only viable way to offer broadband access to the Internet in the foreseeable future for many schools. While not cheap, the only way such services can be offered at an affordable price is for them to be offered on a reasonably centralised

basis. Centralised purchasing and management has become increasingly popular with regard to ICT service for schools generally, hence the intention of the Irish Department of Education and Science to utilise HEAnet, the national Irish Higher education network provider to manage the forthcoming broadband schools service in Ireland¹⁰. Given the price of economic isolation and the need for balanced regional development, satellite technology offers a key opportunity to ensure that the schools' broadband service meets the needs of all Irish pupils and not just those in large cities.

KEY TERMS

Bandwidth: The amount of data per second that can be delivered to your computer. A 56K modem has a bandwidth of 56 kilobits/second. The term bandwidth is also used in conjunction with data rate when discussing video.

Broadband: Broadband is a new way of connecting to the Internet that will ensure rapid access, faster download times and a better overall performance such as high-resolution, graphics and CD-quality sound. Broadband connections are sometimes also called “fat pipes” due to the substantial amounts of data they can carry compared to more traditional “narrowband” connections, such as a modem which delivers variable service quality with slow download speeds. A broadband connection can be delivered in several different ways: Cable, DSL, Fixed wireless and satellite.

Caching: Using a buffer within your own computer’s fast memory to hold recently accessed data. It is designed to speed up access to the same data later.

Digital: Information represented as discrete numeric values, e.g., in binary format (zeros or ones), as opposed to information in continuous or analogue form. Binary digits (bits) are typically grouped into “words” of various lengths—8-bit words are called bytes.

DVB: DVB stands for Digital Video Broadcasting, the European standard for Digital TV. This standard provides a very high-speed, robust transmission chain capable of handling the many megabytes per second needed for hundreds of MPEG-2 digital TV channels.

LAN: Local Area Network.

Multicast: A one-to-many client/server connection in which multiple clients receive the same stream from a server. To receive a multicast, a client listens to a specific IP address on a multi-cast-enabled network, like tuning a television to

a specific channel. In contrast, a uni-cast is a one-to-one connection in which each client receives a separate stream from a server. Multicasting is a technique whereby information is transmitted to a well-defined and controlled group of users on your network.

Chapter 3.24

The Use of Online Technology in the Teaching and Learning Process: WebCT — Communication Technology or Communication Turn Off?

Maggie Ferguson

University of Central Lancashire, UK

Adrian Ibbetson

University of Central Lancashire, UK

ABSTRACT

This paper provides an evaluation of the effectiveness of a year-one module delivered by a combination of traditional and online teaching methods to leisure and tourism undergraduates. The research further considers the value of the extemporized implementation of computer-mediated instructional settings that do not consider or refer to existing evaluative frameworks, in view of the fact that initiatives often are driven more by pragmatism and policy than pedagogy and theory. The findings show that there are negative and positive attributes to both methods of instruction, but overall, traditional methods are seen as preferable to new online developments.

The reasons for this preference are explored and include communication interaction and contact with a tutor. The main positive attributes of the online system are flexibility and accessibility. The issue of appropriateness of online instruction at differing higher educational levels is also considered.

INTRODUCTION

The current UK university sector is subject to a diverse range of environmental factors that have increasing influence on traditionally accepted practices. These environmental factors include increasing competition among institutions, a

dwindling resource base, and a more academically varied student population due to widening participation initiatives and increasing pressures to increase student numbers. The result of this has led to many universities having to revisit their services both in terms of the subjects they offer and in how they are delivered. There is an increase in pressure to sell their product to a much wider market both at home and abroad and, as a result, universities have had to consider alternative methods by which to deliver the curriculum, with by far the most prominent of these being the utilization of education technology. The use of distance education technology is increasingly perceived as the future of education (Leung & Ivy, 2003; McGinn, 2000; Sistek-Chandler, 2000; Webb, 2001), and it is anticipated that increasing utilization will lead to greater profitability for universities due to its ability to increase and widen provision with little or no significant increase to existing resource structures.

UK government initiatives suggest that post-compulsory education will be delivered increasingly by a range of integrated methodologies, including distance learning packages, traditional chalk and talk delivery, and online student support (Thompson, McGivern, Lewis, & Dierck-O'Brien, 2001). The dilemmas presented by such a scenario are multifarious, with perhaps the necessity to use online technology to teach larger numbers of students regardless of the appropriateness of this type of forum for learning being the most significant to course tutors.

The primary objective of this paper is to provide an evaluation of the effectiveness of a year-one module delivered by a combination of traditional and online teaching methods to leisure and tourism undergraduates. The research will consider further the value of the extemporized implementation of computer-mediated instructional settings that do not consider or refer to existing evaluative frameworks, in view of the fact that initiatives are often driven more by pragmatism and policy than pedagogy and theory.

THE FLEXIBLE FRIEND: ANYTIME, ANYPLACE, ANYWHERE

The expected influence of existing and developing learning technologies is an area that is subject to increasing debate, and authors such as Porter, (1996, cited in Segrest, Domke-Amonte, Miles & Anthony, 1998) contend that new technology will stimulate more change in the upcoming years than universities have seen in the last half of the 20th century. Further, writers such as Van Dusen (1997, cited in Evans & Haase, 2001) state that one of the reasons for the rise of online learning is that “the half-life of what a person learns is getting shorter and shorter” (p.248) and that with the rapid changes in technological and societal practices, the education process is becoming more and more of a lifelong journey. A major factor behind the growth of distance education programs is the opportunity to engage and to learn without being restricted by geographical or time boundaries. E-learning as a medium of delivery for education has many advocates (Leung & Ivy, 2003; Salmon, 1998, 2000; Webb, 2001), due to various possibilities such as the enhancement of access and a more flexible learning experience. Webb (2001) further contends that the Internet is a tremendous equalizer as a source of knowledge.

WebCT AND LEARNING

WebCT is one of several existing managed learning environments (e.g., Blackboard, Domino, and Top Class). Many UK institutions are choosing WebCT campus edition, and 38% of institutions worldwide have selected this system over others (e.learning age, 2003). This study concentrates on the use of WebCT as an online teaching medium, as this is the system that currently is utilized by the university in which the research was conducted. WebCT provides a secure environment in which course materials can be placed.

It has the capacity to facilitate the creation of sophisticated World Wide Web-based educational environments by non-technical users and can be utilized on the one hand to create complete online courses or, on the other hand, to publish supplementary materials (Morss, 1999). WebCT provides a number of learning tools, including course content, course calendar, electronic mail, navigational tools, discussion board, and student progress tracking. It is promoted as being easy to use (webct.com/company accessed November 30, 2003), and authors such as Wernet, Olliges, and Delicath (2000) concur with this. It is useful in providing additional information and services to students and is purported to facilitate improved communications among the tutor and the students. Lu, Yu, and Liv (2002) further suggest that WebCT supports development of problem solving and critical thinking, although they do recognize that there is not much existing research to support this view.

ATTRIBUTES AND LIMITATIONS OF ONLINE PROVISION

The Web is increasingly utilized in course instruction, and, according to Leung and Ivy (2003), is seen as a popular tool for enhancing the learning experience for students. Salmon (2001) contends that there would appear to be increased opportunities for student interaction, student centeredness, and collaboration. French, Hale, Johnson, and Farr (1999) note that computer-mediated communication (CMC) can promote more autonomous tutor/learner relationships than those possible in one-to-one contexts, and Burnett (2003) maintains "that reduced to an on screen presence the tutor is less able to adopt a dominant role in digital conversations" (p. 247). Palloff and Pratt (1999) uphold the view that fundamental to the learning processes are the interactions among students and the interactions among students and instructors.

A potentially useful feature of WebCT is the bulletin board, which provides a forum for students to post comments and debate issues and points that are relevant to the course. LaMaster and Morley (1999) recognized this facility as being both meaningful and enjoyable, while studies by Poole (2000) and Teague (1999) ascertained that students preferred discussion boards to online synchronous chat, since they could draft and consider responses to others' ideas. It must be noted, however, that much of this existing research has concentrated mainly upon post-graduate users, and, indeed, the use of distance learning thus far has been predominantly within the sphere of post-graduate education (Gammie, Gammie, & Duncan, 2002). Morss (1999), however, surveyed undergraduate perspectives on the use of bulletin boards and reported mainly positive learning experiences, while Ibbetson (2000) found that students did not engage in the process to any meaningful degree.

Previous studies on student perceptions of course Web sites are limited and conflicting to a certain degree. Montelpare and Williams' (2000) focus-group-based research found that students appreciated the fact that the Web-based activities were relevant, easily accessible, convenient, and self directed. Students also reported that they gained confidence from the hands-on experience and that the exercise encouraged interactive teamwork. However, Lomine (2002) contends that students' opinions of online learning and teaching are varied, with an enthusiastic small number being interested and willing to work with computers as much as possible, while conversely, a reticent small number will be reluctant almost by principle. The research maintained that the majority usually fall somewhere in the middle.

The construction and implementation of complete WebCT courses by instructors/lecturers is arduous and time-consuming, which as yet has not been recognized or acknowledged fully by universities. Hartley (1999) and Witt (2003) recognize the large amount of time and

effort that must be invested by the instructor in compiling and inputting the information and concedes that there is usually little support or motivation to dedicate time to the development and maintenance of Web courses. According to McGorry (2003), many instructors find creating interactivity in an online course one of the greatest challenges in Internet-based education. A National Education Association (Reisman, Dear & Edge, 2000) survey of more than 400 distance learning instructors indicated that more than half of them spends more hours on distance learning courses than on traditional courses. The process also is undertaken in the belief that students will engage either fully or partially in the process and subsequently will benefit as learners as a result of this engagement.

Existing research by Rosen and Petty (1997) contends that this may not be the case for a number of reasons. For example, the use of links to related sites that are intended to provide supplementary information potentially can become the main area on which the students focus and can also direct or misdirect them to further linked sites that are of no relevance to the original course site. Hartley (1999) also argues that repetitive imagery leads to sensorial overload, which may hinder the understanding of the relevant concepts presented, and additional factors, such as previous Web experience and learning styles, are also cited as being influential in participation success, and, according to Roberts (2002), the connections between interaction and learning are not yet fully understood.

Salmon (2000) stresses that the importance of individual access and the existing abilities of participants to use online learning tools are essential prerequisites for successful participation in online learning. The importance of experience is emphasized by Lu et al. (2002), who maintain that access is easier for post-graduate students. These students could be considered to be more mentally mature and to have greater life experience and higher reading levels, which qualify them to

pursue more readily the more impersonal environment created by various online study tools. Thyer, Artelt, Markward, and Dozier (1998) and Siegal, Jennings, Conklin, and Napoletano Flynn (1998) describe additional barriers to learning and cite unreliable technology, lack of technical support, and cost as the most significant. Technical support is crucial in an online learning environment. If students are unable to access course material, their participation will be seriously hindered. McGorry (2003) maintains that initial frustration with technical problems in online courses can cause students to quickly abandon programs, creating long-term negative perceptions of these courses and preventing students from pursuing this type of education.

Basile and D'Aquila (2002) tried to determine whether there is a difference in attitudes among students exposed to computer-mediated instruction (WebCT) and students receiving only traditional instruction. They concluded that there was no difference in attitudes, but they do raise the question of the role of the instructor in implementing pedagogy. They note that the teaching style for one of the two tutors who was used in the research appeared to be more conducive to a traditional format. However, Carey and Gregory (2002) found that completely asynchronous Web-based distance learning was a "generally satisfying and educationally effective experience" (p. 429) and, by and large, perceived to be at least as good as traditional formats and in many regards superior to the existing methods. A later study by Gregory (2003), however, found a change in students' perceptions and attitudes, that illustrated a desire for a return to some form of instructor/tutor interaction, which concurs somewhat with Thyer et al. (1998), who maintain that students preferred lectures to transmitted coursework. Wernet et al.'s (2000) research states more categorically that "traditional students expect ongoing, weekly, personal interaction with an educator" (p. 501), and they believe that this is due mainly to existing preconceived notions of how learning occurs

within education, based on prior experiences and within existing learning environments and, as such, is considered the norm. Therefore, the aim of the study is to evaluate further the effectiveness of a module that was delivered by a combination of traditional delivery and WebCT technology.

METHODOLOGY

This project involved collaboration among lecturers teaching the same module across two geographically separated campuses. The physical construction of the WebCT course was undertaken by two tutors over a period of some months. Financial support was obtained by one of the tutors, which was utilized to provide some relief from teaching duties. In actuality, however, this support proved to be insufficient, as the process took much longer than originally anticipated.

The module in question was a first-year introductory leisure module that was part of the undergraduate syllabus and spanned a full academic year (two semesters). In the first instance, the first half of the module (first semester) was taught in a traditional manner: one-hour lecture plus one-hour seminar. In the second semester, a hybrid approach, as advocated by Gregory (2003), was adopted, where the weekly lecture content was converted into Web page format and used to construct a managed learning environment in WebCT; this included paths of lecture notes, links to useful Web sites, module mail, and discussion boards. This weekly content identified reading to be done in preparation for the seminar, which was conducted using a standard face-to-face format. The pages compiled did not consist of traditional presentation slides and were constructed specifically for WebCT in an effort to maximize the best components of the system. Two different instructors from the same department taught the module on the two campuses, but they did teach the whole module (i.e., in the first semester, they both used a chalk-and-talk approach, and in the

second semester, they both used WebCT to support the teaching/learning process). Thus, the project used the same staff to deliver different methods to the same students and provided an interesting comparison between the two potentially different styles of teaching/learning.

At the end of the module, the students (Campus 1 $n = 7$, Campus 2 $n = 52$) were asked to complete a brief questionnaire (using a Likert scale format) that asked them about their logging on habits, level of satisfaction, perception of the accessibility of the tutor, and perceived level of understanding. Qualitative comments were also sought regarding clarification of the quantitative scores and pertaining to the best features of WebCT, the worst features of WebCT, and potential future improvements to the module. Results are presented for the whole group as the small numbers in Campus 1 precludes comparison.

In addition to completing the questionnaire, students were asked to participate in focus group interviews as part of the module evaluation. The interview template was designed to embellish the issues raised in the questionnaire. These were conducted in seminar groups, one at Campus 1 and two at Campus 2. The focus groups were undertaken by a researcher that was external to the teaching and learning process. The discussions were tape-recorded, and the evidence has been used to form the evaluation.

RESULTS

From Figure 1 it is evident that the majority of students (46%) logged on once per fortnight. Thirty-nine percent of students logged on each week, and a small portion logged on much less frequently (3% once per month, 3% less than once per month, and 7% never). These findings were disappointing, as students were required to log on each week to read the paths of notes, follow the links, and complete the reading in order to inform the preparation for the seminar. From Table 1, it

Figure 1. Frequency of students logging on

is evident that, although 32.1% merely used the managed learning environment to provide them with a comprehensive set of printed notes, the majority of the students (60.8%) did use the site in an interactive manner, even if this varied in degree from limited use of intrinsic features to exploration of links and use of the bulletin board.

Students on the larger of the two campuses bemoaned the fact that they could not easily physically access computers on campus. Their preferred work area appeared to be the library. They reported that having to constantly queue for a machine was a major barrier to logging on regularly. The students reported that the busiest period was from late morning to early evening, and that unless you got up early and laid claim to a workstation, you were condemned to the queue. The students in question reported that on average they logged on twice per week to do general work, answer their e-mails, and surf the Internet. This

should have allowed them to also access WebCT. The picture on the smaller campus was very different. The new Library and Learning Resource Centre currently appears to match comfortably and to satisfy demand.

Table 2 demonstrates that the majority of the students (96.2%) found the package easy to use to varying degrees; this would negate students finding the package difficult to use as a reason for the disappointing logging on habits reported previously. The issue of reliability of the system elicited the following comments: “The Internet [the network/server] is not always reliable.” “It [WebCT/Server] is very slow when lots of people are logged on at the same time.” Physical access was a problem for some, as the following statements illustrate: “Finding available computers on campus is often difficult.” “I find it difficult to find time to go on the Internet — I can only access the Internet on campus and I have to wait around for a computer.”

Table 1. Demonstrating how students accessed WebCT

Description of Use	Percentage
Do not log on; use other people's notes and read books on reading list	7.1
Look over someone's shoulder while they log on	0
Just log on and print pages to minimize time using WebCT	32.1
Log on and read pages but do use other features	17.9
Read the pages and explore the links to other Web sites	25.0
Read the pages, explore the links, and occasionally use the bulletin board	17.9
Read the pages, explore the links, and regularly use the bulletin board	0

Table 2. Demonstrating ease of use of WebCT

Level of Difficulty/Ease	Percentage
Very Difficult	3.8
Difficult	0
Relatively Difficult	0
Relatively Easy	26.9
Easy	46.2
Very Easy	23.1

In terms of perceptions of student satisfaction, Figure 2 demonstrates that the majority of students were satisfied with the delivery of the module, but they were more satisfied with the traditional lecture/seminar method than the WebCT augmented approach.

These findings differ in part with the qualitative feedback stated as follows, relating to the flexibility of access and the permanency of the material that provided a reliable reference mechanism. The flexibility of WebCT was positively supported by the following three statements. "You can read it as many times as you want." "It's a great fallback if you have missed a week." "It's convenient, I can decide when to do the work; it allows me to be more flexible with my time." The structure and

permanency of the system were supported by the following quote:

The notes are more structured [in WebCT], rather than rushing down notes from a lecture which are difficult to understand afterwards.

Negative feedback referred to the reading involved the following: "One of the worst things was finding the time, being motivated enough to complete the reading" and to the cost involved in printing notes from the site.

From Figure 3, it is evident that the students favored the traditional lecture/seminar-type delivery over the online method in relation to their perceptions of the accessibility of the tutor.

The Use of Online Technology in the Teaching and Learning Process

Figure 2. Perceptions of student satisfaction by method of teaching

Figure 3. Student perceptions of tutor accessibility by method of teaching

Figure 4. Student perceptions of level of understanding by method of teaching

The qualitative comments recorded demonstrate that the students' perceptions of accessibility appear to be connected to the question of clarification and explanation. Typical responses include comments such as, "Some things can't be expanded or discussed and questions can't be answered as they would be in a lecture" and "You don't get the interaction with the tutor to ask questions there and then."

In addition, some of the students' comments highlighted additional negatives with regard to the volume of WebCT material available; the following statements illustrate the problems encountered.

I find it easier to take things in, in the traditional lecture, when I am listening and writing rather than having to collect reams of writing off the Internet that I cannot be bothered to read, and when I do it does not sink in.

I tended to just print out the notes and skim over them instead of taking in and understanding the information.

Although the majority of students perceived the module as a whole to have developed a good level of understanding, the traditional lecture/seminar approach was reported to be more successful than the augmented online method (see Figure 4).

As stated previously, the following qualitative comments reported by the students give rise to an element of contradiction. The quote, "WebCT was a new and exciting way of learning instead of traditional lectures," shows that some students appear to have responded more readily to the new and exciting nature of the managed learning environment that WebCT enables. Additionally, statements such as, "WebCT provided more flexibility than the traditional approach ... extra links to further sites was an interesting

addition,” highlighted that the more dedicated students appreciated the additional links within the site, which facilitated more in-depth study and achieved a desired level of differentiation, as planned by the tutors.

DISCUSSION

The disappointing findings with regard to students initially logging on to the system and accessing the path of notes required for the following weeks’ seminar were attributed to a number of factors, including difficulties in getting access to computers, an unreliable server, and slow running capacity at busy times. This was frustrating for both the students and the tutors and emphasized one of the fundamental weaknesses of existing/current online teaching systems provided by universities. Since this research was conducted, the university has invested in a new server that is faster, which has helped alleviate some of the problems encountered. The importance of access as stressed by Salmon (2000), Thyer et al. (1998), and Siegal et al. (1998) was not fully realized in this instance, which raises the question of how future online courses should be developed in order to avoid these problems. It must also be questioned, if these initial difficulties contributed to some of the negative feedback that concurs with McGorry’s (2003) theory that initial technical problems can lead to students negative perceptions. The recognized and promoted anytime, anyplace, anywhere attributes of WebCT were not confirmed/supported by the majority of students within this study, as their logging on habits were consistently disappointing, and their interactions with other sites and the bulletin boards were minimal and underdeveloped.

Few students took advantage of the links provided by the instructors, and they did not use the Web site for feedback and questions. This finding implies that the Internet was used mostly as an information site. These findings are in contrast

to Montelpare and Williams’ (2000) findings that Web-based activities, including use of Web links, were well received by their students. Additionally, Rosen and Petty’s (1997) view that the student can become distracted by links is not evident in this study.

From the students’ perspectives, there was ambivalence toward the bulletin board, despite repeated attempts by the tutors to stimulate discussion. Interestingly, this lack of active engagement on the bulletin board is not a new phenomenon; it was a feature of a similar initiative undertaken at a previous institution by one of the authors (Ibbetson, 2000). One of the primary reasons for encouraging use of the bulletin board is that it provides an arena for virtual interaction, which is desired by tutors but is often suppressed in large group situations. In theory, as participation in online learning is individual in nature, it should follow that the reasons for not contributing in group situations are removed. In actuality, however, the contributions made to the bulletin board appear and remain in the public domain, and, therefore, reticence surrounding fear of failure and social embarrassment remains. When considered in comparison to the positive, meaningful, and enjoyable experiences of the post-graduate students in LaMaster and Morley’s study (1999), the question of level and experience of student would appear to be significant. This is supported somewhat by Lu, et al. (2002), who purport that undergraduate students may not have the mental maturity, greater life experience, or higher reading levels that would make them more able to pursue more readily the impersonal environment of the bulletin board.

The students favored the traditional lecture/seminar-type delivery over the online method in relation to their perceptions of the accessibility of the tutor. This differs from Basile and D’Aquila’s (2002) research that found that there was no difference in students’ attitudes between the two teaching methods. The main reasons stated for preference of traditional methods included

clarification of points and social and intellectual interaction with the tutor.

It appears that some students experienced difficulty in digesting the information in the textual, online format. However, this may reflect more generally individual learning abilities and preferences than the online format per se. For example, students are just as likely to skim over a book or any other printed material, and students have different learning requirements, preferences, and styles. However, it should perhaps be noted again that online learning and teaching strategies are relatively novel and, therefore, unfamiliar to students; thus, their frame of reference is limited. Therefore, the unfavorable comparison of the WebCT-augmented approach to the traditional lecture/seminar format may be a function of its novelty, due to the fact that this was the only module that the students experienced in this manner in their entire first year. This would also concur in part with Wernet, et al.'s (2000) assertion that students have existing preconceived notions of how learning occurs within education, based upon prior and existing experiences within learning environments. If online learning methods are to be utilized more fully in the future within higher education, then this assertion of preconception could be tested further within the bounds of this medium, as it becomes more culturally ingrained.

The majority of students stated that they were satisfied with the delivery of the module but that they were more satisfied with the traditional lecture/seminar method than the WebCT/seminar augmented approach. While this contradicts Carey and Gregory's (2002) study that perceived Web-based learning as being superior in many regards to existing traditional methods, it does concur with Gregory's (2003) most recent research that expressed a desire for a return to more student/tutor interaction and with Thyer et al. (1998), who maintained that students preferred lectures to transmitted course work.

The qualitative data contradicted somewhat the quantitative finding with regard to students' perceptions of understanding by method of teaching. Some students appear to have responded more readily to the new and exciting nature of the managed learning environment that WebCT enables. For instance, the ardent students especially appreciated the additional links within the site that facilitated more in-depth study and achieved the desired level of differentiation planned by the tutors. This concurs with Lomine (2002), who found that students' opinions of online learning and teaching were varied, with an enthusiastic small number being interested and willing to work with computers as much as possible, while, conversely, a reticent small number were reluctant almost by principle.

The impersonal nature of online learning was expressed in a number of statements given, which highlighted the importance to students of tutor contact and interaction. Since this module was delivered to first-year undergraduates who are still initiating and developing networks and learning the norms of university life, it was perhaps a case of too much too soon. The importance of experience, as advocated by Lu et al. (2002), supports the tutor's notion that online learning is best suited to those with more experience of life and university and know more readily what is expected of them. As previously stated, much existing work in this area has concentrated on postgraduate involvement with online learning, and, as such, little research considers effectiveness at differing undergraduate levels. The effectiveness of WebCT would appear to be related to the educational level at which it is undertaken, which poses this question: Can expectations be shaped or changed to account for this, and, if so, how can this be achieved?

It is evident that the role of the tutor is fundamental throughout the whole process of constructing and delivering online teaching/learning systems. Traditionally, a tutor constructs a course,

compiles lectures, and delivers them. For online learning, the construction of the course is only the start of the process; the material then has to be inputted onto the system, which is onerously time-consuming and demanding, and authors such as Hartley (1999) and Witt (2003) recognize this. It is assumed that it is relatively easy to convert and generate material for online consumption in a managed learning environment such as WebCT. However, to go beyond merely converting PowerPoint slides into a Web-page format and developing detailed, coherent material takes a great deal of planning and preparation. It is the contention of the authors that converting and developing material that would have previously been delivered as a one-hour lecture into a path of notes plus integrated Web links in WebCT takes approximately 10 hours. Therefore, to produce a managed learning site in WebCT that has rigor as well as appeal is not something that can be done overnight. While the authors did receive some support for the process, it was not nearly enough to complete the task to a satisfactory standard, and much work was conducted in addition to existing commitments.

CONCLUSION

It is evident that a more comprehensive evaluation of the effectiveness of online techniques is needed before they are implemented as a fundamental teaching tool in universities. The study reveals that students prefer traditional teaching methods and regard them to be more effective than emerging online teaching systems. It is clear that the role of tutors is considered to be important, and that students rely very much on continuous personal contact, communication, and interaction with them. The flexibility of the online course was seen as a positive attribute of the new system as was accessibility, though there were negative considerations regarding reliability of the system.

The previous experiences of the students would also appear to contribute to successful utilization of online systems and, as such, raise questions as to the validity of applying ad hoc standardized online packages at differing levels in higher education. The importance of previous experience is an area that will be investigated further in future research as will the influence of existing and prevailing educational cultures. Prevailing educational cultures cannot be discounted as being a significant factor with regard to student satisfaction and perceptions of effectiveness, which suggests that future utilization and integration of online educational material would lead eventually to similar cultural acceptance of these new systems by students.

Chapter 3.25

The Didactical Potential of Robotics for Education with Digital Media

Andreas Wiesner-Steiner

Heike Wiesner
University of Bremen, Germany

ABSTRACT

The project “Roberta—girls conquer robotics” was launched by the Fraunhofer Institute (AIS) with the aim to help promote girls’ interest in sciences, mathematics and technology. As a summary of this research program, this article presents substantial results from the scientific evaluation of Roberta and suggests a new pedagogical approach towards the use of robotics in education. We discuss how didactics and technology (LegoMindstorms) interact in Roberta courses and how the materiality of robotics itself plays an important role here; that is, it already comes along as gendered material. Due to that, we draw conclusions towards general educational concepts for digital media. If carefully used as a didactical actor, robotics not only suits boys’ and girls’ interest in technological messiness but enables them for a technological-mediated life instead of just feeling overwhelmed. Robotics,

therefore, can function as an appropriate medium for general education in the more comprehensive sense of developing personality and agency.

INTRODUCTION

“Roberta — girls conquer robotics,” a project funded by the German Federal Ministry of Education and Sciences (BMBF), was launched by the AIS with the aim to help promote girls’ interest in sciences, mathematics and technology, and especially to encourage girls’ curiosity for engineering and computer science (Müllerburg, Petersen, & Theidig, 2004)¹. Scientifically escorted by the University of Bremen, Digitale Media in Education (DiMeB) and the Institute for Didactics of Natural Sciences (IDN), Roberta addresses 10- to 16-year-old girls. The project’s basic assumption is that robot construction kits — offering possibili-

ties to develop more self-confidence in one's skills — provide an attractive access to technology for girls. This article presents substantial results from the qualitative evaluation of Roberta courses and suggests a new pedagogical approach towards the use of robotics in education.

Background: Evaluation of the Roberta Project

The robot construction kits (Lego Mindstorm) consist of complementary mechanical, dynamic and electronic parts that allow the construction and programming of different types of robots. Basic models can be equipped with different engines and sensors (contact sensors and optical sensors). The programming can be done in two programming languages (RIS and NQC), the first offering easy-to-combine graphical blocks, the second requiring more teaching and explanation. The programs are transmitted on to the RCX module, a programmable Legobrick with three input sockets for sensors and three for engines. To learn about informatics, the teaching of basic programming skills marks an important aim of the Roberta courses.

While informatics is treated in Roberta as a constructivist science, the educational sciences provide the necessary orientation for both shaping and evaluating digital learning environments. Our evaluation, thus, focused on the following questions:

- How can the interest in technology of girls and women be triggered by the use of robotics?
- How is curiosity for technology generated?
- How should learning environments be designed to satisfy both girls and boys?
- Which didactical concept is appropriate in connection with robotics?
- Are robotics and didactics suitable to influence the self-concept of the students?

Results of the quantitative evaluation show that the course experience in longer Roberta courses are noticeably stronger influenced by the focus of the teacher (didactics, informatics, gender, technology) than in shorter ones (Rethfeld & Schecker, 2005). The didactical focus stages as the most positive influence on the experiences of the participants – which is why the importance of the course-concept increases with the length of the courses. Although the self-concept of informatics and occupational orientation are only affected in medium-size and longer courses, all Roberta courses help to develop a more positive attitude towards informatics with the participants — both concerning the self-estimation of their own competence and their occupational orientation (Hartmann, Schecker, & Rethfeld, 2005). The following qualitative exploration allows for a deeper and more detailed insight into these issues. Methodically, material and video analysis, participative observation, as well as single and group interviews and expert interviews, were combined (Wiesner, 2004).²

De/Construction of Gendered Materials — “Now we add real Formula 1 decorations to it”

Not only does the importance of didactics increase with the length of a Roberta course, the materiality of robotics itself plays an important role. Right from the start the material speaks for itself, because the children handle something they already know. The programmable bricks, engines and sensors, however, provide an unknown means to make experiences, so that children of both sexes are usually confronted with something new, too. The Legomaterial in this sense is evocative; that is, it generates presumptions, experiences and actions by itself. Treated from a gender-sensitive perspective, it even appears to be “gendered material”. A practical example:

The use of a car-like basic model often leads to car-like robots. Triggered by the impulse car-

likeliness, boys — and often girls too — in no time construct vehicles. This phase of construction is often introduced by remarks such as: “*Now we add real Formula 1 decorations to it.*”

Were no (car-like) models given, girls and boys often construct models with strong analogies to humans and animals. If children are left to choose the models themselves, their constructions are observed to be less gender specific. Gender-specific behavior becomes more obvious if given materials, models and tasks that already contain and enforce gender-specific orientations. Although the (Lego) material evokes gender-specific behavior³, didactical interventions and gender-conscious tasks allow to successfully deconstruct the gendered material. This point is made very clear by robotics expert Deirdre Butler:

... a teacher ... noticed ... the fact that the boys' ideas were dominating and they all centered around wheels. They all had to be vehicles that moved fast. Rather than separate the groups - ... for the next project, ... they simply should not [have] made a wheeled robot. They could use wheels to make conveyor belts or create other moving parts ... And that began to change things in her classroom, because they began to make other types of things.

As a consequence, the task not to construct a wheeled vehicle can transform both internalized gender-specific behavior and the use of gendered materials. Combined with a gender-sensitive view on team interaction and help, this can lead to new learning effects.

The Staging of Gender in Robotics — “just stick to the construction manual ...”

Our observations could not support the assumption that girls tend to work in a more team-oriented fashion than boys. In small groups, both sexes

were able to develop social skills and preferred to work in groups. Though in some boys' and girls' teams, alternations between team work and a hierarchical task division can be observed, to us, these differences also had strongly to do with the learning arrangement: The more intense a gender-sensitive approach, the more the boys and girls can work as teams. This aspect became evident in the practice of themes, like moving the robot through a maze, a highly self-designable task where problem-solving strategies often got developed as a team. “Gender-neutral” themes thus helped to prevent particular mixed teams from falling into two gendered groups.

Gender differences and gender-specific behavior brought into the learning environment as a precondition have been, in our view, actively transformed and thus co-produced by both the gendered material and the didactical design of Roberta courses. The consequential “staging of gender” (Wiesner, 2002) thereby takes place, where material and discursive worlds interact in specific ways. Due to that, technical materiality and didactical intervention constitute a switching relation, co-producing each other's effects in learning environments.

In that process, a gender-conscious didactical approach to both the technology and the students becomes essential. This is important to avoid girls being robbed of their fame on a crucial social point, when they present their robot in front of all participants; and to avoid boys from failing if they are driven by a “self-concept of the winner” (Buschmann, 1994). Noticeably often, the boys disturbed the girls' presentations by letting their own robots drive into their presentations. This was amplified by a rather reserved behavior of the girls that displayed gender stereotypes (e.g., “*You go ahead starting, we can present our robot at the end*”). Nonetheless, the boys were also put under stronger pressure by the amount of teacher attention, as a row of unhappy presentations showed. In both cases, LegoMindstorms can work as an exclusive or inclusive technology.

As we know today, bringing technology into schools can be beneficial, but much depends on how the teachers mediate the new tools. No wonder, the necessity of a gender-sensitive training concept for teachers⁴ is an important conclusion from the results of the qualitative evaluation. In Roberta courses, such an approach particularly amplifies positive experiences with technology design by ensuring that girls and boys have equal access and starting points. What we think robotics in education offers new here is that technological interest, creativity and the discovery of new skills, as well as the gaining of knowledge — perceived as a reflexive mixing of didactics and technology — can make kids ready for an increasing sociality with technical objects and processes, which will accompany and transform their life constantly. It is through this very concrete relation and interaction between both the materiality and virtuality of building and programming robots and their didactical mediation that, for us, the specific potential of robotics can get to the kids. The following sections will illustrate how robotics can create diverse potentials to initiate new forms of learning that deal with both the concrete and the abstract world.

Robotic Material and Constructivist Learning

Merging abstract programming and concrete construction worlds, robotics bear a character of challenge. Instead of following instructions, there is not just one way to make a robot. Many possibilities are found to tie to one's imagination. According to Papert, they ought to be things one can think with and that open specific and appropriate possibilities for the individual way of learning (Papert, 1994; Ackermann, 1996). Through concrete handling, the Lego material supports access to abstract concepts and vice-versa: the transfer of abstract programming concepts into concrete motion. Meanwhile, it gives feedback on how successful a construction or programming

process is. Such proceedings offer appropriate conditions to promote girls' and boys' technical curiosity. Girls usually feel inferior with regard to technical constructions, and often fear embarrassment. Robotics technology — combined with a gender-sensitive constructivist learning approach — instead allows for a less biased access.

FUTURE TRENDS: RECOMMENDATIONS FOR EDUCATIONAL CONCEPTS

In this respect, the experience with robotics to promote girls' interest in technology allows conclusions towards general educational concepts for digital media. Robotics as a *relational actor* not only suits boys' and girls' interest in technologies' messiness, but enables them for a technological-mediated life instead of just feeling overwhelmed. It is, however, also an appropriate medium for general education in the more comprehensive sense of developing personality and agency.

The Didactical Agency of Robotics

This study addresses the question how information and communications technology (ICT) affects and transforms identity (Turkle, 1995), resembling one of the major discourses in science and technology studies, where technology is not understood as separate from the behavior and identity of human users, but as a productive (f)actor in hybrid socio-technical settings (Latour, 1998; Rammert, 2002), where it works as an agent and a translator of human practice and experience.

The Lego-Mindstorms technology both in its virtual and material appearance offers exactly that — regarding the design and the use of its inscribed, activity-engaging potential for new learning strategies. During the Roberta courses, students constantly receive system feedbacks (either from the screen or from the robot) that structure their actions together with the teach-

ers' didactical approach. Even if the technology does not act intentionally, different forms of the *attribution of agency* can be observed here, as Rammert and Schulz-Schaeffer (2002) put it. The system reports, or the robot does not work, if incorrect programming commands were entered or technical malfunctions appear. The system suggests new action without pointing to the "right" direction. From the kids' view, the technology at hand "acts" on two levels: They experience an immediate physical, material processing executed through semiotic processes (programming). For this reason alone, students experience a process of the merging of abstraction and experimental interaction, of their own and of technological actions. System feedbacks, thus, are fundamental, simultaneously didactically constructed *and* mediatable agency-pattern, simply because they initiate reactions. They are also gender-neutral, since they occur independent from whomever operates the computer and do not assess changes due to gender differences but on grounds of the given tasks. Many teachers agree that the system feedback particularly activated self-learning effects.

According to our case for gendered materials, however, gender-sensitive didactics is not realized automatically via system feedbacks. If you want to promote girls' interest in technology, LegoMindstorms only becomes a didactical actor through a sensitively designed learning environment. Learning effects, creativity and new actions, thus, not only evolve through successful mastering of technology but by the *translation* of human agency through technological agency. In other words, learning emerges from the collaboration of technological and didactical worlds, the allocation of their different forms of agency and their active transformation by students. The potential of robotics as a didactical actor then lies in this possibility to frame the gradual development, allocation and attribution of both human and technological agency within learning processes (see Wiesner-Steiner, Wiesner, & Schelhowe, 2005).

While sociologists of technology often point to an increasing mangling of technology and sociality (see Latour, 1998), our perspective on robotics as a didactical actor for learning processes is particularly driven by the idea to discover potentials that lie in a gradual development and allocation of *different* forms of agency:

Question: "I have noticed that the robots did not always drive through the maze independently with their light and motion sensors. How come?"

Answer 1: "What I learned – the robots don't like you. You can't always master the technology." (boy)

Answer 2: "The robot is a technical product and then it is our fault that we didn't understand this." (girl)

Answer 3: "I think it's got to do with both. Sometimes the robot didn't do something it was programmed to, but there were also program errors." (girl)

Answer 4: "We have not seen that the robot didn't do what we told him to at all. Sometimes he did something we thought to be wrong, but that was in fact somehow right." (girl)

Answer 5: "I think the most mistakes occurred because we didn't really know the programming language and so the robot did what he was programmed to do but not what we wanted him to." (girl)

Particularly in NQC-related programming and presentation phases of Roberta courses, different forms of the allocation of agency and creatorship by the students and teachers (what "does" the technology, what should students do to make the robots do something ...) can be observed that create a specific form of experimental interactivity with the Lego material: Acting emerges both from an impression of the relatedness of technical and human agency and a clear feeling of their distinctiveness. The allocation of human and/or technological agency by the students based on this ambivalence thus shows relatedness as

well as expresses boundaries (see Gieryn, 1995). Learning experiences are categorized and processed within a highly differentiating cognitive framework. The allocation and distribution of different forms of agency not only display where insecurities regarding causalities and connections in the learning process exist but what students think is special with digital media in comparison to other learning experiences.

Based on their former experiences, boys and girls were most convinced of their own agency in the phase of construction, while in the programming phase they attribute the strongest form of technological agency. Nevertheless, the programming phase marks the time when they are most active in confronting the technology. This becomes evident if a group is observed throughout a long course. A robot programmed by a boy and a girl via NQC in same shares would do something slightly different, often together with what they programmed him to. Altogether responsible for more than 60 tries in their programming phase (2 ½ days), the group would not have stayed on track without the attachment of their programming interest to the concrete object “robot,” nor without any didactical intervention.

In opposition to the programming, in the presentation phase students are particularly interested not only to connect but to perform their own and technical activities. Amplified by the test situation, this is why the allocations the students make in this phase are more goal- and control-oriented than in more experimental course phases. Here, the agency of the technology is perceived as failure or success in relation to the given task, while mastering tasks is seen as both a success of the team *and* the robot. But is this not the place where research points to gender-specific differences? Where boys rather allocate success to themselves, while girls tend to allocate failure to the circumstances? This clearness vanishes in the case of Roberta courses, because — particularly in long courses — it can be observed that boys, like girls, use *both* allocations. The importance

of these allocations regarding the technology and themselves is thereby influenced likewise by the gender-specific orientations and didactical conception of the course.

In consequence, an important didactical task is to help the students find their own initiative. It is not only important to tackle the given task by means of successful control of the technology, but also to provide insights into the connection of human means of action and learning processes with technological agency. A corresponding remark by a Roberta teacher:

In the first 2 days, the students already asked for more help. If this is interpreted, they only made limited use of their means of action. (teacher)

Knowledge of the allocation and gradual development of technical and human agency in learning processes that aim at both the shaping and use of technology can be very instructive for handling situations like this. Recommendations of activity for different learning phases can be given and the technology itself can be continually improved as a didactical actor. Hardware and software used in Roberta courses have a special, technically delegated potential to destructure and restructure established learning routines. Both assist or prolong not only learned behavior and application routines, but also enforce, through their inscribed agency, new and creative forms of appropriation, without the paths being outlined in detail. A gender-sensitive approach can amplify this process (or even initiate it for girls), by ensuring that students have equal opportunities to develop and design.

Following this, examples for possible changes of the self concept are presented next. Here we are less interested in whether the students develop sustainable profession-oriented interests in engineering and computer sciences but whether constructing and programming robots can emulate transferable knowledge that gives them a more active understanding of technology, which goes

beyond surface-level familiarity. To be productive with highly interactive, multi-modal, adaptive and autonomous future applications, students need to apply their knowledge in a wide range of situations.

POSSIBILITIES AND LIMITS OF THE CHANGE OF SELF CONCEPTS BY ROBERTA COURSES

Whether one's own activity in dealing with LegoMindstorms is perceived as strong or weak gives hints to the possibilities for changing the self concept. For this reason, we not only asked students what they learned, but let them reflect on their learning processes. While the students referred to a special form of "experimental interaction" (Rammert, 1999) with the robotics material, in courses of different lengths, it is mainly the programming technique that interacts in specific ways with the social environment:

- "I do think that this has something to do with learning. I wouldn't program just for fun at home." (boy)
- "I think that it is important to connect this to something game-like. Looking at this programming language, I would absolutely not want to have this written on the blackboard. I think it is important to try it playing." (girl)
- "There weren't really disciplinary problems, because the students were challenged by the computers." (short course, teacher 1)
- "After 4 days, social problems are of greater importance than in short courses. In short course, the robot as a medium is such a challenge, that there is hardly a chance for social problems to occur in a team." (Long course, teacher 2)

Question: "Would you wish to learn more in this way?"

- "I wouldn't only refer to it in Physics and Informatics, but to Natural Sciences in general. Chemistry is usually a subject that I really like, but we don't have such good experiments. And this is important: that I don't just get a formula, but that I can also see: it really is like this. To get this confirmation." (girl)
- "What I learned? To start small and proceed in small steps.." (boy)

Besides sequencing the tasks, two wishes are formulated here: the wish for more playful, experimental learning and the wish for transferable knowledge. The question of change of the self concept was finally addressed by the teachers themselves:

- "We actually learned to enter a few commands in NQC. That is what can be tested. Can you program a loop? But we should also make clear that school education is more than the pure transfer of knowledge. That one can learn from mistakes. The students don't even realize that it is also an aim of the course to help them to help themselves. Not experiencing the learning at junctions and parting of ways is what is valuable." (teacher 1)
- "This self-confidence that they gain in both technology and themselves cannot be taken away from them so easy again. This will keep them for a while and then in the higher grades, when a colleague takes this up in Natural Sciences in an appropriate way, it will stay like that. ... those are very subtle mechanisms. That they bear that in mind and may consider it in future decisions in the higher grades, for their hobbies and in leisure time. That they believe in their capability to handle technical questions. In that respect, some technology distance may have been taken away." (teacher 2)

CONCLUSION

Knowledge of the allocation and gradual evolution of technological and human agency in design-oriented learning processes can be instructive for pedagogical concepts dealing with digital media. Recommendations for action can be specified for different courses, settings and learning phases, and the technology as a didactical actor can be improved permanently. The material and virtual aspects of LegoMindstorms thus bear the potential to deconstruct and reconstruct learning routines. They do not only assist or prolong routines of action but, through their inscribed agency, enforce new creative ways of learning that are not determined. A gender-sensitive didactical approach (implemented in a corresponding learning environment) can start and amplify this process by ensuring that the students have equal experimental opportunities. According to the Roberta aim of promoting girls' interest in technology, the following recommendations for the creation of learning environments are given:

- Assist dynamic processes of team formation
- Promote open working environments
- Promote "gender-neutral" project themes and work
- Reflect help and attendance in a gender-conscious way
- Provide a flexible mix of open and structured learning
- Give opportunities for teamwork and promote teamwork
- Schedule for gender-sensitive interventions during the project and presentation phases
- Consider the materiality, resistance and agency of technology in didactical approaches
- De/construct gendered material
- Observe allocation and distribution of technical and human agency gender sensitively.

With such an environment, the techniques of programming and constructing robots with LegoMindstorms not only offer the potential to enhance the room for activity. Purposefully used as a "didactical actor," the interaction with the "social machines" of the Roberta technology even offers possibilities for the change of self concepts *before* (female) students make educational choices and withdraw from computer science, engineering or math courses.

ENDNOTES

- 1 As of summer 2005, 153 courses have been conducted (1,880 students, of which 1,605 were girls. For more information about Roberta, visit <http://alex.ais.fraunhofer.de/zeno/web?action=content&journal=16413&rootid=15465>
- 2 The database contains qualitative interviews with a total of 11 tutors, six group discussions with students, two expert interviews and minutes, and photo and video analysis from six courses. All types of courses (short, medium, long) were analyzed.
- 3 The offered combinations of wheels and engines often leads to the exclusion of other functional lego bricks.
- 4 Gender sensitive didactics consist of:
 - Performance-related praise (particularly girls)
 - Gender-conscious reflection on the given attention and help
 - Gender-sensitive intervention during the project phases
 - “Gender-neutral“ tasks (e.g., circus instead of soccer scenarios)
 - Open learning scenarios
 - De-/construction of the “gendered material“
 - Use of designable technology.

Chapter 3.26

Students' Perceptions of the Laptop Program: What Factors Should be Considered Before Implementing the Program

Chuleporn Changchit

ABSTRACT

Due to a rapid increase in the usage of information technology, several companies are demanding that graduates have more than just the basic computer skills when they graduate. This has prompted many universities to initiate a campus laptop program in order to increase their students' computer experiences and skill sets. The success of a laptop program relies heavily on the extent to which the laptop environment is accepted and wholeheartedly implemented by students and faculty. Defining the conception factors necessary to successfully implement a laptop initiative becomes a critical issue to the success

of the program. This study examines university students' perceptions of a required laptop program to determine what factors that they think are crucial for the success of such a program. By understanding what factors encourage students to support a laptop initiative, such a program can be made more useful to students as well as more beneficial to universities.

INTRODUCTION

At an increasing number of universities, laptop computers have become a requirement for incoming students in preparation for their career success. The demand for technology-enhanced learning

environments no doubt will grow substantially over the next decade, as society, the academic community, and students continue to expect the educational process to employ technology comparable to that found in the real world (Hall & Elliott, 2003). On campuses where all students are expected to have and use computers, laptops appear to be the popular choice. The portability of laptops allows students to take them to classes, libraries, and on trips. It is also argued that their ubiquity makes computer-enhanced classroom instruction possible, decreases the need for labs, and consequently lowers the institution's computer budget (Badamas, 2001).

Laptop computers provide unsurpassed flexibility and convenience for students in the modern academic environment (Bazillion & Braun, 2001; Vaughan & Burnes, 2002). For higher education, providing experiences with computer tools tends to be one of the prerequisites to professional success, because employers value extensive experiences with information technology (Brown, Burg, & Dominich, 1998; Rola, 2002; Tomek & Muldner, 1999). Previous researchers have shown that laptop computers in the classroom can lead to positive educational outcomes (Finn & Inman, 2004; Fouts & Stuen, 1997; Gottfried & McFeely, 1998; Varvel & Thurston, 2002), which provides another incentive for universities to examine a laptop program.

Students' use of laptop computers is becoming more prevalent in today's universities. This more ubiquitous use of technology has forced several universities to discover and manage new perceptual issues in addition to the more familiar issues stemming from the primary use of university labs. Thus, defining the conception factors necessary to successfully implement a laptop initiative becomes a critical issue to the success of the program.

This research was centered on the needs and attitudes of students. Typically, students are still skeptical when it actually comes to requiring them to purchase and to use a laptop in higher

education. This study attempts to investigate what factors are important to students. It is important to understand what factors can influence students' decisions on the laptop program. By understanding what factors encourage students to support a laptop initiative, such a program can be made more useful to students as well as more beneficial to universities.

LITERATURE REVIEW

Laptop computers are used widely in many workplaces and schools and are currently the largest growth area within the personal computer market (Berkhout, Hendriksson-Larséna, & Bongers, 2004). The need to access information technology on a daily basis continues to grow, and the laptop computer's advantages of being portable, lightweight, and space-saving, enabling users to work anywhere and anytime, have increased its popularity among personal computer users.

The decision to require student ownership of computers is not unusual among higher education institutions. Several universities are initiating laptop programs in which all students are required to purchase laptop computers. These universities also offer their students computing and networking facilities that enable them to use many kinds of Web-based resources, from the library catalog to complete graduate degree programs. Within an astonishingly short time, higher education has achieved a ubiquitous electronic presence.

The laptop initiative not only has given students a better education but also has made them more competent in using technology. Several issues comprise a students' perceptual base regarding a laptop initiative. A study reported that key themes related to these issues include (1) academic and social use of laptops, (2) e-mail and instant messaging, (3) faculty utilization, (4) Web uses, (5) comparisons with desktops, (6) cost, (7) library use, (8) problems, (9) family utilization, (10) service and help, (11) convenience, (12) network

Students' Perceptions of the Laptop Program

access, (13) worry, and (14) hardware and software (Demb, Erickson, & Hawkins-Wilding, 2004).

However, since university laptop initiatives are still in their infancy, many people may choose not to support such initiatives (Finn & Inman, 2004). Unless it is imperative for the university that students are willing to support the program, it is quite risky to start requiring all students to purchase a laptop. Not everyone exposed to an innovation will adopt the new technology at the same rate. The speed at which technology diffuses throughout a social system, such as higher education, is believed to be heavily dependent on several factors. The success of the laptop program relies heavily on the extent to which the laptop environment is accepted and wholeheartedly implemented by students and faculty. As with any new technology adoption, the acceptance of a laptop initiative is likely to be quite uneven. Some students will accept it readily, whereas others will resist change actively.

This research was centered on the needs and attitudes of students. Typically, students are still skeptical when it actually comes to requiring them to purchase and to use a laptop in higher education. This study attempts to investigate what factors are important to students. It is important to understand what factors can influence students' decisions on the laptop program. By understanding what factors encourage students to support a laptop initiative, such a program can be made more useful to students as well as more beneficial to universities.

METHODOLOGY

A direct survey was used to collect data for this study. The survey questions were compiled from previous study questions pertaining to information technology innovation as well as suggestions from researchers and students (Demb et al., 2004; Luarn & Lin, 2005; Moore & Benbasat, 1991). These questions were designed to gather data on

students' perceptions on the prerequisite factors necessary to implement a laptop initiative as well as their demographics. To validate the clarity of these questions, three professors and three students were asked to read through the survey questions. Revisions to the survey were made based on the feedback received.

A total of 54 items were used as 5-point Likert-scaled questions with end points rating from "strongly disagree" to "strongly agree." Surveys were divided into three sections. The first section, survey items Q1 to Q28, collected demographic data. These demographic data were collected to find out if there were any specific characteristics of the subjects that might influence their decisions to support the laptop initiative. The second category, survey items Q29 to Q53, measured students' perceptions on the prerequisite factors necessary to implement a laptop initiative. These questions were asked to discover the most important factors that students perceived for the success of the laptop initiative. The third category, survey item Q54, measured students' willingness to support a laptop initiative.

Data Collection

Surveys were distributed to 402 students enrolled in a mid-sized, four-year university. The participants were given a 54-item survey and allowed class time to complete it. All participants were informed that participation in the study was voluntary and that all individual responses would be kept anonymous. The students were asked to rate each of the survey items on a Likert scale from 1 to 5, with 1 being "strongly disagree" and 5 being "strongly agree." Three hundred and eighty-two participants completed and returned the survey instruments.

Approximately 20.2% of the respondents agreed or strongly agreed with requiring all students to purchase a laptop computer for use in their education. Approximately 55.8% of the respondents disagreed or strongly disagreed with

Table 1. Demographic characteristics

Age (in years)						
Under 18	18-21	22-25	26-29	30-33	34-37	Over 37
3 (0.7%)	149 (39%)	118 (30.9%)	41 (10.8%)	20 (5.2%)	17 (4.4%)	34 (8.9%)
Gender						
Female		Male				
219 (57.3%)		163 (42.7%)				
Ethnicity						
African American	Asian	Caucasian	Hispanic	Native American		
20 (5.2%)	18 (4.7%)	196 (51.3%)	140 (36.7%)	8 (2.1%)		
First Generation College Student						
Yes		No				
171 (44.8%)		211 (55.2%)				
Own a Computer						
Desktop		Laptop				
324 (84.8%)		161 (42.2%)				

a laptop computer initiative. The remaining 24% of the respondents were neutral on a laptop computer initiative. Table 1 summarizes additional demographic characteristics of the respondents.

ANALYSIS AND DISCUSSION

The research data showed an odd-even reliability score of 0.946, suggesting internal consistency of the data. In addition, a Cronbach's alpha score of 0.922 was calculated as a second measure of reliability. It should be noted that these high levels of reliability relate to the data resulting from the measurement, not the instrument itself.

Factors Perceived as Critical

To determine which factors were deemed critical to the successful implementation of a laptop computer initiative, the mean responses to each question were calculated and examined. The items with the five highest mean scores were identified. The threshold for these factors was at a relative consensus point of 85% agreement. These fac-

tors, perceived as more critical by students, are presented in Table 2.

Students believe that access to printers is the most important factor for the success of a laptop initiative. This factor had a mean score of 4.47 out of 5 with 89.4% agreeing or strongly agreeing with this factor. This finding is consistent with observed student behavior in physical computer labs. Many students complete their assignments on computers off campus and bring their work to the computer lab to print hard copies.

Following the trend that exists in industry, students believe that it is critical for the university to provide a wireless network in order for them to access information stored at various points on campus and to access the Internet. The mean response for this item was 4.46 out of 5 with 89.2% agreeing or strongly agreeing with this factor.

The notoriously power-hungry laptop computers drove the students to rate the need for sufficient power outlets in the classroom. Students rated the importance of this factor with the same mean score as the need for wireless network of 4.46 out of 5, implying that 89.2% agree or strongly agree with this factor.

Students' Perceptions of the Laptop Program

Table 2. Critical success factors

Question: For the laptop initiative to be successful, the University must....	Mean
.... provide students with access to printers.	4.47
.... provide a wireless network.	4.46
.... provide sufficient power outlets in the class.	4.46
.... provide onsite maintenance support.	4.36
.... provide updates for virus protection.	4.29

Table 3. The not-so-critical success factors

Question: For the laptop initiative to be successful, the university must	Mean
.... require all students to purchase a laptop.	2.74
.... require all students to exchange to a new laptop after two years.	3.00
.... require all students to purchase a backup battery.	3.04
.... provide physical storage space/locker for students to store a laptop.	3.53
.... encourage all professors to fully utilize a laptop in the class.	3.67

Students also believe that it is critical for the university to provide onsite maintenance for laptop computers. This is evidenced by the high mean score of 4.36 out of 5. The majority of the students, 87.2%, agreed or strongly agreed with the necessity for onsite maintenance. If the students are expected to use their laptops as a learning tool, they must be able to have their laptop quickly serviced when needed.

Another factor rated as critical by students was the issue of providing updates for virus protection. The mean response for this item was 4.29 out of 5 with 85.8% agreeing or strongly agreeing with this factor.

Factors Perceived as Not-So-Critical

To determine which factors were deemed not so critical to the successful implementation of a laptop computer initiative, the mean responses to each question were calculated and examined. The five survey items with the lowest mean scores were labeled as the not so critical factors with a perceived limited impact to the success of a laptop initiative (see Table 3).

While students may see the benefits of using laptop computers in their education, they do not

believe that it should be a requirement. This factor had a mean score of 2.74 out of 5 with only 33.8% agreeing or strongly agreeing with this factor.

The majority of students also believe that it is not a critical factor to require a hardware update after two years. The mean score of this survey item was 3.0 out of 5. Only 35.5% agreed or strongly agreed with the requirement to exchange to a new laptop after two years.

Students believe that requiring all students to purchase a backup battery is not a critical issue. This factor had a mean score of 3.04 out of 5 with only 38.2% agreeing or strongly agreeing with this factor. This finding is consistent with the observed critical factor of providing sufficient power outlets in the classroom. With sufficient power outlets available, the need for a backup battery becomes a non-critical issue.

Students also perceived that the necessity of providing physical storage space for the laptop computer when not in use was a non-critical issue. This factor had a mean score of 3.53 with 53.1% agreeing or strongly agreeing with this factor. This finding is consistent with the portability concept of the laptop computer. Laptop and notebook computers are designed to be smaller and lighter, which makes them easy to carry around when not

in use. Hence, physical storage space on campus is not a necessity.

It does not seem to be of critical importance to students that professors should utilize a laptop computer in the classroom. This factor had a mean score of 3.67 with 59.9% agreeing or strongly agreeing with this factor. This finding is consistent with students' attitudes against requiring all students to purchase a laptop. It will be difficult for a professor to utilize a laptop computer in the classroom if not all students possess a laptop computer.

Differences Between Groups

To determine if there were significant differences, t-tests on the means were conducted on the critical factors between the group of students who support a laptop initiative and those students who do not support a laptop initiative. The responses from participants were divided into two groups based on their responses to survey item Q54. The two groups were the support group (those who responded with a 4 or a 5) and the reject group (those who responded with a 1 or a 2). The students who were uncertain on the laptop initiative (those

who responded with a 3) were excluded from the t-tests. Table 4 shows the factors exhibiting a significant difference between the two groups at a p-value < 0.05.

The results of the t-tests revealed a significant difference between the two groups on 11 factors: (1) exchange the laptop for a new one after two years; (2) purchase a backup battery; (3) require all students to purchase a laptop; (4) encourage professors to utilize the laptop in the classroom; (5) demonstrate the laptop's benefits to the students; (6) demonstrate how to fully utilize the laptop; (7) provide onsite maintenance support; (8) provide sufficient power outlets; (9) provide students with e-mail accounts; (10) provide all students with standardized software; and (11) provide access to printers.

It also is interesting to note that the support group rated all factors higher than the reject group. These results demonstrated that the support group tends to pay more attention to the details of program implementation. The findings suggest that the university may want to consider these factors before implementing the laptop program.

Table 4. Significance between group differences

Factors	Support Group	Reject Group	p-value
Exchange the laptop after two years	3.38	2.75 *	*
Purchase backup battery	3.57	2.78 *	*
Require all students to purchase laptop	3.57	2.32 *	*
Encourage professors to utilize laptop	4.22	3.33 *	*
Demonstrate laptop benefits	4.25	3.52 *	*
Demonstrate how to fully utilize laptop	4.25	3.70 *	*
Onsite maintenance support	4.53	4.29 *	
Provide power outlets	4.62	4.41 *	
Provide e-mail account	4.38	4.10 *	
Standardized software	4.46	4.16 *	
Access to printer	4.64	4.40 *	

CONCLUSION

The initiative for the use of laptop computers in higher education is viewed as advantageous, as reported in many previous studies (Finn & Inman, 2004; Fouts & Stuen, 1997; Gottfried & McFeely, 1998; Varvel & Thurston, 2002). Due to the ever-increasing use of technology in primary education and the increasing demand by industry for more computer-savvy graduates, the use of technology in higher education will continue to grow. Nevertheless, in order to smooth the transition, the factors critical to a successful laptop program must be identified and addressed.

This study has provided an empirical glimpse into the minds of students as to what they perceive as critical factors in a laptop initiative. The findings revealed that students, both those who favor and those who do not support laptop initiatives, place a critical level of importance on the following factors: (1) having access to printers; (2) having a wireless network in place; (3) having sufficient power outlets available in the classroom; (4) providing onsite maintenance support; and (5) having continuous and up-to-date virus protection software. Both groups also perceived that the following five factors have a lower degree of importance in the success of a laptop program: (1) requiring all students to purchase a laptop; (2) requiring all students to exchange to a new laptop after two years; (3) requiring all students to purchase a backup battery; (4) providing physical storage space/locker in order for students to store a laptop when not in use; and (5) encourage all professors to fully utilize a laptop in the classroom.

The results also revealed that 11 factors were perceived differently between the groups who support and do not support the laptop program. These factors were: (1) exchange the laptop for a new one after two years; (2) purchase a backup battery; (3) require all students to purchase a laptop; (4) encourage professors to utilize the laptop in the classroom; (5) demonstrate the laptop's

benefits to the students; (6) demonstrate how to fully utilize the laptop; (7) provide onsite maintenance support; (8) provide sufficient power outlets; (9) provide students with e-mail accounts; (10) provide all students with standardized software; and (11) provide access to printers. These findings suggest that the university may want to carefully consider these factors before implementing the laptop program.

The results in this study reveal the factors that are perceived by students as important or not important, if the university were to implement a laptop initiative. Determining such factors may allow educational institutions a base-level awareness of students' perceptions. This awareness could provide insights into what needs to be done to implement an effective laptop program. These initial findings warrant further investigation. To achieve a better understanding of all of the critical factors in a laptop program, future research also should include the perceptions of faculty, administrators, and staff as well as those of students.

Chapter 3.27

Game Mods: Customizable Learning in a K16 Setting

Elizabeth Fanning
The University of Virginia, USA

ABSTRACT

A game mod describes a modification within an existing commercial computer-based game that has been created by a user. By game modding, a user can participate in the creative process by taking the setting of his or her favorite game and customizing it for entertainment purposes or to convey information. For years, commercial computer-based game developers committed considerable resources toward preventing users from hacking into or hijacking their games. Now several computer-based game developers provide editors with their products to encourage users to create content and to allow educators, for instance, to take advantage of the benefits and production quality of commercial computer games in order to create customized instruction. This article focuses on mainstream, accessible games with straightforward modding tools that easily can be integrated into a learning environment.

INTRODUCTION

What Do Computer Games Have to Do With Learning?

Anyone who thinks there is a difference between education and entertainment doesn't know the first thing about either. Marshall McLuhan, Communications Theorist

Learning theorists from Piaget to Jonassen contend that profound, lasting learning culminates from the participant exploring, discovering, and interacting with his or her environment and culture in order to assimilate and create new meaning within his or her personal schema (Donaldson, 1984; Jonassen, 1988; Satterly, 1987). For a computer-based, constructivist learning environment, the quality of the user's learning experience is vested in the extent to which the

computer responds in a way that is consistent with the learner's information processing needs (Jonassen, 1988). The level of the user's interactivity and consequent sense of empowerment and control over his or her learning experience will affect the extent to which surface or deep learning will occur (Jonassen, 1988). Studies using computer games in learning settings, particularly the classroom, indicate that while student test scores may not improve significantly from using games, students do learn on a more profound level and are able to describe, for instance, why an answer to a test question is correct or incorrect (Squire, 2002). While this outcome appears marginal at this point, it is worth exploring what computer games do afford a user empowerment, motivation, insight, and engagement (Gee, 2003; Prensky, 2001).

How might one harness and channel a game's learning opportunities into the classroom in a way that empowers self-directed learning and the development of conceptual tools? Recognizing that emerging and even current learners most likely have grown up with a mouse in hand or at least developed considerable schema shaped by interacting with computer-based technology, computer games have gone beyond satiating the game-playing public as a dalliance or source of entertainment and have evolved into a meaningful, socially expressive medium, a platform for discussion and reflection that continues after the game session is over and outside the context of the game. However, the resources needed to create a commercial computer-based game are formidable, in many cases requiring the expertise of game designers, computer artists, and programmers, not to mention robust marketing support. Many have endeavored to create educational games for the classroom and workplace, but most have neither the resources nor the expertise to match the production quality and comprehensiveness of content characterized by more mainstream, commercial, computer-based games.

Given these requirements and constraints, how might one harness and channel a game's learning opportunities into the classroom? Perhaps game mods could provide a means for educators to use the quality and basic format of commercial games to create customized instruction for enabling students to create meaning in their own learning. A game mod describes a modification within an existing commercial computer-based game that has been created by a user. To do this, a user works with the game's existing assets to alter a small segment of the game's graphics, text, audio, or interactivity. In effect, a user can participate in the creative process by taking the setting of his or her favorite game and customizing it for entertainment purposes or to convey information.

Mods: Rules of the Game and Terms of Engagement

For years, commercial computer-based game developers committed considerable resources toward preventing users from hacking into or hijacking their games (Holt, 2004); however, and perhaps in keeping with the spirit of gameplay, many game users considered these prohibitive efforts simply another challenge to master within the game environment (Holt, 2004). Now, several computer-based game developers are providing editors with their products to encourage users to create content (Marriott, 2003; Prensky, 2003). It is important to note that these editors do not reveal the entire code but only enough for the user to create several levels of modification (Holt, 2004; Marriott, 2003; Prensky, 2003).

Why do commercial game developers even offer this much? According to Chaptman (2004), Holt (2004), and Prensky (2003):

- Within the game cultures, cool game companies encourage modding; they are more respected for their responsiveness and their

Game Mods

show of confidence in their users' technical competencies.

- The game developers are ensured continued play and sales, especially as the user can make the game continue to expand to more levels.

In keeping with the gaming culture, a game's modding capability comes with several rules spelled out in the license that comes with the game's software:

- The modder cannot make money off of their mods.
- The modder needs to own the base games.
- The modder cannot combine mods from different games into one mod.

To what extent does modding serve the modder? According to Holt (2004) and Prensky (2003):

- The mods are free to make.
- Modding provides a way for gamers to make their own games ("I can do it better"). The modder creates a new free game and extends gameplay of a game that otherwise may satisfy for two to three weeks.
- The modder can upload their mod to a modder's forum to showcase their work and to participate in a large community of workers, fans, and game players.

Note, too, that modding can be done at different levels, from a simple change to the appearance of a character to a more complex creation of a completely new setting, complete with AI. For the purposes of classroom use, however, what follows is an examination of how to bring modding into the classroom as a creative learning exercise without the encumbrance of complicated prerequisite technical skills.

Tools for the Classroom

Two popular computer games—Civilization, created by Sid Meiers and published by Firaxis software; and Electronic Arts' The Sims, created by Will Wright—provide easy-to-use, easy-to-access tools for customizing gameplay. Civilization is considered the penultimate commercial educational game (Squire, 2004). Played alone or with several players, Civilization is a geographically oriented and world-history, fact-driven game. Its gameplay requires the user to use maps and resources to manage the development of a civilization, based on the limits and opportunities presented by topography, resources, cultural affectation, and interactions with surrounding cultures (Squire, 2001, 2002, 2004). By comparison, The Sims is another popular but less educational game that allows user customization as well, but its outcomes are shaped less by geographic and political landscape and more by social considerations (Squire, 2001, 2004). The Sims often is described as less of a game and more of a simulation (hence, its name) or a toy, in that it is not designed around a more concrete goal (Fortugno & Zimmerman, 2005). Others argue that the goal of The Sims is to succeed in keeping the Sims going (Wright, 2003). Regardless of the arguments, the game does suggest a potential for application beyond simply engaging the user in a digital dollhouse. The Sims already has been modded for use in language curricula (Squire, 2004). Instructors have gone into the code layer to change the prompting language from English to French, for instance, to encourage incidental language learning via the gameplay experience. Others have taken its modding capabilities even further and into exciting new directions by creating public service advertisements¹ and replications of music videos² with The Sims' video capture tools.

Building a Plantation

To see how game modding can be used in a classroom setting, we used the popular, more flexible game *The Sims*, created by Electronic Arts. The Sims' game engine also allows and encourages the user to create buildings as simple as a modest bungalow, for example, or as complex as a historical landmark, such as Thomas Jefferson's Monticello. We endeavored to create a virtual Monticello (Figure 1) to see how far we could go with *The Sims*' game engine to create a mod based on the structure and its social interaction and then to determine the extent to which the final product might foster motivation, game literacy, or media dialogue.

We spent 20 hours using *The Sims*' tools to create Monticello, based on research of the plantation's blueprints and house plans as well as the historic significance of the time in which it was built. While *The Sims* has an engine that allows for elaborate construction, it did present some limitations:

- Pop art and modern home furnishings that the user can access to decorate the structure, thus interfering with the historical integrity of the house.
- Timed programming variables that can be difficult to alter. At one point, a school bus drove by and took Patsy Jefferson with it. It was necessary to wait until another game-play session in order for Patsy to return (by bus).

To customize a mod further, a user can venture, as we did, into the online community proliferating around *The Sims* in order to find tools for importing furniture. Some of these tools are created by modders not affiliated with *The Sims* who often expanded on the existing Sims editor code to enable more elaborate modifications (Figure 2).

Similarly, to create more real-life, Monticello-based characters, *Sims Creator* (Start/Programs/Maxix/Sims/Sims Creator) was used to create a specific type of person, from personality attributes to physical appearance and gender (Figure 3).

Reactions: The Learner

To begin our study, we opened the mod to a group of four high school students. Two of them were regular Sims players. At first, they wanted to sit back and watch, hoping to observe a historical reenactment of what might have taken place in the plantation they all had visited in person at least once.

As is typical of female Sims players (Chu, Heeter, Egidio, & Mishra, 2004), the girls were more interested in what people in the house were doing and how they got along. Sally Hemmings worked on the first floor. Another cooked in the basement. A butler wandered between the entryway and Thomas Jefferson's bedroom, where Jefferson stood pensively. Eventually, the cook caught on fire, and the girls used their Sims skills to attempt to save the cook—despite their efforts, death intervened. In time, the focus group also explored the mischief that players typically get into by fooling the game and by directing characters to behave badly to see what would happen (perhaps this is the digital-age version of teasing the cat or a prank phone call). Mischief accomplished or not, the focus group collectively expressed interest in accessing the blueprints for the plantation's gardens so that they could recreate them within the mod. Hence, despite the shortcomings of our virtual Monticello, our focus group validated Gee (2003) and answered the call that beckoned from the computer game: to pursue self-directed learning by solving complex problems. Such self-directed exploration to go beyond the boundaries of one's current understanding to create and assimilate meaning is also, of course, rich in constructivist learning implications (Jonassen, 1992; Satterly, 1987).

Reactions: The Classroom Teacher

We then presented the Monticello mod to five middle school and high school teachers for whom we demonstrated the Monticello mod and then asked to explore it on their own. Afterwards, we discussed with them the extent to which they found such a tool feasible for classroom use and how they might use it for learning. All of the instructors in the group were familiar with The Sims, but none had previous experience with it.

The instructors' first responses to the virtual Monticello mod was that it looked like a digital replacement of the traditional, second-grade diorama in the shoebox assignment. Initial issues with the mod were that it does not quite accurately represent the plantation physically. One indicated that they would like the ability to:

- Import historically relevant artifacts into the framework.
- Change character attributes to accurately represent historic personalities.
- Change the rules so that characters could not earn creativity points based on artistic accomplishments but rather earn points based on something that would have been important for that character during a given time period, or remove the point option altogether. "History is not a game," as one ardent history teacher explained.
- Reshape the going-shopping metaphor in the game engine that allows users to spend Sims dollars to construct and furnish the house. We used cheats to access Sims dollars to create this mod, following a financing strategy similar to that which Jefferson sometimes used to construct and furnish his own Monticello.

The teachers also expressed concern that a student might be more engaged in the gameplay than in the learning. One suggested that in the classroom, the student would want to use a mod

Figure 1. Virtual Monticello

Figure 2. Jefferson's revolving bookstand

Figure 3. Peter Fosset description

like the virtual Monticello to emphasize its historical significance, toning down the novelty of its gameplay. Another expressed that that he was

“excited about the possibility of bringing the past to the present” with mods, citing their value as “an observation tool,” and liked the idea of being able to go in and move around, adding, “I can explore the past and explore interactions!” By doing so, he felt that his students could gain insight through exploration and inference by considering the period characteristic values and experiences of historical figures that might shape their choices and behaviors.

Even with programming limits of *The Sims*, most teachers felt that their students could use such mods to experience a “good approximation” of the past, one that would help them to construct their understanding of the time period and issues that shaped decisions. Given this utility, one instructor noted that historically contextual game mods could fortify the development of his students’ mental models, and that as a teacher, he would have better insight into his students’ historical reasoning, based on the decisions they made within the framework.

“I could present [a mod] as an alternative assessment, opposed to a test or paper,” he explained, adding, “That you can change things is very exciting for the study of history.”

Contextualizing the Mod in the Classroom

As teachers explored how they might use the virtual Monticello mod in a classroom setting, their ideas for implementation included:

- A class inquiry. The teacher could run the mod on the projector and discuss how to interact with it with the class. Later, the students could work in groups on their own mods to explore and create shared meanings. The instructor could alternate between using class and group mods to promote inquiry and discussion. As one teacher pointed out, “There’s a lot of value just in creating

the scenario and having the students do the research for that.”

- An examination of character. “I want to see Monticello and send in Nat Turner,” one explained, to see how a character programmed with Nat’s attributes would react in a plantation setting. One instructor suggested replacing Jefferson with Napoleon for the same reasons.
- A yearlong study. One teacher suggested that the creation of the scenario could be an ongoing project, divided across academic quarters, each dealing with a different part of its construction in a way that parallels the course content delivery.

Integrating any type of computer game into a curriculum shifts the culture of the classroom from one that is teacher-driven to one that is a more user-centered learning environment; the teacher becomes a facilitator rather than a proffer of knowledge (King 2003; Squire 2004). However, when computer games are introduced into the classroom, the teacher has an amplifying effect on the learning outcome. If the teacher is appropriately prepared to use a game in his or her curriculum, it augments the learning success. Unfortunately, the inverse is true if the teacher is less aware of how to facilitate learning using computer games (Squire 2004).

Perhaps we can begin managing this amplifying effect by focusing on what the teacher *can* do

Figure 4. Jefferson in his study

Game Mods

to prepare for bringing game-based learning into the classroom by:

- Identifying the equipment and entry behaviors required for the game.
- Determining the time required for the game to make an impact on learning. Typically, a student needs time to understand how to use a game before he or she can begin learning with it.
- Recognizing the types of learning that computer-based learning facilitates, which is more knowledge-based and, to an extent, subjective.
- Determining how computer-based learning can support the learning goals.
- Choosing an appropriate game or game editor for creating mods.
- Contextualizing the game into the curriculum in a way that encourages exploration, discovery, and the development of conceptual tools.
- Including appropriate scaffolding as well as off-line activities that encourage reflection, dialog, and shared meanings among the learners beyond the context of the game.

It is also worth exploring if an IT specialist should be familiar with the utility of game-based learning and how to use it in a classroom setting as well in order to support the classroom teachers in meeting their learning goals. This same person could be called upon to create simple learning mods or skeletons for the students to work with, as specified by an instructor, or based on a given curriculum's learning goals.

Finally, and perhaps most importantly, the instructor needs to be game-literate, recognizing and understanding that computer games are a means of expression and representation (Green, 2004) and that, like reading and writing, game literacy develops when the learner has the tools and ability to create his or her own games (Clark, Perrone, & Repenning, 2005; King, 2003).

CONCLUSION

The purpose of this discussion is to examine how game mods might provide an affordable, comparable, and customizable alternative to wildly successful commercial games, an alternative that could be used in a classroom setting to facilitate a meaningful learning experience. However, the success of the use of game mods in the classroom will depend not only on the novelty of a good idea or on how comfortable the instructor and learner are with using computers and making simple changes to existing applications, but also on how well the modding activities are contextualized within the curriculum. Creating meaning still needs to be forged within an evocative and relevant context.

Chapter 3.28

A Statewide Analysis of Student Web Portfolios in New York Colleges and Universities

John DiMarco
St. John's University, USA

ABSTRACT

This survey research project investigated the existence of Web portfolios on academic Web sites in New York State. The goal of this project was to promote Web portfolios and the main objective was to provide interpretation of the current level of student Web portfolio usage and activity within all New York colleges and universities. Major findings were that there is a low quantity of Web portfolios in relation to overall student enrollment, thus providing impetus to study a new phenomenon, lack of Web portfolios. The study yielded data providing a breakdown of where and how many Web portfolios were found. This study provides a basis for further research by scholars into Web portfolios within academic settings.

BACKGROUND

Understanding what a Web portfolio is and is not is sometimes not easy. Is a Web portfolio a course Web site? No, it is not. Is a Web portfolio a non-professional personal Web site used for posting

personal data related to social outcomes? No, it is not. A Web portfolio is a personal Web site that provides evidence of your skills and expertise in the form of artifacts (photos, professional documents, artwork, and multimedia content, including audio, video, and animation) from any discipline or field. The ideas behind the Web portfolio as a tool for assessment, lifelong learning, and skill building have not been proven nor have they been embraced by society or academia, at large. Those who exude confidence and passion for the notion of universal access to Web portfolios and Web portfolio skills cannot yet say that the Web portfolio has become an accepted, professional cyber identity. This paper yields conclusions that uncover some intriguing dialogue surrounding Web portfolios. There are not very many student Web portfolios found through college and university Web sites. The new phenomenon that has emerged from this research is the lack of Web portfolios.

Goldsby and Fazal (2001) note that student created portfolios are:

[Commonly] used in teacher preparation programs to demonstrate teaching skills and exper-

tise. This practice was introduced as test scores alone lack the comprehensive scope needed for effective assessment and evaluation, portfolios can be implemented to interpret/make decisions regarding learning of teaching competencies. (pp. 607-608)

The case for the student portfolio in any discipline can be made on the same basis; electronic portfolios provide a new level of assessment that cannot be measured by traditional methods, such as standardized tests, applications, and resumes. Electronic portfolios and Web portfolios provide assessment of competency within a discipline as well as a marketable tool for graduates. The Web portfolio has promise as a tool, platform, and impetus for worldwide learning and growth in technological skills. The objective of this research project is to provide an accurate interpretation of the level of Web portfolio usage within the colleges and universities of New York State.

As we move towards more fluent, ubiquitous platforms for Web media, such as Internet-ready phones, Web-based television, and wireless personal digital devices, the Web portfolio and its place as an assessment tool, a learning tool, and a vehicle for lifelong learning has been recently scrutinized by scholars. Scholarly definitions of the electronic portfolio (e-portfolio) vary from discipline to discipline. To define the Web portfolio, we must first define the e-portfolio. DiMarco (2005) put forth this definition:

The electronic portfolio is a collection of artifacts, project samples, cases, and focused content presenting the messages and professional and public appearance of an individual or a company through electronic media (Web, DVD, CD-ROM). The e-portfolio provides evidence of skills, experience, and learning. I define the Web portfolio as: an electronic portfolio that is an internet delivered, interactive, mass communication used to persuade users. (p. 13)

Greenberg (2004) writes:

Ideally, all work in an electronic portfolio not only is digital but also is available on the Internet. Yet even though materials may be visible on the Web, the ePortfolio is not simply a personal home page with links to examples of work. In addition, unlike a typical application program, such as word processing, an ePortfolio is a network application that provides the author with administrative functions for managing and organizing work (files) created with different applications and for controlling who can see the work and who can discuss the work (access). (pp. 28-29)

This definition presents several items for closer analysis. First, Greenberg (2004) makes a distinction that the e-portfolio is not only digital but also available on the Internet. Development of the e-portfolio and delivery are typically centered on using the Web. By using the Internet for delivery, e-portfolios become less effective and more prone to failure. Also, an e-portfolio is not just a home page. Any portfolio needs to be filled with work samples and evidence of growth and learning throughout a career, an amount of information that cannot be delivered effectively in only one page. An e-portfolio must be a narrative that gives perspective to the viewer. The perspective of the viewer is shaped by the content and structure of the Web portfolio. Greenberg also describes the e-portfolio as having a network function. The Web portfolio specifically is a content container that allows dynamic storage capabilities as well as obvious delivery features. Content management is the concept that is essential to bringing Web portfolios into use across jobs and disciplines. The creator of a Web portfolio will gain technical skills by acting as an administrator for his or her own Web site, which will be an e-portfolio. The e-portfolio allows a student to manage his or her work throughout an academic and a professional career.

Either creation of an e-portfolio is fostered within a learning environment, or the skills are gained through self learning. The e-portfolio provides opportunity for both. The e-portfolio is a tool for lifelong learning and will be part of learning and growing throughout a person's college and professional life. Gathering materials and creating Web pages provides a learning experience that will carry over into a professional skill set. As network computers and the Internet become standard in every aspect of our lives, the skills and abilities needed to present creative and intellectual capital will become paramount to success in a technological marketplace.

Greenberg (2004) says there are three types of e-portfolios. Each is defined by the author's assumed goals. This can be helpful in developing content a management structure in a simplified manner. The structure of each type of e-portfolio differs based on the point of origin of the work. Greenberg believes this results in three types of e-portfolios:

1. The *showcase ePortfolio*: organization occurs after the work has been created.
2. The *structured ePortfolio*: a predefined organization exists for work that is yet to be created.
3. The *learning ePortfolio*: organization of the work evolves as the work is created. (2004, p. 29)

Greenberg's (2004) three portfolio types are effective for establishing types of portfolios based on content. A more appropriate structure might focus on the audience for the e-portfolio because it is important that the e-portfolio is user- and audience-centered. Greenberg's e-portfolio types fit into an author-based definition of e-portfolio types, which is a broad approach to classifying e-portfolios. However, referring specifically to Web-based e-portfolios, three types can be defined:

1. The personal Web portfolio for students or individuals,
2. The teacher Web portfolio, and
3. The business Web portfolio.

Scholars, including Sanders (2000) and Moonen and Tulner (2003), have praised the virtues of Web portfolios. These scholars agree that there is a need to embrace the Web portfolio as a tool, regardless of the discipline. These scholars also agree that the Web portfolio is a tool and should be mastered by teachers and taught to students within the appropriate contexts of their disciplines. Specifically, one example would be that of an art portfolio. This type of portfolio has a structure and presentation style that will focus on the artwork and the skills of the artist. The same method can be adapted for a student in the discipline of English. In this case, the portfolio should focus on the writings and literature aptitude of the creator. In his personal case study on Web-based portfolios for technology education, Sanders (2000) states that:

The information age is not just a cliché—we're living it! Global networked information systems such as the World Wide Web are changing nearly every aspect of our lives. These technologies should be prominent within our curriculum. Often, they are not. Web-based portfolios offer a meaningful way for technology students to gain a thorough understanding of these critical new technologies beyond mere Web research. Web-based portfolios provide benefits that can never be realized with conventional portfolios. (p. 11)

The Web portfolio has grown well beyond the boundaries of the education and technology fields. It is finding its way outside of educational institutions and into human resources and other corporate directions. This idea is supported by Moonen and Tulner (2003) who reported:

*But also beyond regular education, interest in electronic **portfolio** is growing. EifEL [7] that commencing in May 2004, EifEL (European Institute for E-Learning) is going to provide all of its Members with an electronic **portfolio**, the most innovative and fastest growing technology in the field of education, training and human resource development. (p.1)*

Mainstream integration of the use of Web portfolios at colleges and universities is a noble and promising endeavor for scholars, administrators, and students. The case for Web portfolios is one that seems to be emerging slowly. With a growing body of evidence supporting Web portfolios, one might assume that searching for and finding Web portfolios on college Web sites would be an easy task. However, finding a multitude of Web portfolios and rhetoric about Web portfolios on the Web sites of New York State colleges and universities was not a fruitful endeavor. Ultimately, this research found small evidentiary pockets of Web portfolios on these Web sites. The data from this research helped identify a new phenomenon—the lack of Web portfolios.

PROJECT GOALS

The goal of this project was to promote Web portfolios, and the main objective was to provide interpretation of the current level of student Web portfolio usage and activity within colleges and universities. For the present study, I examined the number of Web portfolios posted to the Internet by students through a Web portal or academic Web site from each of the 294 private and public colleges and universities in New York State. These were located using the Web site <http://www.nymentor.edu>. This study is exploratory and will be used to enable subsequent action research into the development of a comprehensive statewide Web portfolio program in New York. This study also

provides a basis for further research into Web portfolios within academic settings.

RESEARCH QUESTION

A personal Web portfolio serves as a self-selected, self-developed multimedia presentation of work that offers multiple views of a person's learning and development (DiMarco, 2005). Driven by creative expression and college learning experiences, Web portfolios provide tangible evidence of growth and accomplishment. Web portfolios also allow students to present research papers, essays, and academic projects that incorporate text, images, audio, and video. The disciplines of computer science, art, and education have embraced Web portfolio development most frequently. However students in all disciplines need a Web portfolio when they leave college. Having tools to help illustrate one's skills and experience is critical to a college graduate. A resume is one such tool. However, Web portfolios go beyond the traditional resume in scope of content and presentation by providing a broader platform for visual and interactive communication. After college, the Web portfolio can become a personal hub for professional communication with potential employers and the public. It can serve as a platform for publishing career accomplishments and presenting skills and experiences through content.

There is evidence that the use of Web portfolios in society is surging. This notion is present when reviewing the scholarly literature on academic Web portfolios, as well as content analysis of Google-based searches on Web portfolio programs. For example, Web portfolio programs are campuswide at The Penn State University (DiMarco, 2005) and even statewide in Minnesota (<http://www.efoliominnesota.com>). Web portfolio programs are becoming an important component of academe and are helping build technical com-

munication and presentation skills within today's information society.

The primary research question guiding this study was:

What is the level of Web portfolio usage (as measured by the presence of a Web portfolio) and activity (as measured by content and artifact incorporation) by students within the 294 colleges and universities of New York State?

METHODOLOGY

This study is a basic survey of the Web sites of the 294 New York State colleges and universities, undertaken to determine the level of Web portfolio existence or nonexistence. Data gathering methods included recorded observations of college and university Web sites, combined with content analysis and rigorous note-taking during Web site observations. This data gathering method pointed to specific usage or nonusage of Web portfolios by the students of each institution.

Survey research methods provided this research project with nominal quantitative data from an unknown population of national and international Web portfolios. The study used a sample frame of Web sites (294 out of 294) from New York colleges and universities.

Web portfolio analysis of 294 cases (college Web sites) began with a list that was obtained from nymmentor.edu. This included the demographic and enrollment data on all known colleges and universities in New York State. The nymmentor.edu Web site is managed by the New York State (NYS) Department of Higher Education. The nymmentor.edu site was used for data gathering because it provides topical, credible NYS education data. The site has an edu domain extension, which means that it is an educational domain and provides current data on the colleges and universities of every NYS city and county. After studying initial cases of Web sites, the data revealed no Web

portfolios at college sites for nursing and medical degree programs. The process of data gathering consisted of the following steps:

Step 1: Went to the school Web site based on the Web site address published on nymmentor.edu.

Step 2: Used the site search feature (if it was available) to perform limited keyword searches using the following six terms “web portfolios”; “digital portfolios”; “student portfolios”; “electronic portfolios”; “student websites”; and “student web portfolios.”

Step 3: Performed searches looking for clues to Web portfolios on the school site. After a minimum of 10 minutes of exhaustive searching, the next case was studied. *Step 3: Observation Methods.* Specific Web site sections that were investigated: observed technology services menus, observed home pages, observed sitemaps, observed search features within sites, observed technology departments, observed education departments, observed graphic arts departments, observed computer science departments, observed career services departments.

Step 4: Entered observation notes into MS Excel using the insert comment function. Entered notes for Web sites that had Web portfolios or evidence of articles, press releases, or faculty papers that referred to the use of Web portfolios or the planning of future use of Web portfolios at the institution.

Step 5: Counted total number of Web portfolios for each college or university; entered the data into an Excel spreadsheet containing the listed NYS colleges and universities; and generated percentages of Web portfolios

against enrollments.

Step 6: Read the field notes, reviewed sites again, and generated open-coding content analysis about the Web sites of NYS colleges and universities.

LIMITATIONS

As a researcher with a high level of experience in Web portfolio research, I entered this study with a level of bias that initiated a loosely shaped hypothesis that very few Web portfolios actually existed. However, during data gathering, I remained objective and attempted to uncover Web portfolios, even when my intuition led me to think that there would be none at the particular case Web site.

FINDINGS AND CONCLUSIONS

As this study progressed, it was evident that there were a small percentage of Web portfolios in comparison to total enrollment. The cumulative enrollment total reported by nymmentor.edu for NYS colleges and universities is 1,155,042 students. The total number of Web portfolios found was 4,570, which represents 0.39% of the enrollment population. Nine of the 294 schools had active retrievable Web portfolios. This finding points to the very small percentage of Web portfolios compared to the student enrollment at NYS colleges and universities. The same level of involvement seemed to continue throughout the colleges and universities, where Web portfolios were found. Among the nine schools, where evidence of Web portfolios was found, the highest percentage of Web portfolios was found at Syracuse University where 4,439 alphabetically listed Web portfolios existed in a student enrollment of 16,753. Syracuse University had the highest Web portfolio usage found, with 26.49% of the

students having some form of a Web portfolio on the Internet and accessible through the Syracuse University Web site.

As Web portfolios were found, authorship, content, and context were recorded. The Figure 1 is a breakdown of region, setting, total enrollment, and percentages for Web portfolios together with enrollment data for the nine schools where Web portfolios were found.

The study focused on gaining insight into the existence or nonexistence of student Web portfolios available via the Web sites of NYS colleges and universities. As the Web portfolio situation unfolded during this study, the data revealed some interesting facts that might yield additional parameters for investigating Web portfolio activities within academia. Two facts seemed to evolve from this study. The first fact was few Web portfolios are readily available for viewing at the Web sites of NYS colleges and universities. Also, when Web portfolios were found, there were few in relationship to the total enrollments of the institutions. The largest Web portfolio stake is claimed by Syracuse University, which presents Web portfolios for more than 26% of the total enrolled student population.

The second fact found was that many academic Web sites posted documents regarding the virtues of and an involvement with Web portfolios, yet these institutional Web sites showed no tangible implementation of Web portfolios by students. To elaborate on this point, when searching colleges and university Web sites using the site search engines, much data was found on various case sites that discussed Web portfolio programs and technology grants received by institutions to create comprehensive or pilot Web portfolio programs. Although evidence of this literature was found in the form of faculty newsletters, academic memos, and research proposals, there were few or no Web portfolios found at the institution's Web site.

This was observed in more than a dozen case sites examined. At Adelphi University, for ex-

A Statewide Analysis of Student Web Portfolios in New York Colleges and Universities

Table 1. College and university Web portfolio totals

CASE #	School name	Region	Setting	Total enrollment	Web portfolio link on homepage	Web space provided by school (~ accts)	Total # of working student Web sites/portfolios found	% of Web portfolios to enrollment
10	Bard College	Mid-Hudson	Rural setting	1,726	no	yes	15.00	0.86%
	Bard has a student server that allows students to voluntarily post personal Web pages and Web sites. Found 19 Web portfolio/personal Web sites listed, but only 15 with active content. There were also several blogs.							
88	Hobart and William Smith colleges	Genesee Valley	Small town	1,847	no	yes	10.00	0.53%
	Ten Web pages from a computer graphics class were found. They did not fit the typical Web portfolio criteria; they were class projects only.							
115	LaGuardia Community College	New York City	Urban	12,875	no, but one link away	yes	17.00	0.13%
	Notes: Found 17 Web portfolios posted; entire Web portfolio program; and found some scattered samples of other student portfolios. Summary: The college with the most prominent, pedagogically integrated e-portfolio (Web portfolio) program is LaGuardia Community College. The program is highly visible throughout the college Web site.

Figure 1.

ample, a Web article, written by education faculty members, described the use of an information technology-based system for Web portfolios in use by the special education department. Despite the presence of the article, there was no evidence of Web portfolios. The point here is that there seems to be data pointing to Web portfolios at many institutions, but little or no action to implement a viable, usable, embraceable solution.

The most active Web portfolio program appeared to be at Syracuse University. This conclusion was based on the proportion of users to enrollment. In the case of Syracuse University, the institution provides Web space to all students for the creation and development of a Web portfolio. It also provides instructional technology resources, such as a dedicated system for Web space users, basic tutorials on uploading files, and frequently asked questions. The support and creative freedom provided by the institution might be part of the reason why so many students are taking advantage of the university's Web space.

The most pedagogically integrated Web portfolio program existed at LaGuardia Community College. Formal examples of Web portfolios are showcased along with digital tools and processes. These items are outlined in a dedicated Web portfolio section of the college's Web site that resides only one click away from the home page. Although organized and well funded, the LaGuardia e-portfolio project only showcases 17 Web portfolios, a mere .13% of enrollment. This is substantial because the college has initiated a strict policy of Web portfolio development within the curricula. However, few Web portfolios actually exist for viewing on the college's Web site.

Another area that further research might target is Web portfolio usage within technology- and nontechnology-related disciplines, and Web portfolio use by faculty members to see whether a relationship exists between the existence of teacher Web portfolios, disciplines, and the development of student Web portfolios. Are students more likely to create a Web portfolio if they have a professor facilitating or mentoring

the process? Several trends in this direction were observed when analyzing the data. Some sites showed student projects are a large part of the portfolio population within educational technology departments. SUNY Cortland had a student Web portfolio population from several concurrent sessions of a course in the use of educational technology.

A literature review has shown that the promise of Web portfolios is apparent and usage is growing among academic institutions throughout the world. The present analysis of Web portfolio activities at NYS colleges and universities has demonstrated small numbers of Web portfolios in relation to overall enrollment. I set out to answer the question: What is the level of Web portfolio usage (as measured by the presence of a Web portfolio) and activity (as measured by content and artifact incorporation) by students within the 294 colleges and universities of New York State? The answer is the level of usage is extremely low in relation to enrollments. This fact leads me to view the Web portfolio phenomenon as a research topic that might be studied using exploratory methods. Future research might help indicate why there is such a lack of Web portfolios available for viewing on the academic Web sites of colleges and universities in New York.

ACKNOWLEDGMENT

Professor DiMarco would like to thank Dr. Richard Smiraglia for his mentoring during this research project.

Chapter 3.29

Innovative Technologies for Education and Learning: Education and Knowledge-Oriented Applications of Blogs, Wikis, Podcasts, and More

Jeffrey Hsu

Fairleigh Dickinson University, USA

ABSTRACT

A number of new communications technologies have emerged in recent years that have been largely regarded and intended for personal and recreational use. However, these “conversational technologies” and “constructivist learning tools,” coupled with the power and reach of the Internet, have made them viable choices for both educational learning and knowledge-oriented applications. The technologies given attention in this article include instant messaging (IM), Weblogs (blogs), wikis, and podcasts. A discussion of the technologies and uses, underlying educational and cognitive psychology theories, and also applications for education and the management of knowledge, are examined in detail. The implications for education, as well as areas for future research are also explored.

INTRODUCTION

For many years, the mediums employed for education have remained fairly constant and traditional: tried and true methods such as the blackboard and chalk, whiteboards, flipcharts, and overhead projectors. The employment of computing technologies has resulted in the use of PowerPoint, e-mail, and Web-based course portals/enhancements such as Blackboard and WebCT.

There have been numerous studies done, and papers written, about the use of technology in the classroom, together with work on the related areas of e-learning, Web-based learning, and online learning. The usage of computing technologies in education has been examined in numerous studies, and there is a sizable body of work on Web and online learning, including the studies by Ahn, Han, and Han (2005), Liu and Chen

(2005), Beck, Kung, Park, and Yang (2004), and numerous others.

In particular, some of these technologies have been recognized as useful in the classroom, and have been engaged in innovative ways. The technologies of particular interest are those that are referred to as “conversational technologies,” which allow for the creation and sharing of information (KPMG, 2003; Wagner, 2004). Another term often used to describe these technologies is the concept of “constructivist learning tools,” which encourage, and are focused on, users creating, or constructing, their own content (Seitzinger, 2006).

The interest in employing these kinds of technologies stems not only from the unique pedagogical benefits gained, but also from the basic need to stay in tune with the focus and strengths of today’s students. Prensky (2001) suggests that the students being taught today are “no longer the people our educational system was designed to teach” and that while the students of today can be termed “digital natives,” many educators could be better termed “digital immigrants.” Yet another way to look at this is to view earlier educational approaches as “print-based,” while those of the current environment can be called “digitally-based, secondly-oral” (Ferris & Wilder, 2006).

The purpose of this article is to examine these technologies and explore both the evolution of their use from personal applications to that of educational tools, and also to examine the key educational applications for which these are being used. Relevant research and applications are examined and analyzed. The future of these technologies for educational and professional use, together with viable research areas, is examined as well.

CONVERSATIONAL TECHNOLOGIES AND CONSTRUCTIVIST LEARNING TOOLS

The notion of conversational technologies is not a new one, as it encompasses many types of systems that have been widely used for some time, including e-mail, video conferencing, and discussion forums.

The term “conversational technology” is derived from the work of Locke et al. (2000) relating to conversational exchanges and his Cluetrain Manifesto. One of the key concepts here is that “markets are conversations” and that knowledge is created and shared using question and answer dialog. Specific theses that relate to this form of “conversational knowledge management” suggest that aggregation and abstraction of information helps to create information. Other characteristics of conversational knowledge management include the fact that it is fast, stored in different locations, and does not require sophisticated technologies in order to be accomplished (Wagner, 2004).

Conversational technologies encompass a wide range of systems and software, many of which are familiar, including e-mail, instant messaging, Web pages, discussion forums, video and audio content/streaming, wikis, and Weblogs. While there are specific aspects that are of interest in terms of the more mature technologies, the ones that will be given attention in this article are the issues, impacts, and applications relating to IM, blogs, wikis, and podcasts. These are technologies that are newer, have a growing base of users, and are starting to become recognized as viable tools for education.

The term “constructivist learning tool” has also become associated with these, particularly blogs

and wikis, in that they have a key characteristic of allowing users to develop and maintain their own content. Some of the characteristics of constructivist learning include engagement, active learning, collaboration, real world based, and the usage of reflection as a part of the learning process (Seitzinger, 2006).

It should be noted that these technologies and tools are best suited to course structures where class collaboration and communication are encouraged, rather than those with an emphasis on lectures and a presentation of factual information. In addition, in courses where there is substantial group work, or projects where a collaborative document is created, the use of these would be especially helpful and useful. Both hybrid and full distance learning courses would be situations where these could also be used effectively.

TEACHING AND LEARNING: NEW TRENDS

Conversational and constructivist technologies are certainly here to stay, as evidenced by their extensive role in our society. It would therefore be useful to examine their applicability in the educational realm. While usage based on popularity or student preference seems to be one factor, there are also theoretical and conceptual bases for employing these kinds of technologies in the classroom.

Earlier paradigms of teaching emphasized print-based materials for instruction, which included printed textbooks, paper-based instructional materials, and written tutorials, all of which are grounded in the notion that the teacher, lecture, and instructional materials form not only the basis, but also the authority in the educational process. The transmission of material from the teacher (lecture) and/or textbook to the student (called the “print model”) is still the central basis of most teaching, even if they are supplemented with other methods including discussion and other

forms of student interaction/participation (Ferris & Wilder, 2006).

However, the advent of digital and conversational technologies has brought forth the new concept of secondary orality (Ong, 1982). This concept emphasizes that teaching and learning should go beyond printed materials toward a greater emphasis on group work, fostering student communities, and encouraging student participation. The concept encourages a greater sense of interaction with and “ownership” of knowledge, emphasizing self-awareness and expression, and effectively using electronic tools (Gronbeck, Farrell, & Soukup, 1991).

The use of conversational technologies can have a positive impact, because they attempt to not only improve upon the print approach, but also use secondary-oral techniques. In other words, while a student can still be presented with material (in different formats) using the print model, the introduction of secondary-oral methods can be used to improve the overall learning experience. Using the latter, there is the opportunity to work and learn collaboratively, explore, analyze, engage in discussion, and otherwise “learn” in new and innovative ways (Ferris & Wilder, 2006; Wallace, 2005).

INSTANT MESSAGING (IM)

It is unlikely that there would be many college students who are unfamiliar with the use of IM. Allowing for interactive and real-time synchronous communications with instant response, instant messenger is truly conversational in that it allows for “chat” and communications between both individuals and groups. The major instant messaging systems in use include AOL (AIM), MSN Messenger, Yahoo! Messenger, and ICQ.

IM is a means for users to “chat” and communicate in real-time. While originally the domain of personal users, over time the unique benefits and effectiveness of this medium were realized,

and IM started to become accepted as a form of communication in businesses (particularly high-tech firms), and now has been studied and tested as an educational tool (Kinzie, Whitaker, & Hofer, 2005).

The important features of IM include both its synchronous nature and its ability to support both chat and phone-like interaction. While real-time interaction allows for rapid communications to occur, there is also no need to enter an interaction “space” as with chat rooms. Instead, the main usage of IM is in one-on-one communications, which can be more formally termed as a dyadic “call” model, which more closely resembles phone call interaction. It should be noted that even though much of the communication is done between two individuals, there are some systems that support multiparty instant messaging.

Some of the salient features of IM include the ability for users to see user details as to current status (online, idle, away, out to lunch), and also on a user’s changes in status (active, logged out, etc.). Lists of users can be displayed on the screen, so that contact can be made when desired. If a “chat” is initiated, a special window comes up, and the interaction can commence, provided that both parties are online and willing to proceed.

The real-time nature of IM has resulted in the technology being used for reasons aside from personal “chat.” In business, IM has become in some industries an accepted form of communication. A number of studies have concluded that instant messaging is ideal for informal interaction. In particular, the use of IM has been shown to be helpful in cases where collaborative coordination and problem solving is involved. Social bonding and interaction, which is a component contributing to the success of more complex collaboration situations, is also enhanced by using instant messenger technology (Nardi & Bradner, 2000).

An important difference between IM and e-mail is the tendency for instant messenger interaction to be more casual and informal than e-mails, which helps to bring about a more “friendly”

communication atmosphere. This may in part be due to a reduction in the formalities that are typically involved when using e-mail or the phone. In particular, IM has been considered more suitable for such tasks as scheduling meetings, asking or answering quick questions, and for other kinds of tasks that are brief, require a prompt response, or are less formal. It is perceived to be far simpler to IM someone to ask a quick question, for example, or to confirm a meeting or lunch, rather than to e-mail or call (Nardi & Bradner, 2000).

It is also of interest that IM communications tend to be more flexible in terms of their uses (everything from task-related questions to a new joke), and can allow for greater expressiveness in terms of emotion, humor, and personality (Nardi & Bradner, 2000). Another interesting aspect is what Nardi and Bradner (2000) refer to as “outeraction,” which focuses on the processes associated with IM. These include conversational availability, communications zones, intermittent conversations, awareness, and conversational progress/media switching. IM is useful in certain communications situations, since it tends to be less disruptive and interrupting, while at the same time a user’s availability is more clearly known (scanning buddy list status, for example). It is also a convenient means for setting up more formal interactions, such as arranging a conference call (media switching). Intermittent, dispersed communications can be conducted over a longer period of time, which includes interruptions. Another benefit includes the knowledge that others are “there” and available, even if not currently in chat mode; however there is always the opportunity to make contact, whether through IM or a different form of communications.

While some educators may scoff at and even express criticism at the thought of instant messaging as a viable educational tool, others believe there is potential in the medium.

In terms of educational uses for IM, they are being explored and tested. Clearly, IM not only

Table 1.

INSTANT MESSAGING	
Description	Real-time communications that allow for informal communications to be conducted easily and quickly
Advantages	Availability and acceptance by students Social presence (know the status of other users online) Real-time (synchronous) communications Encourages collaboration Reduces formality in communications
Disadvantages	Distracted attention, especially in a classroom setting “Time waster” that is not directed toward course content, but on personal discussions Expectations of 24-7 instructor access Can be time consuming for instructors Benefits are uncertain in classroom settings
Educational applications	Virtual office hours (instructor-student) Collaboration on group projects Real-time class discussions Mentoring
Course/subject suitability	Courses with group projects and assignments Distance learning support
Theoretical foundations	Active learning Dual (verbal and visual) processing

allows students to collaborate more effectively on homework assignments and projects, but also helps to maintain a closer social network between students, which could have a positive impact on learning. In addition, if IM is carefully targeted and focused toward the material or lecture topic in hand, the use of IM may actually help and stimulate deeper and more active learning.

On the other hand, it has been hypothesized that the distraction of working on various other tasks in parallel with IM, known as “distracted attention,” may have a negative impact on learning (Hembrooke & Gay, 2003).

Active learning (Grabinger, 1996) and dual (verbal and visual) processing (Clark & Paivio, 1991) are at work here. It could be said that using IM to encourage greater discussion and reflection on the course contents would be likened to the use of discussion boards; however, since IM is a real-time technology, the interaction is conducted during the lecture or class, not afterward. Some studies have reported positive effects and student satisfaction from IM being used to discuss course subjects in real-time (Guernsey, 2003).

A study by Kinzie et al. (2005) examined the use of IM during classroom lectures and found

that while the general idea of using IM online discussions was positively received, the actual process and experience of using IM to conduct discussions during class lecture sessions was not found to be less than a positive experience by both teachers and students. It was suggested that the difficulties of multitasking and dividing one's attention between the lecture and instructor, doing the IM discussion, contributed to the lack of satisfaction with the process.

Burke (2004) used instant messaging as a medium for creating course diaries in three different mathematics courses. IM was chosen since it was thought to be popular, widely used by students, and considered more "fun," so there was some hope that this popularity would transfer over to greater and more enthusiastic usage by students. In fact, the choice was made to use IM over a seemingly more suitable choice, blogs. A bot was created that would retrieve IM diary entries from students and store them in a PostgreSQL database, and there was also a program set up to display diary entries from each student, viewable by both the student and the instructor. The main finding of the study was that the IM media was not ideally suited for all kinds of courses, especially those that involved creating longer portions of text, or involved diagramming. Error detection and recovery was also not that well developed, and also there was a need for better editing tools.

In summary, while instant messenger can be appropriate for various applications, in particular for information communications in a business setting, the results from educational studies appear to be mixed, with both positive and negative effects noted. While there seem to be advantages to real-time communications between students, between students and instructors, and also between groups working on a project, it appears that there are problems and limitations if the technology is used in a classroom setting. The challenges of focusing on a class lecture, together with maintaining a conversation online, seem to be a problem that has not yet been resolved. In ad-

dition, while instructors can often establish closer relationships with students using IM, there is also the problem of unreasonable student expectations of continuous teacher access, which may not be present if IM was not available as an option. In connection with this, using IM for student help can result in a greater time commitment, since sessions can become lengthy with many questions and responses being sent back and forth.

BLOGS (WEBLOGS)

Blogs started as a means for expressive individuals to post online diaries of themselves. Complete with text and photos, these logs were essentially an individual's online narrative or diary, with events, stories, and opinions. While its original use was for personal expression, recently its effectiveness as a tool for education has been discovered, including its use as an extension of "learning logs," which are created online (Barger, 1997). One of the earliest blogs, as we know and use them today, was Dave Winer's Scripting News, which was put online in 1997. While the use of Weblogs can be considered generally new, the concepts of keeping a "log" or "learning log" is not.

The concept of "learning logs" has been in use since before the advent of the Weblog. The concept of this is to enable someone to document his or her learning, and also to do some critical reflection (Fulwiler, 1987) and self-analysis. The use of a learning log or journal is related to action research learning strategies (Cherry, 1998) and attempts to link previous knowledge and new information learned. Blogs are a natural extension of learning logs/journals in that they are electronic and can be made available ("published") more easily (Armstrong, Berry, & Lamshed, 2004).

The use of electronic Weblogs as educational tools offers the benefits of increased information sharing, simplified publication of information, and improved instructor monitoring and review (Flatley, 2005; Wagner, 2003). The use of blogs has

been expanding, as Perseus Development reported that there were some 10 million blogs in 2004, and the number is ever increasing (Nussbaum, 2004). The growth in this area is expected to increase in the years to come.

Blogs can be defined more formally as being “frequently updated Web sites consisting of dated entries arranged in reverse chronological order” (Walker, 2005) and can take several forms, including the personal diary/journal, knowledge-based logs, and filter blogs. The first, an electronic, online diary of one’s life events and opinions, is probably the most common. The online diary/journal blog is one that, being on the Internet, is public, as opposed to the traditional (typically paper) diaries, which are generally kept private. It should come as no surprise that there are many different online diary/journal blogs that are currently online, where one can find out details, often much more than one might want to know, about someone’s life and thoughts. Personal blogs form the majority of the blogs that are currently online and available, which make up roughly 70% of all the blogs in existence (Herring et al., 2003).

The second type (knowledge-based) captures knowledge and places it online in various formats. The third type (filter) attempts to select, rate, or comment on information contained in other sites (Herring et al., 2004).

There are software packages that are designed to help users create blogs, including Blogger, Xanga, Blurty, and MovableType. While the basic features of most blog software emphasize the creation of blog pages, some of the more sophisticated ones offer the capability to track readership, see who followed what links, add photos, and set up more advanced structures. When online, blogs can range from being totally public (listed in the blog service directory), to being “unlisted” but still open to being highly restricted (password-protected).

Blogs are also interesting and unique in that they are not merely online versions of paper diaries and journals. Rather, as a communications

medium under the control of the main writer (author), it is reflective of the fact that an audience is “watching and listening.” What is put on a blog is not merely a one-sided set of thoughts and reporting of events; there can also be responses to feedback and reactions from the “viewing audience.” Therefore, blogging is considered a highly social activity, rather than a personal one. In fact, recent work has indicated that the momentum for creating, and also updating a blog, came about as a result of encouragement from friends and the viewing audience (Nardi et al., 2004). In addition, blogging can have negative repercussions when posted information is perceived to be confidential, proprietary, or improper. In some cases, employees posting what was considered by their employers as “confidential” information can cause problems.

Blogs do not, in general, exhibit a free-flow of information between the blogger and the outside audience. While feedback is often requested, received, and desired by the blogger, the level and quantity of feedback from readers is generally limited compared with the output from the blog writer. In addition, while blogs may have sections where hyperlinks are mentioned, the number of hyperlinks in blog pages is frequently not very large (Schiano, Nardi, Gumbrecht, & Swartz, 2004).

More formally, Weblogs can be considered to be objects motivating human behavior, which is related to activity theory. Activity theory states that there are objects that have motives that respond to a human need or desire, and that they manifest a person’s desire to accomplish that motive (Leontiev, 1978; Vygotsky, 1986). The objects that connect bloggers to their own social networks include letting people know what is happening in their lives, voicing opinions, asking for feedback, and “letting off steam” about certain challenges or difficulties currently being experienced, to name a few (Nardi et al., 2004).

Blogs have been categorized by Krisnamurthy (2002) as being categorized into four different

types, along the dimensions of individual versus community, and personal versus topical. A blog can therefore range from being very individual and personal, all the way to being open to the community, however very focused on a particular topic.

The acceptance of blogs for educational purposes is gaining interest, with one university, the University of Maryland, attempting to implement blogging software campus-wide (Higgins, Reeves, & Byrd, 2004).

In addition, the educational uses of blogs take advantage of their ability to encourage expression and the development of online relationships. Blogs allow for learning and interaction to be more knowledge-centered, especially if the assignments are structured in the format of encouraging feedback and input from the instructor and outside experts. Blogs also allow students to gain a better understanding of a subject's knowledge domain (Glogoff, 2005). As an example of this type of blog-enhanced class structure, students might be provided with a Weblog from which to complete certain course assignments. After researching the indicated subject, the student would present the new information by "publishing" it to the Weblog. The Weblog would constitute the student's assignment, which would then be subject to review and critique by not only the instructor, but also by other students in the class. Supplementing this could be discussion boards, where threads would be devoted to discussions on the Weblogs created by the students. This kind of assignment and interaction would be especially useful for both hybrid and fully online distance learning courses (Glogoff, 2005).

There are other benefits of Weblogs. These could be expressed using the learning theories and concepts of guided discovery, directive learning, receptive learning, and social/community-centered instruction.

Guided discovery allows for the exploration and study of a certain topic, which is then followed by assignments that emphasize the synthesis of

information. In effect, a student can be asked to research an area and "construct knowledge" using the Weblog as a medium. Part of the assignment goes beyond merely explaining or presenting the material, and asks for the application of the concept using a real-world situation. The ability for students to post and make comments about other students' blogs provides an atmosphere of interactivity and collaboration. One of the advantages of using blogs together with guided discovery is that it encourages the use of cognitive scaffolding, where students would approach learning (together with the use of blogs and interaction) by repeatedly seeking information, reflecting and thinking about what has been learned, and then going back and obtaining more information, so as to build upon and dig deeper into the subject area. This can result in a more active and productive form of learning (Betts & Glogoff, 2004; Glogoff, 2005).

Directive learning, where responses from students are followed by prompt feedback from instructors, can also be supported using blogs. In this case, students would not only use a blog to submit assignments, but also to review instructor feedback. In addition to feedback, there would be opportunities for the instructor to ask additional questions, in effect, to encourage further exploration and "drilling down" into the subject (Betts & Glogoff, 2004; Glogoff, 2005).

Receptive learning is where instructional modules are presented that focus on certain broader areas, from which certain sub-areas within these are highlighted for a student to research and report on. Generally, the areas are contained within a designated theoretical context (Betts & Glogoff, 2004; Glogoff, 2005).

Social/community-centered instruction is a logical component of educational work using blogs, and in particular the use of peer and social interaction as a part of the learning process. The use of blogs functions as an easily accessible medium for students to present their findings (and to be read by others) and also to integrate not only the information presented, but also related links

and references to other resources. This form of interaction helps to encourage further exploration by students. A blog-based discussion can then be continued by conducting peer reviews of other students' blogs, which may include commentary, critique, the posing of questions, and opening up the way for further inquiry. The ability to share and benefit from the findings of other students (and to explore further) is another important outcome. The theories of community practice (Snyder, 2002), social cognition (Vygotsky, 1978), and communities of inquiry (Lipman, 1991) provide support for the blog-related techniques mentioned previously.

Ducate and Lomicka (2005) discuss their experiences in using Weblogs to support foreign language classes. Weblogs help the foreign language student to learn during the process of reading, and then creating blog entries. Students can learn by reading blogs that are written in the new, target language, including learning new vocabulary, checking out links and further information on words, and learning associated cultural information. The reading and absorption of blogs on the culture associated with the target language, including literature and lifestyles, all would contribute to the learning process.

Another approach would be to have students maintain blogs written in their new, target language, and then the goal would be to seek commentary and critique on these blogs by others in the class. Yet another innovative method might be to share blogs with other classes studying the same language, and for students to read and comment on each other's postings. In the case where students travel to a country where the target language is spoken, the compilation of travel blogs would be a useful learning tool as well (Ducate & Lomicka, 2005).

Wang and Fang (2005) looked at whether the use of blogs encouraged or enhanced cooperative learning in an English rhetoric/writing class taught in Taiwan. The main premise was that blogs can encourage students to spend more time working

within a class "community" and can benefit from a greater sharing of contributions and inputs. In general, cooperative learning benefits can be divided into three different types: formal, informal, and base groups. Formal cooperative learning is where the instructor explicitly provides course materials and assignments to a group and then observes the students' learning processes. When the instructor provides information more generally (such as detailing how to use a blog for course assignments) and then lets the group work out their own methods for handling an assignment, that is known as informal cooperative learning. When a learning-oriented group is maintained for an extended period of time, such as throughout a semester, then this form of cooperative learning is known as a cooperative base group (Johnson & Johnson, 1998; Johnson, Johnson, & Holubec, 1991). The study, run over the course of a semester, found that the use of blogs contributed not only to cooperative learning in general, but also to autonomous learning. Autonomous learning is focused on how much students take responsibility for their own learning, and also develop self-confidence in the task or skill (Wenden, 1991). The use of blog technologies was also found to help improve information processing, learning self-evaluation, and effective time management (Wang & Fang, 2005).

Martindale and Wiley (2005) also used blogs in their courses and looked at two cases of the impact of this technology on teaching and learning. Martindale taught a doctoral-level course on instructional design and technology. In it, students were introduced to blogs and used them throughout the course, which overall tended to promote higher levels of quality in their course work. Blogs were used to post ideas and abstracts of their projects, and also to place links for relevant research papers and Web-based resources. The end result was a course "knowledge base" that represented the cumulative output of the students in the course. The blogs were also used for article critiques, which were an integral part of each weekly class.

Table 2.

WEBLOGS (BLOGS)	
Description	A technology that allows a sequence of entries (online diary, journal) to be posted and published online
Advantages	Reflection and critical thinking are encouraged Authenticity through publication Social presence Development of a learning community Active learning encouraged Ability to receive and respond to feedback
Disadvantages	Controlled primarily by blog author Editing/modifications not open as in a wiki
Educational applications	Online learning journal Problem solving/manipulation space Online gallery space (writings, portfolio, other work) Peer review exercises
Course/subject suitability	Writing courses Foreign language courses Research seminars
Theoretical foundations	Activity theory Guided discovery Cognitive scaffolding Receptive learning Social cognition Community practice Communities of inquiry

Students were given access to the blogs of other students and were able to offer feedback.

Wiley taught two different courses, one on online learning research, and the other on online interaction culture. Both included the use of blogs as a supporting technology, the first employing a general course blog where information about the course, student assignments, and class updates and student/instructor interaction exchanges were posted on an ongoing basis. In the second, blogs were used to discuss experiences using different online communications technologies, causing students to become highly engaged, resulting in passionate discussions and detailed commentaries

posted to the blogs, far exceeding the level and depth of feedback that was expected (Martindale & Wiley, 2005).

In summary, blogs can be useful for educational purposes, particularly where there is the need to encourage and stimulate critical thinking and reflection on a work, concept, or idea. The submission or publication of a document or text as a blog can then lead others in a class to review and comment, setting the stage for greater analysis and study. In particular, blogs are suited to writing courses, where a text can be analyzed and critiqued, or for a situation where a peer review is desired. The use of blogs is also ideal for the

situation where someone keeps an online journal of one's learning, or wants to display her or her work to an audience. The blog approach is also considered useful for group study of a certain focused problem or case, such as those used in graduate courses and seminars.

WIKIS

Yet another technology, known as the wiki, has emerged, which allows for improved collaboration compared with Weblogs. While the major emphasis of Weblogs is the creation of a set of pages and documents primarily by a single individual, the strength of a wiki is the ability for numerous interested readers and users to express ideas online, edit someone else's work, send and receive ideas, and post links to related resources and sites. As a result, wikis go a step further and allow for greater collaboration and interactivity (Chawner & Gorman, 2002). Wikis have been found to have value for educational purposes, and their use has begun to be integrated into a number of university courses, in particular (Kinzie, 2005).

The term "wiki" comes from the Hawaiian word "wikiwiki," which means "fast." The technology is computer-based and can be generally described as a knowledge sharing and creation system that has as its basis a set of Web pages, which can be created and updated on an iterative and collaborative basis, and is in many ways a form of groupware. A wiki is designed to run on the Internet and World Wide Web, uses the HTTP protocol, and resembles traditional Web sites in terms of its underlying structure. Some of the benefits of wikis include the ability to easily create pages (using a simplified form of HTML or basic HTML) and the ability for a document to be authored collaboratively and collectively. In particular, simplicity is the key to wikis, and wiki pages have been designed to be easy to create, (simpler than the process of creating standard Web pages). One of the better-known examples

of a wiki is www.wikipedia.org, which is an online encyclopedia with entries authored and edited by different persons worldwide, and in several different languages as well. In essence, it is an online information resource that is authored by interested and knowledgeable persons from around the world.

Wagner (2004) developed a set of design principles that relate to wikis. These are the principles of open, incremental, organic, mundane, universal, overt, unified, precise, tolerant, observable, and convergent wikis. *Open* means that anyone can edit a wiki, creating an "open source" environment for the sharing of knowledge. *Incremental* means that new pages can be added, even if they do not yet exist. *Organic* means that the information can be continuously evolving, as changes and edits are made. Wikis are *mundane* because they involve the use of a simplified set of essential commands. The design of wikis is also *universal*, meaning that writing and editing is a "combined" activity, formatting is related to input (*overt*), page names are not context specific (*unified*), and pages are generally named with some precision (*precise*). Wikis should be *tolerant* of error; activity should be *observable* by all, and duplications are undesirable and should be deleted (*convergent*).

There are a number of software programs that enable the effective creation of wiki pages, including TikiWiki, TWiki, and Pmwiki. These allow for the effective creation, modification/editing, and management of wikis, including creating pages, creating links, formatting, and feature modules (discussion forums, photo pages, download areas, etc.) (Chawner & Lewis, 2006)

Wikis are set up to allow for easy collaboration, and more specifically, editing. Rather than passively reading a passage of text or related information (which may include graphics, multimedia, hyperlinks, etc.), a reader of a wiki can also take on the role of a writer, making changes to the text (re-organizing, editing, re-writing, and marking up) at will. In essence, the document is

open to changes by a “collaborative community,” which allows for the secondary-oral model in education to be applied.

One reservation on the part of educators to embrace wikis is the fact that wikis are designed to allow for open and free access and editing by all members of a “community.” As a result, if improperly managed, a wiki’s content can become an unreliable, inaccurate, or biased source of information due to its largely unmonitored format. There is also the issue of having little or no “quality control,” resulting in a wiki not being trusted by its readers and users. An example of this was the controversy over the accuracy and reliability of Wikipedia, in the case of John Seigenthaler, in which the subject alleged that false and incorrect statements were posted in his biography (Seigenthaler, 2005). However, other studies have attempted to prove that Wikipedia was overall an accurate information source. One article reported that after analyzing a set of Wikipedia’s science articles, they were judged to be, by the British journal *Nature*, as reliable as the *Encyclopedia Britannica* (BBC News, 2005).

Wikis are useful for education in that they help to promote student participation and also a sense of group community and purpose in learning. Indeed, an important element of this is the relaxed sense of control over the content, allowing students to have a greater role in managing its focus and direction.

Wikis are not all the same, and there is significant diversity between various forms and implementations of wiki systems. In fact, it could be debated what features truly characterize a “true” wiki. The features inherent in most include the ability for users to both read and edit information, without the need for security or access restrictions. The emphasis is on simplicity, and the informal, “never finished” nature of wikis, which may constitute the contributions of multiple authors, is another key characteristic. While the emphasis of many wikis is on simplicity and a lack of access restrictions, that does not mean that

all wikis work this way. In reality, there can be a continuum of features from simple to complex. At the complex end of the scale can be capabilities for security/access restrictions, complex organizational structures, and for integrated with content management systems (Lamb, 2004).

Now that the strengths and weaknesses of wikis have been established, it would be useful to examine the educational applications of wikis. In general, the most suitable applications are those that take advantage of the wiki’s free, open structure. As such, the use of wikis as discussion/bulletin boards, brainstorming tools, and online sketchpads is appropriate. Meeting planning is another viable application area, in that the organizer can start with a preliminary agenda, from which the other participants can then add their own additions or make modifications or comments.

An important application area for wikis has been identified in knowledge management (KM). The use of wikis for knowledge management may allow for an improvement over existing systems and technologies. Currently, with existing KM systems, there does exist a number of bottlenecks relating to knowledge acquisition, namely acquisition latency, narrow bandwidths, knowledge inaccuracy, and “maintenance traps.” Basically, these knowledge acquisition bottlenecks result from a time lag between when the knowledge is created, and then distributed. In addition, there are the problems of limited channels of knowledge input, possibilities of erroneous information being received, and also the difficulties of maintaining the knowledge base as it grows larger (Land, 2002; Wagner, 2006; Waterman, 1986).

The use of wikis to elicit a “bazaar” approach to knowledge management, rather than a “cathedral” approach, is proposed as a better alternative. These terms are derived from software development, whether the “bazaar” allows for more continuous and open access to code (or information), as opposed to the “cathedral” approach where access is only provided on certain (release) dates to certain

persons. The difference between the “cathedral” (closed), sources of knowledge acquisition management and “bazaar” (open) could be illustrated by the difference between encyclopedias that are created by a single firm, such as Encarta or the Encyclopedia Britannica, and those that obtain information from readers and users, such as the well-known Wikipedia.

The emphasis therefore is on teamwork, continuous review and testing, and the development of conversational sharing (Wagner, 2006). Inherent in the workings of wikis is support for an open, collaborative environment, where many people can contribute to the development of knowledge instead of being limited to a set of “experts.” It appears that conversational knowledge acquisition and management are appropriate for wikis (Cheung, Lee, Ip, & Wagner, 2005). As for educational applications and KM, a study by Raman, Ryan, and Olfman (2005) examined the use of a wiki to help encourage and support collaborative activities in a knowledge management course. More specifically, using wikis in the course helped to encourage openness and better sharing and updating of knowledge bases. Many-to-many communication is supported, and the persistence of the created pages formed the basis of a knowledge repository. In short, the impact of easy page creation and improved updating and editing, together with effective maintenance of knowledge histories, were seen as positives (Raman et al., 2005; Bergin, 2002).

Activities in the KM course activities included group article review assignments, answering questions about sharing knowledge and uses of the wiki technology, and also creating a wiki-based knowledge management system. Students were asked to create, update, refine, and then maintain a class knowledge management system. In terms of these experiences, while the use of the wiki technology was generally viewed positively, feedback received indicated that, since the goals of using the wiki were not made clear, using one was perceived to be counter-productive. More specific

guidance on goals and objectives, a clearer system structure, and advanced training were suggested as ways to make the wiki a more effective educational tool. The availability of too many features made the task of doing the course activities more difficult, since much time was spent learning the various features rather than focusing on the task at hand. A simpler, less feature-rich version was therefore preferred (Raman et al., 2005).

Another popular application of wikis in the classroom is in supporting writing courses. The use of this technology can help to foster the impression that writing is “fun,” and that there can be a shared and collaborative side to writing, revising, and commenting on written work. In other words, the technology can benefit not only the writing and editing process, but also in bringing about an awareness that writing is being done for a specific audience.

An example of the use of wikis in English is the Romantic Audience Program at Bowdoin College, where students used a wiki to discuss and examine Romantic literature, focusing on poetry, poets, and related topics. The technology was used to elicit discussion and analyses by the group, encourage elaboration on areas where further study or insight was sought, and to seek out linkages to additional sources and commentary. Another project is Auburn University’s Wikifish, which was created by one school within the university, where questions are posed, and opinions and comments by all are encouraged.

Difficulties encountered in using wikis for education include the difficulty of tracking the new pages and contributions made by students, since modification can be made to another student’s text without specifically identifying the author or editor. As a result, it can be difficult to monitor, and properly attribute, what contributions were made by whom, on a particular page. A proposed solution to this was an instructor’s use of categories and topics, requiring that students link to and add, rather than simply modify, the contributions of other students. Another issue was how much

Table 3.

WIKI	
Description	A technology that allows for material to be easily published online, and also allows open editing and inputs by a group
Advantages	Contributions and editing by a group Open access to all users Collaborative
Disadvantages	Lack of organization and structure may result in an unmanageable wiki Tracking of contributions and modifications can be difficult Quality control
Educational applications	Collaborative writing/authoring Group project management Brainstorming activities Knowledge base creation (knowledge management)
Course/subject suitability	Knowledge management Writing Group work in courses
Theoretical foundations	Conversational technology Constructivist learning tool

of a balance in terms of the tradeoff between total freedom, and total control, was ideal. Since a clear benefit of a wiki is the emphasis on free expression and on spontaneous inputs, reducing this may have a negative effect on open interaction and student contributions (Lamb, 2004).

An interesting application of the use of wikis in the classroom was the work by Bruns and Humphreys (2005), where wikis were used in a New Media Technologies course to collaboratively develop entries for an online wiki encyclopedia called the *M/Cyclopedia of New Media*, an actual live wiki resource made available online. The effort to develop entries involved over 150 students spanning six classes in the program. Feedback indicated that while students had little difficulty with using the wiki system, obstacles came about more with the writing and format of the encyclopedia entries.

Another study examined the use of wiki technology in German-speaking communities

in Switzerland (Honegger, 2005), while Desilets, Paquet, and Vinson (2005) looked at how usable wikis are and found that the main problems encountered related to the management of hyperlinks. Wikis were also examined from the perspective of structure: how did the use of certain templates affect the appearance and layout of wiki pages? The results suggested that they are useful in certain circumstances and could be helpful overall to end users (Haake, Lukosch, & Schummer, 2005).

In summary, wikis are best suited to course and activities where there is a document, text, or other project to be worked on jointly by a class or group. In a sense, it is a tool for collaboration, and a form of groupware. The compilation of a class or group report or project, the creation of a knowledge base, or brainstorming sessions appear to be viable applications. The free and open structure, however, can fall prey to disorganization and degradation in quality, and so it is important

to have safeguards and procedures in place to ensure an effective result.

PODCASTS

While the terms “pod” and “podcast” at first mention might evoke visions of “Invasion of the Body Snatchers,” for most tech people in the know, the reference to Pod is almost certainly a reference to Apple’s popular and ubiquitous iPod.

However, podcasts are in actuality not what their name might imply them to be. A “podcast,” a combination of “iPod” and “broadcast,” neither refers to a technology specifically requiring an iPod, nor broadcasts information to users. Instead, podcasts are multimedia files (typically audio or video) that are downloaded to users on a subscription basis. Because of the potential confusion due to the use of the word “pod,” some have called for the letters to mean “personal option digital” or “personal on demand,” rather than iPod.

Podcasts can be played back on any device or system that can play digital audio (typically MP3) or video files, and are not broadcast to a large audience, in the way that television, radio, or spam e-mails are sent. Instead, they are sent to users who have specifically subscribed to a podcast service, and as such, files are automatically downloaded to the user’s computer when they are ready and available. In addition, podcast files are generally not streamed (as video is streamed), but rather are downloaded for later playback (Lim, 2005; Lum, 2006). Podcasts are delivered to subscribers through the use of RSS or RFD XML format media feeds, rather than more traditional forms of downloading (Descy, 2005).

Podcasts are considered to be a viable educational tool for several reasons. First, because of the popularity and wide use of devices such as the iPod and similar units, it would seem like a good medium from which to distribute educational materials. Secondly, the ease with which infor-

mation can be retrieved and accessed makes this a good choice for students, who are using these devices on a regular basis for music and should have few technical difficulties or learning curves (Lum, 2006).

There are multiple facets to podcasts. First, there is the consumption perspective, where someone downloads the podcast and then listens or views it. This involves subscribing to a service (or enrolling in a course), finding the relevant file, and then downloading and playing it. Alternately, someone can actually create podcasts; an instructor can produce lessons for students, or students can produce an assignment in the form of a podcast file (Lum, 2006).

Education is one area where the power of the podcast has been used in various ways. At Duke University, orientation material was distributed as podcasts, loaded onto iPod units, and given to students in its 2004 incoming freshman class. The units were provided not only for orientation purposes, but also for use in playing podcast lectures when the students take certain courses at the university. At Mansfield University, students were sent podcasts about various student life issues, and at Arizona State University, President Michael Crow used podcasts to deliver messages to the university community (Lum, 2006).

While there appear to be sound reasons for using podcasts, there is also a theoretical basis behind the use of podcasting. This is based on cultural-historical activity theory (Engestrom, 2002) and is based on the fact that podcasting can be considered a tool that can be used to help learners to better interact with or understand a task and its environment. Vygotsky (1978) argues that the effectiveness of podcasts rests in its linkage between social/cultural influences present in the environment and the cognitive development of the learner. Expressed another way, the concept is that since so many student have access to iPods and MP3 players, it would make sense to explore the viability of using such a device for learning and educational purposes.

Table 4.

PODCASTS	
Description	The ability to create audio (and other media) based files to be distributed on a regular/subscription basis to users; these can be easily retrieved and played back on handheld devices, computers, and through other means
Advantages	Allows for information to be retrieved and played back on widely available, ubiquitous devices More suitable to auditory and visual learners
Disadvantages	In consumption (playback) mode, does not directly support collaboration Is not inherently interactive in nature
Educational applications	Recorded class lectures Case-based instruction Guest lectures in the form of podcasts Supplemental course materials Support for distance learning courses
Course/subject suitability	Subject matter lends itself to auditory format
Theoretical Foundations	Cultural-historical activity theory

Lim (2005) discussed experiences in using podcasts for teaching geography. Because of the nature of the subject, it was found that video would have a greater impact and result than audio. Students were asked to submit assignments to be created and submitted as podcasts. Overall, this helped to bring about satisfaction and interest in terms of the subject. Ractham and Zhang (2006) looked at the potential for podcasts in a classroom setting. While there are the obvious benefits in terms of being able to distributing class materials, there also are benefits in terms of contributing to social networking in the class and continuing a flow of academic knowledge. Class discussions, announcements of research activities and conferences, and also campus activities could be distributed as podcasts. Review materials could be distributed effectively on an automatic basis to interested students. In addition, the ability for students to create podcasts to be distributed to others would also be a new means of submitting assignments or expressing creativity.

Podcasts, unlike IM, blogs, and wikis, offer a greater emphasis on providing engaging auditory and visual course materials to students, rather than on collaboration and group work. While not generally a substitute for traditional lectures and knowledge presentation, they offer the benefits of easily accessible and “digestible” course material. Whether it is excerpts from class lectures, highlights from a guest speaker, or an oral test review, the use of podcasts provides a means by which students can obtain and easily receive course-related information. In addition, it also provides a means by which students can express and present their work, which can then be “published” and distributed in podcast format.

DISCUSSION AND CONCLUSION

The face of education, whether online, hybrid, or classroom, is constantly changing, and it is

important for educators to stay abreast of the many opportunities and possibilities that are available.

In this article, several technologies, generally termed as conversational technologies due to their interactive and collaborative nature, were discussed in detail, together with their capabilities, benefits, and educational applications. Relevant research and case studies as they relate to classroom and educational applications were discussed.

In general, the tools discussed here fall into the class known as “conversational technologies” or “constructivist learning tools.” As such, they emphasize student interaction, group learning, and collaboration, rather than the more traditional classroom mode. In light of this, they are more suited to educational courses or environments where the emphasis is on student communication, where students have access to technology, and where creative output and thinking is encouraged.

In the situation where a course is primarily lecture-based, or is mainly concerned with the delivery of factual or conceptual information, these tools may have limited applicability. The one application that may be helpful in this case may be for interaction to be extended outside of the classroom, through the use of instant messenger, or for supplemental materials to be distributed as podcasts.

Since each of the tools has its own characteristics and suitable applications, it would be up to the educator to select those that are most appropriate to one’s course and activity.

Instant messenger, which is commonly used by students for personal use, has found its way not only into the business community, but also into the classroom, because of its strengths in terms of informal communications that are conducted real-time. There are some mixed results regarding the use of IM for use for education; benefits are claimed by some, but there are limitations

as well. The use of IM would best be employed in situations where group work, student communication, and real-time discussion would be helpful. However, it should be used cautiously, since it can be distracting, and students may end up carrying on personal, rather than course-related discussions.

Both blogs and wikis have been hailed as useful tools for education, and the specific advantages and disadvantages of each are noted and discussed. Blogs tend to be more one-sided, with an author presenting his or her information, with generally limited input from the readers and public. However, the use of the technology has been used effectively to promote information sharing and to support writing courses. The use of blogs to support online learning journals, class article/peer reviews, creating online portfolios and galleries, and for solving a specific problem or case would be advantageous. It would also appear to be a good medium for graduate research seminars, where papers and studies are analyzed and critiqued.

Wikis, which allow freedom in creation and in editing and enhancement by others, are especially useful in collaborative situations where the input of an entire group is desired instead of a single person’s contribution. In the classroom, wiki support for collaborative writing and group activities, where students contribute to the creation of a common result, would be useful. In general, any kind of learning activity that involves the collection and maintenance of knowledge or information may benefit from the use of wiki technology.

The use of podcasts, which may include audio or video, is growing in popularity and is being used for delivery of information to subscribers on an automatic basis. Educational podcasts, both for the delivery of audio and video-based knowledge to students, and also as a new medium for the creation and presentation of assignments, appear to have potential. While podcasts are useful as a means for publishing and distributing files of

multimedia-based class materials, there also exists the potential to create new podcast content, both for educators and as a course activity.

Clearly, the use of these new conversational technologies is allowing for the enhancement and continued evolution of new and innovative forms of support for teaching and learning.

FUTURE RESEARCH AREAS

Certainly, there are many benefits to the use of conversational technologies and constructivist tools for educational use. However, more research needs to be done, not only in terms of identifying additional types of applications and uses, but also in terms of how to more effectively identify and apply new approaches to learning with the aid of these kinds of technologies.

Some of the broader research issues that can be examined include measuring both learning, and the perceived quality of education, depending on the specific technology or tool employed. Are there measurable benefits to using a certain technology in terms of the material learned, better class performance, or more subjective factors? It would also be useful to determine, particularly when using blogs and wikis, the neutrality or bias in the entries, and how much these contribute to (or detract from) the material submitted for a course assignment.

Other research areas are more technology specific. It was mentioned earlier that wikis can be a useful tool in knowledge management. The application of wikis to effective knowledge management deserves further attention, both in terms of developing or adapting the wiki structure and features to knowledge management uses, and also for identifying various kinds of user interfaces and functionality that would improve usability. The establishment of wiki-supported communities of practice is one area where the tool could possibly be useful.

Podcasting also has many areas that are ripe for further investigation. There are issues that can be explored in the areas of knowledge management, collaboration, and the adoption of podcasts. Some of the specific topics of interest include the management and sharing of knowledge using podcasts, examining whether their use actually improves learning, studying their effects on collaboration and networking, and what the factors (or features) are that would help to promote its use.

There also has been work on the psychological aspects of distance learning and online courses (Dickey, 2004), and a study of learners' reactions to using IM, blogs, and wikis, for example, would yield insights into its appropriateness for its further use in education. Does the use of these technologies contribute to the satisfaction of students, or is more classroom face-to-face still better?

The realm of these new technologies is certainly ripe with a host of opportunities for both interesting and meaningful research studies.

Chapter 3.30

Introducing GIS for Business in Higher Education

David Gadish

California State University – Los Angeles, USA

ABSTRACT

Schools of business can benefit from adoption of geographic information systems (GIS). A brief overview of GIS technology is presented along with an example showcasing how it can be presented in a business school. GIS benefits for business schools, their students, and faculty are discussed. A comprehensive approach for promoting such spatial thinking is presented. The goal is to empower faculty to adopt GIS for their research and teaching, producing a large number of business school graduates that can promote spatial thinking in their organizations.

INTRODUCTION

This article discusses the introduction of GIS for higher business school education in departments such as management, marketing, economics, finance, and information systems. The goal is to have business school students, faculty, and administrators thinking about location and time issues

relating to their research, teachings, and business decisions using GIS technology to illustrate and to implement business ideas in terms of location and time. We begin with an overview of GIS and its benefits to business sectors and focus on business education. A detailed discussion of the approach ensues. It consists of an awareness campaign in which business school faculty, administration, and students are made aware of the benefits of thinking about business and business education in terms of location and time. Once an agreement is reached regarding the importance of spatial business thinking, resources must be secured to implement the approach. These include the purchasing and setup of GIS software, hardware, and data. Faculty must be trained in the use of GIS technology as well as in incorporating spatial thinking in the classroom. Faculty members also should be introduced to the benefits of GIS in their research activities. The article concludes with lessons learned from the author's experience, including the impact of spatial thinking and GIS technology on course curriculum.

California State University Los Angeles (CSULA) is reaching out to introduce spatial thinking in business education to build more academic-business bridges in the world. The school of business at CSULA, an AACSB accredited institute, is working to promote the use of GIS technology in business education as well as in the multicultural business community that it services.

GIS Overview

GIS is an integrated computer system capable of capturing, storing, retrieving, analyzing, and explaining spatial information that provides the user with knowledge of the location information in the context of time about the world, a business, a project, or an objective. GIS is also a location-based, decision-making tool that helps to produce useful information in a cost-effective manner. The ability of GIS to analyze spatial data frequently is seen as a key element in its definition and often has been used as a characteristic that distinguishes GIS from other systems. GIS facilitates spatial analysis, which is a set of analytical methods. It requires access to both attributes of objects under study and to their locational information and allows referencing traditional data sets to maps. Geographic Information Systems consist of a number of key components. These include computer hardware, software, data, procedures, and people. GIS data consists of spatial or mapping objects as well as non-spatial attribute data. Spatial data include points, lines, polygons, and other graphical representations, as well as text that represents buildings, customers, roads, and other real-world entities. GIS can help to answer different types of questions. It can help one to find what is at a particular location, where something specific is located, what has changed, what is the best way to get somewhere, what the pattern is, and what if certain conditions arise.

Higher education institutions have focused largely on training a select number of GIS special-

ists in certificate and Master's programs. Many of these specialists were hired by governmental organizations, which has resulted in a penetration of the technology in government and some private organizations. GIS currently is entrenched heavily in all levels of government across different departments and is making a substantial impact where it is used, including planning, coordination, and monitoring activities.

GIS Learning Case

Business school students may use GIS to learn about a way to make business decisions based on location. For example, consider using technology to define where a new health food store should be located in a city such as Los Angeles. The students may gather business data about different restaurants in the city, as well as their locations and what type of food they offer. The students then should gather information about the income of the citizens and other demographic information about the population (e.g., age, type of employment) based on zip codes in the city. This information can be overlaid visually on a map of the city using a GIS program such as ArcGIS. The students then can query the software to highlight the location of those zip codes where the income is the largest, the population is the youngest, and that currently do not have a store of the type the student is interested in, starting within a 10-mile radius of the zip code. The student learns that the GIS software supports their decision-making process.

GIS BENEFITS FOR BUSINESS

Business knowledge is power, which can be increased by looking at business data in terms of location and time. GIS enables one to view business information graphically, share information with others, as well as make appropriate business decisions. GIS can be used for managing

Table 1. GIS technology benefits to business organizations

Business Sector	GIS Contribution
Publishing (Newspapers)	Increase newspaper readership by targeting new subscribers, mapping courier routes
Banking	Measure market potential
Retailing	Map customers and provide custom advertising
Health (Gyms)	Evaluate suitability of sites for new gyms
Dental Supply	Realign sales territories of salespeople
Healthcare	Evaluate healthcare resources, analyze demand for specific treatments by location to better serve the public
Real Estate	Determine where to locate commercial real estate — new shopping centers, new stores — by analysis of demographics and competition (Longley & Clarke 1996)
Food (Supermarkets)	Discover efficient delivery methods for food purchased via the Web or by phone order to homes
Insurance	Establish the value of real estate property to be insured

information about a business; a business sector; or business activity in a region, a country, or the world (Grimshaw, 1999).

GIS can be used by businesses at a number of scales. GIS can be incorporated into individual projects, used at the departmental level or at the enterprise level responding to overall organizational needs, or used as a means for collaboration among multiple organizations. GIS allows organizations to make sense of large quantities of information that are prevalent in today’s business environment.

In the last few years, private business organizations started to see the benefits that GIS provides to the public sector and began adopting GIS technology for their own business needs. Table 1 lists a few business sectors and how GIS technology can benefit them (Boyles, 2002; Harder, 1997). This serves to demonstrate the wide-ranging applicability of GIS technology for business.

The GIS adoption process has proven to be lengthy and complex, as there are no sufficient human resources that understand and appreciate spatial thinking and its benefits to business

organizations. This gap in existing business and education appears more clearly as more businesses realize the benefits of the implementation of the technology and their inability to cope with it. This provides business schools with an opportunity to fill an important educational gap and a business need. Business schools, therefore, should begin to enhance their efforts to incorporate spatial thinking in their business education curriculum.

GIS BENEFITS FOR BUSINESS EDUCATION

Incorporating GIS into a business school benefits the school, the students, the faculty, and the business community. The following paragraphs outline key benefits to each stakeholder group.

GIS Benefits for the Business School

Business decision makers realize that the location of their organization’s facilities, employees,

competitors, clients, and potential clients must be taken into account when making business decisions. A school of business that would adopt GIS will be better able to address business needs by educating future business leaders to think and to make decisions in terms of location and time.

Early adopters of spatial thinking and GIS technology will have a competitive edge over other higher education institutions in satisfying the needs of business. Promoting closer ties with these organizations will allow for future collaborations and possible donations by these organizations in support of the business schools.

GIS Benefits for Students

Business school students will be exposed to a new way of thinking about business problems that included the analysis of location (at a specific point in time as well as the analysis of changes in location over time).

This will provide students with a competitive edge over those that have not been exposed to such spatial business thinking. GIS provides a visual learning environment. Visual environments are generally more fun, resulting in increased student interest in all that is business. These activities could allow students to become visionaries that are familiar with basic GIS functionality and can promote spatial thinking in the private sector.

GIS Benefits for the Faculty

School of Business Faculty can use GIS technology in the classroom to illustrate business concepts in terms of space and time. The technology enables them to convey their message more effectively.

Faculty members may use spatial thinking and GIS technology for their research objectives in order to gain a better understanding of business situations that they are researching in terms of location and time.

GIS Benefits for the Business Community

Graduates can look at the existing business processes and suggest new ways in which their organizations can leverage their spatial thinking (Wayne, 2002; Tomlinson, 2003).

THE PROPOSED METHODOLOGY

The author of this article has been working since 2002 to introduce GIS technology into CSULA's school of business. This is a multi-step approach that begins with an awareness campaign led by a champion and supported by one or more sponsors.

Introducing GIS requires a champion, a visionary within the school that believes in the approach and preferably is an expert in GIS technology. This person can be a faculty member in the business school, if such expertise is available, can be hired for this job, or can come from a different college of the same higher education institution. The champion must lead an awareness campaign, which should result in a certain level of interest.

An Awareness Campaign

The proposed approach begins with an awareness campaign in which the benefits of the use of GIS technology are presented to business school administrators, faculty, and students. For an effective and comprehensive campaign, both benefits and costs must be considered. Top school administrators, including the dean and associate deans, must be shown clearly the benefits of the technology. It is important to bring top college administrators, including the dean and associate deans, to sponsor the vision early on in the process. This sponsorship does not need to include a financial backing in an environment of strained resources. Department chairs and their faculty must be behind the campaign, as they will be the ones

implementing it at the grass-roots level. Faculty members, therefore, must believe in the benefits of GIS technology, as it will benefit their students as well as their own research activities.

Incorporating GIS into the Curriculum

Incorporating GIS can be achieved on a number of levels. Initially, one specialized GIS course can be introduced into the curriculum. The course should provide an overview of the theoretical aspects of spatial and temporal thinking and will be complemented by an introduction to GIS technology and its use.

Introduction to GIS Course Objectives

The course should be focused on introductory business GIS applications. Business students will be exposed to ways in which spatial thinking can be incorporated into business decision making, business operations processes, and business management. The course also would show how

GIS technology is used to solve specific business problems in a number of business sectors.

Introduction to GIS Course Outline

At CSULA, no GIS courses were offered at the business school prior to 2002. The author introduced GIS through the Computer Information Systems (CIS) Department of the business school. The author’s course outline used at CUSLA’s business school is presented in Table 2.

This business GIS course is offered at both undergraduate and graduate levels simultaneously and is open to all students at the school of business. The course complements the existing programs in the CIS department as well as those students from other non-CIS majors at the school of business. Some of programs and benefits the course provides are listed in Table 3.

Coursework is complemented with individual student projects. Each student selects an area (business sector or specific organization) that interests them and then pursues a theoretical application of the ideas discussed in the course to the topic. The

Table 2. Business GIS course: Topic outline

Topic ID	Description
1	What is GIS?
2	A Survey of the GIS Industry
3	Foundations of GIS: Data, Hardware, Software, Workflows, Science
4	Spatial Data: Collection, Build, and Maintenance
5	Spatial Data: Additional Sources of GIS Data
6	Analysis of Spatial Data: Buffer Analysis, Network Analysis
7	Business Applications of GIS: Telecommunications, Utilities, Banking and Finance, Retail/Wholesale, Government Sectors
8	GIS Data Display
9	Introduction to the Global Position System (GPS)
10	Applications of GPS Technology to Business
11	Future of GIS for Business: Internet GIS, Intranet GIS, Field GIS, GIS Database Integration
12	Case Studies

Table 3. GIS technology benefits to the business school's programs

Department	Program	Benefits
CIS	BA Business Track	Provides spatial thinking geared toward business applications
	BA Technical Track	Discussion of possible ways to apply software development practices to spatial problems using GIS technology
	MSIS (Graduate)	Provides spatial thinking geared toward effective management of business organizations
Management	Undergraduate and Graduate	Provides spatial thinking geared toward business applications and business management
Marketing	Undergraduate and Graduate	Provides spatial thinking geared toward marketing applications
Economics and Statistics	Undergraduate and Graduate	Spatial thinking about local, regional, and global economic issues, including labor, transportation, international trade, banking, and regulatory agencies
Finance and Law	Undergraduate and Graduate	Spatial thinking about regional and global financial/monetary patterns

result is a paper discussing the existing state of GIS technology in the student's business area of interest. Each student shares his or her findings with the class during the last two weeks of the course. The paper provides students with an opportunity to see what others are doing in industry through Web and literature research as well as to provide them with the ability to come up with new and more effective ways of incorporating spatial thinking in their areas of interest.

Having such a business course can serve as a springboard for students use their theoretical and practical experience in their studies in other courses offered in the business school.

In addition to offering such a new GIS specific course, faculty members can incorporate the use of GIS into a large number of business courses. This can be limited to assignments that ask students to start thinking terms of space and time in order to solve business problems or assignments that explicitly require the use of GIS technology in

order to analyze business data. An introductory course about business information systems could be modified to include a lecture introducing GIS technology. An introductory management course could be modified to include a lecture introducing the benefits of spatial thinking to the management of an organization.

Purchase and Setup of GIS Software, Hardware, and Data

Incorporating GIS technology requires the purchase and setup of hardware and software. For the most part, existing hardware resources can be leveraged for GIS teachings and research. GIS requires more hardware resources than traditional computer programs such as word processors and spreadsheets. GIS software needs more disk space and computer memory. Most modern desktop computers that are two or three years old have

sufficient resources for GIS applications and, therefore, do not require any special or costly upgrades.

Major software vendors are interested in having education institutions adapt their technologies and having their capabilities known to future business leaders. This has created an environment in which GIS software can be licensed for GIS educational institutions at minimal cost.

Spatial data (mapping data) that would complement existing business data for analysis in the classroom as well as for faculty research purposes should be secured. Spatial data can be acquired from a number of sources in a variety of ways. Some GIS data can be downloaded at no cost from the Internet. Business data can be purchased at an educational discount from private sector spatial data vendors. GIS data can be licensed from various levels of government, often at no cost.

GIS Learning Support and Standards

A number of national non-profit organizations provide support for GIS faculty and students. These include URISA and GITA.

Additional support can be provided by the major GIS vendors. These include ESRI, Intergraph, and Bentley.

Training Faculty

Training faculty is fundamental to the success of the proposed approach. It is important for faculty members to feel comfortable in the use of the technology. It is also very important for faculty members to be comfortable explaining the benefits of the technology to themselves as well as to their students. It is important for faculty members to be comfortable with the software and the thinking processes to an extent that they can convey the appropriate message and teach the technology to their students with ease. Arriving at such a level of comfort with GIS technology may take time

and resources. This could include sending faculty members for training by GIS vendors on the use of GIS software. A better approach would be to bring in GIS experts, preferably from within the business school or, if not available, from the Department of Geography of the same university, to teach business faculty members how to use the technology. Initial training must be followed up with regular events (possibly coinciding with the annual World GIS Day) that reiterate and enhance the notion and the benefits of the use of the technology for business education as well as refresh faculty with new GIS capabilities and tools and their benefit for business teachings and research. This ongoing process would be beneficial for existing faculty members as well as new faculty members that join the business school. Such meetings could be used to provide faculty and students with an opportunity to share their research that pertains to spatial thinking and GIS technology as well as their teaching experiences.

CONCLUSION

The introduction of GIS technology to a business school requires a leader and must be done in a methodical way, realizing that the process will take time. Some faculty members may resist change due to fear of technology, in general, and the perceived complications that are added with the adoption of GIS technology, in particular. These concerns can be mitigated with time through a systematic and thorough campaign of educating faculty to the benefits of the technology and its use for their own teaching and research needs and showcasing the benefits gained by those faculty members who have adopted the technology.

Introducing GIS technology should and will have an impact on the course curriculum of the business school. A course specializing in GIS would be added to the curriculum. Other courses could be affected and their curriculum could be adjusted.

Introducing GIS for Business in Higher Education

The proposed approach will, with time and effort, allow an increased awareness of spatial thinking and use of GIS technology to the benefit of business school administrators, faculty, and students. The benefits are expected to propagate further to the business sector and the community.

In the case of CUSLA's business school, the results are positive and promising. Students from various departments of the business school have taken the course and have commented that it provides them with a new way of seeing the business world. Student retention in the course is very high. Twenty percent of the students have indicated their intent to pursue business GIS learning beyond the existing framework. Many of these students are working on various research activities that incorporate GIS and spatial thinking. Spatial thinking has been received positively by faculty in the school of business. The author presents an overview of business GIS as part of a number of other faculty members' courses. The school of business continues to support these efforts in terms of financial and technical resources.

The author recommends the outlined approach to other business schools. The effort should be gradual, taking one small step at a time.

ABSTRACT

This work presents an extension of our study on multimedia patterns of interactions and development of computer aided-learning (CAL) engineering tools. We used four approaches in implementing the CAL tools for user visualization that is, that is, 2-D, 3-D, coach environment and desktop virtual reality. The designed CAL tools have been enhanced to enable the integration and investigation of visualization in various engineering problems for undergraduates with particular weak learners. Each problem was designed using different authoring tool. More significantly, we have enhanced some of the CAL tools to the degree where the user can interact and be coached

independently. This dramatically increases the quality of the tools i.e. patterns of interactions, 2-D and 3-D views of synthetic models. In general the result shows that the CAL tools could alleviate the user interacting and instill a sense of learning and the user understand the engineering problem better.

INTRODUCTION

Multimedia has been applied successfully in diverse areas of medicine, manufacturing, scientific engineering visualization and education (Manjit Sidhu, Selvanathan, Diljit, & Ramesh, 2002; Mcateer, Neil, Barr, Brown, Drapper, &

Henderson, 1996; Sheingold & Hadley, 1990). However today, both multimedia and desktop virtual reality CAL tools are becoming one of the most used technologies in delivering high quality teaching aids and allows virtual perception in general. Thus, the world of virtual perception has now extended into the area of engineering.

Before conducting a complicated experiment, a learner can now rehearse on a virtual engineering problem, that is, by using a computer simulation. By wearing a special pair of glasses, which produce the impression of a three-dimensional object, they are able to manipulate the objects parts as they would in a real situation.

Modern and powerful computers are capable of astonishing things, however they are still a long way from reaching their peak of performance. Engineers and technicians increasingly can enter into and interact with, an artificial, virtual reality environment that is more and more like the real world. Furthermore the computer can provide sensory impulses for our eyes and ears, creating a near perfect spatial object. As such, in the context of engineering users of CAL tools can interact, manipulate, and visualize the objects better.

The major aim of this study is to identify engineering problems that are difficult to visualize and understand among undergraduates with particular weak learners. The weak learners are students who take a longer time to complete the mechanical engineering course. The advanced students normally takes approximately four years to complete the undergraduate degree course, however the weak learners may take up to five years to complete. As such, the weak students need an alternative means of learning to improve their knowledge in the subject matter. Other aims of the study includes, to design and develop interactive multimedia and desktop virtual reality (DVR) CAL tools with appropriate patterns of interactions by providing interactive user interfaces for exploring, visualizing and problem solving. The study also identifies the ways that multimedia and DVR support the approach at both theoretical

and undergraduate practical level in engineering. The application area in this research is engineering mechanics and dynamics because this area contains a wealth of interesting and difficult to understand problems among weak learners at University Tenaga Nasional (UNITEN).

COMPUTERS AND PERCEPTION

Today, with the aid of virtual reality environments, a rich variety of applications and new three dimensional and imaging technologies ranging from automotive, engineering, and aerospace design to weather simulation, climate modeling, and medical applications, with many different research and engineering objectives, and user types are being carried out. Visualization can be useful and important in many ways. For example, an architect can walk in a house that has not been built, a doctor can travel through the respiratory system looking for malignant tumors, a chemist can create new compounds at a three dimensional drawing board and the builder of a new power station can put his designs on different foundations in order to test them for safety.

For many years now, automobile companies have developed their new model, using computer simulations; even high-speed crash tests are carried out with advanced computers. After the virtual crash, design engineers can inspect the vehicle from all sides and look into the mangled interior. Thus the use of computer simulation considerably reduces the number of prototype cars, which must be built before a vehicle is ready for production. Consequently, multimedia and desktop virtual reality CAL tools are increasingly being employed in industry and education.

VISUALIZATION

As an important component of the CAL engineering tools, the use of visualization for engineering

mechanics and dynamics is being studied. In order to facilitate the enhancements of new visualization paradigms as well as the integration of existing methods with the traditional learning process, new and enhanced interactive multimedia CAL tools were required to coach weak learners learn how to solve engineering problems during unsupervised laboratory work.

Existing CAL tools were either general-purpose visualization tools and lacks interactivity (Sheingold & Hadley, 1990). Numerous studies have found that interactivity has a strong positive effect on learning (Bosco, 1986; Cairncross & Mannion, 2001; Gupta, 2002; Hiroshi, 2002). For example, Bosco (1986) reviewed 75 learning studies and found that learners learn faster, and have better attitudes toward learning when using interactive multimedia tools. In addition, a study by Najjar (1996) found that learning was higher when information was presented via computer-based multimedia systems than traditional classroom lectures.

With general-purpose visualization CAL tools previously developed in UNITEN, lack of domain specific refinements limits use to visualization that makes user deployment for learning purposes difficult.

Furthermore, more specialized CAL tools almost lack interaction between user and machine and focus on linear leaning method rather than deep learning (Sheingold & Hadley, 1990). According to Entwistle, Thomson, and Tait (1992), deep learning is associated with not only acquiring the information but also understanding it through relating it to previous knowledge and experience.

In addition, previous studies have not dealt with concepts that lend themselves to visualization (Manjit Sidhu, Ramesh, & Selvanathan, 2003). By visual, the concept is dynamic and therefore more easily shown on a computer screen where the image can change back and forth between screens.

2-D Graphics and Animation

In this context, the previous work focused on the feasibility of using various animation techniques such as tweening an image and good quality graphics and color-coding to draw the users' attention to various concepts being presented. Tweening is a technique that allows "in-between" images to be created between supplied key-frames using linear interpolation. In the initial stage, simple animation of 2-D objects on screen was achieved by coloring significant parts of a structural diagram, connecting each part together to form an animation and then returning them to their original state.

The content contained within the tutorials is intended to provide students with better understanding of the theoretical concepts taught in class as well as to enhance their ability to apply mechanics concepts in a variety of engineering design. One common occurrence in the use of such CAL tool is that the users tend to visualize the same material faster when they do not have to spend extra time using these learning aids (Entwistle et al., 1992; Mcateer et al., 1996). In addition there is compelling evidence that students develop more interest in the subject matter (Entwistle et al., 1992; Kruger, Frohlich, Bohn, Schuth, Strauss, & Wesche, 1995; Mcateer et al., 1996).

Mechanics statics, like many other engineering subjects, is fundamentally about problems solving through the application of scientific principles. However, there are many cognitive steps leading from problem to solution and consequently many educational difficulties such as students lack the ability to translate mathematical word problems into the form necessary for effective computation. These engineering problems are often complex, and relationships among the variables of an experiment can be difficult to visualize. As such, multimedia CAL tool provides an alternative for presenting engineering and scientific information in a way that is easier for students to understand. For instance, when a 2-D image is displayed in the right way, the user often has new insights

into the underlying principle being taught. Furthermore, most CAL tools demands some kind of user navigation. The non-linearity offered by many multimedia CAL tools provides a learner greater navigational and freedom (Manjit et al., 2003). Users may go onto any section in a multimedia tutorial and in any order. Dynamic media such as video and audio can be controlled, that is, pausing, playing and repeating clips.

Problems in mechanics statics are presented to the student as a combination of schematic diagrams and text descriptions. The student must immediately apply learned knowledge in order to form an internal model of what the problem means. The shapes and lines that make up the schematic diagram have very specific engineering meanings, and the words accompanying the diagram could also give rise to student error because critical information about the solution of the problem is often concealed in the text in unexpected ways. Our previous experience showed that an average student would be able to solve the problem at the first try but a weak student would require several trials before solving the problem (Manjit et al.,

Figure 1. To find force C_x , the forces A_y and C_y are made dim. When the forces in the x-direction are being considered, the computation appears in an animated form, i.e. $\sum F_x = 0 \quad C_x + 600 = 0$
 $\therefore C_x = 600 \text{ N}$

2003). The weaker students take a longer time to solve the problem mainly because these students lack the understanding of the theory that has been taught during normal lectures. As such, these students would require an alternative method of instruction to enhance their learning skills.

Therefore, the most effective way of learning the principles of engineering mechanics is to solve

Figure 2. Moments are taken at joint C with the assumption that counter-clock wise moment is positive.

Figure 3. The final solution is analyzed and the correct free-body diagram showing all forces (tensile and compressive) acting in each member is drawn on the screen.

problems. To be successful at this, it is important always to present the work in a logical and orderly manner. In the case of structural analysis as in Figure 1, since all the forces acting at a joint must be taken into account, the importance of drawing the free-body diagram (FBD), Figures 2 and 3, before applying the equations of equilibrium to the solution of a problem cannot be overemphasized. However, prior to this the support reactions must be determined. In the FBD, the forces that are given should be labeled with their proper magnitudes and directions. Letters are used to represent the magnitudes and directions of forces that are unknown, for example in Figure 1, the reactions force components at the supports *A* and *C* are designated as A_y , C_x and C_y . In particular, if a force has a known line of action but unknown magnitude, the “arrowhead,” which defines the sense of the force, can be assumed. The correct sense will become apparent after solving for the unknown magnitude. By definition, the magnitude of a force is always positive so that, if the solution yields a negative scalar, the minus sign indicated that the arrowhead or sense of the force is opposite to that which was originally assumed. At the click of the “Continue” button, the analysis to compute the unknown reactions is carried out in a step-by-step approach. The ability to build a screen sequentially is extremely important to allow students to see the progression of the derivation and process steps. As the user clicks the “Continue” button, relevant forces causing moments about *C* is written on the screen.

Every attempt is made to minimize text on the screen and maximize the computer visualization capabilities. One strategy is to link text and graphics to reinforce a concept (e.g., to display a particular segment of an animation as typically shown in Figure 2, provide clarifying text, and so on). Highlighting text using boldface or color is also useful. Animations can also be displayed in sequence with supporting text to highlight each process as typically shown in Figure 3.

Coach Environment

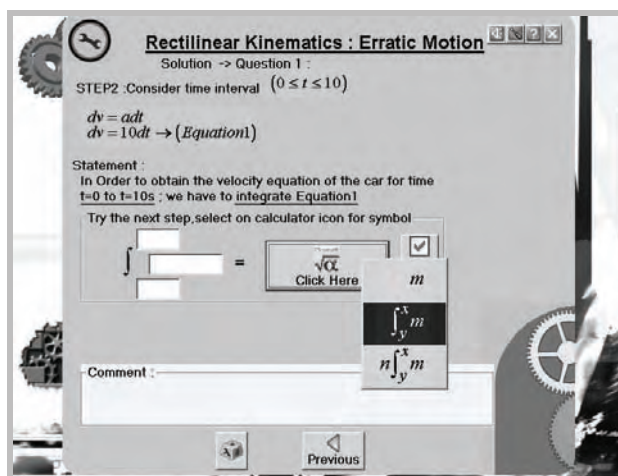

One of the early objectives of this CAL tool was to provide an environment that could help the user solve engineering mechanics problems without the help of a human instructor. We define coach environment as a CAL tool that can guide a user by providing a step-by-step approach to solve a task. In addition it provides the user with more dynamic, interactive support than does help as provided in general CAL tools. In coach environment, the user can approach the “Hint” and “Solve” buttons in the event the user reaches an impasse. Typical example in the coach environment CAL tool includes of basic information, context-sensitive hints or tips, or procedural steps required to solve a problem. Since not all students are capable of solving engineering problems by attending a single tutorial, the CAL tool is designed to help and show the user how to solve a problem leading from the question to a series of steps and solution. Every task and step is shown in an animated process on the screen with audio or video narrating more about the problem as shown in Figure 4. The CAL tool also provides reasoning support and explanations of complicated concepts while the user is trying to solve the problem presented in the tool. Thus this approach can help weak learners make decisions and complete tasks better and provide explanation for reasoning, enabling continual performance and improvement. In addition the CAL tool could further provide more classroom time for demonstrations and coverage of conceptual issues. The focus of this study was to investigate whether such a CAL tool could enhance understanding and effective to be used as an unsupervised learning aid particularly for weak learners.

The coach environment CAL tool was designed in such a way that it would not deviate from the method of teaching adopted by the lecturer teaching the mechanics dynamics course. The tool has striven to embed the same pedagogical philosophy that is used in the classroom. For example in solv-

Figure 4. Video explaining engineering concepts

Figure 5. A selection list of formulas and equations

ing mechanics problem, students are normally encouraged to draw free body diagrams and kinetic diagrams where appropriate, label all known forces, moments and other parameters, select appropriate datum or reference point, use appropriate formulas and equations to solve the problem. Past research [7, 8] indicated that immediate feedback has a positive impact on learning, and thus the tool was designed to provide immediate feedback such as by displaying blue colored messages in the comment box on the computer display to indicate

correct student actions, red to indicate incorrect ones and black to indicate no value entered in the text input box, and so on. In addition, if a student input the wrong answer, he/she may immediately be narrated and questioned prior to giving a hint by clicking the “hint” button.

In this CAL tool, users are encouraged to select and define the correct formula from a drop list and then to use them to enter symbolic equations, and finally to solve for the numerical answer as shown in Figure 5. In order to eliminate poor

algebraic skills from undermining the conceptual issues the user is trying to learn, the tool further enable the user to select an equation, and click on a “solve” button which will then perform the algebraic/arithmetic manipulations necessary to simplify the equation. This feature is considered to be important as it can help the slow learner memorize the correct formula or equation to be used for other similar problems.

The interface of the CAL tool provides an interactive environment in which the user works the mechanics dynamics problem as shown in Figure 6. It consists of several electronic turning pages and multiple user tools, that is, calculator, notepad, and glossary of commands.

In the preliminary development stage, the tool has been designed to solve rectilinear kinematics, erratic motion, and structure problems. It is anticipated that kinematics of a particle and motion of a projectile problems will be implemented and added to the tool in the next stage. This coach CAL tool is basically a powerful and flexible tool that is designed to work the solution of the problem in a step-by-step fashion. As the user click on the “next” button to proceed, the tool would then question the user on the next action by giving three options. In this way, interaction between

the user and the tool is achieved. Although the tool has been implemented using Microsoft Visual Basic and Swish, it is a stand-alone (PC based) application, which is available on the CD-ROM and currently runs on Windows platform.

In general, the evaluation discussed in section 6 revealed that the users gained knowledge from the multimedia session and the level of confidence in solving problems pertaining to that particular engineering problem that has already been taught in the classroom has increased.

Architecture

The coach CAL tool has a user-friendly environment that build on eight major modules: the action interpreter, the assessor, the interface, the help, the calculator, the glossary of commands table, graphs to show (velocity, time, and speed) $v-t$ and $s-t$ and a database to store the students progress score.

System Environment

The system environment consists of the given conditions of a problem and a dynamics problem-solving engine. The problem-solving engine

Figure 6. The interactive interface of the CAL tool

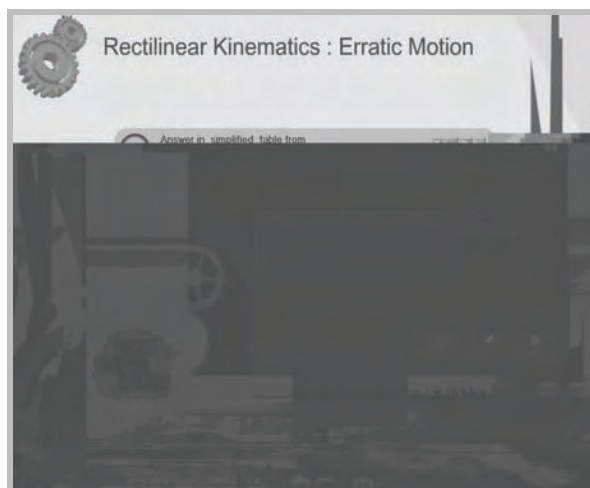

Figure 7. Typical coach CAL problem-solving decision making rules

STEP 1	If	the sub goal is to determine the time needed to stop the car correct kinematics formula applied
	then	create a sub goal to find out how far has the car traveled
STEP 2	If	correct symbolic equation selected correct values input in text boxes and correct value of velocity applied
	then	create a sub goal to determine the next subsequent step
STEP n		

contains approximately 15 conditions comprised of decision-making rules. An example of each type of rule is shown in Figure 7.

The given conditions of a problem are used as input to the problem-solving engine. As a matter of policy, the input matches the written problem statement as the exact answer with interpretation. Outputs from the problem-solving engine consist of all the equations necessary to solve the problem. These equations are then used by the action interpreter and assessor to provide appropriate hints.

Action Interpreter and Assessor

The action interpreter module interprets the user's problem solving action in the context of the current problem and determines the type of feedback to provide. For example, if the user enters an equation, it is compared to the set of equations produced by the problem-solving engine and if a match occurs, the message colored in blue indicating that the equation is right is displayed. If there is no match then the message colored in red indicating incorrect equation is displayed. When

the user has reached an impasse and has no idea how to proceed, he can click the "hint" button; which may aid the user solving the problem.

On the other hand, if the user has input the wrong formula, he will be narrated and ask if he needs a hint. If the answer is wrong again, a "solve" button will be visible. The user can click this button in order to let the CAL tool solve the problem. The solution will be shown in a step-by-step animated form. If the answer given by user is correct, he can then proceed to the next step. If a complete solution has been accomplished, except for numerical substitution, the user can consult the CAL tool to do the appropriate substitution. If the user correctly solves a step, the screen will display the consequent step to be solved. The steps are iterated until the last step is solved. During these actions, the user progress database is also updated accordingly. The progress results of the users are shown at the end of each complete attempt to solve the problem as typically shown in Figure 8.

High quality color graphics are used extensively and design features, such as interactivity, animation and a hypertext facility are used with

Figure 8. Typical user progress screen in the CAL tool

the intention to enhance student learning. Interactivity is promoted in several ways. For example, users are required to:

- Input numeric values in text boxes;
- Interpret time graphs of a car journey; and
- Perform calculations of distance the car traveled.

In addition, users must answer a variety of questions included in each step. These may be selecting the correct formula from a drop list and multiple choices with feedback and so on.

3-D Synthetic Models and Animation

One of the latest developments is the incorporation of interactivity multimedia to study 3-D motion involving the study of mechanics dynamics. As an example, in Figure 9, the movement of the rod as well as the motion of a collar on the rod can be studied simultaneously with the incorporation of multimedia technology. The benefit is two fold; the user can firstly visualize the relative motion of the collar with respect to the moving rod and secondly, that the path of the collar during a given time period, for example, $t = 0$ to $t = 5$ s

can be viewed in real-time and analyzed. This is illustrated in Figure 10 where initially when time $t = 0$ the collar is originally located on the rod at p and after a time interval of say 5 seconds, the collar has moved from its original position to a new position q as shown in Figure 11. Close observation indicates that the collar has taken a curve path and thus has a curvilinear motion.

Desktop Virtual Reality

Virtual reality (VR) is defined as a highly interactive, computer based multimedia environment in which the user becomes the participant in a computer-generated world (Jong Heon et al., 2001). Interaction plays a very important role in virtual environments. Much has been published about interaction techniques in multimedia and virtual reality; however the mission for truly intuitive and natural interaction techniques is still on going. A key feature of VR is real-time interactivity where the computer is able to detect user inputs and instantaneously modify the virtual world in accordance with user interactions. VR environment often consists of technological hardware including head-mounted displays, 3-D goggles and motion-sensing data gloves. Although VR technology could be expensive and difficult to

Figure 9. Linear motion of the rod and collar rotating along y-axis ($t = 0s$)

Figure 10. Linear motion of the rod and collar rotating along y-axis ($t = 3s$)

Figure 11. Linear motion of the rod and collar rotating along y-axis ($t = 5s$)

bring into classroom settings, the advent of new desktop virtual reality (non-immersive) software development tools does not require expensive hardware to be used when interacting with CAL tools. The minimum requirements for interacting with the CAL tools are by using a mouse, joystick, keyboard and simple 3-D glasses. In our latest CAL tool development, progress has been made to implement a 3-D model that is being tested in a desktop virtual reality (DVR) environment for greater interaction and visualization. In user interaction with virtual worlds, consistent realistic behavior of objects is very important (Bowman & Hodges, 1997). As such, it is desired that the objects can respond in a natural and predictable way to the actions.

The CAL tool attempts to help users to enhance their knowledge and understanding of curvilinear motion of engineering members. The virtual environment as illustrated by Figure 12 is a 3-D model of a robot arm (actor) that can be viewed and interacted with in a 3-D environment. Fundamentally the CAL tool assists with the direct visualization of 3-D geometric model created using Alias Maya™ (a 3-D modeler). It allows the users to explore the model by using the built-in features in the tool i.e. moving, walking, flying, examining, resizing, rotating and changing viewpoints. With these features, the user can

move along any direction on the screen and have the displayed 3-D robot arm continuously and instantaneously updated. The main interface of the DVR CAL tool is shown in Figure 13. The interface of this CAL tool has been implemented using Macromedia Director™ (an authoring tool), it is a stand-alone (PC-based) application, which is available on the CD-ROM and currently runs on Windows platform.

To further help the user with regards to visualize the robot arm, the model has been enhanced to animate and show the path of motion of particle in terms of cylindrical coordinates. In addition, a stereoscopic image gallery of the robotic arm is also available. This is the virtual reality part (non-immersive) of the CAL package. The “stereoscopic” button can be activated to get a better view of the 3-D robotic arm. The stereoscopic views are available as static images and 3-D animations. However, to view the stereoscopic images the user needs to wear an inexpensive pair of simple stereo glasses. One benefit of including the stereoscopic images is that the student can gain a better wider view of the trail (path) and motion of the 3-D robotic arm. To further help the users orient them with regards to the robot arm; polygonal views are available with their correct positions and orientations in a wire-frame (the model without textures) representing the physical extends of the robot arm. Figure 14 shows the image of a robot arm along in a wire-frame mode and the motion path trail. The trail is produced in a 3-D environment to show users how the robotic arm has moved from one point to another based on the time input by the user. As such it can be clearly seen that the robotic arm has taken a curvilinear motion.

As expected in most similar visualization CAL tools, the tool is in progress for further enhancements such as interfacing it to other hardware devices, that is, joystick, data gloves, and so on.

RESULTS AND EVALUATION OF THE PEDAGOGICAL EFFECTIVENESS

The CAL tools were evaluated to confirm that the aims and objectives of the presentation had been met:

- To provide the learning opportunity, understanding and appreciate the advantages of incorporating multimedia and DVR as an interactive tool for education.
- To enhance student's knowledge with particular weak learners in the topic "Engineering mechanics and dynamics".

The previously-mentioned objectives were subsequently used as a baseline for the development of a questionnaire that was tailored to suit the audio, video, animation, and CAL tools respectively.

We selected a group of weak learners taking the engineering mechanics subject. The topics of the subject include analysis of an engineering structure, kinematics of a particle, and curvilinear motion. After presenting the CAL tools, we tested the students' knowledge improvement and surveyed the students' attitudes about the CAL tools. In general, the outcome of the pedagogical effectiveness evaluation of the CAL tools was very encouraging. The majority of users were in the agreement that the incorporation of audio, video, and animation in the CAL tools was beneficial in enhancing their understanding of various concepts that has been taught in the lectures. The results as obtained from the student feedback are presented in Figure 15, Table 1, and Table 2.

The beneficial effect of incorporating multimedia in teaching engineering mechanics and dynamics has been revealed. In particular, it can be noted that the level of confidence and understanding of the students in the subject matter greatly improved with the supplement of multimedia and DVR technology.

CONCLUSION

In this paper, four approaches for the study of multimedia patterns of interactions and visualization in engineering problem solution for undergraduates were described. These approaches can be employed and found to be suitable to aid engineering problem solutions in general. In addition to learning applications, the authors have also explored the potential for multimedia and VR as a general CAL tool, for eventual use in practical engineering applications. The educational benefit of multimedia and VR can benefit weak learners in some situations, when it is properly implemented. However these technologies should not be considered as replacement for real experiences but as an alternative to design and implementing additional CAL tools to help weak learners understand the concepts of engineering and learn better.

The present study revealed the following:

- The developed CAL tools are uniquely dedicated to the development and application of visualization in engineering that are difficult to understand and deliver as opposed to the traditional method of learning. In addition, its particular form of extensibility alleviates

Figure 15. Outcome of student evaluation

Table 1. Student response on the presentation format and language usage in the CAL tools

Response	Percentage
<i>Easy to understand</i>	20%
<i>Can understand</i>	80%
<i>Quite difficult</i>	0%
<i>Very difficult</i>	0%
<i>Difficult</i>	0%

Table 2. Typical student perception of the effectiveness of the developed CAL tools for mechanics engineering

Questions	Yes	No
<i>Do you think that all the facts or details in the learning tool are clearly explained and understandable?</i>	100%	0%
<i>Do you think that the learning tool is interesting?</i>	100%	0%
<i>Are you able to visualize the problem in this experiment?</i>	100%	0%
<p><i>What is your opinion about this interactive learning tool for Structural Analysis?</i> <u>Some user responses:</u> i. It is very helpful in the sense that it will enable a person like me who is not knowledgeable in Structural Analysis to understand the concept being explained. ii. May enhance the student's understanding but it is more suitable for self-learning activities. iii. It is suitable and learnable.</p>		

- the often-encountered conflict between the requirements of specialized application and those of a flexible and open architecture.
- The developed prototypes have been found to be useful in reinforcing understanding of concepts such as equation of equilibrium through animation and the graphics give a good global impression in a 2-D image.
 - Preliminary evaluation of the coach environment tool indicated that it has great potential to aid teaching and thus provide an effective learning environment particularly for weak

- learners. In addition such an environment was found to be appropriate when the user want to find out how to do a more complex cognitive task and understand why a specific step must be done, or determine why a specific decision was suggested.
- In a 3-D animation and desktop virtual reality environment, such visualization and simulation tools can greatly benefit from the computational power of personal computers; furthermore problem solving using these powerful multimedia CAL tools permits

approaches beyond those traditionally selected because they minimize computational effort.

- In general, multimedia and DVR technology can facilitate a faster and more complete analysis of design alternatives by providing ways to rapidly create models or prototypes of proposed designs and to then simulate them in a more realistic way.

The pedagogical effectiveness evaluation results of the CAL tools developed and tested with weak learners showed positive feedback from students. In addition the students were motivated to use the CAL tools as they found it easier to learn as compared to textbooks alone.

The CAL tools are in progress of being enhanced to integrate with advanced predictive modeling, sound effects, and increasing functionality for engineering experiments. Thus, it is anticipated that the CAL tools will evolve to allow a broader range of patterns of interactions and visualization methods.

ACKNOWLEDGMENT

The authors would like to express their gratitude to UNITEN and University Malaya for the support provided.

Chapter 3.32

Assessing the Effectiveness of Programmed Instruction and Collaborative Peer Tutoring in Teaching Java™

Henry H. Emurian

University of Maryland, Baltimore County (UMBC), USA

ABSTRACT

Students in two Java programming classes completed an individualized tutoring system that taught a simple applet program. Before and after using the tutor, students completed questionnaires that assessed software self-efficacy and understanding of general programming principles. The questionnaires also were administered following a lecture session on the program that included having the students successfully run the applet in a browser on the Web. For the second class, a collaborative peer tutoring session based on the applet program occurred between completion of the tutor and the lecture session. Students in both classes increased in software self-efficacy and program understanding across the assessment occasions. For students in the second class, correct answers on the final test of understanding were higher than observed in the first class. Col-

laborative peer tutoring used in combination with a programmed instruction tutoring system may potentiate learning for novice students.

INTRODUCTION

Teaching computer programming is not easy (Traynor & Gibson, 2004). Reviews of the instructional literature indicate that many students struggle with their programming courses (Robins, Rountree, & Rountree, 2003), and the complexity and instability of Java pose unique challenges to both educators and students (Roberts, 2004). The research reported here, then, reflects an attempt to improve the effectiveness of Java programming instruction, as evidenced by enhanced student performance, which was accomplished by combining an individualized tutoring system with collaborative peer tutoring. This tactic of teach-

ing students with novel instructional approaches is fundamental to success-oriented classroom strategies, which are mindful of the alarming dropout rates reported for students in many science, technology, engineering, and mathematics (STEM) programs of study (Wormley, 2003).

Tutoring System

The research group previously reported a series of evaluations in the development of a Web-based tutoring system¹ and its classroom application as the first technical training exercise for students in a Java computer programming course (Emurian, 2004, 2005, in press; Emurian & Durham, 2001, 2002, 2003; Emurian, Hu, Wang, & Durham, 2000; Emurian, Wang, & Durham, 2003). The tutor teaches a simple 32-item, 10-line Java applet that displays a Label object in a browser window on the Web.² The learning theory supporting the development of the tutoring system is a behavior analysis model based upon the learn unit formulation (Greer & McDonough, 1999; Singer-Dudek & Greer, 2005) as applied to programmed instruction for technology education (Greer, 2002).

The objective of the tutor is to provide each and every student with elementary knowledge and skill in preparation for continuing study of the Java programming language. The tutoring system is effective in promoting skill and cultivating self-confidence in beginning students by giving them a successful learning experience that motivates their further study of Java using textbooks, lectures, laboratory demonstrations, independent problem solving, and the like. The tutoring system is intended to meet the needs of Information Systems majors, whose professional interests typically are outside of the scope of computer programming.

Dyadic Collaboration

Although group discussions involving three or more participants may have value in facilitating

learning to write computer programs (Davy & Jenkins, 1999), having students study together in dyads recently has been investigated as an even more powerful tactic to improve learning at the level of individuals. There are several variations to the structure of a dyadic interaction, which include reciprocal peer tutoring (Griffin & Griffin, 1998), pair programming (Williams et al., 2000), and interteaching (Boyce & Hinline, 2002). The variant of collaborative peer tutoring that was adopted in the present study is the interteaching dialog, which is a mutually probing, mutually informing conversation between two people (Boyce & Hinline, 2002). Interteaching has the objective of insuring by the participants as a team that each member of a dyad can answer a previously disclosed set of questions. This approach is similar to the peer collaboration paradigm to teach recursion that was studied by Jehng (1997). It is suggested here that an interteaching session following individualized tutoring can potentiate the prior learning and result in enhanced competency and understanding.

Background and Rationale

Our previous research (Emurian, 2005, in press) showed that students who completed the Java tutoring system learned general rules of Java programming that could be applied to answer questions on problems not explicitly presented in the tutor itself. These findings supported the value of the tutor to produce meaningful learning (Mayer, 2002) or far transfer of learning (Barnett & Ceci, 2002), indicating that informed students could apply general rules to solve novel problems. The research methodology is similar to design-based research (Brown, 1992; Design-Based Research Collective, 2003; Hoadley, 2004) in that instructional design effectiveness was assessed within the context of the classroom over several successive semesters. In assessing meaningful learning over the semesters, the number of rule-based questions was increased, and the

opportunity to evaluate tutor effectiveness with several different groups of students showed the reliability and generality of the tutor's application. These outcomes were encouraging, but the magnitude of the learning effects assessed immediately after students completed the tutor and after a final lecture on the material left room for improvement, especially when the number of rule-based questions was increased from four (Emurian, 2005) to 10 (Emurian, in press). The present study intends to potentiate the learning effects by combining programmed instruction and interteaching in the classroom.

The research reported here is based upon two successive offerings of an elective course entitled Graphical User Interface Systems Using Java.³ The first class, offered during the summer of 2004, consisted of master's degree students, and the second class, offered during the fall of 2004, consisted of advanced undergraduate students. The content and objectives of the course were equivalent for both classes. Students in the first class completed the Java tutor only, and students in the second class completed the Java tutor and an interteaching dialog. In comparison to the number of rule questions administered to students in the Emurian (in press) study, the number of rule questions was increased in the present study to 12 for students in both classes. The rationale for adopting this design-based approach to compare learning outcomes between two successive classes will be discussed.

METHOD

Materials

All questionnaires and study materials are available as documents on the Web.⁴ Appendix A presents the interteaching report. An example of one of the 12 questions on the rules test is as follows:

Which of the following sequences is correct?

- a. Declare a TextField object, construct a TextField object, add a TextField object to a container.
- b. Construct a TextField object, declare a TextField object, add a TextField object to a container.
- c. Declare a TextField object, add a TextField object to a container, construct a TextField object.
- d. Add a TextField object to a container, declare a TextField object, construct a TextField object.

Java Tutor

Tutor figures are presented in Emurian (in press). The learning stages in the tutor are as follows:

1. **Introduction.** This stage gives an orientation to the tutor and how it works. It also gives an example of the applet running in a browser window.
2. **Item Familiarity.** This stage teaches the symbols to be used. The student copies each identifier, keyword, or separator, displayed one at a time, into a text field. This stage is invaluable to ineffective novices (Robins et al., 2003) who deserve the opportunity to be prepared adequately for the learning that follows. The fact that students do make errors on this tutor stage is demonstrated in Emurian (2004).
3. **Item Identification.** This stage teaches the student to recognize differences among the 21 unique symbols. This is accomplished by having the student highlight a displayed symbol from a list of all symbols.
4. **Item Learning.** This is the primary stage for learning the semantics of all items in the code and learning to enter the item at the correct sequential location in the program. First, the item is displayed in a highlighted

fashion in a text area at the location in which it will appear in the code. Second, a textual display presents the meaning of the item at that point in the code. Third, a multiple-choice test is presented on the meaning of the specific item. If the answer is incorrect, the explanation is presented again, and the explanation-test cycle is repeated until the test is answered correctly. Fourth, the student types the item into a text field that is displayed in the proper location in the code. If the item is entered incorrectly, the explanation-test cycle is repeated until the item is entered correctly. When the item is entered correctly, the tutor progresses to the next item. As individual items are entered into the text field correctly, the developing program displays cumulatively.

5. **Line Familiarity.** This stage is functionally similar to Stage 2, but the unit of learning is a line rather than an item.
6. **Line Identification.** This stage is functionally similar to Stage 3, but the unit of learning is a line rather than an item.
7. **Line Learning.** This stage is functionally similar to Stage 4. The size of the learn unit, however, is at the level of a line rather than an item.
8. **Program Learning.** This is the last stage in the tutor. This stage requires entering the entire program into a text window. The input is repeated until the code is entered correctly. The learner is able to view the correct program, but selection of that option clears the input window so that the code has to be entered again from memory. The purpose of this stage is to solidify the organizational structure of learning into a manageable sequential stream or a singular unit in which the components have been previously networked into smaller units that can be combined within a new context under conditions showing meaningful learning.

Interteaching

For the interteaching sessions, subjects were paired unsystematically, and a listing of team partners was posted prior to the class meeting. The interteaching reports were available to be downloaded from the course Blackboard site. Subjects were informed to follow the interteaching instructions and to discuss the material together for 30 minutes. At the conclusion of the interteaching session, each team member completed the interteaching evaluation section. Appendix A presents the interteaching report relevant to the present article. The remaining three reports were similar in that they all had questions that could appear on a quiz for the students to discuss.

Subjects

There were 14 students in each of two classes titled Graphical User Interface Systems Using Java. This is an elective course for advanced undergraduate students and for master's degree students. Although the objectives, performance requirements, and prerequisites (one prior programming course) are identical, the classes were offered separately. In this study, the graduate class, identified as the Tutor (T) class, met in the summer of 2004. The undergraduate class, identified as the Tutor-plus-Interteaching (T+I) class, met in the fall of 2004. Background data were collected during the first questionnaire administration (Pre-Tutor Questionnaire). The T class had six female and eight male students, and the T+I class had one female and 13 male students (chi-square = 4.76, $df = 1$, $p < .05$). The protocols, to be presented next, were exempt from informed consent requirements, because they reflected instructional practices in the classroom.

Experience ratings were based on a 10-point scale where 1 = Novice to 10 = Expert. Comparisons between the two classes were based on the Kruskal-Wallis test. Median ratings were as follows: Java experience (T = 3, T+I = 1.5; chi-

square = 3.51, $p > .05$); general programming experience ($T = 4$, $T+I = 5.5$; chi-square = 3.34, $p > .05$); and total number of prior programming courses taken ($T = 3$, $T+I = 4$; chi-square = 2.31, $p > .10$). The median age of the students was 26 years for the T class and 25 years for the T+I class (chi-square = 1.85, $p > .10$). Although the students were undergraduates in one class and graduates in the other, the evidence did not support differences between the classes on these measures. However, the gender composition between the classes differed, with proportionally more female students in the summer graduate class in comparison to the fall undergraduate class.

Procedure

Table 1 presents the sequence of events for each of the two classes. The summer 2004 class met twice each week for six weeks. The fall 2004 class met once each week for 14 weeks. All classes met for

2.5 hours. The students were informed fully about the requirements of each class, and the sequence of events was included on the syllabus. At the first meeting, students in the fall 2004 class were informed that the rules questions would appear later as part of a graded quiz. All students completed the tutor during Session 1, the first class period. After Session 1 for the fall 2004 students, a study manual was released that duplicated the instructional text within the tutor but omitted the multiple choice tests that were embedded within the tutor. The study manual did not present the 12 rules multiple-choice questions. Students were informed that the manual could be used to prepare for the interteaching on Session 2.

The sequence of events was a compromise that allowed student behavior to be evaluated within the context of a classroom. The justification for such a design-based research approach, together with its strengths and limitations, will be discussed.

Table 1. Sequence of events

	Summer 2004 Master's Degree Students n = 14	Fall 2004 Advanced Undergraduates n = 14

Session 3		1. Final Questionnaires <ul style="list-style-type: none"> • Test Credit for Rules

RESULTS

Figure 1 presents boxplots of total correct answers on the rules test across the three occasions for both classes. For the T class, a Friedman's test was significant ($\chi^2 = 18.84$, $df = 2$, $p < .001$). Pairwise contrasts, Bonferroni corrected, were not significant only between the Post-Tutor and Final occasions ($p > .05$). For the T+I class, a Friedman's test was significant ($\chi^2 = 23.57$, $df = 2$, $p < .001$). Pairwise contrasts, Bonferroni corrected, were significant for all pairs ($p < .05$). Kruskal-Wallis tests showed no significant difference between the classes for the Pre-Tutor test ($\chi^2 = 0.24$, $df = 1$, $p > .50$) and the Post-Tutor test ($\chi^2 = 0.00$, $df = 1$, $p > .50$). The difference for the Final test was significant ($\chi^2 = 8.40$, $df = 1$, $p < .005$).

For each of the 12 questions on the rules test, the subject was asked to rate the confidence that the correct answer had been selected among the four alternatives. Figure 2 presents confidence ratings for correct and incorrect answers for the T and T+I classes across the three assessment occasions. The boxplots were calculated from the

set of median confidence ratings for correct and incorrect answers for all subjects. Where there are fewer than 14 subjects for a given boxplot, this indicates that not all subjects made at least one incorrect answer on that occasion.⁵

For the T class, a Friedman's test for confidence ratings of correct answers across the three occasions was significant ($\chi^2 = 19.24$, $df = 2$, $p < .001$). Pairwise contrasts, Bonferroni corrected, were significant for all pairs ($p < .05$) except between the Post-Tutor and Final occasions ($p > .05$). A Friedman's test for confidence ratings of incorrect answers across the three occasions was also significant ($\chi^2 = 21.23$, $df = 2$, $p < .001$). Pairwise contrasts, Bonferroni corrected, were significant for all pairs ($p < .05$) except between the Post-Tutor and Final occasions ($p > .05$). A Friedman's test between confidence ratings for correct and incorrect answers was marginally significant for the Pre-Tutor occasion ($\chi^2 = 3.60$, $p < .06$), significant for the Post-Tutor occasion ($\chi^2 = 7.00$, $p < .01$), and significant for the Final occasion ($\chi^2 = 4.50$, $p < .05$).

Figure 1. Boxplots of total correct answers on the rules test (circles are outliers and triangles are extreme values)

Figure 2. Boxplots of confidence ratings for correct and incorrect answers on the rules test (circles are outliers and triangles are extreme values)

For the T+I class, a Friedman's test for confidence ratings of correct answers across the three occasions was significant (chi-square = 20.54, $df = 2$, $p < .001$). Pairwise contrasts, Bonferroni corrected, were significant for all pairs ($p < .05$). A Friedman's test for confidence ratings of incorrect answers across the three occasions was also significant (chi-square = 13.29, $df = 2$, $p < .01$). Pairwise contrasts, Bonferroni corrected, were significant for all pairs ($p < .05$) except between the Pre-Tutor and Post-Tutor occasions ($p > .05$). A Friedman's test between confidence ratings for correct and incorrect answers was significant for the Pre-Tutor occasion (chi-square = 5.44, $p < .05$), marginally significant for the Post-Tutor occasion (chi-square = 3.57, $p < .06$), and not significant for the Final occasion (chi-square = 2.00, $p > .10$).

Figure 3 presents boxplots of ratings of the effectiveness of the interteaching session in the T+I class for the two types of ratings: (1) effectiveness of the dialog in understanding the material and (2) effectiveness of the dialog in preparing for a test. The figure presents median ratings across

the four sessions for the eight students who were present on all four occasions of interteaching. For understanding, the figure shows graphically that the highest median rating was observed on the first session, in which the value was the maximum of 10. Medians declined thereafter over the next two sessions, and the median increased somewhat during the fourth session. A Friedman's test, however, was not significant (chi-square = 5.10, $df = 3$, $p > .15$), indicating insufficient evidence to conclude that the changes in medians observed graphically were significantly different from each other. For test preparation, the figure shows graphically that the highest median rating was observed on the first session, and ratings were comparatively lower on the other three sessions. A Friedman's test was significant (chi-square = 11.11, $df = 3$, $p < .05$). Figure 3 also shows graphically that the median understanding rating was higher than the corresponding test readiness median across all four sessions. A Kruskal-Wallis comparison of the differences between the understanding and test readiness ratings for all subjects across the four sessions with a population of zeros was

Figure 3. Boxplots of interteaching effectiveness ratings (circles are outliers)

significant (chi-square = 33.75, df = 1, $p < .001$). The correlation between the two sets of ratings was not significant ($r = 0.28$, $p > .10$).

Figure 4 presents boxplots of software self-efficacy ratings across the three occasions for both classes. The ratings are based on the median confidence rating for all 21 unique items of code in the program. The figure shows graphically that students in both classes reported robust increases in confidence between the Pre-Tutor and Post-Tutor occasions, and the median rating reached the ceiling of 10 on the Final occasion. For the T class, Cronbach's alphas for Pre-Tutor, Post-Tutor, and Final occasions were 0.98, 0.99, and 0.99, respectively. The Final alpha was not significant ($p > .05$). A Friedman's test was significant (chi-square = 23.24, df = 2, $p < .001$). For the T+I class, Cronbach's alphas for Pre-Tutor, Post-Tutor, and Final occasions were 0.98, 0.98, and 0.97, respectively. All were significant ($p < .05$). A Friedman's test was significant (chi-square = 20.49, df = 2, $p < .001$). Kruskal-Wallis tests of median ratings between the two classes were not significant for Pre-Tutor, Post-Tutor, and Final occasions (all $p > .05$).

During the Final occasion, students in both classes evaluated the tutor along three dimensions, where 1 = Negative Opinion to 10 = Positive Opinion. The median ratings were as follows: (1) overall impression (T = 8, T+I = 9), (2) effectiveness of the tutor in learning Java (T = 8, T+I = 8.5), and (3) usability of the tutor (T = 8.5, T+I = 9). Kruskal-Wallis tests between the medians were not significant for any of the three scales (all $p > .05$). The generally positive evaluation of the tutor is indicated by the fact that all medians are eight or higher.

DISCUSSION

Students in two classes showed gains in program understanding and software self-efficacy as a function of participation in several consecutive instructional experiences that were designed to facilitate learning a Java computer program. A programmed instruction tutoring system was effective in promoting initial student confidence and learning, and an interteaching dialog also contributed to performance when these tactics

Figure 4. Boxplots of software self-efficacy (circles are outliers and triangles are extreme values)

were used within the context of a classroom. Collaborative peer tutoring may have potentiated a student's understanding of general principles of Java that were intended to be taught by the individualized tutoring system. Regarding confidence in understanding, however, the results showed that as student expertise improved, overconfidence was stated in performance, as evidenced by progressively higher confidence ratings for incorrect answers on the rules test. This finding warrants further analysis, especially in light of recent concerns about the validity of the purported relationship between self-efficacy and future performance (Heggstad & Kanfer, 2005).

Taken together, the outcomes of this investigation show how several instructional tactics, including a traditional lecture, may be managed in the classroom to the benefit of introductory programming students. The several tactics applied in sequence provided the occasion for rehearsal, corrective interactions, and overlearning, and these factors have long been related to knowledge and skill development and retention (Salas & Cannon-Bowers, 2001; Swezey & Llaneras, 1997).

The present study falls within the scope of design-based research. This is an attempt to

engineer a learning environment by applying principle-based interventions to the classroom and by collecting data on learning effectiveness. It is acknowledged that an actual classroom intervention introduces multiple sources of confounding variables that make causal attribution problematic (Brown, 1992; Collins, 1992; Edelson, 2002). Against a background of increasing criticism that hypothesis-driven laboratory experiments or randomized controlled trials, such as advocated by the U.S. Department of Education (2003), may not yield results having relevance to educational practice, design-based research is emerging as an alternative methodological paradigm. Design-based interdisciplinary activities are now evident by collections of papers in recent special issues of *Educational Researcher* (Kelly, 2002), *Educational Psychologist* (Sandoval & Bell, 2004), and *The Journal of the Learning Sciences* (Barab & Squire, 2004).

As a type of formative evaluation (Collins et al., 2004), the essence of design-based research is systematic replication (Sidman, 1960) in the classroom. Improvements to a previously established and meritorious instructional approach are introduced and evaluated iteratively across suc-

cessive offerings of a course. Theory informs the design, and the evaluations stimulate theoretical revisions and subsequent design alterations.

As stated by the Design-Based Research Collective (2003), "Claiming success for an educational intervention is a tricky business" (p. 5). That axiom applies to the present study. To argue that the interteaching improved student performance, it is a given that we accept the potential for confounding influences in the assessments to include the particular students within a class, the gender differences between classes, the time of course delivery, the sequence of events within a class, the sociability of the students, the amount of time spent studying, and perhaps other factors as well. The fundamental question was posed originally by Brown (1992): "What are the absolutely essential features that must be in place to cause change under conditions that one can reasonably hope to exist in normal school settings?" (p. 33). Collins et al. (2004) provide a framework for implementing design-based research to include summative evaluation that is in furtherance of answering that question.

The tactics reported in the present study evolved over several successive semesters. When the author first taught an introductory course in Java, lectures and supervised laboratories were the primary media to deliver information to the students. The reason that the author did that was because he was taught that way, and the traditional approach was the lore of the university culture at the time. The student learning was somewhat active, however, in the sense that students wrote code while the author presented and discussed it. Nevertheless, it was obvious that many bright and highly motivated students, especially international students using English as a second language, were struggling with basic issues such as learning how to type the Java symbols correctly.

In response, an individualized tutoring system was developed that first provided the opportunity for students to learn to type the symbols composing a Java program. The tutor also taught the

meaning of the items of code in the program. From a design-based perspective, the tutoring system followed principles of an applied behavior analysis systems approach (Greer, 2002), and the underlying theoretical rationale for the particular design that was implemented is presented in Emurian, Wang, and Durham (2003) and Emurian and Durham (2003). The first tutoring system, which was based on Java AWT, was reported in Emurian, Hu, Wang, and Durham (2000) and Emurian and Durham (2001). Over the years, the tutoring system content and performance were upgraded (Emurian, 2004), and the textual presentation of information was revised to facilitate meaningful learning (Emurian, 2005).

In that latter regard, the current design of the tutor's textual frames follows many of the guidelines offered by Mayer (2002) to promote meaningful learning, which relates to the goal of having students complete the tutoring experience with new knowledge and skill that can be applied to novel situations. Embedded within the tutor frames are advance organizers; signaling; adjunct questions; immediate feedback for performance accuracy and tested understanding of facts, concepts, and rules; and sequential structure building as a superordinate objective that organizes the learning process within a single conceptual framework — the production and understanding of a Java applet.

The features just mentioned were evident in the tutor presented to the summer 2004 class. Although there were alternatives to the interteaching tactic that was adopted for the fall 2004 class, such as additional lectures and assigned readings, the introduction of a structured social dimension to the classroom learning process was considered the best choice for the next design-based iteration. The theoretical and empirical evidence supporting the value of collaborative peer tutoring was compelling (Rittschof & Griffin, 2001; Slavin, 1996), and teamwork, even in a dyadic situation, provided the occasion for students to accumulate collaborative experiences that are increasingly

important in the workplace. That the interteaching also was valuable to the students was evidenced by their positive evaluations of the sessions and by the enhanced performance on the rules-based questions. The reliability and generality of the current outcomes must be determined by subsequent applications of these instructional tactics in the classroom with new groups of students.

According to the Bureau of Labor Statistics (2005), the demand for computer programmers is expected to grow at an average rate with all other occupations through 2012, and employment prospects will be best for programmers with expertise in such object-oriented languages as Java. However, many students in introductory computer programming courses show poor performance that leads to dropping out of courses and programs of study. The tactics presented here revealed a teaching technology that is intended to improve the performance of novice students when they first learn the syntax and semantics of a computer program.

Attempts to understand and overcome the persistently high dropout rates in STEM courses and programs (Thomas et al., 2000; Wormley, 2003) suggest the potential contributions of this study to that objective. The systematic replications over many semesters, which provide the foundation for the present and future work, repeatedly and consistently show the value of providing students with several instructional opportunities that may interact synergistically to promote skill and confidence that are the intended outcomes of our teaching tactics for each and every student in our classes.

APPENDIX A

Interteaching Report #1

Your name _____ Date _____

Your partner's name: _____

You should understand the components of the program below at a level given in the Java Tutor. Discuss these components with the intention to understand the specific item and any general principle that is reflected in an item or collection of items. An example of a general principle would be to begin the name of a class with a capital letter.

```
import java.applet.Applet;
import java.awt.Label;
public class MyProgram extends Applet {
Label myLabel;
public void init() {
myLabel = new Label("This is my first program.");
add(myLabel);
myLabel.setVisible(true);
}
}
```

How effective was this session in helping you to learn the material?

1 = Not at all effective. The session did not contribute to my learning of the material.

10 = Totally effective. The session contributed to my learning of the material.

(Not effective) **1 2 3 4 5 6 7 8 9 10** (Totally effective)

Enter one number that describes the effectiveness for you: _____.

How confident are you that you could answer all the questions correctly if you were tested on this program right now?

1 = Not at all confident. I could not answer any question correctly.

10 = Totally confident. I could answer all the questions correctly.

(Not confident) **1 2 3 4 5 6 7 8 9 10** (Totally confident)

Enter one number that describes your confidence: _____.

Chapter 3.33

An Interactive Tool for Teaching and Learning LAN Design

Nurul I. Sarkar

Auckland University of Technology, New Zealand

ABSTRACT

It is often difficult to motivate students to learn local area network (LAN) design, because many students appear to find the subject rather dry, technical and boring. To overcome this problem, the author has developed a software tool (named LAN-Designer) that gives students an interactive learning experience in LAN design concepts. The LAN-Designer is suitable for classroom use in introductory computer networking courses. This chapter describes LAN-Designer and its effectiveness in teaching and learning LAN design. The effectiveness of LAN-Designer has been evaluated both formally by students and informally in discussion within the teaching team. The feedback from students indicates that the development and implementation of LAN-Designer were successful. It also discusses the impact of LAN-Designer on student learning and comprehension.

INTRODUCTION

LANs are often included as a topic in computer science, information technology (IT), engineering and business courses, as LANs are a fundamental component of IT systems today. Unfortunately, motivating students to learn about LAN design is often difficult, because they find the subject rather technical, dry and boring. However, the view is frequently supported in educational literature (Anderson, Reder, & Simon, 1996; Young, 1993) that incorporating practical demonstrations into these courses, thereby illustrating theoretical concepts and providing opportunities for interactive learning experiences, significantly enhances student learning about LAN design. Yet, despite the Chinese adage attributed to Confucius (551-479 BC), 'I hear, I know. I see, I remember. I do, I understand,' only a limited amount of material designed to supplement the teaching of LAN design is publicly available, as searches of the

Computer Science Teaching Center (Grissom, Knox, Fox, & Heller, 2005) and SIGCSE Education Links (Anonymous, 2005) sites reveal.

The author strongly believes, as do many others (Belding-Royer, 2004; Casado & McKeown, 2005; Hacker & Sitte, 2004; Lopez-Martin, 2004; Midkiff, 2005; Moallem, 2004), that students learn more effectively from courses that provide for active involvement in interactive learning experiences. To that end, the author has developed LAN-Designer (using Authorware 6 under MS Windows), which facilitates an interactive teaching and learning of LAN design concepts.

LAN-Designer can be used either in the classroom or at home. Both teacher and students can benefit from the use of LAN-Designer in different teaching and learning contexts. For example, a teacher is able to use LAN-Designer in the classroom as a demonstration, to liven up the traditional lecture environment; students, on the other hand, can use server-based networking tutorials and verify the results of in-class tasks and exercises on LAN design.

LAN design concepts are described in many textbooks (Forouzan, 2003, 2004; Kurose & Ross, 2005; Palmer & Sinclair, 2003; Stamper, 2001), and commercial LAN design is described extensively in the literature (Fitzgerald & Dennis, 2002).

The main contribution and strength of this chapter is the emphasis that an interactive learning experience using a software tool is crucial in motivating students to learn LAN design concepts. Perhaps the innovative aspect of this work is the development and evaluation of such a tool so as to be effective in complementing the lecture content of LAN design. The chapter is organized as follows. First is a review of some existing network simulation and modeling tools, followed by a description of LAN-Designer and highlights of its educational benefits. Test results are presented to verify the successful implementation of LAN-Designer. The effectiveness of LAN-Designer is evaluated, and a brief conclusion ends the chapter.

Existing Simulation and Modeling Tools

Many network researchers have developed network simulation and modeling tools suitable for classroom demonstration of various aspects of computer and data communication networks. The motivation for designing such tools is to create a substitute environment for a live network (Tymann, 1991) so students can experiment with various network topologies without any risks of damaging the networks (Davis, Ransbottom, & Hamilton, 1998). Many network simulators provide animation and visualization to develop a better understanding of the real-world systems.

A number of both open-source and commercial simulation and modeling tools are available for developing a variety of LAN models (Chang, 1999; Zheng & Ni, 2003). White (2001) categorized network simulation tools into four classes: 1) network loads and topology display; 2) network topology design; 3) Web traffic analysis and display; and 4) multimedia-based pedagogy. LAN-Designer, further introduced later, is a class of tool for network physical topology simulation and display diagrams. In this chapter, for brevity, we refer only to a selected set of literature indicative of the approaches used in the first two categories mentioned above.

- **ns-2** (Fall & Varadhan, 2003): ns-2 (network simulator) is a powerful text-based simulation software package suitable for modeling and performance analysis of computer and communication networks. It is a discrete event simulator originally developed at Lawrence Berkeley Laboratory at the University of California – Berkeley as part of the Virtual InterNetwork Testbed (VINT) project. The Monarch project at Carnegie Mellon University has extended the ns-2 by adding support for IEEE 802.11 wireless LANs (Monarch, 2004).

- **OPNET Modeler** (OPNET, 2005): Opnet is a popular commercial software package commonly used by researchers and practitioners for modeling and simulation of computer networks. It is menu driven, with an easy-to-use graphical user interface for rapid model construction, data collection and other simulation tasks. It might be suitable for advanced networking classes in which students can develop new network models for experimentation.
- **cnet** (McDonald, 2005): The *cnet* network simulator allows students to experiment with various protocols at the data link, routing and transport layers in networks consisting of any combination of LANs and wireless LAN links. Although *cnet* is being used worldwide, the need to prepare a network topology file as the basis of network topology display might be a challenging task for beginners.
- **DlpSim** (King, 2004): DlpSim (data link protocol simulator) may be suitable for classroom use as an aid to enhance teaching and learning network protocols by simulation. However, DlpSim emphasizes data link layer protocols.
- **JASPER** (Turner & Robin, 2001): JASPER (JAVa Simulation of Protocols for Education and Research) is a protocol simulator that can be used as an aid to enhance teaching and learning communication protocols. It is an extensible tool in which students can readily add new protocols.
- **WebTrafMon** (Hong, Kwon, & Kim, 1999): WebTrafMon is a Web-based system for network analysis and traffic monitoring, including traffic loads, types, sources and destinations. However, the system focuses exclusively on network analysis and traffic monitoring.
- **NetMod** (Bachmann, Segal, Srinivasan, & Teorey, 1991): NetMod is a network modeling tool that uses some simple analytical models, providing designers of large interconnected LANs with an in-depth analysis of the potential performance of such systems. The tool can be used in university, industrial or governmental campus networking environments, and might serve as a useful tool for classroom demonstration.
- **WLAN-Designer** (Sarkar, 2004): WLAN-Designer is a Web-based software tool (prototype) for modeling wireless LANs. The software is easy to use and can be accessed through the Internet. It is suitable for classroom use to enhance teaching and learning various aspects of wireless LAN design. However, the current version of WLAN-Designer requires an improvement.
- **iNetwork** (Sandrasegaran & Trieu, 2005): iNetwork is an interactive software tool for teaching and learning data communication networks. It allows students to assemble and build customized networks using networking devices, such as workstations, switches, routers, domain name system (DNS) and dynamic host configuration protocol (DHCP) servers. Through experimenting with key parameters, students gain insights into the key concepts of communication network design and analysis.
- **Network Intelligence** (Nieuwelaar & Hunt, 2004): Network Intelligence (NI) provides an easy way to view complex traffic patterns in a wide-area networking environment. NI can perform simulations of network topologies using actual gathered data, as opposed to arbitrary data.

In conclusion, the proposed LAN-Designer seems to be almost alone in its goals and capabilities.

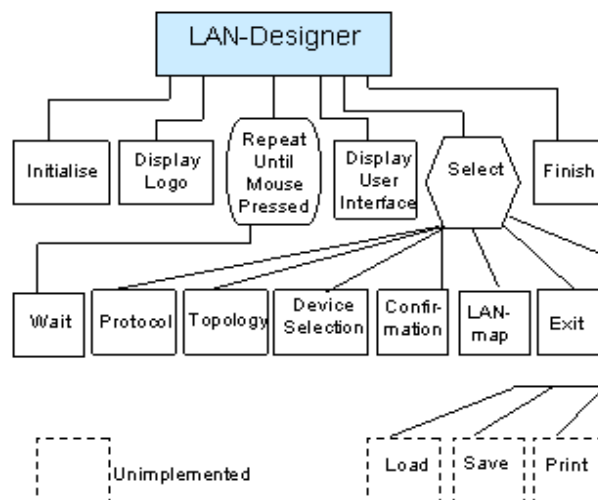

Description of LAN-Designer

Figure 1 shows a structured diagram of the system. LAN-Designer is an easy-to-use, user-friendly

tool and can be used as an aid to enhance teaching and learning LAN design concepts. The main features of LAN-Designer are described below:

- **Channel access protocol:** This is an important parameter that needs to be considered when designing LANs. The channel access protocol efficiently controls the transmission when multiple users shared a common channel (i.e., a transmission medium). LAN-Designer allows users to select either Ethernet carrier sense multiple access with collision detection (CSMA/CD) or token passing network access protocols.
 - **Physical topology:** A topology represents the physical layout (i.e., architecture) of the network. It is another of the important parameters in server-based LAN design. In the case of Ethernet CSMA/CD networks, either bus or star physical topology can be chosen. For token passing networks, either physical ring or bus topology can be chosen.
 - **Network component selection:** This feature allows users to enter LAN components, such as the number of workstations and the number of printers for the proposed LAN design.
- A file server will be selected by default.
- **Confirmation:** This feature allows users to verify LAN components that have been selected for LAN design and make changes if necessary before proceeding to the final step of LAN modeling.
 - **LAN-map:** Based on the user selection of an access protocol, physical topology and LAN components, the LAN-map displays the proposed LAN diagram on the screen. With this, students can verify the solution of LAN design exercises.
 - **Mesh topology:** The mesh physical topology is not very common for a LAN design because of large wiring connectivity and more input/output ports required per node. This feature provides a short tutorial (both textual and graphical) on mesh topology.
 - **Advanced networking:** Both corporate and campus-wide LANs are based on a high-speed switching backbone (for example, Gigabit Ethernet switch). This feature provides a tutorial on switched-based LAN design.
 - **Exit:** It allows users to exit from LAN-Designer at any time.

Figure 1. Structure diagram of the LAN-Designer

The following three features have not been implemented yet, and are considered as future work:

- **Load:** This feature will allow users to view existing LAN modeling for further analysis and modifications.
- **Save:** It will allow users to save LAN modeling on disk for later use.
- **Print:** This feature will allow users to produce a hard copy of LAN diagrams.

Additional information about channel access protocol, physical topology, cabling, hubs and switches is presented at the bottom part of relevant pages (see Figure 2).

To extend the functionality of LAN-Designer, we have recently developed a Web-based tool called WebLan-Designer for interactive teaching and learning both wired and wireless LAN design (Sarkar & Petrova, 2005). Figure 3 shows the wired LAN modeling page of WebLan-Designer. Let us briefly highlight some of the important features of WebLan-Designer. Using the 'modeling' page, students can experiment with a variety of LAN topologies and channel access protocols. Students can also test their knowledge about various aspects

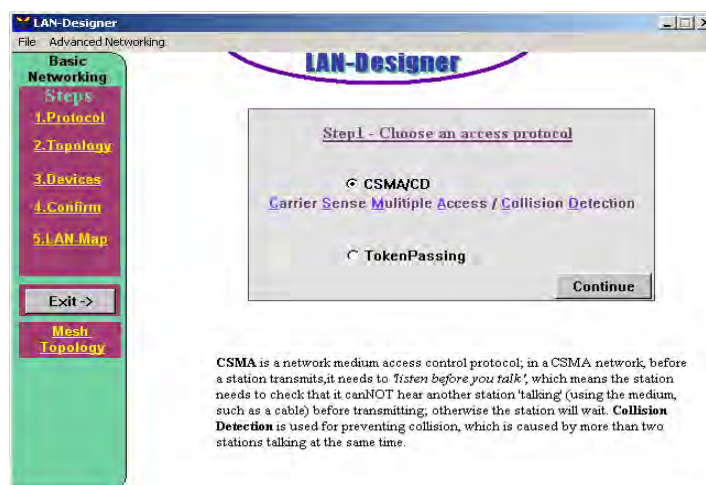

of LAN design by using two interactive quizzes. Each quiz consists of a set of 25 multiple-choice questions, and each question has four possible answers. At the end of each quiz session, the system displays the total score, which allows students to assess their prior knowledge about LAN design. The system provides a friendly environment for interactive quiz management. This is particularly useful for the teacher to update quizzes on a regular basis. Although WebLan-Designer has more functionalities than LAN-Designer, both tools can be used independently.

LAN-Designer in Practice

For simplicity and ease of use, LAN-Designer has been implemented with a graphical user interface (GUI). The point-and-click GUI interface is easy to use and self-explanatory, which makes LAN-Designer well suited to both students and teachers.

Now let us briefly highlight the value of LAN-Designer and how we use this tool in the teaching and learning context. At the Auckland University of Technology (AUT), we teach various aspects of LAN design, including wireless networking across three undergraduate programs (bachelor

Figure 2. A sample screenshot of the interface of LAN-Designer

An Interactive Tool for Teaching and Learning LAN Design

Figure 3. A sample screenshot of the LAN modeling page of WebLan-Designer

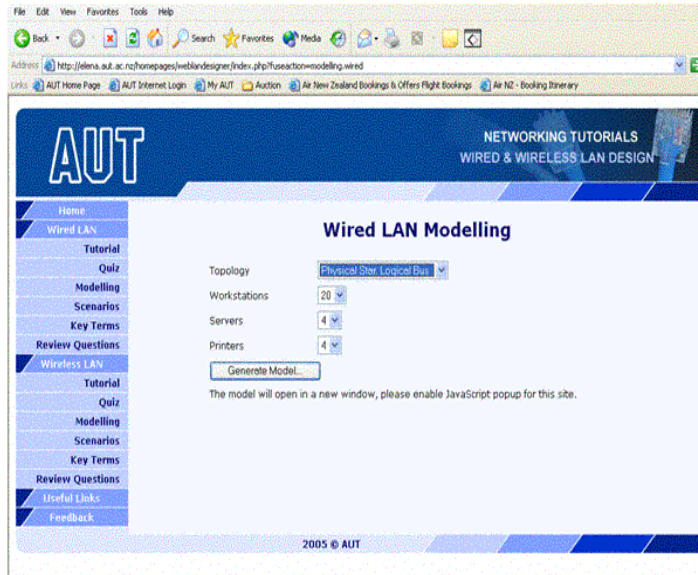

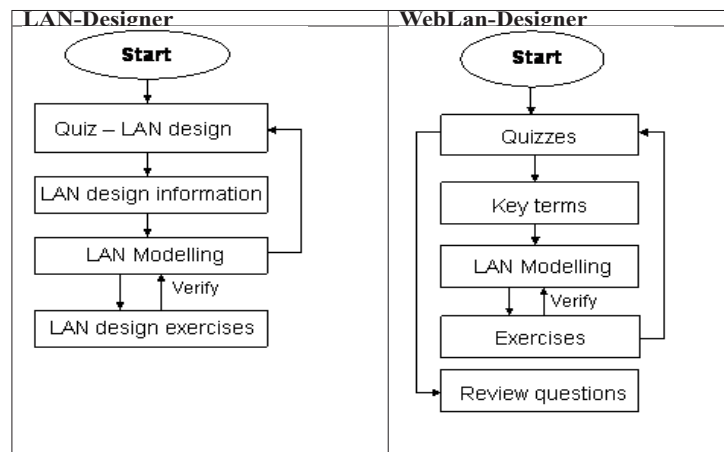

Figure 4. A suggested sequence of study using LAN-Designer and WebLan-Designer

(a)

(b)

of business, bachelor of computer and information sciences, and diploma in IT). We observe that motivating students to learn LAN design concepts using the traditional lecture-only method is very difficult, because students find the subject rather technical and dry and, thus, boring. To make the lesson more interesting and to encourage students' class participation, we use LAN-Designer as an integral part of a 2-hour session. In the classroom, an in-class task is given to the students to design server-based LANs on paper. After a prescribed period of time (for example, 15 minutes), LAN-Designer is introduced to the students on a step-by-step basis to enable them to verify (visually and interactively) their solutions and to learn more about LAN design.

The tutorial covers the following topics: CSMA, CSMA/CD, token passing, Ethernet and token ring hubs, media access control protocols, logical and physical topologies for a LAN, mesh topology, and switched-based LAN design. In addition to classroom use, the students can use LAN-Designer at home and complete exercises and tutorials at their own pace.

As mentioned earlier, WebLan-Designer offers additional learning resources, including quizzes, tutorials, review questions and scenario-based LAN design to supplement teaching server-based LAN design. Both LAN-Designer and WebLan-Designer are available at no cost for educational use (more information about these tools can be found by contacting the author). The suggested study guideline using LAN-Designer and WebLan-Designer are shown in Figures 4(a) and 4(b), respectively.

Benefits of LAN-Designer

LAN-Designer provides the following main benefits:

- **Hands-on:** LAN-Designer facilitates an interactive learning experience in LAN design.

- **Modeling:** It provides a simple and easy way to develop a variety of LAN models. With this, students can experiment with a variety of LAN topologies and channel access protocols to enhance their knowledge and understanding of LAN design concepts.
- **Ease of use:** LAN-Designer is an easy-to-use, user-friendly tool and can easily be installed on PCs operating under MS Windows.
- **Usefulness:** It enhances face-to-face teaching with online learning and can be used either in the classroom or at home.
- **Challenging:** It provides a challenging yet friendly environment where students can test their knowledge about LAN design concepts.

TEST RESULTS

To evaluate its performance and robustness, LAN-Designer has been installed and tested on various PCs in computer laboratories across campuses. Figures 5 and 6 show screenshots of LAN-Designer test results. For 10Base T network, the following components have been selected and LAN-Designer has produced the valid LAN diagram (see Figure 5): Access protocol: Ethernet CSMA/CD; Physical topology: Star; Number of PCs: 5 (excluding a server); Number of printers: 2.

For 10Base 2 network, the following components have been selected and the LAN-Designer has produced the valid LAN diagram (see Figure 6): Access protocol: Ethernet CSMA/CD; Physical topology: Bus; number of PCs: 5 (excluding a server); number of printers: 1.

The screenshots of WebLan-Designer test results for wired LAN and wireless LAN modeling are shown in Figures 7 and 8, respectively.

Figure 5. 10Base T. A server-based Ethernet LAN with five PCs and two printers (physical star topology)

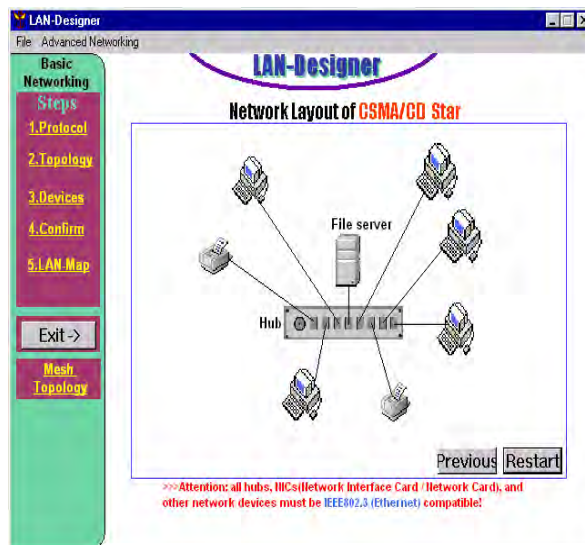

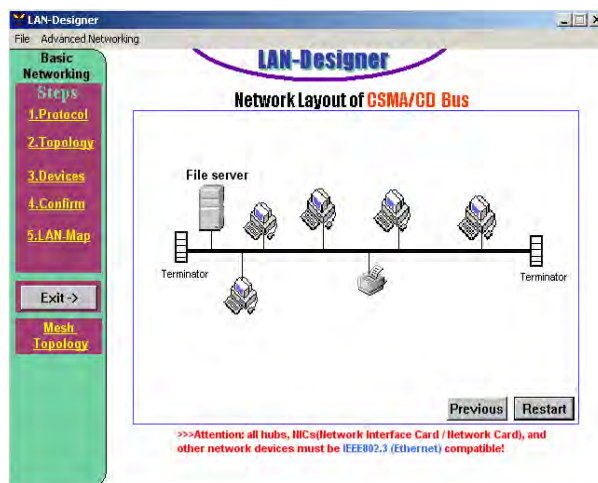

Figure 6. 10 Base 2. A server-based Ethernet LAN with five PCs and one printer (physical bus topology)

Evaluation by Student Feedback

To assess the educational value of LAN-Designer, it has been evaluated extensively both formally by students (in survey form) and informally by discussion within the teaching team. The evaluation

of LAN-Designer was conducted in the classroom by a member of the teaching team, and anonymity of the respondents was protected. As part of the formal evaluation process, students were asked to complete a questionnaire, and were asked the following six questions:

Figure 7. A model of an Ethernet LAN with 12 workstations, two servers and one printer (physical and logical star topology)

Summary

Topology: Physical & Logical Star
Workstations: 12
Servers: 2
Printers: 1

There are many ways of connecting up a network. To see a different way of connecting this network up, press the "F5" button or click *Refresh*.
Once you have finished viewing the model, click *Close*.

1. **User interface:** How useful did you find the user interface of the LAN-Designer to use?
2. **LAN design information:** How useful did you find the information about LAN design to be?
3. **Easy to use:** How easy (overall) did you find the LAN-Designer to use and follow?
4. **Robustness:** How easy did you find it to start and exit from the LAN-Designer?
5. **Measure of success:** How effective was the LAN-Designer in helping you to improve your understanding of LAN design concepts?
6. **Hands-on:** Would you like to have more tools of this kind as part of your course?

A 5-point Likert scale was used in the questionnaire. For Questions 1 to 5, a scale of 1 (Poor) to 5 (Excellent) was used. For Question 6, a scale of 1 (no) and 5 (Yes) was used. Fifty undergraduate students (about 60% male and 40% female) from both E-business IT Infrastructure (EBITI) and Networking and Telecommunications (N&T) courses completed the questionnaire, and their responses are plotted in Figure 9. The responses were interpreted as follows:

1. The GUI of the LAN-Designer is found to be easy to use. Forty-eight students indicated they were quite satisfied with the LAN-Designer interface, whereas the other two students were neutral (see Figure 9a).

Figure 8. Wireless LAN modeling with 10 mobile workstations, eight PDAs and one printer using infrastructure network

- Forty-six students have indicated that the LAN design information presented at the bottom part of each page is very useful. One student was not very satisfied about LAN design information, whereas the rest (three) were neutral (see Figure 9b).
 - LAN-Designer was found to be a user-friendly tool. Forty-seven students indicated they were happy with the current version of the LAN-Designer, and the other three were neutral (see Figure 9c).
 - LAN-Designer is easy to install and run, and can be exited from at any time. All 50 students indicated they found LAN-Designer to be robust (see Figure 9d).
 - Forty-five students indicated that LAN-Designer had clearly assisted them in developing a better understanding of the concepts of LAN design; the other five were neutral (see Figure 9e).
 - Forty-four students indicated they would like to have more hands-on activities in the course. One student was not very interested in trying more hands-on activities, and the other five were neutral (see Figure 9f).
- We observed that by participating in the hands-on interactive activities in the classroom, students became increasingly motivated to learn more about LAN design and enjoyed this course more than previous courses that consisted of lectures only. We are seeking feedback regularly both from students and staff for further improvement of the LAN-Designer.

Table 1. Comparison of student performance in the final examinations with and without LAN-Designer experience

	Semester	Year of study	Student pass rate (%)	
			EBITI course	N&T course
With LAN-Designer	1	2004	100	96
	2	2003	100	95
Without LAN-Designer	1	2003	95	92
	2	2002	93	91
	1	2002	95	92
Pass-rate improvement (with LAN-Designer)			up to 7%	up to 5%

Figure 10. Assignment grade comparison of student performance in the N&T assignment with and without LAN-Designer experience

Impact of LAN-Designer on Students’ Performance

We have run LAN-Designer in our two undergraduate courses, EBITI and N&T, in Semester 1 of 2004 and Semester 2 of 2003. Both the EBITI (Petrova, 2000) and N&T (Sarkar & Petrova, 2001) courses are at level 6, or first-year degree level, and constitute 15 credit points (150 hours of student learning) at AUT. Most of the EBITI students are studying toward their bachelor of business qualification and have a very limited

background in the IT and computer and information sciences (CIS) fields. On the other hand, the N&T students are studying toward the bachelor of IT and have a good background in the IT and CIS fields.

LAN-Designer has had quite a positive impact on students’ learning about LAN design. As seen in Table 1, the overall student pass rate in the final examinations in both Semester 1 of 2004 and Semester 2 of 2003 is slightly higher compared to students in Semester 1 of 2003 and Semesters 1 and 2 of 2002. It is considered that much of this

difference can be accounted for by the fact that students in both Semester 1 of 2004 and Semester 2 of 2003 used LAN-Designer, whereas the students in Semester 1 of 2003 and Semesters 1 and 2 of 2002 did not get an opportunity to use LAN-Designer. We also observed that EBITI students benefited even more from LAN-Designer (7% pass-rate improvement) than the N&T students (5% improvement) did. This is probably due to EBITI students' limited background in the IT and CIS fields compared to N&T students.

In Figure 10, we plot student grade in assignment of the N&T course vs. the percentage of students in Semester 2 of 2003 and Semester 2 of 2002. The grading scheme used for assessing assignment (according to the B.InfoTech program) was as follows: A+ (90-100), A (85-89), A- (80-84), B+ (75-79), B (70-74), B- (65-69), C+ (60-64), C (55-59), C- (50-54) and D (0-49). Note that A+ to C- is pass grade and D is the fail grade.

We found that students in Semester 2 of 2003 have done better in the assignment than students in Semester 2 of 2002. It is believed that much of the improvement in students' grade in the assignment is due to the LAN-Designer experience students had in Semester 2 of 2003.

CONCLUSION

A software tool (LAN-Designer) has been developed that can be used either in the classroom or at home to enhance the teaching and learning of various aspects of LAN design. LAN-Designer was evaluated by students, and their responses to the questionnaire about LAN-Designer were mostly favorable. Students indicated that they found LAN-Designer easy to use and robust, and that it helped them gain an understanding of LAN design concepts. LAN-Designer has had a positive impact on students' performance. Results show that both EBITI and N&T students scored better in the final examinations with LAN-Designer experience students without LAN-designer experience.

Currently, LAN-Designer displays LAN diagrams involving components of up to eight (including a server), which is adequate for demonstration purposes. The software can be easily upgraded to accommodate any number of LAN devices. Features such as access protocol, physical topology, component selection, confirmation, LAN-map, mesh topology, advanced networking and exit have been implemented. More features (e.g., load, save and print) are still under development.

We have developed a Web-based tool called WebLan-Designer to extend LAN-Designer by including wireless LAN components. Both LAN-Designer and WebLan-Designer can be used independently either in the classroom or at home. The incorporation of Gigabit Ethernet and TCP/IP networking is suggested for future work. More information about LAN-Designer and WebLan-Designer can be obtained by contacting the author.

Chapter 3.34

LAN Designer: A Software Tool to Enhance Learning and Teaching Server-Based LAN Design

Nurul I. Sarkar

Auckland University of Technology, New Zealand

ABSTRACT

Until recently, it has been difficult to motivate students to learn about server-based local area network (LAN) design because students find the subject very technical, dry, and boring. A software tool (named LAN-Designer) has been developed at the Auckland University of Technology that gives students an interactive, hands-on experience in server-based LAN design. LAN-Designer is suitable for classroom use in introductory-level courses in server-based networking. This article describes LAN-Designer and its effectiveness as an aid to teaching and learning about LAN design. The effectiveness of LAN-Designer has been evaluated both formally by students (student evaluation forms) and informally through discussion within the teaching team. The conclusions drawn are based on survey data collected from students. The feedback from students indicates that the development and implementation of LAN-

Designer were successful. The article concludes by discussing the strengths and weaknesses of LAN-Designer and its future development. The impact of LAN-Designer on students' performance is also discussed.

INTRODUCTION

Local area networks (LANs) are often included as a topic in computer science, information technology, engineering, and business courses, as LANs are a fundamental component of computer networks today. It is believed that incorporating practical demonstrations into these courses, thereby illustrating theoretical concepts and providing opportunity for interactive hands-on experience, significantly enhances student learning about server-based LAN design. Yet very little material designed to supplement the teaching of server-based LAN design is publicly available,

as a search of the Computer Science Teaching Center (Grissom, Knox, Fox, & Heller, 2004) and SIGCSE Education Links (Anonymous, 2004) sites reveals.

We strongly believe, as do many others (Abe et al., 2004; Bhunia, Giri, Kar, Haldar, & Purkait, 2004; Cigas, 2003; Liebeherr & El Zarki, 2004; Richards & Waisbrot, 2002), that students learn more effectively from courses that provide for active involvement in hands-on learning activities.

Server-based LAN design is one of the most difficult topics to learn and teach in a meaningful way because students find the subject full of technical jargon, dry, and boring, more than other subjects. Researchers at the Auckland University of Technology (AUT) have developed LAN-Designer (prototype) in Authorware 6.X (Authorware, 2004) under MS Windows that gives students an interactive, hands-on learning experience in server-based LAN design. A teacher is able to use LAN-Designer in the classroom, as a demonstration, to enhance the traditional lecture environment at an introductory level, and students can use its tutorials on server-based networking, and to verify (interactively and visually) the results of in-class tasks and exercises on LAN design. LAN-Designer, as reported here, can be used either in the classroom or at home.

The main objective of this article is to describe LAN-Designer and its effectiveness as an aid to teaching and learning about LAN design. The article is organized as follows. First we examine various open source tools and network simulators. We then describe LAN-Designer and highlight its educational benefits in teaching and learning contexts. Test results, which verify the successful implementation of LAN-Designer, are presented. The effectiveness of LAN-Designer is evaluated and interpreted, followed by a brief discussion and conclusion.

RELATED WORK

A detailed discussion on LAN design, in general, can be found in many references (e.g., Dennis, 2002; Forouzan, 2003, 2004; Palmer & Sinclair, 2003; Stamper, 2001), and commercial LAN design and planning is described extensively in literature (e.g., Fitzgerald & Dennis, 2002). A number of open source and commercial network simulation tools exist for building a variety of network models (Chang, 1999; Garrison, 1991; Zheng & Ni, 2003). However, these powerful tools can have steep learning curves and, while excellent for doing in-depth performance modeling and evaluation of computer networks, often simulate a networking environment in far more detail than is necessary for a simple introduction to the subject.

“Netwire emulator” is a software tool which may be suitable for teaching and learning computer networks (Carniani & Davoli, 2001). But this tool is targeted for more advanced networking concepts such as data link layer protocols. ‘EMPOWER’ is another network animation tool that can be used to illustrate the concept of both wired and wireless networking (Zheng & Ni, 2003). To use this tool, students are required to have some basic knowledge and background in networking. Garrison (1991) examined various software tools such as NETWORK II.5, LANNET II.5, and COMNET II.5, which are more suitable for networking research rather than teaching and learning contexts.

Various network simulation software packages are available for modeling and performance analysis of computer networks. For example, ns-2 network simulator (Fall & Varadhan, 2003) is one of the most commonly used simulators and is very popular among researchers, specially CS and EE students around the world. This is partly because ns-2 is open-source software (freely available), and provides an environment for rapid model devel-

LAN Designer

opment and validation. However, it is of limited use as a teaching and learning tool because of its text-based interface which is not user friendly. In conclusion, LAN-Designer seems to be almost alone in its goals and capabilities.

LAN-DESIGNER

LAN-Designer is easy to use and reliable, and can be used to enhance the learning and teaching of various aspects of LAN design. Figure 1 shows a structured diagram of the system. LAN-Designer, as reported here, has the following main features:

- **Channel Access Protocol:** This is an important parameter that needs to be considered when designing server-based LANs. The channel access protocol efficiently controls the transmission when multiple users shared a common channel (i.e., transmission media). LAN-Designer allows users to select either Ethernet CSMA/CD (carrier-sense multiple access with collision detection) or token passing network access protocols.

- **Physical Topology:** A topology represents the physical layout (i.e., architecture) of the network. It is another of the important parameters in server-based LAN design. In the case of Ethernet CSMA/CD networks, either bus or star physical topology can be chosen. For token passing networks, either physical ring or bus topology can be chosen.
- **Component Selection:** This feature allows users to enter LAN components such as the number of workstations and the number of printers for the proposed LAN design. A file server will be selected by default.
- **Confirmation:** This feature allows users to verify LAN components that have been selected for LAN design and make changes if necessary before proceeding to the final step of LAN modeling.
- **LAN-Map:** Based on the user selection of access protocol, physical topology, and LAN components, the 'LAN-Map' displays the proposed LAN diagram on the screen. With this, students can verify their solution of LAN design exercises.
- **Mesh Topology:** The mesh physical topology is not very common for a LAN design

Figure 1. Structure diagram of LAN-Designer

because of large wiring connectivity and more input/output ports required per node. This feature provides a short tutorial (both textual and graphical) on mesh topology.

- **Advanced Networking:** Both corporate and campus-wide local area networks are based on high-speed switching backbone (for example, Gigabit Ethernet switch). This feature also provides a tutorial on switch-based LAN design.
- **Exit:** This feature allows users to exit from LAN-Designer at any time.

The following three features have not been implemented yet, and are considered as future work:

- **Load:** This feature will allow users to view existing modeling for further analysis and modifications.
- **Save:** This feature will allow users to store each and every LAN modeling on disk for later use and further modification.
- **Print:** This feature will allow users to produce a hardcopy of LAN modelings.

TEACHING AND LEARNING CONTEXT

For simplicity and ease of use, LAN-Designer was implemented with a graphical user interface (GUI). The point-and-click GUI interface is easy to use and self-explanatory, which make it well suited both to students and to teachers (Shneiderman, 1998).

Now let us briefly highlight the value of LAN-Designer and how we use this tool in the teaching and learning context. At the Auckland University of Technology, we teach various aspects of server-based LAN design across three different programs, namely B.InfoTech, BBus, and Diploma in IT. It is difficult to motivate students to learn about server-based LAN design

using the traditional lecture-only method because students find the subject full of technical jargon and boring. To make the lesson more interesting and to encourage students' class participation, we use LAN-Designer as an integral part of a two-hour session. An in-class task is given to the students to design server-based LANs on paper. After a prescribed period of time (for example, 15 minutes), LAN-Designer is introduced to the students on a step-by-step basis to enable them to verify (visually and interactively) their solutions and to learn more about server-based LAN design. We also developed quizzes and tutorials based on LAN-Designer to supplement teaching of various aspects of server-based LAN design. By using LAN-Designer, students can go through the tutorials and learn more about networking terms and various aspects of server-based LAN design. The tutorial covers the following topics: CSMA, CSMA/CD, token passing, Ethernet and token ring hubs, media access control protocols, logical and physical topologies for a LAN, mesh topology, and switched-based LAN design.

In addition to classroom use, the students use LAN-Designer at home to work on their homework exercises and tutorials at their own time and convenience. LAN-Designer is freely available for download at <http://homepages.ihug.co.nz/~jasonlhl> and can be easily installed on PCs under MS Windows. Figure 2 shows the suggested study guideline using LAN-Designer.

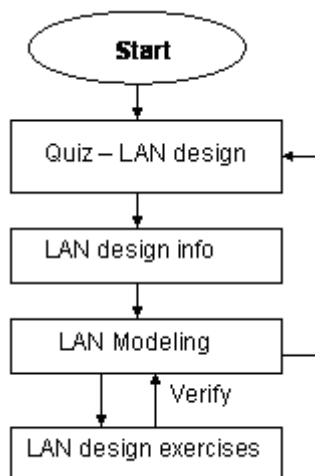

BENEFITS OF LAN-DESIGNER

The main benefits of LAN-Designer are as follows:

- **Hands-On:** Facilitates an interactive, hands-on introduction to server-based LAN design.
- **Modeling:** Provides a simple and easy way to develop a variety of LAN models. With this, students can experiment with a variety

LAN Designer

Figure 2. A suggested sequence of study using LAN-Designer

of LAN topologies, and hence enhance their knowledge and understanding of server-based LAN design.

- **Easy to Use:** The GUI makes LAN-Designer an easy-to-use and user-friendly tool. LAN-Designer can be easily installed and run on any PCs operating under MS Windows.
- **Usefulness:** Enhances face-to-face teaching with online learning and can be used either

in the classroom or at home to provide a hands-on learning experience.

- **Robustness:** Tested on various PCs across campuses and found to be robust.
- **Challenging:** Provides an environment for students to test their knowledge about server-based LANs design.

TEST RESULTS

To evaluate its performance and robustness, LAN-Designer has been installed and tested in various computer laboratories and classrooms around the campus. Figures 3 and 4 show screenshots of LAN design test results. For a 10Base T network, the following components have been selected and LAN-Designer produced the valid LAN diagram (Figure 4): {Access protocol: Ethernet CSMA/CD; Physical topology: Star; number of PCs: 5 (excluding a server); number of printer: 2}.

For a 10Base 2 network, the following components have been selected and LAN-Designer produced the valid LAN diagram (Figure 5): {Access protocol: Ethernet CSMA/CD; Physical topology: Bus; number of PCs: 5 (excluding a server); number of printer: 1}.

Figure 3. 10Base T—a server-based Ethernet LAN with 5 PCs and 2 printers (physical star topology)

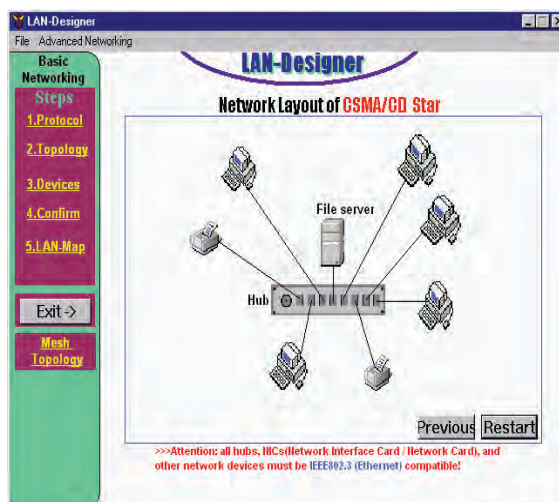

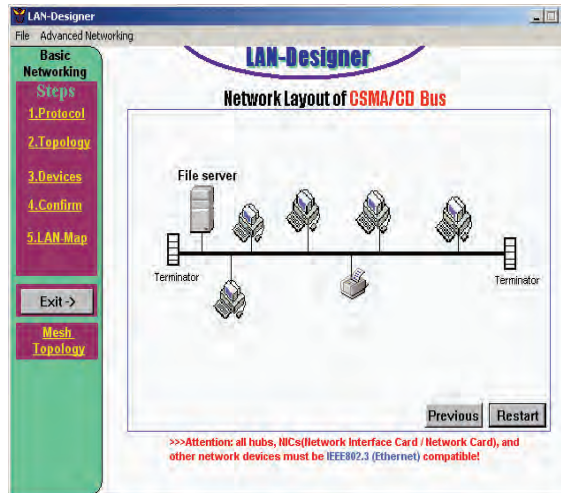

Figure 4. 10 Base 2—a server-based Ethernet LAN with 5 PCs and 1 printer (physical bus topology)

ANALYSIS AND INTERPRETATION

Evaluation

The educational value of LAN-Designer was evaluated extensively, both formally by students (student evaluation forms) and informally through discussion within the teaching team. The formal evaluation of LAN-Designer was conducted in the classroom by a member of the teaching team, and anonymity of the respondents was protected. As part of the formal evaluation process, students were asked to complete a questionnaire. They were asked the following six questions:

1. **User Interface:** How convenient did you find the ‘user interface’ of LAN-Designer to use?
2. **LAN Design Information:** How useful did you find the information about LAN design at the bottom part of each screen?
3. **Easy to Use:** How easy (overall) did you find LAN-Designer to use and follow?
4. **Robustness:** How easy did you find it to start and exit from LAN-Designer?
5. **Measure of Success:** How effective was LAN-Designer in helping you to improve

your understanding of server-based LAN design concepts?

6. **Hands-On:** Would you like to have more tools of this kind as part of your course?

A Likert scale with five points (1-5) was used in the questionnaire. For questions (1) - (5): 1=poor; 5=excellent; for question (6): 1=No, 5=Yes. Fifty undergraduate students (about 60% male and 40% female) from both “E-business IT Infrastructure” and “Networking & Telecommunications” courses completed the questionnaire, and their responses are plotted in Figure 5. The responses were interpreted as follows:

1. The graphical user interface of LAN-Designer is found to be easy to use. About 96% of the students indicated that they were quite satisfied with the LAN-Designer interface, whereas the rest (4%) were neutral (Figure 5a).
2. About 94% of the students indicated that the LAN design information presented in the bottom part of each page is very useful, and the rest (6%) were neutral (Figure 5b).
3. LAN-Designer was found to be a user-friendly tool. About 94% of the students

- were happy with the current version of LAN-Designer, and the rest (6%) were neutral (Figure 5c).
4. LAN-Designer is easier to install and run, and can be exited from the program at any time. About 100% of the students indicated that they found LAN-Designer robust (Figure 5d).
 5. About 90% of the students indicated that LAN-Designer had clearly assisted them in developing a better understanding of the concepts of LAN design, and the rest (10%) were neutral (Figure 5e).
 6. About 88% of the students indicated that they would like to have more hands-on activities in the course. About 2% of the students were not very interested in trying more hands-on activities, and the rest (10%) were neutral (Figure 5f).

We observed that by participating in the hands-on interactive activities in the classroom, students became increasingly motivated to learn more about server-based LAN design and enjoyed this course more than previous courses that consisted of lectures only. We are seeking feedback regularly, both from students and staff, for further improvement of LAN-Designer.

INFLUENCE OF LAN-DESIGNER ON STUDENTS' PERFORMANCE

A trial run of LAN-Designer was conducted in our two undergraduate courses — “E-Business IT Infrastructure (EBITI)” and “Networking & Telecommunications (N&T)” — in two semesters, namely semester 1, 2004, and semester 2, 2003. Both the EBITI (Petrova, 2000) and N&T (Sarkar & Petrova, 2001) courses are at level six or first-year degree level and constitute 15 credit points (150 hours of student learning) at AUT. Most of the EBITI students are studying towards their

Bachelor's of Business (BBus), qualification and have a very limited background in IT and CIS fields. On the other hand, the N&T students are studying toward their Bachelor's of Information Technology, and have a good background in IT and CIS fields.

LAN-Designer has had quite a positive impact on students' learning about server-based LAN design. As can be seen in Table 1, the overall student pass rate in the final examinations in both semester 1, 2004, and the semester 2, 2003, is slightly higher compared to students in semester 1, 2003, and semester 1 and 2, 2002. It is considered that much of this difference can be accounted for by the fact that the students in both semester 1, 2004, and semester 2, 2003, used LAN-Designer, whereas the students in semester 1, 2003, and semesters 1 and 2, 2002, did not get an opportunity to use LAN-Designer at all. We also observed that EBITI students benefited even more from LAN-Designer (up to 7% pass rate improvement) than the N&T students (up to 5% improvement) did. This is probably due to EBITI students' limited background in the IT and CIS fields compared to N&T students.

In Figure 6, we plot student grade in assignment (Networking and Telecommunications course) versus percentage of students in semester 2, 2003, and semester 2, 2002. The grading scheme we use for assessing assignment (according to the B.InfoTech program) is as follows: A+ (90-100), A (85-89), A- (80-84), B+ (75-79), B (70-74), B- (65-69), C+ (60-64), C (55-59), C- (50-54), and D (0-49). Note that A+ to C- is pass grade and D is the fail grade.

We found that students in semester 2, 2003, have done better in the assignment compared to students in semester 2, 2002. It is believed that much of the improvement in students' grades in the assignment is due to the LAN-Designer experience that students had in semester 2, 2003, whereas the students in semester 2, 2002, did not get an opportunity to use LAN-Designer.

Figure 5. Student responses

Table 1. Comparison of student performance

	Semester	Year of study	Student pass rate (%)	
			EBITI course	N&T course
With LAN-Designer	1	2004	100	96
	2	2003	100	95
Without LAN-Designer	1	2003	95	92
	2	2002	93	91
	1	2002	95	92
Pass rate improvement (with LAN-Designer)			u p to 7%	up to 5%

Figure 6. Grade assignment

DISCUSSION AND CONCLUSION

A software tool (LAN-Designer) has been developed that can be used either in the classroom or at home to enhance the learning and teaching of various aspects of server-based LAN design. LAN-Designer is an easy-to-use and user-friendly tool that can be run from any PCs operating under MS Windows. It was evaluated by students, and their responses to the questionnaire about LAN-Designer were mostly favorable. The students indicated that they had found LAN-Designer easy

to use and robust, and that it helped them to gain an understanding of LAN design concepts. LAN-Designer has had a positive impact on students' performance. Results show that both EBITI and N&T students scored better in both the final examinations with LAN-Designer experience than the students without LAN-designer experience.

Currently, LAN-Designer displays LAN diagrams involving components of up to eight (including a server), which is adequate for demonstration purposes. The software can be easily upgraded to accommodate any number of LAN

components (e.g., workstations). Features such as *access protocol, physical topology, component selection, confirmation, LAN-map, mesh topology, advanced networking, and exit* have been implemented. More features (e.g., *load, save, and print*) are still under development. The incorporation of Gigabit Ethernet is also suggested for future work.

LAN-Designer is freely available to faculty interested in using it to supplement teaching courses involving LAN design. More information about LAN-Designer can be obtained by contacting the author, and the software can be downloaded from the Web site at <http://homepages.ihug.co.nz/~jasonhl>.

ACKNOWLEDGMENT

I would like to thank Jason Lian for extensive programming. I am also indebted to the anonymous reviewers for their constructive comments and suggestions.

Chapter 3.35

Mobile ICT

Dermott McMeel

University of Edinburgh, Scotland

INTRODUCTION

Within building construction, the appropriation of a specific technology can vary across different job functions and participants (designer, foreman, stone mason, etc.). Embraced by some yet ignored by others, we can illicit insights into certain technologies and devices by reflecting not only on where they are successful but where they are problematic (Wiszniewski, Coyne, & Christopher, 1999) causing breakdowns and dysfunction in systems.

The rugged nature of the site condition quite often prohibits the proliferation of very delicate or expensive mobile equipment. Laser levels, point cloud generators, proprietary information and communication technology (ICT) devices, and so forth are limited to specific instances on the site where the usage is supervised and controlled, and all too often, “construction organisations have found that the ICT investment has failed to meet their expectations” (Peansupap & Walker, 2005). Robust, less expensive equipment is not subject to such extensive regulation (tape mea-

ures, bubble levels, nail guns), and their usage is often more prolific and creative. Various groups are charged with—and attempt to—fit ICTs into the current construction process; these ICTs are shown to create a much ‘smoother’ flowchart (COMIT, 2004). It is an established fact that the way in which a problem is presented generates a particular type of solution (Ortony, 1979; Schön, 1979); we would then suggest that contrary to popular representation and documentation of the construction process (Cox & Hamilton, 1995), there are perhaps more revealing models for presenting and understanding the communicative processes of the construction site than the established flowchart. Focusing on the ICT technology of mobile phones, we reflect on three different roles within a construction project: a director of a large construction organization, a site manager within that organization, and ‘micro-contractors’ of construction—that is, specialist subcontractors or small building contractors. We explore the usage and effects of the mobile phone in these different roles within a construction project.

OFFICIAL/UNOFFICIAL: THE FALSE DICOTOMY

There has always been unregulated communication within regulated work, and mobile phone usage has contributed to powerful unregulated and ‘unofficial’ (in the litigious sense) means for communication within construction. Theorists readily draw on concepts of space and containment to define communications. At the very least, language is an exercise in categorization, assuming similar meanings under a particular word or sign. Reddy (1979) suggests that these assumptions contribute to miscommunication, particularly when communicating across differing cultural categories. In formal communications there is an understanding that certain communiqués are meant for particular recipients, within certain categories of communications. This bureaucratization of communications has its place, but communication also requires the transgression of boundaries (Deleuze, 1988; Shannon & Weaver, 1963).

It has been suggested in a previous paper that parallels exist between construction and Carnival (McMeel, Coyne, & Lee, 2005). These unofficial means breakdown boundaries and thresholds (a distinctive feature of Carnival) and enables unexpected interaction, not unlike the ‘crossroads’ extensively employed when discussing native American Trickster figures (Hyde, 1998). These unexpected interactions cause discomfort and empowerment, both of which are symptoms of the Carnival condition.

CONSTRUCTION AS CARNIVAL

All the symbols of the Carnival idiom are filled with this pathos of change and renewal...of prevailing truths and authorities. We find here a characteristic logic, the peculiar logic of the ‘inside out’ (a l’envers), of the ‘turnabout,’ of a continual shifting from the top to bottom, from

front to rear, of numerous parodies and travesties. (Bakhtin, 1984)

The construction process too has “prevailing truths and authorities”; we suggest that mobile phones have contributed to further breakdown or “suspension, both ideal and real, of hierarchical rank” (Bakhtin, 1984) within construction. Other features of Carnival introduce notions of re-interpretation and redundancy (Attali, 1985). Here we provide theoretical grounding to such assertions, and draw upon our findings from interviews and observation on the construction site and discuss the pros and cons of mobile ICT in construction under the emergent themes of contiguity, abstractedness, porosity, and instantaneity.

Contiguity (Contact)

This temporary suspension, both ideal and real, of hierarchical rank created during Carnival time a special type of communication impossible in everyday life...permitting no distance between those who came in contact with each other and liberating from norms of etiquette and decency imposed at other times. (Bakhtin, 1984)

According to Bakhtin, the renewal and revitalization are the hallmarks of the Carnival, and are brought about when hierarchical barriers are momentarily dropped and populations cross-pollinate. This created an intriguing relationship between high and low society, and the interstices between. Ritual has played—and arguable continues to play—a part in construction (Jones, 2000). We have previously suggested (McMeel et al., 2005) that traditional ritualistic ceremonies (groundbreaking, topping of) served as a melting pot for laborers, architects, clients, and engineers—groups who would not otherwise meet—to mix. Pedreschi (2000) reflects on the architect/engineer Eladio Dieste and attributes his success, in part, to his skill in choosing excellent interlocutors to work for him, thus his team encouraged discussion rather than dictation.

Our findings suggest that mobile phones encourage this crossing of boundaries and reveal the predominant tendency by users to contact the ‘top of the pile’, as in the case of the director of a small specialist stair manufacturer subcontractor. If the director (SF) as the ‘top of the pile’ is contacted, it will indeed garner results, by virtue of the fact that his company is relatively small and SF oversees every set of stairs manufactured. Within a large construction company, contacting the director (EMC) who is ‘out of the loop’ of the day-to-day running of most projects would still allow him to re-direct the query to achieve resolution. Either way contiguity was expected and, when not achieved, often generated feelings of offense, as discussed with SF who deposits his mobile phone with the administration staff when he is attending a meeting or is on the workshop floor. The administrative staff regularly encounters hostility from callers who take exception to calling SF’s personal number and speaking to someone else.

Distraction (Abstractedness)

Shock from the Carnival-esque can be caused by distraction from it; when surrounded by and embraced, it can be both surreal, exciting, and invigorating; if however it is thrust upon you, it is distracting and perhaps frightening. The construction site differs here in that distraction when in a dangerous environment can be fatal. In the words of EMC: “If you can’t use a mobile phone when you’re driving, you shouldn’t be allowed to use one if your operating heavy machinery should you?”

Perhaps the process of ‘making’ things (either stairs or buildings) has its own unique environment, one of noise and dirt in this particular case. The ‘making’ process perhaps suffers from distraction, not from traditional notions of distraction (i.e., noise and dirt), but from the distraction of outside interventions: “If I’m on the workshop floor it’s not to wander round and have a break...I’m

probably attending to something a dam side more important than a phone call” (SF). Several other examples were discussed where site workers received calls (while guiding cranes, for example), and while no accidents ensued, their concentration on the task at hand was compromised. Whether it was the skill of the workshop environment or individuals in high-risk areas, distractions were problematic and repeatedly caused by incoming messages or calls.

Porosity (Screening)

This comes from the Greek ‘pore’, literally meaning ‘passage’ or ‘gateway’ (OED). When finding the gateway closed, we find callers either lose interest, as in the case of the estate agents who would call CR (site manager of a large construction company) on a daily basis. The information they require can be obtained elsewhere; CR as the site manager is simply most up to date on matters such as completion time, floor areas, and so forth—he is the ‘top of the (sub-)pile’, so to speak. Or callers focus their attention on times when the ‘gateway’ is open, in the case of site manager CR at designated break times, when he would be in his site hut close to his phone.

When receiving calls we have seen smaller ‘micro-contractors’ (7-10 employees) prioritize their calls. By looking at the name and number, they can decide whether the call requires immediate attention or could wait or was unimportant and could be ignored. Depending on the decision, the call is answered, noted for a call back, or ignored.

Within the realm of Web portals, permeability and porosity has been explored (Coyne, Lee, & Parker, 2004) in terms of commerce, discourse, and interaction. At an organizational site level, the porosity of the mobile phone allowed for incoming calls to be prioritized by knowing who was calling and what their role on a specific job was. It could then be determined by the recipient if the call required an immediate quick answer,

in which case it was answered with only a small pause to the task at hand, or if it was urgent and required a substantial break until the matter was resolved. What seemed to be problematic was “this automatic reaction to answer the phone” (director of a large construction company).

Instantaneity (Immediacy)

The quality of being instantaneous; instantaneity. (OED online)

The Carnival—like the construction of a building—is a momentary occurrence, and it is always in flux, changing and evolving; as a result, the ability to make an instant connection is perhaps highly beneficial. An immediate discussion or the ability to make an instant order is strongly valued, particularly by the micro-contractor who may have three or four projects running concurrently: “I can get a call from one of the other jobs about something that has come up and I can give them an answer straight away ... then the job can keep moving ... do you know what I mean?” SF gives this example: “Yesterday ... someone told me we were running low on nails, I forgot until I was in the car and phoned admin to order them and here (holds up an invoice) is the docket confirming the order.”

The mobile phone affordance of going directly to ‘the top of the pile’ would seem to be complemented—in terms of problem solving at least—by the ability to immediately resolve or pass the query from the top of the pile to whomever is appropriate—like the ‘game of catch’ (Attali, 1985), where the ‘ball’ is constantly moving and changing hands, only when it stops is it forgotten about.

This immediacy however also has the tendency to act as a displacement activity and a distraction, which can of course be ameliorated by the porosity of the mobile. Opinion is divided however in its effects on forward planning. EMC, the director of a large construction company, feels there is a

tendency to use the phone as a substitute for planning, leaving things to the last minute and dealing with them on the phone. As a result EMC is quite proactive in methods of training new management staff. The micro-contractor however feels they enhance his planning, he can keep update, make orders, and change his strategy during the course of the day as he gets updates from other sites.

CONCLUSION

While the contact afforded by mobile ICTs would certainly seem to enhance communication within the construction industry, it is undoubtedly in certain environs dangerous to allow devices that cause distraction. With caller id, they also present the opportunity to avoid or displace people or subjects that are particularly problematic to the receiver; unlike formal means of communication, no formal record exists of the process of attempted communication.

Apart from the health and safety issues of distraction, the next major concern with the use of mobile phones was for organization and planning. While the micro-contractor and small subcontractor felt it perhaps enhanced the particular nature of their business, the director of a large construction company felt it was in danger of being used as a substitute for forward planning; while this is discouraged, there is perhaps the anxiety that such behavior undermines the procedural aspects of day-to-day working and—more importantly—the management skill of individuals.

There is no prescription here for successful implementation of mobile ICTs, just the realization that the dispersal of the mobile phone across many groups and participants within the construction industry has affected the dynamics of communication within construction and thus affected construction itself. We suggest alternative models might give insights into understanding communication on the construction site and different technologies’ effects on it. Even usage of the

common phone is both diverse and complex, yet the features of the mobile phone are undoubtedly still underutilized. Our work continues to look into how we might use these devices as portals for site workers to access relevant information.

ACKNOWLEDGMENT

The themes in this article have been inspired and nurtured by discussions with Richard Coyne and John Lee. Thanks must also be extended to E. Mc Kenna, Sean Farrell, and Cyril Ronaghan for their insights into their business and practice, and for their time and patience.

KEY TERMS

Anthropology: Much of the theoretical underpinning for this article comes from anthropo-

logical sources, writers who have studied social and cultural phenomenon. We suggest that this pool of information has much to contribute to the discussion of mobile ICTs in construction.

Bakhtin: Writer who has extensively studied and written on Carnival in its most primitive form.

Carnival: This is taken in the Bakhtinian sense, a primal event in which everyone participates, there is no differentiation—in true Carnival—between spectator and performer, both are one in the same, as such new forms of communication would emerge.

Construction: The process of building a building, and more generally, making something.

Dirt: Anthropologically, ‘dirt’ is a potent metaphor which we invoke here as a representation of things which do not have allotted place. It represents material which is non-placed and problematic for systems to handle.

Information and Communication Technology (ICT): Term usually associated with e-mail, phones, skype, and so on; a technology used for communication. Not however exclusive to digital means, for example a pen could be an ICT.

Micro-Contractor: A term used here to identify a specific sort of building contractor. This type is a contractor/entrepreneurial company of 7-10 people. The size seems important to the adoption and seeming benefits of using ICT.

Chapter 3.36

Innovation in Wireless Technologies

Diego Ragazzi

CEFRIEL – Politecnico di Milano, Italy

INTRODUCTION

There is no doubt that wireless communication technologies have been one of the most interesting innovation fields in the telecommunications industry in recent years. The spectacular rate of innovation in this field has enforced the vision of ubiquitous connectivity: the vision of a world where every human being and every electronic device, from high-end supercomputers to tiny sensors of temperature in your car, can talk to each other through a dense web of communication links. A vision of this kind, although more “human-centric,” is proposed, for example, in the “Book of Visions” (2001) published by the Wireless World Research Forum. Of course, wireless communication technologies are instrumental in accomplishing this vision, as we cannot possibly imagine to connect everything by means of cables. Moreover, wireless communications offer the advantage of supporting mobility even at high speed.

The goal of this short paper is to propose one possible explanation why wireless technologies have shown such a dramatic innovation rate, and to overview some of the main and most recent technology achievements in this field. We will see that innovation is fostered mainly by freedom to experiment, and that countries offering such freedom, by means of wise regulation, can benefit most of these innovations. Wireless technologies, in fact, have a number of features which make them the best candidate solution for developing countries wanting to create a communications infrastructure with low costs and in a short time frame.

One of the main features of wireless technology can be summarized in one word, *freedom*. Freedom, to some extent, from physical constraints, as there’s no need of laying cables through land, roads and buildings, from cost constraints, as most of the times the cost of a wireless infrastructure is significantly lower than that of a wired one, from time constraints, as usually wireless

networks can be deployed in a very short time-frame compared to wired infrastructures, from location constraints, as wireless connections can be established potentially everywhere, even in motion, finally, and most significantly for this discussion, in some cases freedom from access constraints, as some frequency bands have been wisely set aside by national and international regulatory administrations to be used as a “spectrum commons” (Lessig, 2002). These bands, such as the 2.4 GHz “industrial, scientific and medical” (ISM) band, are allocated for license-exempt use, meaning that you don’t need to ask permission to anybody for using the spectrum. “Users in these bands are liable for interfering emissions they cause, but are not protected from interference from others. Significant incentives are therefore created for users to deploy innovative systems” (Lie, 2004, p. 16) which can minimize interference between different transmissions, as well as optimize the co-existence of many different wireless systems. Moreover, the freedom of access to spectrum has fostered innovation, as there’s no administrative or market restriction for innovators to experiment.

Lessig (2002) argues that the staggering innovation fostered by the Internet was mainly due to its character of openness, neutrality and freedom of access. In much the same way, “spectrum commons” have favored innovation at the physical layer, by giving innovators the right to design, implement and deploy innovative systems without asking permission from anybody. Most of the recent technological innovations have been designed to operate in license-exempt bands. On the other hand, if spectrum policy had an impact on the innovation rate of the wireless world, in turn technological advances and innovative services are changing the way regulatory administrations allocate and manage spectrum (Lie, 2004; Reynolds, 2004; see also the “next generation” program of the U.S. Defense Advanced Research Projects Agency).

There is another reason why “spectrum commons” favored innovation, and this is linked in some way to the “end-to-end principle” (Saltzer et al., 1981). This principle, when applied to network design, states that the network should be as simple and neutral as possible, leaving the “intelligence” at the ends, that is to the applications. The reason why this principle fosters innovation is that it allows flexibility for future uses: a very complex architecture might be optimized for one or more uses, but most probably it will not be good for all the future uses yet unseen. In much the same way, radio devices emitting in the spectrum commons have to respect very general rules, mainly aimed at reducing mutual interference and allowing the peaceful coexistence of different systems in the same frequency bands (see for example the Part 15 rules of the U.S. Federal Communication Commission, that define conditions under which radio devices can operate license-free). Moreover, because emission in the spectrum commons is free, developers are pushed to design advanced techniques in order to protect their system from unwanted interference of any kind (e.g., other radio systems, microwave ovens, etc.) and to share the available spectrum in the best way. Traditional wireless systems assume the receiving terminal is “dumb,” in the sense that it cannot easily differentiate between the information signal and background noise. In traditional systems, interference should be avoided at all costs, and this is usually achieved by imposing exclusive licenses and strict regulations about how the spectrum must be used, by whom and for what use. The intelligence is placed in the way the spectrum is managed by regulatory administrations, not at the ends in smart terminals. Recent smart radio terminals developed for use in the license-exempt bands, on the other hand, embed advanced signal processing techniques to sift through interference and pick out the information signal.

REFERENCE MODELS

The vision of the wireless world proposed by the Wireless World Research Forum (The Book of Visions, 2001) puts users and their needs at the core of the definition of network architecture. This user-centric approach can be described by a “multi-sphere model,” where the user and the external resources interact via communication links on different levels that can be depicted as concentric spheres around the user. The inner sphere represents the closest interaction with small devices in the personal area of the user. This involves Body Area Networks (BAN), connecting wearable appliances, body sensors and portable devices, such as cellular phones and audio headsets. The next level of interaction is with objects around us, such as personal computers, TV sets and other home appliances that form our Personal Area Network (PAN). The next concentric sphere outwards represents interaction with resources confined in a limited area, usually building-wide, connected together to form a Local Area Network (LAN). Over wider areas, we can interact with any resource in the world through Metropolitan Area Networks (MAN) at city level and Wide Area Networks (WAN) at regional, national and international level, represented by the outermost sphere. Because of regulatory limitations of the allowed transmission power, the advanced wireless technologies developed for use in license-exempt bands can operate only in the inner spheres, up to LAN level included.

This reference model, however, developed around a human user, is not well suited for yet another increasingly important scenario of innovation: Machine-to-Machine (M2M) networking. In this case, the vision is of a world of interconnected devices with distributed “intelligence” that can talk to each other through a mesh of communication links. Some of these devices can be extremely simple and small, such as tiny sensors or smart tags that can be spread over a wide area for monitoring or control purposes (“sensor

dust”). In this case, the best reference model is arguably a peer-to-peer architecture supported by a “mesh network,” where there’s no central or focal point such as in the multi-sphere model, but every node of the network is functionally identical to every other node.

MULTIPLICITY AND CONVERGENCE

Within the inner spheres of the multi-sphere model, a multiplicity of heterogeneous wireless technologies have been designed and deployed, to better fulfill specific user needs at different mobility levels, bit-rates, costs and services provided. Each radio technology is best suited to specific scenarios and applications, hence multiple wireless technologies are foreseen to co-exist in the short-term at different levels of interaction with the user (Redaelli, De Francesco & Ragazzi, 2003).

The transmission techniques developed for license-exempt use must comply with local regulations and must be designed to cope with harsh propagation environments and all sorts of unwanted interferers. The most important transmission techniques for this kind of applications are: *spread spectrum*, frequently used in today’s wireless products due to its robustness against noise and interference; *orthogonal frequency division multiplexing* (OFDM), implemented in more recent wireless LAN products and considered also for use in Metropolitan Area Networks; *ultra wide band* (UWB), currently under investigation.

Spread spectrum is a technique pioneered by the army trading bandwidth for robustness. It uses more bandwidth than required to reduce the impact of localized interferences. Usually, one of two main spread spectrum technique is used: *direct sequence* and *frequency hopping*.

The principle of direct sequence spread spectrum is to spread the signal energy on a larger band by multiplying it with a *code*, a fast repetitive pattern of bits. In this way, for each bit of

information the system actually transmits many bits of code organized in a pre-defined pattern known both at the transmitter and the receiver. The energy of the signal is spread over so a large bandwidth that it looks just like background noise to “traditional” radio receivers, which may not be significantly interfered with by spread spectrum transmissions. At the intended receiver, the original signal is recovered by correlating the wideband signal with the same spreading code used by the transmitter. Only the original signal gives the best match at the correlator block and therefore the impact of any other interfering signal is reduced. This technique is used, apart from the newest generation of mobile phones also known as Third Generation or 3G, by the widespread WiFi technology based on the IEEE 802.11b standard. The WiFi industry is one of the fastest growing and has a lot of interesting applications in many different market sectors such as home offices, small offices, enterprises, retail, logistic, healthcare, Internet service providers, telecom operators. Direct sequence spread spectrum is also used in the newly born Zigbee technology, backed by IEEE 802.15.4 standard (draft), which has been designed for use in the M2M scenario to interconnect a large number of tiny electronic devices to form what is sometimes termed the “Internet of things.”

Frequency hopping is another spread spectrum technique that divides the available bandwidth into a number of narrow-band channels and uses all of them in a pre-defined sequence. Periodically, the system “hops” to a new channel, following a pre-determined cyclic *hopping pattern*, which is known both at the transmitter and the receiver. The system avoids interferences by continuously jumping from channel to channel. If a channel is interfered, the system might not be able to use it and just waits for the next good channel, thus averaging away the effect of bad channels. This technique is employed by Bluetooth/IEEE 802.15.1, the main technology available today within the inner sphere of the reference model for Body/Personal Area Networks.

The idea behind OFDM is to divide the available spectrum into many sub-channels or sub-carriers. Conceptually, we can think of dividing the original data stream into n parallel data streams, then modulate each of them and transmit all together in the same band. This system, if supported by intelligent optimization algorithms which can adaptively and dynamically choose the best modulation and coding technique to be employed on each sub-carrier, is a powerful tool to cope with dynamically changing radio channels and unpredictable interference patterns. OFDM technology is used today in new generation wireless LAN products of the 802.11 family, notably 802.11g and 802.11a, and it is the basic building block for the next generation of wireless MANs, based on the recent IEEE 802.16 standards family.

The FCC loosely defines “UWB technology” as any wireless transmission scheme that occupies a bandwidth of more than 25% of the center frequency, or more than 1.5 GHz. But the main innovation here comes from the unconventional transmission technique proposed for some UWB implementations. UWB is typically implemented in a carrier-less fashion: conventional systems transmit information by modulating a continuous sinewave; conversely, some UWB implementations transmit a train of ultra short impulses and remain “silent” between consecutive pulses. This technique is also known as “impulse radio” (Sholtz & Win, 1998). Besides claimed advantages of low implementation costs, low power consumption, robustness to both interference and intentional jamming, UWB technology promises to co-exist with other conventional radio systems without causing noticeable interference, due to the extremely low power spectral density of the signal, which is perceived as background noise by conventional receivers. This opens up new possibilities of spectrum re-use, by letting UWB devices transmit on the same frequencies already allocated to other services. Moreover, the ultra short duration of impulses is instrumental in achieving very precise distance measurements (as

a matter of fact, UWB technology was pioneered mainly by the radar industry), thus allowing the design of a radio modem that can simultaneously transmit information and measure the distances of surrounding objects. This could be applied in many applications of great interest, such as monitoring and control systems for warehousing, logistic, public protection, industrial plants.

On February 14, 2002, the FCC adopted a First Report and Order that permits the marketing and operation of certain types of UWB products under Part 15 rules, that is, license-free operation. These rules represent a cautious first step and set very restrictive emission limits, as there is little operational experience with the impact of UWB on other radio services. Nevertheless, putting UWB under the license-exempt regulation will undoubtedly spur innovation in this emerging field in the near future. The most promising applications for UWB technology appear to be in two distinct scenarios: high bit rate PANs for distribution of multi-media contents in homes and offices, and low-rate, low-power networks of sensors and small devices with added localization capabilities.

It is not the goal of this paper to cover all the innovations and research trends in wireless technology, but just to review some of the main innovative techniques proposed for use in the license-exempt part of the spectrum, and to highlight how this wealth of innovation can be related to the existence of "spectrum commons" which give innovators the right to experiment and deploy new systems without asking permission from governments or monopoly holders.

However, the discussion wouldn't be complete without mentioning briefly the need of "technology convergence," at the terminal and network layer, in order to handle the growing number of available radio technologies that otherwise would be unmanageable by users, telecom operators, software developers and service providers. From the user's perspective, convergence of different

wireless communication technologies at the end terminal is a critical point, since it would be obviously impractical to use one terminal per radio interface. The user wants to be always connected in the best possible way using the same terminal. Therefore flexibility and self-reconfigurability are key concepts of current research activities. The system has to dynamically adapt to the changing communication link quality, service requirements and traffic loads supporting different communication protocols. In the long run, software-defined radio concepts (Reed, 2002) may play a key role, for it is conceptually easier to implement advanced self-reconfigurable and adaptive communication interfaces in software rather than in hardwired chipsets.

At the network layer, current trends are towards an integrated, multi-service, packet-switched network based on IP technology. The worldwide deployment of such an integrated network is by no means an easy task. Telecom operators and enterprises have a huge deployed base of legacy communication systems. The entire infrastructure has to move from circuit-switched technology, used for plain old telephone networks, to packet switching, while preserving interoperability between systems in the transition period. Besides traditional and innovative data services, the new IP-based network needs to provide the same services people are used to receiving from circuit-switched systems, including voice and video. Despite the tough challenges, there are a number of good reasons for going in this direction: today's dramatic surge of data traffic as compared to voice traffic, cost reduction due to the deployment and maintenance of a single-technology infrastructure, more efficient use of communication resources, increased interoperability between products and applications, support of new integrated services. To match all these requirements, the IP technology needs to evolve, in order to provide better quality of service, support mobility, improve security and reliability.

CONCLUSION

Wireless communication technologies have been one of the most interesting innovation fields in the telecommunications industry in recent years. Innovation is fostered mainly by freedom to experiment, which could be insured by national and international regulations setting how the radio spectrum is used, i.e., by the specific “spectrum policy.” The freedom of access to the radio spectrum (and therefore freedom to experiment and deploy innovative wireless systems without asking permission from anybody) brought about a multiplicity of wireless technologies, each one suited to different needs and requirements. This multiplicity, which is foreseen to stay in the near future, would be totally unmanageable should it not be accompanied by a convergence at the network and application layers, which is also going on based on the IP framework.

In conclusion, wireless technologies, due to their peculiar characteristics, are the best candidate solution for developing countries wanting to deploy communications infrastructures at low costs and in a short time-frame. But only those countries which will introduce wise regulation of spectrum management will benefit most of the wireless revolution.

KEY TERMS

Bandwidth: The difference between the limiting frequencies (highest frequency minus lowest frequency) of a continuous frequency band.

Bit Rate: In a bit stream, the number of bits occurring per unit time, usually expressed in bits per second. Usually, it measures the rate of transmission of information

(Electromagnetic) Spectrum: The range of frequencies of electromagnetic radiation from zero to infinity. The electromagnetic spectrum has been, by custom and practice, divided into “frequency bands.”

Interference: In general, extraneous energy, from natural or man-made sources, that impedes the reception of desired signals.

Noise:

1. An undesired disturbance within the frequency band of interest; the summation of unwanted or disturbing energy introduced into a communications system from man-made and natural sources.
2. A disturbance that affects a signal and that may distort the information carried by the signal.

Power Spectral Density: The total power of the signal in the specified bandwidth divided by the specified bandwidth. Note: power spectral density is usually expressed in watts per hertz.

(Radio) Channel: An assigned band of frequencies sufficient for radio communication. A channel is usually assigned for a specified radio service to be provided by a specified transmitter.

Signal:

1. Detectable transmitted energy that can be used to carry information.
2. A time-dependent variation of a characteristic of a physical phenomenon, used to convey information.

Since the works of the French mathematician Jean Baptiste Fourier (1768 - 1830), we know that each signal can be represented equally well as a time-varying function or as a sum of sinusoids of different frequencies. Therefore, to each signal can be associated a “frequency band,” that is the portion of the spectrum comprising all the frequencies of the sinusoidal components of the signal.

Chapter 3.37

New Challenges for Smart Organizations: Demands for Mobility—Wireless Communication Technologies

István Mezgár

Budapest University of Technology, Hungary

ABSTRACT

The chapter introduces the different types of wireless technologies that can be applied in smart organizations. Smart organization (SO) is an outstanding representative of networked organizations, as its organization structure, communication, and knowledge-based applications are coordinated and all networked. The chapter describes the communication demands of SO, taking care on wired and especially wireless networks that offer mobility for users. Access at anytime from anywhere to enterprise information for registered users guarantees mobility that is a basic demand for a dynamic organization today. Security, trust, and interoperability aspects are also discussed as important characteristics of the up-to-date infocom systems. Finally, the main

impacts of wireless technologies on smart organizations are summarized. Through the survey of the structure and operation of wireless technologies and their impacts, it is easy to understand that wireless communication technology has a strategic role in the effective, competitive operation of networked organizations.

INTRODUCTION

Today, the developments of information technology, telecommunication, and consumer electronics are extremely fast. The ability of different network platforms to carry similar kinds of services and the coming together of consumer devices such as the telephone and personal computer is called “technology convergence.” The ICT (information

and communication technology), the “infocom” technology, covers the fields of telecommunication, informatics, broadcasting, and e-media. A very fast-developing field of telecommunication, wireless communication gets a growing role in many fields as well. The connection of mobile devices to the Internet established basically new possibilities and services for the users.

Based on the results of the information and communications technologies, a new digital economy is arising, as the result of this technological convergence is not just about technology. It is also about services and about new ways of doing business and of interacting within the society. The impact of the new services resulting from convergence can be felt in the economy and in the society as a whole, as well as in the relevant sectors themselves. Because of this great impact of information, technologies, and the level of knowledge content in products and services, the society of the 21st century is called the Information and Knowledge Society (Ungson, 1999).

This new economy needs a new set of rules and values, which determine the behavior of its actors. Participants in the digital market realize that traditional attitudes and perspectives in doing business need to be redefined. In this dynamic and turbulent environment that requires flexible and fast responses to changing business needs, organizations have to respond by adopting decentralized, team-based, and distributed structures variously described in the literature as virtual-, networked-, cluster-, and *smart* organizations. One main aspect of these approaches is that organizations in this environment are networked; that is, interlinked on various levels through the use of different networking technologies.

Since the base of networked organizations are the interdependent, separate production and service teams and units, cooperation and collaboration among them is of vital importance. The structure, the communication systems and the collaborating people, teams, and organizations that define today’s organizations characteristics

must be harmonized to accomplish complex, demanding tasks. The collaboration means contacts among users, so human beings have outstanding importance. A very important element of this human contact is trust, so in a networked organization, trust is the atmosphere, the medium in which actors are moving.

The collaboration is done through different media according to the actual demands of the tasks. A new way of connection is the application of different wireless technologies for communication in networked organizations where interoperability is an additional important factor. Wireless technology means mobility, namely individuals are available independently from location and time. This mobility is an important attribute of today’s organizations.

The chapter introduces the basic wired and wireless communication possibilities for smart organizations and some connected techniques, and technologies as well. As trust is the base for all cooperation and collaboration, its role in smart organization is also presented. Security is an important component in trust building, so security services and their application in the different networks are introduced as well.

SMART ORGANIZATIONS AND ICT

The Smart Organization

The digital economy offers a market environment for participants with the following characteristics and demands:

- Networking and horizontal communication, including the smart product,
- Networked environment,
- Knowledge-based technologies,
- Simplification and coordination of structure,
- Customer focus and real-time, ubiquitous responsiveness to technical and market

New Challenges for Smart Organizations

- trends (what customers want, anytime, anywhere),
- Flexibility, adaptability, agility, mobility,
 - Organizational extendibility, virtuality,
 - Shared values, trust, confidence, transparency, and integrity,
 - Ability to operate globally, cooperating with local cultures.

In this turbulent environment only those organizations can survive which effectively apply the results of the different disciplines. Smart organization (SO) belongs to this kind of category. A definition of SO is as follows: “The term “smart organization” is used for organizations that are knowledge-driven, internetworked, dynamically adaptive to new organizational forms and practices, learning as well as agile in their ability to create and exploit the opportunities offered by the new economy”(Filos & Banahan, 2000).

There are three characteristics of smart organizations that make them really special:

- They are motivated to build collaborative partnerships, which encourage and promote the discussion of ideas. Customer focus and meeting customer expectations is recognized as a key success factor.
- Smart organizations can respond positively and adequately to change and uncertainty, so they survive and prosper in the new economy.
- Smart organizations can identify and exploit new opportunities through applying the strength of “smart” resources; that is, information, knowledge, relationships, and innovative and collaborative intelligence.

Cooperation and communication are the basic technologies for SO operation. In the following sections the important technologies, services and methods connected to communication technologies will be discussed trust, security and their applications.

Besides the Internet, new (or pilot phase) solutions are offered: powerline communication (using the electric power grid), and as an efficient extension of the Internet the Grid technology and different types of wireless networks.

Demand of Mobility

Mobility means availability everywhere, the possibility to be connected in the office, in the meeting room, in the car, in a train, in the airport, and even at home. Today, most companies are aware of the importance of employees continuously being connected. Being connected and being able to contact anybody associated with the organization (e.g., customers, colleagues) is very important both for the individual and for the overall efficiency of the organization. The “classic” networked companies aspire to mobilize their workforces through application of wireless communication technologies as mobility brings obvious advantages to the enterprises, including increased productivity, improved communications, cost reductions, and revenue creation.

This mobile connection can be either a voice or a data connection to an enterprise network or to the Internet. Depending on the employee’s position inside the organization, the requirements for this connectivity in terms of bandwidth, end user devices, services, and so forth are very different.

Mobility can be addressed with different solutions and technologies; each solution or technology has its own advantages and inconveniences. Mobility can be achieved by using different types of wireless networks such as satellite communication, Wireless Wide Area Networks (WWAN—different types of mobile phone systems—GSM, GPRS, UMTS, iMode), Wireless Metropolitan Area Network (WMAN), Wireless Local Area Networks (WLAN, such as Wi-Fi—also called mobile Internet [IEEE standard 802.11a/b/g]) and Wireless Personal Area (or Pico) Network (WPAN—e.g., Bluetooth, RFID, IrDA2).

The main structural factor for a mobility solution is the radio and access technology deployed. In the last ten years, some technologies have been developed from a technical as well as a business point of view. Two very strong drivers for mobility are now in place at the infrastructure level, one for indoor (WLAN), and another one for outdoor (cellular solutions such as FLASH-OFDM).

For voice transmission, most of these users will want to use the same phone with a single directory, a single voice mailbox, and a common set of services. A single phone using, for example, Voice over IP (VoIP) through a broadband connection when at home or in the office, but switching automatically to a mobile network when on the move.

Beyond the enterprise, consumers are also discovering the advantage of mobility. Phones became mobiles some years ago, and the same trend is currently happening to the computer world, where consumers are shifting from fixed desktops to more convenient laptops. Most users want to be able to communicate on any device, anytime, anywhere, without any configuration limitation. These users want session continuity between various access networks, giving them continuous and seamless connection to the best available network. (e.g., existing Satellite-GSM phones). There are various solutions (some under research still) that enable seamless mobility between different access networks for voice and data connections. These solutions will make the end-user's experience more enjoyable and will open new opportunities for operators and enterprises. With Mobile IP, the enterprise and public operator can provide seamless "always-on" network access to mobile professionals.

Mobility between the different networks (WLAN, WiMAX, UMTS, etc.) can be coordinated at the Internet Protocol (IP) level, where

- no user intervention is required when the access network changes,
- connectivity is not interrupted during the move,

- any application that tolerates packet loss will remain available, allowing ongoing session recovery.

So, main advantages of wireless and mobile communication are that anybody, from anywhere at anytime, can make contacts, which means increased flexibility and time reduction in business processes. Today, some type of mobility is a must for enterprises that want to hold on in the global market competition. According to market researcher Gartner (2003), 45% of the American workforce is using mobile technology of some kind, including laptops, PDAs, and new sensor networks. By 2007 more than 50% of enterprises with more than 1,000 employees will make use of at least five different wireless networking technologies.

Demands of Communication in SO

Communication in SO is very intensive and a great amount of confidential data and information is changed among the partners. The list of general requirements can contain, in some cases, contradictory items as well. The main requirements in case of novel networks are as follows:

- great communication speed,
- shared access to files, data/knowledge bases,
- exchange of picture, voice—multimedia applications,
- online/real-time access,
- access for anybody, from anywhere, at any time—mobility,
- reliable, secure exchange of information,
- intelligent user interfaces,
- easy and cheap installation.

The additional demands for present wireless communication technologies from the side of production systems are:

New Challenges for Smart Organizations

- security level should be equivalent with wired systems,
- increase data transfer speed,
- decrease operation costs,
- develop wireless communication chain (satellite -> WPAN)

The general communication requirements for an SO can be summarized in the following:

- **Integration of different communication forms and resources:** Communication through connected telephone-, computer-, and cable networks, and application possibilities of different protocols, connecting wired and wireless equipment.
- **Reliable and high quality communication services:** Reliability covers the high on-service time (technical reliability), the high availability (well designed/balanced network—resource reliability), the HW and SW security, both for equipment and communication lines (access reliability), well controlled/organized networks (organization reliability), all with reasonable cost.
- **Global time coordination:** It is essential the exact coordination of the different actions in time, so a “general time” has to be declared for communication.
- **Traceable communication:** Traceability means to document and audit the communication in a way that fulfills the requirements of bookkeeping (e.g., delivery report and receipt notification) and legal aspects (e.g., digital signature).

The security requirements for an SO can be listed as follows:

1. Protection of all types of enterprise data (for all company forming the SO). Privacy and integrity of all types of documents during all phases of storage and communication (Data and communication security—Certification, Encryption),

2. To enable companies confidential access control,
3. Authorization and authentication of services (digital signature).

These services need to be flexible and customized to meet a wide array of security needs, including specific high-level requirements. In order to fulfill the communication and security demands, some basic aspects have to be taken into consideration while selecting security and communication technologies:

1. Platform independent SW tools have to be applied,
2. Standards have to be applied (accepted and “de facto” standards as well),
3. Appropriate architectures with ability to integrate different resources.

Fulfilling all types of the introduced requirements for individual enterprises would be very hard if not impossible, so different general network and organizational structures have been developed that have been carefully designed and tested. These structures can be defined as reference architectures, and they are available both for the organization and for the information infrastructure of networked organizations.

Selection of Communication Network Technologies for SO

In the case of networked organizations, the most important market demands are the time-to-market (throughput time) and flexibility, so decreasing time and increasing flexibility are the main goals for enterprises. In order to shorten the throughput and operation time there are numerous opportunities, in the following some of them are listed:

- speed up communication among departments/individuals/machines,

- optimize (business) processes - > optimize information/material flow-routes,
- make more effective the working process—workflow modifications,
- increase availability—extend effective working time (24/7/365 method),
- increase efficiency of information/knowledge exchange (team-work, cooperation, coordination).

Information and communication technologies play a key role in most of the points of the above items. In the cooperation and coordination technologies communication and its speed, and the availability rate of partners, have basic importance.

In communication the conventional tools are the telephone, fax, and writing letters. On the next level are the computer network-based solutions, such as e-mail, ftp, and telnet. A higher quality of communication media is the WEB-based communication solutions. Through WEB pages a secure, easy and fast communication can be realized.

In case of WWAN, SMS, MMS (multimedia messages), and Mobile Internet (WAP) are the forms of communication. Mobile network solutions are spreading quickly also in enterprise communication. Developers and service providers offer compact mobile phone-based packages for enterprises that makes possible receiving e-mails and browsing company databases from anywhere.

Today, there is no communication technology (data or voice) that would entirely fulfill alone the communication demands of smart organization. The main characteristics listed in the previous subchapter cannot be represented by one network type yet, so there are different approaches that cover partially the demands of the market; networked organizations are using both wired and wireless technologies in an integrated way.

Wired communication remains the base for communication, but in many fields mobile and wireless tools take over the first place. Internet

technology (IP) is the base of broadband wireless communication. A smooth integration of wired and wireless, mobile communication technologies can be seen on the market as well. There are some novel wired technologies as Powerline communication (PLC—ease of installation, operation) and the GRID technology (easy information access and handling) that have special characteristics and they are applied parallel with wireless technologies. In the field of voice transfer, VoIP seems to be a ruling technology.

The different wireless networks—Satellite, WWAN, WMAN, WLAN and WPAN—(today) can be partially connected and integrated according to the actual needs, developing very complex and powerful networks for the networked organizations. The new networking technologies extend company data, back-end information systems, and e-mail to mobile employees, broadens the accessibility of mission critical data. Mobile access modifies the way workers interact with colleagues, customers, and suppliers.

Based on the main characteristics of WN the main advantages that wireless communication can offer for DPS are the following:

- mobility—from anywhere,
- availability—at any time,
- flexibility—for anybody,
- easy and fast installation,
- low installation/operation costs,
- competitive (with the wired systems) data exchange speed.
- specialized protocols (e.g., in the case of WPAN)—for sensors and communication.

Comparing the demands of enterprises, firms, and novel production systems with the characteristics of wireless communication systems (that can be/has been already integrated with computer and information systems) it can be stated that wireless networks have an outstanding strategic role in life cycle of enterprises.

Selection Aspects of Wireless Networks

There are different orientations of networked systems approaching production in general: service industry, manufacturing industry, energy industry, and so forth. The applications of the various types of wireless technologies are in these cases extremely diverse. The latest generation of communication technology, the wireless and mobile networking technologies, have an especially great influence on time factor and flexibility that is very critical in today's production, so wireless technology has a strategic role. The aspects that are influencing the application of wireless technologies can be grouped as follows (Lucent, 2003):

- **Need of Users:** The primary driving need for enterprise users to adopt a mobile data service is access. Key horizontal applications that apply to virtually all users are e-mail (with attachments), corporate intranet access, and general Internet access. The always-on, the real-time access is important for field sales and service workers. To be most productive, they require an always-on, high-performance mobile data solution that can be relied upon wherever they need it. Coverage is critical, and adequate speed for their key applications is very important. In order to define a solution that can provide coverage to users wherever they go, it is necessary to understand where mobile workers travel throughout the course of their work day, and what they need to do in different locations.
- **High-Level Security:** applications, speed, and coverage are not enough. Solutions must address corporate security standards for the enterprise. The corporate IT department must be assured that the user's information will be secure and that company PCs, servers, and data networks cannot be compromised through the mobile data network by unauthorized intruders. Ease of use and

cost control are also corporate concerns that are tightly linked and, to a certain extent, addressed by using standardized technologies.

- **Cost Factor:** Installation and operation costs are important for all types of users. In the case of manufacturing companies, the installation costs of a WLAN or WPAN can be far more lower than a wired system. An additional advantage can be that the reconfiguration of their shop floors, cells cost also less than in the case of using wired networks. These aspects are valid of course for all companies.

In order to increase user productivity, combining 3G mobile networks and wireless LANs is a possible way of the future. Wireless LAN is an excellent technology to satisfy the demands of mobile employees within their enterprise locations, or in homes where they have multiple computers. Because of the very high-speed expectations and intrapremises dominated communication, the wireless LAN provides cost-effective mobility functioning as an extension to the wired LAN, optimizing private networking costs and minimizing facilities bottlenecks to speed. Outside the enterprise, 3G wireless technology provides a means for users to do what could not be done before—remain connected to their business critical applications wherever they need to go. The wide area coverage of mobile networks will make it possible for users to do business in entirely new ways, and significantly improve ease of use by using the same connection procedures wherever they may be outside of the office.

COMMUNICATION NETWORKS FOR SMART ORGANIZATIONS

Wired Communication Networks

The Internet and WWW technologies, or some of their protocols and philosophies, are applied also

by the wireless communication technologies, so a short summary will be given on these technologies. Two novel, wired technologies will be also introduced, as they offer technical and service possibilities that are in certain aspects competitive with wireless technologies. PLC offers very low-cost, flexible, reliable, secure communication inside buildings or limited areas. The latest results of GRID technology make possible the very easy, integrated, and user-friendly access to databases, programs, and other computing resources. This section will be closed by the short description of VoIP, as this technology has an increasing importance in voice communication of enterprises.

Internet

Communication systems, wired as well as wireless, employ a layered approach to data transmission protocols. In the following, only the base will be introduced very briefly, in order to give a background for communication technologies presented later on.

Open systems architectures (OSA) have become an important approach to develop flexible, adaptable sets of methodologies, standards, and protocols for structured communication systems. OSA is a layered hierarchical structure, configuration, or model of a communications or distributed data processing system that enables system description, design, development, installation, operation, improvement, and maintenance to be performed at a given layer or layers in the hierarchical structure. It allows each layer to provide a set of accessible functions that can be controlled and used by the functions in the layer above it, enables each layer to be implemented without affecting the implementation of other layers, and allows the alteration of system performance by the modification of one or more layers without altering the existing equipment, procedures, and protocols at the remaining layers .

An OSA may be implemented using the open systems interconnection-reference model (OSI-

RM) as a guide while designing the system to meet performance requirements. The model employs a hierarchical structure of seven layers, Each layer performs value-added service at the request of the neighboring higher layer and, in turn, requests more basic services from the next lower layer. The names of the seven layers and the protocols are shown in Table 1. In the table the security protocols are also shown; they will be discussed in the security section later on. A good and detailed work on computer networks is the book of Tanenbaum (1996).

Transmission Control Protocol/Internet Protocol - TCP/IP

The TCP/IP is two interrelated protocols that are part of the Internet protocol suite. TCP operates on the OSI Transport Layer and breaks data into packets, controlling host-to-host transmissions over packet-switched communication networks (Table 1). Internet protocol (IP) was designed for use in interconnected systems of packet-switched computer communication networks. IP operates on the OSI Network Layer and routes packets. The Internet protocol provides for transmitting blocks of data called datagrams from sources to destinations, where sources and destinations are hosts identified by fixed-length addresses.

The short descriptions of layers are as follows:

- Physical layer transmits information carrying signals over a communications channel. The communications channel (or medium) may be wireless, such as analogue or digital radio, or wired, such as optical fiber or coaxial cable.
- Link layer runs over, and utilizes, the physical layer to carry data from a transmitter to a receiver. The link layer uses frames (e.g., a collection of bytes) as its data communication unit, and is responsible for their transmission between two or more

Table 1. TCP/IP- and security protocols in the network

Layer Number	Layers of the OSI reference model	TCP/IP Protocols	SECURITY PROTOCOLS
7.	Application	FTP, SMTP, TELNET, SNMP, NFS, Xwindows, NNTP, IRC, HTTP, WAP	S-HTTP, SET S/MIME, PEM, PGP, MOSS SMTP
6.	Presentation	ASCII, EBCDIC, ASN1, XDR	SSL, SSH, SSH2
5.	Session	RPC	
4.	Transport	TCP, UDP	TLS (Transport Layer Security Protocol), WAP/WTLS
3.	Network	IP	IPv6, VPN
2.	Data link	X.25, SLIP, PPP, Frame Relay	Electromagnetic Emission standard (89/336/EEC - European Economical Community guideline)
1.	Physical	LAN, ARPANET	

communication nodes sharing a medium. An example of a link layer standard is the (IEEE) 802.11 Wireless Local Area Network (WLAN).

- Network layer enables communication between nodes that do not necessarily share a communications medium. For packet-switched networks, the link layer carries network layer datagram units (or packets) between neighboring nodes in link layer frames. This process may require fragmentation of large packets into smaller datagrams with additional network and link layer-specific headers.
- Transport layer runs over the network layer. It may or may not ensure reliable, in-order delivery of the data generated by the application layer.
- Application layer contains functions for particular application services, such as file transfer, remote file access and virtual terminals.

The World Wide Web

The World Wide Web (“WWW,” or simply “Web”) is an information space in which the items of interest, referred to as resources, are identified by global identifiers called Uniform Resource Identifiers (URI). The term is often mistakenly used as a synonym for the Internet, but the Web is actually a service that operates *over* the Internet.

The Web is made up of three standards: The *Uniform Resource Locator* (URL), which specifies how each page of information is given a unique “address” at which it can be found; the *Hyper Text Transfer Protocol* (HTTP), which specifies how the browser and server send the information to each other; and the *Hyper Text Markup Language* (HTML), a method of encoding the information so it can be displayed on a variety of devices.

Hypertext does not have a linear order from beginning to end. It is not broken down into the hierarchy of chapters, sections, subsections, and so forth. From the Web many kinds of information are available; private persons, organizations,

universities and enterprises have “home pages” that contain basic information on the owner with very easy access. Today a home page is a must-have for enterprises that want to take part in the global competition.

Grid Computing

“Grid” computing is an important new field that has to be distinguished from conventional distributed computing by its focus on large-scale resource sharing, innovative applications, and high-performance orientation. “Grid” can be defined as a hardware and software infrastructure that provides dependable, consistent, pervasive, and inexpensive access to high-end computational capabilities resulting in flexible, secure, coordinated resource-sharing among dynamic collections of individuals, institutions, and resources—to sum up, virtual organizations (Foster, 2000).

The real and specific problem that underlies the Grid concept is coordinated resource-sharing and problem-solving in dynamic, multi-institutional virtual organizations. The sharing is not primarily file exchange, but rather direct access to computers, software, data, and other resources, as is required by a range of collaborative problem-solving and resource brokering strategies emerging in industry, science, and engineering. This sharing is highly controlled, clearly and carefully defined by what is shared, who is allowed to share, and the conditions under which sharing occurs. A set of individuals and/or institutions defined by such sharing rules form is called a virtual organization (VO).

Furthermore, sharing is about more than simply document exchange (as in “virtual enterprises”): it can involve direct access to remote software, computers, data, sensors, and other resources. For example, members of a consortium may provide access to specialized software and data, and/or pool their computational resources. The members of a Virtual Organization do not necessarily have

to work together on the same site, but the Grid will make it feel, to the members, as if they are on the same network.

The Grid architecture is a protocol architecture, with protocols defining the basic mechanisms by which VO users and resources negotiate, establish, manage, and exploit sharing relationships. A standards-based open architecture facilitates extensibility, interoperability, portability, and code sharing; standard protocols make it easy to define standard services that provide enhanced capabilities

The primary goal of the Grid at the moment is to allow coordinated resource sharing in virtual organizations. Current Internet technologies address communication and information exchange among computers but do not provide integrated approaches to the coordinated use of resources at multiple sites for computation. Business-to-business exchanges focus on information sharing (often via centralized servers); virtual enterprise technologies do the same. Enterprise distributed computing technologies like CORBA and Enterprise Java are not able to resource-share within the organization.

Grid is building on these existing technologies, rather than compete with them; the Grid will act as a middleware between high-level behaviors of the Internet (such as its protocols, and the lower levels, for example the application layer), complement its functionality, and to add flexibility. The Grid can be viewed as an extension to the Web, building on its protocols, and offering new functionality (Foster, Kesselman, & Tuecke, 2000).

As the Grid is built on the existing Internet, it will share its capabilities, such as simple data retrieval and transfer, as well as the basic file-sharing functions provided by peer-to-peer applications. The prospects for the future, however, are far greater, and could not only change the way of sharing information, but also the way computers interpret information and even, by integrating developing technologies such as Jini and Bluetooth, how this technology can involve the daily life.

Powerline Communications

As cable, telephone, and wireless companies compete to provide high-speed Internet access to homes, a new challenger is emerging based on a decidedly old technology. The idea is to connect the Internet and network computers in a LAN, by using the world's largest existing network, the power grid. Powerline communications (PLC)—communications over the electricity distribution grid—has become a hot topic recently. Although this technology has been in use for special applications for several decades—for example, street lighting is frequently operated according to this principle—communication in these cases is exclusively in the narrowband range and transmission rates are correspondingly low.

The first attempts to realize the power grid as a communication network were not really successful, but the technological advancements over the last few years have overcome the technical issues, most notably that of line noise or interference from electrical devices plugged into the same electricity grid, which can disrupt data-transmission. PLC works by transmitting data signals through the same power cables that transmit electricity, but it uses a different frequency. To do this, every PC needs to be attached with a PLC adapter, which also functions as a modem (Hübscher, 2004).

The operation procedure of PLC can be divided into two phases:

- **Procedures, which are performed outside the home (outdoor):** The conventional telecommunications infrastructure is used to connect the relevant local network station with the telephone network or a specific Internet backbone. Depending on distance and local conditions, the connection is enabled by radio, copper lines, or optical cables. The local network station combines data and voice signals on the power grid and sends them as a data stream to any socket in connected households; that is, to the end user via the low-voltage network.
- **Procedures inside the home (indoor):** The access point forwards incoming data streams to the indoor network, and an indoor master in the household controls and coordinates all (externally and internally) transmitted data signals. Intermediate adapters separate data and power at the socket and forward the data to individual applications. There is no need for separate telephone or data cabling since the socket, far from being a mere electrical point, becomes a powerful communications interface which bridges the last mile for high-speed Internet access, thus enabling networking throughout the building or household.

The powerline technology applied today transmits data at 4.5 Megabits per second (Mbit/s) via the electricity supply grid—in the medium-term rates of up to 20 Mbit/s are possible—and provides permanent high speed access to the Internet (always online) from every main voltage supply socket in a building, and makes broadband capacity cost-efficiently available over the “last mile.” It is no longer necessary to always dial into the network, or indeed to install additional cabling within a building, so PLC is also an interesting alternative for an in-house data network.

Because PLC uses the existing electrical wirings hidden in the walls of homes and buildings, users can do away with messy cables and do not need to open floorboards, hack walls, and break ceilings to run the wires. PLC also enables indoor networking for PCs and printers, plus shared Internet access between PCs in an office or home. In addition, PLC boasts a superior distance of 300m (without using repeaters), compared to 100m for standard Fast-Ethernet and about 100m for 802.11b wireless connections.

For utility suppliers, PLC opens a whole new revenue stream for them, which they can deploy quickly. For service providers buying wholesale services from utility companies, PLC also offer various benefits, including the speed and cost of

deployment and the ability to break the telephone company monopoly on last-mile access in many countries.

Voice Over Internet Protocol

Voice over Internet Protocol (VoIP) is a technology that allows people to make telephone calls using a broadband Internet connection instead of a regular (or analog) phone line. VoIP technologies convert digitized voice into data packets that are encapsulated in Internet protocol. Internet telephony refers to communications services—voice, facsimile, and/or voice-messaging applications—that are transported via the Internet, rather than the public switched telephone network (PSTN).

The basic steps involved in originating an Internet telephone call are conversion of the analog voice signal to digital format and compression/translation of the signal into Internet protocol (IP) packets for transmission over the Internet; the process is reversed at the receiving end.

There are different services included into VoIP technology. Some services using VoIP may only allow the user to call other users using the same service, but others may allow to call anyone who has a telephone number—including local, long distance, mobile, and international numbers. There are services only working over computer or a special VoIP phone, other services allow to use a traditional phone through an adaptor.

As VoIP technology unites the telephony and data worlds, companies can be the winners of this new technology because VoIP allows users to integrate their phone calls, faxes, and voice traffic over corporate Intranets and the Internet. Companies that use VoIP technologies can save a lot on long distance calls.

Making Voice over IP function efficiently in a corporate enterprise network requires adequate bandwidth allocation and management. For each call to be sent across an IP network, 17Kbps is needed of the total bandwidth. If properly designed and operated, a company's network can use a 56

or 64 Kbps link to simultaneously share several voice calls and data traffic without any delays or problems. In larger organizations, where a large amount of data is carried across a network, Voice over IP would need a separate infrastructure in order to be utilized. Especially in companies where up to 50 phone lines can be used simultaneously, an Intranet type of infrastructure will be needed to process the calls with PSPN quality.

Voice over IP technology has several advantages that will result a fast growth, especially among companies:

- Cost reduction. It is cheaper to make an IP telephony call than a circuit call because the operators avoid paying interconnect charges.
- Better utilization of infrastructure. Circuit switched telephony call takes up 64 KBPS while an IP telephony call takes up 6-8 KBPS.
- Possibilities for new added value services. Such value added opportunities include: IP multicast conferencing and telephony distance learning applications, phone directories and screen popping via IP, and “voice web browsing” where the caller can interact with a Web page by speaking commands.
- Possibility to manage a single network handling both voice and data.

IP telephony will also create great demand for new services. It will allow people to control different media and different types of terminals, such as PC and fixed phone, straight from their Web browser.

The main problems of VoIP technology applications are the interoperability, security, and bandwidth management. When these problems are solved even partially the spread of VoIP will grow extremely fast first of all among enterprises. VoIP technology can revolutionize both telecommunication services and industry and can create many advantages for companies and private users as well.

Wireless Communication Networks

Types of Wireless Networks

Wireless networks (WN) serve as the transport mechanism between and among devices and the traditional wired networks (enterprise networks and the Internet). Wireless networks have many types and are diverse, but can be categorized into four groups based on their coverage range:

- Satellite communication (SC),
- Wireless Wide Area Networks (WWAN),
- Wireless Metropolitan Area Network (WMAN),
- Wireless Local Area Networks (WLAN), and
- Wireless Personal Area (or Pico) Network (WPAN).

The main characteristics of wireless networks are as follows:

- access for anybody, from anywhere, at any time—mobility,
- on-line/real-time access,
- relative high communication speed,
- shared access to files, data/knowledge bases, and
- exchange of picture, voice—multimedia applications.

In the followings the main types of wireless networks will be introduced. In Table 2 the main characteristics of these wireless technologies are summarized.

Table 2. Main characteristics of wireless networks

Wireless network type	Operation frequency	Data rate	Operation range	Characteristics
Satellite	2170–2200 MHz	Different (9.6 kbps - 2 Mbps)	Satellite coverage	Relative high cost, availability
WWAN				
GSM (2-2.5 G)	824-1880 MHz	9.6 - 384 kbps (EDGE)	Cellular coverage	Reach, quality, low cost
3G/UMTS	1755-2200 MHz	2.4 Mbps	Cellular coverage	Speed, big attachments
iMode (3G/ FOMA)	800 MHz	64 - 384kbps (W-CDMA)	Cellular coverage	Always on, easy to use
FLASH-OFDM	450 MHz	Max. 3 Mbps	Cellular coverage	High speed, respond time less then 50 milliseconds
WMAN				
IEEE 802.16	2-11 GHz	Max.70 Mbps	3-10 (max. 45) km	Speed, high operation range
WWLAN				
IEEE 802.11A	5 GHz	54 Mbps	30m	Speed, limited range
IEEE 802.11b	2.4 GHz	11 Mbps	100 m	Medium data rate
IEEE 802.11g	2.4 GHz	54 Mbps	100-150m	Speed, flexibility
WPAN				
BLUETOOTH	2.4 GHz	720 kbps	10 m	Cost, convenience
UWB	1.5 – 4 GHz	50-100 Mbps	100-150 m	Low cost, low power
ZigBee	2.4 GHz, 915 - 868 Mhz	250 Kbps	1-75 m	Reliable, low power, cost effective
Infrared	300 GHz	9.6 kbps-4Mbps	0.2-2 m	Non interfere, low cost
RFID	30-500 KHz 850-950 MHz 2.4-2.5 GHz	linked to bandwidth, max. 2 Mbps	0.02–30 m	High reading speeds, responding in less than 100 milliseconds

Satellite Communication

Satellite communication systems offer the users independent and reliable communication with any chosen subscriber in the world in the covered area, offering high quality telephone calls, fax transmissions, high-speed data access, and e-mail messaging. Today satellite communication providers purchase services and phone sets that are appropriate for dual mode, such as Satellite-GSM Phones.

These handheld satellite telephones provide voice, fax, Internet access, short messaging, and remote location determination services (GPS) in the covered area. All of this is provided through geosynchronous satellites, but when satellite coverage is not necessary, the handset can also access the GSM cellular network. Fax and digital data is transmitted at 9600 bps throughputs, but in case users need high-speed Internet access (144 kbps) this also can be achieved by using special lightweight terminals. In special cases, 2 Mbps data transmission rate can be achieved (Sheriff & Fun Hu, 2001).

A satellite phone can fulfill all the requirements regarding mobile communications in many application fields. Interdisciplinary applications are paralleled with equipment functionality—currently available satellite phones have the size of a standard notebook computer. Their use does not require complicated procedures; activation and call charging is done similarly to cellular phone networks (Elbert, 2004).

Wireless Wide Area Networks (WWAN)

Mobile Phone

Mobile communication is connected to using mobile phones. Mobile phone was the device that offered for a great number of people the possibility to make contact with others from anywhere, at anytime, and for anybody. Mobile phone is the device that realizes mobility on a society level, as

in many countries more than 70% of the population has a mobile phone.

There are different mobile systems/network protocols, which are developing very fast.

- **CDMA (Code Division Multiple Access—2G):** CDMA networks incorporate spread-spectrum technology to gracefully allocate data over available cells.
- **CDPD (Cellular Digital Packet Data—2G):** CDPD is a protocol built exclusively for sending wireless data over cellular networks. CDPD is built on TCP/IP standards.
- **GSM (Global System for Mobile Communications—2G):** GSM networks, mainly popular in Europe.
- **GPRS (General Packet Radio Service—2.5 G):** GPRS technology offers significant speed improvements over existing 2G technology.
- **iMode (from DoCoMo—2.5G):** iMode was developed by DoCoMo and is the standard wireless data service for Japan. iMode is known for its custom markup language enabling multimedia applications to run on phones.
- **3G:** 3G networks promise speeds rivaling wired connections. Both in Europe and North America, carriers have aggressively bid for a 3G spectrum but no standard has yet emerged.

The introduction of WAP (Wireless Application Protocol) was a big step forward for the mobile communication as this protocol made it possible to connect mobile devices to the Internet. By enabling WAP applications, a full range of wireless devices, including mobile phones, smart-phones, PDAs, and handheld PCs, gain a common method for accessing Internet information. The spread of WAP became even more intensive as the mobile phone industry actively supported WAP by installing it into the new devices. WAP applications exist today to view a variety of WEB content, manage

New Challenges for Smart Organizations

e-mail from the handset and gain better access to network operators' enhanced services. Beyond these information services, content providers have developed different mobile solutions, such as mobile e-commerce (mCommerce).

Mobile technology affects the operation of enterprises as well. The main reasons to develop a mobile solution in the enterprise are listed in the following:

- Provide access to company e-mail,
- Provide access to Intranet applications,
- Develop specific company applications,
- Permanent contact with service workers,
- Improve work scheduling,
- Possibility for mCommerce.

Mobile communication extends company data, back-end information systems, and e-mail to mobile employees and broadens the accessibility of mission critical data. Mobile access modifies the way workers interact with colleagues, customers, and suppliers.

FLASH-OFDM

FLASH-OFDM (Fast, Low-latency Access with seamless Handoff—Orthogonal Frequency Division Multiplexing) is a cellular, IP-based broadband technology for data services on the 450 MHz band. It has full cellular mobility, 3.2 Mbps peak data rates, 384 kbps at the edge of the cell and less than 20 milliseconds of latency.

The FLASH-OFDM system consists of an airlink, an integrated physical and media access control layer, and IP-based layers above the network layer (layer 3). The IP-based layers support applications using standard IP protocols.

Radio-router technology uses a radio-transmission framework for packet-based, broadband, IP wireless communications. Radio-router technology is designed to make links in an IP network mobile. A radio-router network can be built atop the existing IP infrastructure, and since

IP network technology is already well-developed and inexpensive, radio-router systems will be relatively easy, quick, and economical to implement (Flarion, 2004).

FLASH-OFDM is a wide-area technology enabling full mobility up to speeds of up to 250 km/h (critical to vehicle and rail commuters). Its ability to support a large number of users over a large area, and nationwide build outs (via wireless carriers), will do for data as the cellular networks did for voice. The IP (Internet Protocol) Interfaces In Flash-OFDM Enable operators to offer their enterprise customers access to their LANs (Local Area Networks) and users the benefits of the mobile Internet.

FLASH-OFDM support voice-packet-switched voice, not circuit-switched voice, Radio routers, IP routers with radio adjuncts, would handle packet traffic, and serve as the equivalent of cellular base stations. Consumers would connect with Flash-OFDM networks via PC cards in their notebooks and via flash-memory cards in handheld devices.

Wireless Metropolitan Area Network (WMAN)

The term WiMAX (Worldwide Interoperability for Microwave Access) has become synonymous with the IEEE 802.16 Metropolitan Area Network (MAN) air interface standard. Metropolitan area networks or MANs are large computer networks usually spanning a campus or a city. They typically use optical fiber connections to link their sites.

WiMAX is the new shorthand term for IEEE Standard 802.16, also known as "Air Interface" for Fixed Broadband Wireless Access Systems. In its original release (in early 2002) the 802.16 standard addressed applications in licensed bands in the 10 to 66 GHz frequency range and requires line-of-sight towers called fixed wireless. Here a backbone of base stations is connected to a public network, and each base station supports hundreds of fixed subscriber stations, which can

be both public Wi-Fi “hot spots” and enterprise networks with firewall.

The 802.16a extension, (issued in January 2003), covers non-line of sight (NLOS) applications and allows use of lower frequencies (2 to 11 GHz), many of which are unregulated. The 802.16a extension is a wireless metropolitan area network (WMAN) technology that will connect 802.11 hot spots to the Internet and provide a wireless extension to cable and DSL for last mile broadband access. The 802.16a provides up to 50 km of linear service area range. The technology also provides shared data rates up to 70 Mbps, which is enough bandwidth to simultaneously support more than 60 businesses with T1-type connectivity and hundreds of homes at DSL-type connectivity.

The 802.16e version is under development (scheduled publication is October 2005), and is expected to support mobile wireless technology—that is, wireless transmissions directly to mobile end users, so mobile applications thus enable broadband access directly to WiMAX-enabled portable devices ranging from smartphones and PDAs to notebook and laptop computers. This will be similar in function to the General Packet Radio Service and the “one times” radio transmission technology (1xRTT) offered by phone companies.

WiMAX is considered the next step beyond Wi-Fi because it is optimized for broadband operation, fixed and later mobile, in the wide area network. It already includes numerous advances that are slated for introduction into the 802.11 standard, such as quality of service, enhanced security, higher data rates, and mesh and smart antenna technology, allowing better utilization of the spectrum.

Wireless Local Area Network (WLAN)

Local area wireless networking, generally called Wi-Fi (also known as 802.11b Ethernet) is a hot topic. Companies, universities, and home users

are setting up wireless access points and running notebook computers without network wires.

Wi-Fi, or Wireless Fidelity, allows users to connect to the Internet from their home, from a hotel room, or from a conference room at work without wires. Wi-Fi enabled computers send and receive data anywhere within the range of a base station with a speed that is several times faster than the fastest cable modem connection.

Wi-Fi connects the user to others and to the Internet without the restriction of wires, cables or fixed connections. Wi-Fi gives the user freedom to change locations (mobility)—and to have full access to files, office, and network connections wherever she or he is. In addition Wi-Fi will easily extend an established wired network (Anderson, 2003).

Wi-Fi networks use radio technologies called IEEE 802.11b or 802.11a standards to provide secure, reliable, and fast wireless connectivity. A Wi-Fi network can be used to connect computers to each other, to the Internet, and to wired networks (which use IEEE 802.3 or Ethernet). Wi-Fi networks operate in the 2.4 (802.11b) and 5 GHz (802.11a) radio bands, with an 11 Mbps (802.11b) or 54 Mbps (802.11a) data rate or with products that contain both bands (dual band), so they can provide real-world performance similar to the basic 10BaseT wired Ethernet networks used in many offices. 802.11b has a range of approximately 100 meters.

Products based on the 802.11a standard were first introduced in late 2001. Its strengths are the high speed and lower risk of radio frequency interference than either 802.11b or 802.11g. Its weakness is that “a” is incompatible with the more popular “b” and the emerging “g,” because it strayed from the 2.4-GHz band. As WLAN is spreading, it could prove essential to serving large populations in a concentrated area, such as downtowns, universities, and business centers.

The 802.11g promises complete interoperability with “b” and transmission rates up to five times faster in the same 2.4-GHz band. Early

products are already on the market. The higher vulnerability to radio frequency interference from other 2.4-GHz devices (late-generation cordless phones) is a big challenge for 802.11g (Engst & Fleishman, 2003).

Wi-Fi networks can work well both for home (connecting a family's computers together to share such hardware and software resources as printers and the Internet) and for small businesses (providing connectivity between mobile salespeople, floor staff, and "behind-the-scenes" departments). Because small businesses are dynamic, the built-in flexibility of a Wi-Fi network makes it easy and affordable for them to change and grow.

Large companies and universities use enterprise-level Wi-Fi technology to extend standard wired Ethernet networks to public areas like meeting rooms, training classrooms, and large auditoriums, and also to connect buildings. Many corporations also provide wireless networks to their off-site and telecommuting workers to use at home or in remote offices.

It is easy to extend the existing networks with a Wi-Fi LAN to add another wireless computer to a Wi-Fi network. There is no need to purchase or lay more cable or find an available Ethernet port on the hub or router; just the card has to be plugged in to the computer and it is connected to the network.

Wireless Personal Area (or Pico) Network (WPAN)

WPAN represents wireless personal area network technologies such as Ultra-wideband (UWB) (Kelland, 2003), ZigBee, Bluetooth, RFID, WiMedia and IrDA.

Designed for data and voice transmission, low data rate standards include ZigBee, (IEEE 802.15.4) (Karayannis, 2003) and Bluetooth (IEEE 802.15.1), and enables wireless personal area networks to communicate over short distances, generating a new way of interacting with our personal and business environment. ZigBee

provides ultra-low cost solutions for applications requiring low data rates and long battery-life, such as remote controls and sensor applications (free frequency bands including 2.4 GHz, 915 MHz and 868 MHz, transmission ranges of 30-100 m are possible). In the home, this will mean a single remote control device will operate TVs, DVD players, audio systems, and other entertainment and computing equipment, as well as controlling lights, heating, home appliances, security systems, and even toys. Bluetooth chipsets, now on their third and fourth generation, are targeted primarily at the cell phone and PC peripheral industries (2.4 GHz band, peak data throughput of 720 KBps, distances about 10 m).

Two technologies of the WPAN group the RFID and Bluetooth will be introduced more detailed in the following.

Radio Frequency Identification (RFID)

The main purpose of the RFID (radio frequency identification) technology is the automated identification of objects with electromagnetic fields. An RFID system has three basic components: transponders (tags), readers (scanners), and application systems for further processing of the acquired data. There is a large variety of different RFID systems; they can use low, high, or ultra-high frequencies, tags may emanate only a fixed identifier or can have significant memory and processing capabilities. Transponders can contain effective security protocols or no security features at all. Most of the tags have passive powered by the radio field emitted by the reader but there are also active tags with a separate power supply (Finkenzeller, 2003).

RFID systems can be distinguished according to their frequency ranges. Low-frequency (30 KHz to 500 KHz) systems have short reading ranges and lower system costs. They are usually used in, for example, security access and animal identification applications. High-frequency (850 MHz to 950 MHz and 2.4 GHz to 2.5 GHz)

systems, offering long read ranges (greater than 25 meters) and high reading speeds, are used for such applications as railroad car tracking and automated toll collection. However, the higher performance of high-frequency RFID systems generate higher system costs.

In determining data transfer rates, carrier wave frequency is of primary importance. In general, a higher data transfer belongs to a higher frequency. In case of the 2.4-2.5 GHz spread spectrum band, 2 megabits per second data rates can be achieved. Spread the spectrum apart, and increasing the bandwidth allows an increase in noise level and a reduction in signal-to-noise ratio, so bandwidth is an important consideration in this respect.

According to the reader's power output and the used radio frequency, the range extends from a few centimeters to 30 meters or more. When an RFID tag passes through the electromagnetic zone, it detects the reader's activation signal. The reader decodes the data encoded in the tag's integrated circuit (silicon chip) and the data is passed to the host computer for processing.

RFID as an automatic identification technology has got an increasing importance in recent years and is now being seen as a radical means of enhancing data handling processes. A range of devices and associated systems are available to satisfy an even broader range of applications. Data within a tag may provide identification for goods in transit, an item in manufacturing process, or the identity of a vehicle, animal, or individual. By including additional data the prospect is provided for supporting applications through item-specific information or instructions immediately available on reading the tag.

Bluetooth

Bluetooth is a short-range radio device that replaces cables with low-power radio waves to connect electronic devices, whether they are

portable or fixed. It is a wireless personal area network (WPAN) specified in IEEE 802.15, Working Group for wireless personal area networks. Bluetooth, named after Harald Bluetooth, the 10th century Viking king, is a consortium of companies (3Com, Ericsson, Intel, IBM, Lucent Technologies, Motorola, Nokia, and Toshiba) bonded together to form a wireless standard (Bakker & Gilster, 2002).

The Bluetooth device also uses frequency-hopping to ensure a secure, quality link, and it uses ad hoc networks, meaning that it connects peer-to-peer. When devices are communicating with each other they are known as piconets, and each device is designated as a master unit or slave unit, usually depending on who initiates the connection. However, both devices have the potential to be either a master or a slave.

The Bluetooth user has the choice of point-to-point or point-to-multipoint links, whereby communication can be held between two devices, or up to eight.

Bluetooth is not only a standard, but it is also a product. The hardware consists of a microchip with a radio transceiver. It can be incorporated into a laptop or wireless phone. It can access other ad hoc networks or local access points. It is a short-range system, operating at a normal range of 10m (0 dBm) and an optional range of 100 m (+20 dBm). It uses 2.4 GHz as its base frequency. It can reach 6 Mbps in a multiple piconet ad hoc structure.

The new version of Bluetooth, Bluetooth 2.0+EDR (Enhanced Data Rate) offers a significant speed over version 1.2. While Bluetooth 1.2 offers a data transfer rate of 1Mbps, Bluetooth 2.0 offers data transfer speed 3Mbps. As an addition, a significant increase in power efficiency results in longer battery life—that is a very important factor for mobile users. The new version is backwards-compatible to earlier versions and allows the connection of multiple devices.

TRUST AND SECURITY IN SMART ORGANIZATIONS

Role of Trust in Smart Organizations

Trust and Trust Building in SO

In all information and communication systems there is a common factor: the human being. This factor plays the most important role in every level and in every aspect. A human can be a designer, a developer, or a user of the system. The most frequent instantiation of the human being is the average user, who maybe is not well-informed or skilled in computer science, but has his or her own personality and psyche.

In order to move the individuals to use a certain information system, they have to be convinced that it is safe to use the system, that their data will not be modified, lost, used in other way as defined previously, and so forth. If the individuals have been convinced they will trust the system and they will use it.

Trust can be defined as a psychological condition comprising the trustor's intention to accept vulnerability based upon positive expectations of the trustee's intentions or behavior (Rousseau, Sitkin, Burt, & Camerer, 1998). Those positive expectations are based upon the trustor's cognitive and affective evaluations of the trustee and the system and world, as well as of the disposition of the trustor to trust. Trust is interpreted in terms of expectation, attitude, willingness, or perceived probability. Trust can cause or result from trusting behavior (e.g., cooperation, taking a risk) but is not behavior itself.

The following components are included into most definitions of trust:

- willingness to be vulnerable or to rely,
- confident, positive expectation and positive attitude towards others,
- risk and interdependence as necessary conditions.

Trust has different forms, such as

- **Intrapersonal trust:** trust in one's own abilities; self-confidence basic trust (in others).
- **Interpersonal trust:** expectation based on cognitive and affective evaluation of the partners; in primary relationships (e.g., family) and non-primary relationships (e.g., business partners).
- **System trust:** trust in depersonalized systems or the world that function independently (e.g., economic system, regulations, legal system, technology); requires voluntary abandonment of control and knowledge (Luhmann, 1979).
- **Object trust:** trust in non-social objects; trust in its correct functioning (e.g., in an electronic device).

Collaboration and cooperation are main characteristics of networked organizations, so the contacts among the users, the human beings, have outstanding importance. A very important element of this human contact is trust. In a networked organization, trust is the atmosphere, the medium in which actors are moving (Castelfranchi & Yao-Hua, 2001). Trust is the base of cooperation, the normal behavior of the human being in the society. The ability of enterprises to form networked systems depends on the existing level of trust in the society and on the capital of society (Fukuyama, 1995). As the rate of cooperation is increasing in all fields of life, the importance of trust is evolving even faster.

In this new organizational environment, new methods and techniques of trust building have to be developed, as the conventional rules cannot be applied. According to different experiments, the level of trust between cooperating virtual teams is highly influenced by the type of communication and the duration of contacts.

Technology Component of Trust

In building trust there are two approaches: information technology approach, and human centered approach, based on culture and morality. Information technology approach means that security has to increase by different architectures, protocols, certifications, cryptography, authentication procedures and standards, and this increased security generates the trust of users. This means access control (passwords, firewalls), protect integrity and privacy of messages and databases (cryptography), and identification of users. Parallel stressing the effectiveness of these technologies for the humans (users) can cause that they will trust in the systems based on these convincing actions. Based on the technological approach, 100% security never can be obtained (there will be always security holes somewhere in the systems), so full trust can not guaranteed based on these mechanisms.

Human Side of Trust Building: Feeling of Trust

The feeling of security experienced by a user of an interactive system does not depend on technical security measures alone. Other (psychological) factors can play a determining role; the user's feeling of control can be one of these factors.

It has to be analyzed why people feel safe and secure, what causes these feelings. The hypothesis of D'Hertefelt (2000) was that "The feeling of security experienced by a user of an interactive system is determined by the user's feeling of control of the interactive system." The more a user feels in control of an interactive program, the more the user will trust the site and the program. From this aspect user interface has the main role, that is, the menu structure, the messages send for the user by the system. In the case the user feels that it is easy to use, it is transparent; he or she can control the system (even with low-level computer knowledge)—that is, the system is "user

friendly," and through this he can be convinced that he is using a trustworthy system.

It would be a mistake to think that applying only the human-centered approach would generate trust; the technological part has to be added as well (e.g., biometrical identification), so the structured integration of the two approaches can result in the expected level of trust.

Relation of Trust and Time

Trust is a dynamic process and it alters based on experience. The trusting process begins when an individual perceives indications that suggest a person or organization may be worthy of trust. These indications can include behaviors such as manners, professionalism, and sensitivity, and these forms are designed to represent trustworthiness. These formal claims to trustworthiness become strengthened over time and are eventually transformed into "character traits," such as dependability, reliability, and honesty.

The process of building trust is slow; trust is formed gradually, and it takes quite a lot of time and repeated positive experiences (Cheskin, 1999). Online trust can be described as a kind of human relationship. The initial stage is that of interest and distrust; there has to be a motivation, a need, to get interested in the service, or coworking. In subsequent phases the trust will evolve, or in the case of negative experiences the cooperation will terminate.

Trust depends on the time span of cooperation and the type of connection as well. It can be stated that there are differences in the trust-building process in short-term and long-term relationships. In the case of short-term relationships (e.g., in a virtual organization), trust must be achieved quickly, and then maintain with no, or rare face-to-face interaction. The members of these teams must assume that other remote team members are trustworthy, and then later on modify their assumptions according their positive or negative experiences.

New Challenges for Smart Organizations

In long-term relationships there are four factors that influence trust-building (Rocco, Finholt, Hofer, & Herbsleb, 2001):

- expectation of future interaction may motivate greater investment in building trustworthy relationships,
- long-term relationships offer more time to establish trustworthiness through routines and culture,
- people have more communication channels, which may affect trust to the extent that participants have additional ways to clarify misunderstandings or to correct failures,
- participants are interested in successful task performance, and trust formation may assume a higher priority.

Developing Trust in Networked Organizations

Today the different types of networked organizations need new types of cooperation; as the members of the working teams are geographically (physically) separated, they use shared documents, and communicate through e-mail and high-quality audio and video channels. These teams are called “virtual teams,” as they never meet personally and they have no face-to-face (FTF) contact. The work of teams without FTF contact is less effective and reliable based on the observation stated by Handy (1995) that “trust needs touch.” According to case studies, it is evident that trust of virtual team members is significantly lower than trust in conventional teams (Rocco, Finholt, Hofer, & Herbsleb, 2001). In other experiments where interaction was primarily via e-mail, very similar results have gained as in geographically distributed teams (Jarvenpaa & Leidner, 1999)

In an experiment introduced in Bos (2002), four media types were compared: Chat (text), phone conference, videoconference, and face-to-face. Chat was significantly worse than each of the other three conditions, but audio and video did

as well as face-to-face in overall cooperation, and were a definite improvement over text-chat only CMC. However, these two channels still showed evidence of delayed trust, in that they took longer to reach high levels of cooperation.

The latest research shows that if people meet before using computer-mediated communication, they trust each other, as trust is being established through touch. In case participants do not meet formally but they initiate various getting-acquainted activities over a network, trust is much higher than if they do nothing before, and nearly as good as a prior meeting. Using chat forums to get acquainted is nearly as good as meeting, and “even just seeing a picture is better than nothing” (Zheng, Veinott, Bos, Olson, Gary, & Olson, 2002).

Security in Smart Organizations

What is Security?

Security is a conscious risk-taking, so in every phase of a computer system’s life cycle must be applied that security level which costs less than the expense of a successful attack. In other words, security must be so strong that it would not be worth it to attack the system, because the investment of an attack would be higher than the expected benefits. Data and system security are needed for all types of network-connected devices, such as a personal computer or a mobile phone. Data security involves protecting user and administrative data against unauthorized monitoring or modification, while system security deals with the consistency of the system component itself. As an addition, communication systems must address the issue of network security, which involves vice versa protection of the user device and the network. In Table 3, the main practical fields of ICT security are summarized.

In essence, security is a practice of risk management. There is no open system that is completely secure, and increases in system secu-

Table 3. Main fields of ICT security

	Organization security	Personal security	Network (channel) security	Computer (end point) security
Human & SW security	Security policy (e.g., access rights).	Trained and reliable staff under control.	Using reliable network tools, and frequently checked communication channels and well configured network elements.	Using tested application SW tools, and frequently checked operation system, and properly configured HW systems.
Physical security	Computers in secure places of the building and offices.	Physical identification technologies (fingerprints, etc.)	Prevent direct, or close access to network cables, or application of special technologies.	Prevent direct physical access to computers by unauthorized persons, or block close access in electromagnetic way.

curity typically decrease system performance and usefulness. At different system levels, different security solutions have to be applied, and these separate parts have to cover the entire system consistently.

A carefully designed security system process has the following basic steps:

- Definition of threats and their attack types from which the system has to be protected.
- The degree of protection that should be applied.
- The place and mode of the protection that should be applied.
- Selection of security mechanisms and services.
- Selection of HW and SW solutions.

To develop the proper security policy, to select the proper equipment, tools, and the best-fitting methodology, algorithm needs high-level expertise as in case such a multidimensional, interdisciplinary decision problem there is no optimal, only suboptimal solution in many cases.

The problem space is extremely complex, as the whole economy is based on networked information management and all sectors are strongly influenced by the ICT, and in the information society the behavior and habits of the people are

dynamically changing, and government supported programs can speed up certain processes.

Threats and Trends of Cyber Crimes

The first step is the definition of the threat model of the ICT system. The threat model is the collection of probable attack types, so it defines the system protection requirements as well. In the following, the active attacks will be described, but passive attacks precede active attacks in many cases.

In order to define a very general, but at the same time very typical, attack tree the CSI statistics will be used. The “Computer Crime and Security Survey” of the Computer Security Institute (CSI) is based on responses from 486 computer security practitioners in U.S. corporations, government agencies, financial institutions, medical institutions, and universities (FBI, 2004). The survey confirms that the threat from computer crime and other information security breaches continues unabated.

The total reported financial loss of 251 responders was \$141,496,560 in 2004, while in 2000 this sum was \$265,589,940 of 249 responders. These numbers demonstrate that the value or the loss and damage caused by the attacks is decreasing. One reason of this shrinkage could be that the companies use security technologies today to a greater extent than they did several years before.

New Challenges for Smart Organizations

The 483 responders use the following security technologies (in %): smart cards-35, intrusion detection-68, encrypted login-56, firewalls-98, anti-virus SW-99, encrypted files-42, biometrics-11, access control-71. The most frequent types of attacks and the financial loss caused by them are listed in Table 4. (The percentage gives the rate of responders involved in the attack; the losses are in USD).

Security Services and Mechanisms

The following services form together the sense of “trust” for a human being who uses a service or a given equipment (Menezes, van Oorschot, & Vanstone, 1996):

- Confidentiality/privacy ensures that only the sender and the intended recipient of an encrypted message can read the contents of that message. To guarantee privacy, a security solution must ensure that no one can see, access or use private information, such as addresses, credit card information, and phone numbers, as it is transmitted over the Internet.
- Integrity ensures the detection of any change in the content of a message between the

time it is sent and the time it is received. In many systems, if an alteration is detected, the receiving system requests that the message be resent.

- Authentication ensures that all parties in a communication are who they claim to be. Server authentication provides a way for users to verify that they are really communicating with the Web site they believe they are connected to. Client authentication ensures that the user is who they claim to be.
- Non-repudiation provides a method to guarantee that a party to a transaction cannot falsely claim that they did not participate in that transaction. In the real world, handwritten signatures are used to ensure this.

The means for achieving these services depends on the collection of security mechanisms that supply security services, the correct implementation of these mechanisms, and how these mechanisms are used. Three basic building blocks of security mechanisms are used:

- Encryption is used to provide confidentiality and can provide authentication and integrity protection.

Table 4. Most frequent types of attacks in US (FBI, 2004)

Type of attack	In %	Caused financial loss
Virus	78	55,053,900
Insider abuse of net access	59	10,601,055
Laptop/mobile theft	49	6,734,500
System penetration	39	901,400
Unauthorized access	37	4,278,205
Denial of service	17	26,064,050
Abuse of wireless networks	15	10,159,250
Thief of proprietary information	10	11,460,000
Misuse of public WEB	10	2,747,000
Web site defacement	7	958,100
Telecom fraud	5	3,997,500

- Digital signatures are used to provide authentication, integrity protection, and non-repudiation.
- Checksums/hash algorithms are used to provide integrity protection and can provide authentication.

One or more security mechanisms are combined to provide a security service, and a typical security protocol provides one or more services. As there are too many security technologies, tools, and equipment to be introduced in this place, only the most frequently used, or some new ones, will be shortly described in the following. Detailed descriptions can be found in Menezes et al. (1996), Anderson (2001), and Schneier (1996).

Tools, Methods, and Techniques for Security

Achieving Confidentiality

The main factor of trust is confidentiality, which can be achieved by technologies that convert or hide the data or text in a form that cannot be interpreted by unauthorized persons. There are two major techniques to fulfill this goal: encryption and steganography.

- Encryption is transforming the message to a ciphertext, so that an enemy who monitors the ciphertext cannot determine the message sent. The legitimate receiver possesses a secret decryption key that allows him to reverse the encryption transformation and retrieve the message. The sender may have used the same key to encrypt the message (with symmetric encryption schemes) or used a different, but related key (with public key schemes). Public key infrastructure (PKI) technology is widely used, as DES and RSA are well-known examples of encryption schemes, while the AES (with the Rijndael algorithm) belongs to the new generation.

- Steganography is the art of hiding a secret message within a larger one in such a way that the opponent cannot discern the presence or contents of the hidden message. For example, a message might be hidden within a picture by changing the low-order pixel bits to be the message bits.

Security Architectures

The security architectures represent a structured set of security functions (and the needed hardware and software methods, technologies, tools, etc.) that can serve the security goals of the distributed system. In addition to the security and distributed enterprise functionality, the issue of security is as much (or more) a deployment and user-ergonomics issue as technology issue. That is, the problem is as much trying to find out how to integrate good security into the industrial environment so that it will be used, trusted to provide the protection that it offers, easily administered, and really useful.

Firewalls

Firewalls can make the user's network appear invisible to the Internet, and they can block unauthorized and unwanted users from accessing files and systems. Hardware and software firewall systems monitor and control the flow of data in and out of computers in wired and wireless enterprise, business, and home networks. They can be set to intercept, analyze, and stop a wide range of Internet intruders and hackers. Like VPNs, there are many types and levels of firewall technology. Many firewall solutions are software only; many are powerful hardware and software combinations.

Virus Defense

Viruses and other malicious code (worms and Trojans) can be extremely destructive to the vital information and the computing systems both for

New Challenges for Smart Organizations

individuals and businesses systems. There are big advances in anti-virus technology, but malicious codes remain a permanent threat. The reason is that the highest-level security technology can be only as effective as the users who operate them. In the chain of computer security, human beings seem to be the weakest point, so there is no absolute security in virus defense.

Virtual Private Network (VPN)

Today most companies use VPN to protect their remote-access workers and their connections. It works by creating a secure virtual “tunnel” from the end-user’s computer through the end-user’s access point or gateway, through the Internet, all the way to the servers and systems of the company. It works both for wired and wireless networks and can effectively protect transmissions, for example, from Wi-Fi equipped computers to corporate servers and systems.

A VPN works through the VPN server at the company headquarters, creating an encryption scheme for data transferred to computers outside the corporate offices. The special VPN software on the remote computer or laptop uses the same encryption scheme, enabling the data to be safely transferred back and forth with no chance of interception. However, VPN access, which enables access to the company network, e-mail, and communications systems, is provided only to those who’ve been given authorization.

To provide a full VPN service, wireless communications systems must support the following requirements:

- broadband data access (e.g., average sustainable throughput of 1.5 Mbps downlink/600 Kbps uplink),
- low latency connectivity (~35 ms roundtrip),
- end-to-end security (authentication, integrity protection, and/or encryption),
- full mobility (at vehicular speeds).

VPN remote access protocols typically reduce throughput by 25-30%. Even without this drawback, dial-up and 2.5G data services (at around 40-56 Kbps) do not support a satisfactory remote VPN experience. VPN requires a broadband connection, particularly for file sharing, enterprise-specific applications, and large e-mail attachments so critical to today’s business communications.

Identification of Persons

Generally, biometrics refers to the study of measurable biological characteristics. In computer security, biometric technologies are defined as automated methods of identifying or authenticating the identity of a living person based on his or her physiological (e.g., fingerprint, hand, ear, face, iris, or retina) or behavioral (e.g., signature, voice, keystroke) characteristic. This method of identification is preferred over current methods involving passwords and pin numbers, as the person to be identified is required to be physically present at the point-of-identification, so the person of user is identified, not the device, as in case of PIN and password.

Biometric techniques provide a significantly higher level of identification than passwords or smart cards alone. Because biometric characteristics are unique to each individual, they can be used to prevent theft or fraud. Unlike a password or personal identification number (PIN), a biometric trait cannot be forgotten, lost, or stolen. According to security experts, biometrics is considered as providing the highest level of security. Biometry can be used in IC systems instead of passwords, as with biometry the person can be identified, not the device.

Smart Cards

There is a strong need for a tool that can fulfill the functions connected to trustworthy services. Smart card (SC) technology can offer a solution for current problems of secure communication

by fulfilling simultaneously the main demands of identification, security, and authenticity besides the functions of the actual application.

Smart card is a plastic plate that contains a microprocessor, a chip, similar to computers. It has its own operation system, memory, file system, and interfaces. A smart card can handle all authorized requests coming from the “outside world.” There are different SC configurations equipped with different interfaces. The crypto-card has a built-in chip for doing encryption and decryption, other cards have keyboards, and the SC for secure identification has fingerprint sensor (Koller, 2001). Smart cards can help in secure signing of digital documents, as well. Smart cards can be read by SC-readers integrated or connected to PCs or any other equipment. Smart cards are also important parts of physical or logical access systems for enterprises.

The application of SCs in the security field can result in the next step of the technological revolution because of new possibilities in effective integration of the functions of security and the actual application field. In this way, the SC can be the general, and at the same time personalized, “key” of the citizens for the information society.

Personal Trusted Device

People like smart, small equipment, tools that they can keep in their hands, can bring them permanently with them, so they can control them both physically and in time. This physical and time controllability makes people think these devices are secure (physically nobody else can access them), so they trust them (even this approach is not always really true). In the case that such a device can be used for communication, it is called mobile phone.

Today mobile phones represent the first generation of Personal Trusted Devices (PTD) as they can be used not only for talking but for different other functions as well, and PKI and

other crypto-systems can be installed on them. The user authentication could be done based on biometry (fingerprint or voice). The connection of mobile phones with the Internet made a big leap in the direction to become mobile phones to PTD. The scale of functions became really wide and different mobile technologies have appeared (*mTechnologies*).

Security Standards

In the field of security standards and quasi standards have an important role. In the following some of the most relevant ones are introduced briefly, only to show the directions and status of these significant works.

In order to classify the reliability and security level of computer systems, an evaluation system has been developed and the criteria have been summarized in the so-called “Orange book” (Orange book, 1985). Its purpose is to provide technical hardware/firmware/software security criteria and associated technical evaluation methodologies in support of the overall ADP system security policy, evaluation, and approval/accreditation responsibilities promulgated by DoD Directive 5200.28.

The ISO/IEC 10181- multi-part (1-8) “International Standard on Security Frameworks for Open Systems” addresses the application of security services in an “Open Systems” environment, where the term “Open System” is taken to include areas such as database, distributed applications, open distributed processing, and OSI (ISO, 1996). The Security Frameworks are concerned with defining the means of providing protection for systems and objects within systems, and with the interactions between systems. The Security Frameworks are not concerned with the methodology for constructing systems or mechanisms. The Security Frameworks address both data elements and sequences of operations (but not protocol elements), which may be used to obtain specific security services. These security services may

apply to the communicating entities of systems as well as to data exchanged between systems, and to data managed by systems.

The ISO/IEC 15408 standard (ISO, 1999) consists of three parts, under the general title “Evaluation Criteria for Information Technology Security” (Part 1: Introduction and general model, Part 2: Security functional requirements, Part 3: Security assurance requirements). This multipart standard defines criteria to be used as the basis for evaluation of security properties of IT products and systems. This standard originates from the well-known work called “Common Criteria” (CC). By establishing such a common criteria base, the results of an IT security evaluation will be meaningful to a wider audience.

Security in Networked Environments

In networked enterprises such as smart organizations the goal for security is to reflect, in a computing and communication-based working environment, the general principles that have been established in society for policy-based resource access control.

Each involved entity or node should be able to make their assertions without reference to a mediator and especially without reference to a centralized mediator (e.g., a system administrator) who must act on their behalf. Only in this way will computer-based security systems achieve the decentralization needed for scalability in large distributed environments.

The resource access control mechanisms should be able to collect all of the relevant allegations and make an unambiguous access decision without requiring entity-specific or resource-specific local, static configuration information that must be centrally administered.

In order to be the security a successful part of the distributed, networked environment—providing both protection and policy enforcement—each principal entity should have neither more nor less involvement than they do in the currently

established procedure that operates in the absence of computer security. Only the form has to be changed, such as a digital signature instead of signing a paper. In case of such system, this sort of a security infrastructure should provide the basis of automated management of resources that precedes the construction of dynamically and just-in-time configured systems to support different user defined application-oriented requirements.

The expected advantage of computer-based systems is in maintaining access control policy, but with greatly increased independence from temporal and spatial factors (e.g., time zone differences and geographic separation), together with automation of redundant tasks such as credential checking and auditing. The security architectures represent a structured set of security functions (and the needed hardware and software methods, technologies, tools, etc.) that can serve the security goals of the distributed system.

As an addition to the “classic” networked environments, companies aspire to mobilize their workforces through application of wireless communication technology. Mobility brings obvious advantages to the enterprises, including increased productivity, improved communications, cost reductions, and revenue creation.

But as the amount of information that is transported over a wireless link increases, security attentions increase. The same security troubles that currently exist in the wired network, fear of identity theft and unauthorized monitoring of financial information and trade secrets, also apply to the wireless world. In addition, the wireless network is an open and easily accessible medium. To address these concerns, carriers must deploy security solutions for wireless technologies that are secure enough to satisfy stringent enterprise requirements.

Wireless communication systems (as well as wired systems) employ a “layered” network protocol design. The physical-, link-, network-, transport-, and application layers are each responsible for certain functions in the network whereby

appropriate security mechanisms are applied at each layer to ensure the optimum combination of high security and peak network performance.

NETWORK SECURITY IN SMART ORGANIZATION

In this subchapter, the security characteristics of the different network types will be introduced briefly. The technologies applied in wired networks will be presented first, as many of them are applied in the wireless networks as well. There are four different concerns that all security systems can address: privacy (confidentiality), integrity, authenticity, and non-repudiation. This is the goal in the case of the different networks as well, independently what type of media they use for data transmission.

Wired Network Security

Internet and WWW

At the beginning of networking there was a need mainly for the reliable operation, but the secure and authentic communication has become a key factor for today. According to Internet users, security and privacy are the most important functions to be ensured and by increasing the security the number of Internet users could be double or triple according to different surveys. The main reason for the increased demand is the spread of electronic commerce through the Internet, where money transactions are made in the amount of millions of dollars a day. It is not just the question of content of the communication or the user account—it is the question of money.

There are several solutions to secure the network; just security is in inverse proportion to usability and the most of the security tools are patches, extra solutions and rather stand-alone techniques. There are alternatives to use secure connections, some examples from the everyday applications (Table 1).

The FTP (file transfer protocol) application is used to provide file transfer services across a wide variety of systems. Usually implemented as application-level programs, FTP uses the Telnet and TCP protocols. The server side requires a client to supply a login identifier and password before it will honor requests. The information travels in plain, and with ftp dump is possible to sniff the communication, therefore advisable to use SSH-based SCP (secure copy) for file transfer. SSH is a Secure Shell, secure access method of a remote server instead of telnet (includes secure copy service instead of FTP, and transfers securely X sessions too).

Instead of HTTP there is SHTTP (secure hypertext transport protocol), which is HTTP over SSL (secure socket layer). Instead of simply e-mail there is the PGP (pretty good privacy) signed e-mail. With these techniques it can be guaranteed that the information in e-mail, file, or on a Web page will be reached only by authorized parties.

Over the Internet, the secure socket layer (SSL) protocol, digital certificates, and either user name/password pairs or digital signatures are used together to provide all four types of security.

SSL uses public key cryptography, bulk encryption algorithms, and shared secret key exchange techniques to provide privacy over the Internet. To provide integrity, SSL uses hashing algorithms that create a small mathematical fingerprint of a message. If any part of the message is altered, it will not match its fingerprint when the message is checked at the receiving end. In this case, the sender is asked to resend the message.

The remaining issue to address is non-repudiation. As with client authentication, most Web applications today simply rely on the entry of a user name and password to provide non-repudiation.

Applications can request a digital signature from a client, which requests that the user specifically authorize a transaction. The authorization is then encrypted utilizing the user's private key from their client certificate. Not surprisingly, a

digital signature is analogous to a real signature on a check and serves the same purpose. So far though, the adoption of client certificates for use by individuals on the Internet has been slow.

Different combinations of all of these security techniques are used for different applications, depending on which forms of security are important and the degree to which the solution needs to be balanced with the convenience for the user. For example, certificate-based client authentication and non-repudiation are not widely used on the Web today because most users don't want to be bothered with the administrative tasks of obtaining and safely maintaining a client certificate.

Security in the Grid

It is important to fix that the Grid can be viewed as an "extension" of the Internet, so it is rather a set of additional protocols and services that build on Internet protocols and services to support the creation and use of computation- and data-enriched environments. Any resource that belongs to the Grid also, by definition, belongs to the Internet.

As a result of the research and development efforts of the Grid community protocols, services and tools have been produced that include, for example, security solutions that support certificate management, coordination policies and services supporting secure remote access to computing and data resources and the co-allocation of multiple resources.

With respect to security aspects of the connectivity layer of the Grid, it is obvious that the complexity of the security problem makes it important that any solutions should be based on existing standards whenever possible. As with communication, many of the security standards developed within the context of the Internet protocol suite are applicable (e.g., user "log on" [authenticate,] integration with various local security solutions, user-based trust relationships).

The public key-based grid security infrastructure (GSI) protocols are used for authentication, communication protection, and authorization. GSI builds on and extends the transport layer security (TLS) protocols to address most of the issues listed above; in particular, single sign-on, delegation, integration with various local security solutions (including Kerberos), and user-based trust relationships.

The Grid will also offer a larger variety of resources; for example, remote execution of software, use of computing power, and secure access to remote networks, similar to virtual private networks (VPN).

Security Issues in PLC

From a cyber security perspective, the electric power grids are now more fragile, and margins for error are significantly less. With diminishing margins and power reserves, the probability for cascading catastrophic effects is higher.

There are opinions that hackers could shut down the Internet and the electric power grid if they wanted to, based on some theories of how networks work. The idea that certain nodes on a network are more important than others is nothing new, but that doesn't explain how the Internet gets shut down or (even more unlikely) how a "hacker" would shut down a power grid. There are theories to suggest some useful things about how certain nodes should be even more carefully protected from such attacks.

But the highly decentralized structure of the power plants—generators are not connected to the networks, which are hooked to the Internet—means that the damage hackers can cause is limited. Power plants are complex technological organizations, so to shut down a generator, one has to open circuit breakers and instruct generators to lower the "set points," the levels at which they are transmitting power. This is not something that can be done solely via a computer network. Security experts say that energy companies are

becoming increasingly sophisticated with network security, and have software systems in place allowing them to monitor any suspicious activity. That's important, because while the networks controlling power grids are currently offline, the utilities will come to rely more and more on the Internet. Companies recently launched a Web-based service for its customers, which will eventually offer services including online bill payment. This is where the companies are vulnerable; hackers could break into the network and "modify" the billing system.

However, there are potential security issues because a single power line from the utility company goes to multiple homes and office buildings. This means that hackers can "listen in" on the shared bandwidth. To further protect the data, this technology includes sophisticated encryption techniques built into the hardware (into powerline network adapters) so all data packets are automatically encrypted prior to transmission over the powerline network. Only computers that know the password can decrypt the packets and read data.

VoIP Security

VoIP systems have the same security risks as other IP-based systems. Systems without effective protection can be wiretapped, spilt (similar to e-mail spam) can be received, and so forth. If a company started to use VoIP focusing only on financial advantages without knowing the "dark side" of the technology, the financial balance could easily turn to negative.

Currently encryption and authentication of user access is only a recommendation by H.323. (H.323 is the international standard for multimedia communication over packet-switched networks, including LANs, WANs, and the Internet.) This means that any H.323-aware user inside the company can tap into any conversation on the system and any outside person can monitor every conversation with access from her or his desk.

In the case VoIP technology is used for a remote access location, another type of serious security risk arises because of problems with firewalls. H.323's firewall negotiation mechanisms require direct access into the corporate network, so the company has to open its entire network up to all UDP and TCP traffic. The solution is to use an H.323-aware firewall.

Security is one issue that most companies have take into account when implementing new communication systems and this is a good reason for gradually introducing new technology.

Security Technologies for Wireless Communication

Wireless Wide Area Networks (WWAN)

Mobile Security

Mobile security is inherently different from LAN-based security. The basic demands for privacy (confidentiality), integrity, authenticity, and non-repudiation are even harder, as the range of users is broader than in traditional networks. As security in the mobile world is more complex and different, it needs more advanced network security models. It can state that mobile communication is one of the biggest changes in the security market. Mobile security measures depend on the types of data and applications being mobilized. The more sensitive the data, the more strict security measures must be introduced.

Enterprises must be aware of how traditional security challenges change in relevance in a mobile world. Some special considerations for mobile security include the following:

- **Problem of authentication.** As companies report very high numbers of mobile device theft or loss, simply authenticating the mobile device is insufficient. A process of "Two Factor Authentication" had to be introduced.

This technology is used to verify both the device and the identity of the end-user during a secure transaction (i.e., two-factor authentication confirms that both the device and the user are authorized agents). Two-factor authentication is critical in protecting network integrity from the inevitability of stolen or lost devices.

- **Minimize end user requirements.** End users are impatient when using mobile services. They want access to applications and data immediately and will resist time-consuming accessing tasks. Requiring end users to conduct complex security processes is counterproductive to the purpose of mobile computing, and further exposes the enterprise to security breach. While a successful mobile application will require some user participation, involvement should be restricted to quick, easy, and mandatory tasks. Password-protect enterprise applications, an alternative to power-on password authentication, require users to enter a password or pen-based signature when accessing company content. This is a critical first-step in mobile security procedures.

It is critical that a mobile application supports industry-standard security protocols, including:

- **SHTTP:** This is Secure Hypertext Transport Protocol run on a Secure Socket Layer (SSL).
- **WTLS:** Standard for Wireless Transport Layer Security. This protocol provides authentication and encryption for WAP devices.
- **WPKI:** WAP PKI (used by VeriSign) to maintain security. PKI provides an infrastructure and procedures required to enable trusted partnerships needed to authenticate servers and clients in wireless application environments.

- **Any type of standard encryption technology:** e.g., RSA, Triple DES.

Implement WPKI authentication technology.

PKI, or Public Key Infrastructure, is a protocol-enabling digital certificates on wired devices. WPKI is an adaptation of PKI for mobile devices that meets m-commerce security requirements. Because PKI functions are bandwidth intensive and require processors tuned expressly for PKI operations, using a PKI proxy server allows balancing processing between the mobile device, the mobile application server, and the proxy server.

WTLS. WAP includes the wireless transport layer security (WTLS) specification, which defines how Internet security is extended to the mobile Internet. WTLS is poised to do for the wireless Internet what SSL did for the Internet—open whole new markets to m-commerce opportunities.

There are three steps to the WAP security model:

- WAP gateway simply uses SSL to communicate securely with a Web server, ensuring privacy, integrity, and server authenticity.
- WAP gateway takes SSL-encrypted messages from the Web and translates them for transmission over wireless networks using WAP's WTLS security protocol.
- Messages from the mobile device to the Web server are likewise converted from WTLS to SSL. In essence, the WAP gateway is a bridge between the WTLS and SSL security protocols.

WTLS was specifically designed to conduct secure transactions without requiring desktop levels of processing power and memory in the mobile device. WTLS processes security algorithms faster by minimizing protocol overhead and enables more data compression than traditional SSL solutions. As a result, WTLS can perform security well within the constraints of a wireless

network. These optimizations mean that smaller, portable consumer devices can now communicate securely over the Internet. The translation between SSL and WTLS takes milliseconds and occurs in the memory of the WAP gateway, allowing for a virtual, secure connection between the two protocols.

FLASH-OFDM Security

FLASH-OFDM has ideal characteristics for VPN application. It has broadband speed, low-latency connectivity, authenticated access, and full mobility. As the application of VPN decreases the downlink rate approximately 25-30%, there is enough reserve in the technology. Its end-to-end latency of 35 milliseconds enables the timely LAN-VPN synchronization so critical to the success of the application.

The FLASH-OFDM link layer security can protect the air interface between the wireless device and the network access node. This involves integrity protection, encryption, or both. Also, to address security concerns that affect multiple protocol layers and applications, an enterprise should cost-effectively employ security at the network layer or higher.

Wireless Metropolitan Area Network (WMAN)

Taking into consideration the problems of the WEP in the 802.11 Wi-Fi history, the standardization bodies have prioritized security from the beginning. Therefore, base station designers require a dedicated high performance security processor. The WiMAX standard requires that all traffic must be encrypted with CCMP (Counter Mode with Cipher Block Chaining Message Authentication Code Protocol). CCMP uses AES to provide the encryption for secure transmission as well as data authentication for data integrity.

WiMAX will face the same challenges once certified equipment starts to become available.

Although the 802.16 standards have far greater security functionality built into the base than Wi-Fi did, the perception of their safety will have to be high before they win the trust of enterprise and carrier users. As in the case of other standards, many advances will come from individual vendors, whether as enhancements that differentiate an individual product, or work that may be fed back into the standards process.

There are security processors that have been specially developed for WiMAX offering a suitable encryption and security solution for the evolving 802.16e standard. The symmetric key cores, which include the ability to perform AES-CCM function, perform at 200 Mbps with 1500-byte packets. It is this small packet performance, coupled with the internal 32Kb of memory, that makes the processor ideal for WiMAX base stations by performing the complex encryption/decryption with minimal latency. For multiple-channel base stations a processor can perform AES-CCM with 1500 Byte packets at 275 Mbps.

The best processors are designed for advanced networking applications like virtual private networking (VPN) broadband routers, wireless access points, VPN edge router/gateways, firewall/VPN appliances, and other network and customer premise equipment. Some of them can handle a variety of IPsec and SSL/TLS protocols including DES, 3 DES, AES and public key. In addition to IPsec and SSL protocols, the temporal key integrity protocol (TKIP) and AES counter mode encryption can be also supported.

Wireless Local Area Networks (WLAN)

A user of the wireless network can apply a variety of simple security procedures to protect the Wi-Fi connection. These include enabling 64-bit or 128-bit Wi-Fi encryption (Wired Equivalent Privacy-WEP), changing the password or network name and closing the network. These basic techniques work in both small offices and large corporations. However, additional, more sophis-

ticated technologies and techniques can also be employed to further secure the business network (WI-FI Alliance, 2004).

WEP and other wireless encryption methods operate strictly between the Wi-Fi computer and the Wi-Fi access point or gateway. When data reaches the access point or gateway, it is unencrypted and unprotected while it is being transmitted out on the public Internet to its destination—unless it is also encrypted at the source with SSL or when using a VPN (Virtual Private Network). WEP protects the user from most external intruders, but to reach a more secure connection additional technologies have to be applied, as WEP also has known security holes. There are several technologies available, but currently the VPN works best.

There are other security technologies that can apply for WI-FI. Kerberos—Another way to protect the wireless data is by using a technology called Kerberos. Created by MIT, Kerberos is a network authentication system based on key distribution. It allows entities to communicate over a wired or wireless network to prove their identity to each other while preventing eavesdropping or replay attacks. It also provides for data stream integrity (detection of modification) and secrecy (preventing unauthorized reading) using cryptography systems such as DES.

The Media Access Control (MAC) Filtering—As part of the 802.11b standard, every Wi-Fi radio has its unique Media Access Control (MAC) number allocated by the manufacturer. To increase wireless network security, it is possible for an IT manager to program a corporate Wi-Fi access point to accept only certain MAC addresses and filter out all others.

The RADIUS (Remote Access Dial-Up User Service) Authentication and Authorization is another standard technology that is already in use by many companies to protect access to wireless networks. RADIUS is a user name and password scheme that enables only approved users to access the network; it does not affect or encrypt data.

Because of the extraordinary success and adoption of Wi-Fi networks, many other security technologies have been developed and are under development. Security is a constant challenge, and there are thousands of companies developing different solutions. There are a variety of security solutions that effectively are put on the “top” of the standard Wi-Fi transmission and provide encryption, firewall, and authentication services. Many Wi-Fi manufacturers have also developed proprietary encryption technologies that greatly enhance basic Wi-Fi security.

An important problem is the Wi-Fi Security in public spaces. Wireless networks in public areas and “Hot Spots” like Internet cafes may not provide any security. Although some service providers do provide this with their custom software, many Hot Spots leave all security turned off to make it easier to access and get on the network in the first place. If security is important for the user the best way to achieve this when one is connecting back to the office is to use a VPN. In case the user does not have access to a VPN and security is important, it is better to limit the use of wireless network in these areas to noncritical e-mail and basic Internet surfing.

Individuals and companies that have the need to go beyond basic security mechanisms can choose to implement and combine these basic technologies to increase protection for their mobile workers and their data. As with any network, wired or wireless, the more layers of security that are added, the more secure the transmissions can be.

Wireless Personal Area (or Pico) Network (WPAN)

Bluetooth Security

As Bluetooth is a relatively new technology and attacks on Bluetooth devices at this stage are relatively new to consumers, the attacks are not widely seen as a real threat. But for today it becomes clear that there are sensitive information on both

company and personal levels that can be accessed relatively easily. So, it is important to know what types of information are in danger, how attacks can be committed, and how to fight against them (Gehrmann, Persson, & Smeets, 2004).

By Bluetooth attacks the following confidential data are in danger:

- In the case of mobile phones the entire phone book, calendar and the phone's IMEI.
- Complete memory contents of some mobile phones can be accessed by a previously trusted ("paired") device that has since been removed from the trusted list.
- Access can be gained to the AT command set of the device, giving full access to the higher level commands and channels, such as data, voice, and messaging.

When Bluetooth are included in laptop PCs this raises the possibility of opening a wireless back door into all data stored on the PCs.

The main attack types and their possible results are as follows:

- The "Snarf" attack—It is possible for attackers to connect to the device without alerting the user, and once in the system sensitive data can be retrieved, such as the phone book, business cards, images, messages, and voice messages.
- The "Backdoor" attack allows attackers to establish a trust relationship through the "pairing" mechanism, but ensuring that the user cannot see the target's register of paired devices. In doing this attackers have access to all the data on the device, as well as access to use the modem or internet; WAP and GPRS gateways may also be accessed without the owner's knowledge or consent.
- The "Bluebug" attack—This attack gives access to the AT command set; in other words, it allows the attacker to make premium-priced phone calls, allows the use of

SMS, or connection the Internet. Attackers cannot only use the device for such fraudulent exercises—it also allows identity theft by impersonating the user.

- "Bluejacking" allows attackers to send messages to strangers in public via Bluetooth. When the phones 'pair' the attacker can write a message to the user. Once connected the attacker may then have access to any data on the user's Bluetooth device, which has obvious concerns.
- Phones are vulnerable when they are in "discoverable" or "visible" mode, and the Bluetooth functionality is enabled. Visible mode lets Bluetooth phones find other Bluetooth phones in their vicinity so phone owners can exchange electronic contact information. Users can turn the visible mode off, but some models can be attacked even when a user turns off the visible mode. There are lists of Bluetooth devices on the Internet that give the security level of each device.

RFID Security

When talking about security it should be taken into account that the primary purpose of the RFID technology is the realization of cheap and automated identification. So, standard security mechanisms cannot be implemented because of their relative complexity compared to the limited computing resources of a tag. Cryptography like DES, AES, or efficient public-key protocols is too memory-consuming for low-cost tags.

Recently, breaking tags and disturbing the identification systems became "popular," so the security of RFID systems came into focus. The communication between reader and tag is unprotected in most cases, so eavesdroppers may thus listen in if they are in immediate vicinity. The tag's memory can be read if access control is not implemented. The attacks against RFID systems can be grouped according to which security service is under fire (Knospe, 2004):

- With the exception of high-end ISO 14443 systems, which use message authentication codes (MACs), the integrity of transmitted information cannot be assured. Checksums (CRCs) are often employed on the communication interface but protect only against random failures. Furthermore, the writeable tag memory can be manipulated if access control is not implemented.
- Any RFID system can easily be disturbed by frequency jamming. But, denial-of-service attacks are also feasible on higher communication layers. The so-called “RFID Blocker” disturbs the communication of a reader with all or with specific tags to protect the privacy of consumers.

RFID systems are already used for a large number of applications related to object identification. But, there remain still a number of issues to be resolved. Open technical issues are related to tag orientation, reader coordination, and the relatively short range, to name a few. Furthermore, a number of security and in particular privacy questions are still open. Consumer concerns may form an obstacle to further commercial deployment. Although today sophisticated mechanisms cannot be implemented on a 5-cent tag, a number of proposals exist even for very restricted resources.

INTEROPERABILITY IN SMART ORGANIZATIONS

Importance of Interoperability

There is an extremely big number of different information systems operating in connecting fields all around the world. Many of them are or should be connected to other systems somehow, as data, information, or knowledge exchange would be needed. The speed and reliability of this exchange is also important. Interoperability deals with the

solution of this problem. Interoperability is the ability of two or more systems or components to exchange information and to use the information that has been exchanged (IEEE, 1990).

Interoperability is the capability to provide successful communication between end-users across a mixed environment of different domains, networks, facilities, equipment, and so forth from different manufacturers and/or providers. In this context, the communication is meant between end-users or between an end-user and a service provider.

Interoperability is a real and expensive problem. A study of National Institute of Standards and Technology (NIST, 1999) reported that the U.S. automotive sector alone expends one billion dollars per year to resolve interoperability problems. Half of this cost was spent on data file exchange issues.

With a good solution millions of dollars can be saved. According to a study of NIST (NIST, 2002) with the application of the most widely used component of the STEP (Standard for the Exchange of Product Model Data) standard (ISO 10303-203 ([ISO 1994b], Configuration controlled design) only the transportation equipment manufacturing community saved over \$150 million per year. This figure is expected to rise to \$700 million by 2010.

The STEP standard became so important and popular that an international organization, the International Alliance for Interoperability (IAI) has been founded to make the new results even more effective (IAI, 2005).

Levels of Interoperability

The exchange of data and information can happen in a very wide range. There is a need to give some type of classification. As interoperability is a practical problem and users and enterprises had to solve these types of problems on their own, so the classifications have evolved according to professional fields and communities. Interoper-

ability is about information exchange, so these questions arise when connecting two or more systems. When approaching this connecting activity from the other side, experts are talking about system integration. There are different approaches to integration according to the object and field of integration.

Interoperability can be qualified at different levels in networking (e.g., protocol interoperability, service interoperability). It can be achieved through various types of interworking and interconnection:

1. Network interworking: interactions between different types of networks, end-systems, or parts thereof, with the aim of providing an end-to-end communication for a specific service;
2. Service interworking;
3. Terminal and peripheral interworking and interconnection.

In the field of manufacturing and design the integration of the application systems of the product model, the CAD/CAM systems can be done at two levels (Eversheim, 1991):

1. Data/information integration through data/information exchange between CAD and CAM applications without losing intention, content, and so forth. Tools: IGES, SET, STEP, etc.
2. Functional integration through the communication between CAD and CAM applications. This communication organizes and links the various functional areas. Integrating all aspects of the information involved in a product life cycle into a single shared information model. Tools: product model, manufacturing model, enterprise models.

In case of smart organizations, the three-level integration/interoperability hierarchy can be applied, originally developed for enterprise integration by the AMICE Consortium (AMICE, 1993).

1. Physical, or System Integration

Integration aspects: basic computer communication, message passing, and interconnection. Applied technologies: OMG/CORBA, TCP/IP, Internet/WWW.

2. Application Integration

Integration aspects: distributed co-operative applications, data/information exchange, and application interoperability. Applied technologies: EDIFACT, STEP/PDES, KIF/KQML, HTML.

There are different big projects, development in progress or already finished in this field. In the followings some of them are introduced briefly:

TMF/NGOSS and OMG/MDA

The mission of Object Management Group (OMG) is to help computer users solve integration problems by supplying open, vendor neutral interoperability specifications. The Model Driven Architecture™ (MDA™ is OMG's current strategy in solving integration problems.

The NGOSS (New Generation Operations Software and Systems) architecture of TeleManagement Forum (TMF) is described using technology-neutral constructs. These include concepts taken from RM-ODP as well as extensions to the basic UML metamodel to represent fundamental NGOSS concepts and principles. It does not prescribe a single new technology—rather, it allows for a federation of different technological approaches, each of which offers particular advantages at the business and system levels

Some of the main goals of TMF/NGOSS and OMG/MDA work are to provide benefits through technology neutral architecture; that is, architecture that is sustainable through technology changes, cost effective application integration, such as interworking and interoperability through application of standards (Faurer, Fleck, Huang, Richardson, & Strassner, 2004).

NIIP (National Industrial Information Infrastructure Protocols)

In the case of virtual enterprises, the National Industrial Information Infrastructure Protocols (NIIP) Reference Architecture (NIST, 1998) has been developed for global information exchange and sharing by the NIST. This architecture is one of the most complete realizations of virtual enterprise architectures. It intends to bring together the product realization process integration efforts, by developing general global protocols for the technical standards of product data definition, communication, and object technology and workflow management. The NIIP doesn't intend to develop a new system, but rather apply existing standards to consolidate, harmonize, and integrate the many sets of existing protocols. The main goals of the NIIP reference architecture is to help the establishing and operating of VEs in the industry by applying standardized solutions for VE connectivity, for industrial information modeling and exchange and management of VE projects and tasks. NIIP defines a series of protocols that make the STEP-defined data available as data objects in an OMG CORBA environment.

KIF (Knowledge Interchange Format)

The application of knowledge-based systems become more frequent, so the knowledge exchange and knowledge sharing have an increasing role. In this field, KIF (Knowledge Interchange Format) is a language designed for use in the interchange of knowledge among disparate computer systems (Genesereth, 1992). It has declarative semantics (i.e., the meaning of expressions in the representation can be understood without appeal to an interpreter for manipulating those expressions); it is logically comprehensive (i.e., it provides for the expression of arbitrary sentences in the first-order predicate calculus); and it provides for the representation of knowledge about knowledge.

PIF (Process Interchange Format)

The PIF (Process Interchange Format) serves to exchange process information (Lee, 1994). The goal of PIF is to offer an interchange format that helps automatically exchange process descriptions among a wide variety of business process modeling and support systems, such as workflow software, flow charting tools, process simulation systems, and process repositories.

3. Business Integration

Integration aspects: business process coordination, enterprise-wide knowledge sharing, interworking. Applied technologies: CIMOSA, GERAM, ENV 40003.

AMIS (Automated Methods for Integrating Systems) Project

In the field of manufacturing automation the NIST has started the AMIS project (Libes et al., 2004).

There are three main areas of work in the AMIS project: interaction ontology formulation, semantic mapping, and connector transformation. Interaction ontology formation is concerned with capturing the "business" and "engineering" interaction concerns in a form suitable for reasoning. Semantic mapping pertains to building tools to create semantic maps among ontologies. Connector transformation is concerned with creating generators for dynamic message converters; this will ultimately expand to support dynamic protocol conversion. Efforts in each of these areas must come together to support automation in the integration process.

Systems engineers use a combination of top-down and bottom-up approaches to match business process objectives with component functionality. The AMIS approach is to formalize and capture the information the system engineer uses to perform this matching and then use software-based

reasoning tools to support automation of the integration task.

IMPACTS OF WIRELESS TECHNOLOGIES ON SMART ORGANIZATIONS

Fields of Impacts

According to different studies, the introduction of new ICT to firms can indicate changes generally in organizational structure, in the competitive strategies, and environment (appearance of new products and services). Other studies declare that the introduction of new ICT and the organizational changes are designed to achieve greater productivity and flexibility. The conclusion of the study (Bocquet & Brossard, 2003) is (probably it is the most realistic) that there is no general model how ICT effects a company; the extent, the fields, and type of changes vary from company to company. So, all the impacts introduced in this chapter usually cannot be detected in one enterprise, and impacts not listed here can be found in other cases.

The new networking technologies extend company data, back-end information systems, and e-mail to mobile employees, broadens the accessibility of mission critical data. Mobile access modifies the way workers interact with colleagues, customers, and suppliers.

The possible fields of impact introducing wireless communication systems are:

- organizational structures
- SW and HW elements
- physical elements in administration/production
- human resources
- working environment—office structure, equipments for people, physical env.
- workflow
- business processes

- speed of communication, the validity/availability of information, reliability of communication, security (trust), cost of implementation, cost of reconfiguration (on shop floor level)
- market strategy
- management

Main Impacts

The first big change for enterprise information systems was caused by the application of Internet, the introduction of the global network. The next step forward was caused by the WEB-based technologies and to a lesser extent the mobile technology also has appeared on the scene. The latest effect on organizations (both in structures and operation) is caused by the different advanced wireless technologies. The result of their integration can be really called “cyberspace.”

Mobile technology affects both the structure and the operation of enterprises. The main reasons to develop a mobile solution in the organization can be to provide access to company e-mail and to intranet applications, to develop specific company applications, to keep permanent contact with service workers, to improve work scheduling, and offer possibility for m-commerce.

The interactions among organizations become easier and more transparent. Wireless technologies simplify the processes of maintaining visibility and control over transactions within a networked organization and allow real-time collaboration. The change from wired to wireless technology is probably even harder than the change in the previous cases, as the application of these technologies and means (e.g., mobile phones) alters not only work processes but the social and cultural environments as well.

The listed influences are general ones, as their effects can vary according to the application field (service company, automated manufacturing company using sensors, etc.), size of the organization, the cultural environment, and many other factors.

New Challenges for Smart Organizations

In the following, only the main areas of impacts will be presented.

Impacts on Organization (Structure and Work Processes)

- Organizational structure has to change to flat, open, lean structure with a 24-hour 365-day availability.
- Traditional functional and hierarchical barriers have to be eliminated while supporting teamwork and open access to people and information.
- Clear responsibilities for basic and auxiliary activities.
- The whole organization has to change to customer-oriented—real-time information collaboration among the participants. Benefits: innovative and agile work process.

Impacts on Working Technology

- It is important to separate basic/core activities from auxiliary activities. A basic activity is one that contributes to the competitive advantage of the organization. Auxiliary activities don't contribute directly to the competitive edge (e.g., administration). The right selection and the balance of the two activities are essential for the organization (Sifonis, 2003).
- The significance of team-work is growing.
- Remote meetings of different groups on different levels help collaboration.

Impacts on Information Technology

- Besides standard word processing and spreadsheet applications, groupware technologies are also included which require not only new technical skills but the development of new ways of working.
- Technologies such as shared databases and a calendaring and scheduling tool support

asynchronous group work, networked electronic whiteboard (which allows for shared viewing and manipulation of files between multiple sites), remote video linkages across multiple sites, and desktop conferencing (joint use of a single application running on two desktops) support synchronous group work.

- The different databases have an outstanding role. The various databases encompass routine and non-routine work, and form a kind of glue that holds different groups together.
- Secure communication is a very important demand in a system continuously connected, as in case of wireless networks, so WNs need stronger security as wired systems (e.g., VPN). This enhanced security demand needs modification in system infrastructure and in architecture as well. Other security related services like access right structure and archiving of documents also has to be modified.

Interoperability

The development of wireless technologies is very fast, and there are solutions that did not exist a year ago. These technologies converge data, voice, graphics, and video over a single network, and they allow each member of the network to access them without any space and time limitation. The representation and exchange form all of these descriptions have to be standardized, or else their access would not be possible for the different systems.

Impacts on Human Resources

- For the management, it is important to re-define authorities and responsibilities more clearly.
- Organizing remote meetings on different levels helps to better solve integrated prob-

lems, and these videoconferences also help trust building among the teams and members of the organization.

- For the staff, continuous training is important in order to use the new technology effectively, so for them the motivation for learning is a basic must.

Future Trends in Communication of Smart Organizations

The development and breakthrough of wireless communication is extremely fast, so today it can be seen what happens when a society, economy, and networked communication goes unwired. The application of mobile/wireless equipment of different kinds is dramatically increasing, and new technologies are appearing. The effects of this mobility are also remarkable in working communities and enterprises.

The basic trend in wireless communication technology is the convergence and integration of the different technologies and the efforts to increase the speed of data transmission rates. An additional reason for integration is to extend the coverage; that is, to increase the geographical availability and reach. Finally, the decrease of service costs is a general requirement of the market. Of course, these are visible technical and economical tasks for the wireless technology; in the background huge investments have to be done to realize these objectives that are important for the users.

Some examples of the efforts to increase speed and covered area include the present effort to develop the fourth generation (4G) mobile communication, which will have higher data transmission rates than 3G and are planned to be up to 20 megabits per second (about 10 times faster than top transmission rates planned for 3G mobile) (Gupta, 2004). In principle, 4G will allow high-quality, smooth video transmission. Another result of the developments is the dual-mode GSM/satellite phones that are switching

automatically according to the covered area using the more economic operation mode.

Parallel with the integration of existing technologies, big efforts are invested into the development and standardization of new wireless technologies (e.g., WiMAX, FLESH-OFDM, UWB). The IP-based fixed and wireless broadband technologies can significantly redraw the world of communication.

WLAN and 2.5/3G can be considered as complementary technologies. Wi-Fi offers great bandwidth in close proximity to a base station, but has limitations as users move out of range, and currently there aren't enough Wi-Fi base stations deployed publicly to support ubiquitous access. GPRS technologies like 2.5 can support speeds that beat dial-up from practically anywhere in the network's coverage area—which in most cases is a substantial range. Manufacturers integrate their data connect product with 802.11 technology—in this case, it is a GPRS-based PC Card for laptops and PDAs.

The wireless network of the future will be a hybrid solution of WWAN/WLAN/WPAN (e.g., 3G/Wi-Fi/Bluetooth/UWB), technologies with roaming and billing systems that provide the bridge. This “wireless chain” will offer continuous Wi-Fi coverage in dense metro areas and 2.5G or 3G in more outlying areas (Vaughan-Nichols, 2003). Wireless systems will become pervasive and will exist in a multitude of flavors (sensors, satellites, LANs, PANs, cellular, access, etc.).

Different wireless communication technologies are developing very fast. From a practical aspect this means that their integration will be holistic; that is, the user can move anywhere smoothly, with full broadband availability and without realizing that he or she changes the different types of network. The user's body area network (BAN) moves together like a “bubble” through the space.

This level and type of availability will result in additional changes in society and all sectors of economy. Smart organizations can operate more

effectively with this information infrastructure, unless there will be new production and service organization structures and smart organization will be history only.

In spite of the many positive characteristics and effects introduced so far, mobile communication has negative sides as well; for example, the possibility of tracking services and routes of owners by agencies and competitors and marketers using information from wireless devices. The same can be applied for RFID technology, so it is not suggested to use this technology in certain states because of privacy reasons. A general problem is that wireless communication is more sensitive for illegal wire-tapping and in some cases (e.g., Wi-Fi) the security of networks is not guaranteed when using improper security packages.

Of course, it is impossible to predict exactly the technology developments and the evolution of culture and customer needs, but customers do not really care about which technology is used, but about cost and speed. Indeed, speed, cost, and coverage are what are likely to decide whether one technology will triumph or the other or whether they'll work best for users together.

CONCLUSION

Network-based organizations, like smart organizations, are the main components of the information and knowledge society. The market competition force networked organizations in the direction of continuous change to be able to follow the frequently changing market demands.

These organizations apply ICT very intensively, both for internal and external communication, supporting their cooperation in order to react flexibly to changing business environment. As wireless information and communication technologies make their operation more effective both in the fields of production and finance, the competitiveness of networked production systems is increased through wireless networks.

The infocom systems applied by the companies have their human part (users) as well, so the importance of trust is increasing very quickly. As it is pointed out by different analyses based on real-life statistics, when users do not trust an IC system or service they do not use it. Security services partially provide this trust for the users, while the human side of trust depends on the media of communication, the structure of interfaces, and on the duration of contacts. The organizations have to adapt their IC systems to these requirements as well, even by slightly changing their culture or organizational structures.

The different types of wireless communication technologies originating from their openness and flexibility will be always a security risk. The managers of information technology have to adapt those technologies, tools, and devices into their systems that can induce high trust-level in all humans involved in different levels of the smart organizations.

The new generations of networking technologies, the different types of wireless communication systems make significant changes not only in the operation of networked-based organizations, but in the cultural and social environments as well. The paper introduced briefly the main groups of wireless networks and their effects on networked organizations. The main conclusion is that the wireless networking technologies can cause remarkable modifications in the structure, in the operation, in the collaboration techniques, in the cost structure, and in business processes of any type of organizations, so their application has strategic importance for all types of companies.

Chapter 3.38

Foreseeing the Future Lifestyle with Digital Music: A Comparative Study between Mobile Phone Ring Tones and iPod

Masataka Yoshikawa
Hakuhodo Inc., Japan

ABSTRACT

This chapter aims to explore the future trajectory of enjoying digital music entertainment among consumers comparing the characteristics of the usage patterns of digital music appliances in the U.S. and those in Japan. As the first step of this research, the author conducted two empirical surveys in the U.S. and Japan, and found some basic differences in the usage patterns of a variety of digital music appliances. Next, a series of ethnographical research based on focus-group interviews with Japanese young women was done and some interesting reasons of the differences were discovered. In Japan, sharing the experiences of listening to the latest hit songs with friends by playing them with mobile phones that have the high quality, ring tone functions can be a new way of enjoying music contents, while hard-disk music players like iPod have become a de facto standard of the digital music appliances in the world.

INTRODUCTION: CENTRAL QUESTIONS

The November 2001 debut of iPod and the subsequent opening of iTunes Music Store have brought a rapid expansion of the digital music market around the world. Some estimate that the market will be worth \$1.7 billion dollars by 2009 (Jupiter Research). Now, iTunes Music Store service is available in 30 countries around the world, with the total number of downloaded songs surpassing the 500 million mark in July 2005.

The store only opened in Japan in August 2005 and sold over 1 million songs in the first 4 days. This is an astonishing achievement, considering that Japan's largest online music store Mora has monthly sales of around 450,000 songs. In March and April 2005, SONY, which has long led the portable music player market, released a new digital music player under the Walkman brand, offering both the hard disk type and USB

flash memory type to launch a marketing drive against iPod. The developments have finally begun to provide Japanese music lovers with an environment whereby digital music contents are broadly enjoyed in terms of both services and hardware devices.

One of the major characteristics of Japan's digital music market has been the presence of digital music contents for use on mobile phones. The use of digital music contents on mobile phones, which started as regular ring tones, has gradually evolved into Chaku-uta® (true-tone ring tones) by December 2002, and to Chaku-uta Full™ (mobile-phone-based music distribution service launched in December 2004 by the mobile carrier "au"). Chaku-uta® and Chaku-uta Full™ have sold over 100 million songs and 10 million songs respectively, making the digital music service the largest segment in mobile-phone content services.

The environment for enjoying digital music content is set to expand even further into the future. How would such a development affect the way Japanese music fans listen to music in general? This paper examines future ways of enjoying digital music content in Japan, and the competition between music players like iPod for use with personal computers and mobile phones that have adopted the usage as music players.

JAPAN'S DIGITAL MUSIC CONTENT MARKET AND THE PROLIFERATION OF MOBILE PHONES BEFORE 2005

Firstly, let us examine past developments of the digital music content market in Japan. Japan's first digital music distribution service started in April 1997. A company called MUSIC.CO.JP began offering songs mainly from independent labels. Coinciding with the launch of numerous music download services in the U.S., a number of online music Web sites opened one after another, orches-

trated by individual artists and record labels. In December 1999, SONY Music Entertainment became the first major record company to start an online music store bitmusic. Toshiba EMI, Avex Records, and other major companies followed suit. Yet, since early 2005, the system for online distribution of digital music contents has been underdeveloped, as can be seen in the fact that Mora's supposed largest online music catalog in Japan contained just 100,000 songs, as opposed to iTunes Music Store's lineup of 1 million songs upon its launch in August in Japan.

There is no denying that mobile-phone-related music services have been the driving force of the nation's digital music market. The launch of the i-mode service by NTT DoCoMo in February 1999 marked the start of digital content downloading services via mobile phones. The connection speed of 9600bps in those days made it, initially, difficult to distribute songs in high audio quality. Faced with the adversity, businesses began offering Chaku-melo music ring tones, instead of distributing actual music contents, achieving dramatic growth. The Chaku-melo market has rapidly expanded to 80-90 billion yen in 2002. What makes this development unique was the fact that this service was initiated not by record companies rather by major online Karaoke service providers like GIGA and XING, computer game companies like SEGA, and other companies operating in the peripheral areas of the music industry itself. The market size of 80-90 billion yen as of 2002 is among the highest of all mobile-related digital content services, proving the market-led proliferation of digital content services for mobile phones.

Amidst the flourishing success of the Chaku-melo market, supported by peripheral music businesses, record companies that lead the music industry initiated a move to provide the Chaku-uta® service, offering true-tone music as ring tones, instead of Chaku-melo MIDI-based ring tone melodies. The service was initially started solely by Japan's second largest mobile carrier au

in December 2002. While the Chaku-melo service was employed by all mobile carriers rapidly, the Chaku-uta® service was not adopted by the industry leader NTT DoCoMo until February 2004 and by the number three mobile carrier Vodafone until March 2004. However, the service picked up substantial support from younger generations. As the preceding proliferation of the Chaku-melo service had already familiarized mobile phone users with the concept of *obtaining music over mobile phone*, Chaku-uta® sales reached 100 million songs by July 2004, and surpassed 200 million songs by April 2005 to establish a market of substantial scale. Record companies joined forces to establish Label Mobile, which currently provides around 300,000 songs, approximately three times the catalog size of computer-based online music stores.

After Chaku-uta® came the Chaku-uta Full™ service, which provides whole songs as ring tones to become a de facto digital music store over mobile phones. It reached its fifth million download in April, just 6 months after its launch in October 2004. The cumulative total of downloaded songs reached 10 million in June, causing a dramatic expansion in market size. Although the number of songs available remains smaller than Chaku-uta® at 37,000, the catalog is expected to keep on expanding.

As described thus far, the digital-music-content industry has rapidly mushroomed as one of mobile phone services, but it has been less than 1 year since a full-scale music distribution service (Chaku-uta Full™) was launched. Music has been merely distributed as an additional function to mobile phones, that is, the ring tone. Consumption has been initiated by mobile phone use, instead of music itself. In other words, an explosive proliferation of a new communications device called mobile phones, has triggered the consumption of digital music content as a natural course of evolution. Amidst this situation, a series of dedicated digital music players called iPod has emerged with major success, triggering the launch

of the iTunes Music Store offering downloads of digital music content. With the development of a fully fledged environment for computer-based consumption of digital music contents, what has been the course of competition between different types of devices in today's digital music content market? Let us examine the overview based on the results of a quantitative survey.

TODAY'S DIGITAL MUSIC CONTENT MARKETS: JAPAN AND U.S. MARKETS

In order to grasp the state of today's digital music content market in Japan, we have simultaneously conducted a survey consisting of identical questions for use in both Japan and the U.S. Results from the two countries were compared against each other in order to identify characteristics of the Japanese market. The survey was titled *Survey on Digital Contents*, and the survey period it ran online was between February and March 2005.¹ The following samples were included: Japan, N=677 aged 15-59 and in the U.S., N=700 aged 18-59.

First, let us take a look at the rate of music-terminal use in the two countries: 6.9% of Japanese respondents used hard-disk music players like iPod, whereas the ratio was almost double at 11.5% in the U.S. The ratio of people using USB flash-memory music players was 7.2% in Japan and 16.1% in the U.S., more than double the Japanese figure. However, the ratio of those using mobile phones as music players was 19.8% in Japan, nearly three times the U.S. result of 6.1%. These figures demonstrated a clear tendency of U.S. users opting for hard-disk or flash-memory devices with music transferred via computers, and Japanese users choosing mobile phones to listen to music.

Next, the survey examined how samples typically downloaded digital music contents: 28.9% of U.S. respondents have downloaded music via

computer, over 10 percentage points higher than the Japanese ratio of 17.4%. On the other hand, 42.2% have downloaded music (music ring tones) over mobile phones in Japan, around three times the equivalent U.S. figure of 14.2%. The ratio of people who have downloaded true-tone ring tones was 20.4% in Japan, an astonishing lead of around seven fold compared to the U.S. result of 3.0%. The clear tendency of computer orientation in the U.S. and mobile phone orientation in Japan, observed in the choice of music-playing terminals, was also evident in terms of the practice of music downloading.

As explained in the previous section, these findings are a natural outcome reflecting how the digital-music-content market emerged and established itself around mobile phones from the early days in Japan in contrast to market development that evolved around computers and the Internet in the U.S. However, there is some interesting data—the survey asked those who do not own a portable digital music player which type of device they would like to possess. The results indicated almost identical tendencies between Japanese and U.S. respondents, unlike the stark differences they demonstrated in previous questions. Those who intend to purchase a hard-disk music player accounted for 26.7% in Japan and 26.1% in the U.S. The figures for flash-memory players were also very similar at 21.4% in Japan and 21.7% in the U.S. Finally, the ratio of those using a mobile phone as a music player is 5.3% in Japan and 3.0% in the U.S. Even though the Japanese figure is slightly higher than the U.S. figure, they can be viewed as almost at the same level, in comparison to the ratio gaps observed in other questions.

This data demonstrates a strong contrast to previous data, which showed a noticeable computer orientation for the U.S., and mobile phone orientation for Japan. In both countries, purchase intention appears higher for computer-based music players based on either hard disk or USB flash memory, and relatively low for mobile phones doubling as music players.

Until now, Japan's digital-music-content market has been characterized, in terms of hardware, with proliferated use of mobile phones, as opposed to the U.S. market where more users download music via computer. However, as the results of the aforementioned survey suggest, computer-based music players will be used increasingly for the consumption of digital music content, in addition to mobile phones, in the future Japanese market. Then, what changes will emerge in consumer's music playing styles when such hardware competition (spread of computer-based music players) evolves?

FUTURE STYLE OF DIGITAL MUSIC LISTENING IN JAPAN: OVERALL TREND

We have projected future changes in the style of digital music listening in Japan, dividing the samples of the aforementioned survey into the following three groups and comparing the profiles, music listening styles, and mentalities of the current and future users.

1. Current digital music content users—Those who own hard-disk/USB flash-memory music players N=42.
2. Digital music content potential users—Those who intend to purchase hard-disk/USB flash-memory music players N=307.
3. Nonusers of digital music contents—Those excluding the above two groups N=319.

We made a particular comparison between current digital music content users who have constituted the computer-oriented digital music market, and digital-music-content potential users who intend to join the market from now, so as to identify how the listening style of this market is likely to change, and what impact such changes will have on the market, which has evolved through downloading by means of mobile phones thus far.

First, we compared samples' demographic profiles and basic indicators in music consumption.

Gender Comparison

Current digital-music-content users mainly consist of men, accounting for 66.7%, as opposed to women at 33.3%. Digital-music-content potential users have a more even gender distribution, consisting of men and women at respectively 54.4% and 45.6%. Nonusers of digital music contents have a greater proportion of women at 58.4%, compared to men at 43.6%.

Comparison by Gender and Generation

The generation factor was then incorporated to characterize the three groups more clearly. Among current digital-music-content users, men in their 20s claimed the largest proportion at 29.6%, followed by women in their 20s at 23.8%, and men in their 30s at 16.7%. These three groups alone represent over 70% (70.1%), indicating that digital music content is primarily enjoyed among younger people—both men and women. In comparison, among digital-music-content potential users, men in various age groups accounted for around 10% each, that is, men in their 20s at 11.1%, men in their 30s at 10.7%, men in their 40s at 15.3%, and men in their 50s at 11.7%. Women in their 20s and 30s also represented, around the same proportion, at 11.4% and 8.5% respectively. Compared to current digital-music-content users, there is a more even distribution of age and gender groups. As for nonusers of digital music contents, women in the middle to high age groups made up over 40%, including women in their 30s at 14.7%, women in their 40s at 12.3%, and women in their 50s at 16.3%. The data analysis incorporating generation factors highlighted distinctive characteristics among the three user categories.

Comparison of the Number of CDs Owned

When asked how many CDs they own, 18.7% of current digital-music-content users said 50 to 99, followed by 23.8% owning 100-199 CDs and 11.9% owning over 200 CDs. These three groups represent over 50% (54.4%). Among digital-music-content potential users, 18.2% own 0-9 CDs, whereas those owning 10-19 CDs, 20-29 CDs, and 30-49 CDs accounted for 14.0%, 13.7%, and 16.3% respectively. Combined, over 60% (62.2%) owned less than 50 CDs. Almost 70% (69.8%) of nonusers of digital music contents also own less than 50 CDs, broken down into those with 0-9 CDs, 10-19 CDs, 20-29 CDs, and 30-49 CDs at respectively 31.7%, 14.7%, 12.2%, and 11.6%. As the figures show, current users have a large proportion of people with a substantial CD collection, whereas nonusers have a large proportion of people with limited CD ownership.

Comparison of Monthly Music Spending

Similarly to the former, the ratio of those spending over 3,000 yen (equivalent to the cost of one CD album) per month was 61.8% among current digital-music-content users but less than 40% (39.1%) among digital-music-content potential users. Over 70% (75.9%) of potential users spent at least 1,000 yen (equivalent to the cost of one CD single) per month. Nonusers of digital music contents demonstrated a similar tendency to potential users, with 28.8% spending over 3,000 yen, and 66.1% spending over 1,000 yen. As the figures indicate, current users have a large proportion of people who spend more on CDs, whereas nonusers have a large proportion of people who spend less on them.

Summarizing the results thus far, current digital-music-content users are mainly young men and women in their 20s, with substantial CD

ownership and high music-related spending per month. They can be described as *music fans* with substantial music-related consumption. Potential users of digital music content, who are expected to enter this market, are distributed across both genders and broad generations, from youth to those in middle age. They are characterized as middle-level users in music consumption. Nonusers of digital music content are mainly women in higher age groups, with relative inactiveness in terms of music consumption. The results illustrate clear differences in demographic characteristics and music consumption behavior. There are major differences between consumers who have bolstered the computer-based, digital-music-content market until now, and those who will support the market from now on. These facts alone point to the possibility that the current market is set to undergo substantial changes in its nature. In order to examine details of anticipated changes, we have compared the three groups in their attitude and mentality in listening to music.

Formats of Music Ownership

Of current digital-music-content users 61.9% acknowledge the desire to store all of their CD collection on the computer, a significantly higher ratio than digital-music-content potential users at 26.7% and nonusers of digital music contents at 17.2%. Current users appear to have a strong desire to manage their music by computer and use computers as the main device for handling music content. In comparison, such desire is not as strong among the other two groups.

Intention Regarding Songs Available for Downloading

Next, in order to examine the number of songs that are available for downloading, we looked at whether people want a greater selection from download services via computer or those via mobile phone. When asked whether the number

of songs downloadable via computer on the Internet should be increased, 45.2% of current digital-music-content users said “yes,” much greater than 30.0% among digital-music-content potential users and 15.0% among nonusers of digital music content. As for whether they want to see the number of songs available via mobile phone increased, just 7.1% of current users agreed, whereas the ratio was more than double at 15.0% among potential users, and 9.7% among nonusers. Although with not as stark a difference as the last paragraph, these groups clearly demonstrated different preferences in catalog enhancement between downloading services via computers or those via mobile phones. In short, current users want to see enhancement of the computer-downloadable catalogs, while potential users want enhancement of mobile-phone-based catalogs just as much as of computer-based catalogs. The results, once again, indicate a strong preference among current users on computer-based services. In comparison, potential users are requesting catalog enhancement to both computer-based and mobile-phone-based services. In other words, potential users and nonusers wish to use both computers and mobile phones to listen to music rather than mere computers.

Style of Using Songs

We also asked several questions on how people wish to use songs they own. Of current digital-music-content users 35.7% said they want to store all CDs they own on a computer and edit them, for example, compiling a collection of favorite songs. The ratio was 22.5% among digital-music-content potential users and 11.0% among nonusers of digital music contents. These figures again confirmed the computer-oriented style of current users and highlighted another of their characteristics, that is, actively using downloaded songs for their personal enjoyment. This characteristic became even more evident in the next question.

Foreseeing the Future Lifestyle with Digital Music

People were asked whether they like to compile a collection of songs from CDs they own according to specific themes and use the original CD as a gift for friends on a suitable occasion of some sort. Of current users 11.9% said “yes,” whereas the ratio was 15.3% among potential users and 6.0% among nonusers. A greater proportion of potential users expressed preference to this style than current users.

The third question was on whether they wanted to burn their favorite songs on CD-R or DVD more casually to give away to friends and acquaintances. The results showed a similar tendency to the results for the second question. Of current users 7.1% agreed, while the ratio among potential users was greater at 12.7%. Even nonusers had a greater proportion at 9.1%. Looking at the results to these three questions, current users have a self-contained approach in enjoying music with a preference to downloading via computers, whereas potential users are more inclined towards exchanging and distributing music with others.

Finally, we asked whether they wanted to give away or exchange songs, downloaded via mobile phone, to friends over the mobile phone. Again, only 7.1% of current users, who have the preference to computer-based song purchase, agreed to the concept, whereas the ratio was greater among potential users (9.1%), with even nonusers reaching the same level as potential users (8.8%). All the numbers point to the computer-oriented and self-contained nature of current users, and the potential users’ tendency of combined computer and mobile phone use and a strong inclination towards distributing and exchanging songs.

When these analysis results are combined with the demographic characteristics and basic indicators in music consumption, current digital-music-content users can be defined as those with a strong computer preference, wishing to use digital music content for their personal enjoyment in a self-contained approach. In contrast, digital music content, potential users who are entering the

market from now, are combining computers and mobile phones for this purpose and are inclined towards enjoying music with others in addition to appreciating it by themselves. This group has a particular tendency of using music as one of the tools for communicating with other people around them.

Let us take a closer look at the results to enable us to explore the direction of how Japan’s digital music market may change, while reflecting upon the trends of both hardware and people’s music listening styles.

The digital-music-content market in Japan originally evolved from the distribution of mobile phone ring tones. Then, music content was merely one of the functions or menus available in using mobile phones. They did not go beyond the ring tone boundary. Amidst this situation, the market embraced the emergence of a new type of music device that contains a hard disk or USB flash memory, designed to be used with a computer. Contemporary music fans were among the first to adhere to such devices, consisting of men and women in their 20s that are most active consumers of music. They stored and managed all music content they already had in a computer, thereby converting them into digital content, and began carrying songs in portable music players and in so doing they were enjoying music for themselves in a rather self-contained fashion.

Today, digital music content that takes the form of mobile phone ring tones exists alongside digital music content that can be carried on hard-disk or USB flash-memory music players. We have investigated the future course of the market in view of the profile and music mentality of potential users of digital music content, who are making a full-scale entry into this market in the future. Future users will be combining computers and mobile phones, and, unlike contemporary users, enjoying music as both a communication tool with others and for personal entertainment purposes. Digitizing music contents gives music a new function as a communication promotion factor,

in addition to the current functions as ring tones and personal enjoyment.

In order to further clarify this new style of enjoying digital music content, we conducted an oral qualitative survey on two groups, that is, current iPod users who represent those enjoying digital music content via computers, and Chaku-uta® and Chaku-uta Full™ users who represent those enjoying digital music content via mobile phones. The survey clarified their styles in listening to digital music content, so as to obtain an insight into the future direction of music-listening styles.

FUTURE OF THE DIGITAL MUSIC CONTENT MARKET IN JAPAN: CHANGES IN MUSIC CONTENT CONSUMPTION

The *Survey on the usage of iPod and Chaku-uta®* was conducted in the period between December 2004 and February 2005. In-depth interviews were held with three male and female iPod users in their 20s and 30s, and with three male and female Chaku-uta® Mobile users in their 10s and 20s.²

Comments From iPod Users

What follows are typical comments made by iPod users on their style of enjoying music:

I find the Random Play function to be very refreshing. I can 'rediscover' songs on CDs that I did not pay much attention previously. [...] I can store a lot of songs without having to worry about how much space is left. Now, I am storing whatever songs I have, even ones that I would skip if I am playing it on CD. [A 37-year-old man who has used iPod for 1.5 years, SOHO, 6,000 songs are held]

I now realize how much I have restricted myself with frameworks of genres and artists when listen-

ing to music. The Shuffle function highlights the raw power of individual songs. [...] Occasions like that have broadened the range of music genres I listen to, making me feel like trying out CDs I would never have dreamed of listening to before. [26-year-old woman who has used iPod for 1 year, office worker, 1,500 songs are held]

I never used to carry music around, but now I do not go anywhere without my iPod. This has widened the variety of occasions I listen to music, for example, while on a train or on the way home after a drink. [...] There are times when a song I frequently listened to on CD sounds very different on a portable player, because of various situations you are in at the time. That gives me fun. [39-year-old man who has used iPod for 6 months, office worker, 700 songs are held]

As suggested in the results of the quantitative survey, they typically—to some extent—have a self-contained approach in music entertainment. Their remarks illustrate new ways of enjoying music (consumption styles) they have attained through hard-disk music players like iPod. For them, a hard-disk music player is a device that allows them to randomly enjoy music out of a greater selection of songs than previously possible in conventional devices (cassette player, MD player), loaded from their CD collection. A hard-disk music player is a true portable music player strictly for personal use. In order for the device to be self-contained, it must be able to carry a massive number of songs, which in turn, facilitates random playing. This random playing then releases listeners from the boundaries of existing music context (by genre, by artist, etc.) and invites the creation of new contexts, thereby enhancing the self-contained nature even further. They are enjoying music in this cycle.

For them, consumption of music content is not about listening to each individual song, but about enjoying a stream of music. It must always be a fresh string or stream of music different from

what they have already experienced previously. Their consumption of digital music content is characterized as *self-contained context consumption*. This is an emergence of a new style of music consumption, only possible for hard-disk music players like iPod. The style is facilitated with the concept of *play list* in iPod and other devices. The ability to compile a new string or stream of music, has diluted the concept of *album*, presented conventionally from package providers and artists as producers, and encouraged individual users to compile their own music streams. Consequently, music is increasingly evaluated on the merit of each song. One example is the way iTunes Music Store presented its proliferation scale in the unit of individual songs downloaded, rather than albums. This kind of presentation appears to depict a transition of mentality, with listeners focusing more on individual songs, rather than embracing the supplier-defined unit of *album*.

The following comments are derived from Chaku-uta® Mobile users on their style of enjoying music:

During a break time at work, I just leave my mobile phone to play songs to provide some background music. [...] They are all songs that everyone knows, and will not trigger any music talk. However, it is better than having no music, and stimulates conversation. [...] I don't mind if each song may be just 30 seconds long. It is actually better to have short tunes to enjoy them with my colleagues and build up a lively atmosphere. [25-year-old man who has used Chaku-uta® Mobile for 6 months, office worker, 10 songs are held]

I like upbeat Techno music. I use these types of songs as Chaku-uta, and play them during break time when my friends are around, so that I can show them how to dance to the tunes. [...] The other day, I had my mobile hanging around my neck, and playing Chaku-uta, as I danced across a Shinjuku intersection with my friend. [21-year-old woman who has used Chaku-uta® Mobile for 6 months, university student, three songs are held]

I might listen to and check out music with my friends, but I am more likely to use it as the Sleep Timer when I go to bed. [...] I can operate it by hand, and put it on charge at the same time. It is very convenient. [...] I don't care about (each song being the ring tone length of 30 seconds and) not having the complete song. I fall asleep as I listen to the same songs repeatedly. [19-year-old woman who has used Chaku-uta® Mobile for 1 year, vocational school student, five songs are held]

The analysis of the quantitative survey results also indicated that persons entering the digital-music-content market from now use *both computer-based music players and mobile phones*, and use music to enhance their relationship or communication with their friends and acquaintances instead of merely enjoying music by themselves. Comments from Chaku-uta® Mobile users substantiate the tendency, that is, using music as a tool for sharing various occasions with friends.

As part of the quantitative survey described earlier, people were asked how they use ring tones and Chaku-uta® on mobile phones. The top three answers were as “ring tones (87.3%),” “alarm clock (60.4%),” and “other alarm sounds (46.3%),” The fourth highest ranked answer, however, was to “enjoy them alone as music” (44.0%), and 41.7% said they “enjoy them together with friends or use them to entertain others”—as such indicating that people are beginning to enjoy mobile-downloaded tunes as stand alone songs with friends.

What can be noted in these comments is that songs are enjoyed in the ring tone length of 30 seconds, rather than in their entirety, which is quite different to that of hard-disk music player users, who consume a massive amount of randomly replayed music in various contexts. Their consumption style is summarized as “sharing the occasion of playing popular songs, rather than personal favorites with others to magnify enjoyment.” What counts is how good each NETA (=song as conversation topic) is, rather than how many songs you have in store. Their consumption

of digital music content is characterized as “NETA consumption to be shared among friends.” For them, Chaku-uta® Mobile is perceived as a “music player that plays 30-seconds of everyone’s favorite songs for a shared experience.” The emergence of a new service called Chaku-uta® has brought about this new style in music consumption, while now, the style seems to transform formats of music content.

CONCLUSION

As we have examined, Japan’s digital-music-content market—which started off with the distribution of ring tones as one mobile phone service—has embraced the arrival of fully fledged digital music players and online stores, both designed to be used via computers, such as iPod and iTunes Music Store. From the viewpoint of hardware competition, the market has now entered a stage of combined development of mobile-phone-based devices and computer-based devices. It has brought about two contrasting consumption styles with distinctive characteristics (computer-based and mobile-phone-based consumption of digital music content), and diversified people’s styles in enjoying music at the same time.

People who use a computer-based means to enjoy digital music content, have a self-contained style of consuming music in a specific context, loading a hard-disk music player with a greater amount of music from their personal CD collection than previously possible and enjoying songs in random order. In contrast, people who use mobile-phone-based devices, employ a mobile phone as a communal music player for playing 30-second tunes of high popularity and consume music as topics (information) for sharing various occasions with friends or enhancing the atmosphere.

At present, these styles are separate tendencies and can be observed among users of hard-disk music players and users of mobile phones as music players as two extremes. However, a steady

proliferation of hard-disk or USB flash-memory music players may cause these styles to merge on the side of individual users. Competition between two types of devices has created two distinctive styles of listening to music. Now, each user may start using both of these devices at the same time, hence adopting both styles alongside each other. Such a user may eventually begin to seek both of the styles in one of the two types of devices, which may amount to hardware integration, brought about by the symbiosis of the two different music-listening styles. Closely paying attention to consumer behavior and practices in the future will then give way to rich empirical data to be used to develop and elaborate the stream of thought outlined in this study further.

Chapter 3.39

Screening in High Standard: Innovating Film and Television in a Digital age through High Definition

Bas Agterberg

Utrecht University, The Netherlands

ABSTRACT

This chapter introduces the innovation of television by looking at the development of high definition television (HDTV). It argues that the way that the interaction of technological, industrial, and political actors has been crucial in several stages of the development of this innovation. Central question is how industry, broadcasters, and consumers have debated and defined a medium and consequently redefine a medium through innovations. The complexity and the way actors have played a part within the changing media environment is analyzed by looking at the necessity for technological change of the television standard, by relating the media film and television in transition from analogue to digital and by studying case studies of political debates and policy in Europe and the United States.

INTRODUCTION

As a domestic medium, television has basically not changed since the 1950's. The programming, the way of viewing and the technological quality of the image all suggest that the medium's history is a stable one. The major changes have been the introduction of colour in the 60's and cable and satellite in the 80's, offering more channels. The VCR influenced the viewers' possibilities for time shifting. Despite these changes William Uricchio (2002) argues that the applications, cultural status and our assumptions regarding the medium have hardly changed over the past half-century. Digitalisation has offered new possibilities for the medium, but so far consumers have hardly adopted digital television. One of the developments associated with Digital Television (DTV) has been the innovation of the television screen in High Definition Television. This chapter explores

aspects that have affected the so far unsuccessful implementation of HDTV.

The way in which innovation of a medium is promoted often resembles the discourse that was used with the introduction of a previous medium; in the case of Digital TV it's for instance radio and television. William Boddy (2004) argues that the digital moving image has been celebrated within "compelling imaginary scenarios of work and leisure, identity and community" (p. 1). Obviously the cultural and economic stakes in the transition from analogue to digital should be considered by looking at the way the media have been anticipated, debated and taken up by the industry, politics, and audiences.

Technology has to be considered as a cultural construct, so it is essential to look at the way that medium has developed. In terms of television this means how industry, broadcasters and consumers have debated and defined a medium and consequently redefine a medium through innovations.

Within this context the introduction of High Definition Television offers a compelling case study for the pattern in such a technological innovation. The changing media environment is studied by looking at the necessity for technological change of the television standard, by relating the media film and television in transition from analogue to digital and by studying case studies of political debates and policy in Europe and the United States.

DEVELOPING THE HIGH STANDARD

The process of defining a standard for the television image at the beginning of the medium shows the complex interaction of different actors involved in television technology.

The standard for the black and white television image has been set in the 40's and 50's and for colour in the 50's and in the 60's. Andreas Fickers (2004) argues that in the process of standardisation three actors or terrains were active,

the technological, the industrial and the political. The standardisation of the television image has an important political dimension. The difference in the development of colour television in the US and Europe is exemplary for this process. In the U.S. the Federal Communications Commission (FCC) already forced the television industry in 1948 to develop colour TV by freezing the granting of frequencies for television. In 1950 the National Television Committee (NTSC) was founded to create a colour television standard compatible with black and white. In cooperative research of the American radio and television industry an electronic and compatible system was developed within three years. The FCC made the NTSC, with 525 lines, the U.S. standard of colour TV in 1953. In Europe however the black and white television standard was still debated in the beginning of the 50's. Colour would not be introduced until the 60's. The different European countries—Britain, Germany and France—had different standards, PAL (625 lines) and SECAM (819 lines). National interests were more important than the European interests at that moment. The international authorities and organisations such as the International Telecommunication Union (ITU), founded in 1865, and the International Consultative Committee for Radio Transmission (CCRT) did not have the authority to prevent the different standards. As Andreas Fickers (2004) concludes, the decision remained a national one. The choice for a television standard could not be made on the basis of quality of the picture and thus became a political and industrial decision. For the industry the prospect of a reasonable share was better than ending up as the "losing" system. The introduction of two standards of colour television in Europe in 1967 was the result.

The world standards of television are still NTSC (525 lines), PAL (625) and SECAM (625). The digitalisation of media technology makes the improvement of the quality of the screen only a matter of time. However, the development of so called High Definition Television started decades

ago and what seems to be a matter innovation of the quality of television has become an interesting case to show the effects of the transition from analogue to digital, in terms of the changing roles of industry, global politics, of broadcasters and the convergence of different media like television, film and computer.

DEFINING A NEW STANDARD

The Japanese public broadcaster NHK worked on a new television standard since 1968. The idea was to design a system of 1125 lines and a wide screen ratio of 16:9. The necessity for research seemed a bargaining strategy of NHK, according to Winston (1998) it was tradition to use technological advances such as colour or teletext for the renegotiating of the domestic television licence fee level with the Japanese government.

When NHK presented the new HDTV system at international meetings, the quality of its images was admired, but the innovation was observed with suspicion.

During the meetings of the CCRT in 1983 in Algiers a worldwide standard for HDTV was mandated. Three years later, in 1986 at a meeting in Dubrovnik HDTV was put on hold. Technically it was the incompatibility with the existing television standard that was considered a problem by many countries. Yet more important was a socio-economical fear for a Japanese take over that led to a hold.

By putting the world standard for HDTV on a hold in 1986, Winston (1996) slows down the process of innovation, because of fear of losing a market share. It was not the technology, but the economic stakes that suppressed the potential of HDTV (p. 94). This period can be considered the first phase in the development of HDTV.

Technologically the HDTV of the 80's was far from perfect. Although most of the technical problems could be solved within the near future, it was an analogue system in a digitalizing world.

The signals of High definition require a lot of bandwidth, which means that consumers would only get one fifth of the number of television channels. It was however the digital High Definition could use compression techniques to solve this problem.

Most important was that in the 80's the infrastructure was not equipped to deliver HDTV. Therefore in the early stage HDTV was no competitor for film or television in production, distribution or exhibition. It was however promoted as a challenge to the existing concepts of film and television. It was believed that HDTV would change both media fundamentally.

The introduction of HDTV in the 80's has to be considered within a broader range of changes. William Boddy (2004) argues that the new TV delivery systems of cable and direct broadcast satellites, the ongoing consolidation of the telecommunications and computer industries, the international trend toward broadcast deregulation, and the growth of significant new transnational entrepreneurs all point to the late 1980s as the beginning of a period of the greatest change in global television since the decisive growth of international television in the second half of the 1950s. HDTV can thus only be understood in an international context in which the infrastructure and political deregulation play a crucial part in the development (Berghaus, 1994).

INNOVATING AUDIOVISUAL MEDIA

The objective for improving the quality of the image was to achieve an electronic equivalent 35mm film. If the television screen equals the cinema, how does it affect the film industry in terms of production, distribution and exhibition?

Francis Ford Coppola claimed he would never make movies on 35mm again after shooting *One from the Heart* in 1981 with Sony's HDTV equipment (Winston, 1996). Coppola's film failed, costing him his Zoetrope studio and he continued making films on 35mm.

Film industry has in general responded conservatively to digitalisation. Brian Winston (1996) shows in *Technologies of Seeing* that Hollywood responds conservatively to innovation by analysing the way in which Hollywood responded to colour film, 16mm film and HDTV.

In film production nowadays, digital techniques such as video assist for instant reviews of what is shot on film during production on the set, editing and creating visual effects in postproduction are in general use. The shooting and exhibition have remained analogue in a 35mm standard. Some films used the video camera as an aesthetic choice, such as *The Blair Witch Project* (1999) or the Danish DOGMA 95 films. In the case of *The Blair Witch Project* the documentary look, the suggestion that the depicted events actually took place, was also used for a new way of promoting the film through the Internet. Despite specific use of new technologies, these examples do not differ much from traditional ways of producing and releasing a film.

High Definition however offers the possibility to change cinema fundamentally. In shooting a digital file would replace the vulnerable celluloid. Exhibition would even be possible through satellite, involving no material at all. Costs would especially be reduced in distribution and exhibition. How have different actors play a significant part in a possible change to digital cinema so far?

Both film and television are considered “old” media. In this case you might say that in terms of organisation of industry and content the traditions have led to a resistance to innovations.

Thomas Elsaesser (1998) argues that “For this remarkably stable product, digitalisation is a contradictory factor, at once an ingenious technical process of translation, generation and storage, and the totem-notion around a notoriously conservative industry is in the process of reorganizing—and this eventually means reinventing—itsself in order to do much the same as it has always done” (p. 203). The Hollywood industry has already changed a lot after 1950, the

blockbuster films and cinema are only one part of a marketing of products such as related video games, theme parks and the video/DVD market, the pay tv and cable tv.

Within the film infrastructure the exhibitors have no gain in investing in new digital equipment. The distributors would benefit, but are unable to invest in theatres. For Hollywood the change for delivering digital films would only work if it could deliver digitally worldwide. The complex interaction in distribution and exhibition means that little has changed so far.

The transformation of film and television cannot be restricted by looking at the technological innovation, but has to be considered as a fundamental transformation of the concept of the media. Siegfried Zielinski (1999) argues that ‘the particular constellations that arise in this way under the hegemony of the culture industry, structure the process historically’ (p. 19) He distinguishes four dispositif arrangements, the production of illusions of motion in space and time with the aid of picture machines, the cinema, television and advanced audiovision, The transformation is a process in which the periods overlap, interlock, attract and repel each other. In this sense we do not only look at the way the innovation has been developed and implemented, but how it redefines the existing media in a changed system of advanced audiovision that differs fundamentally from the traditional constellations that we knew as cinema and television.

THE INTERNATIONAL POLITICS IN TECHNOLOGICAL INNOVATION

In the development of HD it has been the electronics industry that has played a major part Although HDTV became a public debate in the 80’s, different countries already researched new standards. The American Society of Motion Picture and Television Engineers (SMPTE) set up an HDTV Study Group in 1977. Initially they felt that home

HDTV would depend on audiences becoming used to the standard first in the theatres. But without the interest of the film industry, the researchers introduced it as a new television standard.

In Japan, Europe and the US the electronics industry used the technology debate for lobbying in politics to make governments invest in research.

After 1986 the innovation of HD became a national interest. As Republican congressman Norman Lent put it in 1989 “our future competitiveness in high tech electronics could be at stake here”, or even more fundamental as another republican said “[HDTV] is one of the most important inventions of the 20th century. This is a crown-jewel product” (Winston, 1996, p. 95).

In comparison to the 60's the European Community had in the 80's gained power as a political force. The European Commission launched its strategy on HDTV in 1985. The five year program was called Eureka and was aimed at cornering a lucrative multi-billion dollar market for European electronics companies. It was to help producers, broadcasters and studios to make HDTV format programs.

The Dutch electronics giant Philips and French company Thomson worked together to develop a European HDTV standard. At first it was the analogue MAC device that was subsidized by the EC. In Japan the government supported the electronic industry to develop the MUSE system. Both examples indicate the high expectations for the national electronic industries in the development of HDTV. Despite a political lobby, the US government was reluctant to subsidize the industry. In 1989 Jeffrey Hart argued that the U.S. policy should adapt a national standard to add to U.S. competitiveness in consumer electronics and second that the formation of R&D consortia to develop HDTV technologies should be encouraged and assisted. In short term the development of HDTV was interesting for producers of semi conductors because the digital TV needs much more chips than the Standard Television.

During the 90's the electronic industries tend to cooperate intensively in research and development of new television sets. Philips and Thomson worked in Europe, but also participated in an American research program with Sarnoff Research Laboratory, thus creating a win-win situation (Anonymous, *Economist*, 1992).

IMPLEMENTING THE NEW SCREENS

During the early 90's the first steps in implementing HDTV were taken. In Europe the industry and several (public) broadcasters worked together to produce and screen a growing number of programs in 16:9 with 1250 lines as standard. It was meant to boost the sales of 'wide screen' televisions.

The European countries also created national platforms to promote the changes. In the Netherlands the HDTV Platform was established in December 1989 as a national mechanism to prepare for the introduction of HDTV (Van der Louw, 1990). Basically, coordination, research, information and international cooperation were the key issues for this platform. The foundation was formed by the National Broadcasting Corporation (NOS), the Broadcasting Service Corporation (NOB), the Dutch Telecom service (PTT Telecom), the association of Cable Antenna Operators and Authorities (VECAI) and Philips. Three governmental departments were involved.

The platform had three taskforces, one to stimulate the number of HDTV productions, one to coordinate transmission and one to investigate other electronic services of HDTV (van der Louw, 1990).

Subsidizing HD productions, demonstrating programmes at festivals and research, made promotion for HD. A channel, TVplus, was created in 1991. It broadcasted four hours HD weekly.

Transmission of the HDTV signal became one of the crucial problems to be solved. Therefore cable operators were essential. In the Netherlands

Screening in High Standard

90% of the country is supplied through cable. Although the network was not able to transmit the HD data in the early 90's, solutions were foreseen in the near future (van der Louw, 1990).

The proposed non-broadcast services were for instance HDTV pictures of collections of various museums, or an HDTV theatre showing public events. Most of these services in fact reflect the way in which television was promoted in the 30's and at trade shows throughout Europe and the U.S. in the 40's and 50's.

The platforms were the cooperation between the local governments, cable and telecom organisations and local industries. In the Netherlands the platform played an important part to promote the use of HDTV, but the long term development was decided by European politics.

In the U.S., the FCC played a central part in developments. In 1987 the FCC began to define the technical and juridical aspects of HDTV. In 1990 it held an open entry for the new HDTV standard. The compatibility with the existing NTSC was to be ensured and the enhancement signals were to be sent through a second channel. This solution was possible because in parts of the U.S. there were still channels available. None of the three main consortia, that were in the game for the frequencies, offered the solution. For the FCC it was clear that the digital TV would be the solution and therefore the three consortia were asked to cooperate. In 1993 a so-called Grand Alliance was founded with the companies Zenith, AT&T, General Instruments, that also had MIT and several small companies. To prevent Anti-trust lawsuits, European Philips and Thomson were included as well as the promise to release the patented technology (Kleinstauber, 1994).

In the meantime the EC debated the subsidy, the standards and implementation. The idea was to renew the EUREKA project. But the UK vetoed the program, because it argued that the analogue-based system would be overruled by the digital development in the U.S. Other arguments were the advantages such as interactivity and suitability

for all forms of distribution, terrestrial, cable and satellite. Some European members feared that the fact that British view on European subsidies was motivated by the fact that British electronics industry was foreign owned.

The EC launched the Advanced Digital Television Technologies, Eureka 1187 in 1994. The Dutch Platform wrote that one and a half year were lost due to the debate and that it meant the end of the European HDMAC system. According to the platform it was a pity because HDMAC was semi digital and it did not share the American optimism on the digital HD. Despite an initial European initiative in developing HD, once again a division within the EC resulted in a slowdown of the process.

By the mid 90's HDTV was a technology that mostly interested the electronic industries, hardly anyone was interested in the content. "The only people talking about HDTV are those who are developing it" according to management consultant John Rose (*Economist*, 1994)

In 1993 Philips announced it was halting its production of HDTV sets and would review its entire strategy if the EC would not come up with the promised subsidy (Barnard, 1993).

For the success of HDTV, not only a subsidy for developing the technology and the infrastructure was required, but also the introduction to the market needed state intervention. However the growing tendency towards liberal market policy made governments careful in subsidizing implementing an innovation like HD.

It turned out that neither the broadcasters, nor the consumers were interested. Was there no audience because there was no content? Or were broadcasters right that the audience did not want to buy expensive HDTV sets?

When television was introduced in the late 40's it was the medium itself that was being sold From manufacturer Allan B. Dumont, "... Sell television on what it can do for the customer. You are selling more than just a gadget—you are selling television itself" (Boddy, 2004, pp. 53-54). With

HDTV the customer knows what television as a medium offers. As van Vliet (2002) observes, "HDTV does not work, because better picture and sound quality do not change Sesame Street."

During the 90's there is a growing market for wide screen televisions, although they only partly offer the quality of the high definition. Advertisements appeal to quality of the screen in relation to lifestyle, offering status, financially as well as a sign of taste. The flat screens of the late 90's are an example of this. However a massive breakthrough has not been achieved.

By the end of the 90's there were two HD world standards, of 1080 and 720 lines. Most technical problems in HD equipment and delivery were solved, so there was no reason why broadcasters and audiences would not adopt the new standard. But in fact especially in Europe at that moment HDTV was unimportant for the broadcasting industries.

THE END OF HDTV?

During the 90's the attention for HDTV faded. The Dutch Platform wrote in September 1994 that all goals had been achieved within four years. It suggests that it created the infrastructure, but denied responsibility for the implementation of HD (Van Eupen, 1994). The way in which HDTV was studied and promoted showed a technological interest, but failed to take into account the social status of film and television at the period. The audience was not attracted to HD by initiatives such as activities by the platform, in 1996 the platform was resolved (Vos, 2000).

None of the initiatives in Europe and the U.S. in the early 90's led to a regular production and screening of HDTV. In 2000, a Dutch professional production magazine Call Sheet wrote:

if you wonder when the HDTV format will be there? It will not. Some years ago the NOB (facility service television) has thrown all standards and

equipment over board, and thus all broadcasting in HD are history. All well known manufacturers have developed HD techniques, but aim at the US, where special TV-stations broadcast in this standard. In the Netherlands HDTV is restricted to some experiments. (Een overzicht, p. 12)

The failure of HDTV is international. The innovation was promoted within the context of television, but did not add anything to the existing concept of television. Brian Winston (1998) offers a model for development of technologies in which this interaction of competence of science is related to social necessity and processes of diffusion. If we consider the case of HDTV in this model, the lack of social necessity and the way of diffusion have been crucial in the innovation's slow acceptance.

Even in several studies at the end of the 1980s noted some of the problems. *Is HDTV a new medium?* was the question at a conference organised by German broadcaster ZDF in 1990. (Lüscher, Paech, & Ziemer, 1991). It was an attempt to discuss the innovation in an interdisciplinary approach, looking at technical aspects, the aesthetics of HDTV and the social consequences of the changes of television.

According to participants a change of content for HDTV was required due to the quality of the screen. As long as there would be compromises with the existing forms of television, HDTV would fail. One of the conclusions was that the innovation could only be successful after 2000 (Lüscher et al., 1991).

Why have governments and electronic industry tried to start the medium a decade earlier? There is a similarity in the development of television standards in Europe in the 50's. Fear of a monopoly made it more attractive to get a part of the cake instead of risking getting none at all.

Consequences of the transformation of this new medium were issues that put the relation of viewer and medium into question. It was the VCR, cable and satellite that played a significant

part in debates on changing media environments. Only few academics discussed issues such as telepresence and a development in aesthetics that would change the concept of television in terms of its social status. At the start of the 90's none of these changes were related to digitalisation, for instance in interactive services in television and other media. It was only five years later that the debate on media shifted to concepts of interactivity and connectivity. HDTV, however, has hardly been part in this debate. Of the few studies, the most compelling one is Brian Winston's case (1996), set as an example for his model technological development and views on how we tend to forget the process of media changes.

REVIVING HDTV IN A DIGITAL CONTEXT

A third phase of HDTV started when it was linked to digital television in the U.S.

Digital television is most of all the change in accessibility of large quantities of digital content on a huge scale. It was no longer cinema that was related to television, but television partly merging with the Internet. The consumer's needs individualize and therefore new services are directed to the individual demands, for instance in electronic program guides (EPG) and video-on-demand (VoD). Harry van Vliet (2002) argues DTV will affect the content, economics and politics of the television business. In short term digital television has not been a commercial success. William Boddy's (2004) examination of digital television's distinct fortunes in the U.S. and GB offers revealing insights into some of the most persistent and difficult issues in media historiography, including roles of national culture, market structures, and ideological valence in setting the course of technological innovation.

In 1997 the FCC granted the free duplicate UHF channels to each U.S. broadcaster. The strategy was due to the political lobby by the

broadcasters, in cooperation with the consumer electronics industry, who were hoping to revive the domestic market. The FCC planned to shut down and auction off all analogue television channels by 2006. Even in a continuing internationalization of media ownership and programme flows, the nationalist sentiment remained a crucial element within political debates.

Immediately after the allocation, broadcast executives expressed reservations about the costs involving HDTV for networks and consumers. The HD broadcast made only one channel available, whereas multicasting in standard definition and interactive services were more attractive for broadcasters.

Only CBS started to produce HDTV programs. But with the approaching 2006 deadline, other broadcasters started to do the same. By 2003 both ABC and CBS delivered their entire prime-time slate of about 15 hours a week in high definition (Snider, 2003).

Despite the slow start in the new millennium more HD content is produced in the U.S. By the end of 2004, 10% of U.S. households had a television capable of displaying HDTV. The question is whether this is the critical mass of 12.8 million sets to make a turning point in the technology's adoption (Harrison, 2005).

In the UK the development of digital television has not been related to HD. The difference between the U.S. and the UK in infrastructure is significant. Britain had a low penetration of cable, only five terrestrial channels and a satellite service by Rupert Murdoch delivering to 3.6 million households. In this context two digital services were launched in Britain in 1998. The first one was Murdoch's new digital satellite service of BskyB, offering 140 channels, and the second one OnDigital by a consortium of ITV broadcasters, offering 30 channels. BskyB offered limited interactivity, OnDigital none at all. The number of channels, all in standard definition, was the main selling point. Despite 1.2 million subscribers, OnDigital failed due to a variety of problems, technological as well as in marketing and management.

Yet digital television in the UK is successful, 44 % of British household had digital television in 2003, more than anywhere in the world (Boddy, 2004). Especially BskyB was successful. To attract the audience Murdoch had given away set top boxes to subscribers in 1999.

Digital television in Britain offered nothing new, but due to the infrastructure its selling point was the number of channels. Within Europe differences in infrastructure have probably determined the adoption of digital television. In the Netherlands the liberalisation of media politics resulted in seven new commercial channels within 15 years, apart from three existing public ones and some regional channels. With a cable penetration of 90%, Dutch viewers receive about 20 foreign channels and some pay TV channels. In 2004 Dutch Telecom company KPN was the first to offer a digital service. Several cable companies, also offering telephone, Internet and television services, soon followed KPN. In 2005 Internet provider Versatel started offering all football matches live. About 10% of Dutch consumers switched to digital television by 2005. In a European context the development is similar to a country like Germany (Döbler, Mühlendorf, & Stark, 2003).

Although the innovations have not been successful yet, it shows the instability of the media constellations. First of all cable companies and telephone companies offer services in delivering a variety of services in Internet, television and telephony. Another thread for existing models of broadcasting are technological devices such as the digital video recorder—especially its possibility of recording and watching with a small delay changes television's sense of liveness or simultaneity. The fear of advertisers and commercial networks is a decrease of revenues. Therefore ways of advertising and participating in programmes or offering onscreen services will change content of television.

These changes will affect the social position of television in terms its relation to the audience. As Boddy (2004) quotes a newspaper statement

by BBC chairman John Birt, “the end may be in sight for broadcasting as a communal experience” (p. 86). Of course the traditional models of broadcasting will exist in future, but not be as dominant as it used to be in the second half of the 20th century. Changes in the relation to the audience and the way cultural products are consumed have and will change in digitalisation if television and Internet tend to merge.

With the development of digital services, HD has become a small part in the discourse on changing media. Yet in recent years it seems to become more important. The U.S. strategy definitely plays a part. The necessity to produce HDTV has resulted in an increase in HD productions. The improvement of the equipment is another reason. Within the context of digitalisation changes within cinema create possibilities as well.

To promote digital cinema, the European Media program has subsidized a project offering equipment to arthouse cinemas at low costs. The condition is to screen national and European films digitally. Especially documentaries have found a possibility for theatrical release.

It seems that it's not the Hollywood industry that initiates a change to digital high standard, but the marginalized media industry. Most European films are low budget and the production costs are hardly affected by producing digitally. But because public broadcasters and national film funds finance most European films, by stimulating digital cinema they also play a part in distribution and screening.

Although Peter Greenaway already used HD in his feature film *Prospero's Books* (1989), in 2003 the first Dutch feature was to be shot in HD completely. In postproduction the film *Pipo and the PPParelders* was transferred to 35mm released in theatres. Since then more films have been shot digitally and some of them also released digitally. The film *0605* (2005), a conspiracy thriller about the murder of politician Pim Fortuyn in 2002, was even first released on the Internet by co-producer and provider Tiscali. It caused a media hype, but eventually only a few people did download, pay and watch the film.

Now that broadcasters, independent producers and related industries seem to adopt the HD technology, the consumers will have to follow. Although so far consumers have not adopted HDTV, for several reasons HD will become standard for consumers. Even computer monitors have a higher resolution than standard television, thus if Internet and Television merge, it might use a higher standard to do so.

Van Vliet (2002) argues that media developments can be considered in the context of what Pine and Gilmore call the new economy, meaning that people do not want 'just' a product, but want an experience. HD as an innovation has been promoted as a new experience. In this sense HD also recalls film historian Tom Gunning's concept of early cinema as a cinema of attraction, because it was the sensation of imagery that was the attraction for the cinema audiences before 1905.

This sense of attraction is reflected in the European broadcaster Euro1080, set up as an HDTV channel. Gabriel Fehervari, a Belgian Hungarian launched the channel in 2004. It aims at producing sports and concerts, making 1200 productions each year. In an interview with Belgium newspaper *De Standaard* Fehervari argues that other initiatives by broadcasters like French TF1 or BskyB make clear that HDTV is becoming more important to European broadcasters (Petitjean, 2005). In the Netherlands regional broadcasters, public channels that deliver to a small market of several million viewers, announced to experiment with HDTV in April 2005 by opening its channel for programmes of Euro1080. But the promotion of a sensation has been the sole attraction of the innovation of HDTV up until 2005.

CONCLUSION

The case of HD shows that within 25 years the media landscape has changed. The initial innovation of HDTV was the quality and ratio of the electronic picture. The idea was that it would

change television and film into a new medium. More important, the development of HDTV was a necessity for the consumers electronics industry; it would boost sales of chips and sales of new sets. The dichotomy between possibilities and necessity has determined the developments of HDTV.

In response to Japanese prototypes, the American and European industry made sure that a new standard would not lead to a Japanese monopoly. National interests made the innovation of television a political issue.

The electronics industry convinced regulators since the 1980's that HDTV is necessary for consumers electronics industry and for the economy. The U.S. and Japanese authorities as well as the European Union have in different ways contributed to the eventual success of HDTV.

Despite political back up, especially in Europe, the implementation of HDTV did not succeed. HD did not only concern the technology of television, but also of infrastructure through cable and satellite. The infrastructure did improve, but broadcasters and film industry were only interested in HDTV in controlling their position within the media. Consumers seemed to be ignored, there was, and perhaps still is, no demand for improvement of the pictorial quality by the audience. By the middle of the 1990s the HDTV hype was over. The European authorities cut subsidies for HD developments. The U.S. authorities granted UHF channels for digital broadcasting in HD to the American broadcasting companies.

After 2000, the digital HD revived. The FCC grant of free spectrum to the broadcasters to produce digital HDTV television may have been crucial for HD, but changes within cinema and the change of interaction between media such as telephony and the Internet has changed the actors involved. New digital services of interactivity change the traditional concept of television as a domestic broadcast medium. The opportunities for theatrical release at low costs, combined with other media for releasing films in high definition standard do offer new ways of thinking about traditional media film and television.

Initially the promise of new content, for instance in a change of aesthetics in programmes or in a concept like telepresence, was discussed as consequence of HD. However the electronics industry was depending on companies that used HD in traditional production. Thus the audience could hardly be shown the advantages of the innovation.

The HD technology has improved over the past 15 years. The compatibility, the definition of a world standard and improvement of camera equipment all made it easier for broadcasters or independent producers to adopt the HD technology. In different ways we see changes in production, postproduction and distribution in which HD plays a part. So far, these changes do not change the traditional concept of film or television. Now that both industry and broadcasters finally plan to use HD, the audience will be forced to buy HDTV-sets. The FCC will shut down analogue television in the near future.

Therefore it can be argued that HD will succeed, due to political and manufacturers persistence. For the audience the main attraction in digital television is the number of channels and interactivity. If HD is associated with these services, consumers will be more eager to adopt.

The digital developments will change the use of "old" media like film and television, although the traditional concepts will remain, at least for a while. The question remains in what way the developments will change socio-cultural concepts. How does digital HD affect ways of production, distribution and exhibition? In what way will it change the content of this Audiovision?

The study of innovating a medium like television shows that an unstable constellation of audiovisual media has developed. The consequences for media organisations, content and audience trends involve many different actors. It's my belief that the process of transition of traditional concepts into a new audiovision will only be developed in adoption and applications of an innovation by new generations.

Chapter 3.40

Digital Cinema as Disruptive Technology: Exploring New Business Models in the Age of Digital Distribution

Nigel Culkin

Norbert Morawetz

University of Hertfordshire, UK

ABSTRACT

The distribution and exhibition of motion pictures are at a crossroads. Ever since the medium was invented in the 1890s the “picture” has been brought to the spectator in the form of photochemical images stored on strips of celluloid film passed in intermittent motion through a projector. Now, at the beginning of the 21st century, an entirely new method has emerged, using digitally stored data in place of film and barely needing any physical support other than a computerised file. This opens an intriguing portfolio of revenue-generating opportunities for the movie exhibitor. This chapter

will give an overview of current developments in digital cinema (d-cinema). It will examine potential new business models in an industry wedded to the analogue process. The authors will consider the strategies of companies at the forefront of the technology; implications associated with the change; and how different territories might adapt in order to accommodate this transition.

INTRODUCTION

In this chapter we will consider how the transition from film to digital product is likely to affect an

industry that has been wedded to an analogue process for more than 100 years. Rather than contributing further to the debate about the qualities of competing technologies or the creative merits or demerits of digital product, this chapter will focus on the development of potentially new business models in the global film industry. The authors will examine the strategies of the companies at the forefront of the technology; the financial implications associated with change; and how different territories are adapting in order to accommodate this transition.

D-Cinema: An Idle Revolution?

Ever since 1999, when George Lucas launched *Star Wars: Phantom Menace* on four digital screens in America, prophets of d-cinema (that is using digitally stored data in place of film) have proclaimed that it will change the film industry forever. Six years later d-cinema is still far away from wide implementation.

Belton (2002) has even declared d-cinema to be a “false revolution” because it does not transform the nature of the motion picture experience for the audience, stating that “One obvious problem with digital cinema is that it has no novelty value, at least not for film audiences.” He argues that in a marketplace in which the word “digital” sells consumer products, “it is digital sound (and not digital projection) that marks for consumers the entry of motion pictures into the digital era.”

His arguments cannot be easily dismissed especially when considering the explicit goal of digital projector manufacturers to produce an image quality that *equals* that of traditional film prints. Slater (2002) has compared the cinema exhibition chain of traditional film and electronic/d-cinema. When looking for an answer to the question what problem electronic/d-cinema is trying to solve, he could not find “one single good technical or operational reason why the whole system should

be replaced” (p. 43), with film being high quality, flexible, and most important future proof.

Still key players in the industry seem to be determined to make d-cinema happen, such as John Filthian, president of the National Association of Theater Owners (NATO) in America, who has said that “digital cinema will be the biggest transition technology in the history of the movie industry” (Baird, 2004).

The Dilemma

However, with just over 120,000 screens worldwide, the cinema market has been deemed too small to support any major technological innovation by itself (*Screen Digest*, 2003). This means that no manufacturer is currently in the position to produce a digital projector at such a competitive price, that exhibitors could afford to pay for the switching costs themselves. Consequently, the matter of financing the conversion to d-cinema has been passed on to distributors, who are claimed to benefit the most from d-cinema by saving on print costs.

The problem is further intensified, when more than one company for d-cinema equipment tries to serve the market, and more than one standard exists. For distributors however, it does only make sense to fund d-cinema conversion, if a single standard exists (similar to the 35mm standard), otherwise the cost savings of digital are offset by producing several masters for different standards.

Thus the need arises for a clearly specified standard—an issue that took the participating players more than 6 years to resolve.

These players can be categorized into three basic groups: equipment manufacturers, institutional players, and distributors. In the following section the major players and their stakes in d-cinema will be introduced briefly while reflecting on their role in the search for a single standard.

SETTING A STANDARD, SHAPING THE MARKET

The earliest attempts to gain a dominant market position and to set standards have been made by the main competitors in digital projector manufacturing, Texas Instruments (TI) (DLP Cinema), Sony (GLV), and JVC (D-ILA).

While JVC's position in the market has been marginalised, TI has licensed its DLP Cinema technology to projector manufacturers such as Barco, Christie Digital, and DPI/NEC and has by doing so gained an early advantage for its standard over Sony. It soon became evident however, that a working business model for d-cinema has to include not just a projector, but must consist of a bundle with digital distribution and server hardware. The main competitors in this area are companies such as QuVis, GDC, XDC, and AccessIT.

As technology companies are clearly wedded to their own solutions, pointing out flaws in competing technologies while downplaying the shortcomings of their own, institutional players stepped in to help specify a single standard and support the development of d-cinema.

In the U.S. the institution in charge is a special commission (DC-28) of the Society of Motion Picture and Television Engineers (SMPTE), in Europe it is the European Digital Cinema Forum (EDCF), in Japan the Digital Cinema Consortium of Japan (DCCJ NPO), and in China the State Administration of Radio, Film, and Television (SARFT).

The power of these institutions has however been limited, as they tend to avoid taking sides and promote all solutions equally.

In 2002 the Digital Cinema Incentive (DCI) was formed, a joint venture of the seven major Hollywood studios (Disney, Fox, MGM, Paramount, Sony Pictures Entertainment, Universal, and Warner Bros.) that has dwarfed the importance of the other institutions to establish guidelines for

d-cinema into insignificance. Although it still is the SMPTE that ratifies technical standards for cinema and television in America, even Peter Symes, vice president engineering at SMPTE has to admit that "the DCI represents a significant party of interest" and it was very unlikely that the SMPTE could reach consensus on something if the DCI was in favour of something else (Crabtree, 2004).

In July 2005 the DCI had published its final overall system requirements and specifications for d-cinema. In their guidelines they have opted for a scalable solution from 2K to 4K and have therefore left the decision which projector technology will be used in theatres to the market.

They have however selected JPG2000 as the image coding system to be used in the delivery of digital motion pictures. This decision is very likely to eliminate competing systems, such as various MPEG standards or newcomer eTreppid from the market and forces all major manufacturers to comply with the standard (Crabtree, 2004).

DCI specifications have consequently been branded to be synonymous with the term *d-cinema*, as Tim Partridge, senior vice president and general manager of the professional division for Dolby Laboratories has explained: "I think we [Dolby Laboratories] use the terms in what has become the standard way. D-cinema to us means DCI standard equipment, E-cinema is everything below that" (DCR, 2005b).

The question arises, why the *d-cinema revolution* still has not fully begun, when the dominating market forces (the Hollywood studios) can so easily safeguard their interests. One might argue that all they have to do, to continue their international market supremacy, is to replicate the existing power structure and apply it to the d-cinema market. What does stop them? Can the hesitancy of the "majors" to move along with d-cinema quickly be interpreted as an indication of concern about the impact the digital transition will have on the industry?

D-CINEMA: A DISRUPTIVE TECHNOLOGY?

Digital cinema [...] is perhaps the most significant challenge to the cinema industry since the introduction of sound on film. As with any new technology, there are those who want to do it fast, and those who want to do it right. As we move down this path, let's not forget the lesson learned with the introduction of digital audio for film in the '90s. Cinema Digital Sound, a division of Optical Radiation Corporation, was the first to put digital audio on 35mm film. Very, very few remember CDS, who closed their doors long ago. Such are the rewards for being first. (MKPE Consulting LLC, 2005)

As the previous statement shows, there are considerable risks attached with moving into a market too fast. Indeed some of the companies who tried to find an early foothold in d-cinema have already closed their business in this field (most notably Boeing).

However as the literature on *disruptive innovation* and *disruptive technology* has pointed out, one of the biggest risks for incumbents in any market is to move too slowly.

Disruptive innovation and disruptive technology are emerging and increasingly prominent business terms describing a revolutionary change in an industry (Thomond et al., 2003). The term disruptive technology was first marked by Christensen (1997) to describe a technological discontinuity that causes the failure of incumbents in a market. Danneels (2004) defines disruptive technology as a technology that changes the bases of competition by changing the performance metrics along which firms compete. Customers seeking certain benefits determine which attributes they value in a product, with different customer groups valuing different attributes. New products based on a disruptive technology have different attribute sets than existing products. They tend to have initially a lower level of performance on

dimensions relevant to mainstream market segments but have higher performance on dimensions valued by remote or emerging market segments. Christensen (2000) has characterized disruptive technologies as typically “simpler, cheaper, and more reliable and convenient than established technologies” (p. 192).

When the disruption has established itself in an underserved customer segment, major players may be displaced as disrupter's develop new wealth opportunities. The consequences of not securing disruptive innovations can be “far more devastating than simply lost opportunities or lost market share” (Thomond et al., 2003, p. 6). Following these definitions d-cinema can easily be identified as a disruptive technology.

In the following sections we will map out current important issues stopping incumbents from embracing the technology and exploiting its full potential. We will show how d-cinema changes the basis of competition in the industry and helps new markets to emerge. We will also show how incumbents can slow down the development to their advantage, and in doing so deliberately risk losing niche markets.

Single Standard vs. Consumer Market

One of the prerequisites for a wide roll out of d-cinema has been the readiness of tested equipment. There is a broad consent among industry experts that the problems of digital projectors with image quality have now been solved. However the availability of technology that meets the requirements has not propelled the number of installed d-cinema projectors tremendously. Walt Ordway, chief technology officer for the DCI, does not see a wide implementation of d-cinema for at least 4-6 years, although an initial roll out could take place “in the next year or so.” Ordway notes that one problem with the systems that are currently fielded is their lack of security constraints and a common standard (DCR, 2005a).

On an exhibitor's wish list for regulators of d-cinema, a common global standard would rank among the top objectives.¹ There are two rivalling technologies in the projector market, namely TIs 2K (DLP) standard, and Sony's 4K (GLV) standard.² TI has invested an "unspeakably large amount of money" (Screen Digest, 2003, p. 30) into its DLP technology, revealing the exact amount not even to its shareholders, and currently controls the market. Sony on the other hand keeps announcing its 4K projector and plays on the preference of studios for a 4K solution. Despite Sony's de facto, zero-market share, the DCI (in which Sony is a member) has endorsed both 2K and 4K standards when choosing the JPEG 2000 codec for studio d-cinema release masters.

Although the revenues from the high-end d-cinema market can be substantial, the real market to be won is the home cinema market. For both companies the market for d-cinema is therefore a kind of branding exercise for reaping rewards in the consumer electronics (CE) market. The underlying logic (e.g., for TI) is the following:

Cinema audiences will see the DLP logo before the start of every film in a d-cinema and come to associate it with the highest quality of picture viewing. They will then seek it out or of opt for it in their local CE market. (Screen Digest, 2003)

The situation is similar to the introduction of digital sound into cinemas, which was also seen as a preliminary battle "for the potentially much more lucrative market for digital sound in the home" (Belton, 2002, p. 101). During the 1990s three different companies tried to establish their proprietary technology as a cinema standard, namely DTS (Universal/MCA), SDDS (Sony), and Dolby digital (Dolby Laboratories). Since each standard was able to capture a sufficient market share, multi-standards in cinema sound continue to exist.

Multi-standards in d-cinema are certainly not a desired outcome for film distributors as well as

exhibitors. Still, as long as d-cinema is only considered as a prefacing market for the companies who actually develop the technologies in use, standards will be an issue.

A Market with Network Effects

One of the reasons why a common standard is so desirable is that the market for d-cinema exhibits positive consumption and production externalities. Positive consumption (network) externalities exist, when the value of a unit of the good increases with the expected number of units sold (Economides, 1996).

If both TI (2K) and Sony (4K) establish their incompatible projectors in the market, the market is split into two different networks, one for 2K projectors and one for 4K projectors. Each of these networks consists of sellers (the Hollywood studios plus independent content producers) and buyers (exhibitors). If an exhibitor installs a 2K projector he joins the 2K network, and the utility of this projector increases with every exhibitor who joins this network because the increasing size of the (2K) market increases the expected utility of all participants as they have more partners to trade with. This is especially true for the Hollywood studios, as for them the utility of the market is at a maximum, when there is only one standard (either 2K or 4K) and they can trade with all the exhibitors without incurring any additional costs.

Charles Swartz, CEO of the USC Entertainment Technology Center, has stressed the importance of a single, global, interoperable standard for d-cinema by referring to 35mm which had all these characteristics; the single standard ultimately enabled film to become a "medium of tremendous power" (Crabtree, 2003). A situation with a double standard would therefore not be progress but a step backward for the industry.

Waiting for Sony

As a vertical integrated corporation Sony faces competition on each stage of the value chain,

with contradicting objectives adding to the complexity.

Being a member of the DCI, Sony, the studio, has been able to secure that the DCI agreed on scalable format standards from 2K to 4K, and has thereby strengthened the position of Sony, the projector manufacturer. On the other side however, it has also agreed to accept rival technology as a standard.

There is a strong and compelling argument that says that since the studios are the real beneficiaries of d-cinema (through print savings) they should also fund the projector installation (Baird, 2004).

One possible way to realize this funding sees the majors setting up an independent financing entity that allows cinema owners to decide on their own on how to use the funds to upgrade their cinemas along DCI standards (Kilday, 2004).

If this happens, Sony will find itself in the contradictory situation, where as a member of the DCI it will have to (directly or indirectly) subsidize its competitors in equipment manufacturing.

As an equipment manufacturer Sony competes against TI and its licensees Christie Digital, Barco, and NEC. It has to do so because it wants to protect its market prospects in consumer electronics, where it again competes against TI licensees, for example, Samsung, Sanyo, or Marantz.

On each stage of the value chain Sony has more to lose than its competitors (the subsequent market) but it is also the only player that can exacerbate power at a higher level by participating in the DCI. Although Sony has not even proved yet that its 4K projector is more than a functioning prototype, it is therefore still a market force one has to take into account.

Sony's strategy clearly is to play on time, and by cleverly doing so, it has managed to stay in a race that otherwise would have been long over. Through repeatedly announcing its 4K projector it has raised industry uncertainty and stopped investments. As Travis Reid, president of the cinema chain Loews Cineplex said:

... the fact that (a 4K projector) exists is making everyone stop to think, and admitted that if there was no deployment (of 4K), then 2K would have been the initial rollout. (Sperling, 2004)

An exhibitor quoted in *Hollywood Reporter* said that:

They [Sony] are clearly trying to slow down the forward momentum of 2K being adopted and rolled out. It will be interesting to see how they've come along to being a real live projector; there are a lot of studios saying, "If this is close, then let's wait." TI [Texas Instruments] can't be happy about it. (Sperling, 2004)

Doug Darrow, Project Manager for d-cinema at TI challenges Sony with the strong argument that it has not demonstrated that 4K projectors will actually work in theatres for a few years, in contrast to TI. However, this argument could backfire. If there is no pressing economic need (and there is none) to switch to digital projection immediately, then exhibitors and studios might well postpone their investment decisions and wait to see if Sony's 4K projector can deliver.

TI has expressed little interest in the race to 4K and focuses on the commercialisation of 2K, with "the biggest challenge not lying in resolution but in costs" (Kaufman, 2004).

A Complex Transition

John Fithian, president of the National Association of Theatre Owners (NATO), states "it is fairly clear that studios will fund the transition," since "they will save a tremendous amount of money from the conversion" (Baird, 2004).

The modus operandi of this transition is far away from being "fairly clear," though. The roll-out plan that determines which cinemas will get converted first must be consensually negotiated with all interest parties. Should the transition start only in North America or internationally, by state, by exhibitor, by market, or where low

technology and penetration allow for fast entry? (Fuchs, 2004b).

The Board of directors of the NATO (2004) has formulated a resolution of requirements that need to be fulfilled for the transition to be a success. A key point for them is that interoperable, reliable equipment is in place (both NATO and DCI have pledged for a beta testing phase) that at least equals the image quality of 35mm. The equipment must further be easy to upgrade at reasonable cost, as technology advances; must be built around clearly defined standards; and has to be produced by competing multiple vendors.

For exhibitors a desirable financing plan for the transition has to ensure that all movie complexes and auditoriums, regardless of size or geographic location can participate within reasonable time, studios are committed to provide digital content, and exhibitors can independently select the equipment, and own it at the end of the financing period. Furthermore they ask for a “no dark screen” policy, meaning that films play in a nonrepudiate manner unless the exhibitor attempts to play the film in a completely different venue and that they can decide on their own about schedules, advertisements, trailers, and other content (NATO, 2004, p. 3).

From a studio point of view, subsidising the full cost of the equipment without any obligations to exhibitors does not seem to be a very healthy economic proposition. A solution that does not contain any obligations to exhibitors to show content is a de facto cross-subsidisation for independent filmmakers, as they will benefit from the installation without contributing to the costs.

In the question of ownership therefore rests a crucial point in the transition to d-cinema. The immense undertaking to convert thousands of screens in America and internationally is not an “everyday” logistic and organisational challenge. To resolve the major issues it will take time. For the moment this will delay the d-cinema revolution further, as exhibitors have little incentive to enter the market on their own before the studios have come to a decision.

THE NEW DIGITAL DEAL

The paralysis that results from the funding problem has left the market for the moment to third-party players.

A first wave of third-party players proposed to pay the upfront costs for digital projectors in return for a fee (per-print, per-screening, per-ticket, or an annual contract) and promised to ensure that there is no shift in the balance of power between distributors and exhibitors (*Screen Digest*, 2003). The success of these companies (with some exemptions such as Kodak) has been very modest so far. In 2003 Boeing Digital Cinema closed its d-cinema business that was once projected to bring \$1 billion a year in revenue (Gates, 2003). At the same time, Technicolor has scaled down its ambitions and based on latest reports, Elsacom is still in the testing phase.

A new wave of investment into d-cinema comes from state initiatives and independent film distributors. By targeting niche markets these players fragment the market and can then gradually expand their business into the mainstream.

These dynamics are reflected in Christensen’s (1997) disruptive technology framework. He argues that incumbents are resource dependent (Pfeffer & Salancik, 1978) on their most demanding customers and focus their investment towards innovations that are valued by their mainstream customers. In contrast to this, new entrants are not constraint by and can not rely on an existing customer base, thus they are “forced to identify consumers who value the new features offered by the new technology and support its further development” (Adner, 2002).

In this regard, it seems as if the first wave of new entrants into d-cinema failed to correctly identify these “new customers.” Most of these ventures were aimed right from the beginning at the mainstream market, ignoring the importance to segment the market that has been strongly underlined by Moore (1991). This is in stark contrast to the new wave of entrants, who are very

focused on niche markets, namely the distribution of independent content.

It is remarkable in this context that major new initiatives (e.g., the UK Film Councils Screen Network) are state driven. So far government support for the film industry was mainly aimed at subsidising film production, often resulting in the so-produced films not finding exhibition and reaching only a very limited audience. The idea to provide distribution and exhibition for this content through installing digital screens is a strong shift away from the traditional production-oriented subsidy logic to a more market oriented one. It directly addresses a market failure in exhibition that provides only very limited “screen space” to “art-house” films.

While d-cinema might potentially help independent filmmakers to overcome the market barriers to distribution, this does not necessarily mean that the even bigger barriers of consumer habits and tastes can be overcome as well. The American film industry has shaped audience tastes for generations resulting in a market share of up to over 90% in Western countries. Although this domination might be a portrait of distorted consumer preferences, resulting from restricted consumer choice offered in local cinemas, the majority of mainstream audience taste is unlikely to change overnight. It will take more than access to the market to re-win significant audience shares for independent (European) cinema. Nevertheless higher exposure to content is an essential first step to alter cinema goer’s habits in the long run.

IMPLICATIONS FOR THE CURRENT STRUCTURE OF THE FILM INDUSTRY

As the aforementioned examples clearly show, d-cinema not only allows smaller competitors to carve out viable market niches but can bring completely new markets into existence. Remote areas whose access to audiovisual content that has been limited so far will now be as easily reached

as regions with developed infrastructures. Both developments will increase competition: Firstly through players who fragment the market and then try to expand their strongholds into the mainstream market, and secondly through companies who operate from new strong domestic markets.

Without additional costs in supplying additional “prints” for screens, economies of scale that have shielded Hollywood studios from low-budget competitors for nearly a century are eradicated. Consequently, the release of a film will become “less of a financial decision and more of a marketing decision” (TI, 2003). If this will truly give independents leverage remains to be seen.

The majors themselves have hardly ever regarded printing costs as an obstacle to distribution. With “ultrawide releases” (3000+ prints) on the rise (*Screen Digest*, 2003), d-cinema opens the door to an ever higher pervasiveness of Hollywood product.

The studios have recently shortened the time lags between release dates in international markets and global, simultaneous, film starts have become a trend (e.g., *The Matrix II, III*, *Star Wars*, *Harry Potter*, *Lord of The Rings*). One reason for this might be that the Internet has facilitated the development of a global film audience with increasingly convergent tastes. This audience readily turns to pirated copies of films if time lags between national releases are too long. The combination of d-cinema and global simultaneous film starts is likely to propel this trend further with studios staging and marketing their productions as global events for a global box office.

Another advantage studios will take along into the era of d-cinema will be their business model of a portfolio approach to film production and distribution. The strategy to spread risk onto a slate of films is even more effective with d-cinema: If a film is a success, studios can immediately supply additional screens at virtually no cost, if a film is a failure, it can be withdrawn without bearing the sunk costs of film prints.

In this context d-cinema appears to be less a disruptive but rather a sustaining technology for the majors. Sustaining technologies are consistent with a firm's business model (Christensen & Raynor, 2003) and improve the performance of established products through the "current technology product paradigm" (Kostoff, Boylan, & Simons, 2004). D-cinema bears both the characteristics of a sustaining and a disruptive technology, making it difficult to recognize the distinction. It is exactly this failure to address technological innovations appropriately that according to Christensen causes successful incumbents to stumble or even disappear from the market.

Historically, the film industry has already mastered a number of disruptive technologies (e.g., television, video recorder), despite its traditional reluctance to embrace new technologies. Its nostrum on how to deal with new technologies seems to be a combined strategy of vertical disintegration and diversification, which has led to an oligopolistic industry structure.

During the 1990s the major studios diversified themselves into the independent market by setting up or buying independent distributors (New Line Cinema, Miramax, Fox Searchlight, etc.), a trend that is likely to be intensified by d-cinema. Thus, if entrepreneurial firms take advantage of the disruptive technology d-cinema and "redefine current markets" (Kostoff et al., 2004) the majors might simply counter them through acquisition and integration into their corporate structure.

As local independent distributors develop an expertise on how to successfully handle "difficult" films in their markets, the majors might also begin to disintegrate further and try to outsource some of their distribution to these companies in the same way that they have outsourced production through flexible specialization (see Christopherson & Storper, 1986, 1989).

As the importance of a physical distribution structure diminishes their means to keep control over the industry would then be through controlling intellectual property rights as well as keeping

a strong stake in development, packaging, and financing and providing expertise in film production, marketing and distribution to contractors.

The Hold Up Problem

Figure 1 shows a simplified model of money flows in the traditional film industry value chain and in a system of d-cinema (a comprehensive discussion on profit calculation and accounting practices in the Hollywood studio system can be found in Daniels, Leedy, & Sills, 1998).

In the current system, box office receipts are first split between exhibitors and distributors. Exhibitors are the first to deduct their expenses, the value they appropriate is E. Distributors then deduct their *distribution fee*, which is intended to cover their overhead costs (offices, corporate expenses, distribution efforts) and the *distribution expenses* (prints and advertising). The distribution fee varies according to geographic area and market between 25% and up to 50% of the revenue. The value the distributors appropriate is D. The remainder, P, is allocated to the producers of the film.

After the transition to a system of d-cinema, cost savings arise: distribution expenses are reduced through cutting print costs, distribution fees are lowered through reduced studio overhead. It will be interesting to see if studios can appropriate the added value they have created through cost savings for themselves or if they will have to share it with the other parties. If studios pay for the transition costs, they are likely to demand the added value on the ground that they have paid for it (scenario 1 in Figure 1). However, if a new distributor enters the game at this stage ("Maverick distributor"), he/she would be able to offer both exhibitors and producers a better deal than the existing studios (scenario 2, Figure 1), since the distributor can pass on the cost savings to them without having paid for them. In this scenario, studios will eventually have to pass on cost savings to producers as well, if they do not

software and straightforward test routines. As a consequence d-cinema projectors will be far easier to remotely control when connected via a cinema management system that both controls their inputs and outputs. AccessIT's Theatre Command Console is therefore a predecessor to an era where it will be possible to look after hundreds of screens in the country from a single control room (a situation that already has come true for UK broadcasting [Slater, 2004]).

The simplicity of a graphical interface and remote control dismisses concerns from exhibitors that new digital projectors will require advanced technical knowledge (McQuire, 2004) but could mean bleak prospects for some projector staff.

CONCLUSION

In this chapter we have tried to situate current developments in d-cinema within Christensen's framework of disruptive technologies. We have focused the attention on what we see as the major players in d-cinema, namely the major Hollywood studios and have tried to map the implications of d-cinema on the relationships within the film industry value chain. It was shown that the market for d-cinema exhibits network externalities and that therefore a common standard is desirable. The discussion on standards also revealed the conflicting interests a diversified and vertical integrated corporation such as Sony faces, as the competition in d-cinema becomes a "preliminary battle" for the CE market. As a major incumbent, Sony is able to delay the progress of the whole transition to d-cinema for its own benefit, a strategy worth examining more closely.

We have also briefly outlined some of the complexities linked to organising a satisfying transition to d-cinema for all parties.

The emergence of new markets and new entrants into the d-cinema market was examined in respect to the implications for major players in the industry. Although d-cinema was found

to benefit independent players that can carve out market niches, it was also shown that the majors have a strong leverage to exploit the technology to their advantage. However, the combination of a change in the terms of competition and a potential hold up problem, are likely to lead to a further diversification and possibly a further disintegration of major distributors.

In addition we have discussed important issues associated with d-cinema, such as alternative content, training, and digital rights management.

Further research is needed to explore strategies of new entrants and incumbents in this market, survey successful and unsuccessful business models, and discuss how the research on d-cinema can contribute to and be enriched by literature on strategic management and disruptive technologies. Interesting research questions are related to the performance of third party initiatives such as the UK Film Council's Screen Network (2005); the complexity of organising a transition to d-cinema for the mainstream market; and the role of diversified, vertically integrated corporations in the process of setting standards for d-cinema, branding for subsequent markets, and market fragmentation.

In conclusion it shall be mentioned that d-cinema has not solved the problem of long-term digital storage yet. As Phil Feiner, CEO of the renowned optical service company Pacific Title Digital, has remarked: "It's not archival" (Parisi, 2004). Digital intermediates are stored on magnetic tapes that have an archival life of 30 years at best. In contrast, a three-strip black-and-white masters, the current archival standard, lasts as long as 1,500 years. This means that even if a film is shot, edited, distributed, and projected digitally, in the end it has to be transferred to film.

Therefore, in the uncertain future of d-cinema, at least one thing is for sure: Even if the "d-cinema fairy" converts all the screens in the world overnight to digital, traditional film is still going to stay with us for a very, very, very long time.

Chapter 3.41

Access to the Living Room: Triple Play and Interactive Television Reshaping the Producer/Consumer Relation

Eggo Müller

Utrecht University, The Netherlands

ABSTRACT

Whereas the advent of interactive TV has been discussed as one of the key added values of digitization and convergence of “old” and “new media” for years, current marketing strategies of the big players in the Dutch telecommunications market avoid the term interactivity. Providers promise users “more fun” and increased ease of media consumption when connected digitally to the media world by offering broadband Internet, cable television, and telephone services in one package. They aim at another added quality of interactive media consumption: gaining access to the living room means gaining access to consumption patterns that can be traced back to the individual consumer. This article discusses media convergence and the current development of interactive television in the context of the re-configuration of the relation between producers and consumers in the new online economy.

CONCEPTS OF INTERACTIVITY

For almost three decades, one magic word has dominated professional and public debates on the future of television: *interactivity*. The story goes that when finally provided with a return channel, our “good old television” would become a true means of real two-way-communication. Viewers would not only compose their own program schedules, watch any program at any time, get more background information, and do their shopping at home, they would also contribute to and participate in programs and would even become directors themselves. Although the first field tests of interactive television services in the U.S. in the 1970s, then still based on analogous technologies, failed (Richeri, 2004), and although audience research in the early 1990s still showed that the average public was not ready for interactive television programming (Berghaus, 1995), the industry’s expectations remained optimistic, especially since the introduction of the Internet

in the early 1990s; progress in digitization and compression of audiovisual information; and household's fast growing computer and broadband penetration. The convergence of television and computer-based communication technologies would help to finally disseminate the envisioned interactive television or multimedia system (Owen, 1999; Van Vliet, 2002).

This vision of the industry was echoed by a new brand of media theory that in the name of technological potentials of new media uncritically promoted a fundamental transformation of traditional power relations that were inherent to "old-fashioned" broadcast media and their traditional forms of mass communication. For example, Pearce (1997) praised this "interactive revolution" in a McLuhanian style:

The interactive revolution is [...] about creating machines that extend our mental and creative faculties, that enable us to store, manage, and most important, share massive amounts of knowledge on a global level. It is about using powerful tools to create our own educational and entertainment experiences rather than passively accepting that which is fed to us by so-called experts. It is about the dissolution of boundaries and the translation of all thought into a common vocabulary. Binary code is the digital Esperanto that is leading concurrently to individual empowerment and worldwide unity. (p. xvii)

According to this view, the New Media technologies would fundamentally transform the relation between producers and consumers. Through interactive media, consumers would increasingly gain control of the means of production and distribution, contribute to public opinion, and participate in cultural production processes. Interactive media would help to empower the, by then passive, media consumers and transform them, as the argument goes, into active "prosumers" (Toffler, 1981).

Pearce's (1997) view can be characterized as a quite extreme example of what Boddy (2003) has called the "polemical ontology" (p. 191): the ideological self-promotion of a new medium that highlights the technological features and social advantages of the new medium and, at the same time, disparages those of the old media. In the past few years, this utopian view has been challenged by more critical if not dystopian accounts of New Media (Andrejevic, 2003) and especially by the development and introduction of interactive television. As Kim (2001) and Kim and Sawhney (2002) argue, the concepts of interactive television as envisioned by firms rooted in the traditional television business do not sufficiently take advantage of the new possibilities interactive technologies provide to extend the user's control of mediated communication. On the contrary, according to Kim and Sawhney, interactive services such as enhanced television, video-on-demand, or Web TV as developed by the TV industry cannot be regarded as "interactive" at all. These services fail to realize the "inherently" participatory, empowering, and democratic potential of the new computer-based communication technologies:

[...] interactive TV requires television to change its historically and culturally built-in centralized character. Due to this built-in bias, the TV communication model limits interactivity to mechanical transactions, while the center retains in control. In interactive TV, 'interactivity' is artificially grafted onto TV without taking into consideration the contradiction between interactivity and TV. (Kim & Sawhney, 2002, p. 224)

This view obviously implies a normative definition of the concept of interactivity and subsumes that there are inherent qualities of a technology as such. Like many other scholars, Kim and Sawhney (2002) define interactivity in qualitative terms as the radical sharing of power and control between producers and consumers in mediated communication (Jensen, 1999; Pearce,

1997; Rafaeli, 1988)—a quality that has to be unfolded when interactive television is developed. But as numerous studies of technological innovation have shown, technology is constructed in a social environment and thus shaped by the economic, political, and cultural contexts in which a technology is developed, realized, and introduced (Bijker & Law, 1992; Williams, 1974; Winston, 1998). In an international survey of producers' and developers' concepts of interactivity concerning the new interactive technologies, Van Dijk and De Vos (2001) have shown that the concepts of experts working in television-based industry differs significantly from those experts affiliated with the world of the Internet. Television defines interactivity "as an extension of current TV with a number of additional facilities" (p. 457), while interactive applications on the Internet are associated with the transformation of the television viewers "into users and producers of audiovisual programs, or into more active participants in e-commerce by making continuous price comparisons and by offering products themselves" (p. 457). Depending on different business models, different concepts of interactive TV are developed. Considering the economic, political, and cultural power of the established transnational media firms that invest massively in the growing online economy, and engage in the development and exploitation of interactive services and applications, their concept of interactivity will increasingly shape interactive media technologies and, as a consequence, reconfigure the relationship between producer and consumer in the media and communication market. In the following paragraphs, the launch of the Windows Media Center and the competition of the distributors of digital television on the Dutch market will be discussed as two indicators of this reconfiguration.

TARGETING AT THE LIVING ROOM

When Microsoft launched the Windows XP Media Center Edition 2005 in the beginning of 2005, the

magic word that for decades propagated the key-added-value of new digital media in public and scholarly discourses did not show up even once in Microsoft's Dutch marketing campaign. Instead of promoting "interactivity," the company chose a more accessible value in simply promising: "It's more fun." On Microsoft's Web site, the advantages of the new system software are explained in the following tempting words:

Microsoft Windows XP Media Center Edition 2005 lets you do everything other Windows XP PCs do—and a whole lot more. Browse the Web, play your favorite PC games, e-mail and instant message your friends, and install and use programs designed for Windows XP. Media Center also delivers a powerful yet familiar way to enjoy all of your digital entertainment—photos, music, TV, movies, home videos, radio, and a world of applications and services whether you're sitting in front of your Windows desktop or across the room with a remote control. Media Center is your all-in-one PC and home entertainment center. (<http://www.microsoft.com/windowsxp/media-center/evaluation/features.msp>)

The same is true for Hewlett Packard's (HP) marketing campaign of its new Media Center PC that was released at the same time, dovetailing with Microsoft's new version of the system software. The Dutch folder for HP's Media Center PC shows four young people sitting on a huge designer couch in front of a big flat screen television enjoying the new possibilities of the Media Center. One of the male participants points to the significant start menu on the big TV screen with its standard options that suggest a personalizing character of the applications: Online Spotlight, My Videos, My Pictures, My TV, My Music, More Programs, and so forth. The text praises the following advantages of the Media Center PC:

HP introduces the HP Media Center for the living room. TV and stereo, your pictures and films, Internet and many other technological triumphs

Access to the Living Room

all in one set. Operated by only one remote control and a very easy accessible menu on your television screen. The whole family will enjoy anything that home entertainment offers to you. That's what we call Digital Entertainment. (Hewlett Packard, 2005, p. 1)

The marketing campaign of a Dutch computer brand adapted this model of addressing the consumer in terms of the accessibility, ease of technical handling, and the promise of personal entertainment. As the flyer for the Paradigit Enjoy TV 2005 promises:

The Enjoy TV 2005 transforms your living room into the ultimate media center. In one top designed system you'll combine the best of a computer and home entertainment! Beyond that, the Enjoy TV2005 is noiseless. All your photographs, videos and music documents will be accessible from your couch. You'll be able to pause and rewind all your TV programs 'live.' Programs to be recorded, you'll chose in the online program guide by pressing just one button. (Paradigit, 2005, p. 1)

By deliberately avoiding the term *interactivity* and replacing it with concepts like “fun,” “entertainment,” or “easy handling,” these marketing campaigns obviously aim at a more and more crucial target: the living room as the headquarter of a family's media consumption. The Media Center PC is designed to replace different analogous hardware systems such as the stereo and VCR, by *one* computer. This central computer is not only used to digitally store and manage a family's music, photos, videos, and computer games. Logged on to the Internet, it also allows e-mailing, surfing on the Internet, e-banking, online shopping, and so forth. It can be used for Internet information retrieval as well as for downloading any information, service, or entertainment product required. Although in technological terms it is not necessary to login when starting up the computer, using a Media Center PC would practically imply that

the user will be connected to the Internet at any moment that they are engaged with media. The Media Center software is designed in such a way that listening to music, watching “regular” television programs, or archiving photographs would mean that the user *is* connected, unless he or she actively changes the default options of the software. For the industry this is not only a prerequisite in terms of exploiting online services and e-commerce, but according to experts the interesting fact arises that whenever the consumer is connected to the Internet, any act of consuming a media product or an online service can be monitored, registered, and related to the individual's profile. As Bertelsmann Group media consultant Carel Mackenbach explained bluntly in a Dutch TV documentary on the future of the media market, this data is the target of the media and communication industry:

If you look at the big international media concerns, be it Bertelsmann, AOL/Time Warner, or Vivendi: these are global players that engaged in television, radio, and print at the same time, and right at the moment there is a battle for the consumer going on in The Netherlands and in Europe. All these concerns are investing in pan-European databases of consumer profiles on a large scale. The following generation of consumer databases does not just register names, addresses and more or less accidental subscription of a daily newspaper, it registers behavior like what you think about certain topics, when you buy goods or when you require a financial service of a certain type or when you plan to change your telephone provider and what the reasons are to do so. (Rottenberg, 2005)

Compared to data utilized by traditional audience research such as the Nielson Media Research, the “new generation” of data Mackenbach (Rottenberg, 2005) refers to is of special value for providers and advertisers. These data not only register patterns of media and consumption behavior, they can be related to profiles of

individuals. An individual user's phone numbers would be accessible to the provider when the user has subscribed for all three services, Internet, television, and telephone, the so-called triple play or "multi play."

Although regulations and privacy legislation do prohibit the industry from registering such personal data, the example of Californian-based provider and distributor of personal or hard disk recorders TiVo clearly shows that there is no technological problem in doing so. In the U.S., TiVo is a widespread brand of digital video recorder that not only allows users to capture television programming on internal hard disk storage for later viewing, it also registers viewing habits and program preferences of the individual viewer in order to help him to "personalize" the overall television programming: a TiVo preselects and records a user's preferred programming and alerts the viewer when a preferred shows is on. Therefore, these digital video recorders are also known as "personal video recorders." The crucial difference between this and average hard disk recorders that have been marketed in the last few years all over the world, is that a TiVo must be connected via a telephone line to the provider that not only sends the program schedule to the hard disk of the user, but also registers his or her viewing habits. As Martin (2001) has convincingly shown by analyzing the log files automatically transmitted from the individual TiVo box at home to the TiVo headquarters, these files not only tell down to the second what has been watched, which commercials have been skipped, and what moments have been rewind and played again. According to Martin's (2001) findings, TiVo:

gathers enough information to track back individual user's home viewing habits while apparently promising not to do so; could identify the personal viewing habits of subscribers at will; has a much more explicit privacy policy disclosure on its Web site than in the printed material that accompanies the purchase of the product. (p. 2)

Though TiVo spokespeople admit that TiVo could investigate an individual's viewing habits, they recurrently deny that TiVo would do so (Charny, 2004). However, taking Carel Mackenbach's statement into account, the long term strategy of cable distributors, telephone companies, and Internet providers is obvious: gaining digital access to the living room means access to an enormous capital in the online economy, by providing information about individual user's consumption habits (Rottenberg, 2005).

Only against this background can one understand the enormous competition in the Dutch telecommunication market that arose in 2004 when the former national postal and telephone company, KPN (Royal Dutch Post) launched the first set top box in the Dutch market for terrestrial digital television broadcasting. As the former national telephone provider, the KPN has traditionally held a strong position in the market of (mobile) telephony and broadband Internet. Yet since about 96% of television broadcasting is distributed regionally by commercial cable companies, only a few public channels are broadcasted terrestrially and there is no significant satellite penetration (Koetje, 2003), KPN would miss television programming as an indispensable part of a future triple-play strategy. Media experts expected—then and right now—that by means of new media technologies replacing the good old "telly" in the living room, one could get the economically crucial access to the average family's living room, since television was and still is the most frequently used domestic medium.

The competing cable distributors took their chance and denied KPN access to cable distribution, while getting the coaxial cable system ready for broadband Internet, analogous and digital telephony and for digital television distribution for themselves. In neighboring countries such as Flanders, the government forced entrepreneurs to agree on one common standard accessible for digital encoding for any provider (Baaren, 2006). In Germany, public and commercial broadcasters

defined one standard for terrestrial digital broadcasting (DBV-t). However, in The Netherlands, the Dutch authorities defined neither a common standard for digital broadcasting, nor one for terrestrial, cable, or satellite distribution. The result of this neo-liberal policy is that besides the KPN there are other competitors on the market offering television via the cable—each using its own exclusive standard to encode the digital signal: cable television companies that formerly operated only regionally such as Casema and Essent, but also UPC and Versatel, two competitors that operate nationally (Gorter, 2005, pp. 28-29). Some of these and some new competitors prepare digital television distribution via the next generation of broadband Internet (ADSL-2); each company making use of its own standard and thus set top box, respectively smart card, offering its own, exclusive package of TV channels via Internet Protocol Television.
